CLASS III. HÆMATICA.

DISEASES OF THE SANGUINEOUS FUNCTION.

ORDER IV. DYSTHETICA. CACHEXIES.

ORDER IV. DYSTHETICA. CACHEXIES.

MORBID STATE OF THE BLOOD OR BLOODVESSELS; ALONE, OR CONNECTED WITH A MORBID STATE OF THE FLUIDS, PRODUCING A DISEASED HABIT.

THE words ordinarily used to import the diseases meant to be comprehended under the present order, are CACHEXIA and IMPETIGO, or, as the Greeks expressed it, λύης, LUES, or LYES. None of these, however, exactly answer, and that on two accounts: first, because the order is limited to those depravities which seem to originate or manifest themselves chiefly in vessels or fluids of the sanguineous function; and, secondly, because no very definite sense has hitherto been assigned to either of these terms, and they have in consequence been used in very different meanings by different writers, from the time of Celsus to our own day.

Upon this subject the author has dwelt at large in his volume of Nosology, and it is not necessary to add to the remarks there offered. The word DYSTHETICA has hence been adopted for the purpose of avoiding confusion, and is justified by the EUSTHESIA and EUSTHETICA (ΕΥΣΘΕΣΙΑ) and (ΕΥΣΘΕΤΙΚΑ) of Hippocrates and Galen, importing a "well-conditioned habit of body," as their opposite, DYSTHETICA, from the same root, imports "an ill-conditioned habit," but a habit, as just observed, originating in, or dependant upon, the organized parts or fluids of the sanguineous function. Thus explained, it will be found to embrace the following genera:—

I. Plethora.	Plethora.
II. Hæmorrhagia.	Hæmorrhage.
III. Marasmus.	Emaciation.
IV. Melanosis.	Melanose.
V. Struma.	Scrofula. King's Evil.
VI. Carcinus.	Cancer.
VII. Lues.	Venereal Disease.
VIII. Elephantiasis.	Elephant-skin.
IX. Catacausis.	Spontaneous Ignescence.
X. Porphyra.	Scurvy.
XI. Exangia.	Vascular Divarication.
XII. Gangrena.	Gangrene.
XIII. Ulcus.	Ulcers.

GENUS I. PLETHORA. PLETHORA.

COMPLEXION FLORID; VEINS DISTENDED; UNDUE SENSE OF HEAT AND FULNESS; OPPRESSION OF THE HEAD, CHEST, OR OTHER INTERNAL ORGANS.

PLETHORA is seldom ranked as a disease, and hence seldom treated of in a course of medical instruction. From what cause this omission proceeds I know not, nor is it worth while to inquire. That it is an important omission, will be obvious to every student before he has been six months in practice; for there will probably be few affections on which he will be sooner or more frequently consulted. Yet, the subject has not always been neglected by nosologists; for plethora, as a genus, occurs in the classifications both of Linnæus and Sagar.

In a state of health, the quantity of blood produced from the substances that constitute our common diet, bears an exact proportion to the quantity demanded by the vascular system in its ordinary diameter and the various secretions which are perpetually taking place in every part of the body. But the quantity of blood produced within a given period of time may vary; and the diameter of the bloodvessels, or the call of the different secretory organs, may vary; yet, so long as a due balance is maintained, and the proportion of new-formed blood is answerable to the demand, the general health continues perfect, or is little interfered with. Thus, a man exhausted and worn down by shipwreck, or by having lost his way in a desert, or who is just recovering from a fever, will devour double the food and elaborate double the quantity of chyle, in the course of four-and-twenty hours, to what he would have done in the ordinary wear of life: but the whole system demands this double exertion; the double supply is made use of, and the general harmony of the frame is as accurately maintained as at any former period; there is no accumulation or plethora.

It should also be observed, that in this case, the same remedial or instinctive power that stimulates the sanguific organs to the formation of a larger proportion of blood, stimulates also the bloodvessels to a diminution of their ordi-

nary capacity, and lessens the activity of the secretions; and hence the difficulty to which the animal machine is reduced is also met-another way, and a balance between the contained fluid and the containing tubes is often preserved as completely during the utmost degree of exhaustion as in the fullest flow of healthy plenitude.

We sometimes, however, meet with cases in which an increased supply of blood is furnished when no such increase is wanted, and the vessels remain of their ordinary capacity. And we also sometimes meet with cases in which, from a peculiar diathesis, the capacity of the vessels is unduly contracted, while no change takes place in the ordinary supply of blood. It is evident that in both these contingences, there must be an equal disturbance of the balance between the substance contained and the substance containing, and that the measure of the former must be too large for the measure of the latter. In other words, there must be in both cases an excess of fluid, or a plethora, though from very different, and what are usually regarded as opposite, causes: and hence it has been distinguished by different names; that proceeding from an actual surplus of blood being denominated a plethora *ad molem*, or a plethora in respect to its general mass or absolute quantity; and that proceeding from a diminished capacity of the vessels being denominated a plethora *ad spatium*, or a plethora in respect to the space to be occupied.

It is possible, however, for both these causes of plethora to exist at the same time, and for the vessels to evince a contractile habit or diathesis, while the blood is produced in an inordinate proportion. And this, in truth, is by no means an uncommon state of the animal frame; for, where the excess of blood is the result of a highly vigorous action or entony of the organs of sanguification, we often see proof of the same entony or highly vigorous action through the whole range of the vascular system, and, indeed, of every other part of the machine; the pulse is full, strong, and rebounding; the muscular fibres firm and energetic, the complexion florid, the whole figure strongly marked. We have here the sanguine temperament; and this kind of plethora has hence been called the **SANGUINE PLETHORA**.

But we often meet with an inordinate formation of blood in a constitution where the vascular action is peculiarly weak, instead of being peculiarly vigorous; the muscular fibres are relaxed, instead of being firm; and the coats of the vessels readily give way, and become enlarged, instead of being diminished in their diameter; and where, instead of entony, or excess of strength, there is considerable irritability, or deficiency of strength in the organs of sanguification.

Yet though the cause is different, the result is the same; the vessels, notwithstanding their facility of dilatation, at length become distended, and a plethora is produced which has been denominated a plethora *ad vires*; or a plethora as it respects the actual strength of the system.

The pulse is here indeed full, but frequent and feeble; the vital actions are languid; the skin smooth and soft, the figure plump, but inexpressive; all which are symptoms of debility of the living power, or rather of that peculiar diathesis which has been distinguished by the name of the serous, phlegmatic, or pituitary temperament; and hence this sort of plethora has been commonly denominated **SEROUS PLETHORA**.

We have hence a foundation for the two following very distinct species of this affection, the names of which are derived from their proximate causes.

- | | |
|-----------------------|--------------------|
| 1. Plethora Entonica. | Sanguine Plethora. |
| 2. ——— Atonica. | Serous Plethora.* |

SPECIES I.

PLETHORA ENTONICA.

SANGUINE PLETHORA.

PULSE FULL, STRONG, REBOUNTING: MUSCULAR FIBRES FIRM AND VIGOROUS.

SANGUINE plethora is more common to men; serous to women. It is the disease of manhood, of the robust and athletic. Plethora of this kind must be distinguished from obesity; in effect, they are rarely found in conjunction, for the entony, or excess of vigorous action, is common to every part of the animal frame; and hence, though it is probable that a larger portion of animal oil is secreted than in many other conditions of the body, yet it is carried off by the activity of the absorbents, and there is no leisure for its accumulation in the cellular membrane. And hence, persons, labouring under sanguine plethora, are rather muscular than fat, and their distended veins lie superficially, and appear to peep through the skin.

In this state of the bloodvessels, slight excitements produce congestion in the larger vessels or organs. The head feels heavy and comatose; the sleep is disturbed by tumultuous dreams; the lungs labour in respiration; and the muscles feel a want of freedom or elasticity in exercise. If fever arise, it will assume the inflammatory type; and a slight excess in feasting or conviviality will endanger an apoplexy.†

The cure, however, is not in general accom-

* Dr. Barlow distinguishes plethora into *absolute* and *relative* (Cycl. of Pract. Med., art. **PLETHORA**); the former term implying that the redundancy of blood exceeds what the healthy state of the individual constitution would require or bear; the latter, that its quantity, without being absolutely excessive, is so in relation to the deficient powers of the constitution to dispose of it. But as these varieties of plethora do not comprise the whole subject, he notices a third condition of the blood, which takes place when, under moderate nutrition, there is defective excretion. In this state the system is oppressed, not so much by the quantity of nutriment, or the labour of disposing of it, as by the load of excrementitious matter with which the blood is overcharged.—Ed.

† Instead of saying that plethora is "the parent of pure inflammation" (Cyclop. of Pract. Med.), it would be more correct to regard it as creating a predisposition to inflammatory disorders.—Ed.

panied with much difficulty; and far more easily effected in this species than in the ensuing: for the entonic power may readily be lowered by venesection and purgatives; and its disposition to return may commonly be prevented by the use of refrigerants, as nitrate of potash, or other neutral salts, and an adherence to a reduced diet and liberal exercise; at the same time it should be observed, that, where the plethora depends upon a sanguineous temperament or phlogistic diathesis, venesection, though rightly employed at first, should be repeated with great caution, as it will tend to generate in the system a periodical necessity for the same kind of depletion, and consequently promote the disease it is designed to cure.*

SPECIES II. PLETHORA ATONICA. SEROUS PLETHORA.

PULSE FULL, FREQUENT, FEEBLE: VITAL ACTIONS LANGUID; SKIN SMOOTH AND SOFT; FIGURE PLUMP, BUT INEXPRESSIVE.

THE general pathology we have already treated of: and the reasons given under the last species for the usual appearance of sanguine plethora in persons of a spare and slender make, will explain the plumpness of figure and glossiness of skin which so peculiarly mark the species before us. In the first, there is great and universal vigour and rapidity of action; the secretions are all hurried forward in their elaborations, and carried off as soon as produced. In the second, there is little vigour or activity of any kind, and whatever is eliminated is suffered to accumulate. Hence costiveness is a common symptom; the ankles are cold and pitted; and the animal oil, when once separated and deposited in the chambers of the cellular membrane, remains there, becomes augmented, and produces corpulency and sleekness. The inertness of the body is communicated to the mind; every exertion is a fatigue; and the mind thus participating in the inertness of the body, the countenance, though fair and rounded, is without expression, and often vacant.

Debility is always a source of irritability;

* An increase of bulk and a florid complexion, as Dr. Barlow observes, in which so many exult as evincing sound health, and which they endeavour by all the aids of good living to promote, should not be a source of unmixed congratulation; because they predispose to consequences by which both health and life may be forfeited. "Up to this period, however, disease cannot be said to have commenced, however it may have approached; and reduction of diet, with free bowels, and increase of active exercise, would suffice for getting back to sounder health, without any need of medical interference. When abatement of healthful energies becomes evinced by a low and oppressed pulse, diseased actions may be said to commence; and when the stage of irregular action ensues, sensible progress may be considered as made towards the establishment of febrile action and inflammatory disease." Medical aid and active discipline now become indispensable.—See Cyclop. of Pract. Med., art. PLETHORA.—Ed.

and hence there is great irregularity, and a seeming fickleness in many of the symptoms by which this species of plethora is characterized, and the results to which it leads. The bowels, though usually quiescent and costive, are sometimes all of a sudden attacked with flatulent spasms, or a troublesome looseness. The appetite is languid and capricious; the heart teased with palpitations, the chest with dyspnoea and wheezing; the head is heavy and somnolent; the urine pale, small in quantity, and discharged frequently.

In this species, as in the last, we are compelled to begin with cupping or the use of the lancet. But though the distended and overflowing vessels demand an abstraction of blood, it should never be forgotten, that the relief hereby afforded is only temporary; and that, as the disease is, in this case, an effect of debility, we are directly adding to the cause as often as we have recourse to the lancet. Our leading object should be to give tone to the relaxed fibres; and to take off the morbid tendency to the production of a surplus of blood by counteracting the irritability which gives rise to it. Our attack must be made upon the entire habit, which, as far as possible, should undergo a total change. The diet should be nutritious, but perfectly simple, and the meals less frequent, or less abundant, than usual; the sedentary life should give way to exercise, at first easy and gentle, but by degrees more active, and of longer extent or duration. Tonics, as bitters, astringents, and sea-bathing, may now be employed with advantage; and the muscular fibres will become firmer as the cellular substance loses its bulk.

The whole, however, must be the work of time; for although in morals it is a wholesome principle, that bad habits cannot too speedily be thrown off, it is a mischievous doctrine in medicine. Health being the middle term between excess and deficiency, every day is giving us a proof, that, where either of these extremes has become habitual, the system can only be let up or let down by slow degrees, so as to reach and rest at the middle point with certainty and without inconvenience. Professor Monro has furnished us with several very striking examples of this fact: and particularly among those who had acquired a habit of drinking very large quantities of spirituous potation. A man of this description, who had broken both bones of one leg, and was put, for a more speedy recovery, upon a diet of milk and water and water-gruel, was hereby thrown into a low fever with an intermitting pulse, twitching tendons, and delirium; during which he got out of bed and kicked away the box in which his leg was confined. A by-stander and friend of the patient's, of the same irregular habit, ventured to tell the professor, that he would certainly kill him if he did not allow him ale and brandy; since, for several years antecedently, he had been accustomed to both these as his common drink: a little of each was, in consequence, permitted him, but the patient's friends did not tie him down to this little; for, extending the grant of an inch to an ell, they instantly gave the man a Scots quart of ale and a gill of

brandy, which was his usual allowance for the evening: he slept well and sound; the next morning was free from delirium and fever; and, by a perseverance in the same regimen, obtained a speedy cure without the least accident *

GENUS II. HÆMORRHAGIA. HEMORRHAGE.

FLUX OF BLOOD WITHOUT EXTERNAL VIOLENCE.

THE term hæmorrhagia, or hemorrhage, is derived from the Greek *αἷμα*, "sanguis," and *ῥύσις*, "rumpo." Dr. Cullen has adopted the same name for an order of diseases; but few parts of his arrangement are more open to animadversion, and in fact have been more animadverted upon, than the present. The order of hemorrhages, or fluxes of blood, ranks in Dr. Cullen's system under the class pyrexia, or febrile diseases. Pyrexia, however, is only an accidental symptom in idiopathic hemorrhages of any kind, and has hence been omitted by all, or nearly all, other nosologists in their definitions: while Dr. Cullen himself has found it impossible to apply it to many hemorrhages, among which are all those that are called passive; and he has hence been obliged to transfer the whole of these to another part of his system, notwithstanding their natural connexion with the active, and to distinguish them by the feeble name of *profusions*, instead of by their own proper denomination.

Blood, from whatever organ it flows, may have two causes for its issue. The vessels may be ruptured by a morbid distention and impetus; or they may give way from debility and relaxation, their tunics breaking without any peculiar force urged against them, or their exhalants admitting the flow of red blood, instead of the more attenuate serum.† To the former de-

* Edin. Med. Ess., vol. v., part II., art. XLVI. With regard to the treatment of plethora from inadequate excretion, Dr. Barlow has remarked, that a constitution naturally feeble, especially if insufficient exercise be taken, sends the blood to the surface too languidly for proper exhalation from the skin to take place. The best preventive of this diseased condition seems, to him, to be exercise, slighter degrees of which would also be the most effectual cure. Dr. Barlow is likewise an advocate for warm bathing, combined with frictions, and other means of softening and detaching hardened cuticle. The Russian vapour-bath, so accurately described by the late Dr. Clarke, appears well calculated for establishing a healthy state of the cutaneous functions.—Ed.

† On this subject some judicious observations are made by M. Andral (Anat. Pathol., tom. i., p. 338), who cautions the practitioner not to confound discharges of blood from mucous membranes with other affections, of which a degree of inflammation is necessarily a part. In hemorrhage, there may, indeed, be determination of blood to the part; but it seems as if the fluid, instead of accumulating in the vessels of the mucous membrane, escaped as soon as it reached them, owing to some unknown modification of them. There may also be a passive fulness of them, as in obstruction of the venous circulation.

scription of hemorrhages, Dr. Cullen has given the name of active; to the latter that of passive. The distinction is sufficiently clear; and, under the names already employed in the preceding genus of this system, will lay a foundation for the two following species:—

1. Hæmorrhagia Ento- Entonic Hemorrhage.
nica.
2. ——— Atonica. Atonic Hemorrhage.

SPECIES I.

HÆMORRHAGIA ENTONICA. ENTONIC HEMORRHAGE.

ACCOMPANIED WITH INCREASED VASCULAR ACTION; THE BLOOD FLORID AND TENACIOUS.

As the outlets of the body are but few, and all of them communicate with numerous organs, we cannot always determine with strict accuracy from what particular part the discharge flows. We have, however, sufficient reason for the following varieties:—

- | | | |
|---|--------------|-------------------------------|
| α | Narium. | Entonic bleeding at the nose. |
| β | Hæmoptysis. | spitting of blood. |
| γ | Hæmatemesis. | vomiting of blood. |
| δ | Hæmaturia. | bloody urine. |
| ε | Uterina. | uterine hemorrhage. |
| ζ | Proctica. | anal hemorrhage. |

The great predisponent cause of active hemorrhage, wherever it makes its appearance, is plethora or congestion. A plethoric diathesis will, however, only predispose to a hemorrhage *somewhere or other*; and hence there must be a distinct local cause that fixes it upon one particular organ rather than upon another.*

But an unusual flow of blood to, or fulness of the vessels, is not essentially concerned in every kind of hemorrhage; for the qualities of the blood may be so altered, that the natural cohesion of its particles to one another may be weakened, and then it may readily escape from the vessels, producing hemorrhage, quite independent of irritation, in several parts of the system at the same time. This is what is observed in scurvy and typhoid fevers, and in every case where attention to causes, and the look of the blood itself, afford a conviction that this fluid is materially altered.—Ed.

* The reader will find many valuable observations on internal hemorrhages in the Lumleian Lectures, delivered at the College of Physicians in May, 1832, by Dr. Watson, and published in the Medical Gazette, vol. x. He espouses the doctrine that, in a great majority of instances, the escape of the blood is not dependant upon rupture of the vessels, but is effused through those pores or outlets which afford a passage to the natural fluids of the part, and to which we apply the name of exhalants. These hemorrhages by exhalation he divides into the *idiopathic*, or such as are independent of any discoverable change of texture in any part of the body; and the *symptomatic*, or those which are connected with organic disease; and this latter class is subdivided into two species; the first including cases in which the hemorrhage is dependant upon disease in the part from which the blood proceeds; and the second, those examples in which the disease is situated in some other part, capable of influencing the circulation in the

The chief local cause is a greater degree of debility in the vessels of such organ, than belongs to the vascular system generally. But there are other and more extensive causes that operate upon some organs, and which consist in an unequal distribution of the blood, and its peculiar accumulation in some vessels rather than in others. Thus, some organs acquire development and perfection sooner than others, of which the head, peculiarly large, even in infancy, furnishes us with a striking example; and, in the promotion of such development, the flow of the blood is directed with greater force and in greater abundance. And hence while the coats of the bloodvessels in this organ are yet tender, and destitute of that firmness which they derive from age, we have reason to expect hemorrhage as a frequent occurrence, and particularly from the vessels of the nostrils; because there is in the nose, for the use of the olfactory sense, a considerable network of bloodvessels expanded on the internal surface of the nostrils, and covered only by thin and weak integuments. And on this account, we see why young persons are so much more subject to bleedings from this organ, than those in mature life. Hæmoptysis, or spitting of blood, takes place more commonly a few years later, and when the animal frame has acquired its full growth, and, consequently, the vascular system its full extent or longitude. Antecedently to this, the impetus and determination of blood are greater in the aorta and its extreme ramifications than in the pulmonary artery, because more of the vital fluid is demanded for the progressive elongation of the very numerous arteries that issue from the former: and consequently, a greater tendency to plethora exists in this direction till the age of about fifteen or eighteen, than in the direction of the lungs. Till this period of life, therefore, we have no reason to expect hemorrhage from the respiratory organs. When this term, however, has arrived, the bias is thrown on the other side: and, the vessels of the corporeal and of the pulmonary circulation being equally perfected, the tendency to accumulation will be in the latter, in consequence of their shorter extent. This tendency will continue till about the age of thirty-five; which is exactly correspondent with the observation of Hippocrates, who has remarked, that hæmoptysis commonly occurs between the age of fifteen and that of five-and-thirty. We have explained why it does not often occur before fifteen; but what is the rea-

former, by reason of some intelligible connexion between them, either of structure, or function, or mutual relation. Dr. Watson adverts to the fact, that hemorrhage by exhalation occurs much more frequently from the mucous membranes, than from any other tissues of the body; and also to the remarkable circumstance, that hemorrhage from the brain differs from most other internal bleedings, in not taking place by exhalation, but from actual rupture of a bloodvessel. This is attempted to be accounted for, partly by a reference to the structure and arrangement of the cerebral arteries, but chiefly by the consideration of their great liability to disease.—Ed.

son of its seldom occurring after the latter period? Dr. Cullen has ingeniously explained it in the following manner. The experiments of Sir Clifton Wintringham, he observes, have shown, that the density of the coats of the veins, compared with that of the arteries, is greater in young than in old animals; from which it may be presumed, that the resistance to the passage of the blood from the arteries into the veins is greater in young animals than in old; and while this resistance continues, the plethoric state of the arteries must be perpetually kept up. The very action, however, of an increased pressure against the coats of the arteries gradually thickens and strengthens them, and renders them more capable of resistance; whence in time they come not only to be on a balance with those of the veins, but to prevail over them; a fact which is also established by the experiments just adverted to.

After thirty-five, therefore, the constitutional balance becomes completely changed, and the veins, instead of the arteries, are chiefly subject to accumulation. The greatest congestion will usually, perhaps, be found in the vena portarum, in which the motion of the venous blood is slower than elsewhere; and such congestion alone will frequently act upon the neighbouring arteries, and induce what may be called a reflex plethora upon them, in consequence of their inability of unloading themselves: and hence the chief origin of hæmatemesis, anal hemorrhage, and various other hemorrhages from the abdominal and pelvic organs.*

All these organs, however, are exposed to hemorrhage from incidental causes, as well as

* The following conditions are specified by Andral, as liable to bring on hemorrhage from the mucous membrane of the digestive tube (*Anat. Pathol.*, tom. ii., p. 150):—1. A mechanical obstruction of the circulation in the vena portæ. 2. Irritation of the mucous coat of the stomach and bowels. Thus, certain corrosive poisons, taken into the stomach, will be followed by hæmatemesis, and strong drastic medicines will occasion hemorrhage from the bowels. 3. Sanguineous congestion, neither of a mechanical kind, as in the first case, nor the result of irritation, as in the second. The blood simply accumulates at a certain point, and makes its escape, and that is all that can be ascertained. 4. Certain states of the blood itself, making it disposed to quit its proper channels, as exemplified where particular poisons are absorbed; in typhus, and also in yellow fever, with black vomit. 5. Lastly, blood in the cavity of the stomach and bowels may have got there by being swallowed, as happens when an aneurism of the aorta bursts into the œsophagus.

In hæmatemesis, the blood is usually poured out by a kind of exhalation; the bleeding from ulceration of any considerable artery, or vein, being comparatively rare. Three examples of the latter occurrence are quoted by Dr. Watson (*Med. Gazette*, vol. x., p. 434); one from the *Journ. Hebdomadaire* for May, 1830; a second from Dr. Latham's patients in St. Bartholomew's Hospital; and a third from the practice of Dr. Clark. In all these cases, there had been marked symptoms of gastric disorder for some time previously to the hemorrhage, and two of the subjects had been habitual drunkards.—Ed.

that constitutional change which has a tendency to produce the disease vicariously.

Thus, hemorrhage in all of them is occasionally produced by violent exertion, as great muscular force, vehement anger, or other passions or emotions of the mind; severe vomiting, or coughing; suppressed evacuations of various kinds, especially hemorrhoids of long standing, catamenia, habitual ulcers, issues, or chronic eruptions of the skin;* as also by the wound of a leech swallowed accidentally.† But in this last case it is probable, that the living principle of the stomach is in a state of weakness, as in all other cases in which exotic worms are found to continue alive under its action: since we know that this action, when in full vigour, is sufficient to destroy oysters, frogs, slugs, leeches, and various other cold-blooded animals in a short time. Hæmoptysis is also said by many writers to have been produced by leeches accidentally taken into the stomach by a draught of water.‡ But it is probable, that in this case there is a deception; and that the blood, discharged by coughing from the trachea, has first passed into it from the stomach and mouth.

Local stimulants are also an occasional cause. Thus the vessels both of the kidneys and rectum have been excited to hemorrhage by an injudicious use of aloes, terebinthinate preparations, and pungent alliaceous sauces. And the former by cantharides, whether applied externally or internally: for Schenck and other writers have given examples of hæmaturia excited in irritable constitutions by vesicatories alone.§

Occasionally, however, all the various kinds of hemorrhages before us have assumed a different character, and proved salutary and critical. Thus, cephalitis has often ceased suddenly on a free and sudden discharge of blood from the nostrils; pneumonitis, from what has been deemed an alarming hæmoptysis: visceral infarctions, from a liberal evacuation of the hemorrhoidal vessels; a jaundice has been carried off by a profuse hæmaturia,|| and fevers of various kinds have instantly yielded to a spontaneous appearance of any of them.

Such hemorrhages, however, though salutary in their onset, must be cautiously watched; since, if not checked when they have accomplished their object, they are apt to pass into a chronic or periodic form. Hence, many persons have monthly discharges from the rectum; others from the nostrils; others, again, occasional or periodic, from the lungs; and a few from the stomach.¶ Tulpus gives a case of chronic hæmoptysis that continued for thirty years; ** and there are other instances of much longer duration.††

¶ Rhodius, cent. ii., obs. 94.

** Lib. ii., cap. ii.

†† N. Act. Nat. Cur., vol. i., obs. 1.

There is also another reason for an early attention to spontaneous hemorrhages, and that is, the profuseness of the discharge which sometimes takes place, and the alarming exhaustion which follows. Dr. Banyer* gives a case of this sort, in which the discharge was from the bladder: Büchner, another case from the same organ, in which it amounted to not less than four pounds:† and other writers bring examples of its having proved fatal.

The largest quantities, however, are usually lost from the nostrils. Ten, twelve, and upwards of twenty pounds have been known to flow away before the hemorrhage has ceased. Bartholin mentions a case of forty-eight pounds;‡ Rhodius another of eighteen pounds lost within thirty-six hours;§ and a respectable writer, in the *Leipsic ACTA ERUDITA*, a third, of not less than seventy-five pounds within ten days;|| which is most probably nearly three times as much as the patient possessed in his entire body at the time the hemorrhage commenced. In the *Ephemeræ of Natural Curiosities* is a case in which the quantity indeed is not given, probably from the difficulty of taking an account of it, but which continued without cessation for six weeks.¶

IN ACTIVE HEMORRHAGES FROM THE NOSTRILS, the epistaxis of many writers, the discharge is usually preceded by some degree of local heat and itching; and occasionally by a flushing of the face, a throbbing of the temporal arteries, a ringing in the ears, or a pain or sense of weight and fulness in the head. Yet, not unfrequently, the blood issues suddenly without any of these precursors; for, as we have already observed, the arteries, distributed over the Schneiderian membrane, are very numerous and superficial, and a very slight irritation is often sufficient to rupture them. That insolation, or exposure to the direct rays of the sun, a cold in the head, or cold applied to the feet or hands, coughing, or sneezing, especially upon the use of sternutatories, an accidental blow upon the upper part of the nose or forehead, or a jar of the entire frame, as on stumbling, should be sufficient to produce this effect, can easily be conceived; and these, in truth, are the common occasional causes: but it is singular that it should follow, in some highly irritable idiosyncrasies, upon such very trivial excitements as have been noticed by many pathologists. Thus, Bruyerin** gives an example in which the nostrils flowed with blood upon smelling at an apple; Rhodius,†† upon the smell of a rose; and Blancard,‡‡ upon the ringing of bells: and when we find the same effect produced by various emotions of the mind, as terror, anger, and even a simple excitement of the imagination,§§ we may readily trace by

by what means the philosophers and poets of the eastern world, and even some of those of the western, were led to regard the nose as the seat of mental irritation, the peculiar organ of heat, wrath, and anger; and may discover how the same term *אף* (ap or aph) came to be employed among the Hebrews to signify both the organ and its effect, the nose and the passion of anger to which it was supposed to give rise.

We have already observed, that the quantity of blood discharged by a spontaneous hemorrhage from the nostrils, is sometimes enormous. This, however, is a more common result of passive than of active hemorrhage; and is more usually found in advanced than in early life: the two stages in which nasal hemorrhage chiefly shows itself. And where it frequently returns, it is apt, like the hemorrhoids, to form a habit of recurrence that cannot be broken through without danger, except by an employment of evacuants, or some other drain.*

If it be evidently connected with entonic plethora, or accompanied with the local symptoms just enumerated, it will afford a more effectual relief than bleeding in any other way, and should not be restrained till it has answered its purpose. Even a small portion of blood, not amounting to more than a table-spoonful or two, when thus locally and spontaneously evacuated, has afforded, on some occasions, a wonderful freedom and elasticity to an oppressed and heavy head: and, when more copious, has probably prevented an apoplectic fit, as it has often formed a salutary crisis in inflammation of the brain, or fevers in which the brain has been much affected.

But when these reasons do not exist, the bleeding should be checked by astringent applications. Cold is the ordinary application for this purpose, and it commonly succeeds without much trouble. Cold water may be sniffed up the nostrils, or thrown up with a syringe; but the exertion of sniffing, or even the impetus of the water alone, where a syringe is employed, sometimes proves an excitement that more than counterbalances the frigid effect. Independently of which, there is an advantage in leaving the blood to coagulate on the ruptured orifice of the vessel, which these methods do not allow. By means of a syringe, however, we can throw up, when necessary, astringents of more power than cold water, as vinegar, or the sulphuric acid properly diluted, or a solution of sulphate of zinc, copper, iron, or lead; after which we should force up tents of lint moistened with the same, and particularly with extract of lead diluted with only an equal quantity of water, as high as we are able, with a probe or small forceps, so as to form a tight compress: the styptic agarics can be rarely used to advantage. The face may, at the same time, be frequently immersed in ice-water, or water artificially chilled to the freezing point; and the temples, or even the whole of the head, be surrounded with a band or napkin moistened

with the same, and changed as soon as it acquires the warmth of the skin. When tents are used, they have sometimes been dipped in moistened powder of charcoal, which, of itself, has proved an excellent styptic. Cold applied to the back sometimes succeeds, but often fails; it is more certain of success when applied to the genitals.

Emetics have occasionally been of service, and are recommended by Stoll.* The principle upon which they may be presumed to act will be noticed under hæmoptysis. The bleeding has sometimes been checked by a sudden fright,† probably from the cold sweat that so often attends such an emotion: and Reidlin gives a case in which it was cured by sneezing;‡ but this was probably a case of atonic hemorrhage, in which the spasmodic action might assist in corrugating the mouths of the bleeding vessels.

It is rarely necessary, or even proper, in this variety of hemorrhage, to employ any internal astringent or other tonic; but if this discharge should be excessive, and produce debility, the same plan may be resorted to as will be recommended under the ensuing species.

In HÆMOPTYSIS, or SPITTING OF BLOOD, it is not always easy to determine from what vessel, or even from what organ, the bleeding proceeds: for the blood may issue from the posterior cavity of the nostrils, or from the fauces, as well as from the lungs. If, however, from the first, it will cease upon bending the head forward, or lying procumbent, and will probably flow from the nose: if from the second, we shall commonly be able to satisfy ourselves by inspection. Blood from the stomach is of a darker colour, thrown up by vomiting, and betrays an intermixture of food.

If the hæmoptysis be from the lungs, and belong strictly to the present species, and more especially if it be a result of entonic plethora, the blood will be chiefly thrown up by coughing; and the discharge will be preceded by flushed cheeks, dyspnoea, and pain in the chest. There is usually, also, a sense of tickling about the fauces, which often descends considerably lower: Salmuth asserts, that he has known it extend to the *scrobiculus cordis*.§ These symptoms, moreover, indicate that the blood flows from a branch of the pulmonary, rather than of the bronchial artery. The blood is here of a florid hue, and the hemorrhage sudden and often copious. If a branch of the bronchial artery give way, the flow of blood is usually much slower, and smaller in quantity; there are no precursive symptoms, the blood is rather hawked or spit up intermixed with saliva, and, from being longer in its ascent, is of a darker colour. From its lodgment, however, in the air-vesicles, it becomes a cause of irritation, and a frothy cough ensues, sometimes accompanied with a little increase of the pulse and other febrile

symptoms, as a feeling of heat and some degree of pain in the breast, which subsides after the ejection, and returns if there be a fresh issue.

If the structure of the lungs be sound, we have no reason to prognosticate danger. On the contrary, it often affords great relief to a gorged liver, and has proved critical in obstructed menstruation.* Excreted with the sputum, it is frequently serviceable, as we have already observed, in cases of asthma, pleurisy, and peripneumony. But if it have been preceded by symptoms of phthisis, or a strumous diathesis, there is a great reason for alarm; for we can have little hope that the ruptured vessel will heal kindly and speedily, and have much to fear from the fresh jets by which the extravasated blood becomes deposited, and forms a perpetual stimulus in an irritable organ.

The general pathology has been already laid down. The incidental causes are, misformation of the chest; undue exertion of the respiratory muscles, whether in running, wrestling, singing, or blowing wind instruments; excess in eating and drinking; or a violent cough. As a symptom or sequel, it occurs in wounds, phthisis, or the suppression of some accustomed discharge.

In active hemorrhage from the lungs, venesection is one of the most important steps towards a cure; and the blood should be drawn freely at once, rather than sparingly and repeatedly; though a second and even a third copious use of the lancet will often be found expedient. Emetics have been recommended, but they are of doubtful effect. They augment the vascular volume by relaxing the capillaries; but they stimulate locally by the act of rejection. Drastic purgatives are avoided, because of the straining; but the straining in vomiting is greater and more direct.

Dr. Brian Robinson of Dublin, who was one of the most strenuous promoters of this mode of practice in his day, accounted for the benefit of emetics by the constriction which he conceived they produce upon the extreme vessels everywhere; but, to act thus, they should rather nauseate than vomit; for in nausea we have great vascular depression, and a cold and general collapse on the surface; while vomiting is known to rouse the system generally and determine towards the surface. Upon the recommendation of Dr. Robinson, Dr. Cullen followed the plan in several cases: "but in one instance the vomiting," says he, "increased the hemorrhage to a great and dangerous degree; and the possibility of such an accident again happening

* In the Lumleian Lectures for 1832, Dr. Watson related some striking examples, in which the menstruation, as one might say, took place for several years through the lungs, without any apparent injury of the general health. Among the patients of the celebrated Hoffman was a woman, who, for eight years, remained subject to a bleeding from the nose, which came on regularly every month, a few days before the menstrual period, and ceased upon the flowing of the catamenia. Then the direction of this periodical discharge was changed; and, for six years more, instead of epistaxis, she suffered hæmoptysis, and afterward this was exchanged for hæmatemesis.—Ed.

has prevented all my further trials of such a remedy."* Nauseating has on this account been preferred on the continent to full vomiting in hemorrhage from the stomach, and indeed various other organs, as well as from the lungs; and ipecacuanha in small doses has been generally preferred to the metallic salts, as more manageable; half a grain, or even a quarter of a grain, being given every quarter of an hour, for many hours in succession.†

In general, however, we shall find it as successful and far less distressing to employ mild aperients and sedatives. The first, and particularly neutral salts, are alone of great benefit, and their action should be steadily maintained. Sedatives are of still higher importance, and especially those that reduce the tone of the circulation, as nitre and digitalis. The first, in about ten grains to a dose, should be given in iced water, and swallowed while dissolving; the dose being repeated every hour or two, according to the urgency of the case. If there be much cough, it must be allayed by opium and blisters. Local astringents we cannot use, and general astringents are here manifestly counter-indicated, however useful in passive hemorrhage: though it should be recollected that, when an active hemorrhage from the lungs is profuse and obstinate, the vessels lose their tone, and fall into a passive state.

