YAC GROWTH

1 Streak YAC on -URA plate. Grow for 2 days at 30 C

2 In 500ml sterile flask add;

200ml -URA Broth
20ml Glucose (20%)
2ml Tryp (5mg/ml)
4ml Leu (5mg/ml)

Large blob of YAC. Shake at 200rpm, 30 C, 24hrs.

YAC HARVEST

1 Melt (1% LGT agarose, 0.1M EDTA) at 100 C, hold at 42 C.

2 Distribute medium equally into 4 blue-cap 50ml tubes. Spin at 2000rpm, 5mins. Discard supernatent and allow to drain.

3 Add 10ml EDTA (50mM, pH8) to one tube, dissolve pellet and collate into next tube until you are left with one tube. Spin at 2000rpm, 5mins and discard supernatent. Pellet should be approx. 2-3ml.

4 Resuspend pellet with EDTA (50mM, pH8) to a final volume of 20ml.

5 In 2 NUNCLON 24-well plates dispense 0.4ml YAC solution into each well. There is enough to make 48 plugs (long-type variety).

6 Spin plates at 3000rpm, 2mins. Aspirate the supernatent with a drawn pateur. Vortex pellet hard.

7 Add 20ul EDTA (50mM), vortex gently.

8 Add 16ul solution I to first row, vortex gently. Add 16ul solution I to second row, vortex gently.

9 Prepare mould by sealing one side with magic tape.

10 To each well of the first row in turn add 120ul (1% LGT agarose, 0.1M EDTA), pump 2-3 times without sucking air, transfer to mould sealing the edges.

11 Add 16ul solution I to third row, vortex gently then perform step 10 on second row. Repeat for all the rows until both plates complete.

12 Once mould full, leave in fridge for 3-4mins until agarose has set. Meanwhile, prepare 2 more NUNCLON 24-well plates with 0.4ml solution II in each well.

13 Remove tape from the mould and push out plugs, one for each well with plunger. Seal with parafilm and incubate at 37 C overnight.

14 Aspirate with drawn pasteur, protecting the plug with a spatula Add 0.4ml solution III to each well, seal with parafilm. Incubate at 50 C, 1.5 days.
15 Aspirate with drawn pasteur, protecting the plug with a spatula. Add 0.4ml EDTA (0.5M, pH9) and store in fridge.

SOLUTIONS

Solution I
1mg zymolase 100T
1ml SCE (Sorbitol (1M),Sodium Citrate (0.1M),EDTA (0.06M,pH7))
50ul beta-mercaptoethanol

Solution II
20ml EDTA (0.5M,pH9)
1.5ml beta-mercaptoethanol

Solution III
20ml EDTA (0.5M,pH9)
20mg proteinase K
0.67ml Sarcosyl NL30

PULSED-FIELD GEL ELECTROPHORESIS

1 Prepare gel (350ml 0.5 X TBE + 2.45g LGT agarose). Boil, cool. Tape a turntable with tape to form a wall. Pour gel mix, support a comb by a horizontal rod. Set in cold room for at least 2hrs.

2 Soak plugs at least 1hr in 2 changes of 0.05 X TBE.

3 Remove comb, fill wells with 0.5 X TBE and insert plugs with 2 bent spatulas.

4 Drain old buffer from gel chamber by disconnecting back hose and tilting slightly. Reconnect hose and refill chamber with approx. 2L 0.5 X TBE.

5 Mount turntable, check field direction and rotation. RUN at 150v, 35s, 27hrs. These conditions are suitable for YACS of 250-450Kb.

6 Wells are cut after approx. 5hrs to reduce background smears.

7 After the run, the gel is cut away from the velcro and placed into a tub containing 500ml distilled water. Ethidium Bromide is added (50ul, 10mg/ml) and the gel stained for 1.5-2hrs.

8 The ethidium bromide is removed by syringe to a waste can and the gel washed in 1L of 0.5 X TAE.

9 The gel is viewed on a glass plate on a long wave box and the YAC strip excised with a double scalpel. It is stored in the fridge until extraction.

YAC EXTRACTION

1 Add 30ul NaCl (1M) and 1/100th (v/v) 50 X TAE to YAC strip and melt at 64 C (15-20mins).

2 Equally distribute 1ml to eppendorf tubes (2ml) and add 1ml phenol. Shake, keep on ice for 5mins, spin at 13000rpm for 5mins. Take upper layer.

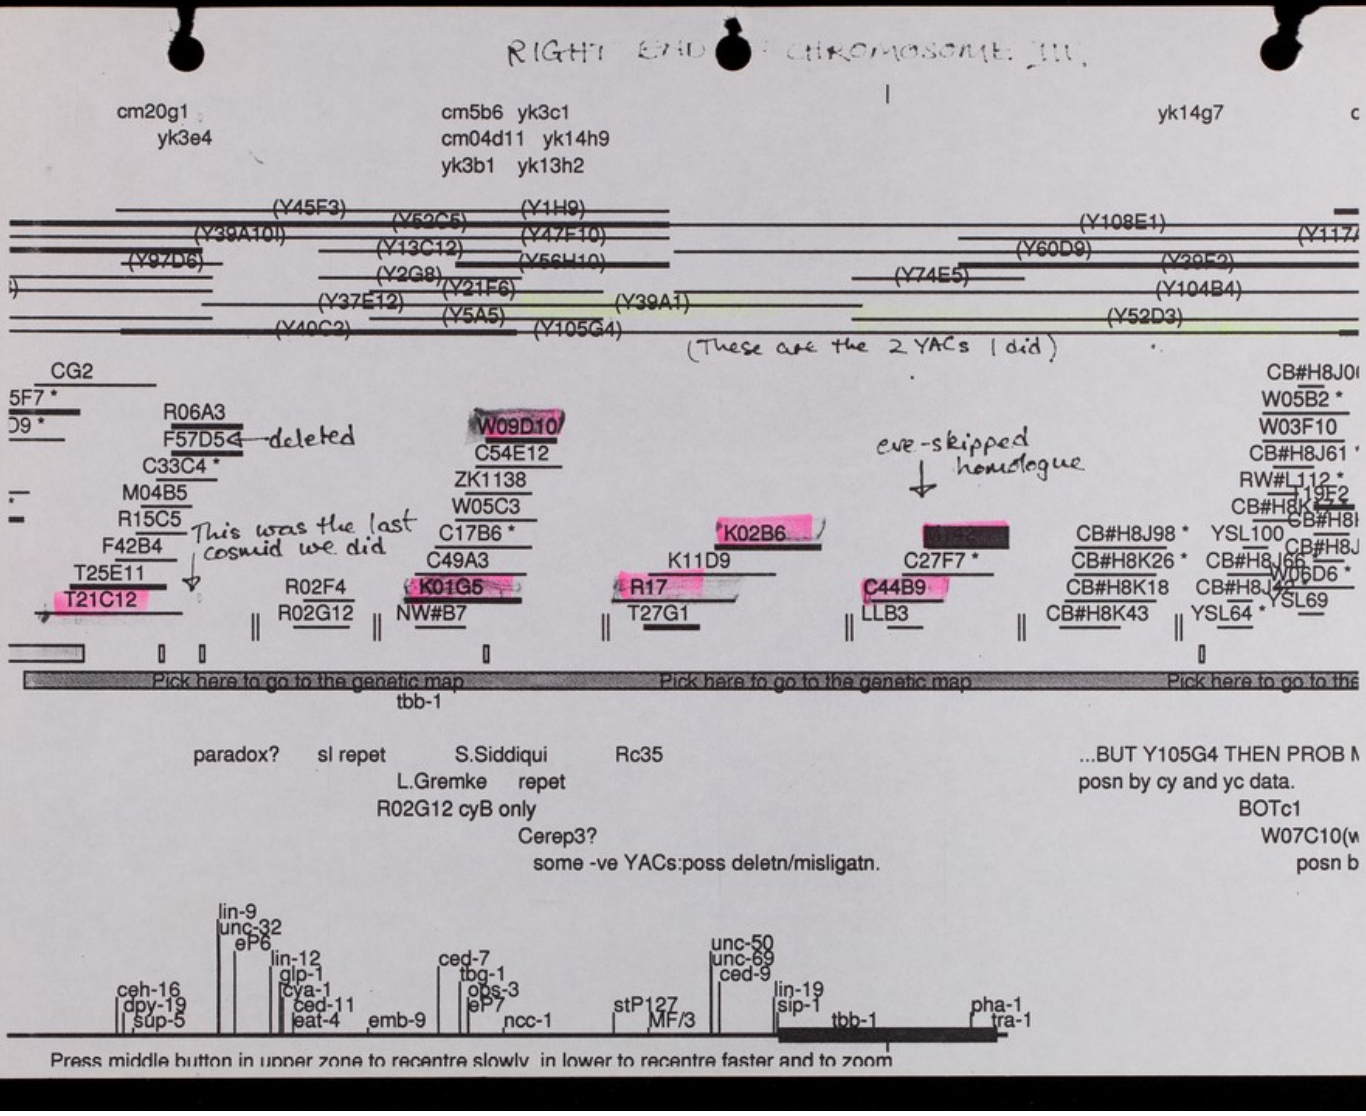
3 With remaining white emulsion layer in each tube, collate into one tube and spin as step 2. Add upper layer to other layers taken.

4 Add 1ml phenol and repeat step 2.

5 Add phenol/chloroform (500ul each) to each tube. Ice 2mins, spin 13000rpm, 2mins. Take upper layer.

6 Add 1ml iso-butanol to each tube. Spin 13000rpm, 2mins. Discard upper layer. Repeat until you end up with approx. 300ul.

7 Transfer to an eppendorf tube (1.5ml), add 700ul chilled ethanol (96%), store at -20 C overnight.



RIGHT END OF CHROMOSOME III.

Subject: Re: mab-3 etc.

Dear Alan,

You've made my day (and trust me, that took some doing today)! I do think it would be a great plan to put Y53C12 into production and for us to proceed with our current plans in the meantime. If we had even some shotgun sequence from inside the bridge we could start pulling out clones [redacted] fingerprint and test for rescue, and we might be able to find an orphan cosmid contig or get more fosmids. Also, from our standpoint, even if our Tc1 screen works, having some sequence or physical map in the region would be a huge help. One could make a case that as a biggish bridge in a gene-dense and otherwise sequenced region, this one makes sense to tackle now.

