NATURE

NUMERALISED PROFILES FOR CLASSIFICATION AND RECOGNITION.

WHEN children or savages attempt to draw a human profile, the result is usually a rude figure that lays stress on five cardinal points. These are the notch between the brow and the nose, the tip of the nose, the notch between the nose and the upper lip, the parting of the lips, and the tip of the chin. Supposing these five points, B', N', L', L', and C', to be located with fair precision, as will shortly be shown to be feasible, then Fig. 1 is directly deducible from them, including the vertical and horizontal axes, C'B', and C'X at right angles to C'B'. The position of the five cardinal points varies in different profiles much more than the probable error of measurement. So though Fig. 1 is a mere skeleton, which determines what may be called the set of the features, and corresponds to the primary triangulation of a country, other points are to be derived from it, such as the intersection with the outline by perpendiculars, drawn from the middle or other specified division of the lines, etc. This skeleton also serves as an excellent basis for the classification of profiles and for anthropological statistics.

Peculiarities of profile, as a racial or family characteristic, can be expressed numerically by an extension of this system in a way that promises to be serviceable for eugenic records. It was, in fact, largely with this object in view that I began the inquiry. The replacement in all scientific work by numerical values, in the place of vague adjectives, is a gain of first-class importance. There is no way known to me, other than this, by which likenesses can be "lexiconised," that is, arranged as words in a dictionary. A needed portrait may be thus discovered by a formula, as a spoken word is found in a dictionary, by means of the letters that express its sound. There are many simple purposes of newspaper interest to which this same method might be applied, but with more elaboration.

The practice of cataloguing profiles may perhaps become useful as a secondary means of identification when the number of persons who are catalogued shall have become too large to be readily dealt with by finger-prints alone. It will also be shown that four

FIG. 1 FIG. 2 FIG. 3

telegraphic "words" are sufficient to convey a very fair profile likeness. The cost of sending an extra four words by telegram to any part of the British Isles being only twopence, and of a moderate amount over-sea, the practice of telegraphing profiles, of all kinds, might become common. A refugee criminal could easily be outstripped by his portrait, sufficiently like to him to justify, in connection with corroborative evidence, his being placed for a while under police observation. The measures of profiles must, of course, be reduced to uniformity. Then, by utilising two out of the five cardinal points to give direction and scale, the mean positions of the remaining three points may be determined for any given race or family, together with the frequency of deviations of any given amount from those mean positions, and such other conclusions as can be reached by the modern methods of statistics.

The corrected values are here described by the same letters as the original ones, but without the dashes. The standard scale that is used is such that BC, the corrected value of B'C', shall be always [illegible] units in length. The reduction is, of course, effected by multiplying each measure in the portrait by [illegible] divided by its B'C'. The number [illegible] is preferable to [illegible], which would probably first suggest itself, for a variety of practical reasons, into which I need not enter here. Two figures are assigned to each measure, so the values [illegible] have to be written [illegible]. The measures are rounded to the nearest integer, there being no room for fractions, decimal or other. A millimetre is a convenient unit for purposes of drawing, more so than one-tenth of an inch; therefore, in reproducing the corrected measures, BC becomes [illegible] millimetres, and the other measures are altered in the same proportion.

A thick beard interferes with determining L' and L', but their positions can usually be inferred with a useful degree of precision in moderately bearded faces.

The accuracy with which the five cardinal points can be located differs considerably. The most exact determinations in an unbearded face are those of the points C' and N', and the direction of the line C'B'. L' comes next in order of exactness, then B' and, lastly, L'. The distance between C'N', or either of the diagonals, and a parallel line tangential to L' can be found with precision, but is not used here. C' and N' are each defined by the intersection of two tangents, as shown for N' in Fig. 3.

It is well to examine these conditions more closely, as they bear on the treatment of curvatures generally. A knowledge of them permits of rough and ready drawing, in which the principal matters being attended to, the less essential ones being more or less disregarded. One of the tangents is parallel to C'B', which is treated as vertical; the other is inclined to the vertical at 45°. Consequently, the curve of N' is contained in an obtuse angle of [illegible]. The tip of each prominence and the bottom of each hollow is represented by one or other of the three short circular arcs shown in Fig. 2, which are sufficiently numerous for the purposes to which they are here applied. The centres of all circles that touch both the vertical and the diagonal will necessarily lie in the line that bisects the obtuse angle between them; consequently, VO forms an angle with the vertical that is equal to half [illegible]. The tangent of this angle is [illegible]; therefore the position of the line of centres may be found by laying off a point V in a vertical direction, at [illegible] units of length from O, and by drawing another line from V horizontally to W, at a distance from it equal to [illegible] of the same units as before. Then the line of centres passes through O and W. It is easily shown (Fig. 3) that the points of contact between the circle and the two tangents are exactly [illegible] of arc apart. The length of the chord of that angle is equal to about three-quarters of the radius. The shortness of the chord, when the radius is small, is well seen in Fig. 2, and must be borne in mind; it accounts for the scarcely noticeable differences in the curvatures, and consequently for the fewness of the standard arcs that are necessary. The arc of [illegible] is shown by a heavy line in Fig. 3, where the circle has a radius of [illegible] mm. There is often a colloquial confusion between the obliquity of the planes between which an edge lies and that of the sides of the edge itself. The former may be very acute, and the angle of the edge would be equally acute if the planes were prolonged until they met; but usually they do not meet, the edge itself being more or less rounded. The acutely inclined faces of a knife may have a blunted edge, that fails to cut the skin without much pressure, while a broken piece of glass, the fracture of which is perpendicular to its face, but the edge of which is not blunted, cuts too readily makes a gash.

The arcs of [illegible] in Fig. 2 all refer to the cutting edge, so to speak. The direction of the lines within which the cutting edge is situated is determined by the adjacent cardinal points towards which they point.

Referring back to Fig. 3, [illegible], the radius, [illegible]; therefore the distance between N and the circle is only [illegible], which for a radius [illegible] mm. is about three-quarters of 1 mm. This small value is diminished in proportion for lesser values of r (see Fig. 2), so for practical purposes N (and similarly C) may be considered to lie only just outside the convex circumference of the arc by which they are in each case represented.

The values of r which are used as standards for the lesser curvatures are [illegible] mm., [illegible] mm., and [illegible] mm. The drawings in Fig. 2 are not exactly on this scale, but the differences are unimportant. It is unnecessary to divide these small curves into concave and convex, as their condition in that respect is indicated by the part they play in the profile. Two other curvatures of the larger radii, [illegible] mm. and [illegible] mm., are used to express and to define the concavity or the convexity of the ridge of the nose.

It is well, at the risk of some repetition, to describe in a single paragraph the nomenclature of the five cardinal points in the original portrait. B' is the point in the fronto-nasal notch at what is judged to be its deepest part; N' is the tip of the nose, found in the way already described; L' is the point of contact between the nasolabial notch and a tangent, drawn diagonally to it and parallel to the other diagonal; L' is a point half-way between the furthest positions at which the lips would touch one another if they were lightly closed; C' is found by a similar method to that used for N'.