In HÆMATEMESIS, the blood is evacuated from the alimentary canal at either extremity, whether that of the mouth or of the anus; for the term is used thus extensively by the Greek writers. In both cases it is discharged in active hemorrhage with a considerable expulsive effort; and the discharge is preceded by tensive pain about the stomach; and accompanied with anxiety and faintness.

The quantity discharged from the stomach is in most cases larger than what is discharged from the lungs, and of a deeper hue: it is also thrown up by the act of vomiting, and usually intermixed with some of the contents of the stomach. And hence there is no great difficulty in determining as to the source of the hemorrhage.‡ Hæmatemesis, however, is far more frequently a disease of atony than of entony, and hence, chiefly belongs to the next species. Its usual exciting causes, when it occurs under an entonic character, are concussion or other external violence, as a shock of electricity,§ some strong emotion of the mind, as rage or terror, vomiting, or pregnancy. It has also occasionally been found to afford relief in suppressed catamenia, or been vicarious of it.

The pathology we have already given: the blood may proceed from the spleen, the liver,

* Mat. Med., part ii., ch. xix., p. 470.

† Keck, Abhand. und Beobach. Med. Wochenblatt, 1783. No. xlix.

‡ The blood, which comes from the lungs, is commonly florid, and mixed with bubbles of air, frothy; that which proceeds from the stomach is usually dark-coloured, coagulated, or grumous, and mingled with fragments of the food, with mucus, or bile.—Dr. Watson in Lumleian Lectures for 1832.—Ed.

§ Percival's Essays, vol. ii., p. 181.

the pancreas,* the stomach itself, or the smaller intestines; and the mode of treatment should be as already advised for hæmoptysis. [From the effects of that insidious disease, chronic inflammation of the stomach, an hæmatemesis is sometimes produced, that rapidly cuts off the patient.—(*Dr. Abercrombie, in Edin. Med. Journ., No. lxxviii., p. 2.*) Hæmatemesis is also one of the earliest symptoms of scirrhus or cancer of that organ; taking place long before the commencement of ulceration, as well as in the ultimate stages of the disease. Then, as Dr. Watson conceives (*Med. Gaz., vol. x., p. 436*), it may be owing to a breach in some vessel of magnitude, though he represents it as being more commonly a general oozing or exhalation from the ulcerated surface.]

In HÆMATURIA, the blood is evacuated at the urethra, and the evacuation is preceded by pain in the region of the bladder or kidneys, and accompanied with faintness. The blood is sometimes intermixed with urine, but occasionally flows pure and uncombined: and, in this last state, the disease is called by Vogel stymatosis, and the bleeding is supposed to proceed from the bladder rather than from the kidneys; that from the latter being smaller in quantity, and remaining a longer time in the passages, and consequently of a darker colour. There is some ground for this opinion; for, when the bladder is the seat affected, there is far more local pain and faintness than when the affection is in the kidneys. Hippocrates, indeed, has observed, that when the blood flows pure, copiously, and suddenly, and without pain, it proceeds from the kidneys, but, when it is small in quantity, and of a blackish colour, and accompanied with much heat or pain, or both, its source is the bladder. But this remark, instead of opposing, tends rather to corroborate, the preceding; for, according to both views, the seat of disease is distinguished by the greater or less degree of uneasiness that attends the discharge; and this whether the quantity discharged be larger or smaller.

It is not often, though sometimes, an entonic disease, or an active hemorrhage. Its exciting

* The statement with respect to the blood proceeding from the spleen, liver, or pancreas, is not correct. Disease of these organs may lead to hæmatemesis, or exist simultaneously with it; but the source of the blood is in the vessels of the mucous coat of the stomach itself. As Dr. Watson has observed, a great majority of cases of hemorrhage from the stomach are symptomatic. That which depends upon incipient cancer of the stomach, while it is by no means of rare occurrence, is also more frequently obscure than other instances. In general, an attention to symptoms, and the past history of the patient, will readily elucidate hæmatemesis from the action of corrosive poisons; from the rupture of an aneurism; from the influence of scurvy, or purpura; from cancer of the stomach in its advanced stages; from organic diseases of the liver, spleen, or heart; from an attack of yellow fever; from suppressed or imperfect menstruation; or from the pressure of the gravid uterus.—See Dr. Watson's Observations, as published in *Med. Gaz., vol. x., p. 439.*—Ed.

cause is frequently a stone in the bladder, or a violent blow on the kidneys, or on the bladder, especially when the latter is full. It is also said by Schenck (*Lib. vii., obs. i., 24*), and other writers, to be occasionally produced by cantharides, whether employed externally or internally.*

In connexion with the general course of treatment already recommended in the preceding varieties, the compound powder of ipecacuanha may here be employed with great advantage: for the pain and irritation are often intolerably distressing, and, on this account, demulcent drinks are frequently found to produce considerable relief.

In UTERINE HEMORRHAGE, the blood is discharged from the womb with a sense of weight in the loins, and of pressure upon the vagina. This is the menorrhagia of most of the nosologists, and is often, but very erroneously, described as an excess of the menstrual flux. It is, in truth, a real hemorrhage or issue of blood, instead of menstrual secretion, which is often entirely suppressed, though sometimes a small but inadequate portion is intermixed with the uterine bleeding: and hence Hoffman has properly denominated it uteri hemorrhagia. It occurs both in an entonic and an atonic state of the vessels, and especially of the general system: and, from the remarks offered under PLETHORA, it is not at all to be wondered at that

* *Hist. Mort. Uratislav., p. 59.* The editor has known hæmaturia occur in several cases in which cancerous disease of the neck of the uterus had extended by ulceration into the bladder. In one woman, whom he lately attended in Boswell-Court, Devonshire-street, the bladder would sometimes become so full of coagulated blood, that a retention of urine used to be induced, in which the catheter had little effect, unless introduced much further than usual. He has also known profuse hæmaturia arise from a cancerous disease of the bladder; a case that was remarkable as having been attended with a spontaneous fracture of the left thigh bone and one rib. The particulars have been published in the *Trans. of Med. Chir. Society, vol. xvii.* M. Andral mentions a very curious example of hæmaturia.—(*Anat. Pathol., tom. i., p. 339.*) It took place in an old woman who had a cancer of the stomach. A fortnight before her death, numerous purple spots appeared on her skin, and a remarkable quantity of blood was daily voided with her urine. Red spots occurred on the conjunctiva, and one of them, rendered very prominent by the blood under it, formed a purple ring round the cornea, like what is observed in chemosis. On opening the body, numerous ecchymoses were found in the cellular texture on the outside of the peritonæum and the pleura, on the inside of the cavities of the heart, and in different parts of the alimentary canal. The urinary passages contained a bloody fluid, which might also be pressed out of the mammillæ of the tubular substance of the kidneys. No blood was anywhere found, except what was of a purple colour, and quite liquid, without any appearance of coagulum. A similar case is recorded by M. Stoltz.—(*Archives de Méd., tom. xv.*) The patient, in the latter instance, was a pregnant woman, and it is curious that ecchymoses, resembling those noticed in most textures of her body, were also found in the lungs, pericardium, heart, and vessels of the fœtus.—Ed.

hemorrhage should in both conditions take place from the uterus very frequently, and, perhaps, more so than from any other organ.

For reasons we shall have occasion to explain in a subsequent part of this work, the uterus, from the period of the completion of the female form, is stimulated, once in every lunation, to the secretion and elimination of a peculiar fluid, which exhibits the colour, though it is deficient in many of the properties, of blood; and for this purpose the uterine arteries are, at such seasons, peculiarly turgid and irritable. There is hence always a tendency on such occasions to a hemorrhage in this quarter in females of a firm and robust texture, and of a plethoric habit. But if, from cold or any other cause, the uterine secretions do not at these seasons fulfil their office, and throw forth the proper fluid, the uterine arteries will be inordinately gorged; the regular stimulus will be greatly augmented; pain, tension, and spasm will extend over the loins, and the extremities of the vessels be ruptured, or their mouths give way by anastomosis, and a considerable hemorrhage be the consequence.

This is the ordinary period in which uterine hemorrhage takes place, though it may occur during any part of the interval between the catamenial terms, upon any of the occasional causes that operate upon other organs, and form the preceding varieties; as it is well known to occur at times, with great violence, during pregnancy and in childbed.

When we come to treat of diseases appertaining to the sexual organs, we shall have to notice some singular cases of precocity in female infants, and especially that of a regular menstruation. It is upon this principle alone that we can account for uterine hemorrhage in new-born infants, of which the medical records give several examples, and especially the *Ephemeres* of Natural Curiosities.

In suppressed menstruation, uterine hemorrhage affords relief to the spasms and pains that harass the loins, and the headache and difficulty of breathing which have usually preceded the lumbar distress. But the discharge may be immoderate, and become habitual. And it is hence best to be upon our guard, and to use venesection as a substitute, and to prevent or diminish the spasmodic action by gentle aperients and the sedatives already recommended in hæmoptysis, after which the case will become a disease of suppressed menstruation alone, and must be treated according to the method recommended under that malady; for a restoration of the catamenial secretion is its natural cure. I may observe, however, that, when the suppression of this secretion has been of some standing, and a uterine hemorrhage has periodically taken its place, accompanied with distressing pains in the whole circle of the pelvic region, we can sometimes suddenly restore a healthy action to the organ by a plan of anticipation. For this purpose, I have prescribed venesection about ten days before the return of the monthly paroxysms, and having thus taken off plethoric impetus, I have, a few days afterward, recommended the hip-bath to be used in a tepid state

every night, and persevered in till the period of relapse; when I have often found that there has been neither tension nor spasms, that the loins have continued easy, and the hemorrhage has yielded to the natural secretion.

IN HEMORRHAGE STRICTLY ANAL, the flux of blood issues chiefly from the hemorrhoidal vessels, and, as these are large, and but little supported by any surrounding organization, they readily give way both in an entonic and atonic state of the frame, and particularly in case of plethora upon very slight excitements, as in straining to expel hardened feces, taking cold in the feet, or walking a little too far. Irritants introduced by the mouth have also proved a frequent cause of this variety of hemorrhage; as an injudicious use of aloes, terebinthinate preparations, or even pungent alliaceous sauces. The irritation of piles is also a very common cause, and hence by some writers anal hemorrhage is only treated of as a symptom of that variety of this last disease, which is known by the name of bleeding piles. But this is highly incorrect, as anal hemorrhage often occurs, and very profusely, where no piles have ever been experienced. This power of hemorrhage, when active, as it is called, or in an entonic habit, is usually preceded by a sense of weight and pain within the rectum, and sometimes by a load in the head. And it has often, as already observed, proved critical and salutary, and carried off congestions from the abdominal viscera. It is, however, peculiarly apt to become profuse, and to establish an order of recurrence, and hence must be overpowered by the reducent and sedative plan, recommended in most of the preceding varieties, and particularly in that of hæmoptysis. The aperients employed, however, should here be peculiarly mild and alterant; and sulphur, which does not readily dissolve in the course of the intestinal canal, and often reaches the rectum in an unmixed state, is one of the best, and is often found strikingly serviceable. All stimulant foods, moreover, must be especially avoided; and the ordinary drink should be water, soda-water, or lemonade.

Here also we are able, as in the case of hemorrhage from the nose, to employ local astringents, though it would be improper to use those that act generally, so long as plethora or an entonic habit continues. The patient may sit in a bidet of ice-water, or water cooled artificially to the freezing point, or may use a cold hip-bath, and have injections of cold water, or astringent lotions, as of alum, zinc, or even lead, thrown up the rectum; the latter of which should be in such proportions as to remain there for half an hour or an hour.

SPECIES II.

HÆMORRHAGIA ATONICA.

ATONIC HEMORRHAGE.

ACCOMPANIED WITH GENERAL LAXITY OR DEBILITY, AND WEAK VASCULAR ACTION; BLOOD ATTENUATE, AND OF A DILUTED RED.

THOUGH the effect in this species is the same as in the preceding, the proximate cause, as

well as the more obvious signs, are directly opposite. The general pathology has been given in the introductory remarks to the genus, and the more common organs from which the hemorrhage proceeds are the same as already noticed under the preceding species; and hence the varieties of that may be regarded as those of the species before us.

When plethora is the remote cause, which it often is, it is atonic plethora, or plethora of debility; but whatever has a tendency to loosen or enervate the tone of the solidum vivum, or living fibre, will lay a foundation for this kind of hemorrhage. It is hence a characteristic disease of advanced age, as entonic plethora is of youth and adult life; and often takes place in those whose vigour is reduced by meager or innutritious food, close confinement, without exercise, in a foul and stagnant atmosphere, or immoderate indulgence in the pleasures of wine or sexual intercourse. Hence, too, its frequent occurrence, as a symptom, in tabes, atrophy, struma, scurvy, and low fevers.*

The characters of the several varieties of this species, as distinguished from those of the preceding, are as follow; for it is not necessary to put the varieties themselves into a tabular form:—

In HÆMORRHAGE FROM THE NOSTRILS, the blood flows without heat or headache.

In that from the RESPIRATORY ORGAN, it is usually produced without even the exertion of coughing, and is often accompanied with a scirrhus or calculous affection of the lungs; the countenance is pale and emaciated.

In HÆMORRHAGE FROM THE ALIMENTARY CANAL, the blood is discharged without tensive pain: though there must necessarily be an expulsive effort; and, from the inanition hereby produced, some degree of nausea and faintness.

When evacuated by the URETHRA, there is, for the same reason, faintness, but little or no previous pain. The most singular and severe examples of hemorrhages from the urethra are those that have occurred during coition; sometimes intermixed with semen, sometimes instead of it, and sometimes immediately after emission. The individuals have been generally persons of highly irritable and delicate habits; and who have weakened themselves by too free an indulgence in pleasures of this kind. Numerous instances of this sort of hemorrhage are given in the Collections of Medical Curiosities, and especially in several of the German Ephemerides.†

* The more correct principles, on which the fact is accounted for by Andral, are adverted to in some of the notes in the preceding pages.—Ed.

† The employment of caustic bougies, or the rough introduction of instruments into the urethra, occasionally causes profuse hemorrhage. The editor is attending a man at this time (Nov., 1830), who was cut for the stone in Guy's Hospital about twenty years ago, and who is voiding a considerable quantity of blood from the urethra, in consequence, as he states, of slipping down with his thighs widely and very forcibly separated. Hæmaturia atonica may attend typhus fever, smallpox, and purpura hæmorrhagica. When entirely passive and unaccompanied by inflamma-

There is little pain in ATONIC HÆMORRHAGE FROM THE UTERUS: and it generally occurs at the natural cessation of the menstrual flux, or within a few years afterward. As a concomitant, hemorrhage from this quarter is also frequently found in a scirrhus, cancerous, or other morbid states of the uterus, in whatever period of life these may occur; which, however, they do most usually after the age of forty or fifty.

ATONIC HÆMORRHAGE FROM THE ANUS ordinarily takes place spontaneously, with little or no pain; but commonly with varices or congestions of the hemorrhoidal vessels, and is very apt to produce a habit of recurrence.

In all these varieties, venesection must be had recourse to sparingly, and never, unless where we have satisfactory evidence of atonic plethora or congestion. It may sometimes be requisite to use the lancet in nasal hemorrhage, for the head may feel oppressed and drowsy: and it will still more frequently be necessary in hemorrhage from the uterus; but the blood extracted should rarely exceed seven or eight ounces; and, in all other varieties, as a general rule, it will be better to withhold our hand, and to proceed at once with a tonic plan of treatment.

Into this plan we may, in the present species, freely admit the use of general astringents, in conjunction with their local application, however objectionable in the preceding; for a laxity and inelasticity of the fibrous structure are among the chief symptoms we have to oppose: and hence the mineral acids and metallic salts may be had recourse to with great advantage, along with bitters; and, with a few exceptions, we cannot well err in the selection. The preparations of iron may be rather too heating in hæmoptysis, and perhaps in all atonic hemorrhages accompanied with much irritability. One of its mildest and best forms is that of a subcarbonate; and perhaps the best mode of obtaining it in this form is by the celebrated composition of Dr. Griffiths. The myrrh is also in his preparation a useful article for the present purpose, and we shall rarely do better than employ it. In the London Pharmacopœia, it is given under the name of *mistura ferri composita*.

From the manifest power of opium to restrain most evacuations, it has often been employed in hemorrhages. It does not appear, however, to have any direct effect in checking the discharge; and in entonic hemorrhages, and especially when employed early, has been highly mischievous. But where, in hæmoptysis, there is a perpetual cough from irritation, or in uterine hemorrhages a frequent recurrence of spasmodic pains, it has been tried with considerable success. And the same remark will apply to hyoscyamus, and various other narcotics, which seem to be only useful on the same account.

Cinchona, which is peculiarly objectionable in the preceding species, may here be had re-

tion, the exhibition of turpentine in small doses, from twenty to twenty-five drops, every six hours, should be adopted, and the system supported.—See Elliotson's Lects., delivered at Lond. Univ., in Med. Gaz. for Aug., 1833.—Ed.

course to with considerable promise. It seems, however, to be chiefly serviceable in uterine hemorrhage, where the disease depends upon a laxity of the extremities of the vessels, which are therefore readily opened by every irritation, applied to the system or to the diseased part. Whether in this case it acts altogether as a bitter, as supposed by Dr. Cullen, or partly also as an astringent, it may be difficult to determine; but the question is not of importance.

For other general roborants to which it may be necessary to have recourse, the reader may turn to the treatment of *limosis dyspepsia*, or indigestion (Class I., Ord. I., vol. i., p. 98); and he may govern the patient's diet and regimen by the general plan there laid down.

The local astringents and refrigerants already recommended under the former species, may be here employed with even less reserve: and where the bleeding has become chronic, which it is far more likely to do than in entonic hemorrhage, or has been so profuse as very considerably to exhaust the system, a little wine or some other cordial should be administered as soon as we are consulted: for, however small the vessel that is ruptured, its orifice is incapable of contracting from a total loss of tone; and hence a diffusible stimulus gives it the irritation it stands in need of, and forms a salutary constringent. A striking case of this kind has already been given in treating of accidental hemorrhages from extracting teeth; and it is not long since, that the author was requested to attend in a similar hemorrhage from the nose. The patient was a lady of about fifty years of age, of slender and delicate frame, who had for some years ceased to menstruate. The bleeding had continued incessantly for three or four days, during which she had been restrained to a very low diet, and allowed nothing but toast and water for her common drink. She was faint, felt sick, and had a feeble pulse, and must have lost many pounds of blood, though no exact measure had been taken. I gave her instantly a free draught of negus made with port wine, prescribed camphire mixture with the aromatic spirit of ammonia, had the nostrils syringed with equal parts of tincture of catechu and water, and applied a neckerchief wetted with cold water round the temples, directing it to be renewed every ten minutes. In half an hour the hemorrhage ceased, and, on the ensuing day, I found no other symptom than weakness, for which a nutritious but irritant regimen was prescribed. A few days afterward the hemorrhage returned from sneezing or some other incidental stimulus, and was restrained, as I was told, for I did not see her, by a recurrence to the same plan. I recommended, however, carriage-exercise, and an excursion to the seacoast, which was immediately complied with, and there was no recurrence of the disease.

To effect the same intention, I have occasionally advised cardiacs combined with astringents in hæmatemesis, where the discharge of blood has been profuse, and has continued for some days, and the patient has become considerably exhausted: and I do not recollect an

instance in which the plan has proved unfriendly. In like manner, in very great faintness or deliquium produced by a copious and protracted hemorrhage from the uterus, I have had the vagina injected with equal parts of port wine and water acidulated with sulphuric acid, and have found it equally successful.

The acetate of lead is also a preparation which, in all such cases, ought to be tried internally. It was at one time greatly out of favour, from the writings of Sir George Baker, and the concurrent opinion of Dr. Heberden. Of the mischievous effects of various preparations of this metal when employed internally, the former has given numerous examples, and concludes with the following corollary: "that lead taken into the stomach is a poison. I do not say *ex proprietate naturæ et totâ substantiâ*; but which is capable of doing much more hurt than good to the generality of men in all the known ways of using it; and, consequently, that it cannot be avoided with too much caution."—(*Med. Transact.*, vol. i., p. 311.) In corroboration of which Dr. Heberden tells us, that its good effects are by no means so certain as its mischief; and, in most cases, would be far overbalanced by it. In the form of an acetate, however, all its evils seem to be subdued by a combination with opium; for the first distinct knowledge of which the medical world is indebted to the penetration and judgment of Dr. Reynolds, who tried it, in this state of union, in various cases, with the most perfect success, and without the least unfavourable symptom whatever, whether of pain or even costiveness. He also employed with equal benefit the old tinctura saturnia, and the sugar of lead: of the former, giving eighteen drops with three drops of laudanum to a dose, and repeating the dose every four hours in a little barley-water; of the latter, giving one grain with three drops of laudanum mixed into a pill with conserve of roses; to be repeated every six hours. And, under both forms, he employed these materials with great and unalloyed advantages in hemorrhages of most sorts, especially uterine, pulmonary, and nasal.—(*Med. Transact.*, vol. iii., art. xiii.)

Dr. Latham (vol. v., art. xxi.) has since confirmed this practice of Dr. Reynolds in its fullest degree, and even extended its range; and so little inconvenience has he found from the use of the acetate, that he has employed it "in doses of a grain three times a day for six, eight, and ten weeks successively; usually, but not always, combining it with opium or saturnum; without any other precaution than desiring the patients to obviate any costiveness by oleum ricini or confectio sennæ." He has occasionally given two grains of the acetate as an evening dose; once, in consultation with Dr. Reynolds, five grains; and mentions another case in which he was concerned, where ten grains a day were taken without any inconvenience. By a mistake for sugar, a young woman, respecting whom he was consulted, swallowed at one time about two drachms of it, yet without any serious evil: the fauces and œsophagus were considerably constricted, and this seems to have been

the chief mischief; for the bowels were opened by oleum ricini and other purgatives in the course of the day, and the patient was not at all worse for the accident on the ensuing morning.

Imboldened by these facts, Dr. Latham has employed the same medicine in other diseases in which irritant astringents and tonics seem requisite, as in colliquative diarrhoeas and hectic perspirations, and more especially in that semipurulent expectoration which too often terminates in pulmonary ulceration and consumption: and, as he confidently assures us, with great advantage. And he hence concludes, that whatever deleterious properties may appertain to lead in some of its salts and oxydes, nothing pernicious exists in its acetate; in the process for which, he conceives it either to be more completely freed from arsenical or other poisonous minerals than in its other forms, or rendered innocuous by the addition of the acetic acid.

It only remains to be added, that where entonic hemorrhage has occurred so profusely, or has continued so long, as to reduce the system to an atonic state, it then becomes a disease of debility, and is to be treated as though originating under the present species.

GENUS III.

MARASMUS.

EMACIATION.

GENERAL EXTENUATION OF THE BODY, WITH DEBILITY.

MARASMUS is a Greek term, derived from *μαραίνω*, "marcesco," "marcescere reddo." It was long ago used collectively to comprehend atrophy, tabes, and phthisis; and in employing it therefore in the present system as a generic name, we only restore it to its earlier sense. The generic character is common to all these subdivisions; for each is distinguished by a general emaciation of the frame, accompanied with debility, and consequently forms a species to marasmus as a genus.

With these species the reader, however, will now find two others united; *M. ANHÆMIA*, to which I shall advert presently, and *M. CLIMACTERICUS*: the last from a high authority, with which I fully coincide; and which is intended to embody that extraordinary decline of all the corporeal powers, which, before the system falls a prey to confirmed old age, sometimes makes its appearance in advanced life without any sufficiently ostensible cause, and is occasionally succeeded by a renovation of health and vigour, though it more generally precipitates the patient into the grave.

Extenuation or leanness is not necessarily a disease; for many persons who are peculiarly lean are peculiarly healthy, while some take pains to fall away in flesh, that they may increase in health and become stronger. But if an individual grow weaker as he grows leaner, it affords a full proof that he is under a morbid influence; and it is this influence, this conjunction of extenuation with debility, as noticed

in the definition, that is imported by the term MARASMUS, and its synonyme EMACIATION.

It is curious to observe how much more easily the body wastes under a disease of some organs than of others; and it would be a subject of no small moment to inquire into the cause of this, and to draw up a scale of organs effecting this change, from the lowest to the highest degree. Dr. Pemberton, in a work of considerable merit, published many years ago, threw out some valuable hints upon this subject, which it is to be lamented that he did not afterward follow up to a fuller extent. The following passage is well worthy of notice, and aptly illustrative of what is here intended. "Let us take," says he, "the two cases of a diseased state of the mesenteric glands, and a diseased or scrofulous affection of the breast. In the former, we shall find there is a great emaciation; in the latter, none at all. In an ulceration of the small intestines, great emaciation takes place: in scirrhus of the rectum, none. In a disease of the gall-bladder, which is subservient to the liver, the bulk of the body is diminished; but in a disease of the urinary bladder, which is subservient to the kidneys, scarcely any diminution of bulk is to be perceived. In an abscess of the liver, the body becomes much emaciated; but in an abscess of the kidneys, the bulk is not diminished.

"If we examine into the function of those parts, the diseases of which do or do not occasion emaciation, we may perhaps be led to the true cause of this difference of their effect on the bulk. In order, however, to understand more clearly how the functions of these parts bear relation to each other, it may be necessary to premise, that the glands of the body are divided into those which secrete a fluid from the blood for the use of the system, and those which secrete a fluid to be discharged from it. The former may be termed glands of supply; the latter, glands of waste.

"The smaller intestines, in consideration of the great number of absorbents with which they are provided for the repair of the system, may be considered as performing the office of glands of supply. The large intestines, on the contrary, may be considered as performing the office of glands of waste; inasmuch as they are furnished very scantily with absorbents, and abundantly with a set of glands which secrete or withdraw from the system a fluid which serves to lubricate the canal for the passage of the feces, and which itself, together with the feces, is destined to be discharged from the system. The glands which secrete a fluid to be employed in the system, as well as the glands of direct supply, may be considered the liver, the pancreas, the mesenteric glands, perhaps the stomach, and the small intestines; and the glands of waste are the kidneys, breasts, exhalant arteries, and the larger intestines."

The first set are, in fact, the general assemblage of the chylific organs; and it is upon their direct or indirect inability to carry into execution their proper function, that the first of the species we are now about to enter upon, that of ATRO-

PHY, is founded in all its varieties. How far these remarks will apply to the other species of the present genus is not quite so clear. The seat of the third and fourth may be doubtful, perhaps variable; that of PHTHISIS, or the fifth, admits of no debate. Are the lungs to be regarded as an organ of waste or of supply? The question may be answered in opposite ways, according to the hypothesis adopted respecting the doctrine of respiration. They throw off carbonic acid gas. Do they introduce oxygen or any other vital gas into the circulating system? As an organ of waste, we cannot, upon the principle here laid down, account for the emaciation which flows from a diseased condition of them. If it can be substantiated that they are an organ of supply, they confirm and extend the principle. Will this principle, moreover, apply in dropsy, in which there is even more emaciation than in phthisis? The subject is worth enunciating; but we have not space for it, and must proceed to arrange the five species that appertain to the genus before us:—

- | | |
|-----------------------|------------------|
| 1. Marasmus Atrophia. | Atrophy. |
| 2. ——— Anæmia. | Exsanguinity. |
| 3. ——— Climactericus. | Decay of Nature. |
| 4. ——— Tabes. | Decline. |
| 5. ——— Phthisis. | Consumption. |

Most of these follow in regular order, as genera or species in most of the nosological arrangements, and are set down as subdivisions of macies or marasmus. By Dr. Cullen, phthisis is regarded as a mere sequel of hæmoptysis, upon which we shall have to observe in its proper place; while atrophia and tabes are given as distinct diseases under the ordinary head, only that for macies or marasmus he employs *marcores* as an ordinal term. The common distinguishing marks are, that atrophy is emaciation without hectic fever; tabes, emaciation with hectic fever; and phthisis, emaciation and hectic fever coupled with pulmonary disease. And such, with the exception of phthisis, is the distinction continued by Dr. Cullen in his Synopsis. But, in his Practice of Physic, he informs us that his views upon this subject had undergone a change, not only in respect to the subdivisions or varieties of these two diseases, but as to the diseases themselves. "I doubt," says he, "if ever the distinction of *TABES* and *ATROPHIA*, attempted in the Nosology, will properly apply; as I think there are certain diseases of the same nature, which sometimes appear with and sometimes without fever."—(Vol. iv., part iii., book i., sect. 1618.) This is written in the spirit of candour that so peculiarly characterizes this great man. But I cannot thus readily consent to relinquish a distinction which has received the sanction of so many observant pathologists, and which appears to me to have a sufficient foundation. It is difficult, undoubtedly, to assign a proper place to all the varieties or subdivisions of these species; but this is a difficulty common to many other diseases equally; for we perceive fevers, nervous affections, and those of the digestive organs perpetually running into each other in different varieties, yet

we find it convenient to arrange and describe them as distinct diseases. And, with the caution attempted to be exercised in respect to the species before us, I trust that the reader will not discern a greater transgression of boundary in the present, than in various other cases of general allowance.

SPECIES I.

MARASMUS ATROPHIA.

ATROPHY.

COMPLEXION PALE, OFTEN SQUALID; SKIN DRY AND WRINKLED; MUSCLES SHRUNK AND INELASTIC; LITTLE OR NO FEVER.

THE specific is a Greek term deduced from a privative, and *τροφή*, "nutrio," and is literally, therefore, INNUTRITION; a designation peculiarly significant, as the disease, in all its forms or varieties, seems to be dependant on a defect in the quantity, quality, or application of the nutrient part of the blood; and thus lays a foundation for the three following varieties:—

- | | |
|----------------|---|
| α Inopie. | Blood innutritious from scarcity or pravity of food. |
| β Profusionis. | Blood deprived of nutrition by profuse evacuations. |
| γ Debilitatis. | Nutrition not sufficiently introduced into the blood by the chylific organs, or not sufficiently separated from it by the assimilating. |

In order that the body should maintain its proper strength and plumpness, it is necessary that the digestive organs should be supplied with a proportion of food adequate to the perpetual wear of its respective parts: for this wear, as we all know, produces a waste; and hence the emaciation sustained by those who suffer from famine, in which there is no food introduced into the stomach, or from a meager or unwholesome diet, in which the quantity introduced is below the ordinary demand. It is this condition that forms the first of the subdivisions or varieties, the *ATROPHY OF WANT*, under which the species before us is contemplated in the present arrangement.

But the ordinary demand may not be sufficient for the body, or some part of it may be in a state of inordinate wear and waste, as in very severe and protracted labour, in which the supply is rapidly carried off by profuse perspiration, or in rupturing or puncturing a large artery, in which the same effect is produced by a profuse hemorrhage. Any other extreme or chronic evacuation may prove equally mischievous, as an excessive secretion from the bowels, from the vagina, from the salivary glands, from the breasts; as where a delicate wet-nurse suckles two strong infants. And hence the origin of the second of the above varieties, or the *ATROPHY OF WASTE*.

Now, in all these cases, wherever the system is in possession of an ordinary portion of health, there is a strong effort made by the digestive powers to recruit the excessive expen-

diture by an additional elaboration of nutriment ; and the instinctive effort runs through the entire chain of action to the utmost reach of the assimilating powers, or those secretions with which every organ is furnished, to supply itself with a succession of like matter from the common pabulum of the blood. Hence, the stomach is always in a state of hunger, as in the case of famine, profuse loss of blood, or recovery from fever ; all the chylific organs secrete an unusual quantity of solvent juices, an almost incredible quantity of food is demanded, and is chymified, chylified, and absorbed almost as soon as it enters the stomach ; the heart beats quicker, the circulation is increased, and the new and unripe blood is hurried forward to the lungs, which more rapidly expand themselves for the purpose, to be completed by the process of ventilation : in which state it is as rapidly laid hold of by the assimilating powers of every organ it seems to fly to, and almost instantly converted into its own substance. Such is the wonderful sympathy that pervades the entire frame ; and that runs more particularly through that extensive chain of action which commences with the digestive and reaches to the assimilating organs, constituting its two extremities.

So long as the surplus of supply is equal to the surplus of expenditure, no perceptible degree of waste ensues ; but the greater the demand the greater the labour, and the turmoil is too violent to be long persevered in. The excited organs must have rest, or their action will by degrees become feeble and inefficient. And if this take place while the waste is still continuing, emaciation will be a necessary consequence, even in the midst of the greatest abundance ; and hence, an explanation of the variety of emaciation before us, constituting the second.

Thus far we have contemplated the animal frame in a firm and healthy constitution : and have supposed a general harmony of action pervading every link of the extensive chain of nutrition, from the digestive organs to the assimilating powers. But we do not always find it in this condition ; and occasionally perceive, or think we perceive, that this necessary harmony is intercepted in some part or other of its tenour : that the digestive powers, or some of them, do not perform their trust as they should do, or that the assimilating powers, or some of them, exhibit a like default ; or, that the blood is not sufficiently elaborated in its course, or becomes loaded with some peculiar acrimony. And hence another cause, or rather an assemblage of other causes, competent to the disease before us.

It is from the one or the other of these sources that we are in most, perhaps in all cases, to derive the third modification of this disease, which is here distinguished, for want of a better term, by that of *ATROPHY OF DEBILITY*. The disease under this form is often very complex, and it is difficult to trace out what link in the great chain of action has first given way. Most probably, indeed, it is sometimes one link, and sometimes another. But, from the sympathy

which so strikingly pervades the whole, we see at once how easy it is for unsoundness in one quarter to extend its influence to another, till the disease becomes general to the system. Yet I am much disposed to think that the atrophy so conspicuous in feeble habits, and the feeblest periods of life, as infancy and old age, commences most usually at the one or the other end of the chain, and immediately operates by sympathy on its opposite. This remark is in consonance with a very common law of life, by which impressions are more powerfully and more readily communicated from one extreme of an organ to another, than they are to any of the intermediate points. It is hence the will operates instantly on the fingers, the stomach on the capillaries of the skin ; and that the irritation produced by a stone in the bladder is felt chiefly in the glans penis. And hence the close correspondence which we have already seen to prevail between these two extremities of the nutritive function in the case of want and hunger.

Where atrophy is connected with a morbid state of the digestive organs, we have a little light thrown on the nature of the disease, but not much. For first, indigestion does not necessarily produce this effect, since it is no uncommon thing for dyspeptic patients to become plethoric, and gain, instead of lose, in bulk of body. And next, the morbid state of these organs may be a secondary, instead of a primary affection, and be dependant upon a general hebetude, or some other unsound condition of the assimilating powers, constituting the other end of the chain ; and hence exercising a stronger sympathy over them than over any intermediate organs whatever : as the digestive organs themselves, if the disease should have originated in them, may exercise a like sympathy over the assimilating powers, and hence produce that general extenuation which, as we have just observed, is not a necessary consequence of dyspepsy. It is at least put, I think, beyond a doubt, that more than one set of organs are connected in the atrophy of debility.

Where this atrophy takes place in infants at the breast, or young children, it is ushered in by a flaccidity of the flesh, a paleness of the countenance, sometimes alternating with flushes, bloated prominence of the belly, irregularity of the bowels, pendulousness of the lower limbs, general sluggishness and debility, and, where walking has been acquired, a disinclination to motion, with fretfulness in the day, and restlessness at night.

There is at first no perceptible fever, no cough, nor difficulty of breathing : but if the disease continue, all these will appear as the result of general irritation, and the skin will become dry and heated, and be covered over with ecchyma, impetigo, or some other squalid eruption. The breath is generally offensive ; the urine varies in colour and quantity ; and, in infants at the breast, the stools are often ash-coloured or lien-teric, or greenish, loose, and griping. The appetite varies ; in some cases it fails, in others it is insatiable.

Where these symptoms or the greater part of them occur to an infant at the breast, it becomes us, in the first place, to be particularly attentive to the manner in which it has been nursed, in respect to cleanliness, purity of air, warmth, and exercise; we have next to turn our attention to the nurse's milk; and afterward to an examination whether the infant is breeding teeth, or has worms, or there be any scrofulous taint in the blood. For the last we have no immediate remedy; the rest we must correct as we find occasion. And if we have no reason to be satisfied upon any of these points, it may still be advisable to change the milk. It is not easy to detect all the peculiarities of milk that may render it incapable of affording full nutrition: and there is reason to believe, that one infant may pine away on what proves a healthy breast to another. I have given this advice in some dilemmas, and have often found a wonderful improvement on its being followed.