I pulled out my notebook and had a look at the PFG picture, and the YAC runs just below the second chromosome, if I have my names right - the chromosome that is about 300 kb. There is reasonable separation - about the same width as the YAC band. We did two runs on your PFG apparatus at the LMB; in one the YAC and chromosome were a poorly resolved doublet, and in the second longer run under slightly different conditions there was better resolution and I would guess there was not much yeast DNA around (the YAC was about 1/4 of the distance from chromo 2 down to chromo 1). I could certainly send you what is left of my prep if you are interested, but I suspect there isn't enough DNA to get a decent quality library. I also have the PFG conditions, as recorded by Rachel Aronoff, with whom I shared the gels, in case those are of interest: run length was 54.5 hr, 1% LMP gel, 150 V, about 150 mA; times: 18s, 16h; 21s, 5h; [23s, 3h; 28s, 18h - maybe this part could be longer]; 33s, 6h; 38 s, 6h.

If you think lambda walking would be sufficiently fast, I'll look into vectors - let me know if it makes any difference to you in terms of fingerprinting etc. I was just going to see which commercial kits seemed to have the best system for making end probes and getting rapid turnaround between steps. I also intended to use CES200 unless a better host strain [redacted]rns up.

Thanks again for the good news. You guys are giving the field a huge boost, and our pleading and wheedling is just evidence of it!

Best wishes,

Dave

Hi Alan
        Great to hear that you are interested in the clones. I'm sure it would be useful to fingerprint map them as independent confirmation that they overlap. Shall I send you DNA (Qiagen pure) or stabs, or both ? Let me know and I'll fedex them immediately !
        YAC Y95G10 is 450Kb on PFG. Y59A8 is around 350Kb-The two span the cosmid gap between K03D8 and C48B12.

        Thanks again

        Edith

Hi Alan

It occurred to me last night that since Y59A8 is in the offing for sequencing, you are probabely planning to also do Y94A7. Is this right ? It is the smallest (170Kb) of the YACs spanning K03D8 to Y59A8 and runs faster than the smallest yeast chromosome. I am very excited, of course, that you guys are working in this region ! Do you have any rough timescale of when you will start to get sequence data ?

Best wishes

Edith

Think I misinterpreted 4/9 mail
i.e. Y59A8 + another YAC (Y95G10, Y94A7sg)
are required to span K03D8/C48B12

Hi Alan

I sent the stabs and DNA last week, so you have probabely received them by now. I pulled them out of a library made from total DNA from strain Y95G10 (if you have a protocol for making libraries from purified YAC, I'd love a copy !). A while ago, I isolated a phage clone from another sub-library using a PCR fragment from the left end of Y59A8(I got the primer sequence from you). I used the phage insert to screen my fosmid library and got 3 duplicate positives. These are clones 1, 2 and 4. Clone 4 clearly contains approx. 35 Kb worm DNA, and looks the same as genomic DNA on blots. Clones 1 and 2 pick up only 9Kb of genomic DNA and this does not look the same as the YACs. I know that 1 and 2 hybridise with clone 4, so it is definately worth fingerprinting rthem. This region is so rich in repeat DNA that I have to compete all my probes to see any clear bands on blots. I guess this will complicate the analysis.

Clones 5, 7 and 8 were pulled out using a 1 Kb Hin D111 fragement om the left end of clone 4. Clone 8 looks kosher with respect to genomic DNA, but 5 and 7 both only pick up a 9Kb fragment on Eco R1 digests of genomic DNA. Again this might be because of repeat DNA(ie that the band actually represents several tandem repeats). I know that all the clones have sequences in common from hybridisation and double digests (and that they all map to my region. So I think it's definately worth looking at all of them. I'm making DNA from the phage clone today, and

will send it, since it would be good to see the extent of overlap of all the clones I have

Thanks again, and let me know if you have any questions

Edith Cookson

DEAR ALAN.

HERE ARE THE FOSMID CLONES (#1, 2, 4, 5, 7 + 8) ENCLOSED ARE STABS + DNA SAMPLES (~10 μg OF EACH. A COUPLE OF THE CLONES LOOK ~~&~~ STRANGE ON GENOMIC BLOTS IN THAT THEY ~~@~~ PICK UP ONLY 1 9Kb EcoRI BAND. THIS COULD BE SEVERAL COPIES OF A REPEAT, OR IT COULD MEAN THAT THE CLONE IS A CO-LIGATION OF WORM + YEAST DNA (SINCE I MADE LIBRARY FROM ~~to~~ WHOLE YEAST STRAIN). I'M STILL WORKING ON WHAT'S GOING ON, AND WILL E-MAIL YOU.

THANKS.

EDITH COOKSON.

Hi ALAN.

- HERE IS THE MAP OF DY4-21 YACS ETC, ACCORDING TO MY INVESTIGATIONS
- SO TO GET THE WHOLE REGION BETWEEN K0308 + C48B12 WILL REQUIRE ~~SOL~~ SEQUENCING SUB-LIBRARIES OF Y94A7 + Y59A8.

- HAVE YOU FOUND ANY ORFs YET!

EDITH.

DPY-21 GENOMIC REGION.

Subject: doubts on the physical map and cosmid T26E3 and R09B9

Dear Dr. Coulson:
I had one puzzling result when I was trying to align the cosmids between W05A3 and W02A11. To further define the overlapping relationship of these cosmids, I did a southern hybridization with a 1.5 Kb EcoRI fragment of R02E6 to probe cosmids in the region. A 1.5 Kb E.coRI band of R09B9 was lit up as the same intensity as the one of R02E6. This leads me to think that R02E6 overlaps with R09B9. That is to say, there is no gap at all between R02E6 and R09B9 as shown on the physical map.
I have one more line of evidence to support the argument that the tiny cosmids bunch between R02E6 and R09B9 do not belong there. Using PCR-based deletion mapping, I found that hDf15 deletes W02D9, R02E6, W01F5 but not C10D1. The result could be simply explained by the possibility that C10D1 is not between R02E6 and W01F5.
To further map this region, I want to ask for two cosmids: R09B9 and T26E3. I am asking for R09B9 again because I want to confirm my result mentioned above. Thank you for your assistance. I look forward to your feedback on my thoughts.

Subject: mab-3

Dear Alan,
I wanted to get some info on the mab-3 region from you so we can plan our next move. My student is finally settling in and getting geared up. My main question for you is do you have any near-term plans for the Y53C12 bridge that appears to contain mab-3? You had mentioned the possibility of long PCR at some point, but I'm pretty sure the bridge is in the 100-150 kb range (we got CB#1162 from Jonathan to test the remote possibility that it and the nearest fosmid on the other side overlap, but we're not holding our breath). It seems to me that the current options are for you guys to try sequencing one of the spanning YACs like Y53C12, or for us to try everything we can think of.

If there are no plans for the genome project to go after that region (and I'm writing to you because I'm assuming that region is a Cambridge region), we have several things in mind. First, we are continuing to make fosmid end probes to send Stephanie to see if we can extend the existing contigs with fosmids. This is not very likely because probing with purified Y53C12 DNA did not get us anything new, but there was a lot of background from repetitive clones, so it is worth a try. Second, we are setting up a Tc1 screen based on the fact that mab-3 mutations activate a gfp reporter in the male gut. This may solve our problem if mab-3 is a Tc1 target, but won't help you much. Third, we will probably make smaller YAC derivatives by recombination, using our fosmid end-sequences. These could then be subcloned into phage to be tested for mab-3 rescue, and might also help you with your sequencing efforts. Fourth, and I hope finally, we could try a phage walk from the left side of the bridge, using libraries made from yeast containing the three YAC clones that cover the bridge. Caroline Shamu tried walking from the right side using libraries that John Sulston made from purified YAC DNA, but got stuck, and CB#1162 was the best extension she got. Nobody has tried to go in from the left because it probably is the long way, but at this point it seems worth a try.

Ok, so that's where we stand. Obviously what I would most like to hear is that you are currently sequencing purified Y53C12 and should have finished sequence in several weeks! If there is no near-term plan for that region, I would very much appreciate any advice you could give me on choice of vector and host for the walk. I had thought lambda might makes sense because we are looking at a region of about 100-150 kb, and with lambda

clones the number required to span it would be reasonable, and the logistics of isolating the gene after rescue also would be reasonable. We could try cosmids or P1 vectors, but in that case while very few clones would be needed to span the region, getting our gene out might be a lot of work and require lambda subcloning anyway. You have a lot more experience with this, so suggestions please! The final issue is whether the Cambridge group would be interested/willing to fingerprint clones if I could assemble a contig by walking. Seems like something that would be mutually beneficial, but I don't want to impose. Sorry to go on at such length, but we need, in the local vernacular, to fish or cut bait, and I want to make sure we don't waste a lot of effort if the professionals are already working on the problem. Regards to all. I'm about to start teaching for the first time, and appreciate the postdoc lifestyle all the more! Our first snow is forecast for tomorrow; summer is short in these parts.

Best wishes,
Dave

Dear Alan,
I quick addendum to my note of yesterday: To explore further the idea of convincing you (the genome project that is) to sequence Y53C12 YAC DNA, I wondered if it would be a more tempting prospect if we were to make a smaller derivative of Y53C12. We don't know the orientation of it, but could find out, and then recombine one end off, which should get the size down by several cosmid lengths. The only drawback other than the time it would take to make and characterize the derivative is that such a DNA might be harder to purify cleanly than Y53C12, which separated quite well for us from the yeast chromosomes on a pulsed field gel. I don't even know if you are the one to bother about this, so do let me know if I am barking up the wrong tree!
Best wishes,
Dave

Subject: Re: mab-3 etc.