The portraits are described by numerical formulæ. Each formula consists of four groups of figures, five figures in each group. The shapes of the profile at and immediately adjacent to the cardinal points, and

of the intermediate links, are expressed by single numerals, as set forth in tabular form in Fig. 4. Six are provided in each case. The radius of the standard curve that best fits the brow-nasal notch, b, is expressed by its appropriate numeral, as shown in the first line of Fig. 4; also the inclination of the brow immediately above b, whether it slopes forwards, backwards, or is upright. The ridge of the nose g is counted as either sinuous, concave, or convex, in two or three different degrees, or else as straight. The letter n includes

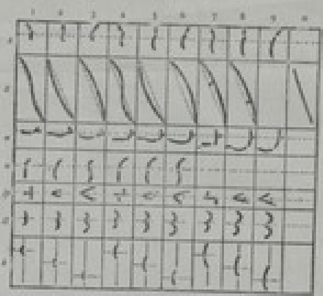

Fig. 4.

both the very tip of the nose and the outline underneath it, which leads towards the naso-labial notch. The lips require two statements, and therefore two separate figures; the former, lp, shows whether the lips are shut, parted in the portrait by 1 or 2 mm., or open by 3 or more, and, again, whether they project evenly, or are overhung or underhung. The latter notation, ll, expresses the sizes of the upper and lower lips respectively, whether they are small, medium, or large. The outline between the lower lip and the chin is always notched, and k describes the size and position of the notch, whether it be small, medium, or large, and whether it be high, medium, or low. The curve of the chin itself at C' is not given.

I have called these profiles "numeralised" to express the fact that they are transformed into numerical formulæ. Twenty figures enter into each formula; they are arranged, as for telegraphy, in the way already described, into four groups of five figures in each group. A "figure," in telegraphic language, includes not only the ten numerals, 0 to 9, but the three symbols in addition, of a stop (.), a hyphen (-), and a short oblique line (/), such as is used in fractions. The arrangement in groups of five, or in "quintets," proved suitable to other similar work on which I was engaged, so it has been adopted throughout. In the four quintets, or, we may say, in the four words that compose a formula, the first three refer respectively to N, L, and L, and in that order. The first two and the last two figures, in each of the first three quintets, give the position of the point in question in X and in Y to the nearest whole millimetre. The middle figure of the quintet is used in connection with Table IV., to describe the peculiarities of the profile at and immediately adjacent to that point. The fourth and last of the quintets is preceded by a dot (.), to show that it belongs to a separate category, namely, to the peculiarities of b, g, ll, and k, as set forth in Table IV., and in that order. When proceeding to draw a figure from a formula, it is advisable for a beginner to use tracing paper. Then, after drawing an arbitrary line in any convenient place, of 50 millimetres in length, to serve for BC and for the vertical axis, and another line CX, at right angles to it at C, for the horizontal axis, to plot the positions of N, L, and L; then, laying the transparent paper upon Fig. 4 to trace, or copy on an enlarged or reduced form, according to the space available, the figures of n, u, and lp, very faintly. Next to do the same to b, g, ll, and k. Afterwards to harmonise the whole tentatively, with faint and brush-like strokes; then with a free and firm hand to draw the outline through them. Tracing paper may otherwise be convenient, because when the original profile looks to the left, by the simple act of turning the traced outline it affords an almost equally close profile, looking to the right.

When transforming the portrait into a formula, the reverse process has to be followed with little alteration. Before finally adopting any formula, the portrait should be reconstructed from it and the formula revised where necessary. It is easy after a little practice to mentally compose a formula so far as the seven small letters are concerned, from a brief inspection, either of the picture or of the living face. Also to reproduce by copying the symbols from Fig. 4 without caring to trace them. In short, the whole operation may be satisfactorily gone through by an intelligent person in a rapid and off-hand way. This might become a popular game for the members of a party to practise this art upon one another, care being taken that the five cardinal points should be truly laid down.

Eight couplets of portraits are given in Fig. 5, both for illustration and for the reader to practise upon. Each couplet contains the original portrait on the left, its formula along the bottom, and the reproduction from the formula (to the standard scale) on the right.

It will be seen from Table V. that four-word portraits are by no means deficient in resemblance to their originals. I think they are considerably more like to them than the sketches, usually printed in the illustrated newspapers, are to the public characters whom they profess to represent. They are, to say the least, of considerable negative value, sufficing to eliminate at the rate of about nineteen out of every twenty individuals as not being the person referred to.

Any form of telegraphy suffices to transmit these four-word profiles. In other respects they are far inferior to those complete pictures now transmitted between certain offices, by means of costly and delicate apparatus, by a method at present undeveloped to its utmost.

It will be observed in the second of the portraits, that of Dr. Bennet Langton, the point L lies to the left of CX, and has therefore a negative value. This is -4, which is expressed here as -04, reckoned to the nearest integer. It is, however, recorded as 96, that is to say, as 100-04, an artifice which practically transfers the horizontal measurement from CX to another

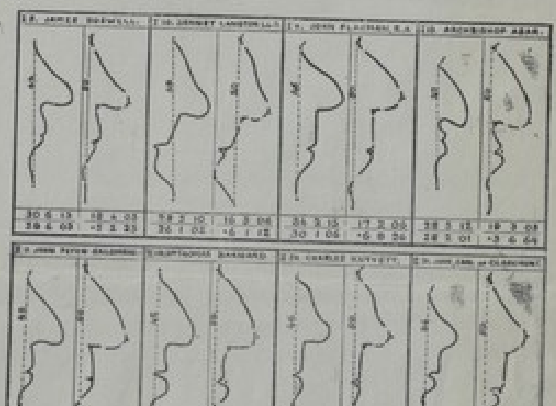

Fig. 5.

line drawn parallel to CX and 100 mm. to its left. No confusion need arise through this transformation, since it leads to very large values lying adjacent to very small ones, and therefore showing that they belong to a different category. The minus values in Y are similarly treated. The process may also be extended beyond the eight squares that surround the primary one.

My experiments have been chiefly made upon the "Collection of Portraits by George Dance, R.A., Sketched from Life and Engraved in Imitation of the Original Drawings" (Longmans and Co., 1809). They were convenient to work with, being all drawn on scales differing little from that of the standard. All the portraits are unbearded and in exact profile, with three or four exceptions. Those that are available are sixty-eight in number. The name of the person to whom each of the eight portraits in Fig. 5 applies is written along its top, and the volume and page of the two folios by Dance, from which the original was traced, are given in the upper left-hand corners. There are several notabilities in his collection besides those in Fig. 5. Among these are Horace Walpole, General Paoli, Haydn, and John Philip Kemble. An exhibition of Dance's pictures was recently held in London. He had a considerable reputation in his time as a portrait painter.

Methods have been used to aid the recollection of dates and other figures. That by Gray, in his "Memoria Technica," was to transform each numeral into either a consonant or into a vowel or diphthong, as might be the most convenient, and thereby to build up words easy to pronounce and to remember. Those who are familiar with such a process might apply it here, and convert the four quintets of numerals into four words, getting over the difficulty of employing the three additional symbols as best they can. If they succeed, the phrase of "four-word profiles" would be literally exact.

I do not find that a general resemblance can be much increased by using one or a *few* more quintets or words. A fifth quintet might perhaps be usefully employed in extending the range of the profile, if it contained one figure to describe the chin and just below it, another to describe the brow, and two figures, 00 to 99, which would suffice to give the general shape of the head.

The next distinct stage in order of accuracy is separated by a great distance from the present one. It requires so large a number of dots that straight or slightly curved lines drawn through them will flow smoothly when seen at the ordinary reading distance from the eye. It needs as many as perhaps fifty quintets to describe a profile with exactness and the rest of the head with rough precision, and still more to include the eye and ear. I have made many of these, which, when reduced to the standard scale of BC = 50 mm., are practically identical with the originals, when viewed in a somewhat careless way by a normally sighted person at a distance of 12 inches. A different use is made in this case of the middle figure of the quintet. Thus: the numeral 1 means that a half-unit is to be added to the first two figures; 2, that it is to be added to the last two; and 3, that it is to be added to both of them. This power of doubly minute description is often wasted in the outline that joins and includes the nose-tip and the two lips. Another use for the middle figure of the quintet is to tell that a dotted line should be drawn from the preceding point, to signify doubt of some kind. A hyphen (-) in the middle of the quintet means to begin; an oblique line (/) to end; and a point (.) means an isolated point. But I will not go further into this now; neither will I do more than hint at the way of dealing with portraits that are not in exact profile, by multiplying their horizontal measures into the secant of the angle through which the profiles are turned away from it.