In children on their feet, who are confined to the filth and suffocating air of a narrow cell, the common habitation of a crowded family from Sunday morning to Saturday night; or who are pressed into the service of a large manufactory, and have learned to become a part of its machinery before they have learned their mother-tongue; there is no difficulty in accounting for the atrophy that so often prevails among them. The appetite does not here so much fail as the general strength; their meals are, perhaps, doled out at the allotted hours by weight and measure: but still they are falling victims to emaciation; and are affording proof, that air and exercise are of as much importance as food itself; that there are other organs than those of digestion, upon which the emaciation must depend: and that, unless the supply furnished by the food to the bloodvessels be sufficiently oxygenized by ventilation, and coagulated by exercise, the blood itself, however pure from all incidental defect or hereditary taint, will never stimulate the secretions of the various organs to which it travels to a proper separation of its constituent principles, and a conversion to their own substance.

In all these cases, therefore, the proximate cause seems to be lodged principally in the assimilating powers of the system; and whenever the digestive organs grow infirm also, it is rather by sympathy with the former than by any primary affection of their own.

There is a singular case of atrophy quoted by Sauvages, to which he has given the name of *lateralis*, and which unquestionably belongs to this variety. It occurred in a young child, and took possession of just one half the body; the left side, from the axilla to the heel, being so completely wasted, that the bones seemed only to be covered with skin, while the right side was fat. Under the influence of topical antispasmodics, and sudorifics continued for seven years, the writer of the account tells us that he began to get better—"melius habere cepit."—(*Nos. Med.*, cl. x., ord. i.; *Ex. Collect. Acad.*, tom. iii., p. 693.)

In the atrophy of debility, common to old age,

the cellular membrane, that is, the part containing, as well as the parts contained, seems rather to shrivel away, in many cases to be carried away, by absorption, and the muscular fibres to become dried up and rigid, rather than loose and flabby. In this case, the assimilating powers seem to have done their duty to the last, and, like an empty stomach when loaded with gastric juice in a moment of sudden death, to have preyed upon and devoured themselves: since it is probable, that nearly all the animal oil, and more than half the bulk of the muscles and of the parenchyma of many of the organs, is carried off in the same manner; for, that all these are capable of being converted into a like substance is clear, since all of them are transformable into adipocire by a chymical action after death, and into a steatomatous material by a morbid action of the living power, while every other organ continues in good health; and there are many facts that lead to the conclusion that all, under the circumstances before us, are capable of yielding a common substitute for the natural food of the system. Here, therefore, we are to look for the proximate cause of the disease towards the other end of the chain, or among the chylific viscera. And we shall not in general look in vain. Not, indeed, that we shall always, or even commonly, find it in the stomach or in the liver, for the appetite may not fail, though its demand is but small and is easily satisfied; and it probably digests what is introduced into it. Yet here the greater part of the food rests; or rather, most of it passes through the intestines, and very little goes into the lacteals; insomuch that many of our most celebrated anatomists have thought, as I have had occasion to observe (vol. i., p. 228, *Parabysma Mesentericum*), that the mesenteric glands of old people become obliterated; while Ruysch contended, that mankind pass the latter part of their lives without lacteals, and that he himself was doing so at the time of writing.

The mode of treatment needs not detain us. Where the disease depends upon a want of wholesome food, or of food of any kind, the cure is obvious: where upon profuse evacuations, it falls within the precincts of some other disease, and is to be governed by its remedies. And where the cause is an infirm condition of any part of the chain of nutritive functions, from the chylific to the assimilating organs, the same tonic course of medicine that may be advisable in the one case, will be equally advisable in the other. The bowels should be kept in a state of regularity; mercurial alterants may sometimes be required, though less frequently than under one or two varieties of tabes; the different preparations of iodine will often exercise a healthful stimulus, and prove the deobstruent that is stood in need of; the bitters and astringents enumerated under *DYSPEPSY* may also be had recourse to, according to the peculiarity of the case; and cleanliness, fresh air, exercise, and cold-bathing will complete the rest. The atrophy of old age is to be met by the richest foods, wine, and the warmth of another person sleeping in the same bed.

SPECIES II.
MARASMUS ANHÆMIA.
EXSANGUINITY.

FACE, LIPS, AND GENERAL SURFACE GHASTLY PALE; PULSE QUICK AND FEEBLE; APPETITE IMPAIRED; ALVINE EVACUATIONS IRREGULAR, BLACK, AND FETID, OCCASIONALLY WITH SEVERE GRIPINGS; LANGUOR AND EMACIATION EXTREME.

THE specific name for this disease is sometimes written ANÆMIA, but incorrectly; for the aspirate ought to be retained, and is so, indeed, in common usage, as in *anhæmous*, *vulnerable* or *styptic*, from the same root; *enharmonic*; *errhine*; *cachexy*; *amphemeræ*; *anthelmintic*. The most striking peculiarity of the affection is, that the bloodlessness of the exterior precisely corresponds with that of the interior; since dissections show that the largest and deepest vessels are nearly as destitute of blood as those on the surface.* It is in this ghastly pallor of the whole exterior, as directly expressive of the same condition within, that this disease chiefly differs from the atrophy of want, of waste, and of debility, which constitute the different modifications of the preceding species.

The disease itself has often been referred to, and at times described by the old writers, as Becher (*Diss. Resolutio casus practici Anæmiæ, Sanguinis miros fructus representantis*, Leid., 1663), Albert (*Diss. De Anæmiâ*, Hall., 1732), and Janson (*Diss. De Morbis ex Defectu Liquidi vitalis*, Lugd. Bat., 1748); and still more lately by Hoffman, De Haen, and Isenflamm. Several of their cases, however, are confounded with the different forms of the preceding species, and consist of nothing more than an exhausted state of the bloodvessels, from hemorrhage or other profuse evacuations, in one case, indeed, from hemorrhoids.—(*Robin, Journ. de Médecine*, tom. xxxii., p. 48.) And hence Lieutaud and Isenflamm undertook, in the middle of the last century, to distinguish the real disease from those which were thus confounded with it; tracing out the separate causes and symptoms, and marking them by different names; as *anæmia chlorosis*, and *anæmia consecutiva*, which were the appellations of Lieutaud (*Précis de la Médecine Pratique*, 1761); and *a. vera*, and *a. spuria*, which were those of Isenflamm. These distinctions, however, seem to have made less impression on the world of medicine than they ought to have done: for we find M. de Sauvages, in the first edition of his *Nosologia Methodica*, published subsequently to Lieutaud's Summary,

* The blood may be so diminished in quantity, that it seems, during life, to forsake the surface, which is only pervaded (to use Andral's expression) by a kind of serosity; and, after death, no blood is found, not only in the arterial trunks, great veins, and right cavities of the heart, but in the several capillary networks, all of which seem remarkably pale. In this state, completely destitute of blood, are found all the membranous and parenchymatous tissues, as the brain, the lungs, the liver, the kidneys, the alimentary canal, and the texture of the heart and muscles.—See Andral, *Anat. Pathol.*, tom. i., p. 80.—ED.

following Strach and Ramazzini in describing anæmia, if, indeed, he has described it at all, as a modification of spurious chlorosis, or pallor, under the name of *chlorosis rhachialgica*.—(*Nos. Med.*, cl. x.; *Cachexia*, ord. vi.; *Ictericæ*, gen. xxxv.; *Ramazzini De Morbis Artific.*, cl. i., ii.)

Of late years, however, something more of light and far more of correct description have been thrown upon this very extraordinary malady by the contributions of several writers, and particularly of Professor Halle, of Paris, and Dr. Combe, of Edinburgh.* Nothing can be more different than the occupations, habits, and modes of life, of two distinct classes of individuals, who are hereby brought forward as the subjects of anæmia. And yet the close resemblance, and, allowance being made for incidental circumstances, we may say the identity of the symptoms exhibited in situations so perfectly unlike, furnish an adequate proof of an identity of disease.†

The most strictly idiopathic example, and the one most free from influential incidents, is that of Dr. Combe.—(*Case of Anæmia*; *Transact. of Med. Chir. Soc. of Edin.*, vol. i., p. 194.) The patient was forty-seven years of age, was born in the country, and for the most part had been occupied in agricultural employments: he was married, but without a family; was leading a regular and temperate life; had enjoyed perfect health ever since childhood, and had never been blooded. At the time of his applying to Dr. Combe for advice, he had been unwell for about two months, or something more; his chief complaint having been loss of strength, uneasiness in the head, and a sickly complexion. "I was much struck," says Dr. Combe, "by his peculiar appearance. He exactly resembled a person just recovering from an attack of syncope. His face, lips, and the whole extent of the surface, were of a deadly pale colour: the albuginea of his eye bluish. his motions and speech were languid: he complained much of weakness; his respiration, free when at rest, became

* Professor Samuel Jackson, of Philadelphia, considers anæmia under four divisions: complete and incomplete; general and local or partial; under each division he has made some very pertinent remarks:—When anæmia becomes a complication superadded to other affections, an epiphenomenon, as it was formerly expressed, the treatment of the original disease must be modified by this circumstance.—See Hays's *Cyclop. of Med.*, art. ANEMIA.—D.

† A general anæmia may come on without any discoverable cause. Andral noticed its existence in the bodies of several individuals who died dropsical, and in whom no alteration whatever of the solids could be traced.—(*Clinique Méd.*, tom. iii., p. 558, et suiv.) The restriction to a diet not sufficiently nutritious, the habitual respiration of impure, damp air, deprived of the sun's influence, and which prevents the elaborating functions of the skin and lungs from being duly performed, a disease that affects the direct or indirect organs of hæmatosis, are the circumstances adverted to by Andral as capable of producing a more or less complete general anæmia.—See *Anat. Pathol.*, tom. i., p. 81.—ED.

hurried on the slightest exertion : pulse eighty, and feeble : tongue covered with a dry fur ; the inner part of the lips and fauces nearly as colourless as the surface." His bowels were very irregular, though generally relaxed : the stools very dark and fetid ; urine copious and pale : appetite impaired, and latterly a rejection of almost every kind of food ; constant thirst ; no pain referable to any part, nor any determinable derangement of structure.

These symptoms continued with little variation for about three months, with the exception that, for a short time, he appeared to be improving. Yet, upon the whole, the disorder gained ground ; the feeble pulse was easily excited ; a copious perspiration followed any exertion ; the veins on the arms and neck could be felt on making pressure, but the colour of the blood did not appear through the skin. At one time, an affection of the liver was suspected ; at another, from the thirst and great flow of urine, *paruria mellita* ; but none of these indications were stationary. Tonics did no service, nor a sea-voyage, which was tried, nor the use of a chalybeate spring. He grew gradually weaker, continued to lose flesh ; but, with a strong resemblance to the delusive confidence of phthisis, his spirits remained for the most part undepressed, and he still looked forward to a speedy recovery. Meanwhile all the symptoms were deteriorating, and the constitution was evidently sinking under their pressure. In about six months from the period of his application for relief, the œdema extended over his face and upper extremities, evident marks presented themselves of effusion into the chest, and he died with all the symptoms of hydrothorax.

The body was examined thirty-six hours after death. The waxy pallor of the surface remained unchanged : the subcutaneous fat was scanty, of a pale yellow, and semi-fluid. Not a drop of blood escaped on dividing the scalp : the dura mater was pale, presented few vessels, and those empty. The pia mater was equally pale, its bloodvessels contained a pale serum and a considerable quantity of air. The lateral sinuses were moderately filled with a pale fluid blood ; the arteries at the basis were empty. The substance of the brain was very soft and pultaceous, mapped with very few vessels. The lungs were of a pale gray, without any marks of gravitated blood. The heart, when cut into, was of a pale colour, and did not tinge the linen when rubbed upon it ; it appeared like flesh macerated many days in water. The right ventricle contained a pale coagulum. The left side was wholly empty. The coronary arteries were sound. The inner coat of the aorta was of a fine red colour for some inches, without any turgescence or ossification. All the valves were sound. A considerable moisture bedewed the viscera of the abdomen. The liver was of its proper size and structure, but of a light brown colour ; there was no exudation of blood on cutting into its substance. The spleen was the only viscus of its usual colour : it was very soft, and its contents, when pressed, turned out as from a sac. The kidneys were nearly blood-

less : the pancreas of a pale reddish hue. The stomach and intestines were perfectly sound, thin, showing no vessels, and transparent. The muscular substance throughout the body was, like that of the heart, very pale, and exuded no blood, but only a pale serum when cut into. The arteries were universally empty, as were also the jugular, humeral, and femoral veins. The lower cava alone, about the bifurcation, with the exception of the lateral sinuses, contained any appreciable quantity of blood.

Besides these appearances, about three pounds of a lemon-coloured serum was found effused in the thorax, and a considerable ossification, about an inch long, rough and irregular, was traced imbedded in the plicæ of the dura mater near the vertex, being almost the only morbid deviations, with the exception of those that relate to the sanguineous system ; the first of which Dr. Combe justly regards as a mere consequence of the disease ; while he thinks it may admit of a doubt whether the second had any connexion with the bloodless state of the system. In truth, it seems to have been an incidental concomitant.

It is impossible to conceive a more total exhaustion of the vital fluid from the entire system, than this singular case presents to us ; and instead of wondering at the deadly waxiness of the complexion, the feebleness of the pulse, the utter debility and emaciation which this incarnate ghost must have presented, the greater and almost the only wonder is, how the living principle could so long have remained attached to so exhausted a receiver, and the sensorial power have derived its means of recruit ; at a time, too, when all the functions, in the midst of their feebleness, were urged on by the force of the morbid excitement to the performance of double duty : the pulse was quickened ; the animal spirits were maintained above the standard of sober health ; the peristaltic action, though irregular, for the most part accelerated, the perspiration redundant, and the urine often profuse.

The post-obit examination, while it unveils little or nothing of the proximate cause of the disease, discloses to us most manifestly the inroad that had been made upon the general substance of the frame for the want of a due supply of nourishment, and how completely every organ had been living upon itself, and the whole had been living upon the remnant of the blood almost to its last drop. The fault does not, therefore, so much seem to have been in the secretory system, or assimilating powers, as in the lacteals, or digestive function : in the commencement, rather than in the termination of the chain.

It was the opinion of Ruysch, as we have lately had occasion to observe, that this commencing part of the catenated organ of supply gradually loses its power with the advance of years, and that, in old age, it entirely ceases to act : so that being himself, at the time of writing, in this very season of life, he conceived he was then living, and had been living for a long period, upon himself : upon such nourishment as the fat, blood, flesh, parenchyma, and even brain,

can produce when melted down by the action of the absorbents. And he further conceived that, from the little wear and tear which usually takes place in old age, the flame of life might be kept burning for a considerable term by the fuel hereby supplied; the growing emaciation being a pretty correct measure of the material consumed.

How far such may have been the fact with Ruysch himself, or with any other person in the ordinary advance of life, we need not at present examine: but something very like it appears to have occurred in the extraordinary malady before us. We have seen that the digestive function was habitually impaired, and that at length food of all kinds was rejected from the stomach; and we shall find by other instances presently, that the stomach, under the influence of this disease, seems to be always, even at the best estate, capricious or fastidious.* But the lacteals seem to have participated in the same infirmity; and to have laboured under an atony or paresis so considerable, though invisible to the eye of the anatomist, as to have transmitted whatever aliment might have been subacted very imperfectly, or not at all, into the course of the circulation. And hence, while the blood actually in existence was perpetually drained off in support of the different organs and their respective functions, a small quantity only of an unelaborated fluid was able to reach the heart and larger arteries, which were, in consequence, pale and empty, or only partially supplied with a thin, watery, and scarcely tinged liquid. And, in confirmation of this idea, we shall find in the sequel of our examination, that the mesentery, in various instances, gives proof of disturbance, and appears enlarged, even to an external examination, while the hypochondria are free from such affection.

Such then seems to have been the proximate cause, though undeveloped by dissection, if we may be allowed to hazard a conjecture upon a subject involved in so much obscurity. Yet the exciting cause seems still more effectually to elude our penetration: for the constitution of the individual seems to have been strong and hearty, and every thing in his situation, occupation, and habits of life, apparently concurred in promising him a long continuance of health.

In various cases of the disease, however, that have occurred, we have some degree of insight into the occasional, as well as into the proximate cause. And I now particularly allude to the endemic appearance of this complaint at Auzain near Valenciennes, as described by Professor Halle.†

* After speaking of the effects of a scanty quantity of blood in the system, upon the nervous system, respiratory organs, &c., Andral observes, that digestion is likewise disturbed, because, after the stomach has received food, the regular performance of that important function requires that the stomach shall become the seat of sanguineous congestion, which, in persons labouring under anæmia, cannot take place.—See Anat. Pathol., tom. i., p. 82.—Ed.

† Journ. de Médecine, Chirurg. Pharm., &c. Par MM. Corvisart, Leroux, et Boyer, tom. ix., p.

At Auzain is a large coal-mine, reaching to two or three adjoining villages. It was in one of the galleries of this mine that the complaint made its appearance, and to this it was confined, though no difference had hitherto been detected between the contaminated gallery and the rest. It is of the same depth, being a hundred and twenty fathoms from the level ground, and excavated in the same manner, but is longer, and hence does not so readily admit of an efflux of pure air. Its temperature is 64° Fahrenheit: it exhales an odour of sulphuretted hydrogen gas, which renders respiration difficult. Some caustic mineral, perhaps some metallic salt, appears to be dissolved in the water that drips from the mine, as it produces blains or blisters on any part of the body to which it is applied. Yet the water has been occasionally drunk to allay thirst, and the mine had been worked for eleven years without any such complaint as that before us: and it is hence obvious, that some new combination of vapour, incapable of detection by the senses, had found vent into the atmosphere of the gallery; or some new mineral substance had become dissolved in its percolating water, which had a direct power of loosening and destroying the tone of the restorative system, at the commencement of its chain.

The symptoms, in their general features, were strikingly similar to those we have just described; and seem only to have been modified by the peculiarity of the exciting cause, being often, though by no means always, accompanied from the first with severe gripings, and more violent affection of the abdominal viscera, and hence more rapid in their progress. Dr. Combe is inclined to think from these symptoms, that this disease was not a strict idiopathic anæmia, but a modification of rhachialgia, the colic of lead or arsenic, and that it is hence more nearly allied to the *chlorosis rhachialgica* of Sauvages, than to the *anhæmia chlorosis* of Lieutaud. But in no instance do I find the back-bone ache, or spine-ache, from which rhachialgia derives its name, and by which, together with an extension of this aching over the upper and sometimes the lower extremities, with a strong tendency to paralysis, it is specifically distinguished. Neither indeed is the colicky pain itself to be regarded as a pathognomonic sign, or necessary attendant: for of the four patients who were sent for examination and treatment from Auzain to Paris, while two suffered from it, the other two were without any such symptom. Nor did the treatment usually found most serviceable in rhachialgia, prove of much, if indeed of any, benefit in the anæmia of Auzain; so that the medical superintendents, who had at first embraced this idea, found themselves obliged to abandon such a course, and the view of the disease on which it was founded, and to regard it as a direct exemplification of idiopathic anæmia.

At the time of opening their correspondence

3, Paris, An xiii.—See a translation of this in the Edin. Journ., vol. iii., p. 170.

with the School of Medicine at Paris, fifty patients, all belonging to the same gallery, had been attacked with the disorder, three of whom had died, and the number of patients was almost daily increasing, notwithstanding that the gallery was at this time shut up. Some of the sufferers had been ill for fifteen, others for twelve, others for eight months: and many were recent cases. It was obvious, however, that those were the most unfortunate subjects, and exhibited the highest degree of severity, who had been attacked while actually employed in the gallery: while those who did not complain till it was closed, passed through it, not indeed with speed, but in a more favourable way. So that the disorder seemed capable of being divided into two distinct states or varieties, an acute and a chronic.

The general symptoms under the former, independently of those of colic, were pallor of skin, great emaciation, weak, feeble, quick, contracted pulse palpitations of the heart, anhelation, extreme debility, so as to render walking difficult; bloated countenance, habitual perspiration, especially at night; stools black or greenish. These symptoms often continued without much change for many months, sometimes for upwards of a year; when they were united, manifestly from augmented weakness, with headache, frequent faintings, intolerance of light and sound.

Where colic was an accompaniment, there was much griping pain in the stomach and intestines, inflation of the abdomen, and at times, towards the close, purulent stools.

Four patients were selected out of the aggregate body to be sent to the School of Medicine at Paris for examination and advice. They were all young; their ages being from sixteen to twenty-one: one of them had worked in the mine for six years, the others for ten or eleven; and as they had all been ill for nearly a twelve-month, it is obvious that they had been attacked while labouring in the gallery; and were hence regarded as having received the complaint in its acute state.

We have already observed, that, of these four, two had experienced colicky pains from the first, and two had not been troubled with them. The pulse varied from seventy to a hundred and four strokes in a minute, but the stroke was extremely feeble and scarcely perceptible; the least excitement, moreover, would accelerate it almost beyond the power of counting.

The stomach appears to have been generally capricious; they could relish food if allowed to exercise a choice; but one of them was subject to frequent vomiting; and in all the digestion was manifestly imperfect, as the food was partially discharged with little change, intermixed with black or greenish feces. The mesentery, as we have already observed, seemed considerably enlarged to the touch, but was destitute of pain on pressure: nor did the enlargement extend to any other region.

So extreme was the weakness, that none of these patients were able to walk more than a

few steps without palpitation of the heart, and being compelled to sit down, and especially on mounting a staircase. Yet the same delusive hope, the same eparsis, or mental elation, that often accompanies consumption, and appeared, as we have already observed, in Dr. Combe's patient, was generally conspicuous in the cases before us. Even the death of one of them did not seem to destroy this enviable feeling. "We were afraid," says Professor Halle, "lest the melancholy fate of the first patient should have had an influence on the minds of his companions; but we had here no difficulty to encounter. The hope that the opening of his body would put us upon a more successful mode of treatment predominated in their minds, without taking away their regret for his loss." It is thus that we sometimes meet with a few cordial drops intermixed with the bitterest cup of suffering, and enabling the patient to support his trial, not only with composure, but with an elevated spirit.

The individual who thus fell a sacrifice, seems to have been attacked with more than ordinary severity at the very onset of the disease: and was one of those who had to contend with the pains of colic in addition to the specific symptoms. Mercurial inunction was early tried, but abandoned in a few days, from its being found to augment the pulse and increase the tendency to fever. When he reached Paris he had been ill for eleven months, having previously been employed in the mine for a period of eight years. He at length gave manifest proofs of hectic fever, the remissions of which became gradually shorter, till at length the fever assumed a continued type. But, though the skin was burning hot, it did not lose its paleness, nor was the slightest blush discernible on the tongue, the lips, or the conjunctiva: a remark which is indeed equally applicable to all the rest. He seems to have sunk under the pressure of debility alone; his most prominent symptoms at last being those of great difficulty of breathing, a feeble and intermitting pulse, and cold extremities.

The appearances on dissection were, as nearly as may be, those of Dr. Combe's patient, as we have already described them. The parenchymatous viscera were all pale, diminished, and shrivelled, with the exception of the heart, which preserved its natural size. Even the spleen, which, in the preceding case, retained its proper colour, and does not seem to have had its size much interfered with, was here of a reduced magnitude, and of the same spongy softness which the preceding case disclosed.

The almost utter bloodlessness of all the vessels, however, formed the predominant feature. "In the three cavities all the vessels, as well arteries as veins, were destitute of coloured blood, and contained only a small quantity of serous fluid. No blood was found in the aorta, as far as its crural subdivisions, nor in the accompanying veins, nor in the system of the hepatic vessels, nor in any of the sinuses of the brain. Upon making a deep incision into the

flesh of the thighs, a small quantity of liquid and black blood flowed out; but none issued from a cut in any other part whatever. The flesh of the muscles which cover the thorax was exceedingly red, but that of the extremities much less so. And we are told that the same destitution of blood which distinguished this case, occurred also in all the other dissections that were made at any time; so that the want of colour in the interior precisely corresponded with that of the surface, and of the whole capillary system. "This condition, therefore," observes M. Halle, "may be regarded as peculiarly dependant on the disease; as exhibiting itself by manifest signs during its entire progress; and as reaching its height when it is on the point of terminating, and has reached its last stage."

From the extensive spread of the malady, there was a pretty ample opportunity of putting various plans of treatment to an effective test; and the opportunity was not neglected.

Mercury, as we have already observed, did not seem to answer. Two cases recovered under its use; but, in general, it produced febrile excitement, and hence no credit was given to it even in the instances of restoration. Emetics, sudorifics, acids, sedatives, tonics, and stimulants were all tried simultaneously, or in succession. But by far the most successful, as, indeed, the most rational plan, and that most corresponding with the nature of the proximate cause we have endeavoured to illustrate, consisted in a combined employment of the two last of these classes, stimulant and tonic medicines, with a free use of opium where the tormina required it, and the employment of gentle laxatives on the return of constipation. The best stimulants appear to have been camphire and ether; the best tonics, bark and iron.* While this plan was continued the patients generally improved in strength, lost their palpitation on walking, and evinced a slight return of colour; and in every instance in which this process was discontinued at too early a period, they appear to have relapsed; and only to have renewed their advantage upon a return to the same treatment. The diet was generous and nutritious, and altogether harmonized with the pharmaceutic intention.

SPECIES III.

MARASMUS CLIMACTERICUS.

DECAY OF NATURE. CLIMACTERIC DISEASE.

GENERAL DECLINE OF BULK AND STRENGTH, WITH OCCASIONAL RENOVATION, AT THE AGE OF SENESCENCE, WITHOUT ANY MANIFEST CAUSE.

For the groundwork of this species of marasmus, I am entirely indebted to Sir Henry Hallford's elegant and perspicuous description of

* The subcarbonate, in doses of one or two drachms, three times a day. In the anæmia connected with enlarged spleen, preparations of iron are extremely beneficial. This fact is mentioned by Tomassini, in his Clinical Reports.—Ed.

it in the Medical Transactions. The disease has hitherto never appeared in any nosological arrangement, but it has characters sufficiently distinct and striking for a separate species. In several of its features, it bears a strong resemblance to the marasmus or atrophy of old age, described under the first species: but it differs essentially in the instance which it affords of a complete rally and recovery: and, if the train of reasoning about to be employed in developing its physiology proves correct it will be found to differ also in its chief seat and proximate cause.

The ordinary duration of life seems to have undergone little or no change from the Mosaic age, in which, as in the present day, it varied from threescore and ten to fourscore years. In passing through this term, however, we meet with particular epochs at which the body is peculiarly affected, and suffers a considerable alteration. These epochs the Greek physiologists contemplated as five. And, from the word climax (*κλίμαξ*), which signifies a gradation, they denominated them climacterics. They begin with the seventh year, which forms the first climacteric; and are afterward regulated by a multiplication of the figures three, seven, and nine, into each other; as, the twenty-first year being the result of three times seven; the forty-ninth, produced by seven times seven; the sixty-third, or nine times seven; and the eighty-first, or nine times nine. A more perfect scale might perhaps have been laid down; but the general principle is well founded and it is not worth while to correct it. The two last were called grand climacterics, or climacterics emphatically so denominated, as being those in which the life of man was supposed to have consummated itself; and beyond which nothing is to be accomplished but a preparation for the grave.

With the changes that occur on or about the first three of these periods we have no concern at present, and shall hence proceed to that which frequently strikes our attention as taking place about the fourth, or in the interval between the fourth and fifth. This change is of two distinct and opposite kinds, and it is necessary to notice each.

We sometimes find the system, at the period before us, exhibiting all of a sudden a very extraordinary renovation of powers. The author has seen persons who had been deaf for twenty years abruptly recover their hearing, so as in some cases to hear very acutely: he has seen others as abruptly recover their sight, and throw away their spectacles, which had been in habitual employment for as long a period; and he has seen others return to the process of dentition, and reproduce a smaller or larger number of teeth to supply vacancies progressively produced in earlier life. Under the genus ODONTIA, in the first class and first order of the present system, several of these singular facts have been already noticed, and examples given of entire sets of teeth cut at this period. That the hair should evince a similar regeneration, of which instances are also adduced in the same place,

and of which Forestus affords other examples (Lib. xxxi., obs. 6), is, perhaps, less surprising, since this has been known to grow again, and even to change its colour, after death.* But I have occasionally seen several of these singularities, and especially the renewal of the sight and hearing, or of the sight and teeth, occur simultaneously. And hence Glanville spoke correctly when he affirmed that "the restoration of gray hairs to juvenility, and renewing exhausted marrow, may be effected without a miracle."

On the other hand, instead of a renovation of powers at the period before us, we sometimes perceive as sudden and extraordinary a decline. We behold a man apparently in good health, without any perceptible cause abruptly sinking into a general decay. His strength, his spirits, his appetite, his sleep, fail equally, his flesh falls away, and his constitution appears to be breaking up. In many instances this is, perhaps, the real fact, and no human wisdom or vigilance can save him from the tomb. But, in many examples also, it is an actual disease in which medical aid and kindly attention may be of essential service, and upon an application of which we behold the powers of life, as in other diseases, rally; the general strength return; the flesh grow fuller and firmer; the complexion brighten; the muscles become, once more, broad and elastic; and the whole occasionally succeeded by some of those extraordinary renovations of lost powers, or even lost organs, to which I have just adverted.

The subject is obscure, and it is as difficult, perhaps, to account for either of these extremes—for the sudden and unexpected decline as for the sudden and singular restoration. That the decline, however, is a real malady, and not a natural or constitutional decay, is perfectly obvious from the recovery. And hence Sir Henry Hallford, in reference to the period in which it occurs, and by which, no doubt, it is influenced, has emphatically denominated it the **CLIMACTERIC DISEASE**.

Under the first species the author observed, that the great chain of the organs of nutrition extends from the chylific viscera to the assimilating secernents; that these form the ends of the chain; that a powerful sympathetic action runs through the whole: but that this action is more powerful between the one end of the chain and the other, than between any of its intermediate links. He observed farther, that, in the atrophy of old age, the failure of action seems to commence and to be chiefly seated at the chylific or chyliferous end, and that the assimilating secernents exhibit the same failure only afterward and by sympathy: that the lacteals become generally, and sometimes altogether obliterated, while the assimilating process is supported by an absorption, first of the animal oil deposited in the cellular membrane, then of this membrane itself, and, lastly, of much of the

muscular and parenchymatous structure of the general frame. In the disease before us, the reverse of all this seems to take place; and for its origin we must look to the assimilating powers constituting the other end of the chain. The patient falls away in flesh and strength before he complains of any loss of appetite, or has any dyspeptic symptoms; which only appear to take place afterward by sympathy. And that the mesentery and lacteals are not paralyzed and obliterated, as in the atrophy of old age, is incontrovertible, from the renovation of power and reproduction of bulk that form an occasional termination of the disease.

In watching carefully the symptoms of this malady when totally unconnected with any concomitant source of irritation, either mental or bodily, we shall often perceive that it creeps on so gradually and insensibly, that the patient himself is hardly aware of its commencement. "He perceives," to adopt the language of Sir Henry Hallford, "that he is tired sooner than usual, and that he is thinner than he was; but yet he has nothing material to complain of. In process of time, his appetite becomes seriously impaired; his nights are sleepless, or, if he gets sleep, he is not refreshed by it. His face becomes visibly extenuated, or perhaps acquires a bloated look. His tongue is white, and he suspects that he has fever. If he ask advice, his pulse is found quicker than it should be, and he acknowledges that he has felt pains in his head and chest, and that his legs are disposed to swell; yet there is no deficiency in the quantity of his urine, nor any other sensible failure in the action of the abdominal viscera, except that the bowels are more sluggish than they used to be."

Sometimes he feels pains shooting over different parts of the body, conceived to be rheumatic, but without the proper character of rheumatism; and sometimes the headache is accompanied with vertigo. Towards the close of the disease, when it terminates fatally, the stomach seems to lose all its powers; the frame becomes more and more emaciated; the cellular membrane in the lower limbs is laden with fluid; there is an insurmountable restlessness by day, and a total want of sleep at night; the mind grows torpid and indifferent to what formerly interested it; and the patient sinks at last; seeming rather to cease to live than to die of a mortal distemper.

Such is the ordinary course of this disorder in its simplest form, when it proves fatal, and the powers of the constitution are incapable of coping with its influence. Yet it is seldom that we can have an opportunity of observing it in the simple form, and never perhaps, but in a patient whose previous life has been entirely healthy, and whose mind is unruffled by anxiety. For if this complaint, whatever be its cause, should show itself in a person who is already a prey to grief, or care, or mental distress of any kind, or in whom some one or more of the larger and more important organs of the body, as the liver, the lungs, or the heart, has been weakened or otherwise injured by accident or irreg-

* Eph. Nat. Cur., passim. The growth of the hair after death is a manifest impossibility, unless it be assumed that vascular action, circulation, deposition, and secretion, can continue after the extinction of life.—Ed.

ularity, or is influenced by a gouty or other morbid diathesis, the symptoms will assume a mixed character, and the disease be greatly aggravated. It is these accidents, indeed, that for the most part constitute the exciting cause, as well as the most fearful auxiliary, of the disease; for, without such, it is highly probable that the predisposition might remain dormant; and that many a patient who falls a sacrifice to it, would be enabled to glide quietly through the sequestered vale of age to the remotest limit of natural life, and at length quit the scene around him without any violent struggle or protracted suffering, with a euthanasia sometimes, though rarely attained, but ardently desired by us all.

Sir Henry Halford has remarked, that the disease, according to his experience, is less common to women than to men. The author's own experience coincides with this observation. And we can be at no loss to account for the difference, when we reflect on the greater exposure of the latter than of the former, to those contingencies which so frequently become occasional causes or auxiliaries, and which, at the period now alluded to, strike more deeply and produce a much more lasting effect, than in the heyday and ebullency of life.

There are some events, however, that apply equally to both sexes, and which very frequently lead to this affection; as, for instance, the loss of a long-trying and confidential friend; of a beloved or only child; or of a wife or husband assimilated to each other in habits, disposition, general views, and sentiments, by an intercourse of perhaps thirty or forty years' standing. This last, as it has occurred to me, is a more marked and more frequent cause of excitement than any other. I have seen it in some instances operate very rapidly: and have my eye at this moment directed to the melancholy fate of a very excellent clergyman, between fifty and sixty years of age, the father of ten children, who were all dependant upon him, and whose beneficence would have enabled him, in all probability, to provide for them respectably had he lived; but who, having lost the beloved mother of his family while lying-in of her tenth living child, was never able to recover from the blow, and followed her to the grave in less than three months.

I have at other times seen the same effect produced as clearly and decidedly, though with a much tardier step, and unaccompanied with any sudden shock. I attended not long since a lady in Edgeware Road, who died of a consumption at the age of fifty-four. Her husband, though not a man of keen sensibility, had attentively nursed her through the whole of her lingering illness, and had lived happily with her from an early period of life. He was aware of her approaching end, and prepared for it: and, in a few weeks after her decease, seemed to have recovered his usual serenity. Not long afterward, however, he applied to me on his own account. I found him dispirited, and losing flesh; his appetite was diminishing, and his nights restless, with little fever, and alto-

gether without any manifest local disorder. The emaciation with its accompanying evils nevertheless increased, the general disease became confirmed, and, in about five months, he fell a sacrifice to it.

Occasionally, however, where the climacteric temperament, if I may so express myself, is lurking, a very trivial accidental excitement proves sufficient to rouse it into action. "I have known," says Sir Henry Halford, "an act of intemperance, where intemperance was not habitual, the first apparent cause of it. A fall, which did not appear of consequence at the moment, and which would not have been so at any other time, has sometimes jarred the frame into this disordered action. A marriage, contracted late in life, has also afforded the first occasion to this change."

It has in some instances followed a cutaneous eruption, of which the ensuing case will afford a very striking example, and show in the clearest colours the general want of tone, which, under this morbid influence, prevails throughout the system.