Yo Dave
I was about to reply and say that, since you reckon the gap to be over 100kb, we should perhaps put Y53C12 into production. I was also going to say that sin our only PFG of the YAC, it runs on top of the second chromosome the whole process would be rather lengthy since I am trying to move these co-migrating YACs into Eric Green's 'window' strains in order to avoid sequencing more than 50% yeast. However, since you say that the YAC is, in fact, seperable (does it run slightly slower than the second yeast chromosome?) this should simplify things. But you have to be aware that we are only just getting going on the YAC sequencing and the whole process is inevitably lengthy anyway. In addition there is already a queue of YACs in the system at various stages (we have most been concentrating on YACs from the arms in the expectation that some proporti of bridges in the clusters will be filled by long-range PCR, fosmids etc, effo for which are ongoing). It is very hard for me to put a time on when useful in for Y53C12 might start to appear. But I don't think it can be consisered 'near Consequently, I wonder if you shouldn't try the lambda walk? We obviously have unknowns either way. Should we just embark on both?
We certainly would fingerprint any lambda clones you generate (I would think l are the things to go for).
Best wishes
Alan

Genetics

Isolation of yeast artificial chromosomes free of endogenous yeast chromosomes: Construction of alternate hosts with defined karyotypic alterations

(chromosome fragmentation/*kar1*-mediated transfer/genome mapping)

LISBETH HAMER*†, MARK JOHNSTON‡, AND ERIC D. GREEN*§

*Diagnostic Development Branch, National Center for Human Genome Research, National Institutes of Health, Bethesda, MD 20892; and ‡Department of Genetics, Washington University School of Medicine, St. Louis, MO 63110

Communicated by Francis S. Collins, National Institutes of Health, Bethesda, MD, August 16, 1995 (received for review May 30, 1995)

ABSTRACT **An intrinsic feature of yeast artificial chromosomes (YACs) is that the cloned DNA is generally in the same size range (i.e., ≈200–2000 kb) as the endogenous yeast chromosomes. As a result, the isolation of YAC DNA, which typically involves separation by pulsed-field gel electrophoresis, is frequently confounded by the presence of a comigrating or closely migrating endogenous yeast chromosome(s). We have developed a strategy that reliably allows the isolation of any YAC free of endogenous yeast chromosomes. Using recombination-mediated chromosome fragmentation, a set of *Saccharomyces cerevisiae* host strains was systematically constructed. Each strain contains defined alterations in its electrophoretic karyotype, which provide a large-size interval devoid of endogenous chromosomes (i.e., a karyotypic "window"). All of the constructed strains contain the *kar1-Δ15* mutation, thereby allowing the efficient transfer of a YAC from its original host into an appropriately selected window strain using the *kar1*-transfer procedure. This approach provides a robust and efficient means to obtain relatively pure YAC DNA regardless of YAC size.**

The development of yeast artificial chromosome (YAC) cloning (1, 2) has greatly advanced the ability to analyze complex genomes. Specifically, segments of DNA spanning upwards of 1000 kb (or more) can be isolated in YACs, thereby allowing studies that were previously unapproachable using bacterial-based cloning systems. However, YACs have several inherent properties that reduce accessibility to the cloned DNA; in particular, YACs are (*i*) maintained in roughly single-copy in yeast cells, (*ii*) generally in the same size range (i.e., ≈200–2000 kb) as the 16 endogenous yeast chromosomes, and (*iii*) linear DNA molecules with the same general structure as other yeast chromosomes. As a consequence, the isolation of purified YAC DNA, most often performed by preparative pulsed-field gel electrophoresis (PFGE) (3–7), yields relatively small amounts of material for subsequent manipulation. Frequently, the purification of YAC DNA is further hindered by the presence of comigrating or closely migrating endogenous yeast chromosomes, which inevitably results in the presence of large amounts of unwanted yeast DNA. Contaminating yeast chromosomes can hamper subsequent applications that demand highly purified preparations of YAC DNA, such as exon trapping/amplification (8–10), direct cDNA selection (11, 12), construction of random libraries for DNA sequencing (13), and other methods where smaller-insert subclones must be obtained from the purified YAC DNA (14).

To ameliorate this problem, we have developed a strategy that allows the reliable isolation of YAC DNA free of endogenous yeast chromosomes. Specifically, we constructed a series of *Saccharomyces cerevisiae* host strains whose endogenous chromosomes have been systematically altered by recombination-mediated chromosome fragmentation (15, 16). Each strain represents the product of a different set of fragmentation events and contains a unique chromosome-free region (i.e., a "window") in its electrophoretic karyotype. Using the recently described *kar1*-transfer procedure (17, 18), a YAC of interest can be readily moved from its original host into one of these newly constructed strains, such that the YAC will migrate within the host's window during PFGE and thus can be isolated free of endogenous yeast chromosomes. Here we describe the construction of the yeast window strains[¶] and demonstrate that YACs of various sizes can be transferred into the new hosts for subsequent isolation. This approach eliminates a major limitation of YAC cloning and should facilitate the direct use of YACs for a larger array of molecular genetic techniques.

MATERIALS AND METHODS

Construction of a Universal Fragmentation Vector. pLB503 (Fig. 1) was constructed from the following components using standard molecular biology methods (6, 21): (*i*) a backbone of pBluescript (Stratagene), (*ii*) an *Xho* I fragment of pYAC4 containing the *Tetrahymena* telomeres and intervening stuffer (1), (*iii*) the yeast *URA3* gene flanked by direct repeats [*Salmonella hisG* sequences (20)], and (*iv*) a PCR-generated fragment containing the yeast CEN4 sequence (GenBank no. X70276). Additional details about plasmid construction are available on request.

Yeast Chromosome Fragmentation. *Strategy 1.* Two pairs of oligonucleotide primers were used for PCR amplification of adjacent segments of a target gene sequence. For each target, the two segments were designed such that they were slightly different in size, were completely within the open reading frame of the gene, contained engineered *Not* I sites at their internal ends (via the artificial placement of a *Not* I recognition sequence within the internal-most PCR primers), and were devoid of a *Bam*HI, *Sac* I, *Xba* I, or an additional *Not* I site. The resulting two PCR products were digested with *Not* I, ligated, and used as template for a second round of PCR that employed the two external-most primers (i.e., the ones devoid of *Not* I sites). The final PCR product, which represented a disrupted target gene sequence (lacking 5′ and 3′ portions of coding sequence) with an asymmetrically placed, internal *Not*

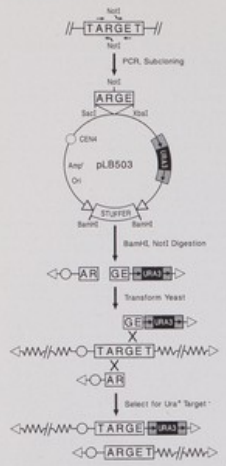

FIG. 1. Fragmentation of a yeast chromosome by recombination at a natural endogenous target (strategy 1). The plasmid pLB503 contains a yeast centromere sequence (CEN4), two *Tetrahymena* telomeres (triangles), a stuffer fragment (1, 19), and the *URA3* gene flanked by direct repeats (20). A target corresponding to a sequence fully contained within the open reading frame of a yeast gene required for prototrophy was engineered to contain an internal *Not* I site (and a small deletion) and subcloned into pLB503 (via unique *Sac* I and *Xba* I sites) in both orientations (only one orientation is depicted). Following digestion with *Not* I and *Bam*HI, the resulting vector fragments are transformed into yeast, where homologous recombination of the target sequences results in fragmentation of the endogenous chromosome (depicted with wavy lines) to yield two smaller derivative chromosomes. The resulting yeast cell is Ura$^+$ and auxotrophic due to disruption of the target gene. Of note, an earlier generation vector (pLB301) is similar to pLB503 but contains the *HIS3* gene on the CEN4-containing side of the *Sac* I/*Xba* I cloning site. pLB301 was only used to fragment chromosomes I and XI at the *CYS3* and *MET14* genes, respectively (see Table 1).

I site, was directly subcloned into pT7Blue (Novagen). The orientation of the cloned insert in multiple isolates was established by digestion with *Xba* I and *Not* I and/or by PCR analysis using T7 and T3 primers in combination with the two internal-most target-specific primers. An isolate containing the target in each orientation was selected, the *Bam*HI site was destroyed by *Bam*HI digestion, Klenow treatment, and self-ligation (21), and the target was excised by digestion with *Xba* I and *Sac* I and cloned into *Xba* I/*Sac* I-digested pLB503 (Fig. 1). Details about the primers used for PCR amplification of target sequences (in strategy 1 and strategy 2) are available on request.

Yeast were transformed with *Bam*HI/*Not* I-digested fragmentation vector using the lithium acetate method (22) and plated on SC-Ura plates (23). Ura$^+$ transformants were tested for disruption of the target gene (i.e., auxotrophy) by replica plating onto the appropriate dropout medium (e.g., SC-Ura-Met for the *MET14* target). The frequency of auxotrophs among the Ura$^+$ transformants was generally quite low, typically ranging from 1% to 10%, and auxotrophs containing an appropriately fragmented chromosome were only recovered with the target sequence in one (of the two) orientations. Auxotrophs for the target gene were analyzed by PFGE to verify the presence of an appropriately fragmented chromosome. Following each fragmentation event, strains were propagated on SC medium containing 1 g of 5′-fluoroorotic acid per liter (23) to select for isolates that had excised the *URA3* gene via the flanking direct repeats (24).

Strategy 2. A DNA fragment containing the yeast *HIS3* gene flanked by target sequences was generated by PCR (Fig. 2). Primers containing a 45-bp target sequence (on the 5′ end) and a 19-bp *HIS3*-specific sequence (on the 3′ end) were used for

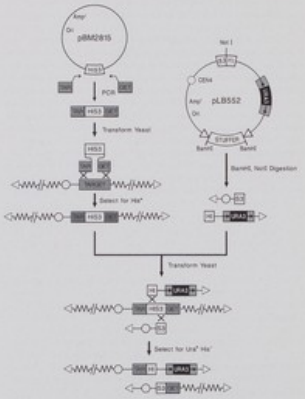

FIG. 2. Fragmentation of a yeast chromosome by recombination at an artificially integrated target (strategy 2). A target-specific integrative fragment containing the *HIS3* gene is generated by PCR using the plasmid pBM2815 (which contains the *HIS3* gene subcloned into pBluescript) as template and primers containing 45 bases of appropriate target sequence at their 5′ ends. Following yeast transformation, integration into an endogenous chromosome occurs by homologous recombination between the target sequences flanking the *HIS3* gene. Authentic integrants, containing the *HIS3* gene at the correct target site, are then transformed in parallel with *Bam*HI/*Not* I-digested fragments derived from pLB552 (depicted here) and pLB553 (identical to pLB552 except with the *HIS3* target sequences in the opposite orientation). Virtually all Ura$^+$His$^-$ transformants contain two smaller derivative chromosomes resulting from fragmentation at the integrated *HIS3* gene. Note that the relative positioning of the two parts of the *HIS3* target sequence in pLB552 and pLB553 is distinct from the approach used for subcloning target sequences in strategy 1 (see Fig. 1). Strategy 2 was designed to better ensure that no homologous sequences remained in the two derivative chromosomes following fragmentation.