Much more might be added on extensions of this method, especially as regards its facilities and limitations in conveying plans—ceremonial, strategic, and others—for newspaper use. But its general principles have been explained, and as this letter is already too long I will end it abruptly here.

FRANCIS GALTON.

Data for Classifying profiles

Use is made of four curves in the profile, to each of which tangents can be drawn

α is the depression between the brows & the nose

β is the outline of the nose tip

γ is that of the front of the chin

δ is that which separates the upper lip from the septum that divides the nostrils

S_0S_1 is a tangent to α & γ; it determines the standard direction.

p_0p_1 is a tangent to β, parallel to A_0A_1; it determines the extreme projection of the nose

r_0r_1 is a tangent to β and to γ; its intersection with S_0S_1 determines the point C, that with p_0p_1 determines N

q_0q_1 is a tangent to α passing through N; it determines B

t_0t_1 is a tangent to δ parallel to r_0r_1; d is the distance between t_0t_1 & r_0r_1

NM is a perpendicular falling from N on to S_0S_1

The figures for classification are 100 multiples of NM/BC, MC/BC and d/BC each multiplied by 100

Groups of 4 in all, preceded by a determinant that counts as a figure

The 4 consists of 2 couplets A & B.

Preceded by Determinant X

Both couplets are in the standard unit, A is the ordinate in X, B is that in Y, both measured from bottom left hand corner of the square. ∴ They refer to a cardinal point

Y

A is measured from the last cardinal point in units, of a ..

B is an offset measured in 1/4 units to the desired point

The dots are of 2 kinds, Primary & Secondary. The unit of scale is 1/100th of the height of the square border of the picture, reckoned from the left-hand bottom corner of the frame.

The Primary dots are situated at the intersection of ordinates, without decimals, near the outline of the provisional drawing; they accepted drawing must be slightly modified until they do. [?] If no such intersections occur, with the outline certain convenient points. Each successive pair of primary dots is connected by links.

So a primary dot is located by 4 figures (A)

The Secondary dots are measured along the links, successively following the course of the outline from the last primary dot. They are located by offsets from these links, reckoned as negative when the offset is towards the interior, positive when it is outwards.

Refinements being required in measuring the offset, the measurements are reckoned in quarter units, and as 50 ± the lengths of the offset as the case may be.

So a secondary dot is also located by 4 figures with equal exactitude.

One of the symbol (. or /) which is accepted as reckoned equivalent to a figure in the form of a determinant, determines whether the subsequent group of 4 letters are A or B.

Outline is followed from Brow to Chin

STANDARD CURVES AND THEIR SYMBOLS

	V/C	r/C
7	1/2	0.500
5	1/4	0.625
3	1/8	1.062
1	1/16	2.031
0		infin:
2	1/16	2.031
4	1/8	1.062
6	1/4	0.625
8	1/2	0.500

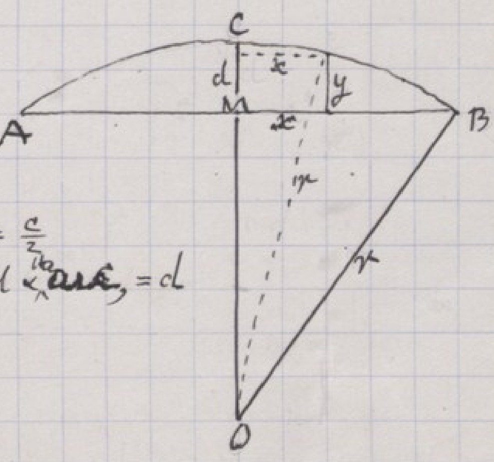
F. 45

In circular arcs whose chord = 10.00

* Symbols expressing the Curvature	I or II	III or IV	V or VI	VII or VIII
Radius of curvature	5.00	6.25	10.62	20.31
Distances of arc from chord				
at the middle of the chord	5.00	2.50	1.25	0.63
at its 1st and 3rd quarter parts	4.33	1.98	0.93	0.49
at its 1st and 7th eighth parts	3.36	1.29	0.57	0.27

Note the numbers are changed I & II with VII & VIII

In those curves whose convexity is outwards in respect to the profile, bear even numbers; those whose convexity is inwards bear odd numbers



Given the chord AMB of a circular arc, in which MA = MB = $\frac{c}{2}$
and MC, the intercept between the middle of the chord and the arc, = d
to find r in terms of c and d

$$r^2 = (r-d)^2 + \left(\frac{c}{2}\right)^2$$

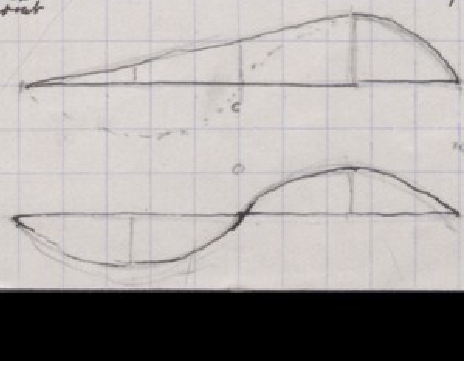
whence $r = \dfrac{4d^2 + c^2}{8d}$.

Given also a point on the chord whose distance from M = ± x
to find the intercept, y, at that point

$r^2 =$ [illegible]

$$= \{(r-d) + y\}^2 + x^2$$

whence $y = \sqrt{r^2 - x^2} - (r-d)$.



In these arcs the length of the chord is ½ c, consequently the tabular values when halved, will apply to them

f. 46r

$$r^2 = \{(r-d) + f\}^2 + e^2$$

write it $v = r-d$ $\quad r^2 = \{v+f\}^2 + e^2$

$v^2 = r^2 - 2d + f^2$ $\quad r^2 = v^2 + 2vf + f^2 + e^2$

$v.2f = r2f - d2f$ $\quad r^2 = r^2 - 2d + f^2 + f\{2r - 2d\} + e^2$

~~$f(2d-2r) = f^2 + e^2 - 2d$~~

$$f^2 + 2fv = 2d - f^2 - e^2$$

$$f^2 + 2fv + v^2 = v^2 + 2d - f^2 - e^2$$

$$= (r^2 - 2rd + d^2) + 2d - f^2 - e^2$$

$f + (d-r) =$

$$r^2 = (r-d+f)^2 + e^2$$

write v for $(r-d)$. This becomes $r^2 = (v+f)^2 + e^2$

$v^2 = r^2 - 2rd + d^2$ $\qquad = (v^2) + (2vf) + f^2 + e^2$

$2f.v = 2fr - 2fd$

$$r^2 = (r^2 - 2rd + d^2) + 2f(r-d) + f^2 + e^2$$

$$0 = -2rd + d^2 + e^2 + f^2 + 2f(r-d)$$

$$f^2 + 2f(r-d) = 2rd - d^2 - e^2$$

$$\{f + (r-d)\}^2 = (r-d)^2 + 2rd - d^2 - e^2$$

$$= r^2 - 2rd + d^2 + 2rd - d^2 - e^2$$

$$= r^2 - e^2$$

$f + r - d = \sqrt{r^2 - e^2}$

$f = \sqrt{r^2 - e^2} + d - r$ $\quad$ (use of 2nd working.)