Most of my readers of this metropolis have heard of, and many of them have perhaps had the pleasure of being personally acquainted with, the late James Cobb, Esq., Secretary to the East India Company, the history of whose life, from his intimate and extensive connexion and correspondence with the most brilliant and distinguished characters of the age that have figured either in political or fashionable life, and more especially from his own fine taste and commanding talents, and his unwearied efforts to patronise merit in whatever rank it was to be found, ought not to have been withheld from the world. In November, 1816, this gentleman, then in his sixty-first year, and blessed with one of the firmest and most vigorous constitutions that I have ever known, applied to me for an erysipelatous affection of the face. It was troublesome, and for nearly a fortnight accompanied with a slight fever, and a good deal of irritation. It subsided at length, but left a degree of debility which called for a change of air, and relaxation from public duty. He made a short excursion to France, and returned much improved, but evidently not quite restored to all the strength and elasticity he formerly enjoyed. Insensibly, and without any ostensible cause, he became emaciated, walked from Russell Square to the East India House with less freedom than usual, and found his carriage a relief to him in returning home. His appetite diminished, his nights were less quiet, and his pulse a little quickened. At one time he complained of an inextinguishable thirst, and voided an unusual quantity of urine, so as to excite some apprehension of *paruria mellita*. But the urine evinced no sweetness, and both these symptoms rapidly disappeared under the medical treatment laid down for him. The general waste and debility, however, continued to increase; his natural cheerfulness began to flag occasionally, and exertion was a weariness. At this period an inflammation commenced suddenly on the left side of the nates, which

soon produced a tumour somewhat larger than a goose's egg, and suppurated very kindly. Sir Gilbert Blane and Sir Walter Farquhar were now engaged in consultation with myself, as was Dr. Hooper afterward. It was a doubtful question, what would be the result of this abscess? It might be regarded as an effort of nature to re-invigorate the system by a critical excitement; and, in this view of the case, there was reason for congratulation. But it was at the same time obvious, that if the strength of the system should not be found equal to this new source of exhaustion, and could not be stimulated to meet it, the abscess might prove highly unfavourable. The tumour was opened, and about a quarter of a pint of well-formed pus discharged: but the morbid symptoms remained without alteration, and the cavity seemed rather disposed to run into a sinus along the perinæum than to fill up. The opening was enlarged, but no advantage followed: it was evident there was too little vigour in the system to excite healthy action. The abscess was alternately stimulated with tincture of myrrh, a solution of nitrate of silver, and red precipitate; but the surface continued glassy, with a display of pale and flabby granulations, that vanished soon after they made their appearance. Mr. Cline was now united in consultation, and concurred in opinion, that the wound was of subordinate importance, and would follow the fortune of the general frame. The issue was still doubtful, for the constitution resisted pertinaciously, though upon the whole the disorder was gaining ground. Yet, even at this time, there was not a single organ we could pitch upon, with the exception of the abscess, that gave indication of the slightest structural disease. The lungs were perfectly sound and unaffected; the heart without palpitation; the mind in the fullest possession of all its powers; the head at all times free from pain or stupor, even after very large doses of opium and other narcotics: the bile was duly secreted; the urine in sufficient abundance; and the bladder capable of retaining it without inconvenience through the whole night. The pulse, however, was quick, the stomach fastidious, and the bowels irregular, sometimes costive, and at others suddenly attacked with a diarrhœa that required instant and active attention to prevent a fatal deliquium. The wound continued on a balance: there was energy enough to prevent gangrene, but too little for incarnation.

A clearer example of the disease before us cannot be wished for or conceived. Unfortunately, its progress, though retarded by the arms of medicines, was retarded alone. One of the last recommendations was a removal into the country; but Mr. Cobb was now become so debilitated and infirm that this was found a work of some difficulty, and required contrivance. His Royal Highness the Duke of Sussex, however, being kind enough to accommodate our patient with the use of his easy and convenient sofa-carriage, for as long a period as he might choose, he proceeded without

much fatigue to a house provided for him on the borders of Windsor Forest. The distance was now become too considerable for me to attend him statedly, and I visited him but once or twice afterward. He continued, however, to decline gradually, and, in about a month from the time of his going to Windsor, sunk suddenly under a return of the diarrhœa.

In the progress of this disease, medicine will generally be found to accomplish but little. The constitutional debility must be met by tonics, cordials, and a generous diet: and a scrupulous attention should be paid to such contingencies of body or mind as may form an exciting cause, or aggravate the morbid diathesis if already in a state of activity. Congestions must be removed where they exist, and every organ have room for the little play that the rigidity of advanced life allows to it: and where aperients are necessary, they should consist principally of the warm and bitter roots or resins, as rhubarb, guaiacum, and spike-aloes. In many instances the Bath water, and in a few that of Cheltenham, will be also found of collateral use; and especially where we have reason to hope that a beneficial impression has been made on the disease, and that the system is about to recover itself.

The last remark I shall beg leave to offer, I must give in the words of Sir Henry Hallford himself. If not strictly medical, it is of more than medical importance; and I have very great pleasure in seeing it put forth from so high an authority, and finding its way into a professional volume. "For the rest," says he, "the patient must minister to himself. To be able to contemplate with complacency either issue of a disorder which the great Author of our being may, in his kindness, have intended as a warning to us to prepare for a better existence, is of prodigious advantage to recovery, as well as to comfort; and the retrospect of a well-spent life is a cordial of infinitely more efficacy than all the resources of the medical art."*

SPECIES IV.

MARASMUS TABES.

DECLINE.

GENERAL LANGUOR; DEPRESSION OF STRENGTH, AND, MOSTLY, OF SPIRITS; HECTIC FEVER.

TABES is a Latin term, of doubtful origin. The lexicographers derive it from the Greek *τάχω*, "macero," varied in the Doric dialect to *τάκω*,—whence Scaliger makes a compound of *τακόβιος*, "macerans vita," "a consuming life, or life of consumption;" and supposes that such a word existed formerly, and that tabes is

* In the medical writings of Dr. Rush may be seen a paper of peculiar interest, entitled, "An account of the state of the Body and Mind in Old Age, with Observations on its Diseases and their Remedies." Many of the remarks of Dr. Rush are particularly applicable to this species of marasmus. Dr. Rush puts much stress upon circumstances connected with hereditary predisposition.—D.

a derivative from it. This is ingenious, but nothing more. *Tab-co* or *tab-es*, is most probably derived from the Hebrew *תָּבַע* (*tab*), literally "to pine away or consume;" which is the exact meaning of the Latin terms.

Tabes is sufficiently distinguished from atrophy by the presence of hectic fever; from climacteric decay, by the tendency to depressed spirits, as well as its appearing at any age; and from consumption, by the local symptoms of the latter.

Its ordinary causes are commonly supposed to be an absorption of pus into the blood, or the introduction of some poisonous substance, as quicksilver or arsenic; or a scrofulous taint; or an irritation produced by excess in libidinous indulgences; thus laying a groundwork for the four following varieties:—

<i>a</i> Purulenta.	Purulent decline.
<i>β</i> Venenata.	Decline from poison.
<i>γ</i> Strumosa.	Scrofulous decline.
<i>δ</i> Dorsalis.	Decline of intemperance.

In the FIRST OF THESE VARIETIES, the absorbed pus may be contemplated as acting the part of a foreign and irritating substance,* and as acting upon a peculiarity of constitution: but, unless the latter be present, pus will rarely, if ever, be found to produce a tabid frame: for, as already observed under hectic fever, if absorbed pus be capable, independently of idiosyncrasy, of inducing a decline in one instance, it ought to do so in every instance; yet this we know is not the case, since buboes, empyemas, and other apostemes and abscesses of large extent, have been removed by absorption, and yet no *tabes* has accompanied the process. It is said to occur more frequently where an abscess or a vomica is open; in consequence of pus becoming more acrimonious by the action of the air. But this supposition is altogether gratuitous: and where hectic fever accompanies a sore or open abscess, it is more probably from increased irritation on the edges or internal surface of the cavity, as already observed when treating on psoas abscess.

In *TABES VENENATA*, Dr. Cullen conceives that one cause of emaciation is produced by an absorption of oil from the cells of the cellular membrane into the blood, for the purpose of inviscating the acrimonious spiculæ of the poisonous substance. This, however, is mere hypothesis, without a shadow of proof; and by far the greater number of poisons that enter the blood, whether by deglutition or inhalation, act by a chymical rather than by a mechanical

power. Let them, however, act as they may, the hypothesis is not necessary to account for the emaciation; for the offensive matter with which the blood is hereby contaminated, is alone sufficient to excite and maintain the hectic; as the hectic is alone sufficient to wear away the strength and substance of the system, and produces the waste. It is a disease, as Scheffler has observed, chiefly common to miners and mineralogists (*Von der Gesundheit der Bergleute*, Chemnitz, 1770); and, next to these, is to be found, perhaps, most frequently, among the labourers in chymical laboratories.

There are other poisonous irritants which are altogether ingenerate or hereditary, that, by their perpetual stimulation, ultimately produce the same effect; as those of chronic syphilis, cancer and scurvy.

A more common cause, however, than any of these, is to be found in a state of the system which has apparently a very near relation to that of scrofula, though it is difficult precisely to identify them. The VARIETY FROM THIS CAUSE is hence frequently treated of under the head of scrofula or struma; but as it is peculiarly connected with a morbid condition of one or more of the organs of nutrition, including those of digestion and assimilation, and is uniformly accompanied with emaciation, irritation, and some degree of hectic fever, it more properly falls within the range of the genus *MARASMUS* than that of *STRUMA*, and constitutes a peculiar variety of *DECLINE*.

Of all the contaminations that lurk in the blood, and are propagable in a dormant state, that of scrofula shows itself sooner than any of the rest. It is curious, indeed, to observe the different periods of time that hereditary diatheses of a morbid kind demand for their maturity, unless quickened into development by some incidental cause. Scrofula very generally shows itself in infancy; phthisis, rarely till the age of puberty; gout, in mature life; mania, some years later; and cancer still later than mania. Scrofula runs its course first, and becomes dormant, though rarely extinct; phthisis travels through a term of fifteen or twenty years, and if it do not destroy its victim by the age of thirty-eight, generally consents to a truce, and is sometimes completely subjugated. All the rest persevere throughout the journey of life; they may indeed hide their heads for a longer or shorter interval, but they commonly continue their harassings till the close of the scene.

When the strumous taint is excited into action in infant life, it generally fixes itself upon the chylific or chyliferous glands, especially when they are in a weakly state; most commonly upon the mesentery, and to this quarter it often confines itself; inasmuch that "I have frequently," says Dr. Cullen, "found the case occurring in persons who did not show any external appearance of scrofula; but in whom the mesenteric obstruction was afterward discovered by dissection."—(*Practice of Physic*, part iii., book i., § 1606.) It is supposed by Dr. Cullen, and by most pathologists, that the emaciation is,

* Armstrong, Diss. de Tabæ Purulentâ, Edin., 1732. Pus, when absorbed into the circulation from common abscesses, is thought by Cruveilhier (*Anat. Pathol.*) to undergo some change by the action of the absorbing vessels on it, which change prevents it from having hurtful effects on the constitution; whereas, if pus be introduced directly into the circulation, without being acted upon by the absorbents, it causes capillary venous phlebitis, visceral abscesses, and severe and fatal consequences; but no disorder resembling what Dr. Good calls *tabes purulenta*.—Ed.

in this case, produced invariably by an obstruction of the conglobate or lymphatic glands of the mesentery, through which the chyle must necessarily pass to the thoracic duct. That an obstruction thus total may occur is not to be altogether disputed, because the lymph has been found stagnated in its course by such an obstruction of lymphatic glands in other parts; but I have already observed that it is an interruption of very rare occurrence (Vol. i., p. 228, Cl. I., Ord. II., *Parabysma Mesentericum*); so rare that Mr. Cruickshank affirms he never saw such a stagnation on the dissection of any mesenteric case whatever. And that scrofulous enlargement of the glands of the mesentery does not necessarily produce a total obstruction is certain, because children in whom mesenteric enlargement can be felt in the form of knots protuberating in the abdomen, have lived for a considerable number of years, sometimes ten or twelve, and have at last died of some other disease. And hence it is perhaps more frequently the hectic fever, kept up by the local irritation of the mesentery, and the scrofulous taint in the blood, that produces the emaciation in this case, than the pressure of a scrofulous infarction.

"The mesenteric decline," says Dr. Young, "is generally preceded by more or less of a headache, languor, and want of appetite. It is more immediately distinguished by acute pain in the back and loins, by fulness, and, as the disease advances, pain and tenderness of the abdomen. These symptoms are accompanied or succeeded by a chalky appearance, and want of consistency in the alvine evacuations, as if the chyle were rejected by the absorbents, and left in the form of a milky fluid in the intestines; and the functions of the liver were at the same time impaired, the natural tinge of the bile being wanting. The evacuations are also sometimes mixed with mucus and blood; and are attended by pain, irritation, and tenesmus, somewhat resembling those that occur in a true dysentery. Occasionally, also, there are symptoms of dropsy, and especially of ascites; as if the absorption of the fluid, poured into the cavity of the abdomen, were prevented by local obstacles: the absorbent glands, which are enlarged, being rendered impervious, and pressing also on the lacteals and lymphatics which enter them and pass by them." The appetite is generally good, and often ravenous; probably produced by some remote irritation acting sympathetically on the stomach: as that of the mesentery, or more likely that of the assimilating powers that constitute the opposite end of the chain of nutrient organs, and which, from their morbid excitement, produce a morbid waste, and demand a larger supply than they receive. As worms are easily generated, and multiply in the digestive organs when in a state of debility, they have often been found in a considerable number in this disease, and have sometimes been mistaken for the cause of the malady instead of the effect.—(*Chesneau*, lib. v., obs. 27.) Balme gives a case in which they were equally discharged by the mouth and anus.—(*Journ. de Méd.*, 1790, Sept.,

No. i.) In the struinous enlargements are occasionally found calcareous concretions; and similar concretions are sometimes discovered in the lacteals and the liver.—(*Histoire de l'Acad. des Sciences*, &c., 1684.) Where the irritation or inflammation is considerable, the intestinal canal is peculiarly apt to unite in the morbid action, producing, with many of the symptoms we have just noticed, hectic fever, and forming what has often been called the FEBRIS INFANTUM REMITTENS.

The decline from an intemperate indulgence in libidinous pleasures has been denominated *TABES DORSALIS*, from the weakness which it introduces into the back, or rather into the loins. It is a disease of considerable antiquity; for we find traces of it in the oldest historical records that have reached our own day; and it is particularly described by Hippocrates under the name of *ΦΘΙΣΙΣ ΝΩΤΙΑΣ* (*Περὶ τῶν ἰσχυρῶς Παθόντων*, Opp., p. 539, as also *Περὶ Νουσῶν* ii., Opp., p. 479), literally "HUMID TABES," from the frequent and involuntary secretion of a gleety matter, or rather of a dilute and imperfect seminal fluid. He explains it to be a disorder of the spinal marrow, incident to persons of a salacious disposition, or who are newly married, and have too largely indulged in conjugal pleasures. He represents the patient as complaining of a sense of fornication, or a feeling like that of ants creeping from the upper part of his body, as his head, into the spine of his back; and tells us, that when he discharges his urine or excrements, there is at the same time a copious evacuation of semen, in consequence of which he is incapable of propagating his species, or answering the purpose of marriage. He is generally short-breathed and weak, especially after exercise; he is sensible of a weight in his head, his memory is inconstant, and he is affected with a failure of sight, and a ringing in his ears. Though without fever at first, he at length becomes severely feverish, and dies of that variety of remittent which the Greeks called *leipyrria*, a sort of caustus or ardent fever, attended with great coldness of the extremities, but with a burning fire and intolerable heat within, an insupportable anxiety and unconquerable dryness of the tongue. This description is fully confirmed by Professor Frank in his history of the miserable condition of two young men who had induced the same disease by a habit of self-pollution, one of whom, together with extreme emaciation, suffered excruciating pains in every limb from head to foot, was incapable of standing, and subject to epileptic fits; while the other, after a long career of acute suffering in various ways, was at length seized with a hemiplegia.—(*De Cur. Hom. Morb. Epit.*, tom. v., p. 259.)

From this sketch it is obvious that the disease is one of great danger, though it is occasionally combated with success. In the *Hôpital des Enfants Malades* at Paris, the fatal cases are calculated by M. Guersent, one of the physicians to the establishment, at from five to six in every hundred of boys, and from seven to eight in every hundred of girls, whose names enter in the tables of mortality.—(*Dict. de Méd.*,

art. CARREAU.) Upon the treatment, we shall offer a few remarks towards the close of the species.

Dr. Cullen does not think that the quantity of seminal fluid discharged by undue indulgence can ever be so considerable as to account for this general deficiency of fluids in the body, and the debility that accompanies it, and adds, that we must therefore seek for another explanation of these evils. "And whether," says he, "the effects of this evacuation may be accounted for either from the quality of the fluid evacuated, or from the singularly enervating pleasure attending the evacuation, or from the evacuation's taking off the tension of parts, the tension of which has a singular power in supporting the tension and vigour of the whole body, I cannot positively determine; but I apprehend that upon one or other of these suppositions, the emaciation attending the *tabes dorsalis* must be accounted for."—(*Pract. of Physic.*, part iii., b. i., § 690.)

It is not difficult to trace this result in a less doubtful and more direct way. The sexual organs, both in males and females, have a close and striking sympathy with the brain. Morbid salacity is no uncommon cause of madness, as we shall have occasion to observe hereafter. Irritation of the uterus shortly after childbirth, is a still more frequent cause of the same mental affection. The testes are not capable of secreting their proper fluid till the sensorial organ has acquired, or is on the point of acquiring, maturity, so that both become perfect nearly at the same time; the mere apprehension of failure, when in the act of embracing, has at once, in a variety of instances, unnerved the orgasm, and prevented the seminal flow so effectually, that the unhappy individual has often required many weeks, or even months, before he could recover a sufficient confidence to render the operation complete; while, as Dr. Cullen has correctly observed, the evacuation itself, even when conducted naturally, produces a pleasure of a singularly enervating kind. It is in truth a shock that thrills through all the senses; and hence, in persons of an epileptic temperament, has been known, as we shall have occasion to observe more fully hereafter, to bring on a paroxysm while in the act of interunion.

It is hence easy to see, that an immoderate excitement of the generic organs, and secretion of seminal fluid, must weaken the sensorial powers even at their fountain; and consequently that the nervous and muscular fibres throughout the entire frame, and even the mind itself, must be influenced by the debility of the sensorium. This we might suppose if there were no chronic flux from the seminal vessels. But when we consider the effect often produced on the general frame by the discharge, or rather the irritation, of a single blister; or, which is perhaps more to the purpose, of a small seton or issue, we can be at no loss to account for all the evils that haunt the worn-out debauchee, and especially the self-abuser, from involuntary emissions of a seminal fluid, however dilute and spiritless, in connexion with the dreadful debil-

ity we have just noticed, and which is the cause of this emission. The nervous irritation which results from this debility, is the source of the hectic by which the miserable victim is devoured; and hence the heavy terrors and insupportable anxiety, corporeal as well as mental, the sense of formication and other phantasms, the flaccidity of the back and loins, the withering of the entire body, the constant desire of erection, with an utter inability of accomplishing it, which haunt him by day and by night, and throw him into a state of despondency. A fearful picture, which cannot be too often before the eyes of a young man in this licentious metropolis, in order to deter him from plunging into evils to which he is so often exposed.*

Even where sexual inability has not taken place, the system, by an habitual excess of libidinous indulgence, is not unfrequently roused and kept up to such a state of excitement as to produce hectic fever and great debility, or other derangement of the spinal cord. Of this we shall hereafter have to give a most appalling example (when treating of paraplegia) in a young debauchee, who, at the age of forty-five fell a sacrifice chiefly to this enervating propensity, after refusing to take the warning that a constitution naturally feeble and rachetic was well calculated to offer; but which might, by care and prudent nursing, have held out to the ordinary term of old age. The upper limbs were, for years before his death, motionless and rigid; and the spinal marrow, through a considerable portion of its length, was found disorganized and liquescent.

Much of the medical treatment it may be proper to pursue, has been anticipated in several of the preceding species.

The first variety, in which the decline is dependant on the stimulus of an abscess or sore, or the introduction of pus into the circulation, can only be cured by a cure of the local affection. The strength may in the meanwhile be supported by a course of inirritant tonics, as cinchona and the mineral acids, nutritious diet, gentle exercise, and pure air. And, if stimulants be at any time employed with a view of acting more directly on the morbid irritation, and changing its nature, they should be limited to the milder resins, as myrrh, or the milder terebinthines, as camphire, and balsam of copayva.

In decline from the inhalation of metallic or other deleterious vapours, if Dr. Cullen's hypothesis were established, that the emaciation is the mere result of the *vis medicatrix naturæ*, and produced by an absorption of oil from the cellular membrane for the purpose of sheathing the minute goads of the poison, it would be our duty to follow up this indication, and employ inviscating demulcents, both oils and mucilages. But this practice has rarely been productive of any success; and we have much more reason

* Lewis's Essay upon the *Tabes Dorsalis*, Lond., 1758. Brendal, *Diss. de Tab. Dorsali*, Goett., 1748. Swediaur, vol. i., p. 251. *Spermocrasia Asthenica*.

to expect benefit from a use of the alkalis, which, by uniting with the metallic salts, if they still exist in the circulation, may disengage their acid principle, reduce the metallic base to a harmless regulus, and, by the new combination hereby produced, form a cooling, perhaps a sedative neutral. The first step, however, is to remove the patient from the deleterious scene to an atmosphere of fresh air, then to purify the blood, whether we employ the alkalis or not, with alterant diluents, as the decoction of sarsaparilla, and afterward to have recourse to bitters, astringents, and the chalybeate mineral waters.

In strumous decline, the mode of treatment should run precisely parallel with that for most of the species of PARABYSMA, or VISCERAL TURGESENCE, already laid down under their respective heads, and particularly with that for mesenteric parabysma, to which the reader may turn.

In the treatment of *tabes dorsalis*, or decline from intemperate indulgence, our attention must be directed to the mind as well as to the body: for it is a mixed complaint, and each suffers equally. A summer's excursion with a cheerful and steady friend, into some untried and picturesque country, where the beauty and novelty of the surrounding scenery may by degrees attract the eye, and afford food for conversation, will be the most effectual step to be pursued if the symptoms be not very severe. The hours should be regular, with early rising in the morning; the diet light, nutritive, and invigorating, and a little wine may be allowed after dinner; since it will almost always be found that the patient has too freely indulged in wine formerly; and he must be let down to the proper point of abstinence by degrees.* The metallic tonics will commonly be found of more use than the vegetable, with the exception of iron, which is generally too heating: though the chalybeate waters may be drunk, if sufficiently combined with neutral salts. The local cold bath of a bidet should be used from the first, and afterward bathing in the open sea.

If the disease have made such an inroad on the constitution that travelling cannot be accomplished; if the mind be overwhelmed, the back perpetually harassed with pain and feebleness, and the nights sleepless with hectic sweats and a frequent involuntary discharge, two grains of opium, or more if needful, should be taken constantly on going to bed; diluted acids, vegetable or mineral, should form the usual beverage, and a caustic be applied to the loins on each side. Hippocrates recommends the actual cautery, and that it should descend on each side of the back, from the neck to the sacrum. Savin bougies have been prescribed by some writers as a topical stimulus; but a bidet of cold water is preferable; with injections of zinc or copper, at first not rendered very astringent, but gradually increased in power.

* See Wichmann, *De Pollutione Diurna*, frequentiori, sed rarius observatâ, Tabescentiæ causâ, Goett., 1782.

SPECIES V.

MARASMUS PHTHISIS.

CONSUMPTION.

COUGH: PAIN OR UNEASINESS IN THE CHEST, CHIEFLY ON DECUMBITURE: HECTIC FEVER: DELUSIVE HOPE OF RECOVERY.

CONSUMPTION, or PHTHISIS, as it is sometimes called by old medical writers, is by Dr. Cullen contemplated as nothing more than a sequel of hæmoptysis, instead of being regarded as an idiopathic affection; and his species, which are two, can only be viewed, and so appear to have been by Dr. Cullen himself, as separate stages in the progress of the complaint; his first species being denominated *phthisis incipiens*, and characterized by an absence of purulent expectoration; and his second *phthisis confirmata*, distinguished by the presence of this last symptom.

This, however, is a very unsatisfactory as well as a very unscientific view of the subject, and evidently betrays the trammels of Dr. Cullen's classification; since he seems only to have placed the disease in this position because he could find no other to receive it: for he admits, in his First Lines, that "phthisis arises also from other causes besides hæmoptysis."—(Part i., book iv., ch. i., sect. 852.) No man of experience can doubt that phthisis occurs, or at least commences, more frequently without hæmorrhage from the lungs than with it, and consequently that hæmoptysis ought much rather to be regarded as a symptom or sequel of phthisis, than phthisis of hæmoptysis.

"Hæmoptysis," observes Dr. Young, in a work that has the rare advantage of combining great research and learning, comprehensive judgment, and a study of the present disease in his own person, "is usually enumerated among the exciting, or even among the more remote causes of consumption; but, in a healthy constitution, hæmoptysis is not materially formidable; and it is conjectured that, when it appears to produce consumption, it has itself been occasioned by an incipient obstruction of a different kind."—(*Treatise on Consumptive Diseases*, p. 45.) So that, on a concurrence of the two, we may commonly adopt the opinion of Desault, and call it an hæmoptysis from consumption, rather than a consumption from hæmoptysis.—(*Sur les Mal. Vén., la Rage, Phthisie*, &c., Bord., 1733.)

Of the three varieties we are about to describe, we shall find hæmoptysis a frequent cause of the second, but rarely of either of the others. These varieties I have taken from Dr. Duncan's valuable "Observations" on consumption: they are evidently drawn from a close and practical attention to the disease, and are as follow:—

- α Catarrhalis. Catarrhal consumption.
- β Apostematosa. Apostematous consumption.
- γ Tubercularis. Tubercular consumption.*

* The editor prefers considering no case as true phthisis that is not accompanied with tubercles. If once this criterion be deviated from, the pathologist is obliged to confound diseases which have not the slightest analogy to one another. Chronic

In the FIRST VARIETY the cough is frequent and violent, with a copious excretion of a thin, offensive, purulent mucus, rarely mixed with blood; generally soreness in the chest, and transitory pains shifting from side to side. It is chiefly produced by catching cold, or the neglect of a common catarrh.*

In the APOSTEMATOUS VARIETY the cough returns in fits, but is dry: there is a fixed, obtuse, circumscribed pain in the chest, sometimes pulsatory; with a strikingly difficult decumbiture on one side; the dry cough at length terminates in a sudden and copious discharge of purulent matter, occasionally threatening suffocation; the other symptoms being temporarily, in a few rare instances, perhaps, permanently relieved.

In the TUBERCULAR VARIETY the cough is short and tickling; and there is an excretion of the watery whey-like sanies, sometimes tinged with blood; the pain in the chest is slight; and there is mostly an habitual elevation of spirits. Usually the result of a scrofulous diathesis.

In Dr. Duncan's observations, consumption or phthisis is introduced as a genus, and consequently the varieties now offered are reckoned as so many species; yet as the tubercular may run into the apostematous variety, and the catarrhal into both, according to the peculiarity of the constitution and other concurrent circumstances, and more especially as a common cause may produce all of them in different idiosyncrasies, the present subdivision will perhaps be found the most correct.

Dr. Wilson Philip has formed another variety (with him species) of consumption, to which he has given the name of *Dyspeptic Phthisis*, and which he supposes to be produced by a previously diseased state of the digestive organs, in which the lungs ultimately participate. "Drunkards," says he, "at that time of life which disposes to phthisis, frequently fall a sacrifice to this form of the disease; and those who have been long subject to severe attacks of dyspepsy, and what are called bilious complaints, are liable to it. What is the nature of the relation observed between the affection of the lungs and that of the digestive organs, in this species of phthisis? Is the one a consequence of the other, or are they simultaneous

catarrh may partially resemble phthisis in symptoms; but its nature is totally different, and this, notwithstanding it may sometimes even lead to the production of tubercles, or real consumption, where the constitution is so disposed. As for apostematous consumption, it is only a particular stage of the tubercular. With respect to the species described by Bayle, under the name of *granular, ulcerous, calculous, cancerous*, and *with melanosis*, Laennec observes, that the first is a mere variety of the tubercular; the third is a partial gangrene of the lungs; and the three others are affections which have nothing in common with tubercular phthisis, except that they have their seat in the same organ.—See Laennec on Diseases of the Chest, &c., 2d edit., p. 272, tr. by Forbes.—Ed.

* Broussais's History of Chronic Phlegmasiæ, or Inflammations, translated from the French by Drs. Hays & Griffith, vol. i., Philad., 1832.

affections, arising from a common cause! They are not simultaneous affections, for the one always precedes the other. In by far the majority of cases in which both the lungs and digestive organs are affected, the affection of the digestive organs precedes that of the lungs. In some instances, we find the affection of the lungs the primary disease; but, in these, the case does not assume the form above described, but that of simple phthisis; and the hepatic affection, which is always the most prominent feature of this derangement in the digestive organs, does not show itself till a late period of the disease, and then little, if at all, influences the essential symptoms."—(Trans. of Medico-Chirurg. Soc., vol. vii., p. 499.)

These remarks show clearly that dyspeptic phthisis is a sequel of a prior disorder, rather than an idiopathic affection; and, as such, needs not be pursued further in describing the present species. If it outlast the primary malady, or this disease, as is sometimes the case, is converted into it, the digestive organs recovering health, and the lungs appearing to concentrate the morbid action in themselves, it is then reduced to a case of simple or idiopathic phthisis of the one or the other of the varieties now offered.

It would, however, be tedious, and of no practical use, to notice the different ramifications into which consumption has been followed up by many pathologists. Among modern writers more especially, it has been very unnecessarily subdivided: thus Bayle gives us six species, derived from supposed organic causes (*Recherches sur la Phthisie Pulmonaire*, Paris, 1810), of most of which we can know nothing till the death of the patient; Portal fourteen (*Obs. sur la Nat. et le Traite. de la Phthisie Pulm.*, 2 tom., 8vo., Paris, 1809), the first two of which, the scrofulous and plethoric, are peculiarly entitled to attention, while the rest are drawn from other diseases with which it is often complicated, or of which it is a sequel. In Morton and Sauvages, the divisions and subdivisions are almost innumerable. The Greek pathologists are not chargeable with the same error; for in general they treat of the disease under two branches alone, phthisis and phthoe: the first importing abscess of the lungs, or the apostematous variety of the present classification; and the second, ulceration of the lungs, embracing perhaps the greater part of the other two. The terms are those of Hippocrates, and they are thus interpreted by Aretæus.—(*Morb. Chron.*, i., 10.)

Of the varieties here noticed, by far the most frequent is the TUBERCULAR; concerning which it is necessary to offer an explanation, as the term TUBERCLE has been used in very different senses by different writers, and as the morbid change it imports has been derived from very different sources.

The term, considered etymologically, is a diminutive of *tuber*, a bump or knot of any kind; in the present work *PHYMA*; and has hence been conveniently applied to minute prominences generally: though, when accompanied with in-

inflammation, they are usually called *papulae* or pimples, and when filled with a limpid fluid, vesicles: and if the vesicles, or rather the vesicular cysts, be supposed to possess an independent or animalcular life, hydatids.

There is not an organ of the body but is capable, as well in its substance as its parenchyma, of producing tubercles* of some kind or other; and occasionally of almost every kind at the same time; for Bonet, Boerhaave, and De Haen, as well as innumerable writers in our own day, have given striking examples of clusters of cystic tubers, or enlarged tubercles, of every diversity of size, existing both in the abdomen and in the thorax, formed in the interior of their respective viscera, or issuing from the surface of their serous membranes, some of which are filled with a limpid fluid, others with a gelatinous, a mucous, or a puriform, and others again with a cheesy, pulpy, or steatomatous mass.

It is not improbable, that even a certain degree of inflammation itself is often favourable to the growth and general spread of tubercles. In their origin they seem to be single cysts, or often perhaps single follicles, but as they enlarge, the interior is at times divided by reticulations of vessels, or membranous bands, or distinct

cells, thus exhibiting almost every variety of the animal structure; while the external tunic usually becomes stouter, sometimes duplicate, and at times cartilaginous.†

ered by Professor Carswell as quite an accidental circumstance. The tubercle assumes the form of a shut or open globular sac, if confined to the secreting surface, and of a solid globular tumour of various sizes, if it fills completely the cavity of the air-cells; and, for similar reasons, it presents in the bronchi a tubular or cylindrical form, having a ramiform distribution, terminated by a cauliflower arrangement of the air-cells. In the mucous follicles, its shape is similar to that which it receives from the air-cells. The granular arrangement of tuberculous matter in the lungs, is ascribed by Dr. Carswell to its accumulation in contiguous cells; and the lobular character, to its being confined to the air-cells of a single lobule.—(See illustrations of the Elementary Forms of Disease, fasc. i.) Their derivation from obstructed follicles and inflammation, is a doctrine which Andral, as well as Laennec, rejects, as a general proposition, which, indeed, in relation to inflammation as a cause, it is right to say, the words of Dr. Good would by no means countenance. The sequel of the text will show that, on this point, he inclined to the opinion of Bichat. In the text, however, cysts of nearly every kind, simple and complicated, with fluid, fatty, or fleshy contents, and contents of various other sorts, are all comprised under the term: a view not adopted at the present time, when so much light has been thrown upon the subject by the researches of MM. Lombard, Laennec, Andral, Armstrong, Cruveilhier, Carswell, and other distinguished cultivators of morbid anatomy. Although a tubercle assumes different appearances in its different stages, its transformations are less numerous than Dr. Baron and M. Dupuy (*Traité de l'Affectation Tuberculeuse*, 8vo., 1817) imply in the hypothesis which they maintain, that a tubercle is at first a transparent vesicle, or hydatid. The following is Dr. Carswell's definition of tubercle, or rather of the tuberculous matter, which constitutes the essential anatomical character of those diseases to which the term tubercular is now exclusively restricted. Tuberculous matter, says he, is a pale yellow, or yellowish-gray, opaque, unorganized substance, the form, consistence, and composition of which vary with the nature of the part in which it is formed, and the period at which it is examined. He describes it as an unorganized secretion, or as a cheesy-looking material without any trace of organization. When the process of softening takes place in tubercular matter, it is clear, as Dr. Carswell observes, that the change cannot originate in the inorganic substance itself. "After having become firm, it may be converted into a granular-looking pulp, or pale grumous fluid of various colours, from the admixture of serosity, pus, blood, &c., which have been effused or secreted by the tissues subject to its irritating influence. The pus and serosity pervade the substance of the tuberculous matter, loosen and detach it. These changes are further promoted by atrophy, ulceration, or mortification of the surrounding or enclosed tissues, the bloodvessels of which have been compressed or obliterated by the tuberculous matter." Dr. Carswell considers the doctrine, that the softening of tubercles always begins in their centre, as extremely incorrect. According to his researches, when tuberculous matter is formed in the lungs, it is generally contained in the air-cells and bronchi. "If, therefore, this morbid product is confined to the surface of either, or has accumulated to such a degree as to

* In whatever organ the formation of tuberculous matter takes place, "the mucous system, if constituting a part of that organ, is, in general, either the exclusive seat of this morbid product, or is far more extensively affected with it than any of the other systems or tissues of the same organ."—(See Carswell's *Illustrations of the Elementary Forms of Disease*, fasc. i.) In the lungs he exhibits the tuberculous matter formed on the secreting surface, and collected within the air-cells and bronchi; in the intestines, within the isolated and aggregated follicles; in the liver, within the biliary ducts and their extremities; in the kidneys, within the infundibula, pelvis, and ureters: in the uterus, within the cavity of that organ and Fallopian tubes; and, in the testicle, within the tubuli seminiferi, epididymis, and vas deferens. The formation and subsequent diffusion of tuberculous matter are also described, by Dr. Carswell, as taking place likewise on the secreting surface of serous membranes, particularly the pleura and peritoneum, and in the numerous minute cavities of the cellular tissue. The accumulation of it in the lacteals and lymphatics, both before and after they unite to form their respective glands, he finds to be often very considerable. Dr. Carswell has also given representations of tuberculous matter in the substance of the brain and cerebellum, in accidental cellular tissue, and in the blood; and adverts to its occasional formation in accidental products.—Ed.