PCR amplification of the *HIS3* gene using DNA from the plasmid pBM2815 as template (Fig. 2). The resulting PCR product was used to transform yeast directly (25) as described above and cells were plated on SC-His medium. The fraction of His$^+$ transformants containing authentic integration of the ≈1-kb *HIS3* gene at the appropriate site varied widely among the different targets. As a result, we found it essential to test the resulting transformants by PCR using primers that flank the expected integration site to identify authentic integrants. The resulting strains were then transformed (as above) in parallel with the *HIS3*-specific fragmentation vectors pLB552 and pLB553. The latter vectors, which contain engineered *HIS3* target sequences in opposite orientations (see Fig. 2), were constructed by subcloning PCR-generated fragments (≈500 bp each) of the *HIS3* gene into pLB503. Disruption of the *HIS3* gene in the resulting Ura$^+$ transformants was tested by replica plating to SC-Ura-His. Generally, 10–15% of the Ura$^+$ transformants were His$^-$, and virtually all Ura$^+$His$^-$ strains contained the expected fragmented chromosome, as assessed by PFGE. Auxotrophs were processed as described above for strategy 1.

Transfer of YACs into Window Strains. YACs were transferred from their original host into an appropriate window strain (Table 1) using the *kar1*-transfer procedure (17). Briefly, 5×10^8 cells each of a YAC strain (*MAT*a) and a window strain (*MAT*α) were combined, incubated at 30°C for 6 h, plated on AHC medium (26) containing 3 mg of cycloheximide per liter, and incubated at 30°C for 3–4 days. Two major types of Cyh^R colonies were typically encountered: YACs appropriately transferred into the recipient window strain (Ura$^+$Trp$^+$*MAT*α) and YAC-containing diploid cells (Ura$^+$Trp$^+$*MAT*a/α). An efficient approach for distinguishing between these two types of colonies is by direct PCR analysis of yeast cells using *MAT*-specific primers (27). In our experience, 85–95% of the resulting colonies are *MAT*α, with virtually all of these containing the window strain nucleus along with a transferred YAC. Successful YAC transfer was verified by PFGE analysis of the resulting *MAT*α clones in parallel with the original YAC strain and the recipient window strain (e.g., see Fig. 4).

RESULTS

Construction of Window Strains. A set of nine yeast strains (Table 1), each containing defined areas in the electrophoretic karyotype devoid of endogenous chromosomes, was systematically constructed by recombination-mediated chromosome fragmentation (15, 16). Our general approach involved the transformation of yeast cells with two small linear DNA fragments, each terminated on one side with a functional telomere sequence and on the other side by a target sequence also present in an endogenous chromosome (Figs. 1 and 2). One fragment contained a yeast CEN sequence, while the other harbored a marker (the *URA3* gene) used for selection of transformants. Recombination across the common (i.e., homologous) target sequence present in each fragment resulted in the introduction of the *URA3* gene, the disruption of the endogenous target gene, and the creation of two smaller derivative chromosomes from the starting endogenous chromosome. Since only one orientation of the target sequence (relative to the CEN- and *URA3*-containing fragments) resulted in the formation of two stable (i.e., monocentric) derivative chromosomes, parallel experiments using the target sequence subcloned in both orientations within the fragmenting vector were always performed.

Two strategies for chromosome fragmentation were employed. Initially, genes required for prototrophy (e.g., *CYS3, MET10, THR4, THR1, HIS1,* and *MET14*; see Table 1) were used as the targets for fragmentation (strategy 1). In these cases, target sequences within the coding region of the gene were subcloned in both orientations into pLB503 (Fig. 1). Subsequent restriction enzyme digestion released the two fragmenting DNA molecules, which were transformed into yeast. This strategy was effective, accounting for 6 of the 15 chromosome fragmentation events required for constructing the strains listed in Table 1. However, this approach was found to be limiting, because for some chromosomes, appropriate genes with known DNA sequence (for convenient generation of PCR primers) either were not available or were located near a chromosome end, which would have yielded a derivative chromosome that remained within the desired window. Fur-

YLBW1–YLBW9 are YPH925-derived yeast strains containing windows in their electrophoretic karyotype. Indicated for each strain are the fundamental YPH925 genotype (italics) with any additional features (due to disruption of a gene required for prototrophy) indicated in boldface italics, the target sequence(s) used for fragmentation (with each corresponding chromosome number given in parentheses), and the approximate size range of the resulting window. In many instances, the site of fragmentation resided upstream or downstream of the indicated target gene, and thus the gene itself was not actually disrupted by the fragmentation event. The approximate sizes (in kb) of the resulting fragments for each chromosome are as follows: I (110, 140); VI (50, 230); III (110, 220); IX (140, 310); V (270, 320); VIII (150, 440); XI (240, 440); X (280, 475), (350, 460); XIV (330, 480); II (340, 500); XIII (460, 490); XVI (300, 685); VII (540, 580); XV (530, 600); and IV (500, 1140).
*The precise size of the window varies, since the length of the ribosomal repeats contained in chromosome XII is polymorphic in different isolates.

thermore, the construction of multiple chromosome-specific fragmentation vectors became a slow and tedious process.

As an alternative, a second strategy for chromosome fragmentation was utilized. In this case, a universal sequence (i.e., the *HIS3* gene) was "artificially" positioned at a desired site in an endogenous chromosome by integrative recombination (28) (Fig. 2) and the chromosome was then fragmented at this site by an approach analogous to strategy 1 [using common fragmentation vectors (pLB552 and pLB553) containing cloned *HIS3* gene sequences]. The initial integration of the *HIS3* gene at a site of interest was accomplished by transforming yeast with a PCR-generated *HIS3* gene fragment flanked on each side by a 45-bp chromosomal target sequence (25) (Fig. 2). The target sequences used for directing integration of the *HIS3* gene into an endogenous chromosome typically corresponded to a noncoding region near a known sequenced gene (e.g., *HIS5, ARG3, LEU4, RAD16, ILV2, ARO7, LEU1, ADE2,* and *GAL3*; see Table 1). Chromosomes containing the *HIS3* gene at the desired site were then fragmented using either pLB552 or pLB553 (Fig. 2), depending upon the orientation of the target sequence on the chromosome.

Using the strategies described above and in the legends to Figs. 1 and 2, we constructed a set of yeast strains that together provide a series of overlapping windows covering the typical size range of YACs. In all instances, YPH925 (*MATα leu2-Δ1 trp1-Δ63 ura3-52 ade2-101 his3-Δ200 lys2-801 cyh2*^{R} *kar1-Δ15*) (29) was used as the starting strain, since it (*i*) is auxotrophic for a number of yeast genetic markers that are routinely used for YAC selection and subsequent manipulation (e.g., *URA3, TRP1, HIS3, LEU2, ADE2,* and *LYS2*) and (*ii*) contains the *kar1-Δ15* mutation, allowing the strain to be a YAC recipient during the *kar1*-transfer procedure (17, 18). In some instances, fragmentation of a single chromosome (e.g., chromosome I) was sufficient to create a desirable window for subsequent YAC isolation. However, in four cases (e.g., the doublet of chromosomes V and VIII at 590 kb; the doublet of chromosomes XIII and XVI at 950 and 985 kb, respectively: the doublet of chromosomes VII and XV at 1120 and 1130 kb, respectively; and the triplet of chromosomes X, XIV, and II at 755, 810, and 840 kb, respectively), a window of desired size could only be created by the successive fragmentation of multiple chromosomes. For this purpose, the fragmentation vectors used in strategy 1 and strategy 2 (Figs. 1 and 2) were engineered to contain the *URA3* gene (for positive selection of yeast transformants) flanked by direct repeats. Thus, after each round of fragmentation, the *URA3* gene was eliminated from the yeast strain by growth on 5′-fluoroorotic acid [which allows selection of clones that have excised the *URA3* gene via recombination of the flanking direct repeats (20)], thereby enabling another round of fragmentation with *URA3* selection. In the end, we constructed the nine strains listed in Table 1 by employing strategy 1 and/or strategy 2 to fragment up to three endogenous chromosomes. Importantly, these nine strains together provide an overlapping set of electrophoretic windows extending from ≈140 kb to ≈2000 kb (Fig. 3).

Transfer of YACs into Window Strains. Key to the utilization of the window strains for YAC isolation is the ability to transfer a YAC of interest into an appropriately selected strain in a convenient and efficient fashion. The presence of the *kar1-Δ15* mutation in all the newly constructed strains allows the transfer of a YAC from its starting host (e.g., AB1380) into a window strain. YACs have been successfully transferred into each of the window strains listed in Table 1. More than 30 different YACs, ranging in size from 240 kb to >1 Mb, have been transferred, with three examples shown in Fig. 4. In general, 80–90% of the Ura$^+$Trp$^+$Cyh^R colonies are *MATα*, and virtually all of these *MATα* clones represent authentic YAC-transfer events. Significant differences in the growth characteristics or the frequency of authentic YAC transfers were not observed among the different strains. Furthermore,

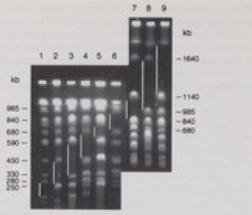

FIG. 3. PFGE analysis of window strains. The chromosomes of the various yeast window strains (Table 1) were separated by PFGE (lanes 1–6, 30–90 sec switching time, 24 h; lanes 7–9, 80–150 sec switching time, 36 h) and detected by ethidium bromide staining. YLBW1–YLBW9 were analyzed in lanes 1–9, respectively. The windows in the electrophoretic karyotypes are indicated by white lines. For PFGE, 1% agarose gels were electrophoresed in 0.5× TBE (1× TBE: 90 mM Tris/64.6 mM boric acid/2.5 mM EDTA, pH 8.3) with the following parameters: 6 V/cm, 120° angle, 12°C.

the fragmented chromosomes and the windows themselves have generally remained unchanged during YAC transfer. Similarly, there has been no evidence of additional YAC instability following transfer, beyond that encountered with the YAC in its original host strain. Thus, similar to previous experience (17, 18), we find that transfer of YACs by the *kar1*-transfer procedure is highly robust and efficient, thereby providing a reliable method for moving YACs into the new window strains.