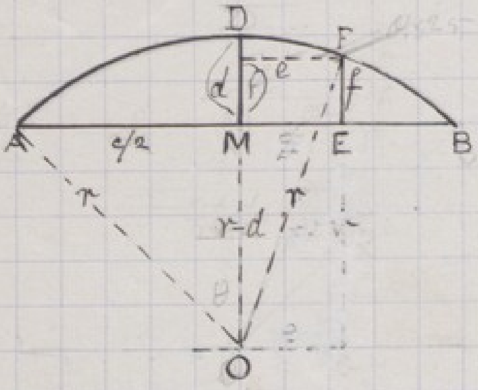
F. 48v



AB is a chord to a circular arc (= c)
MD a perpendicular through its centre (= d)
find O in the line DM produced that shall be
the centre of the circle through A, D, & B. (DO = r)

$r^2 = (r-d)^2 + (\frac{c}{2})$

whence $r = \frac{4d^2+c^2}{8d}$

Given in addition ME (= e)
draw EF perpendicular of ⊥ A, meeting the circle in F. EF = f
find f. (write v for r-d)

$r^2 = (v+f)^2 + e^2$

$r^2 = v^2 + 2vf + f^2 \quad + e^2$

$= r^2 - 2rd + d^2$

$+ 2rf - 2fd + f^2 + c^2$

$o = r 2(d+f) + d^2 - 2fd + f^2 + c^2$

whence $r = \frac{d^2+f^2+c^2 - 2fd}{2d-f}$

$(v = r-d)$

$f^2 + 2vf = r^2 - f^2 - e^2$

$f^2 + 2vf + v^2 = r^2 + e^2 \quad (+f^2 - f^2)$

$f + v = \sqrt{r^2+e^2}$

$f = \sqrt{r^2+e^2} - r + d$

$e = 0.25 \quad r = 0.625 \quad d = 0.25$

$r^2 = 0.3906$
$e^2 = 0.0625$
$r^2 + e^2 = 1.0156$

$.625^2 = 39.06$

F. 63v

Do not mention)

(how much can be expressed pictorially by means of a few [illegible] coordinately & the general character of the [illegible]

Now how easily the conditions of telegraphy, which count five "figures" as the equivalent of a "word", enable simple outlines to be sent by wire.

(A "figure" may be any one of the 10 numerals 0 to 9; or any one of the 3 symbols a dot . , a hyphen –, or the oblique stroke used to signify a fraction)

I find that a profile from brow to chin can be adequately conveyed by eight or nine telegraphic "words" of which the first is a Code word, and that a specifically exact outline of the entire head & face can be conveyed by from 40 to 50 words.

The outlines of [illegible] coasts & harbours, of the [illegible] of groups or shapes, admit of similar treatment, but they will not be discussed now. The feasibility of the method would largely depend on the skill of newspaper correspondents in adapting it to the simple plan. ~~[illegible]~~ [illegible] verbal descriptions

By confining the following remarks to profiles, I have done [illegible] of which the measurements of the profile derived from the cardinal points & the "straight" lines that connect these points (forming as a [illegible] or triangulation) [illegible] the features of different portraits may be compared in equal terms, thus affording a groundwork for accurate anthropology in respect to family features [illegible]

I have already said something about this in Nature [illegible]

The radius, r, of curvature of a small circular arc can be found by measuring its chord arc = 2s and its versine = v. Then

$r^2 = r^2 - 2rv + v^2 + s^2$

$r^2 = (r-v)^2 + s^2$ whence $r = \frac{1}{2v}(v^2 + s^2)$

For present purposes I adopt one ~~it is convenient to have two alternative~~ constant value for v. ~~the one when the arc is very small, the other when it is larger that gives more trustworthy results.~~ Taking AC = 100 millimetres (for purposes of illustration) the ~~alternative~~ values of v, that I employ, is ~~3 and 6~~ 2, in which ~~in the~~ first case $r = \frac{1}{4}(4 + s^2)$ and ~~in the second $r = \frac{1}{12}(36 + s^2)$~~. The typical curves which are employed to description ~~have s = 3, 6, 12, 21 & 30 v~~ are in number & have for chords (= 2s) the respective values of 2, 4, 8 & 14 millimetres ~~[illegible]~~ with corresponding radii of 2, 5, 17 and 50 millimetres

$\frac{1}{2v} = \frac{1}{4}$; $v^2 = 4$

$s = 2$, $r = \frac{1}{4}(4+4)$, $r = 2$ chord = 4 $r = 2$	$s = 4$ — $r = \frac{1}{4}\{4 + 16\} = \frac{1}{4}.20$, $r = 5$ chord = 8 $r = 5$
$s = 8$. $r = \frac{1}{4}(4 + 64) = \frac{1}{4}.68 = 17$. chord = 16 $r = 17$	$s = 14$. — $r = \frac{1}{4}(4 + 196) = \frac{1}{4}(200) = 50$ chord = 28 $r = 50$

(5) is the space between adjacent curves

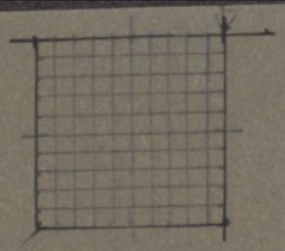
f. 74v



Toh

	Outlines.
1	Straight.
2	Slightly convex.
3	" Concave.
4	Markedly convex.
5	" Concave.
6	Arc, somewhat wider than it follows.
7	Arc, when radius = 5 profile-units.
8	Sharp Curve.
9	Angular notch.
0	Omitted.

	Lips.
. 1	Compressed.
. 2	Normally parted slightly.
. 3	Opened.
. 4	Upper lip overhangs.
. 5	Under lip protrudes.
. 6	Both lips protrude.