† Some of the opinions here delivered are not universally admitted; the productions to which several pathologists now restrict the name of tubercle, being, in fact, less diversified than those described in the text. Thus Andral defines those of the lungs to be of a pale yellow colour, mostly of a globular form, and of infinitely various sizes; at their commencement firm, but brittle; afterward softening; and, in a later stage, changing into a substance which is not homogeneous, but consists of whitish friable masses, suspended in a sero-purulent fluid.—(*Anat. Pathol.*, tom. i., p. 408.) The round form of the tubercular substance is consid-

In many cases the cysts or niduses of tubercles possess so little energy of action,* as never to exceed the size of small shot, or to consist of more than an insipid fluid, rendered glairy or caseous by an absorption of the finer particles of the material effused or secreted;† but which, by being united with a few corpuscles of red blood, or of carbonaceous matter, become not unfrequently of a black or chocolate hue, the melanosis of Bayle, but not that of Breschet and Laennec; and which, by other unions or other changes, produced, perhaps, by the anomalous operation of the still inherent principle of life, furnish us with all those appearances which dissections bring to light on the surface or in the substance of the lungs, or whatever other organ may chance to be affected.

Many writers conceive that, for the growth of tubercles, it is absolutely necessary that inflammation should take place, and that the whole of the new matter must be supplied from the sanguiferous system immediately: a doctrine rather upheld by Mr. Hunter's followers than by himself, and directly opposed, as Bichat has justly observed (*Anat. Gén.*, tom. iv., p. 517), by the absence of all the signs of inflammation in by far the greater number of passing cases, at least till the morbid growth has fully established itself, and operates by mechanical pressure or some other excitement. While other physiolo-

gists have limited such morbid growths to the operation of the absorbent system, or to minute bladders containing a limpid fluid which they have called hydatids; the term being sometimes employed as a mere synonyme of bladders or turgid vesicles of serum, in the language of Boerhaave, "hydatids, sive vesiculæ sero turgentes" (*Epist. Anat. ad Fred. Ruysch*, p. 82); and at other times importing a parasitic animalcule forming a subdivision under the genus *tænia* of Linnæus, and of which we have already spoken under turgescence of the liver.—(Vol. I., Cl. I., Ord. III., Gen. IV., Spe. 1.)

leave only a limited central portion of their cavities unoccupied, it is obvious that, when they are divided transversely, the following appearances will be observed—1. A bronchial tube will resemble a tubercle having a central depression, or soft central point, on account of the centre of the tube not being, or never having been occupied by tuberculous matter, and of its containing a small quantity of mucus or other secreted fluids. 2. The air-cells will exhibit a number of similar appearances, or rings of tuberculous matter grouped together, and containing in their centre a quantity of similar fluids. When the bronchi or air-cells are completely filled, the tuberculous matter presents no such appearances."—(Professor Carswell's *Illustrations of the Elementary Forms of Disease*, fasc. i.) Softening, he says, most frequently begins at the circumference of firm tuberculous matter, where its presence, as a foreign body, is most felt by the surrounding tissues.—Ed.

* In the lungs, the idea of encysted tubercle appears to Dr. Carswell erroneous, the distended walls of the air-cells being commonly mistaken for cysts. He admits, however, that tuberculous matter is sometimes encysted, but not until it has undergone changes preparatory to its ultimate removal from the organ in which it is formed.—Ed.

† The common pulmonary tubercle is most indurated in its early stages, and the change which it afterward undergoes is a softening or dissolution, which Andral refers to the effect of the pus secreted around it. An increased hardness of the tubercular matter, after its first secretion, has not yet been proved, with the exception of a few instances, in which a large proportion of phosphate and carbonate of lime is deposited in the substance of the tubercles. According to M. Andral, this happens chiefly in cases where these bodies have for a long time ceased to have any serious effect upon the constitution. In this respect, the earthy transformation is quite the converse of the process by which a tubercle is softened.—Ed.

VOL. II.—C.

[With regard to the important question, whether tubercles of the lungs are the product of inflammation, the subject is one concerning which some of the greatest men in the profession are yet divided. "If," says Laennec, "we question any practitioner, ignorant of morbid anatomy, but who is a man of observation and free from prejudices, he will give it as his opinion, that the symptoms of phthisis very rarely supervene to acute pneumonia. Even in the cases where this sequence is observed, it is impossible to say whether the pneumonia has given rise to the tubercles, or whether these, acting as irritating bodies, have not excited the pneumonia." The latter view was adopted by a late eminent physician of this country; for, he distinctly observes, that the number and the increase of the size of tubercles frequently create irritation in their vicinity, so that a consequent inflammation of the surrounding texture is not an uncommon circumstance.—(*Armstrong's Morbid Anat. of the Bowels*, &c., p. 16, Lond., 1828, 4to.) The solution of the question by a reference to pathological anatomy, Laennec deems far more simple, since it is certain, that we very rarely find tubercles in the lungs of those who die of pneumonia, and that the greater number of consumptive subjects exhibit no symptom of this disease during the progress of their fatal malady, nor any trace of it after death. Many of these have even never been affected with it during the whole course of their lives. If tubercles were merely a product of acute peripneumony, we should be able to ascertain the different steps of the transition of the one into the other, which is not the case. It is said that chymical analysis discovers no difference between the softened matter of tubercles and true pus: * in

* As already observed, the softening of tubercles is ascribed by Laennec, Andral, and Carswell, to the effect of suppuration around them; in other words, the tubercular matter dissolves in the pus. If this explanation be correct, though disagreeing with the admission of Andral, that the softening of tubercles often begins in their centre, it is not surprising that the analysis of suppurated tubercles should resemble that of purulent matter. But the analysis of a solid tubercle is different, being, according to M. Thénard, animal matter, 98.15; muriate of soda, phosphate of lime, carbonate of lime, 1.85; with some traces of oxyde of iron. There are tubercles, however, the analysis of which is still more different from that of pus; viz., those which contain a very large proportion of phosphate and carbonate of lime, and which are generally such as have existed a long while, with-

like manner, Laennec replies, it discovers none between the albumen of the egg and the secretion of certain cancers. These facts only prove the imperfection of chymistry, and not the identity of the matters in question. In almost all their physical characters, tubercles differ from pus. After the complete evacuation of a softened tubercle, its contents are never renewed; while the sides of an abscess, after it is opened, are well known to continue to secrete pus. Laennec admits that acute pneumonia and tubercles occasionally coexist; but the complication is rare, when the great frequency of both diseases is taken into consideration. In nineteen twentieths of the cases of this complication, the tubercular affection evidently precedes the other; and we may therefore infer, either that the tubercles are the occasion of pneumonia, or that the diseases, although co-existing, have no etiological relation to each other. Laennec concedes, however, as a matter of no evil consequence in practice, and of no importance in theory (although he thinks it supported neither by direct experiment nor positive observation), that in the small number of cases where phthisis is seen to arise during the convalescence from acute peripneumony, the inflammation may sometimes accelerate the development of tubercles, to which the patient was disposed from some other cause, of the nature of which we are ignorant, but which is assuredly different from inflammation.—(Op. cit., p. 291.) According to M. Andral, if the disposition to tubercles be very strong, the slightest local congestion of blood will give rise to them; wherever such congestion takes place, the same product appears, or the tubercular diathesis is produced. If this disposition be less strong, it is requisite for the formation of a tubercle, that the congestion of blood should be so considerable and permanent, as to amount to inflammation. But, when there exists no such predisposition, the most intense and the longest inflammation will not produce a tubercle.—(Andral, *Clinique Méd.*, tom. iii., p. 13.)

The latter admission is virtually an acknowledgment, that the formation of tubercles depends essentially upon a peculiar diathesis. Against the idea of tubercles being simply the

out any serious effect on the system. They consist of animal matter, 3; saline matter, 96. These are the only kind of pulmonary tubercles which can be said to become more indurated with time. Professor Carswell observes, that the chymical composition of tuberculous matter varies not only at the different periods at which it is examined, but in different animals, and probably in different organs. In man, he says, it is chiefly composed of albumen, with various proportions of gelatin and fibrin. The most important fact relating to this part of the subject is, "that either from the nature of its constituent parts, the mode in which they are combined, or the condition in which they are placed, they are not susceptible of organization, and consequently give rise to a morbid compound, capable of undergoing no change that is not induced in it by the influence of external agents."—See Professor Carswell's *Illustrations of the Elementary Forms of Disease*, fasc. i.—Ed.

effect of inflammation, Dr. Armstrong instances the following fact: in many cases, where tubercular points are scattered over the pleura or peritoneum, the serous membrane is transparent up to these points, and only becomes reddened or opaque when the tumour has enlarged so as to produce local irritation. The tubercle, he admits, is probably connected with effusion of fibrin, but, according to his observations, such effusion is not necessarily connected with inflammation.—(Armstrong's *Morbid Anatomy of the Bowels*, &c., p. 17, 4to., Lond., 1828.)*

The ancients ascribed to inflammation all kinds of scirrhi, tumours, and tubercles. In the course of the eighteenth century, this doctrine encountered opposition; but it was not till M. Bayle directed his powerful mind to the subject, that many positive facts were collected in formidable array against the hypothesis. On the other hand, the celebrated Broussais (*Exam. des Doctr. Méd.*, 1816) has continued to be an active defender of the ancient opinion; and, as far as tubercles of the lungs are concerned, he can still boast of distinguished partisans, among whom he is sufficient to mention the name of Alison. The cases which this gentleman has seen, and which seemed to him to furnish the best evidence on this point, have occurred, he says, in young children. From them he has been led to think, that when the constitutional tendency to them prevails, tubercles may form in very different circumstances, and probably with various rapidity. He has little doubt, that they do often form without being preceded by inflammation of such a character as to be detected by symptoms during life; and that, in the lungs at least, the inflammation, of which the undeniable marks are so often found along with them after death, has really often been posterior to them in date. But he has also been led to believe that it is not merely, as Laennec states, a possibility, but a real and frequent occurrence, that inflammation, acute or chronic (to which he would add febrile action), however produced, becomes, in certain constitutions, the occasion of the development of tubercles.—(Edin. Med. Chir. Trans., vol. i., p. 407.)

The cases which seem to Dr. Alison to confirm the doctrine, that tubercles sometimes form in consequence of inflammation, he arranges under two heads:—

1. The first consists of cases in which the tubercles did not cause death, and were found on dissection in an incipient state, but so imme-

* A late American writer, Dr. Morton, adduces much able reasoning to prove, "1st. That tubercles are an altered secretion of the albuminous halitus, proper to the cellular tissue forming the parenchyma of organs. 2d. That inflammation is not necessary to their development. 3d. That the cellular tissue which envelops and intersects tubercles, sooner or later takes on inflammation and secretes pus, by which process the tubercular matter is eliminated and an abscess is formed."—See *Illustrations of Pulmonary Consumption*, its anatomical characters, causes, symptoms, and treatment, with 12 plates, drawn and coloured from nature; by Samuel George Morton, M. D., Philadelphia, 1834.—D.

diately succeeding to the symptom, and so closely connected with, or even passing by insensible degrees into, the undeniable effects of inflammation, that it was impossible to suppose their formation independent of it.

2. The second consists of examples in which children, previously in good health, or at least unaffected with any pulmonary complaint, have been seized with well-marked inflammatory symptoms, generally from a known cause, certainly adequate to that effect. These symptoms have lasted some time, and been manifestly dangerous to life,—have subsided very imperfectly,—the children have passed into the state of phthisis, and died within a few months; and, on dissection, tubercles have been found in various stages of progress, but with little or no other appearance which could be considered either as the effect of the inflammation known to have existed, or as the cause of death.

In a paper of later date,* Dr. Alison strength-

* Edin. Med. Chir. Trans., vol. iii., p. 274. The expression, "in certain constitutions," employed by Dr. Alison, is an important limit to the doctrine. With this understanding, there is no material difference between his views and those of Laennec and Andral. The latter pathologist distinctly affirms, that irritation alone will not necessarily give rise to tubercles, which are frequently formed without any irritation that can be perceived. Without the concurrence of other causes, mere irritation will not account for their production.—(Anat. Pathol., tom. i., p. 438.) Like many other writers, he ascribes much to peculiarity of constitution. Tubercles, he says, are particularly apt to form in individuals whose skin is very white, and, as it were, shrivelled, without any traces of colouring matter in its capillary network; and whose cheeks exhibit a red patch, making a singular contrast to the dead white of the rest of the face. The colouring matter is also deficient in the eyes, which retain the blue colour of infancy; and the hair is of a light hue, and its quantity small. The muscles are slender and flabby, with little strength of contraction. The blood is serous, and poor in fibrin and colouring matter; and the mucous secretions predominate. In persons of this diathesis, sanguineous congestions readily take place in the skin and mucous membranes; and, when once produced, do not terminate, but continue in a chronic form, and are frequently followed by ulcerations, and various disorganizations very difficult of cure, and often needing remedies of an opposite nature to such as are termed antiphlogistic. These individuals seem to retain in adult age several traits which appertain to infancy, considered both in its healthy and diseased state; and the development of their organization is impeded. This kind of constitution may be formed without the influence of any manifest external cause. In other instances it appears to be acquired: a residence in an impure air, or such as is not renewed often enough; the crowding of many persons together; absence of the sun's rays; an habitually damp atmosphere; food of a quality inadequate to repair the strength of the system; and various excesses, which exhaust the strength and nervous influence, and injure nutrition, are enumerated by Andral as so many causes which, at the same time that they render the blood so poor as to account for the state of the skin and muscles externally, give a chronic character to every inflammatory complaint, and a

ens, by additional facts and observations, the proposition that, in certain constitutions, inflammation, acute or chronic, but most generally chronic, does frequently and directly lead to the deposition of tubercles.

The first fact to which he adverts is, that tubercles are very seldom found in the bodies of children who are stillborn, or die very shortly after birth.—(Denis, *Recherches d'Anat. et de Physiologie Pathologiques sur plusieurs Maladies des Enfants nouveau-nés.*) Velpeau and Breschet had frequently sought for tubercles in the fœtus, but could never find them; and though Orfila and West have seen them, it was only in small number.* Dr. Alison therefore infers, that in most of the numerous cases where tubercles are found in the bodies of young children, the diseased actions by which they are formed originate after birth, parents transmitting to their offspring only the tendency to this kind of diseased action, and very seldom the actual disease.

Dr. Alison next quotes the observation of Magendie, that in those cases where he had detected tubercles of the smallest size, and apparently in the earliest stages of the bodies of young children, they were surrounded by circumscribed vascularity. This Dr. Alison has also observed, not uniformly, but in many cases. Lastly, Dr. Alison, in support of his views, adverts to the frequency of phthisis in masons, as is supposed from the irritation of the particles of sand inhaled; and to certain experiments by Dr. J. P. Kay, in which the introduction of a globule of mercury into the tracheæ of rabbits led to the production of clusters of tubercles in the lungs, each tubercle containing in its centre a small particle of mercury. As for these experiments, and others recorded by Cruveilhier (*Anat. Pathol.*), the editor thinks that they merely show that the particles of mercury, like other extraneous bodies, led to the effusion of lymph around them, by which they became encysted, just as a leaden shot or bullet has frequently been observed to be, when it has been lodged in the lungs for some time previously to death. The same process happens in all other parts, so as to circumscribe extraneous bodies.

tendency in every organ to the tubercular secretion. It is not to be supposed, however, that tubercles form only in these constitutions; and Andral admits that it is not uncommon for phthisis to destroy persons of dark complexion, very black hair, and a muscular system strongly developed. We know, indeed, that so far is a dark complexion from being a certain protection from phthisis, that the blacks of Africa, when brought to this climate, are particularly liable to the disease; though here the disposition to it may be set down as acquired. At this present time (Dec., 1830), the editor has a patient with phthisis, in the King's Bench, whose complexion is remarkably dark, and his hair black. However, he believes with M. Andral, that the natural disposition to tubercles is most frequent in the above description of subjects, and especially the tendency to their simultaneous production in several organs.—Op. cit., p. 434.—Ed.

* One or two additional cases of this kind are recorded in Lloyd's work on Scrofula. The preparations are in Mr. Langstaff's museum.—Ed.

The analogy between these cases and others in which tubercles are produced extensively throughout the lungs, by a process in which frequently the presence of no extraneous body can be suspected, certainly does not seem very evident.]

A few years ago, Dr. Baron brought forward an hypothesis, founded upon the hydatid basis. Waving the question of the animalcular origin of the hydatid, as contended for by Dr. Jenner and others, and resigning the critical meaning of the term tubercle as a diminutive substantive, he employs tubercle, vesicle, and hydatid as nearly synonymes. Tubercles in their incipient state being with him "small vesicular bodies with fluid contents" (*Inquiry illustrating the Nature of Tuberculated Accretion, &c.*, p. 214), the hydatids of his friend Dr. Jenner, and vesicles being parallel with both, and distinguished from tumour as follows:—"I would employ the word tubercle to denote those disorganizations that are composed of one cyst, whatever may be its magnitude or the nature of its contents; and by tumour I would understand those morbid structures that appear to be composed of more than one tubercle."

From this source Dr. Baron derives tumours of almost every kind, varied merely by the peculiarity of the constitution, or the concomitant circumstances of the organ in which their vesicular or hydatid form first makes its appearance; and hence ramifying into encysted tumours, however diversified in their contents,—whether limpid, gelatinous, cheesy, pultaceous, medullary, or steatomatous,—sarcomatous tumours, scirrhus tumours, cartilaginous tumours, cancer, and the fungus hæmatodes. He limits their formation to the absorbent system alone, conceiving the sanguiferous to have little or nothing to do with the morbid productions; and upon this point it is that he is chiefly in a state of challenge with the ablest supporters of the Hunterian doctrines.

According to Dr. Baron, the tubercle "may be pendulous, or imbedded in any soft part, or it may be found between the layers of membranes, and wherever the textures are of such a nature as to admit of its growth. It may be so small as to be scarcely visible, or it may acquire a very great magnitude. Single tubercles are often seen in a viscus, while all the rest of the organ is free from disease, and its functions are performed in an uninterrupted manner. But it is evident that the same state of the system, whatever that may be, which calls one tubercle into existence, may generate an indefinite number: that they may be diffused through the whole of a viscus, leaving nothing of its original texture; or they may occupy any portion of it, or extend to the contiguous parts, and involve them in the same form of disease."—(P. 216.)

If the organ or the general constitution be not much predisposed to a generation of tubercles, a few may remain for a long time inert, and without any multiplication whatever; but there is often a particular diathesis that favours such a complaint, and facilitates its being called from a latent state into an active manifestation

by a thousand little accidents; and which, when once excited, encourages the growth of tubercles in great abundance, and finds a rich and ready soil for them, not in one organ only, but in every one. A case, strikingly illustrative of this form of the disease, is recorded by Mr. Langstaff.—(*Med. Chir. Trans.*, vol. ix.)

[Some valuable observations, lately published by Dr. Abercrombie (*Edin. Med. Chir. Trans.*, vol. i., p. 682), are very unfavourable to the hypothesis that tubercles consist of hydatids. A chymical examination of the mesenteric glands affected with tubercular disease, he found to present some curious results. When a gland, having a soft fleshy appearance, is plunged into boiling water, it instantly contracts considerably in its dimensions, its textures become much firmer, and its colour changes from that of flesh to an opaque white or ash-colour. By boiling for a short time, it loses a great part of its weight; but a residuum is left, which has increased much in firmness during the boiling, has lost entirely the flesh colour, and exhibits the appearance, consistence, and properties of coagulated albumen. The part that is lost seems to consist partly of water, but chiefly of the muco-extractive matter; sometimes, but not always, there is a mixture of gelatin; and, in some specimens, the coagulated part gave traces of fibrin, but in small quantity.]

According to Dr. Abercrombie's report, the proportions of these ingredients varied exceedingly in different specimens, and apparently in different periods of the disease. In the softest state, glands which were considerably enlarged, lost by boiling about five sixths of their weight; the remaining one sixth being a firm mass, with the appearance of the firm white tubercle, and the properties of coagulated albumen. Glands, examined in a more advanced stage of the disease, lost by boiling perhaps from two thirds to one half. Portions in the semi-transparent, cartilaginous state, lost about one fourth, leaving three fourths of their weight in the same state of firm, opaque, albuminous coagulum. The white, opaque, tubercular matter lost a still smaller proportion, and what was left was a firm white substance, resembling coagulated albumen. The same results were obtained from an examination of the white tubercle of the lungs, the tubercular disease of the bronchial glands, tubercles of the liver, certain tumours of the brain, and of similar masses in other situations.

As the mesenteric and lymphatic glands, approaching the healthy state, do not exhibit any traces of albumen, Dr. Abercrombie infers, that the deposition of this substance in them is a morbid process, and that there is good ground for conjecture that this deposition of albumen is the origin of tubercular disease.

The tuberculated disease of the peritoneum, on which so much of Dr. Baron's hypothesis is founded, presented, in Dr. Abercrombie's experiments, characters considerably different from those of tubercles of the lungs, or of the tubercular disease of the lymphatic glands. The specimens presented an irregular surface, eleva-

ted into variously-shaped nodules of a semi-pellucid appearance and firm texture. By boiling in water, these nodules were nearly dissolved, leaving only a small central part, to which they seemed to have been attached, and which had undergone little or no change during this first boiling. The part that was dissolved seemed to consist entirely of the muco-extractive matter, and the part that remained was the same substance in a more concrete state, with a small trace of albumen. In all Dr. Abercrombie's examinations, this substance seemed remarkably different from what is observed in the proper tubercle. They both differ, however, from the contents of a hydatid, which consist of water, holding in solution about one hundredth part of saline matter, and one fortieth part of muco-extractive animal matter; a fact weighing heavily against Dr. Baron's hypothesis.*

The researches of Dr. Armstrong taught him that the vesicular appearance of a tubercle is an accidental occurrence, dependant on the texture of the part in which it is placed; a fact agreeing with Dr. Carswell's investigations. Thus, tubercles in their origin may have the vesicular appearance in the lungs; but if minutely examined, he says they will be found to be the extremities of the bronchial tubes, or air-cells, into which the peculiar deposit constituting tubercle often takes place. He has frequently examined them in a strong light, and never found them to be, strictly speaking, vesicles, though the tubercular points have been in many cases extremely minute.†

Dr. Baron attempts to prove that tubercles are essentially hydatids, and that the progress of tubercular disease is precisely the reverse of Laennec's description; and that, instead of passing from an indurated to a softened and fluid state, they are first simple vesicles of fluid;‡ and that they generally pass through a

process of inspissation, until they become quite hard, in which state, he says, there is the strongest reason for believing that they do not subsequently soften! This theory seems to Dr. Forbes incompatible with the best established facts, and susceptible of ready refutation by any person versed in modern pathology. Dr. Baron, as a critic has remarked, has betrayed not only a singular misapprehension of the pathology of the diseases of which he treats, but actually not a due acquaintance with the natural history of hydatids themselves, on which all his opinions repose. He reproaches Laennec with indulging in unnecessary minuteness in his description of tubercles; forgetting, in his zeal for the hydatid doctrine of disease, that nature's forms may be very diversified, and that it is the privilege of theory only to be just as simple as the theorist could desire. Real instances of hydatids in the lungs are extremely rare, Andral having met with only four or five cases among six thousand subjects.*

its primitive state, in the bronchi, air-cells, and other situations, resembling a mixture of soft cheese and water.—(See Illustrations of the Elementary Forms of Disease, fasc. i.) M. Cruveilhier believes, that previously to the period when a tubercle presents itself as a firm substance, it has a less advanced stage, in which it exists in a fluid form. In his experiments to produce tubercles artificially in animals, on an examination of their bodies at the very commencement of the disease, he found, close to the white bodies, which were already indurated, other productions, which differed from them only in having less consistence, and being in a state of fluidity. In the human lungs, filled with tubercles, M. Andral has also seen dispersed, throughout the interior of those viscera, white points, consisting of a liquid matter, like a small drop of pus. Yet he is of opinion, that the doctrine of M. Cruveilhier has not been sufficiently proved; and that the above appearances are only accidental, and not constant; and that, however minute a tubercle may be, it is mostly met with in a solid shape. At all events, there is one great difference between M. Cruveilhier and Dr. Baron, inasmuch as the former does not suppose that hardened tubercles cannot soften.—Ed.

* Laennec on Diseases of the Chest, note by Dr. Forbes, 2d edit., p. 298. Andral, Clinique Méd., tom. iii., p. 93. In another publication (Anat. Pathol., tom. i., p. 408), the latter author mentions, that he has seen only a single instance of transparent vesicles in the human lungs, accompanied by tubercles; but he has met with this association more than once in phthisical horses, and, in some of these examples, the fluid of the vesicle became turbid, and surrounded by a white opaque cyst. His inferences are, that the transparent vesicles observed in a few uncommon cases, in the vicinity of tubercles, are an accidental complication. If they were the original form of tubercles, they would be more frequently noticed. They may sometimes secrete, instead of their usual contents, a peculiar matter, the physical qualities of which may have more or less resemblance to those of a tubercle; but this is no proof of the latter having been always preceded by a serous cyst, and secreted from it. As well might it be argued, that a tubercle is always secreted by a mucous follicle, or lymphatic vessel, because a substance like that of tubercle has been occasionally observed within

* Dr. Carswell has always found tuberculous matter in scrofulous glands; and, when the cutis is pale, and they happen to lie directly under it, they are almost completely filled with this morbid product. "When, therefore, enlarged glands, in a scrofulous patient, ultimately disappear, we may conclude, almost with certainty, that we have witnessed the cure of a tubercular disease."—See Illustrations of the Elementary Forms of Disease, fasc. i.—Ed.

† See Morbid Anatomy of the Bowels, &c., p. 16. Dr. Armstrong's belief that tubercles are originally the extremities of the bronchial tubes, or air-cells, may have been derived from the fact, that tubercles are sometimes situated in the substance of the parietes of the air-cells, and of the minute ramifications of the bronchiæ. Matter, like that of tubercles, has been found, however, in cavities lined by mucous membrane, after ulceration has taken place. Mucous follicles and lymphatic vessels have been occasionally remarked to contain a similar substance.—(Andral, Anat. Pathol., tom. i., p. 419.) The cellular tissue is, then, not the only nidus for tubercles.—Ed.

‡ According to Professor Carswell, tuberculous matter does not acquire its maximum of consistence until an indefinite period after its formation: and he states that it is frequently found in

When the morbid action commences in the abdominal organs, it far more readily passes into those of the chest, than when it commences in the chest, into those of the abdomen; instances of which have been sufficiently noticed under the complicated species of *Parabysma*.—(Vol. i., Cl. I., Ord. II., Gen. IV., Spe. 7.) These, however, are extreme examples; for, in most cases of tubercular phthisis, the disease has made far less progress at the time of its proving fatal, and is often confined to the seat of the lungs alone, and even to an evolution of tubercles of minute size and uniform simplicity of contents, mostly consisting of a whey-like or cheesy material. A certain but low degree of inflammatory action, however, seems to favour a more rapid formation of fresh tumours, and an enlargement of those already in existence; and the same may be observed of the accompanying hectic fever. If this be decided and considerable, the disease may run its course in four or five months, and sometimes sooner. If the hectic be undecided and only occasional, the disease may play about the system for some years, and at length prove equally fatal. If the inflammatory action exceed the low degree we have just adverted to, ulceration and suppuration usually follow, and the tubercular form passes into, or is united with, the apostematous.

M. Louis, like his friend M. Laennec, refers every case of phthisis to a tubercular origin; and where the predisposition to the formation of such growths is very predominant, he has traced them, in post-obit dissections, to a still wider range than the example furnished by Mr. Langstaff: in various instances, indeed, over almost every viscus of the abdominal, as well as of the thoracic cavity. In one or two of these, he has even found the tubercular structure to have been far more manifest and elaborated than in the lungs, and especially in the stomach, the mesenteric glands, the ileum or jejunum, but rarely in the duodenum. But he positively asserts that he has never traced these morbid appearances in other parts, without some kind of manifestation of them in the lungs: and he hence concludes, that a development of tubercles in this last organ is essential to their formation elsewhere. So far as he has examined, however,—and his field of observation has been very extensive, as well as closely followed up, in the Hôpital de la Charité,—phthisis has seldom limited its structural ravages to the region of the lungs. Tubercles, or ulcerations, have usually been detected elsewhere on dissection; often, indeed, in the trachea, larynx, and epiglottis, and occasionally in the pharynx and œsophagus, as well as in the stomach. And when the hectic has been active, there is scarcely an organ but what he

such parts. Transparent cysts are very common in the diseased lungs of pigs, where they even exceed tubercles in number; and it seems to M. Andral, that this fact is the chief ground of the opinion that tubercles commence in the shape of hydatids. He also warns us not to mistake the deposition of tubercular matter around hydatids (an instance of which he met with in a rabbit) for the conversion of vesicles into tubercles.—Ed.

has found at times entering more or less into the general circle of action; as the large intestines, the liver, the spleen, the peritoneum, the lymphatic glands, the aorta, and even the brain. The heart, and the urinary organs, have usually escaped with less structural injury than any others.—(*Recherches Anatomico-Pathologiques sur la Phthisie*, par P. Ch. A. Louis, Paris, 8vo., 1825.)

With one exception out of 350 dissections, whenever M. Louis found tubercles in the lungs, he always found them in other organs.* In a few instances, however, Laennec found tubercles to commence in other parts, especially in the mucous membrane of the intestines, and in the lymphatic glands, their formation in the lungs having been secondary.—(Laennec, op. cit., p. 285.) The occurrence of tubercles in various organs without the presence of any in the lungs, has been noticed by M. Andral more frequently than by M. Louis. Such cases are more common in children than adults. In the former, there is a disposition to tubercles in a larger number of parts at once; and the organs most frequently affected in them are not the same as in the adult subject. The parts which are most frequently the seat of them in the adults are, first, the lungs, and then the small intestines: in children, first, the bronchial glands; secondly, the mesenteric glands; thirdly, the spleen; fourthly, the kidneys; and fifthly, the intestines, &c. In children under fifteen, tubercles are least frequent between the first and second years of their age; and most common from the end of the fourth until the commencement of the fifth.—(*Anat. Pathol.*, tom. i., p. 424.)

Phthisis, as already observed, is a disease of high antiquity, as well as of most alarming frequency and fatality. So frequent, indeed, is it, as to carry off prematurely, according to Dr. Young's estimate, and the calculation is by no means overcharged, one fourth part of the inhabitants of Europe (*On Consumptive Diseases*, ch. iii., p. 20): and so fatal, that M. Bayle will not allow it possible for any one to recover who suffers from it in its genuine form.—(*Recherches sur la Phthisie Pulmonaire*, Paris, 1810.) I can distinctly aver, however, that I have seen it terminate favourably in one or two instances, where the patient has appeared to be in the last stage of disease, with a pint and a half of pus and purulent mucus expectorated daily, exhausting night-sweats, and anasarca; but whether from the treatment pursued, or a remedial exertion of nature, I will not undertake

* *Recherches sur la Phthisie*, &c., p. 179. In the 350 post-mortem examinations mentioned in the text, M. Louis found tubercles in various organs besides the lungs, in the following proportions:—In 2-3 of subjects, small intestines; in 1-9, large intestines; in 1-4, mesenteric glands; in 1-10, the cervical glands; in 1-11, the lumbar glands; in 1-13, the prostate; in 1-14, the spleen; in 1-20, the ovaries; in 1-40, the kidneys; 1-350, the womb; 1-350, the brain; 1-350, the cerebellum; 1-350, the ureter. M. Louis makes no mention of tubercles in the testis, which are common; nor does he say any thing about their occasional formation in the bones.—Ed.

to say. Dr. Parr affirms that he has witnessed six cases of decided phthisis recover spontaneously.

[Previously to the knowledge of the true nature of tubercles, and while consumption was considered simply as a consequence of chronic inflammation and suppuration of the pulmonary tissue, phthisis was deemed curable, at least, when properly treated before it had made too much progress. But, says Laennec, it is now the general opinion of all well-informed pathologists, that the tubercular affection, like cancer, is absolutely incurable. The observations contained in the treatise of M. Bayle, as well as Laennec's remarks on the development of tubercles, prove how illusive the idea is of curing consumption in its early stage. Crude tubercles tend essentially to increase in size, and to become soft. Nature and art may retard, or even arrest their progress, but neither can reverse it. But, while Laennec admits the incurability of consumption in the early stages, he is convinced, from a great number of facts, that, in some cases, the disease is curable in the latter stages, that is, after the softening of the tubercles, and the formation of an ulcerous excavation.*

* Laennec on Diseases of the Chest, 2d edit., p. 299. In Dr. Carswell's Illustrations of the Elementary Forms of Disease, fasc. i., the reader will find some particularly interesting facts, confirming Laennec's views of this part of the subject; for he has traced the several steps of the curative process in the bronchial glands, in individuals who had recovered from scrofula and phthisis, but died some time afterward of other diseases. He has found in these glands a greater or less quantity of a substance resembling putty, or dry mortar, the consistence of which was sometimes equal to that of sandstone or bone, and presented spiculae, which had excited inflammation, ulceration, and perforation of the lining of the bronchi or trachea with which they were in contact. A direct communication was thus formed between the cavity of the air-tubes and the diseased glands, through which the cretaceous bodies passed; and they were rejected along with the expectorated fluids. Dr. Carswell has seen several examples of cure of tubercular disease of the bronchial glands in the manner just described. When these glands have discharged the whole of their contents, they are found atrophied, and converted into a fibrous tissue, which fills up the external orifice of the perforated tube. The accidental opening now contracts, becomes obliterated, and leaves in its place a puckered depression or cicatrix, seen on the internal surface of the air-tube. Dr. Carswell adds, that similar appearances, indicating the removal of the serous and albuminous parts of the tuberculous matter, and the condensation of its earthy salts, have frequently been observed in the lungs of persons whose history left no doubt of their having been affected, at some period of their lives, with tubercular phthisis. For a particular description of the changes referred to, as leading to this fortunate amendment, the reader is advised to consult Carswell's Illustrations of the Elementary Forms of Disease, fasc. i. It appears, that if the bronchi remain pervious, the tubercular matter is gradually removed by expectoration; and, if they are closed, it is removed by absorption.—ED.

Eight or ten cases of cicatrization of the lungs after tubercles are recorded by Andral.—(*Clinique Méd.*, tom. iii., p. 382.) The learned translator of Laennec's work is of opinion, however, that this author has exaggerated the frequency of recoveries in this way; and that he has considered certain appearances as signs of cicatrization, which were probably owing to other causes. Dr. Forbes considers it likely, that simple pneumonia, or pleuro-pneumonia, may give rise to many of the slighter deviations from the natural structure, considered by Laennec as tubercular cicatrices.—(See note in translation of Laennec, p. 311, 2d edit.; also, *Louis, Recherches, &c.*, p. 36.) Notwithstanding what has here been advanced, many experienced practitioners still incline to Bayle's opinion, that tubercular consumption is incurable; the disease, however, may be retarded, and patients may live with it sometimes thirty or forty years.]

The ordinary period of the consumptive diathesis has been stated to be from the age of eighteen to that of thirty-five, occasionally anticipating the first, and overpassing the second of these limits: the mean term of its proving fatal has been fixed at about thirty; and the annual victims to its ravages in Great Britain, Dr. Woolcombe has calculated at fifty-five thousand.—(*Remarks on the Frequency and Fatality of different Diseases, &c.*, 8vo., Lond., 1808.)

During the last half century, it is said to have been considerably on the increase; but this is, perhaps, chiefly owing to the greater number of infants of delicate health who are saved from an early grave by the introduction of a better system of nursing than was formerly practised; yet who only escape from a disease of infant life to fall before one of adolescence or adult years. And, for the same reason, savages rarely suffer from consumption, as they only rear a healthy race, and lose the sickly soon after birth.