DISCUSSION

The YAC cloning system has rapidly become a critical tool for the dissection of complex genomes and for the study of large genes and their associated regulatory elements. One limitation

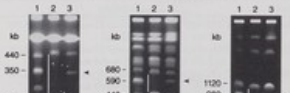

FIG. 4. Transfer of YACs that comigrate with endogenous chromosomes into window strains. Three YACs [yWSS2319, yWSS2764, and yWSS647 (lane 1 in *A–C*, respectively), previously described (30)] each comigrated with an endogenous yeast chromosome(s). YLBW2, YLBW4, and YLBW7 (lane 2 in *A–C*, respectively) contain windows of the appropriate size for these three YACs. Using the *kar1*-transfer procedure (17, 18), each YAC (arrowhead) was transferred into the corresponding window strain, thereby allowing its free migration within the available window (lane 3 in *A–C*, respectively). The chromosomes of the various yeast strains were separated by PFGE (*A*, 15–35 sec switching time, 24 h; *B*, 60–120 sec switching time, 24 h; *C*, 80–150 sec switching time, 32 h) and detected by ethidium bromide staining. Additional details about the PFGE conditions are the same as in Fig. 3. Note that there are some natural size polymorphisms between certain chromosomes in YPH925 and AB1380.

of YACs is that the cloned DNA cannot be readily purified in large quantities, even by preparative PFGE. This problem is exacerbated when a YAC is the same size as one or more of the endogenous yeast chromosomes. Even when a YAC is slightly different in size than an endogenous chromosome(s), PFGE-based separation can often be tedious and challenging on a preparative scale, especially when high concentrations of yeast DNA are loaded onto the gel and low-melting-point agarose is employed, which requires different electrophoretic conditions than regular agarose. Thus, the subsequent utilization of a YAC that is similar in size to an endogenous yeast chromosome(s) may be limited, especially for applications that demand relatively pure preparations of the cloned DNA.

To minimize this limitation, we have devised an approach that greatly facilitates PFGE-based isolation of YAC DNA away from endogenous yeast chromosomes. Our approach capitalized on two important advances in yeast genetics: homologous recombination-based chromosome fragmentation (15, 16) and movement of YACs from one yeast cell to another by the *kar1*-transfer method (17, 18). Here we report the construction of a set of yeast host strains whose chromosomes have been systematically altered to produce large windows in their electrophoretic karyotypes. These strains were produced by up to three sequential rounds of recombination-mediated chromosome fragmentation using the strategies depicted in Figs. 1 and 2. By careful selection of the yeast targets that served as fragmentation sites (based on their relative positions on the yeast chromosomes), each resulting strain contains a window covering a different size range within the electrophoretic karyotype. Importantly, the presence of the *kar1-Δ15* mutation allows each newly constructed strain to act as a YAC recipient following mating with a YAC-containing strain. Thus, a YAC of any size can now be efficiently transferred into an appropriately selected window strain and purified by PFGE without concern about the presence of closely migrating endogenous yeast chromosomes.

Other approaches to deal with the problem of YAC DNA isolation were also considered. For example, one possibility was to create a set of fragmentation vectors that could be used to fragment a closely migrating yeast chromosome in the starting YAC strain. Inherent problems with this approach include (*i*) the high frequency of resulting transformants that do not contain a fragmented chromosome, which would have to be screened through and analyzed in every experiment, and (*ii*) the need to successively perform two (or more) rounds of chromosome fragmentation in the case of YACs that migrate close to two (or more) endogenous yeast chromosomes (such as chromosomes V and VIII at 590 kb or chromosomes X, XIV, and II at 755, 810, and 840 kb, respectively). Thus, constructing a universal set of strains with preexisting windows was viewed as more desirable than performing chromosome fragmentation in every instance where a YAC was similar in size to an endogenous chromosome. A second possibility for creating karyotypic windows was by the recombination of endogenous chromosomes to yield larger DNA molecules. For example, established recombinase systems from bacteriophage P1 (31) or *Zygosaccharomyces rouxii* (32) could, in principle, be utilized for systematically recombining endogenous yeast chromosomes. However, this approach seemed less straightforward and potentially more problematic than the strategies we utilized for chromosome fragmentation.

We have found that *kar1*-mediated transfer of a YAC from its original host into a window (or other *kar1-Δ15*-containing) strain is a highly robust procedure. Other endogenous chromosomes can move into the recipient strain along with the YAC at a frequency as high as 20% (17, 18). However, for the window strains, the cotransfer of a YAC and an endogenous chromosome that migrates within the window should occur at a frequency of at most 2–3% and will likely not represent a significant problem. Armed with the newly constructed window strains and a reliable and routine means for moving YACs from one host to another, it is now possible to isolate YAC DNA away from other yeast chromosomes in an efficient fashion.

We thank L. Riles for providing pBM2815, Dr. F. Spencer for providing YPH925, and Drs. P. Hieter and R. Rothstein for helpful advice regarding this project. We also thank Drs. P. Hieter, R. Rothstein, and Gabriela Adelt Green for critical review of the manuscript.

Version 10/95

BACKGROUND

The isolation of YAC DNA by preparative pulsed-field gel electrophoresis (PFGE) is often hampered by the presence of closely migrating or co-migrating endogenous yeast chromosomes. We have developed an approach for the reliable isolation of YAC DNA free of endogenous yeast chromosomes regardless of YAC size [described in detail in Hamer *et al.* (submitted) and illustrated in Figure 1]. Our general strategy involves: (1) The use of an established set of yeast strains with chromosome-free areas (i.e., "windows") in their electrophoretic karyotypes (Figure 2 and Table 1); (2) The transfer of a YAC of interest into an appropriate "window" strain (Figures 3 and 4); and (3) The isolation of YAC DNA by preparative (PFGE).

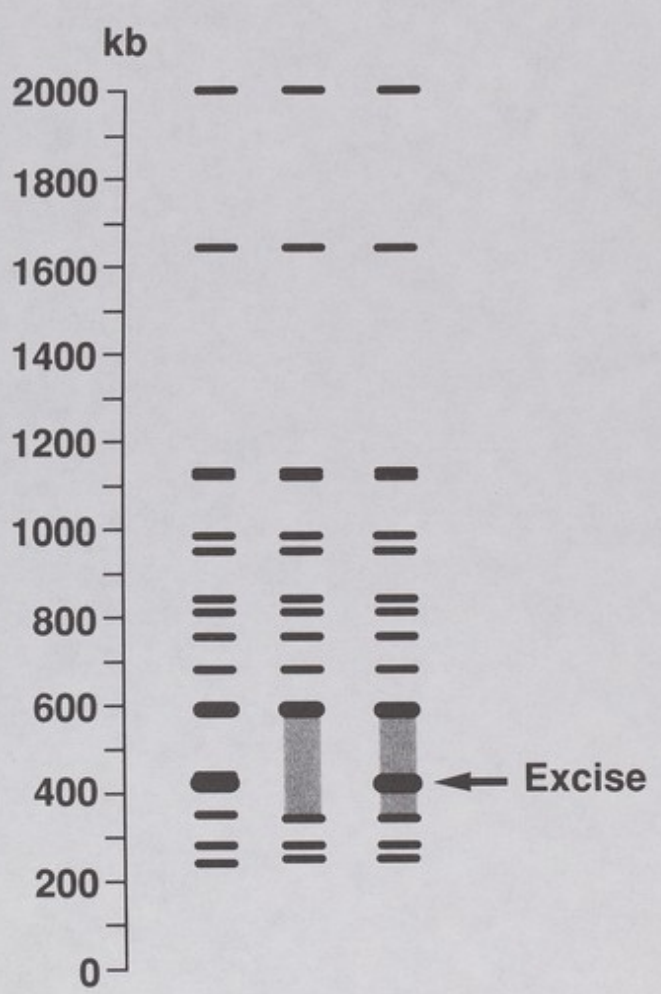

Figure 1: Isolation of YAC DNA Following Transfer into a Yeast "Window" Strain. YAC DNA is typically isolated by preparative PFGE, with the YAC DNA band simply being excised from the gel. However, as shown in the left lane, this approach can be confounded by the presence of closely migrating (or co-migrating) endogenous yeast chromosomes. A solution to this problem is depicted. The center lane shows the results of PFGE analysis of a yeast strain whose chromosomes have been systematically altered to create a chromosome-free "window" in the electrophoretic karyotype (shaded area). Following transfer into the "window" strain, the YAC can be readily excised free of endogenous yeast chromosomes, as shown in the right lane.

To construct the "window" strains, we used recombination-mediated chromosome fragmentation as described by Vollrath *et al.* (1988). Yeast cells were transformed with two small linear DNA molecules: one harbored a centromere, while both contained a telomere and a sequence homologous to a target region on an endogenous yeast chromosome. Recombination across the homologous regions resulted in the fragmentation of the endogenous chromosome and the formation of two smaller derivative chromosomes (which then typically migrate faster than the intact target chromosome). We have created a set of "window" strains (each with a unique "window") by the strategic fragmentation of different combinations of yeast chromosomes (Figure 2).