Seabrooke
2nd attempt
July 31 1908

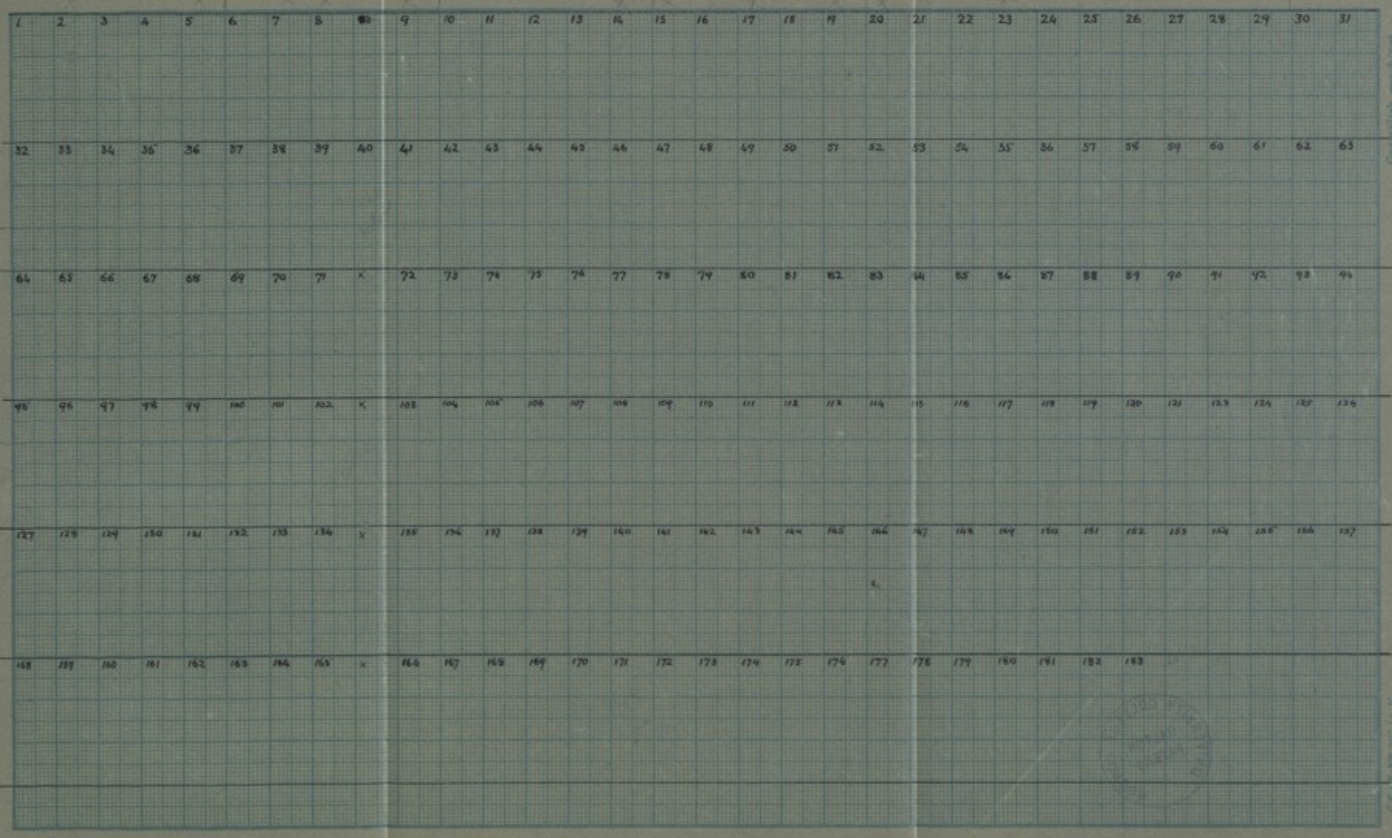
Wagnwell



f. 1r

Grand Union Hotel
Dresden
Friday Mar 4

My dear Uncle Frank.

I hope I have found what you want in the way of paper - I enclose the address where it is to be got for future reference - but I will go & buy any you would like while I am here - if you will send me a line - The small size is in books of 100 sheets - or one can buy it by the sheet. The large size in rolls. one can buy by the yard - 70 cent wide - I should send it without asking - but am not sure what size you want -

We had a most beautiful
crossing. on Monday night, &
after a weary train journey
got here 10. P.M. Tuesday.
On the journey we were
most struck with the windmills
in Holland - & the hopeless state
of damp - it must have rained
far worse than in England.
& much land was flooded -
There was nothing in the fields
but an occasional pig - &
a Gk headed crow -
we went through a desolate
country of peat - rather like
Ireland - & then came

f. 2r

to the extensive cultivation
of Germany - I don't remember
it 28 years ago - but perhaps one
did not notice them. Acres &
Acres of ploughed land - & large
peasant proprietors houses -

all on this
sort of plan -
the upper rooms
apparently used as store rooms. the
entrance for family - carts & fowls
by double door - The country was
not yet dried till we had passed
Hannover - but here it is dry
and sunny - We saw the "art treasures"
"grüne Gewölbe" have been
yesterday - & today

f. 2v

to the picture gallery - & are now just off for a drive - It is unfortunate poor Alice can't walk more - a very little makes her very lame - We are enjoying ourselves very much. Last night we went to the Opera - Wagner's "Das Rheingold" - Alice & I dare not own to it here - but we don't appreciate Wagner operas!

Much love - to you & Eva! & let me know about the paper -

Yr. affecte. niece
Mary L. Wheler.

A THEATRICAL ENGAGEMENT.

MR. CHARLES QUARTERMAIN AND MISS MADGE TITHERADGE, WHO ARE TO BE MARRIED ON THE 8th OF MARCH.

Miss Titheradge is a beautiful and talented actress who has been playing for some time with Mr. Lewis Waller, and Mr. Quartermain is now playing the name part in "Don" at the Kingsway Theatre. The bridesmaids will be Miss Stella Patrick-Campbell, Miss Marie Löhr, Miss Rosalie Toller, and Miss Beatrice Terry.

THE "DAILY GRAPHIC" FREE MEAL FUND.

A MEAL OF BREAD—PURCHASED BY THE SALE OF PUSSY.

DONATIONS TO DATE: £3,835 3s. 6d.

(BY OUR SPECIAL COMMISSIONER.)

When visiting a Plumstead family a DAILY GRAPHIC investigator found them dividing a piece of bread for their dinner. The pennyworth had been obtained by selling the cat for that sum to a neighbour who, strange to say, was anxious one of the feline species—strange, because in mean streets poverty seems to be no excuse for not keeping a cat. These poor people, I may add, have one cripple child very ill, while a son aged sixteen is suffering from heart disease.

As an example of the way in which disease is spread, the case of a Peckham family may be cited. Eight occupy two small rooms, and most of them occupy one room at night. The father, a printer's labourer, is ill with bronchitis, and one child has hip disease and is an epileptic. The rooms are very nearly bare, and there is no bedding.

An unemployed journalist, who went through the Boer war and has lately been helped by the DAILY GRAPHIC Fund, writes:—

"I thought I would let you know that I received the articles, and now wish to express my gratitude to you. I think that nothing inspires more confidence in a man than the feeling that he is well clad and shod. I know that few in London have suffered more than I have this winter from want and hunger, tramping the streets all night long, with no prospect when morning arrived save a repetition of each previous night. Notwithstanding my hardships, I ever had the feeling of being merely repulsed, not defeated.

"There is a little matter that I feel a delicacy in putting before you, and yet you may be good enough to consider it. Last November I was compelled to pawn my war medal, with six clasps, including one for the relief of Ladysmith. I obtained 5s. on it, and the parting with it has worried me much ever since, as I have been unable to redeem it. Believe me, it was dire poverty alone that caused me to part with it. Would it be possible, through your fund, to obtain its release?"

Cheques and postal orders, which will be acknowledged in these columns, should be crossed and made payable to the "Daily Graphic," and addressed to the "Free Meal" Editor, "Daily Graphic," Milford House, Milford Lane, Strand, W.C., the words "Free Meals" to be written on the left hand corner of the envelope.

The "Daily Graphic" Free Meal Coupon is on page 16.

DEATH AT A BALL.

During the progress of Edinburgh University ball on Tuesday night, the death occurred, with tragic suddenness, of Mr. R. H. Johnston, Writer to the Signet, and secretary to the university curators. Mr. Johnston dropped down in a faint, and died soon afterwards.

Mr. Johnston was a noted amateur golfer, one of the hardest hitters of his time in Scottish cricket—he twice captained an eleven at Edinburgh against the Australians—and he was a good three-quarter of the Edinburgh Academicals in Mr. H. J. Stevenson's time.

In presence of the Emir of Bokhara, who presented the site for the building, the foundation stone of the first Moslem mosque built in St. Petersburg was laid yesterday.

HOW A LIFEBOAT WAS INVENTED.

The story of the invention of the self-righting lifeboat was told by Sir John Cameron Lamb last night in an address before the Society of Arts on "The Lifeboat and its Work." The inventor was William Greathead, of South Shields, who received £1,200 from Parliament and a gold medal and fifty guineas from the Society of Arts, besides other rewards. He conducted his experiments in a tank at a local brewery. In a ramble, early in 1789, he happened to see a woman who had just been drawing water from a well. On the surface of the water floated the half of a circular wooden dish. While he chatted with her he tried to make the wooden fragment turn over, but at his every attempt it righted. He ran back to his tank, and soon afterwards announced he had discovered the principle he was looking for.

CITY CEREMONY RESTORED.

The ceremony of confirming the election of Bishops of the Southern Province in the Church of St. Mary-le-Bow, Cheapside, has been restored by the Archbishop of Canterbury. It was abandoned in 1901 in consequence of the disorder attending the confirmation of the present Bishop of London, and the place was changed to Church House, Westminster. The confirmation of the Bishop designate of Norwich will take place in Bow Church, the home of the provincial judicature from which the Court of Arches takes its name.

TO-DAY'S CAUSE LIST.

PRIVY COUNCIL.—10.30.—Appeals: Wertheim v. Chicoutimi Pulp Co.—Hamilton Gas Co. v. Mayor, etc., of Hamilton.