The question, however, concerning the actual range of the consumptive diathesis, or in other words, at what period of life consumption is most frequent, is still open to inquiry. It was a common doctrine among the Greek physicians, and it has very generally descended to our own day, that phthisis rarely occurs before fifteen or after thirty-five years of age; and Dr. Cullen has entered into an ingenious argument to show why it should be so. Yet the tables that have been kept in most parts of the world seem to indicate the contrary; or that, at least, as many die of this disease, and even originate it, after thirty-five or forty years of age, as antecedently to this period. One of the first pathologists who appears to have called the public attention to this general concurrence of the tables and bills of mortality, is Dr. Woolcombe; and he particularly adverts to the proportions observed in the Dispensary of Plymouth, as being the chief source from which he drew his calculations. He tells us, that of seventy-five deaths from consumption, which occurred within the range of this establishment, ten took place before the age of fifteen, sixteen between fifteen and thirty, and forty-nine above the age of thirty; twenty-

three of these forty-nine, moreover, being above the age of forty.—(Op. cit., &c., p. 75.)

Dr. Alison (*On the Pathology of Scrofulous Diseases*; *Transact. of the Medico-Chir. Soc. Edin.*, vol. i.) has given the result of various other tables, most of which are in consonance with Dr. Woolcombe's. Thus Bayle, in his *Treatise on Consumption*, notices a hundred cases above fifteen years of age, all of which terminated fatally in the hospital of La Charité at Paris, and after the following proportions: thirty-three below the age of thirty, and sixty-seven above it, of whom forty-four were upwards of forty.* So Haygarth, in his account of the deaths from phthisis in the course of two years at Chester, makes the total a hundred and thirty-five; of which twenty-five occurred before the age of fifteen, forty-two between fifteen and thirty, and sixty-eight above thirty; forty-four of these last being above forty.—(*Phil. Transact.*, lxiv., lxxv.) "In the practice of the New Town Dispensary at Edinburgh, Dr. Alison tells us, there have been fifty-five deaths from phthisis in the last two years; of these, eight occurred before fifteen years of age, thirteen between fifteen and thirty; thirty-four after thirty; and of these last, twenty-four after forty."

So in Sussmilah's table of deaths at Berlin in 1746, out of six hundred deaths from phthisis, two hundred and fifty-one are stated to have occurred before fifteen years of age, seventy-three between fifteen and thirty, and two hundred and ninety-six above the age of thirty; two hundred and thirty of which occurred after the age of forty.

In this last table, a greater number of deaths took place within the first fifteen years than in any fifteen years afterward. And a like surplus occurs in the calculations at Warrington recorded by Dr. Aikin: the proportions being twenty-four below the age of fourteen, thirty-six between fourteen and fifteen, and the same number above the age of forty-five.—(*Phil. Trans.*, vol. liv.) While at Carlisle, as we learn from Dr. Heysham, out of two hundred and fourteen deaths, fifty-nine anticipated the age of fifteen, sixty took place between this period and thirty, and ninety-five above the age of thirty; sixty-one of these being above that of forty.†

The general result, therefore, seems, at first sight, to oppose in a very striking degree the doc-

trine of the Greek schools, and those who have followed them; and to show that the age from fifteen to thirty is most exempt from consumption, while that above thirty, or even forty, to the close of life, is most distinguished by fatality from this disease, though the period below fifteen is also seriously invaded by it.

But the doctrine of the Greek schools relates to idiopathic consumption as the product of a phthisical diathesis; or, in other words, affirms that this diathesis, when not called into action by accidental excitements, is most disposed to show itself between the ages of fifteen and thirty-five. And, thus modified, it is probable that the doctrine holds good to the present day, notwithstanding the apparent contradiction of the tables now adverted to. For, with respect to the cases of consumption that anticipate the age of fifteen, by far the greater part of them are secondary, instead of primary or idiopathic affections, and follow as sequels of a strumous habit that has previously shown itself in a morbid condition of the mesentery or some other organ, with which the lungs at length associate in action; though, but for such an incidental excitement, they would probably have remained quiescent for several years longer. In many instances, indeed, they are to the last rather *tabes strumosa*, strumous or mesenteric decline, than phthisis or consumption properly so called, though included in the bills of mortality or other tables under this last name. And as we have already observed, that variolous and vaccine inoculation carry various sickly infants through the period of infancy, who would otherwise have fallen victims to the smallpox, yet who, a few years afterward, from the same sickness of constitution, sink beneath the assault of decline or phthisis, we see sufficient reason for the greater number of early deaths in our own day from what is ordinarily called consumption, and what often is strictly so, though of a secondary or catenating, instead of a primary or idiopathic kind, than was known to the Greek authorities, whose doctrine relating to idiopathic phthisis alone is not hereby interfered with. The observations of M. Louis, to which we have just adverted, and which seem to have been made and persevered in with great accuracy, are directly coincident with these remarks, and support the calculation of the Greek school. "The number of individuals who die of phthisis," says this attentive pathologist, "is more considerable between the ages of twenty and forty than between forty and sixty, although the general mortality is less in the first than in the second of these periods." And, in support of this assertion, he subjoins the following table as the result under his own eye:—

Age.	No. of Deaths.	Age.	No. of Deaths.
From 15 to 20	- 11	From 40 to 50	- 23
20 - 30	- 39	50 - 60	- 12
30 - 40	- 33	60 - 70	- 5

scrofula is more likely to occur in the lungs between the ages of 18 and 30, than at any other time of life.—See *Lect. at Lond. Univ.*, as published in *Med. Gaz.* for 1833, p. 231.—Ep.

* Bayle, p. 42. Of 223 deaths from phthisis, recorded by Bayle and Louis, 21 occurred between the ages of 15 and 20, 62 between the ages of 20 and 30, 56 between those of 30 and 40, 44 between those of 40 and 50, 27 between those of 50 and 60, 13 between those of 60 and 70.—See Laennec, *tr.* by Forbes, note, p. 352.—Ep.

† Milne, on *Annuities*, vol. ii., p. 464. After puberty, Andral has calculated that tubercles are most common in men between the age of 21 and 28; but that females are most liable to the disease ere they attain their 21st year.—(*Anat. Pathol.*, tom. I., p. 429.) These estimates, it is to be observed, refer only to the periods of the existence of the disease, and not to the time of life in which the greater or lesser number of deaths takes place from it. The latter is a very different question; because numerous consumptive patients linger many years. Dr. Elliotson observes, that in this country

And in effect the proportions, as arranged by M. Bayle, do not essentially vary when given in his own tabular form, instead of being generalized, as they are by Dr. Alison, in the reference just quoted. In this form they occur as follows:—

Age.	No. of Deaths.	Age.	No. of Deaths.
From 15 to 20	- 10	From 40 to 50	- 21
20 - 30	- 23	50 - 60	- 15
30 - 40	- 23	60 - 70	- 8

In respect to the exuberant cases that occur in later life than thirty, they are, for the most part, far less a result of a phthisical diathesis than of an accidental exposure to causes peculiarly operating upon the lungs, and exciting them to a morbid action, so as to produce the disease, whether there be any hereditary taint or predisposition to consumption, or whether there be none.

These causes are chiefly the habitual influence of a higher degree of heat or of cold, and especially the latter, than is consistent with that eudymia or perfection of constitution on which sound health depends; and particularly the mischievous influence of a temperature perpetually varying from high degrees of heat to those of cold; and a like mischievous exposure to irritating gases, or spicular dust, perpetually inhaled in various chymical or handicraft occupations. Above thirty years of age, the stations of mankind are usually fixed, and whether healthy or unhealthy, they cannot easily be abandoned.

If, then, we examine the kind of consumption which takes place above this age, we shall find it, in by far the greater number of cases, confined to the lower classes—to those engaged in the occupations just noticed, or who have injured themselves by intemperance; while the classes above them, who have passed safely through the period of from fifteen to thirty or forty years of age, and are free from the incidental excitements alluded to, rarely add to the number of deaths from consumption; and may be regarded as having, in a considerable degree, lost whatever predisposition they had to the disease in an anterior stage of life. Thus again confirming the correctness of the earlier and more common doctrine upon this subject, which refers chiefly to consumption as issuing from a phthisical diathesis.

Hence a material difference is very generally discernible in the nature of the disease as occurring in earlier life, or during the natural range of the predisposition, and as occurring from incidental excitements afterward. The first is usually, though not always, of the tubercular variety; the last, as usually of the catarrhal or apostematous, most commonly of the catarrhal modification, originating from habitual irritation and repeated and neglected inflammation, not at first of an unhealthy character, for the most part more active than tubercular inflammation; and, where suppuration does not take place freely, leading to a dark-hued or hepatized induration.

The causes of phthisis, then, are of two

kinds; the predisponent, and those that excite the predisposition into action, or operate even where there is no predisposition whatever.

Of the nature of the predisponent cause, we know little more than that it appertains to a peculiarity of constitution, which will be noticed presently.* The exciting or occasional causes are very numerous, as mechanical irritation of the lungs from swallowing a piece of bone; the dust of metallic or other hard substances perpetually inhaled; frequent and sudden changes of temperature, or exposure of the body to cold when in a heated state and unprepared for it; overaction in speaking, singing, or playing on a wind instrument; the irritation of various other diseases, as worms, scrofula,† syphilis, or measles; too rapid a growth of the body; and various passions perpetually preying upon the individual, as mortified ambition, disappointed love, home-longing (*R. Hamilton, in Duncan's Med. Comm.*, xi., p. 343), when at a remote distance from one's friends and country.

Examples of consumption from a mechanical irritation of the lungs are peculiarly numerous, and they furnish cases of every variety of the disease, according to the habit or idiosyncrasy, though the apostematous is less frequent than the rest. So common is this complaint among persons employed in dry grinding, or pointing needles in needle-manufactories, that Dr. Johnstone, of Worcester, informs us they seldom live to be forty, from the accumulation of the dust of the grindstones in the air-cells of the lungs, and the irritation and suppuration which follow. —(*Mem. Med. Soc.*, v., 1799, p. 89.) It appears to be little less common among knife and scythe-grinders, whence, according to Dr. Simmons, the disease thus originating is called the grinder's rot (*Pract. Observ. on the Treat. of Consumptions*, 8vo., 1780); and Wepfer gives an account of its proving endemic at Waldshut, on the Rhine, where there is a cavern in which mill-stones are dug and wrought: the air is always hot, even in the winter, and a very fine dust floats in it, which penetrates leathern bags, and discolours money contained in them. "All the workmen," says he, "become consumptive if they remain there for a year, and some even in a shorter time; and they all die unless they apply early for assistance." —(*Observationes de Affect. Capitis*, 4to., Schaff., 1727-8, quoted by *Young on Consumptive Diseases*, p. 206.) And hence, Dr. Fordyce had much reason for regarding the dust of the streets of London as a se-

* Many would escape the disease were it not for their being exposed to wet and cold, for want of proper lodging and clothing. These circumstances, together with unwholesome food, are well known to create a tendency to, and even to excite, scrofulous diseases in general, among which must undoubtedly be placed tubercular phthisis. It is alleged, says Dr. Elliotson, that formerly in Scotland the people were all dressed in woollen, and phthisis was rare among them; but that since they have changed it for cotton, the disease has become very prevalent in that country.—Ed.

† Tubercular phthisis is considered, by the most accurate pathologists of the present day, as a scrofulous disease itself.—Ed.

rious cause of pulmonic disorders (*Trans. of Soc. for the Impr. of Med. and Chir. Knowledge*, vol. i., p. 252), though it is a cause that has been much diminished since the introduction of paving and watering.* As these are causes that operate at all ages, consumption among such persons occurs at all ages also; in patients, however, beyond forty, it may for the most part be regarded as a strictly original disease, the consumptive diathesis having by this time, as already observed, gradually lost its influence. And it is on this account that Dr. Alison regards the tubercular or strumous form as rarely taking place after the age of thirty-five or forty (*Edin. Medico-Chir. Transact.*, vol. i., 1824), thus confirming the ancient, and indeed the common opinion, how much soever opposed by the tables we have already referred to.

A lodgment of some fragment of a bone even in the œsophagus has, in like manner, been a frequent cause of phthisis, which has often been protracted through a long period of time. Thus Claubry gives a case of this kind which had continued for fourteen years, and the patient seemed to be in the last stage of a consumption, when he was fortunate enough to bring up the piece of bone spontaneously, in consequence of which he recovered, though for the preceding four years he had laboured under an hæmoptysis.—(*Sedill. Journ. Gen. Med.*, xxxiv., p. 13, 1809.) Mr. Holman describes a similar case that had run on for fifteen years, accompanied with cough, hæmoptysis, and hectic diarrhœa; and which was also speedily relieved in consequence of the bony fragment, three quarters of an inch in length, and apparently carious, being suddenly coughed up after the discharge of a pint of blood.—(*Lond. Med. Journ.*, vii., p. 120.)

A moderate use of the vocal organs, as of any other, tends to strengthen them, and to enable public speakers, singers, and performers on wind-instruments to go through great exertion without inconvenience, which would be extremely fatiguing to those who are but little practised in any of these branches; but the labour is often carried too far, and the lungs become habitually irritated, and hæmoptysis succeeds. I have known this terminate fatally among clergymen; who have lamented, when too late, that in the earlier part of life they spent their strength unsparingly in the duties of the pulpit.† Hence,

* The diminution of the supposed cause, and the undiminished frequency of consumption, seem to contradict Fordyce's hypothesis.—Ed.

† On this subject Dr. John Ware, of Boston, very justly remarks (*Med. Dissertations*, Boston, 1820), "The most obvious cause of this liability to pulmonary disease in clergymen is the great and long-continued exercise of the lungs, required in the performance of public worship. To this, as the peculiar duty of the profession, our attention is apt to be principally and almost exclusively devoted; we are too ready to consider it as a sufficient cause in itself; and to avoid examining the influence of other circumstances. It is not found that members of other professions who are in the habit of exerting their lungs, are more liable than the average of mankind to pulmonary disease. We do not hear of any extraordinary proportion of deaths from consumption among lawyers, public

Dr. Young observes from Rammazini (*On Consumptive Diseases*, p. 264), that public speakers, readers, and singers are most liable to pulmonary diseases, and that Morgagni and Valsalva have confirmed the observation. Cicero himself felt it necessary, as he tells us in his book on orators, to retire from the forum for two years, during which he travelled into Asia, and afterward returned with renewed vigour to the duties of his profession; and Molière died of hæmoptysis, immediately after performing, for the fourth time, his *Malade Imaginaire*.—(*Van Swieten*, Aph. iv., § 1201, p. 49.)

Many diseases have a peculiar tendency to excite phthisis, from their close connexion with the lungs, or affinity to hectic fever, which is one of its most prominent symptoms. Thus, neglected catarrhs form a frequent foundation, and measles for the same reason.

[This hypothesis of the origin of consumption from catarrh is very ancient, but not at present universally admitted. In most phthisical cases, as Laennec allows, the first symptoms are catarrhal; but, as he also acknowledges, we find very large and very numerous tubercles in subjects who exhibit no signs of catarrh. If it be said that the tubercles are the product of former catarrhs, Laennec replies, that they exist in persons who have not had catarrh for years, or even at all. Pulmonary catarrh is, indeed, often the first symptom of tubercular phthisis: this, however, may have existed long in a latent state; since we find, on examining the chest of such persons, all the physical signs of tubercles, and sometimes even of tubercles already excavated. On the other hand, thousands of persons have catarrh several times every year, and yet very few of them become phthisical.—(*Op. cit.*, p. 293.) Some arguments and facts against the doctrine of tubercles being a consequence of pleurisy, peripneumony, and catarrh, are noticed by M. Louis. Of eighty phthisical subjects, into whose previous history he had particularly inquired, only seven had ever been affected with pneumonia, and four of these had been perfectly free from any pectoral affection for several years before the invasion of phthisis. He notices the fact, mentioned by Laennec, of tubercles being most frequent in the upper lobes, while peripneumony most commonly occupies the lower. He adds, that pneumonia rarely af-

actors, public singers," &c.—"The reason I believe to be this, that the duties of the profession are only occasional, and occur at too great intervals to allow the formation of a habit; while at the same time they are sufficiently difficult to over-exercise, fatigue, and exhaust the organ. They are from the first as long and laborious as they ever will be, and there is no opportunity for that slow and gradual increase which enables one to acquire strength and facility of exertion."—"Occasional extraordinary exertion, carried to the point of fatigue, and then omitted until the fatigue is entirely removed, can only have the most injurious effect, and it is exactly in this way that the lungs are exercised in preaching. They are wearied by the services of the Sabbath, and are then suffered to remain perfectly at rest through the interval of the week."—D.

fects both lungs, while phthisis almost always does so; and that the former is most common in men, while the latter is so in women. The same remarks, he says, apply to pleurisy and catarrh, with this addition, that in cases of chronic pleurisy, he has found as many tubercles in the lung of the sound as in that of the diseased side. Out of the eighty cases of phthisis above alluded to, only twenty-three had been particularly subject to catarrh.—(*Louis, Recherches*, &c., p. 503, et seq.; also, *Forbes*, in note to *transl. of Laennec*, p. 323, 2d edit.)]

Whether the tubercles found in the substance of the lungs, in the tubercular variety of consumption, be, in every instance, strictly scrofulous, may admit of a doubt; that they are so in many cases is unquestionable; and hence scrofula becomes very generally an exciting, and not unfrequently, perhaps, a primary cause of this disease.*

The tendency of the syphilitic poison to pro-

* In Great Britain, where strumous habits are admitted to exist much more extensively than in the United States, the connexion between scrofula and consumption ought not to be questioned. In this country scrofula is rare when compared with Great Britain, and yet the mortality by consumption is nearly the same as there. To what circumstances is this to be attributed? To the extraordinary vicissitudes in the climate, "to the mischievous influence of a temperature perpetually varying from high degrees of heat to those of cold." Consumption too is evidently increasing among us, and within the city of New-York the weekly number of deaths from this disease within the last five years, has risen from 18 to 36; a ratio of one hundred per cent., while the increase in population is not more than ten per cent.; thus, notwithstanding the improvements in medicine, our treatment is not much more successful than it was formerly: this increase may be ascribed partly to the modified habits and manners of our people, especially in the larger cities, where greater errors of life prevail; to imprudence in dress, improprieties in diet, and the excesses and indiscretions which mark the extremes of society, the rich and the poor. The truth of this remark will be readily seen by comparing the mortality by consumption at the present time with that which prevailed about a century ago. Dr. Cullen, speaking of the climate of New-York some ninety years since, remarks, "the air of the country being almost always clear, and its spring strong, we have few consumptions or diseases of the lungs. Persons inclined to be consumptive in England, are often perfectly cured by our fine air."—(*Am. Med. and Phil. Reg.*, vol. i., p. 309.) If these premises be allowed as correct, we have strong reason to think that inflammation is the more common cause of consumption, and to regard with more favour than many eminent writers abroad, the principle of the entonic or acute character of the disease. Dr. Rush was unguardedly led into an error in stating that the Indians are exempt from pulmonary disease; an acute observer, one who resided long among those "sons of the forest," remarks, that consumption is one of the common causes of death among them.—(See *Hunter on Diseases of the Indians*, in the *N. York Med. and Phys. Journal*, vol. i.) Nine deaths from the same cause have occurred in the family of the celebrated Indian chief Red-Jacket.—(See *Francis on the Mineral Waters of Avon*.) The liability of blacks to consumption is well known.—D.

duce phthisis has been noticed by almost every writer from the time of Bennet, who particularly dwells upon it (*Vestibulum Tabidorum*, 8vo., 1654, Leyd.); but whether this would be adequate to such a purpose without an hereditary predisposition is uncertain.* And the same remark may be made respecting worms, which Morgagni has stated to be a very common cause.—(*De Morb. Thoracis*, lib. ii., Ep. Anat. xxi., 43.) Indeed, any habitual irritation in any part of the alimentary canal, seems capable of exciting a sympathetic action in the lungs: and hence Wilson, in Dr. Duncan's *Annals*, gives a case of hectic in a child produced by swallowing a nail two inches long, which remained in the stomach fifteen months, and was then thrown up, and succeeded by a recovery of health.†

Rapid growth is always attended with debility; and, where there is a predisposition to consumption, it often becomes its harbinger. Richerand relates a case of this kind that terminated fatally, the individual having grown more than an English foot in a year.—(*Sedill. Journ. Gen. Med.*, xx., p. 255.) I have known a still more rapid growth, without any other inconvenience than that of languor; but, in this case, there was no phthical predisposition.

Where the chest labours under any misformation, we can readily trace another cause of excitement, and are prepared to meet the examples that from this source so frequently occur to us in practice. But it is less easy to explain by what means persons otherwise deformed, and particularly those who have had limbs amputated, should be more liable to consumption than others; yet this also is a remark that has been made by Bennet.‡

Of all the occasional or accidental causes of phthisis, however, frequent and sudden vicissitudes of temperature are probably the most common (*Broussais*, ut sup.; *Hastings, Essay on Bronchial Inflammation*); so common, indeed, and at the same time so active, as often to be a cause of consumption in constitutions where we cannot trace any peculiar taint or predisposition whatever. Several hundred cases of phthisis from this cause, among which were many fatal ones, occurred in the channel fleet that blockaded the port of Brest in April, 1800. The summer was hot and dry, the duty severe,

* "The varieties termed scorbutic, venereal, &c. are all essentially tuberculous, differing only from the common species by the cause (perhaps gratuitous) to which the development of the tubercles is attributed."—(*Laennec*, p. 272.) No modern practitioner of any judgment now believes in the existence of a form of phthisis depending upon and kept up by the syphilitic poison.—Ed.

† Vol. i., 1796. Our author here, and in some other places, seems not to have made an adequate distinction between phthisis and hectic fever.—Ed.

‡ *Tabid. Theatr.*, p. 99. Perhaps some explanation of the circumstance, if true, might be deduced from the consideration that most amputations, in this country at least, are done for scrofulous diseases of joints, and consequently on individuals of strumous diathesis; in whom alone, probably, tubercles of the lungs ever form.—Ed.

the sailors, wet with sweat, were frequently exposed to currents of air at the port-holes; and little time was allowed for refitting.*

Hence, the most frequent examples of consumption are to be found in countries which are most subject to changes of temperature. In Great Britain it is calculated that this disease carries off usually about one fourth of the inhabitants; at Paris, about one fifth; and at Vienna, one sixth: while it is by no means common in Russia, and still less so in the West Indies;† for it is checked in both regions by the greater uniformity of the atmosphere, whether hotter or colder.‡ It is a singular fact, and not well accounted for, that of all places which have hitherto been compared, the proportional mortality from consumption appears to have been the greatest at Bristol; and this, not among its occasional visitors, but its permanent inhabitants; and yet, as though in defiance of experience, this very place has been chosen as the great resort of consumptive persons.—(Young, ut supra, p. 42.) Nor does its mineral water seem entitled to any higher compliment than its atmosphere. Dr. Beddoes affirms, in direct terms, that it is of no manner of use.—(*Manual of Health*, &c., 12mo., Lond., 1806.)

Heat, when above the range of health and antony, is often found a cause as well as cold, though it does not act so manifestly or so rapidly. But of its power of action, we have a clear proof in the greater frequency and fatality of consumption among the native troops of hot climates during the fatigues of war, than among

Europeans who have just been inured to the climate, and have for a less period of time been under the influence of its relaxing agency. "We know at least," observes Dr. Alison, "that a great majority of the inhabitants of these climates, both negroes and Hindoos, are unusually prone to scrofula when they come to temperate climates, and even suffer from it, in some instances, in their own, where Europeans are nearly free from it. I was favoured by Dr. Fergusson, lately inspector of hospitals in the Windward and Leeward Islands, with a perusal of the report of the deaths and chief diseases occurring in the army in these colonies, in each quarter, from March, 1816, till March, 1817, distinguishing the deaths among the white and black troops."—(*Trans. Medico-Chir. Society Edin.*, vol. i., p. 397.) According to these reports, the average strength of the army, for the entire year, consisted of seven thousand three hundred and thirty-seven whites, and five thousand seven hundred and seventy-two blacks: out of which there died of fever, whites, one in 15.3; blacks, one in 151.8: of dysentery, whites, one in 21.4; blacks, one in 58.9: but of pulmonic disease, whites, one in 89.1; blacks, one in 45. "Fever, therefore," remarks Dr. Alison, "caused ten times as great a mortality among the white troops as among the blacks, and dysentery nearly three times as great; but pulmonary complaints caused twice as great a mortality among the blacks as among the whites. The deaths from this cause were one in 10.9 of the whole mortality among the whites; and one in 2.06 of the whole mortality among the blacks. The pulmonic disease among the black troops was almost exclusively phthisis, which attacked them chiefly in the more elevated situations of the interior of the islands, where the heat is least oppressive, and where the Europeans were most free from the diseases which, to them, are in that climate most fatal."—(*Trans. Med.-Chir. Soc. Edin.*, vol. i., p. 398.)

On this account we can readily see whence, in numerous instances, a residence in the warmer regions of Europe proves remedial to occasional visitors from colder and less genial countries, although the tables of mortality do not show a much greater immunity from consumption among the natives than exists in higher latitudes. Negroes and Hindoos are by no means exempt from this disease; and we shall presently have to notice, that the southern borders of the Mediterranean give proofs of a frequency and fatality that would be sufficient to deter strangers from trying those coasts as a cure, did not daily observation justify our recommending them to patients of a more northerly origin.*

* An exact comparative view of the degree in which consumption prevails in different parts of the world, has not yet been satisfactorily obtained. According to Laennec, the complaint is very rare among the natives of high mountainous countries, particularly the Alps. Dr. Forbes thinks it tolerably well made out, that, in the most northern parts of Europe, particularly Russia, and still more conspicuously between the tropics, the disease is

* Trotter's *Medicina Nautica*, vol. iii., p. 325. While Laennec partly admits the truth of the statement respecting the effects of vicissitudes of temperature, he observes, that too light clothing, and the impression of cold, when the body is heated, much more frequently give rise to catarrhs, peripneumonies, and pleurisies, which are not followed by the tubercular disease; so that he concludes that phthisis, when it follows these complaints, has been merely accelerated by them, the tubercles having previously existed. In opposition to Dr. Trotter's account, Laennec says, that most naval surgeons whom he has conversed with, inform him that they had scarcely ever known a man become phthisical in the course of a long voyage, and that they had frequently seen sailors who had pulmonary complaints at the time of putting to sea, return benefited or cured.—Op. cit., p. 352.—Ed.

† If we examine the official records of mortality, we shall find that consumption annually destroys its thousands in the United States also. The statistical tables of Dr. Emerson, of Philadelphia, present the following as the relative number of deaths by consumption in the principal cities of the union. Deaths by consumption in proportion to the whole mortality—New-York, 1-5.23; Boston, 1-5.54; Baltimore, 1-6.21; Philadelphia, 1-6.38. Number of deaths in proportion to the population—New-York, 1-39.36; Baltimore, 1-39.17; Boston, 1-44.93; Philadelphia, 1-47.86. The number of deaths by consumption in the city of New-York during the last seven years, is nearly eight thousand.—D.

‡ Woolcombe (Dr. W.), remarks on the Frequency and Fatality of Diseases, 8vo., London, 1808. Southey (Dr. H. H.), Observations on Pulmonary Consumption, 8vo., Lond., 1814.

Where a consumptive diathesis has once originated, it is often very evidently transmitted to succeeding generations; and there is great reason to believe that the disease is in a certain degree contagious. M. Portal, and a few other pathologists of distinction, have doubted or denied that it possesses any such property; but the apparent instances of communication among near relations and close attentive nurses, and especially between husbands and wives, who have fallen victims to it in succession, are so frequent, that its contagious power has been admitted by most practitioners, and in most ages. Aristotle appeals to it as a matter of general belief among the Greeks in his day (*Problem*, sect. i., 7); and it has since been assented to in succession by Galen, Morton, Hoffmann, Vogel, Desault, Morgagni, Darwin, and most modern writers.*

I have myself been witness to various cases which could not be ascribed to any other cause; and Dr. Rush has given an account of a consumption manifestly contagious, which spread from the proprietors of an estate among the negroes, who were neither related to the first victims, nor had been subjected to fatigue or anxiety on their account, and among whom it scarcely ever makes its appearance.—(*Medical Inquiries and Obs.*, &c., vol. i., 8vo., Phila., 1789.) The disease, however, is but slightly contagious, admitting it to be so at all; and seems to demand a long and intimate communion, as, for instance, that of sleeping or constantly living in the same room, to render the miasm effective.

[Respecting the contagious nature of phthisis, the editor must take this opportunity of observing, that a belief in it is not entertained in this country: Laennec distinctly affirms, that the disease does not appear to be contagious in France. When the great frequency of consumption, and other pulmonary complaints confounded with it, is fairly considered, the extensive co-existence of such cases, or their continual succession, or seeming transmissions from one individual to another, can be very well accounted for, without unnecessarily resorting to the doctrine of contagion. If one fourth or one fifth of the population die phthisical, such events

considerably less prevalent than in more temperate climates. It is extremely prevalent in every part of Great Britain, Germany, France, Italy, Spain, and in the islands and on all the coasts of the Mediterranean sea. Laennec believed the inhabitants of maritime situations to be less liable to consumption than those who reside away from the sea; but in England this is not found to be the fact.—See note by Dr. Forbes, in Laennec's *Treatise*, p. 324.—Ed.

* In Languedoc, Spain, Portugal, Italy, and Malta, phthisis is yet regarded as contagious. When the editor was in the latter island, many years ago, a consumptive person could hardly procure a lodging for money; and in Spain and Portugal, the clothes of persons who die with consumption are burned by the civil authorities. Morgagni was so frightened about its contagiousness, that he would not open the bodies of those who died of it.—Ed.

must of course be frequent. Is it meant to insinuate that all phthisical diseases are contagious, notwithstanding the wide difference in their nature, even as viewed by the author of the present work? Or is it intended to limit the doctrine exclusively to tubercular consumption?]

The diathesis strictly consumptive is usually associated, in the language of Hippocrates (*Epidem.*, v., p. 1142) and Aretæus (*Chron.*, Diss. i., 10, 12), with a smooth, fair, and ruddy complexion, light or reddish hair, blue eyes, a long neck, a narrow chest, slender form, and high shoulders, or, in the words of Hippocrates, shoulders projecting like wings, and a sanguine disposition. In some instances, however, the skin is dark, and the hair almost black.* According to Dr. Withering and Dr. Darwin, the most constant mark of a consumptive habit is an unusual magnitude of the pupil, to which some have added long and dark eyelashes; but this last character seems loose and unestablished. It is a remark far better supported, that the teeth are peculiarly clear, and the eyes exceedingly bright; and that both become more so when the disease has once commenced its inroad; the former assuming a milky whiteness, and the latter a pearly lustre.

Professor Camper, and most physicians with him, affirm that this appearance accompanies all the varieties of the disease; but Dr. Foart Simmons limits it to the tubercular alone, and conceives it to be a distinguishing characteristic of this form of the disease, or of a predisposition to it. And he remarks further, that, of those who are carried off by tubercular phthisis, the greater number will be found never to have had a carious tooth.—(*Practical Obs. on Consumption*, 8vo., London, 1779.)

The earliest symptoms of phthisis, in whatever manner excited, are insidious, and show themselves obscurely. The patient is, perhaps, sensible of an unusual languor, and breathes with less freedom than formerly, so that his respirations are shorter and increased in number. He coughs occasionally, but does not complain of its being troublesome, and rarely expectorates at the same time; yet, if he make a deep inspiration, he is sensible of some degree of uneasiness in a particular part of the chest. These symptoms gradually increase, and at length the pulse is found quicker than usual, particularly towards the evening; a more than ordinary perspiration takes place in the course of the night; and if the sleep be not disturbed by coughing, a considerable paroxysm of coughing takes place in the morning, and the patient feels relaxed and enfeebled. This may be said to form the first stage of the disease; and it is the only hopeful season for the interposition of medical aid.

The malady is now decidedly established,

* Nearly two thirds of the consumptive patients seen by Dr. S. G. Morton, have had dark eyes and hair, and sallow or dark complexions, and many of the remainder had reddish hair and a sandy complexion.—(See his *Illustrations of Pulmonary Consumption*, &c., Philadelphia, 1834.)—D.

the cough increases in frequency, and from being dry is accompanied with a purulent mucus, varying, according to the peculiar modification of the disease, from a watery whey-like sanies, occasionally tinged with blood, to a sputum of nearly genuine pus: which, as Aretæus has well observed, may be livid, deep black, light brown, or light green; flattened or round; hard or soft; fetid or without smell.* In many cases it is very scanty; and we may also add, with Aretæus, that, in some consumptions, there is no expectoration at all: for in the apostematous variety, the sufferer has sometimes died before the vomica has broken. The uneasiness in the chest, only perceived at first on making a deep inspiration, is now permanent, and attended with a sense of weight;† the hectic fever has assumed its full character; the patient can only lie with comfort on one side, which is usually the side affected; and the breathing, as Bennet has remarked, is frequently accompanied by a sound like the ticking of a watch. The strength now fails apace; the pulse varies from about a hundred to a hundred and twenty or thirty; the teeth increase in transparency, and the sclerotica of the eye is pearly-white; "the fingers," to continue the elegant description of Aretæus, as given by Dr. Young, "are shrunk, except at

* In the earliest stage of the disease, according to Dr. Forbes's valuable description, the cough is either quite dry, or attended by a mere watery, or slightly viscid, frothy, and colourless fluid. This, on the approach of the second stage, gradually changes into an opaque, greenish, thicker fluid, intermixed with fine streaks of a yellow colour. At this period, also, the sputa are sometimes intermixed with small specks of a dead white, or slightly yellow colour, varying from the size of a pin's head to that of a grain of rice. After the complete evacuation of the tubercles, the expectoration puts on various forms of purulency; but frequently assumes one particular character, which has always appeared to Dr. Forbes pathognomonic of phthisis, although he says it has been noticed by other pathologists in simple catarrh. This expectoration consists of a series of globular masses, of a whitish yellow colour, with a rugged woolly surface, and somewhat like little balls of cotton or wool. They commonly, but not always, sink in water. They are most common in young scrofulous subjects, in whom the disease is hereditary. At other times, in cases where these globular masses are observed, and also in those in which they have not appeared, the expectoration assumes the common characters of the pus of an abscess, with an occasional tinge of red, and sometimes more or less fetor.—See Laennec, by Forbes, note, p. 352, 2d edit.

† The researches of M. Louis tend to support the opinion, that the pain in phthisis depends upon slight chronic pleurisies, which occasion the adhesions found after death, and not upon the tubercles.—(Recherches, &c., p. 205.) As, however, one direct effect of tubercles in the lungs is to lessen the capacity of these organs for the air of respiration, and to diminish that surface by which the purposes of breathing are accomplished, it is difficult to conceive this approach to suffocation, slow as it is, unattended with more or less uneasiness and pain. The tubercular matter itself, being unorganized, cannot, of course, be susceptible of pain.—Ed.

the joints, which become prominent: the nails are bent for want of support, and become painful; the nose is sharp, the cheeks are red, the eyes sunk, but bright, the countenance as if smiling; the whole body is shrivelled; the spine projects, instead of sinking, from the decay of the muscles; and the shoulder-blades stand out like the wings of birds."

The third stage is melancholy and distressing, but usually of short duration. It commences with a depressing and colliquative diarrhœa; but, till this period, and occasionally indeed through it, the patient supports his spirits, and flatters himself with ultimate success, while all his friends about him are in despondency, and find it difficult to suppress their feelings. The voice becomes hoarse, the fauces aphthous, or the throat ulcerated, with a difficulty of swallowing. Dropsy, in various forms, now makes its approach; the limbs are anasarctous, the belly tumid, or the chest fluctuating; and the oppression is only relieved by an augmentation of the night-sweats or of the diarrhœa; for it is generally to be found, that the one set of symptoms is less as the other is greater. "A few days before the patient's death, he is frequently unable to expectorate from apparent weakness, and sometimes dies absolutely suffocated: but much more commonly the secretion of pus, as well as the expectoration, has ceased: as if the capillary arteries had lost their power, or the fluids of the system were exhausted. There is also sometimes a degree of languid delirium for some days, and occasionally a total imbecility for a week or two: though, in general, the faculties are entire, and the senses acute, the patient being perfectly alive to the danger and distress of his situation, and retaining, even when his extremities are becoming cold, a considerable quickness of hearing and feeling. The closing scene is often painful, but it sometimes consists in the gradual and almost imperceptible approach of a sleep which is the actual commencement of death."—(Young on Consumptive Diseases, p. 28.)