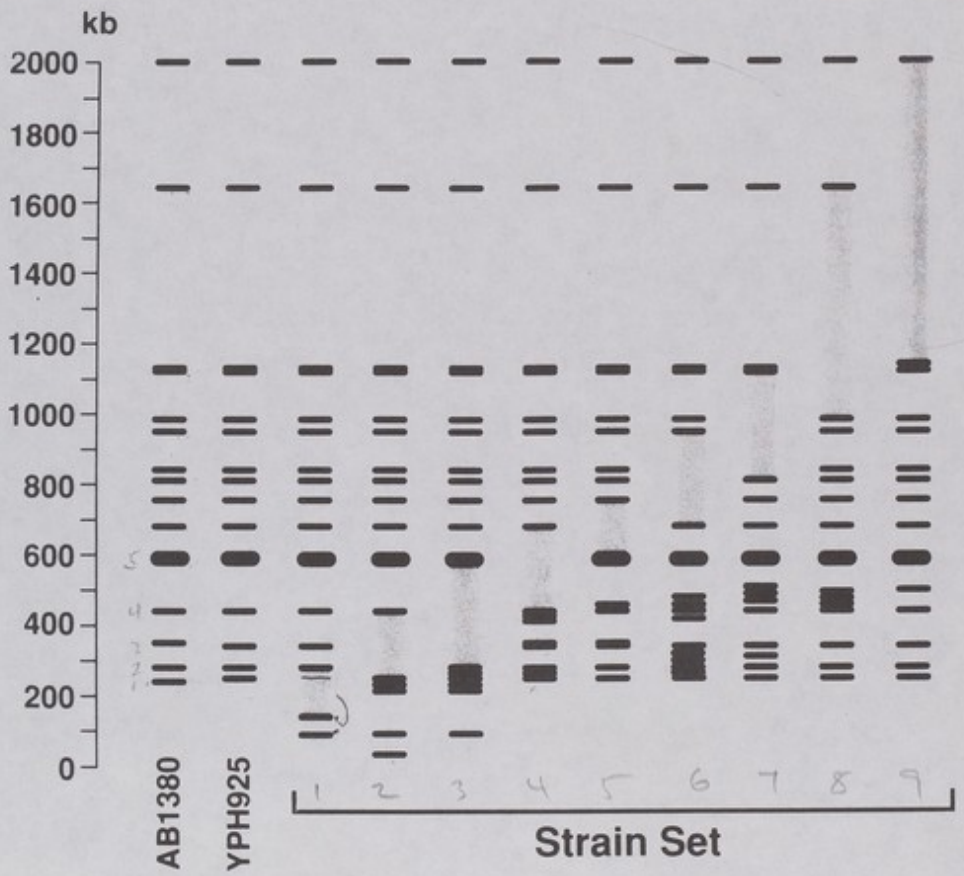

Figure 2: PFGE Analysis of the Yeast "Window" Strains. The results of analyzing the set of 9 "window" strains by PFGE are schematically illustrated. The first 2 lanes from the left show the electrophoretic karyotypes of AB1380 (the most common YAC host strain) and YPH925 (the strain used to construct the "window" strains), respectively. The next 9 lanes show the set of "window" strains. Note the overlapping electrophoretic "windows" (depicted as shaded boxes). Some "windows" resulted from fragmentation of a single chromosome, while others resulted from the successive fragmentation of 2 or 3 chromosomes. There is a complete overlap from one "window" to the next, starting with the "window" at 150-280 kb and ending with the "window" at ~1140-2000 kb (see Table 1). Importantly, these "windows" cover the size spectrum of most YACs, and include the regions where YACs are frequently co-migrating with closely-spaced yeast chromosomes (e.g., the doublet of yeast chromosomes at 590 kb, the triplet of yeast chromosomes from 755 kb to 840 kb).

Table 1: Yeast Strains Containing "Windows" in Their Electrophoretic Karyotypes. The "window" strains YLBW1 through YLBW9 are listed along with each respective genotype, target(s) for fragmentation [with the corresponding chromosome(s) indicated in parenthesis], and size range of the "window". The upper size of the "window" in YLBW9 varies due to the presence of ribosomal repeats in chromosome XII (indicated by a "*").

KAR-CROSS TRANSFER OF YACs INTO YEAST "WINDOW" STRAINS

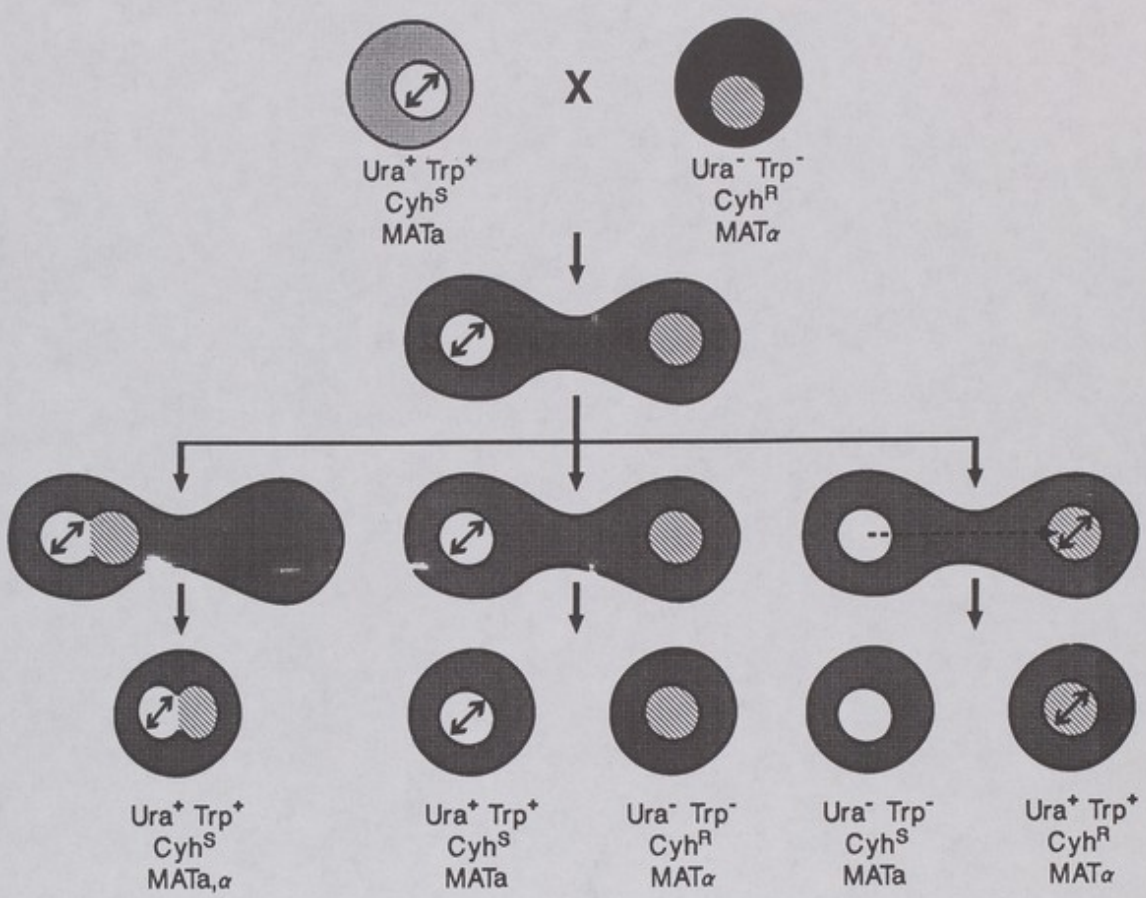

Figure 3: Transfer of YACs into New Hosts by Kar Crossing. YACs can be transferred into new host strains by the *kar*-cross method developed by Spencer *et al.* (1994) and Hugerat *et al.* (1994). Shown in the upper left is a typical YAC in its cycloheximide-sensitive (Cyh^S) host of mating type **a** (e.g., AB1380). The YAC renders the cell Ura^+Trp^+. Shown in the upper right is a "window" strain (i.e., the recipient cell). This strain is cycloheximide resistant (Cyh^R), mating type α, and Ura^-Trp^-. Normally, when yeast cells of opposite mating type mate, nuclear fusion (karyogamy) follows cell wall fusion to form a diploid cell. However, strains with a mutation in the *kar1* gene are deficient in karyogamy. All the "window" strains are *kar1-Δ15* mutants. In crosses involving a *kar1-Δ15* mutant, haploid progeny budding off from the heterokaryon share parental cytoplasm but have one or the other of the parental nuclei (because the nuclei remain unfused). At a frequency of ~10^{-3} to 10^{-4}, a chromosome from one nucleus is transferred to the other. When the transferred chromosome is a YAC, the resulting recipient strain is $Ura^+Trp^+Cyh^R$ (lower right). The *kar1-Δ15* mutation is slightly leaky, so that some diploid cells are formed (lower left), and-- since the Cyh^S allele is dominant-- these diploids are sensitive to Cyh. However, at relatively low frequencies, these diploids can become Cyh^R (presumably from the loss of the Cyh^S allele through mitotic recombination or chromosome loss). Since these diploids are also Ura^+Trp^+, they must be distinguished from the products of authentic YAC-transfer events, and this can be conveniently performed by assessing the mating type of the cells. Diploids are heterozygous at the mating type (*MAT*) locus (**a**/α), while the desired $Ura^+Trp^+Cyh^R$ haploid cells are mating type α.

Storage and Propagation of Yeast "Window" Strains

The *kar1-Δ15*-containing yeast "window" strains should be stored at -80°C in sterile 20% glycerol. For YLBW2-9, routine propagation should be performed in YPD medium. For YLBW1, routine propagation should be performed in YPD supplemented with 40 mg/liter of cysteine (Sigma C-7880). YLBW1 was created by fragmentation within the *CYS3* gene of yeast chromosome I, making it an auxotroph for cysteine. At low frequencies, the derivative smaller chromosomes in this strain tend to recombine, "reforming" the starting chromosome I (thereby eliminating the "window") and restoring cysteine prototrophy. This effect can be minimized by the inclusion of extra cysteine in the medium used to culture YLBW1.

Kar-Cross Transfer of YACs

The basic procedure for transferring YACs into the "window" strains (or other YPH925-derived strains) by *kar*-crossing is depicted in Figure 4.