COURT OF APPEAL.—Court II.—The Master of the Rolls and Lords Justices Fletcher Moulton and Buckley.—10.30.—Appeals—Judgment.—Probate and Divorce [illegible] [illegible]

CHANCERY.—Lord Chancellor's Court.—Mr. Justice [illegible] [illegible]

KING'S BENCH.—Court VII.—Divisional Court.—[illegible] [illegible]

PROBATE, etc.—Court I.—Sir John Bigham.—10.30. [illegible] [illegible]

OFFICIAL REFEREES.—Court I.—Room 195.—Mr. Terry.—10.30.—[illegible] [illegible]

TO-DAY'S ARRANGEMENTS.

Captain Jessel, M.P., at House Dinner of Ladies' Imperial Club; Discussion on "The Issues of the Forthcoming L.C.C. Elections."

Viscount Tredegar presides at Annual Dinner of Glamorgan Society, Holborn Restaurant, 7.

English Church Union: Meeting to consider Education Question, Viscount Halifax presiding, Church House, 7.30.

Festival of Empire and London Pageant: Mr. Kenneth H. Vickers gives First of Series of Lectures on "The History of London," London Day Training College, Southampton Row, 8.

Rev. W. Marshall on "English Medieval Fonts and Monuments," Dean of Westminster presiding, Carpenters' Hall, 8.

Royal Institution: Professor S. P. Thompson's First Lecture on "Illumination, Natural and Artificial," 3.

Royal Society of Arts: Mr. G. O. W. Dunn on "The Bombay Housing Question," Lord Sandhurst presiding, 4.30.

Royal Geographical Society: Dr. Vaughan Cornish's Third Lecture on "Waves in Water, Sand, and Snow," 3. Child Study Society: Mr. J. Lionel Tayler on "Types of Children: Their Observation and Nature," 90, Buckingham Palace Road, 7.30.

Racing: Warwick.

SALE AT DICKINS AND JONES, Regent Street. Further reductions in all departments.

What are They Doing?

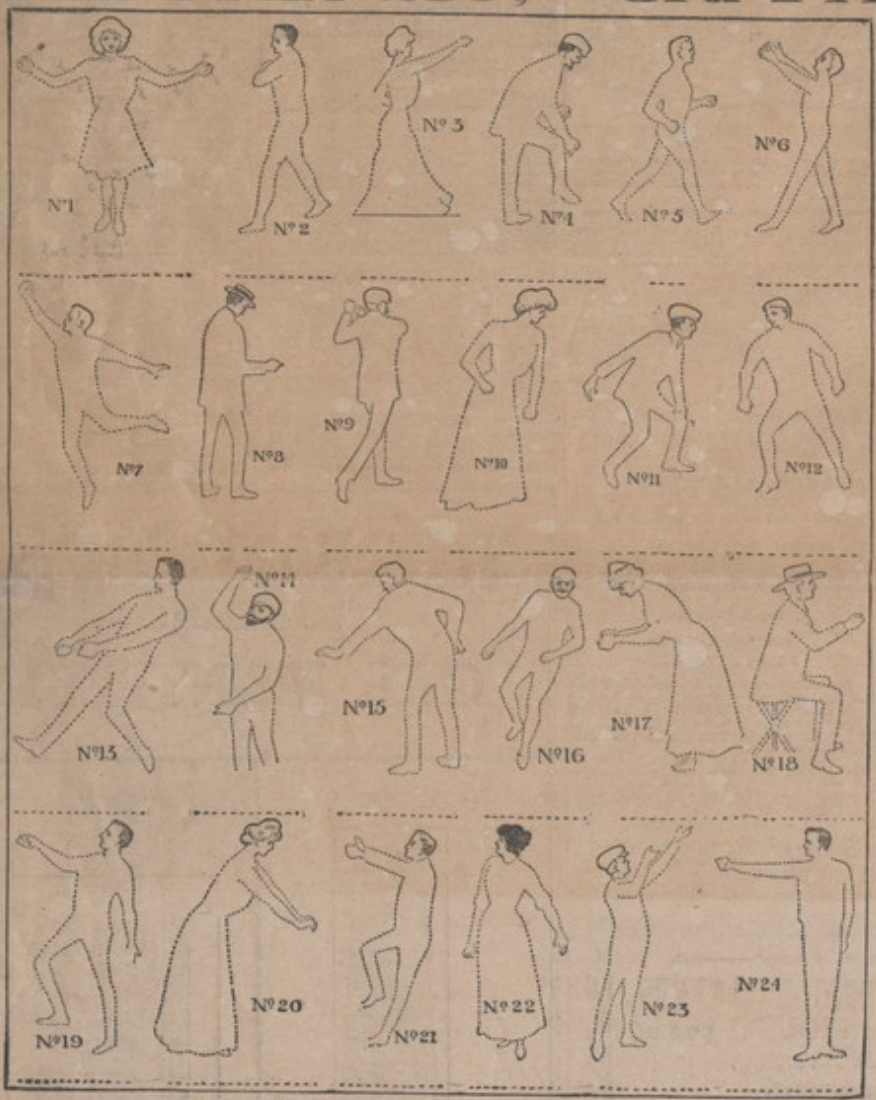
£150 IN PRIZES

offered by the Proprietors of **WRIGHT'S COAL TAR SOAP** for the solution of this novel Competition.

Apart from the chances of a big prize, the Competition should prove most interesting to both young and old.

1st PRIZE £100;

2nd Prize £30; 3rd Prize £20.



Read carefully what you have to do, and also the conditions.

WHAT YOU HAVE TO DO.

The dotted outline simply indicates position or attitude of a person in the act of doing something.

All that is required is to write ONE WORD (in ink) underneath each of the pictures in the space provided, and describe in that ONE word what each figure is doing (see example).

If preferred, however, competitors may give their solutions, numbered 1—24 consecutively, on a sheet of paper.

Then post the set of pictures, and coupon, or the list with name and address added, to Proprietors, Wright's Coal Tar Soap, 66/68, Park Street, Southwark, London, S.E., accompanied by three outside wrappers of WRIGHT'S Coal Tar Soap. It is sold everywhere in boxes of three tablets for 1s. Competitors may send as many lists as they like, provided each one has the requisite three wrappers attached to it and otherwise complies with these conditions, but anyone sending any other wrappers than WRIGHT'S will be disqualified.

The keys of all these figure positions, with the words describing what they are doing printed beneath each sketch, are deposited in a sealed packet, and will not be opened until the Competition is closed.

If competitors cannot solve ALL the picture positions, send in as many as possible.

The words supplied by the successful competitors must be the same as those printed on our Key.

Example Key

Jumping

CONDITIONS.

Every attempt sent in will be carefully examined before awards are made. In the event of ties prizes will be divided.

No correspondence can be entertained. The decision of the Advertising Manager will be final.

Last day for receiving replies, March 31st.

Results will be advertised in the "Daily Mail" on April 30th, when the complete key to all the positions will be published.

Additional copies of this advertisement can be obtained from "Competition," Wright's Coal Tar Soap, 48, Southwark Street, S.E., on receipt of a stamped directed envelope.

WRIGHT'S COAL TAR SOAP COUPON.

NAME .....

ADDRESS .....

.....

The structure of the retina sets a physiological limit to the ~~acuity or~~ sharpness of vision which is further blurred by faults in ~~the optical perfection~~ of the eyeball, considered purely as an optical instrument. In the normal eye the sharpness of vision is usually reckoned to be such as to be able to distinguish well definable ~~[illegible]~~ objects at one minute of a degree apart, which in the above decimal nomenclature is between a third & a fourth part of a millerad, ~~[illegible]~~ ~~[illegible]~~ which itself is as already explained one hundredth part of an inch viewed at ten inches from the eye. It would be just possible for a normal eye to discriminate a ~~[illegible]~~ row of between 30 & 40 similar specks ranged side by side across the disc of the sun, when it is sufficiently veiled by cloud or mist to enable the eye to view it in comfort. ~~On the other hand~~ When the objects are not sharply defined the power of discrimination suffers so much that an interval of even one millirad or the 100th part of an inch at a 10 inches distance is barely noticeable. Taking it all in all the half of a millirad may be taken as the smallest interval worthy of consideration under ordinary circumstances; in short that a row of 200 dots within the length of an inch, clearly visible as dots under a lens would be indistinguishable by the naked eye from a continuous line, at the distance of 10 inches.