[One very frequent symptom is not noticed in the preceding account: the editor alludes to a sore oppressive sensation in the throat, attended with a feeling as if an extraneous mass were lodged in the larynx, and generally accompanied by more or less difficulty of swallowing. In numerous cases seen by him, this symptom occurred a few days before death: it depends upon ulceration within the larynx, which is often noticed on dissection.]

In the dissections performed by M. Louis, the mucous membrane of the trachea was found either red, or somewhat thickened and softened, in one fifth of the cases, and ulcerated in rather less than one third, while the larynx and epiglottis were ulcerated in one fifth. According to Bayle, the proportion is one sixth, and to Andral, three fourths. The ulceration of the larynx, and more particularly of the trachea and epiglottis, is deemed by M. Louis peculiar to phthisis. Dr. Bright says, it is generally betrayed by the hoarseness of the voice, and the clanging sound which accompanies the cough. The most usual

seat of it, he observes, is immediately below the rima glottidis, where it begins with one or two very small round ulcers, which soon extend, and become irregular in form, assuming the appearance of superficial abrasion. The situation and extent, however, vary a little: sometimes the epiglottis itself is ulcerated, and, occasionally, small independent ulcers take place in the mucous membrane of the trachea, two or three inches below the larynx. When the ulceration in the larynx has taken place early, it has not unfrequently, according to Dr. Bright, drawn the attention both of the patient and the practitioner from the more important seat of disease; for the irritation and uneasiness occasioned by it is more forced upon the attention than the inconvenience and dyspnoea, seldom amounting to pain, which accompany the tubercular deposit in the lungs.—(See *Bright's Reports of Medical Cases*, p. 149, 4to., Lond., 1827.)]

Such is the common progress and termination of the disease; but it varies considerably in the character and combination of its symptoms, and particularly in the tardiness or rapidity of its march, according to the habit or idiosyncrasy of the individual, or the variety of the disease itself. Where the constitution is firm, and the hereditary predisposition striking, it commonly assumes the apostematous form, and runs on to the fatal goal with prodigious speed, constituting what among the vulgar is called, with great force of expression, a galloping consumption. In this case, the activity of the lymphatic, and, indeed, of every other part of the general system, is wonderful: the whole frame is in a state of estuation, and greedily preying upon itself. The animal spirits are more than ordinarily recruited, and all is hope and ardent imagination; the secretions play with equal vigour, and the skin is drenched with moisture; the bronchial vessels are overloaded with mucus, vomica after vomica becomes distended with pus, and the bowels are a mere channel of looseness. The absorbents drink greedily; and animal oil, cellular membrane, parenchyma, and muscle, are all swallowed up and carried away, till every organ* is rapidly reduced to half its proper

* This statement should be qualified: it is true, as Laennec explains, that the greater number of phthisical subjects, before they die, fall into that extreme degree of emaciation, from which the Greeks derived the name of the disease. This emaciation is strongly marked in the adipose cellular membrane and muscles, but, with the exception of the heart, *not at all in the internal organs*. The intestines may appear contracted, but this is chiefly owing to their containing very little air. The brain, nerves, genital organs, spleen, pancreas, and other glands, present no marks of emaciation. The bloodvessels usually seem dwindled, owing to the quantity of the circulating fluid having been reduced by copious evacuations and low regimen. The bones are not at all shortened; but Laennec thought that he had frequently noticed, in protracted cases, a diminution of their diameter, and their specific gravity is certainly lessened. The narrowness and contraction of the chest are known to everybody.—(See *Laennec*, by *Forbes*, p. 286, 2d edit.) With regard to the heart, the statement of Andral is different from that above given; for

weight and bulk, and the entire figure becomes a shrivelled skeleton. So swift was the progress of the disease in the case of the Dutchess de Pienne, that M. Portal informs us she died in ten or twelve days from the first alarm.

If, before this, an extensive vomica burst suddenly and with a wide opening into the trachea, or larger bronchial tubes, suffocation follows instantly. If its aperture be small, a purulent matter, often diversicoloured, is expectorated in the course of a violent fit of coughing: the expuition then ceases for a few days, and, at times, with an apparent relief to the patient; but it returns in a short time, and is always ushered by an increase of the febrile state for the preceding four-and-twenty hours. The breath now becomes tainted, and is offensive to by-standers; the appetite is lost, and the lightest foods and most desirable dainties produce a sense of increased languor and anxiety. The patient becomes daily more emaciated: all the symptoms just noticed are exacerbated, till, at length, a supervening colliquative diarrhoea first diminishes, and then totally suppresses the expectoration, and the sufferer turns himself unexpectedly on his back, and, in a very few days afterward, draws up his legs, and, in this position, usually expires suddenly.

[A tuberculous cavity sometimes opens into the pleura. In the cases recorded by M. Louis, the rupture was indicated by an instantaneous acute pain at one point of the chest, with dyspnoea and extreme anxiety, followed by the common symptoms of acute pleurisy, and death within a period varying from one to thirty-six days. "In every case of this kind," says Dr. Forbes, "the diagnosis derives unerring certainty from auscultation and percussion." In five of the cases described by M. Louis, the perforation took place opposite the angle of the third and fourth ribs of the left side, and it did the same in a case attended by Dr. Forbes.—(See *Laennec*, by *Forbes*, p. 341; and *Louis sur la Phthisie*, ch. vii., p. 446.)]*

On other occasions the march of the consumption is remarkable for its tardiness. This is particularly the case with the tubercular variety, when not quickened in its pace by returns of hæmoptysis. Hoffmann gives instances of two or three who lived under the disease for

he observes, that although, in several diseases which carry off the patients in a very emaciated condition, the heart partakes of the atrophy of the rest of the muscular system, this is not constantly the case, and the hearts of many consumptive persons, who die in the extreme of marasmus, are quite free from atrophy. If, in such a case, the heart should appear diminished in size, it is because, being empty of blood, it has contracted; its cavities are small, but its parietes are of their natural thickness.—Andral, *Anat. Pathol.*, tom. ii., p. 288.—Ed.

* Dr. Morton, in his valuable *Illustrations of Pulmonary Consumption* already cited, has figured a case (Pl. viii., ix.), in which pus passed between two ribs, infiltrated into the muscles of the back where a large abscess formed, by which the spinous processes of several vertebræ were exposed.—D.

thirty years :* and in the Edinburgh Communications is the case of an individual, who passed nearly the whole of a long life under its influence, who was consumptive from eighteen to seventy-two, and died of the complaint at last. Of two hundred cases, however, selected by M. Bayle, a hundred and four died within nine months, which may hence be regarded as the mean term.

Dissections concur in showing, in almost every instance, an indurated and ulcerated state of the lungs, while the changes thus exhibited vary greatly in the morbid structure they develop; the more obvious of which, though perhaps constituting the two extremes of these changes, are the white and the dark-coloured or hepatized knobs. The first seems to move forward to a state of inflammation with a slow and pausing step, and forms the basis of the tubercular variety before us. The second is more rapid and uniform in its action, and constitutes the catarrhal or purulent modifications. While, not unfrequently, we meet with both these appearances intermixed in every possible proportion. Yet we perceive, concurrently with the diagnostics of the disease, that its most frequent form is the tubercular; so much so, indeed, that M. Laennec has confined his attention to this variety alone, and will hardly admit of any other.—(*De l'Auscultation Médiate; ou Traité du Diagnostic des Maladies des Poumons*, &c., 2 tomes, Paris, 1819.) The tubercles are found indiscriminately in all parts of the cellular texture of the lungs, but more abundantly at the upper and posterior parts. As already observed, they exhibit every diversity of size; are often very minute, but more generally consist of those circumscribed nodules or indurations which Wesser has called *granulines*. They are whitish and opaque, like small absorbent glands, but sometimes more transparent, like cartilage, with black dots in their substance. They augment by degrees, till they are half an inch or more in diameter; but in general, when they have acquired the size of large peas, they begin to soften in the centre, and then open by one or more small apertures into the neighbouring bronchiæ, or remain for a longer time closed, and constitute small *vomicæ*, containing a curdy half-formed pus. Occasionally, as we have stated, they are found to unite into large abscesses.† [Whatever be the form under which the tubercular matter is developed, it presents at first, according to Laennec,‡ the

appearance of a gray, semi-transparent granulation, which gradually becomes yellow, opaque, and very dense. Afterward it softens, and gradually acquires a fluidity nearly equal to that of pus. It is then expelled through the bronchiæ, and cavities are left, vulgarly called *ulcers of the lungs*, but which Laennec designated *tubercular excavations*.] Now as we have before observed from Dr. Baillie, that nothing like a gland is to be found in the cellular membrane of the lungs in a sound state, constituting the seat of these tubercles,* and as scrofula selects for its abode a glandular structure, tubercular consumption cannot perhaps with strict propriety be called a scrofulous disease; yet as the untempered fluid contained in the tubercles resembles that of scrofula, and, more especially, as this variety of consumption is very generally found in constitutions distinctly scrofulous, the analogy between the two is extremely close, and has often led to a similar mode of treatment. M. Portal, indeed, contends that glands exist in great numbers through the whole structure of the lungs, but rather from analogy than from demonstration. And to the same effect M. Laennec; "The

noticed in lymphatic glands, in which a tubercle can be examined in every stage of its progress? Have they ever been seen in the brain, liver, spleen, or the cellular tissue under mucous or serous membranes, or between the muscles? The small, grayish, irregularly globular bodies, dispersed sometimes over the free surface of serous membranes, he contends, are as different as possible from ordinary granulations of the lungs. As for the grayish granulations, sometimes noticed on the surface of mucous membranes, they seem to Andral to be merely enlarged follicles. At the same time, he admits that tubercular matter may be formed within granulations of the lungs.—*Anat. Pathol.*, tom. i., p. 411.—Ed.

* This doctrine does not coincide with Andral's observations, whose researches lead him to consider tubercles as a secretion, which may take place indifferently, either in the ultimate bronchial tubes and air-cells, in the cellular tissue interposed between these, or in the interlobular cellular texture. He inclines to the opinion, adopted also by Professor Carswell, that the tubercular matter is at first liquid, and afterward becomes solid; and that a congestion, and even inflammation, are often concerned in giving rise to their production. "Observation proves," says he, "that the tubercular matter may be deposited on the surface of the mucous lining of the bronchiæ or air-cells, or in the cellular tissue uniting together the different parts of the lung." M. Magendie, and subsequently M. Cruveilhier, promulgated the opinion, that tubercular matter might be formed in the ultimate ramifications of the bronchiæ; and Andral confirms its truth by various facts, and, among others, by the appearances found in the lungs of a glandered horse. Andral also proves, by dissection, that tubercles may sometimes occur primarily in the lymphatic glands within the lungs; and he relates two rare instances, in which the tubercular matter filled the superficial lymphatic vessels of the lungs, and, in one of the cases, the lymphatics of other parts, and likewise the thoracic duct.—(*See Clinique Méd.*, tom. iii., p. 13-20.) The corroboration of Andral's views by Professor Carswell's observations, as given in his *Illustrations of the Elementary Forms of Disease*, fasc. i., has been noticed in the foregoing pages.—Ed.

* In 1828, a person named Robert Jeffries, aged 56, died in the Fleet prison, who had had a cough and shortness of breath for thirty years, and whose lungs were found, after death, filled with tubercles and abscesses.—Ed.

† Young, ut supra. Portal, *Observations sur la Nature et le Traitement de la Phthisie*. Bayle, *Recherches sur la Phthisie Pulmonaire*, Paris, 1810.

‡ On Diseases of the Chest, by Forbes, 2d edit., p. 272. Andral objects to Laennec's view, that if a tubercle necessarily began as a grayish semi-transparent granulation, this would be found in every situation where tubercles are met with. But, he asks, have such granulations ever been

tubercles in the lungs," says he, "differ in no respect from those situated in the glands; and which, under the name of scrofula, after being softened and evacuated, are often followed by a perfect cure." Here, however, the hollows are not incased or filled up with a new material, but have their surfaces covered with a semi-cartilaginous membrane, which, as they thus heal, leave as many sound fistulæ as there were formerly tubercles.

In some cases, proper abscesses or larger vomicae are found without any trace of tubercles: and especially when the disease has rapidly followed peripneumony, or taken place in persons of robust or plethoric habits. And when the catarrhal symptoms have been striking, and, in the increasing hoarseness and free discharge of muculent pus, have evinced extensive inflammation on the surface of the trachea, M. Portal has found the whole extent of the tube lined by a crust resembling bone. In some instances, the lungs, from the accretion of new matter, have weighed not less than five or six pounds, which is nearly four times their ordinary weight; but, in others, they have been so reduced as, in the language of the same writer, to leave "a vacant space" in the chest; or, in that of M. Bayle, "to be shrivelled into leather." On this account, breathing would be impossible, if it were not that the lungs in a state of health are capable of containing ten times as much air as is received by an ordinary act of inspiration; and hence are capable of losing a very large portion of their capacity without suffocation. In some cases, one lung has been entirely destroyed, and the office of respiration maintained by the remaining lung alone for many years.—(*Boneti Sepulchr.*, lib. i., sect. ii., obs. 167; *Parotti. Raccolti d'Opuscoli Scientifici*, xlv., p. 275.) In other cases, blood, and even pins have been thrown up from time to time in considerable quantities without the least trace of ulceration, or breach of continuity in the membrane, or any part of the structure of the lungs.—(*De Haen, Ratio Med.*, i., xi., p. 60; *Willan's Reports*, 1796, March 20.)

[Laennec has particularly invited the attention of practitioners to the successive development of tubercles in different parts of the lungs, as very important in a therapeutical point of view. Tubercles, he says, begin to show themselves in the first place, almost always in the top of the upper lobes, more particularly the right; and it is in these points that tubercular excavations of large size are most commonly met with. M. Louis coincides with Stark in stating, that such excavations are nearer the posterior than the anterior part of the lungs. According to Laennec, it is by no means unfrequent here to meet with cavities of this kind, when the rest of the lungs is quite sound, and does not contain a single tubercle; but, in this class of cases, the symptoms have only been equivocal, and the patient has died of some other disease. It is much more usual, however, to find one single excavation and several crude tubercles, in a pretty advanced state, in the upper part of the lungs; and the remainder of

these organs, though still crepitous, and in other respects sound, crowded with innumerable tubercles of the miliary kind, extremely small, semi-transparent, and hardly any of them with the yellow speck in the centre. This secondary crop of tubercles Laennec represents as being produced about the time when the first set begin to be softened. A third, still later crop, composed of crude miliary tubercles, with some yellow points in their centre, is situated still lower, and, finally, the basis and inferior edge exhibit the most recent formation of all.—(*Op. cit.*, p. 282.)

The preceding account, given by Laennec, of the greater frequency of tubercles in the right than the left lung, does not agree with the statements of other distinguished pathologists. Of thirty-eight cases, in which M. Louis found one upper lobe wholly disorganized, twenty-eight were on the left side; of eight cases of perforation, seven were on the left side; and of the seven cases in which the tubercles were confined to one lung, five were on the left side.—(*Recherches sur la Phthisie Pulmon.*, p. 7, et seq.) According to Stark, the left lungs are more frequently affected than the right; an observation agreeing with the researches of Dr. C. Smyth.—(See note by Forbes in *Laennec*, p. 283.) The secondary production of tubercles is not confined to the lungs; and, at the period when the first crop is being softened, others make their appearance in various other organs. In fact, it is observed by Laennec that it is very rare in phthisical subjects to find these bodies only in the lungs; they almost always exist at the same time in the coats of the intestines, where they give rise to ulcers, which become the cause of the colliquative diarrhoea so often accompanying phthisis.—(*Op. cit.*, p. 284.) With respect to the origin of intestinal ulcers, as described by Laennec and Dr. Bright, Andral admits that it may be the case in some instances but he contends that it is not so in all; for he has examined the bodies of several phthisical subjects, where the intestines presented an infinite number of ulcers, yet without any appearance countenancing the idea that they had originated in tubercles under the mucous membrane.—(*G. Andral, Anat. Pathol.*, tom. ii., p. 95.) In five sixths of the cases adverted to by M. Louis, the small intestines were more or less ulcerated. The ulcers were also nearly as frequent in the large intestines, the whole, or a great portion of the mucous membrane of which, in one half of the cases, although often red and thickened, was as soft as mucus. In only three cases did M. Louis find the large intestines universally healthy.—(*Louis, Recherches Anat. Pathol. sur la Phthisie*, p. 175, Paris, 1825.) In sixty-seven cases out of a hundred, Bayle also found the intestines in a state of ulceration; while Andral's dissections* con-

* Andral, *Clinique Méd.*, tom. iii., p. 306. In his latter publication he remarks, that in phthisis the digestive canal is so commonly unsound, that this state may be considered, in some measure, as one of the elements of phthisis, and almost a constitu-

firm all these reports by the fact, recorded in his most valuable work, that the intestines were perfectly sound in only one fifth of all the numerous cases under M. Lermnier in La Charité. The morbid changes in the mucous membrane of the intestines in phthisis are particularly noticed by Dr. Bright. They are denoted, he says, by unequivocal symptoms during life, and are traced in two different forms after death; "sometimes giving proof of a diffused irritation along the whole membrane from the pylorus to the termination of the rectum, evinced by increased vascularity, or by the appearance of innumerable minute black specks, which give a general gray colour to all the parts where they are most frequent; and sometimes affording evidence of a more severe affection, by the formation of numerous ulcers, which are found sometimes in the upper part of the duodenum, frequently dispersed along the whole course of the small intestines, but usually most abundant about the valve, and through the whole extent of the colon. These ulcers, as found in the small intestines, are usually, in the first place, very small and circular, and appear to originate from round, opaque, white bodies, about the size of half a sweet pea; but, whether these are altogether morbid tubercles, or are only enlarged mucous glands, it is no easy matter to decide. Certain it is, that they are most generally placed in that part of the circumference of the intestines which is most distant from the mesentery, and where the mucous follicular structure is most developed."—The ulceration of the large intestines is, according to Dr. Bright, most conspicuous about the cæcum and valve of the colon, where it also begins, as in the small intestines, by opaque deposits; but the disease proceeds to a much greater extent, sometimes involving the cæcum in one continued ulcer, and occasionally, though rarely, affecting the lining of the vermiform process itself. In the colon, the ulcers are generally oval, with elevated edges, and more or less distributed along the sides of the longitudinal bands. They are frequently found as low as the sigmoid flexure, and sometimes even in the rectum. They appear to Dr. Bright occasionally to undergo a healing process, their tubercular edges becoming softened down, and their flattened edges adhering

ent part of it. In about four fifths of consumptive patients who die in an advanced stage of this disease, the intestines are found seriously affected. Ulcerations are the most common change in them, and ordinarily situated at the end of the small intestines, and in the cæcum. Varying in number, shape, and size, and occupying (though not constantly) the follicles of Peyer, they are produced most frequently without pain, and occasion merely a more or less copious looseness. Even in the very commencement of phthisis, it is not uncommon to observe slight marks of intestinal irritation, alternations of constipation and diarrhoea, the latter gradually becoming permanent, like the lesion on which it depends.—(*Anat. Pathol.*, tom. ii., p. 222.) The great opportunities which I have had of observing the progress of phthisis in the branches of the public service with which I am connected, lead me to recognise fully the truth of these valuable observations.—Ep.

to the parts denuded by ulceration; but he states that this is not a frequent occurrence, because the more usual course of phthisis is to go on from worse to worse till it terminates in death; and little attempt is made by practitioners to change the condition of the intestines, while they consider the more urgent disease to be in another organ.—(*Reports of Medical Cases*, p. 151, 4to., Lond., 1827.) Sometimes, when phthisis is accompanied by numerous ulcerations of the intestinal canal, one of them makes its way completely through the bowel, and the immediate cause of the patient's death is peritonitis.—(*G. Andral, Anat. Pathol.*, tom. ii., p. 106.) The inflammation thus excited in the peritoneum is generally acute and rapidly fatal; but sometimes of a chronic character, with symptoms of slower progress. Thus, Andral says, he can never forget the case of a consumptive young man, from whose navel, one day, an ascaris lumbricoides was discharged. He lived several weeks after the occurrence, the fistulous opening daily emitting a small quantity of matter resembling what the intestines usually contain. Examination of the body after death disclosed the existence of chronic peritonitis, with numerous pseudo-membranes, between which were formed several worms of the above kind, floating in the extravasated matter, some of which issued from the navel every day.—(*Op. cit.*, vol. cit., p. 114.)

Besides the morbid appearances already mentioned as often complicating phthisis, are to be enumerated a softening of the mucous coat of the stomach, and frequently a general attenuation of all its coats; but, according to Andral, it is not usual to meet with ulcerations or tubercles in it (*Andral, Anat. Pathol.*, tom. ii., p. 222), an increased vascularity and softened state of the brain, and disease of the absorbent glands of the bronchiæ and mesentery. In phthisical persons, the cartilages of the ribs and larynx are observed to become prematurely ossified.—(*Andral, Anat. Pathol.*, tom. i., p. 300.)

Many ingenious experiments have been invented to distinguish between pus and mucus, in order to determine the actual nature of the disease. Such trials may gratify the curiosity of the pathologists, but from the variable and frequently complicated nature of the expectoration, as well in the most dangerous as in the earlier stages of the complaint, we can derive little assistance from this distinction. Mr. Hunter, as a test, employed muriate of ammonia, having observed that a drop of pus, united with a drop of this fluid, is rendered soapy, while neither blood nor mucus is affected by it.—(See *Apostema Commune*, vol. i., 503.) Mr. Charles Darwin—

"Heu miserande puer! si quâ fata aspera rumpas
Tu Marcellus eris!"—

proposed a double test of sulphuric acid and a solution of pure potass. If, on the addition of water to pus dissolved in each of these separately, there be a powerful precipitation, the matter made use of is determined to be pus; if there be no precipitation in either, it is mucus. But the simplest and truest character of pus, as was first observed and described by Sir Everard

Home, is, that it is a whitish fluid composed of globules contained in a transparent liquid; that it does not coagulate by heat; and is only condensed by alcohol. The presence of the globules, as remarked by Dr. Young, may be easily determined by putting a small quantity of the liquid between two pieces of plate-glass. If it be pus, we shall perceive, on looking through it towards a candle placed a little way off, the appearance, even in the daytime, of a bright circular corona of colours, of which the candle will be the centre; a red area surrounded by a circle of green, and this again by another of red; the colours being so much the brighter, as the globules are more numerous and more equable. If the substance be simply mucus, there will be no rings of colours; though a confused coloured halo may sometimes be perceived by the mixture of mucus with blood or some other material.

As, however, consumption is by far more frequently a tubercular than a strictly purulent disease, and, perhaps, more generally fatal under the former than under the latter modification, the distinction here sought for is of less importance. It is of more consequence to ascertain whether morbid excavations from any cause, ulcerative or tubercular, have taken place at all; and to this point the attention of physicians has been peculiarly directed, for the purpose, if possible, of obtaining a criterion.

It is now well known that M. Avenbrugger of Vienna suggested, more than half a century ago, the possibility of determining whether there were such morbid hollows, or other diseased condition of the chest, by the means of percussion by the hand (*Inventum Novum ex Percussione Thoracis Humani*, Vienna, 8vo., 1761); and that M. Corvisart was so much impressed with the importance of the suggestion, that he not only translated Avenbrugger's work on the subject from the German into the French tongue, but recommended his method warmly in his Clinical Lectures, and employed it so generally in his practice as to obtain for it a considerable degree of reputation. There is no doubt of its giving us a correct information at times: but the whole process is accompanied with difficulties which we shall notice presently, and its application is also of limited use. To remedy these evils, M. Laennec, from an early period of his life, conceived it possible to attain the same end, and with much greater exactness, by an acoustic instrument.* His mind was directed

to the fact, that if the ear be applied to one end of a beam of wood, we may distinctly hear the scratch of a pin when made at the other end: and, taking advantage of this hint, he first made a roll of a sheet of paper, wound up close, and well tied, when "applying," says he, "one end of it to the region of the præcordia, and placing the ear at the other end, I was as much surprised as gratified on hearing the heart beat more clearly and distinctly than I had ever done by a direct application of the ear itself." And hence he foresaw that the same instrument might also be employed to ascertain a variety of modifications in the pulsation of the heart and the larger arteries.

Having experimented upon a series of substances, he found that bodies of such a density as folded paper, wood, or cane, were best calculated for the purpose; and he at length fixed upon a cylinder of wood of a foot long, and an inch and a half in diameter, with a bore or canal in the centre three lines in diameter. To render this instrument more portable, he made it divisible in the middle, like a German flute, the parts, however, being united by a screw.

When this cylinder, to which he gives the name of a *stethoscope*, is applied to the chest of a healthy person in the act of speaking or singing, nothing is heard but a kind of low murmuring, more distinct in some parts of the chest than in others: yet where an ulcer or other morbid excavation exists in the lungs, a very singular change takes place; for the voice of the invalid is no longer heard by the disengaged ear, but comes entire to the observant ear that is applied to the end of the cylinder opposite to that affixed to the chest. This phenomenon M. Laennec ascribes to the greater degree of strength which the vocal sound exercises in a cavity of wider calibre than the bronchiæ themselves. And the opinion is rendered probable as the same phenomenon occurs when the cylinder is applied to the trachea or larynx. To this apparent transfer of the voice to the chest, the experimenter has given the awkward name of *pectoriloquism*, or *mediate auscultation of the voice*. And as the same instrument, or with slight variations, is capable of determining the morbid changes that take place in the breathing or contraction of the heart, he hence employs it in like manner to obtain a *mediate auscultation of the respiration*, or of the *pulsation of the heart*, or the *aorta*. For the first of these two purposes, however, the canal should be

* De l'Auscultation Médiate, ou Traité du Diagnostic des Maladies des Poumons et du Cœur, 2 tom., 8vo., Paris, 1819. Two years previously, M. Double had brought out his *Seméiologie Générale*, in which he mentions auscultation as a method peculiar to himself.—(See tom. ii., p. 31.) In the history of auscultation is a curious passage in Hook's *Posthumous Works*, p. 39, who, though not of the medical profession, actually foretold, as Dr. Elliotson has observed, the invention and uses of the stethoscope. The following short biographical notice of Avenbrugger is from the pen of Dr. Forbes:—Avenbrugger was born at Graets in Styria, in 1722. He graduated at Vienna, and afterward became physician in ordinary of the Spanish nation, in the Imperial

Hospital in that city. In Ersh and Puchelt's *Literatur der Medicin*, he is recorded as the author of two other works, relating to madness, one in Latin, published in 1776, and the other in German, in 1783. In the same record, Avenbrugger is stated to have died so late as the year 1809, in the 87th year of his age. The *Inventum Novum* was first translated into French in 1770, by Rozière; but the subject attracted little attention till a second translation was published by Corvisart in 1808. The only English translation came out in 1824, with a selection of Corvisart's Commentaries, and additional notes.—See *Original Cases, &c.*, by John Forbes, M. D., 1824; and art. *AUSCULTATION*, in *Cyclopædia of Pract. Med.*—Ed.

gradually widened at the end applied to the chest, in a funnel-form, to an ascent of about an inch, and then suffered to return suddenly to its general calibre. For the second purpose, the canal should be entirely obliterated, which may be easily done by a plug of the same kind of wood; the pulses being propagated through the cylinder by vibratory chords.*

PERCUSSION and AUSCULTATION are used simultaneously by many physicians in France; they were so by Laennec himself; and their comparative pretensions have been ably estimated in the same country by Dr. Colin (*Des Diverses Méthodes d'Exploration de la Poitrine*, Paris, 1824), as they have in our own by Dr. Forbes.—(*Original Cases*, &c., 8vo., London, 1824.)

The diseases in which the former method is chiefly employed, are phthisis, dropsy of the chest, chronic pleurisy, chronic peripneumony, emphysema of the lungs, pneumo-thorax, or a morbid communication of the interior of the lungs with the thoracic cavity, and hypertrophy of the heart, or a morbid enlargement of its substance.

In the use of this kind of exploration, the patient should be in a sitting posture, the points of the fingers brought close together may be employed, or the flat of the hand, and either upon the naked chest or with the body linen drawn tight over it. The action of percussion is applied, as circumstances may direct, to the forepart of the chest, the sides, or the back. In the first of which cases, the patient is to hold his head erect, and throw back his shoulders, that the chest may be protruded, and the skin and muscles drawn tight over its bones, by which the sound is rendered most distinct. In striking the lateral parts of the chest, the patient is to hold his arms across his head, so that the walls of the thorax may become tense, and the sounds rise distinct, as in the former instance. If the back be operated upon, the patient is for the same reason to bend forward, and draw his shoulders towards the anterior part of the chest, hereby rounding the dorsal region. The degree of percussion is to be varied according to the subject and the place; so that a more powerful impulse is to be employed in a fat or robust, than in a slender and emaciated subject; for the stroke that is sufficient to educe a clear sound in the latter case, may draw forth none in the former.

The amount of the sound must depend upon the general sum of the hollow contained in the chest, as in striking a cask, to which M. Avenbrugger very forcibly compares it. And hence, to determine whether this amount be more or less than it ought, it is necessary we should become first acquainted with its character in a healthy state, and accustom ourselves to the

percussion of those who are well. Its changes from this standard are of three kinds: it may be greater or stronger than natural; dull or obscure; or totally wanting. The first takes place where the cavity or hollow is enlarged, as in emphysema of the lungs, which, so to speak, resembles a cask comparatively empty, or rather containing a large volume of air: the second in œdema of the lungs, severe catarrh, or the earlier stage of peripneumony; in which the interior is more than usually occupied with dense matter: and the third in a tuberculated or hepatized state of the lungs, or when they are crowded with any other morbid secretion or induration, so as to be choked up, and leave no room for resonance.

The chief difficulties attending the diagnostic of percussion, are the long habit required for its use before it can be employed with any advantage, and the peculiar tact or address with which the stroke must be applied to produce its proper effect: the limited power of our having recourse to it in many cases of females, on the score of delicacy; and its occasional uselessness, perhaps deception, in other cases. Thus it is altogether unavailing in patients possessing much corpulence; and, although it affords a pretty clear indication in hydrothorax, when the chest is but partially loaded, and in peripneumony, before suppuration has taken place, yet as no sound is yielded when the chest is quite full of fluid, and a very different sound to what was at first elicited when a vomica has burst, both these diseases may be mistaken in their most important stage. In nervous coughs, asthmas, dyspnœas, and polypous concretions about the heart in young subjects, M. Avenbrugger himself admits the total inefficiency of his method.

The diagnostic of AUSCULTATION has some advantage in most of these respects. It is employed, as we have already observed, for three distinct purposes; as a test of the VOICE, of the RESPIRATION, and of the ACTION OF THE HEART AND AORTA.

When employed for the first purpose, or that of determining the state of the voice, it affords, under different circumstances, four different kinds of measure: as that of its degree of intensity, which M. Laennec has denominated *resonance*; its articulation, to which, as above stated, he has given the name of *pectoriloquism*; its suppression, or under-tone, which, from its supposed resemblance to the voice of goats, he has called *agophonism*; and its vibratory clink, distinguished by the name of *metallic tinkling*. The first of these tests, when existing in a higher tone than natural, is supposed, for the most part, to indicate a certain degree of induration in the substance of the lungs. The second, or that of pectoriloquism, we have already noticed: it is a measurer of tubercular excavations communicating with the bronchia. The third indicates, in the opinion of M. Laennec, a flattening of the bronchial tubes. And the fourth a morbid communication of the interior of the lungs with the cavity of the chest.

Where the stethoscope, or chest-sound, is

* De l'Auscultation Médiate, &c., par R. T. H. Laennec, 1818. For a particular description of the construction of the stethoscope, consult Dr. Williams's Rational Exposition of Physical Signs, ed. 2, 1833. The best maker of stethoscopes that he has been able to meet with, is Grumbridge, turner, 42 Poland-street, Oxford-street.—ED.

employed as a measure of the RESPIRATION, it runs parallel with the modifications of percussion, and determines its intensity, its atony, and its absence; and detects also its combination with foreign sounds. Under the first modification it strikes the ear like the strong and sonorous breathing of children, into which the action of the trachea greatly enters; and on this account, the present modification is distinguished by M. Laennec by the name of *puerile*, or *tracheal*. It occurs especially in cases in which an entire lung, or a considerable portion of both, is rendered impervious to air, and particularly in acute diseases. The modifications of a *weak* or *absent* respiration upon the use of the cylinder indicate a general obstruction in the respiratory organ, and only vary in the degree or extent of such morbid change; and hence, as in the parallel modifications of percussion, they become tests of certain different stages of hydrothorax and peripneumony. The *foreign sounds* with which the cylinder detects the respiration to be occasionally combined, are various kinds of *râle* or *rattle*, to which the inventor of the present method has given the name of *crepitous*, and *subcrepitous*, *mucous*, *sonorous*, *sibilous*. The first, or *crepitous rattle*, is denominated from its resembling in sound the crepitation of salt in a heated vessel, or that emitted by frying butter. It is supposed to be a pathognomonic sign in peripneumony on its first attack, and occurs sometimes in hæmoptysis. The *subcrepitous* is an under-sound of the same kind, and indicates an œdematous state of the lungs. The *mucous rattle* is that peculiar kind of stertor called "the dead rattles" by the vulgar of our own country, though in a less degree of intensity. It is produced by a transmission of the breath through fluids accumulated in the trachea or bronchiæ, and measures the extent of such accumulation in catarrhal phthisis, hæmoptysis, and other important diseases. The *sonorous* and *sibilous* rattle are of less importance as diagnostics, and exhibit considerable ramifications in their character. The former gives sometimes a loud, and sometimes a deep snore, and sometimes the cooing of a wood-pigeon; the latter consists of a whizzing, or whispering tone, or of chirping like that of birds, often alternately ceasing and renewing its murmur. Both descriptions indicate some partial obstruction of the bronchial tubes; the latter perhaps of the smaller cells.

But the method of mediate auscultation is also employed to determine the degree of the STRENGTH AND ACTION OF THE HEART. And it is supposed to do this in four distinct ways: by measuring the extent of the pulsation; its shock or impulse; its sound; and its rhythm.

In a healthy person, of moderate stoutness, and well-proportioned heart, the action of this last organ, upon an application of the stethoscope, is not found to EXTEND beyond the range of the cardiac region, or the space comprised between the cartilages of the fifth and seventh ribs, and under the lower end of the sternum. It is, however, often traced, in a state of disease, through the whole of the left or the right

side of the chest, as well as in the region posterior to them: which is generally owing to the feebleness of the heart, and the extenuation of its walls. It may therefore be taken as a general rule, according to M. Laennec, that a perceptible extent of the heart's action is in the direct ratio of its thinness and weakness, or inversely to its substance and power. A wide range of sound is often, indeed, traced when the heart is enlarged; but in this case its walls are often morbidly slender; and the enlargement consists in a mere dilatation of its ventricles. And hence this diseased extent of action is often traced in particular kinds of a hypertrophy of the organ.

The heart is also frequently found to be hereby affected in the SHOCK OR IMPULSE of its stroke. The stouter and thicker the walls of the heart, the more violent is the impulse, inasmuch that, as we have already had occasion to observe, the bed-clothes have sometimes been seen to be hereby elevated. This impulse is peculiarly caught hold of by the stethoscope: and is in some cases so energetic as even to lift up the observer's head, and to give an unpleasant shock to his ear. In proper hypertrophies, therefore, or such enlargements of the heart as are opposed to the preceding, in which the natural cavities are not much interfered with, and the augment consists altogether in a thickening of the parietes, we have reason to expect the present effect; which, in like manner, becomes a pathognomonic sign of such a disorder, and indicates its existence.