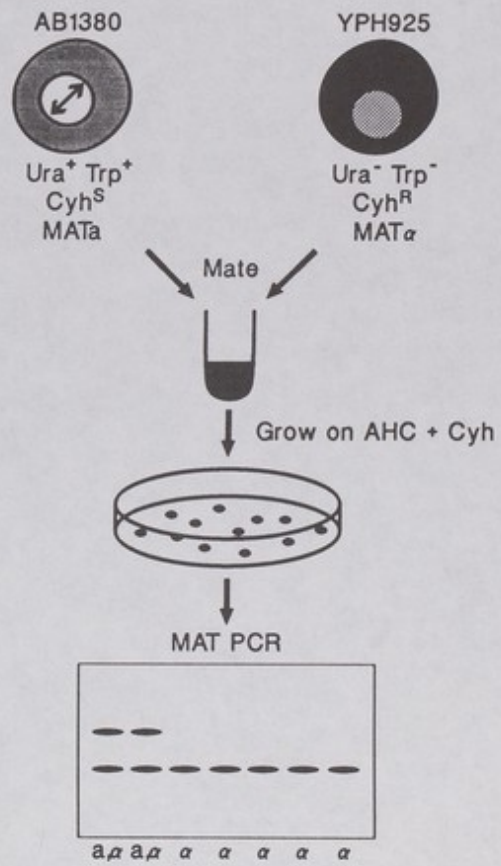

Figure 4: Experimental Procedure for Performing a Kar-Cross. A YAC clone (e.g., in host AB1380) is mated with a "window" strain derived from the *kar1-Δ15*-containing YPH925. The cells are plated on AHC medium (to select for the YAC) containing cycloheximide (to select for the "window" strain nucleus and against the starting YAC host nucleus). Most of the resulting clones represent authentic YAC-transfer events (haploids), while a minor fraction are diploids that have become Cyh^R. These can be distinguished by assessing the mating type, performed either by *MAT*-specific PCR (see below) or a replica plate test. Virtually all *MATα* cells will contain the YAC in the recipient "window" strain.

PROTOCOL

1. Inoculate 25 ml of YPD broth in a 50-ml tube with an appropriately-selected "window" strain (see Figure 2 and Table 1) and inoculate 25 ml of AHC broth in a 50-ml tube with the YAC clone.

   Note: For YLBW1, use YPD broth containing 40 mg/liter of cysteine (Sigma C-7880).

2. Incubate at 30°C shaking at 250-300 rpm for 1 overnight.

3. Determine the cell concentration in each culture using a hemocytometer.

4. Mix $5x10^6$ cells from each culture in a 50-ml tube.

   Note: The rest of the cells from each culture can be used to prepare agarose-embedded high-molecular-weight yeast DNA (see attached protocol). These DNA samples can be used as controls during PFGE analysis to verify authentic YAC transfer into the "window" strain.

5. Centrifuge the cell mixture for 5 minutes at 4000 rpm, discard the supernatant, and add 1 ml of fresh YPD broth.

6. Resuspend the cells and incubate stationary at 30°C for 6 hours.

7. Plate 300 µl and 500 µl aliquots of the cell mixture on separate AHC+Cyh plates.

   Notes:

   It is important that the AHC+Cyh plates are poured "thick" (i.e., contain 35-40 ml of medium in an 85-mm diameter petri plate).

   For YLBW1, use AHC+Cyh containing 40 mg/liter of cysteine (Sigma C-7880).

8. Incubate plates at 30°C for 4-5 days.

   Note: Typically, the faster-growing diploid cells will be seen after 3 days. Wait and analyze the colonies that become visible on the 4th and 5th day.

1 ml

100 µl M Ammonium sulphate

400 µl Tris

25 µl $MgCl_2$

475 µl H_2O

9. Assess the mating type of 10 independent, medium-size colonies by *MAT*-specific PCR analysis (Huxley *et al.*, 1990), as follows:

A. Prepare an appropriately-sized master PCR cocktail based on the number of samples to be analyzed. Be certain to include 3 extra reactions for testing: (1) a known *MAT***a** strain (e.g., a YAC in an AB1380 background), (2) a known *MAT*α strain (e.g., a "window" strain), and (3) a blank sample (no added yeast cells).

	Per Reaction (5 µl)	
Sterile Water	3.35 µl	3.65
5X PCR Buffer [50 mM Tris-HCl (pH 8.3), 250 mM KCl, 12.5 mM $MgCl_2$]	1.0 µl	0.5 10X
dNTP Mixture (@2.5 mM)	0.4 µl	0.8 1.2 mM
Primer Mixture (3 primers, each at 25 µM)	0.2 µl	Dry Supplied at ~30 pmol/µl ≈ 25µM
WIN1 5'AGTCACATCAAGATCGTTTATGG3'		
WIN2 5'GCACGGAATATGGGACTACTTCG3'		
WIN3 5'ACTCCACTTCAAGTAAGAGTTTG3'		
AmpliTaq Polymerase (5 units/µl)	0.05 µl	
		5

B. Dispense 5 µl of the cocktail to the bottom of each PCR tube.

C. Lightly touch the pointed end of a sterile toothpick to each yeast colony, place in a tube containing the PCR cocktail, and twirl the toothpick briefly to suspend the cells.

Notes: A "large" amount of yeast cells will inhibit the PCR. The optimal amount to add is a "barely visible" collection of cells at the tip of a toothpick. Be absolutely certain <u>not</u> to touch the agar with the toothpick, as components in the medium can inhibit PCR.

D. Overlay samples with mineral oil (if necessary), and then subject samples to 35 cycles of 92°C for 1 minute, 58°C for 2 minutes, and 72°C for 2 minutes.

Note: These conditions have been established using a Perkin-Elmer TC1, 480, and 9600 thermal cyclers. The use of another brand of thermal cycler may require prior optimization to establish the appropriate conditions.

10. Analyze PCR products by agarose or acrylamide gel electrophoresis.

PCR Product(s)	*MAT* Type	Frequency	Interpretation
404 bp	*MAT*α	Most	Desired YAC Transfer
404 bp and 544 bp	*MAT*α/**a**	Intermediate	Diploid
544 bp	*MAT***a**	Rare	Starting YAC Strain

11. Select at least 2 *MAT*α colonies, and inoculate each into a separate 25-ml AHC culture (in a 50-ml tube).

12. Incubate shaking at 30°C for 2 days.

13. Prepare agarose-embedded high-molecular-weight yeast DNA (see attached protocol).

14. Analyze purified DNA by PFGE (see Table 2 for suggested conditions). Include the following samples: (1) a lambda concatamer; (2) the initial YAC clone; (3) the "window" strain; (4) each of the YAC-transfer candidates (*MAT*α colonies from step 11).

    Note: Because of the presence of "remnant" homologous sequences among the various fragmented chromosomes (deriving from the fragmentation vectors), there is the possibility for recombination (and therefore the formation of new derivative chromosomes). Therefore, the starting "window" strain should always be tested by PFGE in parallel with the initial YAC clone and all YAC-transfer candidates. Such analysis allows confirmation that the "window" is still devoid of endogenous yeast chromosomes.

Table 2: Suggested Parameters for Analysis of "Window" Strains by PFGE. The indicated conditions are based on the use of a Bio-Rad CHEF System, 1% SeaPlaque GTG agarose (FMC), 0.5X TBE maintained at 12°C, and a 120° angle used during electrophoresis.

Strain	"Window" (kb)	Switching Time (Linear Gradient)	Total Time of Electrophoresis
YLBW1	~150-280	15-25 seconds	24 hours
YLBW2	~250-450	20-35 seconds	24 hours
YLBW3	~310-590	35-60 seconds	24 hours
YLBW4	~450-680	50-70 seconds	24 hours
YLBW5	~590-755	50-80 seconds	36 hours
YLBW6	~680-950	60-100 seconds	36 hours
YLBW7	~810-1120	70-120 seconds	48 hours
YLBW8	~985-1640	80-130 seconds	48 hours
YLBW9	~1140-2000	100-160 seconds	48 hours

Preparation of "High Quality" Yeast DNA for Gel-Purifying YACs

[Adapted from Southern et al. (1987) and Anand et al. (1989)]

1. Inoculate each YAC clone in 25 ml of AHC medium (in a 50-ml tube), close caps to the point where they will remain in place during vigorous shaking (or spinning), and incubate at 30°C shaking at 250-300 rpm (or spinning) for 2 overnights.

   Note: Alternatively, a 25-ml YPD culture can be inoculated and incubated for a single overnight at 30°C. YPD medium must be used for culturing yeast strains devoid of a YAC.

2. Centrifuge the culture at 2000 rpm for 10 minutes and discard supernatant.

3. Add 20 ml of 50 mM EDTA (pH 8.0), resuspend cells by gentle shaking, repeat step 2, and briefly invert tube to drain.

4. Add 100 µl of **Solution I** per 200 µl of cell pellet and resuspend cells by gentle vortexing at the lowest speed.

Solution I [1 M sorbitol/20 mM EDTA/14 mM 2-mercaptoethanol]
91 g of Sorbitol 20 ml of 0.5 M EDTA (pH 8.0) 500 µl of 2-Mercaptoethanol dH_2O to 500 ml

5. Add 25 µl of 10 mg/ml Zymolyase-20T (ICN, prepare fresh in sterile dH_2O) per 100 µl of **Solution I** added in step 4.

6. Immediately add 1 to 1.3 volumes of 2% SeaPlaque GTG agarose (FMC) prepared in **Solution I**, melted, and equilibrated at 50-60°C. Using a blue tip, mix thoroughly but carefully (bring up and down 3-4 times with the pipetman, avoiding formation of air bubbles), and place mixture in an individual plug mold that is sealed on the bottom with tape.

7. Chill the mold at 4°C until the agar is solidified.

8. Dislodge the solidified plug using a bent 21-gauge needle or a pasteur pipette and place in an individual well of a 6-well culture plate containing 8-10 ml of **Solution II**.

Solution II [1 M sorbitol/20 mM EDTA/14 mM 2-mercaptoethanol/ 10 mM Tris (pH 8.0)/0.5 mg per ml Zymolyase-20T]
99 ml of **Solution I** 1 ml of 1 M Tris (pH 8.0) 50 mg of Zymolyase-20T (ICN) [Note: Add immediately before use]

9. Incubate at 37°C for 2-4 hours.

10. Carefully remove solution (e.g., using an aspirator) and add 8-10 ml of **Solution III**.

Solution III [1% lithium dodecyl sulfate/100 mM EDTA/ 10 mM Tris (pH 8.0)]
5 g of Lauryl Sulfate, Lithium Salt (Sigma L-4632) 100 ml of 0.5 M EDTA (pH 8.0) 5 ml of 1 M Tris (pH 8.0) dH_2O to 500 ml FILTER STERILIZE AND STORE AT ROOM TEMPERATURE

11. Incubate at 37°C overnight.

12. Repeat steps 10 and 11.

13. Carefully remove solution, add 8-10 ml of 0.5 M EDTA (pH 8.0), incubate at room temperature overnight, and repeat twice.