There are two ways of looking at an object, that of taking the whole in to equal view at once and that of scrutinising it in details. The latter is expressed sufficiently well by the term inspection, but there exists no word for the former. Circumspection means looking round it, retrospection means looking back at it; the desired word is to express ~~the~~ looking at it. For present purposes I will coin the word aspection, of which the a stands for ad, as in 'aspect' (which is the appearance of an object 'aspected' from a particular point of view). Aspection, visual scrutiny, when the attention ~~and is directed~~ is confined to a minute area such as a millerad or less, & is sharply focussed & specific ~~[illegible]~~, When no special direction of the eye or attention is given to any portion of the wide field of view & no effort is made to focus the eye the picture is large but indistinct. Between these wide limits there is an infinity of ~~degrees of aspection~~ intermediate stages of aspection.

The art of looking for an object on the ground ~~[illegible]~~ of finding it with a minimum of trouble is to keep uniformly to a suitable area of aspection, small if the object be easily overlooked, large if it conspicuous, and to go over the whole methodically backwards ~~[illegible]~~ and forwards like a ploughman. It is fatiguing to do so, but it pays in the end. Having fixed on the suitable width of the area of aspection it is well to standardise it roughly, by the length of a finger or

finger joint held at a ~~suitable~~ constant distance from the eye. Uncivilized man are quick at finding lost objects and I used to be surprised to find the frequency with which quickness in this respect was associated with incompetence of scrutiny. I feel sure that the attention is often unduly narrowed by overmuch reading. We should be more alive to what is going on about ~~us~~ it is were not for this habit of contracting the field of inspection.

The travel of the eye in a strange place is extraordinarily rapid and irregular. It is best appreciated by training the hand to move a pencil in accordance with the direction of the glance and to allow it to scrawl freely on paper. The irregularity of its motion is partly due to the muscular ~~arrangement~~ attachment to the eye ball, which work somewhat on the principal of coordinates and therefore not with equal ease in every direction. Those who have used a pentagraph are familiar with this restriction to its freedom of motion, the hand that works it is conscious of a varying amount of strain. So when the axis of the eye is compelled to ~~travel in a circle~~ ~~and to~~ follow an imaginary circle on the wall, there is a sense of jar and roughness. The ~~axis of the~~ eye travels very irregularly in speed as well as direction, darting from one point to another, fixing itself for a moment & then darting off again. There must be considerable individuality in the travel of the eye of different persons, at least as much as in their handwritings, but I know no way of testing the ~~fact~~ supposition except by comparing the above mentioned scrawls. It has often seemed to me that the repose felt in returning home was largely due to repose of the eye. It is not tempted to explore ~~or~~ ~~scrutinize~~ Every thing is recognized to be in its proper place by vague inspection, without ~~the~~ need of directing & focussing the eye ~~upon~~ upon a multitude of details successively.

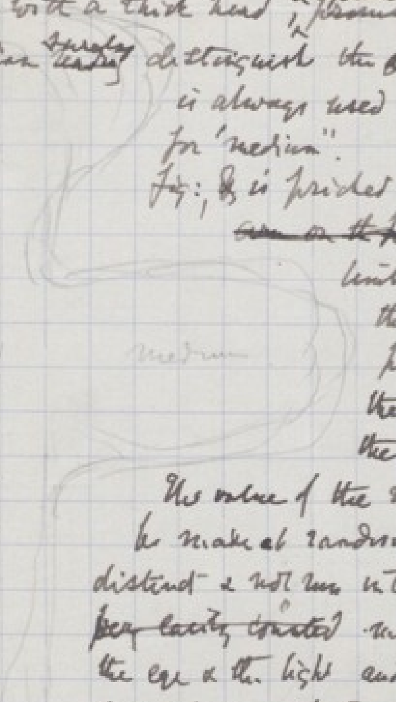
The sense of repose given by the best pictures composed by great artists is due chiefly to what is seen by general inspection only. I have spent some ~~an~~ hours in picture galleries armed with a pencil as above described or ultimately with one that I made faggot-wise out of four differently colored cores Red blue green & ordinary black lead. I cut them out of colored pencils; they were square in section and easily admitted of ~~being~~ ~~[illegible]~~ wrapped & pasted up in thin paper forming a single poly chromatic pencil. When held slopingly the lowermost crayon alone made a mark. Turning this slowly in the hand while scrawling, the sequence of the parts of the entangled drawing was more easily traced. The complexity of the scrawl seemed to me independent of the quality of the picture for every part of it had in each case to be gone over. ~~Sti~~ Still, I am not quite sure of the trustworthiness of my conclusions. Others should test it. It would be interesting to compare the independent records by different persons.

Perspective deformation. ~~The~~ By life long training unconsciously given to the brain almost incapacitates us from perceiving objects, such as the furniture in a sitting room, in the way they really appear. Imagine an adult who had been blinded all his life by some removeable cause, as a congenital cataract, to have been successfully operated on and after wholly recovering from the operation in darkness to be introduced into a room with which he was familiar. It must further be supposed that he possessed by hereditary instinct, the power of directing and focussing his eyes, to the same extent as a chicken which ~~is found~~ learns almost immediately to pick up crumbs after having been hatched & allowed to grow strong in a dark bag. His surprise at every step at the corresponding deformations in the appearance of the chairs & tables would be extreme. He would have assured himself by frequent handling, during his period of blindness that their shapes were constant, yet he would see those shapes to change as he moved. Each square topped table would appear to be an irregular rhomboid, the ~~relative~~ lengths of whose several sides, & the angles ~~at~~ which they made with one another would vary with every ~~and after~~ movement ~~of~~ his. We have quite ceased to be troubled about this. A square table is always perceived by us to be square however much its image may be deformed perspectively. If not square, we should observe its deficiency by rapid but unconscious brain work.

Perception differs from observation in many noteable ways one is as to ~~the~~ angular size, for instance that of the sun. We know it is roughly one centesimal, that is ~~the same size~~ its apparent diameter is one tenth of an inch at 10 inches from the eye, a quarter of inch at 25 inches distance, but if a person even a professed artist, is asked to draw a circle that should represent the ~~size~~ sun at ~~any~~ either of these or any other distance, he will almost invariably draw it too large.

Again it ~~seems also~~ is hard to appreciate the fact that a coarse mosaic can be indistinguishable at a distance from a highly finished picture, and that the degree of coarseness that becomes unseen at a ~~certain~~ specified distance ~~can~~ be easily calculated, as already explained. These considerations will be seen to have a close bearing on what is discussed later on.