    Note: Alternatively, plugs can be taken immediately from **Solution III** and loaded in a gel (as long as the gel is then equilibrated overnight in the circulating buffer prior to electrophoresis).

14. Store plugs in 0.5 M EDTA (pH 8.0) or TE (pH 8.0) at room temperature or at 4°C.

TIPS FOR IMPROVED VISUALIZATION OF YEAST CHROMOSOMES AFTER PFGE

1. Gel Volumes:	Large Bio-Rad Casting System	180 ml
	Small Bio-Rad Casting System	85 ml

2. Sample Loading:
- Create loading "trough" by excising entire top 1-2 cm of gel
- Place plug directly on side of remaining gel (in trough)
- Be certain that there is no air trapped between plug and gel
- Seal plug in place with melted agarose equilibrated to 50°C
- Pour in rest of melted agarose to fill "trough"

3. Equilibration:
- Equilibrate gel in 0.5X TBE at 12°C overnight in gel chamber
- Circulate TBE with pump set at "90"
- Remove as much air from the tubing as possible
- Be certain that the TBE is well circulating

4. Electrophoresis:
- Lower amperage to ~100-115 mA by removing TBE from chamber
- Level of TBE should be only 2-3 mm above the gel
- Be certain that the gel chamber is level

MEDIA

AHC Medium

A rich -Ura-Trp ("double drop-out") complete medium for the routine culturing of YACs. The acid-hydrolyzed casein contains no vitamins or nucleosides and is low in salt, but provides virtually all of the necessary nutrients for yeast growth except for uracil, tryptophan, and adenine. Adenine is added such that growth is limited, and the red pigment forms as a consequence of the nonsuppressed *ade2* mutation.

1. Dissolve the following components in water:

	Per 1 liter:
Yeast Nitrogen Base Without Amino Acids (Difco 0919-15)	6.7 g
Casein Hydrolysate Acid, Low Salt (U.S. Biochemicals 12852)	10.0 g
Adenine Hemisulfate•H_2O (Sigma A-9126)	0.02 g

Note: Instead of the above yeast nitrogen base without amino acids, 1.7 g/liter of yeast nitrogen base without amino acids and without $(NH_4)_2SO_4$ (Difco 0335-15) plus 5 g/liter of $(NH_4)_2SO_4$ can be substituted.

2. Bring volume to 950 ml and adjust pH to 5.8 (with HCl).

3. For plates, add 20 g/liter of Bacto agar

Note: Difco brand is highly recommended, otherwise a precipitate may form upon autoclaving.

4. Autoclave 20 minutes (for 1 liter) and allow to cool (to 65-80°C).

5. Add 50 ml of sterile 40% (w/v) glucose per liter and mix well.

Note: Alternatively, 20 g of solid glucose per liter can be added before autoclaving; however, the resulting medium will be markedly darker in color (although still usable for YAC culturing).

6. For AHC+Cyh, add sterile cycloheximide (Sigma C-7698) to a final concentration of 3 µg/ml.

YPD Medium

A general purpose non-selective, complex medium for the routine culturing of yeast. Yeast cells grow vigorously, regardless of the presence of a YAC. Promotes growth to a high density, but is not selective for YACs.

1. Dissolve the following components in water:

	Per 1 liter:
Yeast Extract (Difco 0127-01)	10 g
Peptone (Difco 0118-01-8)	20 g

2. Bring volume to 950 ml and adjust pH to 5.8 (with HCl).

3. For plates, add 15 g/liter of Bacto agar.

4. Autoclave 20 minutes (for 1 liter) and allow to cool (to 65-80°C).

5. Add 50 ml of sterile 40% (w/v) glucose per liter and mix well.

Note: Alternatively, 20 g of solid glucose per liter can be added before autoclaving; however, the resulting medium will be markedly darker in color (although still usable for yeast culturing).

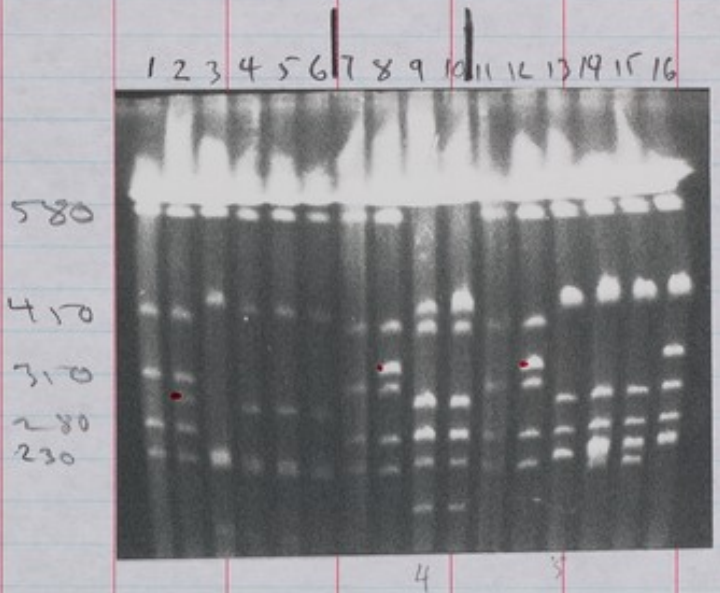
probes provided by the community. In addition, repeat sequences can cause severe problems. Figs N - N show a variety of probings having different degrees of interpretability. (Efforts were made to overcome these problems by prehybridistion to eliminate repetitive sequences from probes (ref Southern), but without success).

Directed efforts

A few recalcitrant regions have been mapped in some detail as a result of intensive efforts to locate a particular gene. A good example of the complexities that can arise is seen in the cloning of tra-1 (LGIIIR) (Hodgkin 1987, 1993). Attempts to clone this gene by transposon tagging had been unsuccessful. A number of Bergerac-derived Tc1 polymorphisms were identified and mapped relative to genes surrounding the tra-1 locus. None appeared likely to be within 200 kb of tra-1 (interpolating between genetic and physical distances using wabt was thought to be a typical metric for the chromosome arms). Unique fragments adjacent to three Tc1 insertions (eP1, eP2 and eP10) were selected as start points for walking. No positive phage (lambda 2001, plated on the standard rec+ host Q358) were found by hybridisation with the eP1 fragment (believed to be the closest to tra-1) but two YACs were detected. These in turn led to the identification of a small previously unmapped cosmid contig. RFLP analysis of rearrangement alleles showed that this contig was in the region of tra-1. The cosmid contig was oriented by differential screening of lambda clones with the two cosmids that wholly represented the cosmid contig. Walking in the required direction from this contig was only achieved by the isolation of phage clones from an unamplified library of lambda 2001 clones plated on the rec- host CES 200 (recBC sbcB) (Wyman et al). (Other hosts were assayed but were not as satisfactory). Extension of the cosmid contig was determined by fingerprinting of the isolated lambda phage. These extending phage then led to the isloation of a further YAC which was used to indentify two more small cosmid contigs. Overall, the region around tra-1 was found to contain at least four sites that cannot

11/11



1	ABJ380
2	Y71A12 (340)
3	YCBW2
4	Y71A12W2B
5	" C
6	" D
7	ABJ380
8	Y1029J3 (670).
9	YCBW4
10	Y1029J3W4A
11	ABJ380
12	Y1029J3
13	YCBW5
14	Y1029J3W5A
15	" B
16	" C

So:

Y71A12 transfer (B, C, D) all good but unnecessary.

Y1029J3 transfer to YCBW4 probably failed but 4A appears to be not of expected size i.e. apparently 400 rather than 670. Y1029J3W4A does look to have an additional band at ~ 470.

If Y1029J3 really is ~400, transfer to Y1029J3W5C may be good. But A and B appear to have gained products at ~ 200 kb. Perhaps Y1029J3 is unstable?

(Probing 1 cosmid grid with ~670 kb band gave poor probing but generally in accordance with cy and PCR data).

18/10.

From: Michael Quail <mq1@sanger.ac.uk>
To: Alan Coulson <alan@sanger.ac.uk>
Subject: window strains
Content-Type: TEXT/PLAIN; charset=US-ASCII

Dear Alan,

The list of clones I know of that require window transfer are:

D.discoideum
DY3567 (800kb)
DY3689 (260kb)
DY3180 (225kb)

malaria ch.5
MY227
MY415 (250kb)

Dave may well know of one or two more by now, and he will have the gel pictures for the above, so you should chat to him.

Best of luck

Mike

Y56F9 280 for window transfer >W2
Y18D10 280 for window transfer >W2
Y47E12 380 ? big YAC for poss small gap; try other methods first?
Y50B1 230 sepn may be OK (but preliminary PFG)

Y6B3 230 sepn OK
Y66F9 310
Y71A12 340 window transfer good (but unnecessary): use Y71A12W2B
Y63D3 230 window transfer awaiting PFG assay (22/11)
Y112D2 or Y120H4 being sized
Y54E5 290 window transfer awaiting PFG assay (22/11)

7/11/96

Window transfer summary.

Y39	G8	→ 1	good			
Y48	B6	2	good			
Y48	C3	2	good			
Y71	A12	2	under assay			
Y102	G3	4	" "			
Y102	G3	5	" "			
Y39	E4	2	" "			
Y41	C4	2	needs repeat			
Y45	F10	3	under assay			
Y37	H2	3	" "			
Y38	E10	2	" "			
Y40	H7	230	do	do	→	W1
Y71	A9	230	do	do		W1
Y41	E3	280	do	do		W2
Y53	C10	350	do	do		W2
Y63	D3	230	do	do		W1
Y54	E5	290	do	do		W2

For preliminary assay if necessity for window transfer:

Y18	D10	280	
Y26	G10	230	
Y38	H6	280	
Y47	D3	350	
Y47	H10	350	
Y50	B1	230	
Y56	F9	280	
Y105	C5	790