Estimation of types or likenesses. Most of our conclusions about typical characteristics are based on the recollection of the estimates of our individual selves. A further step towards ~~statistical~~ scientific treatment is to record those ~~estimates~~ and treating the records ~~scale~~ statistically to compare them with those of others. We can therefore learn something of our personal equation whether dependent on inaccuracy of judgement or on having a mental standard of reference that differs from those of others. A simple and sure way of making records is therefore a desideratum, and one that can be carried on without attracting observation. I will mention a method that I have found very successful and describe one way in which it has been used, in illustration. Beauty of feature is very unequally distributed about the United Kingdom. Different persons have different standards and it would be interesting to compare them. All I do now is to describe my own procedure according to my own standard in attempting a Beauty-map of the British Isles. I prefer I have to make my records by pricking a piece of paper that has been torn into a suitable shape ~~roughly torn, for the purpose~~ from any spare paper at hand, as the envelope of a letter or a piece of newspaper. The pricker is a needle, (not a pin) pasted or sealing-waxed between two small strips of card, leaving the point projecting between a twentieth and a tenth of an inch. It can be held firmly, flatways, between the fore and middle fingers of the right hand. This is easily kept in my card case. The paper is torn into the shape, (rudely resembling that of an F dotted) ~~(Keyhole)~~ with a thick head, a protruding middle ~~prominent projection~~, and a long tail, so that the touch alone can speedy distinguish the three divisions ~~head middle & tail~~. The head is always used for 'much', the tail for 'little', the middle for 'medium'. It is held by the left thumb as in the Fig.; & is pricked by ~~the passing the pricker with appropriate~~ taking the appropriate limb between the first two fingers and the thumb of the right hand and pressing down on the pricker through the paper against the thumb. There is no need to hurt the thumb, which might be drawn if desired.



The value of the method is that a multitude of pricks may be made at random in a small area and yet ~~they~~ each be distinct and not run into each other, as pencil marks do. They are ~~very easily counted~~ most easily seen by holding the paper between the eye and the light and easily counted either in that position or when looking down on the embossed side. They are also durable. It is easy ~~when~~ in a crowd to record in this way the much, little, or medium of any observed characteristic, as statistical data. Of course a more elaborate plan can be devised to meet special requirements.

As illustration I will mention one inquiry to which it has been applied more or less fitfully, namely the distribution of beauty of feature among the female population of the British Isles. Each person has of course his own standard of beauty and maps of distribution made by different observers would be expected to disagree, but not very much. My procedure was when in a new place and the whim seized me to prick down my quick estimate of the features of every woman of what might be described as a dancing-age, whom I met, & classifying them as highly attractive, indifferent, or repellent. The constancy of my judgement was tested and shown to be trustworthy by the agreement of the statistical data derived from different portions of the same crowd. I carried on this inquiry in a desultory way, as occasion served, but carelessness in preserving the data prevents me now from charting the results in the form of a Beauty map. London ranks highest in my list; and I also found two poles of ugliness, one in the North (under restrictions) the other in the South, of which I will say no more. Perhaps the average beauty of the female face, would perhaps rank highest of all in some parts of Ireland.

Differentiated Description

Descriptions with reference to types

One does many things without recognizing their precise character; and one of these is the subject of these remarks. Their object is more generally the advantage of using definable types to describe complex social arrangements.

The subject of description being then an enumeration of differences.

To take a concrete case it is desired to describe the administration of a particular learned society. Now all such societies have normally 5 elements

President, Secretary, Treasurer, Council and place of meeting

This is a stable and well defined organisation a typical form basis of societies. This being taken as the basis, the particular society can be described by its peculiarities in each of the above 5 respects much more easily than if it were a disconnected phenomena and no such basis were supplied. Again each of the 5 elements admits of sub classification.

A President may be merely a man of social eminence, or a man of distinction in the subjects with which the society is concerned itself. The Secretary may be active or the reverse, or may be practically autocratic

The treasurer may take a large or a small part in administration

The Council is formally nominated by the preceding one, though formally elected at a general meeting, but its quality is various. Frequently business is largely in the hands of a few active members. Attendance may be frequent or rare, and discussions useful or progressive or controversial

(See over)

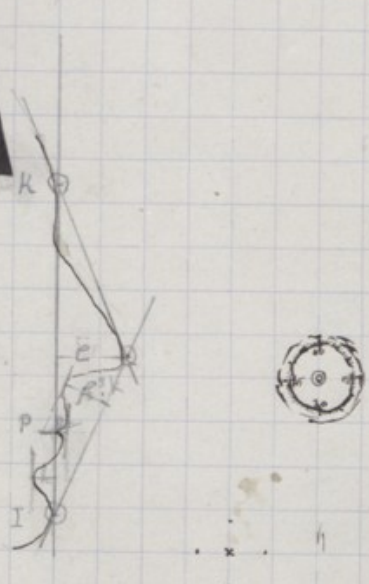
Classification of objects that are ill defined

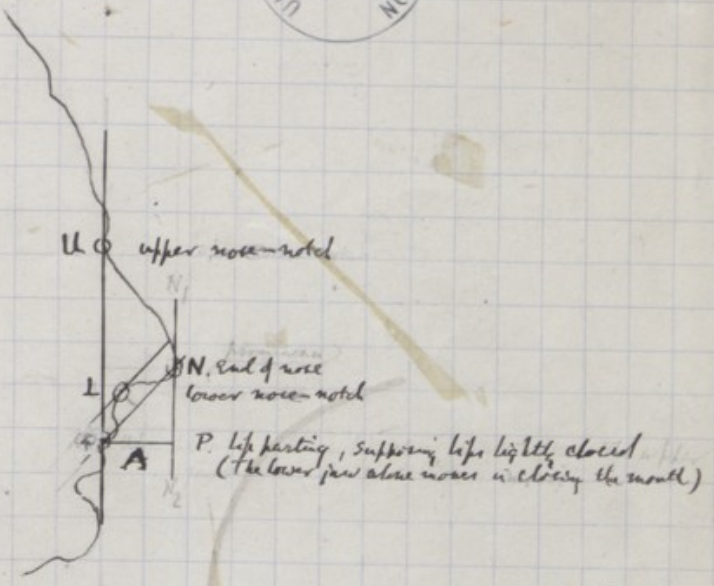
Each may fall into 2 or more categories.

A skeleton key = nearly each w.d. open a particular lock

N a number — how to express N ± a

How to Index. given $N_{\pm x}$, $N \pm x_1$ &c





H = UP
A = distance between UP and N
B = distance between NP and L

From my ignorance of ~~the~~ facts

I ~~cannot~~ am unable to testify to your qualifications in respect to the ~~subjects~~ duties of the post you desire to fill but I can testify heartily to the admirable ~~contents~~ Record of Family History which you sent me years ago in a prize competition. You were if not the very best, an equal best with one other of ~~any~~ the numerous competitors. I heard then of your strenuous efforts under great difficulties to educate yourself & have always respected you for them. It would give me great pleasure to know ~~that~~ if you gain the post

POST CARD.

WOODLAND GROVE,
TORQUAY.

7. 4. 10.

My dear Sir Francis Galton,

Since I read the article I have been very "full" of profiles, & as you may see have had my own taken to see what I look like!

The friendship of the Superintendant of police here - a nice fellow - has turned my thoughts to profiles of criminals & their recognition. Especially as he told me that a pick pocket was caught at the Easter races here & no one knew him. He at once ordered his finger prints to be taken, sent up to Scotland Yard(?) & by return came 23 previous convictions!

Now my idea has been why only chart the profile, when there's really the whole head to work at?

We will suppose the enclosed card is made in very transparent celluloid, & hangs vertically, that the centre of this "head-meter" is put over the tragus of the ear, & the angles & distances of certain points - the head recorded - I have suggested a few by red dots on my profile - would that not give for police purposes an easy method of making the head-chart, & one easy to describe? for the angles & distances would always be taken in the same serial order, & therefore each one need not be defined.

If you think anything of this idea, a celluloid one could be easily made & tried. The circles are one centimetre apart, & the lines 15°. You want want further explanation!

With a little practice one minute would suffice for completing any head measures.

Should you follow your article up by a sequel. I do wish you would deal fully with the question of accents & portraits other than profiles, for the idea has always troubled me.

Would it be any use for you to have my face taken full-face & then every 15° & profile? I could easily get it done cheaply (2½ pence each) & you need not mention my name if it were published. Such a series would be instructive & many.

I hope you will soon be well. This weather tries one dreadfully.

Ever yours

F. Howard Collins

Please thank Miss Biggs for her post card.

F. H. C.