The stethoscope, also, measures the SOUND of the heart's pulsation. When the action of the heart is peculiarly violent, as in vehement palpitations, the individual himself becomes sensible of a peculiar sound, as well as of an increased impulse; and it has, indeed, in a few rare cases, been heard at a distance from the patient's person. Now, the application of the stethoscope heightens the sound of the pulsation considerably at all times, inasmuch that, in its ordinary tenour of health, it communicates a certain degree of sonorous vibration, which cannot be perceived otherwise; the sound, however, produced by the contraction of the ventricles, and which is accompanied by the stroke of the pulse, being much clearer than that produced by the contraction or systole of the auricles, so that there is at all times to the ear of the experimenter a double or alternate sound, consisting of a louder volume succeeded by a lower. The seat of this double sound, in a state of health, is the cardiac region, to which it is limited; but in a state of disease it spreads much wider, and is heard distinctly in other places. The sound, moreover, varies from the standard of health both in intensity and in hebetude. Where the diameter of the heart is enlarged by a dilatation of its cavities, while its walls are weakened and rendered thinner, the sound is loud and distinct; but where, on the contrary, its walls are considerably thickened and enlarged, the cavities remaining but little disturbed, the sound is morbidly dull or obscure; and where the same organic thick-

ening exists in considerable excess, the contraction of the ventricles produces a mere shock or impulse without any sound whatever.

The sound, moreover, is not only varied in its intensity, but in its vibration from a natural state. It is sometimes accompanied with a peculiar hissing, like that of a pair of bellows, and is in this state either continuous or intermittent, indicating, according to M. Laennec, a spasm or some other temporary and partial obstruction of the first organs of the circulating system. At other times, the accompanying noise is like that of a rasp or file; which is always permanent, and evinces a permanent obstruction in some of the orifices of the heart. And in one or two instances, Dr. Colin has observed it combined with a crackling like that of new leather, which he supposes to be a pathognomonic indication of an inflammation of the pericardium, from his having traced this affection in a person who died during its existence.

The stethoscope is also supposed to detect in a peculiar degree the RHYTHM or relative duration and succession of the ventricular and auricular contractions. These are sometimes alternated with considerable but irregular intermissions, and sometimes far too rapid in their succession: both which changes from the rhythm of health indicate that kind of organic affection which is dependant upon delicacy of constitution, and is often congenital. They do not, however, augur the existence of any dangerous or even very serious malady.

It appears from this general outline, that the method of MEDIATE AUSCULTATION may be advantageously applied in one or all its forms to a detection of various important diseases of the chest, and especially to the different varieties of phthisis; that it may be more generally employed than that of percussion, since corpulency will seldom prove a bar to its use; and that it is often more definite in its results.*

Notwithstanding, however, all the ingenuity that it evinces, it must often be found an imperfect guide in deciding on the actual state of a disease, or even indicating the disease itself, to say nothing of the long and repeated experience which is absolutely necessary to its being employed with precision. For, first, it

gives us a very doubtful kind of information concerning the existence of tubercles or vomicae till they have actually broken, and produced numerous excavations, and consequently is of little use in the earlier stages of the disease.* Next, as it has been observed by M. Laennec himself, that some persons have an habitually relaxed state of some of the bronchial vessels, from hooping-cough or chronic catarrh, or a few

* The following information is derived from Professor Elliotson's Lectures:—It is only when the tubercles increase to a certain size, and approximate so as to form a mass, that you can expect any symptoms that are discernible by the ear. You will easily see that this must be the case, when you consider that, in the first instance, the tubercles which constitute this disease are exceedingly small and few, leaving a large portion of pulmonary structure perfectly healthy. The parts in which the symptoms cognizable by the ear are first noticed, are those below the clavicle, and this even before the tubercles have softened; but, when they have become sufficiently large and numerous to occupy some space, you will not find, on striking the part under which such deposit is situated, the hollow sound of health, but a degree of dulness. In proportion to the size of the tubercular deposit, is the dulness of the sound. Then, if you listen with the stethoscope, and make the patient speak, you will find the voice resounds there in an unnatural way, because the solid substance of the tubercles is a much better medium for the conveyance of sound than the loose structure of the healthy lung. The sound, therefore, where the tubercles exist, is louder than elsewhere. You will likewise perceive what is termed *bronchophony*; the same sound you hear on putting the stethoscope over the large bronchiae. But it is to be remembered, that the voice naturally sounds louder under the clavicle than elsewhere, on account of the large tubes being there, and consequently you should not depend on this symptom alone; but, to justify a decided inference that the bronchophony depends upon tubercular deposition, it should be united with the dead sound on percussion. Dr. Elliotson very properly also advises a careful comparison of the sounds perceptible on each side of the chest. When the tubercular mass softens, and a portion is discharged, so that the cavity is emptied, or nearly so, a new symptom presents itself, viz., *pectoriloquy*, or *pectoriloquism*; for, as the bronchial tubes enter this cavity, you hear with the stethoscope the same sound as is heard on putting it over the trachea. If you make the patient cough, you hear a mucous rattle; and, in proportion as more and more of the tubercular matter is spit up, and mere mucus remains in the cavity, the gurgling sound becomes louder and more distinct. In thin persons, pectoriloquy under the clavicles is natural, though no tubercles may exist: it should be heard decidedly in other parts of the chest to be sufficient evidence of the disease. When pectoriloquy is established, the dull sound on percussion ceases. The tubercular solid mass, which gave the dull sound, no longer exists; and the part being now excavated, yields the same hollow sound as in health. It is to be remembered, says Dr. Elliotson, that though you have pectoriloquy, and a large space which ought not to be there, yet the phenomenon does not show the nature of the cavity, and it is only from the general symptoms that you are satisfied it is the cavity of the phthisis. A part of the lungs is sometimes separated by gan-

* For an extensive practical application of this method, see Andral's *Clinique Médicale, ou Choix d'Observations Recueillies à la Clinique de M. Lerminier; Médecin de l'Hôpital de la Charité, Deuxième Partie, Maladies de Poitrine*, 8vo., Paris, 1824; also Colin, *des Diverses Méthodes d'Exploration de la Poitrine, &c.*, 8vo., Paris, 1824. D., *on Diseases of the Heart*, fol.—Ed.

minute excavations in the organ of the lungs, without any serious deviation from a state of ordinary health; as also that patients occasionally recover from the tubercular species of consumption, and have the interior of the hollows or fistulæ hereby produced not filled up, but lined with a semicartilaginous membrane, thus effecting a natural cure,—the phenomenon of pectoriloquism will here be as distinct as in a morbid state of the pulmonary organ, and consequently may often lead the practitioner astray. And, lastly, as the stethoscope is limited, or nearly so, to the ulcerative forms of phthisis, the disease may exist in the catarrhal variety, and still elude its power. For these and other reasons, little dependence is placed on this instrument by M. Rostan, and still less by M. Foderé; nor is it likely to obtain a very extensive use in our own country.* [It has

grene, and a cavity will remain; so that you may here have pectoriloquy; but the nature of the case is denoted by the fetor of expectoration, sudden extreme debility, &c. In chronic bronchitis the bronchial tubes may be very much enlarged at one spot; and here, also, there may be pectoriloquy; but the general symptoms of phthisis will be absent. No reliance is to be placed on the ear alone; the symptoms which are audible, are only to be taken in conjunction with those which are general. Certainly, a very wrong view is taken of auscultation, when it is regarded as superseding the necessity of attending to the whole of the symptoms. As Dr. Elliotson further explains, a person may be labouring under ulceration of the lungs, and yet he may not afford the sign of pectoriloquy. If the cavity be near the surface of the chest, and the walls of the cavity be very thin, and if the bronchial tubes that open into the cavity have mouths so small as to bear no proportion to the cavity itself, you may have a large cavity, and yet no pectoriloquy at all. Here is another instance of the fallacy of observations made by the ear alone, to the exclusion of the other symptoms. The walls of the cavity must be of a certain thickness for pectoriloquy to be produced, and the bronchial tubes, opening into the cavity, must bear a certain proportion to it; but, when the cavity is near the surface of the lung, and only covered by pleura, there will be no pectoriloquy. If, however, you had seen the patient before the cavity became so large as to be out of proportion to the bronchial tubes opening into it, and before the sides of the cavity had become so thin, you would have had pectoriloquy. When the excavation is very large indeed, you will sometimes hear the metallic tinkling, a silvery-ringing sound, when the patient coughs, speaks, or breathes. The metallic tinkling, however, as Laennec observed, is heard also whenever a communication is formed between the air-cells and the cavity of the pleura. In the first stage of phthisis, nothing is to be learned from the ear; and as the case proceeds, the case is generally clear enough without the information to be derived from this source; but, when it is questionable whether the disease be bronchitis or phthisis, the existence of pectoriloquy in the latter affection, previously to the excavation becoming too large, will prove the true character of the complaint, and serve for the discrimination of one case from the other.—See Professor Elliotson's Lectures at the Lond. Univ., as published in *Med. Gaz.* for 1833, p. 227.—Ed.

* The editor does not coincide in this remark; but he believes, that, for the elucidation of many

also been employed to ascertain the existence of pregnancy; by catching the sounds of the pulsations of the foetal heart, and of the movement of the blood in the utero-placental arteries.]

Such is the general history of phthisis. The pathology and practice are in a most unsatisfactory and unsettled state: nor can any thing be conceived more contradictory than the writings upon both these subjects. Boerhaave regarded consumption as a local disease, or conversion of all the blood and chyle into pus by means of an erosive ulcer seated in the lungs: Stahl as a general disease, unaffected by pus or any other acrimony. The latter ascribed consumption to the very abundant use of bark which was then prevailing in Europe; while Morton regarded bark as his sheet-anchor in effecting a cure. Consumption, according to Brillouet and many other writers, is identic with scrofula, and is only to be cured by tonics, alkalis, corrosive sublimate, or other mercurial alterants employed for the cure of scrofulous affections.—(*Journ. de Méd.*, 1777.) According to Cullen, though it has an apparent connexion with scrofula, the analogy affords us no assistance in the treatment, and the remedies for the one are of no avail in the other.

Dr. Rush contemplated it for the most part as an entonic or inflammatory disease, and particularly in its first stage, though it is sometimes accompanied with a hectic, or even a typhus fever. And hence his principal remedies were, salivation, or bleeding, which he sometimes prescribed fifteen times in six weeks; emetics, nitre in large doses, a milk and vegetable diet, walking in cold air even during an hæmoptysis, and afterward severe exercise. The hardships of a military life, says he, have effected cures in a multitude of cases of confirmed consumption; and a riding postman has been relieved more than once by the pursuit of his occupation.—(*Med. Inquir. and Observ.*, i., 8vo., Phil., 1789; ii., 1793; v., 1802.) This bold practice excited many followers, and was tried with variable success upon a large scale. But a practice of an opposite kind, equally bold, and which soon became equally popular, was proposed at the same time by M. Salvadori, of Trent.—(*Del. Morbo-Tisico*, 2 vols., 8vo., Trent, 1787.) Consumption, in the view of this pathologist, is an atonic, instead of an entonic disorder from the beginning—a disease of direct debility, and not of inflammation; and hence is only to be cured by an active plan of stimulants and roborants from the first. The patient's diet is to consist of copious meals of meat and wine, and his chief regimen to be that of climbing

ambiguous cases in the practice both of physic and surgery, the stethoscope will always be a valuable instrument. Its use in the examination of tumours, suspected to be of the aneurismal kind, but attended with obscurity, is generally recognised. For ascertaining doubtful fractures, and sometimes the presence of a calculus in the bladder, the stethoscope has also been recommended.—See Lisfranc, *Mém. sur les Nouvelles Applications du Stéthoscope*; or Alcock's Translation; and Dr. Ferguson's *Obs. in Dublin Trans.*, vol. i.—Editor.

hills, or precipitous steeps, in the morning, as quickly as he is able, till he is out of breath and bathed in sweat, and then augmenting the perspiration by placing himself near a large fire. Mr. May, who adopted the same general principle, seems to have postponed the gymnastic part of the process till the symptoms were alleviated, and to have called in the aid of medicines which Salvadori regarded as superfluous. May's medicinal means were emetics, bark, and laudanum night and morning; and for diet, he prescribed soup, meat, wine, porter, brandy and water, eggs, oysters, with proper condiments. Swinging was interposed twice a day, and horse-exercise was to complete the cure.—(*Lond. Med. Journ.*, ix., 1788.)

Many later writers believe consumption to be very generally produced by a habit of drinking vinegar daily to improve the figure: and Desault relates a case in which this effect was produced in the course of a month.—(*Sur les Maladies Vénériennes, la Rage, et la Phthisie*, 12mo., Bord., 1739.) Galen recommends vinegar as the best refrigerant we can employ: and Dr. Gregory, in 1794, gave the case of a patient, who recovered by using three dozen lemons daily. Dr. Beddoes felt justified in declaring fox-glove a cure for consumption as certain as bark for agues (*Essay on the Causes, Early Signs, and Prevention of Pulmonary Consumption*, 1799); Dr. Barton, of Philadelphia, has never known but one case cured by it, though others may have been palliated (*Collections for a Materia Medica*, 8vo., Philadelphia, 1798); and Dr. Parr asserts roundly, that it is more injurious than beneficial.—(*Med. Dict. in verb.*, *Phthisis*, vol. ii., p. 410.)

Contradictory, however, as are these statements with each other, they are chiefly so, as being either too highly coloured or too indiscriminate. We have already considered phthisis under three varieties or modifications, chiefly in respect to its being deep-seated or superficial; the apostematous lying lowermost, the tubercular somewhat higher, and the catarrhal on the surface. But each of these, as it occurs in different constitutions, or under different circumstances, may exhibit very different symptoms, and demand a very different, and perhaps an opposite mode of treatment. And hence, most of the principles on which the preceding opinions and modes of practice are founded, may derive authority from particular examples of success; and are so far correct, though, perhaps, none of them will apply to the whole. So considerable, indeed, are the shades of distinction from this multiplicity of causes, that every separate case of consumption should be allowed to speak for itself, and must call for much deviation from the widest line of treatment we can ever propose to ourselves under the form of general rules.

[Whether tubercular phthisis be ever really curable, is yet a contested point. It is certain, however, that the progress of the disease may be checked, and that some patients will live thirty years or more, without sinking under its effects. From various cases which Laennec

has reported, this distinguished pathologist concludes that tubercular phthisis is not beyond the powers of nature, though he admits that art possesses no certain means of accomplishing a cure. We may be well assured, he says, that a disease is irremediable, when we find employed in its treatment almost every known medication, however different, or even opposite in effect; when we see new remedies proposed every day, and old ones revived, after having lain long in merited oblivion; when, in short, we find no plan constant but that of giving palliatives, and no means persevered in but such as are proper for fulfilling indications purely symptomatic.

With respect to what our author denominates *catarrhal phthisis*, if it be unattended with tubercles, the frequency of its cure is as undoubted as its total difference from a case of tuberculated lungs. But the apostematous phthisis, spoken of in the preceding pages, seems to imply either an abscess in the lungs from some cause not essentially connected with tubercles, or else the effect of that process by which pulmonary tubercles become more or less dissolved, and converted into a fluid exhibiting many of the qualities of pus. Apostematous phthisis, in the first of these meanings, must often admit of cure; but, in the second, the frequency and even the possibility of cure are matters of dispute. After a careful perusal of the facts recorded by Laennec, in illustration of the mode in which nature sometimes cures phthisis, or repairs tubercular excavations, and after an impartial consideration of Professor Carswell's observations (*Illustrations of the Elementary Forms of Disease*, fasc. i., 4to., 1833), the editor conceives that the absolute incurability of apostematous phthisis must not be positively asserted, though the extreme rarity of a cure is as certain as any fact whatsoever in the whole mass of medical knowledge.*

According to Laennec, and with reference to the ascertained progress of tubercles, as detailed in the foregoing pages, the following are the most rational indications:—

1. As soon as we have ascertained the existence of the disease, our aim should be to prevent the formation of the second set of tubercles; as, in this case, says Laennec, if the primary tubercular masses be not extremely large or numerous, which they very seldom are, a cure will necessarily take place after they are softened and evacuated.

* The following is Professor Elliotson's opinion on the important question of the curability of tubercular phthisis:—"I am quite sure, on account of the succession of tubercles, that persons rarely recover; and I doubt whether the cavities heal so often as Laennec thought they did." The puckering and subjacent induration, noticed by Laennec as proofs of cicatrization of the lungs, are not considered by Dr. Elliotson to furnish unequivocal evidence of the fact, because similar appearances are commonly observed in the liver, under circumstances where there could have been no suppuration and ulceration.—(See Lect. at Lond. Univ., as published in *Med. Gaz.* for 1833, p. 230.) Andral has arrived at the same conclusion.—ED.

2. The second indication should be to promote the softening and evacuation, or the absorption of the existing tubercles. These indications being comprised in the following ones, considered by the author of the present work, though expressed in different language, the editor does not find it necessary to deviate from the arrangement preferred by Dr. Good.]

The general intentions by which practitioners seem to have been guided in the midst of all the above contrarieties of practice, are the ensuing:—

- I. To take off the inflammatory action.
- II. To correct the specific cause, or phthisical diathesis.
- III. To support under debility.
- IV. To subdue the local irritation, and improve the expectoration.
- V. To excite a change of action.

I. If the patient be of a robust habit, and in the prime and vigour of life, and if the symptoms indicate considerable inflammation, whether in the lungs or bronchiæ, such as, in the former case, fixed pain and weight in the chest, increased by lying on one side, with a dry but troublesome cough; and in the latter, a general soreness rather than pain in the chest, frequent and violent cough, with a copious excretion of a thin, offensive, and purulent mucus; and, in both cases, with a full and strong pulse, the fever, though remissive, making an approach towards a crura, constituting the plethoric species of Portal, and the inflammatory of Dr. Rush, our object in both these cases should be to diminish vascular action by every means in our power. Venesection should be had recourse to with all speed: and though we shall seldom be called upon so closely to follow the steps of Dr. Dover as to repeat the operation fifty times in succession (*Ancient Physician's Legacy to his Country*, 8vo., Lond.) before we desist, it may be necessary to follow it up rapidly to the third, fourth, or fifth time. Portal, in the catarrhal variety, bled a man, seventy-eight years old, three times, with the happiest effect.*

[With regard to bleeding, Laennec does not consider it as a means of curing, or even preventing phthisis, but only as calculated to allay the inflammatory affections with which it is sometimes complicated. Laennec, as we have already explained, conceived that inflammation had little share in the production of tubercular phthisis, and he positively asserts that bleeding can neither prevent the formation of tubercles, nor cure them when formed.—(*On Diseases of the Chest*, p. 362, 2d edit. by Forbes.) The

* The patient may occasionally have attacks of inflammation, and suffer violent stitches in the side, with aggravation of the cough. Under these circumstances a few ounces of blood may be taken away, or the chest may be cupped and blistered. You have then, as Dr. Elliotson observes, to treat the case as one of inflammation of the chest, in a constitution of little power.—(See his *Med. Lect.* at Lond. Univ., as published in *Med. Gaz.* for 1833, p. 235.) If the patients be seized with hemorrhage, it is often necessary to treat them in the same way, and keep them on low diet.—Ed.

latter part of the proposition is more generally admitted than the former; and the celebrated Broussais declares, that, in putting a stop to catarrh, a mild peripneumony, and pleurisy, by very active treatment at their onset, the occurrence of phthisis may be rendered very rare, whatever be the constitutional predisposition of the patient.—(*Doct. Med.*, p. 686.)]

Immediately after the use of the lancet, we should employ small doses of ipecacuanha or antimonial powder, so as to maintain a nausea till the pulse is lowered. Where the symptoms approach to peripneumony, the latter is to be preferred; where they lean to an inflammation of the mucous membrane of the bronchiæ, the former, of which three or four grains may be given three or four times a day, and will often prove expectorant, and unload the mucous follicles of the air-cells. The bowels should, in the meantime, be thoroughly opened by neutral salts, or uniting three or four grains of calomel with the nauseating powder: and after this, the fox-glove may be prescribed. Van Helmont first employed this last medicine as a specific for scrofula; but the only specific influence we know it to possess is on the kidneys, and on the action of the heart and arteries. It is for this last effect that we look to it in the present instance; the only effect, in all probability, that renders it of any advantage in consumption. In catarrhal phthisis, it seems sometimes, however, to improve the character of the expectoration: but this is, perhaps, a collateral result of the diminished action of the arterial system.

When a sufficient inroad has thus been made upon the inflammatory diathesis, we may content ourselves with an administration of the cooling neutrals, of which the nitrate of potash is one of the best. It may be given in almond emulsion in the proportion of a scruple to half a pint; and, if the cough be still troublesome, may be conveniently united with some light narcotic, as the extract of hyoscyamus or white poppy. The diet and general regimen are points of great importance; but upon these we shall have to speak presently.

It is not often, however, that phthisis commences with the inflammatory action we have been contemplating. Its ordinary march is unostentatious and insidious; and it takes possession of the fair and delicate, rather than of the firm and athletic frame, and chiefly in those possessing this figure who can trace the disease in their ancestors.

II. Of the proximate cause of this predisponent diathesis we know nothing: it is generally supposed to have a near analogy to that of scrofula; and when called into action, it commonly shows itself in the form of the tubercular variety; the tubercles themselves, though not occurring in a structure strictly glandular, bearing a considerable resemblance to scrofulous indurations. And on this account, as there are various medicines and a particular regimen that seem to have a beneficial effect upon a scrofulous habit, the same have often been resorted to for the cure of consumption. Thus, sea-water, the alkalis, almost all the metallic salts, and especially those

of mercury, have been repeatedly tried, but apparently with very doubtful success. Mr. Spalding gives the case of a patient who had taken nearly two pounds of potash and soda, intermixed like common salt, with his ordinary food; and, he states, with considerable benefit, after fox-glove, sulphuric acid, and bitters, had been successively found to disagree (*American Med. Repository*, vol. v., p. 220); and Dr. Trotter affirms, that among seamen in scrofulous consumption, as he calls the tubercular, salt and salt diet have proved of eminent service, but that the most effectual remedy is cinchona with sulphur.—(*Medecina Nautica*, vol. ii., p. 359.) Yet, though serviceable in particular cases of tubercular consumption, this class of medicines is far less efficacious than in strumous affections; and the remark of Dr. Cullen, which he has confined to two or three varieties of them, may be extended to the whole. "In scrofula," says he, "the remedies that are seemingly of most power are, sea-water, and certain mineral waters; but these have generally proved hurtful in the case of tubercles of the lungs. I have known," he adds, "several instances of mercury very fully employed in certain diseases in persons who were supposed at the time to have tubercles formed, or forming, in their lungs: but though the mercury proved a cure for those other diseases, it was of no service in preventing phthisis, and, in some cases, seemed to hurry it on."—(*Pract. of Phys.*, vol. ii., sect. 907, p. 293.)

Nor have any other metallic salts been of more use than those of mercury. Dr. Roberts has had the spirit and perseverance to run through the whole range of such of them as can in any way be thought applicable to this complaint; and has also had the candour, after a sufficient scale of trial in St. Bartholomew's (a candour how seldom to be met with!), to confess that none of them were administered with success. The experimental list consisted of silver in its nitrate; lead in its superacetate, combined with opium, for counteracting its deleterious effects, zinc, in its sulphate and oxyde; and the precipitate from the sulphate of potash, combined with myrrh; arsenic in the neutral salt formed by a combination with potash; manganese in its white oxyde, in doses of ten grains every six hours; cobalt in its black oxyde, in doses of from one grain to four; ammoniated copper, and muriate of barytes. And with a like want of success, he tells us, in addition, were employed the vegetable narcotics aconite, hyoscyamus, stramonium, belladonna, as also toxicodendron.* We may hence, I think, nearly

* *Med. Trans.*, vol. iv., p. 129. Professor Carswell has traced abundance of tubercular matter in scrofulous lymphatic glands; and since swellings of this kind are sometimes cured, he regards the circumstance as a consideration against the inference, that tubercles of the lungs are absolutely incurable.—(See his *Illustrations of the Elementary Forms of Disease*, fasc. i., 4to., Lond., 1833.) The tubercular substance being unorganized, cannot itself be affected or influenced by medicine; and hence no doubt one principal difficulty in the attempt to cure phthisis.—Ed.

conclude with Dr. Cullen, that "the analogy of scrofula gives no assistance in this matter."—(*Pract. of Phys.*, vol. ii., sect. 907.) And it is probably on this account, that M. Foderé has treated of tubercular and scrofulous consumption as two distinct forms of the disease.—(*Leçons sur les Epidémies et l'Hygiène Publique*, tom. ii., Paris, 1823.)

The preparations of iodine have a fair claim to attention here, as well as in scrofula, though great caution is necessary in employing them; while it is only where the affection is pretty evidently tubercular that we have any reason to expect success from their use; and even here, only in an incipient state of this variety. I have found a local application of the ointment relieve the cough and pain in the side, in some cases, more effectually than the tartar-emetic eruption. And if the erythema hereby produced should prevent a continuance of the application,* we may substitute the form of pills or of tincture; giving half a grain of the iodine, in either mode of preparation, two or three times a day. [From the remarkable power of iodine in removing bronchocele, and reducing the size of diseased lymphatic glands on the surface of the body, the employment of it for the dispersion of pulmonary tubercles, as Dr. Forbes observes, was at once prompted and justified by the fairest analogy.† But, says he, there exists so material a difference between tuberculous diseases of the lungs and bronchocele, or enlargement of the external glands, notwithstanding their seeming analogy, as renders the efficacy of iodine in the former disease more than problematical. He considers it, however, as deserving of further trial.]

This part of our subject, however, ought not to be closed without briefly adverting to the practice of giving very small doses of tartar-emetic, dissolved in a large body of some simple menstruum, and continuing it for an almost indefinite period of time. Dr. Balfour dissolves two grains in six ounces of water, and prescribes an ounce of this mixture, that is, a third part of a grain of the tartarized antimony, to be taken every hour, and a smaller quantity where this is found to nauseate. M. Lenthois, in his *Méthode Préserveuse*, first directs a grain of tartarized antimony to be dissolved in eight tablespoonfuls of distilled water, and then six or eight pints of water, and sometimes not less than twelve, to be added. The solution, thus weakened, is employed by the patient for common drink in every case and stage of consumption, either alone or with some other drink at meals, or occasionally with wine. [Tartarized antimony was strongly recommended by Dr. Jenner (*Letter to Dr. Parry*, 1822), but Dr. Forbes says that he has tried it, as well as setons, blisters, &c., without any benefit.]

III. Although in consumption we can avail

* For its other troublesome effects, see Vol. II., Cl. VI., Ord. I., Gen. II., Spe. 1, *Emphyéma Sarcoma Bronchocele*, p. 315.

† See Baron's *Illustrations of the Inquiry respecting Tuberculous Diseases*, p. 220, and Gairdner on the Effects of Iodine, 1824.

ourselves but little of the treatment which applies to scrofula, and know nothing whatever of the nature of its specific cause, we see enough to convince us that consumption, in its general character, is, like scrofula, a disease of debility; and that wherever it exhibits an excess of vascular action, it is merely in consequence of being planted upon a plethoric or entonic temperament.* And hence another principle, conspicuous in most of the remedial plans to which it has given birth, is that of supporting the system while labouring under its influence.

This principle is well founded, but of difficult application; and, like the opposite principle of reduction, has been often carried to an extreme. During the last century, Salvadori in the Tyrol, and, in the present day, Dr. Stewart of Edinburgh, are justly chargeable with having done this by a very general allowance of nourishing diet, in conjunction with pure or diluted wine, bark, steel, and other tonics; exercise on horseback, and affusion with vinegar and cold water. In its ordinary course the disease itself is not only peculiarly prodigal of animal strength, but extremely protracted in its duration; while the fever, though remissive, rarely subsides altogether, or allows any interval of which we can avail ourselves.

In some instances, however, it does allow such interval, and especially where it has continued for a long period, and has broken down the general vigour of the frame; in which case, Moreton occasionally found the inflammatory form with which it commenced converted into a low intermittent, sometimes assuming the quotidian, but more generally the tertian type; beginning with cold fits, and succeeded by intense heat and profuse sweats, which exhausted the patient, though they left him in high spirits during the intermissions. And in such instances, it is possible that the tonic and stimulant plan of bark, wine, and even high-seasoned dishes, with cold air, cold bathing, and active exercise, so warmly eulogized by the writers just referred to, as well as by many others, may occasionally prove successful; and particularly where the disease is of the apostematous or catarrhal variety, and there is no constitutional taint to oppose at the same time. And it is here also, if anywhere, that the bustling and violent exercise, so strenuously recommended by Dr. Rush and Dr. Jackson, have a chance of proving beneficial. Dr. Chisholm tells us that, in particular cases, he found both these plans of decided service.—(*Climate and Diseases of Tropical Countries*, &c., 8vo., p. 112, Lond., 1822.)

But these are plans which cannot be brought into general practice; and, in supporting the strength of the system, we are ordinarily compelled to pursue a very different course: a doctrine, in a few rare instances, admitted even by Dr. Stewart himself.

The first means by which we are to aim at

* Excess of vascular action sometimes depends upon phthisis being conjoined with various degrees of inflammation in the chest.—ED.

accomplishing this is of a negative kind; and consists in saving the frame as much as possible from the profuse exhaustion it is daily sustaining, by calming the febrile irritation, and checking the colliquative sweats, which, as already observed, are never of a critical kind.

"I have sometimes succeeded very decidedly," says Dr. Young in a note to the author, while the first edition was printing, "in checking the sweats by Dover's powder; but I do not know that the progress of the disease has been much retarded by this palliation."

Bleeding, however plausible and even advantageous when the pulse is full and strong, and the pain in the side acute, can rarely be allowed when the frame is delicate and irritable, and the pulse small and weak. Where the local distress is considerable, it may be had recourse to as a palliative, but never carried beyond a few ounces, nor repeated without great hesitation.

To emetics there is less objection, but vomiting is here to be preferred to nauseating. The latter, though it lowers the pulse, produces considerable fatigue and distress. The former emulges the bronchial glands, and diminishes the local irritation by transferring it, through the means of a general glow and moisture, over the system at large. The dose may be repeated three or four times a week, and should have its power limited, as nearly as may be, to a single inversion of the stomach.

In the selection of emetics, some judgment is required; for those should be carefully avoided which, like the antimonial preparations, produce loose evacuations, and excite considerable sweating. The ipecacuanha is, perhaps, one of the simplest and the best. Dr. Simmons, however, preferred the sulphate of copper, giving first of all half a pint of water to the patient, and then the blue vitriol from two grains to twenty, according to his age and strength, dissolved in an additional cupful of water. In general he found, that the moment the emetic reached the stomach it was thrown up again, upon which the patient was ordered to swallow another half pint of water, which was sufficient to take off the nausea.—(*Practical Observations on the Treatment of Consumption*, &c.)

[Besides the use of ipecacuanha as one of the best emetics in phthisis, it is an important medicine for palliating the diarrhoea, under which many patients sink. This complaint, it is true, is often quite incurable, being connected with morbid changes in the bowels, already described in the preceding pages; but whatever benefit it does admit of will be derived from small doses of ipecacuanha. Thus, Dr. Bright says, when the disorder of the mucous membrane of the bowels is a prominent feature in phthisis, the purging may often be diminished, and the stools rendered natural in appearance, by giving the patient two grains of ipecacuanha three times a day.—(*Reports*, &c., p. 152.) The editor can add his testimony in favour of the practice, especially when the ipecacuanha is made into a pill with four or five grains of the *confectio opii*.]

The reason that prohibits nauseating, prohibits also the use of fox-glove: for though the

pulse may be diminished, nothing more is obtained, and even this is obtained at too great an expense of sensorial power in the degree of debility we are now contemplating: and the remark will apply to most of the narcotics, whether of the umbellate or solanaceous order. The neutral salts answer better, and especially nitre; and there is no modification of the disease in which this may not be given, and will not prove an excellent refrigerant as well as sedative. The general error, however, has been in administering it too freely, as in doses of fifteen grains or a scruple; in which case it becomes a direct irritant, and does much more harm than good. Seven or eight grains at a time, as already observed, is a far better proportion, and even in this quantity it will answer best if considerably diluted. It is often united with narcotics; but these are never found of use, unless they palliate the cough or local distress; for otherwise they increase the heat and quicken the pulse.

Most of the acids may also be employed for the same purpose, and with equally good effect. They may, indeed, be regarded in the joint character of sedatives, refrigerants, and astringent tonics: and have hence every claim to attention. The mineral have been most commonly in use; but, from their erosive quality, they cannot be thrown in sufficient abundance into the circulating fluids: and, on this account, the vegetable are to be preferred; and, of the vegetable, the fermented acids, which, though somewhat less grateful than the native, seem to be more effectual as tonics. The acetous acid was employed freely by Galen, diluted with water, who regarded it as the best refrigerant we can select. It is continued to the present day among the Moorish physicians at Tunis, and, according to the late M. Orban, with decided success. He observed its effects, during three months, upon one patient who appeared to be labouring under a confirmed phthisis from a neglected catarrh. The quantity of vinegar drunk in the course of every twenty-four hours, was seven fluid ounces intermixed with seven times as much rain-water, and sweetened with two ounces of refined sugar. This apozem was accompanied with astringent and tonic pills, composed chiefly of alum and sulphate of iron, of each of which two grains and a half were taken daily. The diet allowed was very slender, and consisted of nothing more than vermicelli or millet, boiled in water, and seasoned with a little oil and salt. Of this, only two meals in the four-and-twenty hours were allowed for several weeks. And, on the patient's becoming very costive under its use, the Moorish physician paid no attention to the symptom, but told M. Orban that a constipated state of the bowels was the best symptom that could occur, and that the more strikingly this prevailed, the more certain he was of a cure. M. Orban* left his patient in

a state of convalescence bordering on perfect health; and, on his return to France, pursued the same plan, with the exception of the iron, which he omitted as too stimulant, and found it, in many cases, eminently successful, though not in all. It has since been tried in our own country, and has often proved equally advantageous. Dr. Roberts has paid particular attention to its effects; and, upon a pretty extensive scale, has been satisfied with them. One of his cases was of a very unpromising aspect, and consisted of a young gentleman, seventeen years of age, whose elder brother had died of phthisis. The cough, which in the morning was very considerable, was accompanied with expectoration sometimes streaked with blood; a confirmed hectic preyed upon him, and the night-sweat was so profuse that his hair was drenched with it. "My patient," says Dr. Roberts, "was at once relieved by the use of the acid, and in a short time so lost his complaints, that, by advice, he discontinued the remedy."—(*Med. Trans.*, ut *suprà*.) The acetic and acetous acid seem to have been employed indiscriminately; over which the citric, which was also tried, did not seem to have any advantage. The acetous was usually given in half-ounce doses, with an ounce of infusion of cascarrilla, and a little mucilaginous powder or sirup, the dose being repeated three or four times a day.

From these facts, as well as from a host of others of the same kind that might be adduced, the acetous acid appears to be a powerful sedative. It diminishes action generally, checks night-sweats, restrains hæmoptysis, retards the pulse, and produces costiveness. In hæmoptysis, I have carried the use of the acetous acid much farther than was prescribed by Dr. Roberts, and with manifest and unmixed advantage.

The proper astringents have also not unfrequently been employed in phthisis for the same negative purpose of producing strength by checking the exhausting discharges of sweat, pus or mucus, blood, and often diarrhœa; but they have rarely proved successful. Some degree of benefit seems occasionally to have been derived from the use of oak bark, several of the agarics (*De Haen, Rat. Med.*, tom. ii., 567; *Dufresnoy, in Corvisart, Journ. Med.*, cent. vii., 531, 1804) given in the form of lozenges, and the acetate of lead;* but they have far more generally been employed without success, or with more mischief than advantage.

The most direct means of supporting the system would be by those tonics that unite an astringent with a bitter principle; but we have

* *Med. Trans.*, vol. v., art. xviii. This treatment with vinegar falls under the head of what is called the empirical practice. The account is altogether unsatisfactory: the case is called a confirmed phthisis; but was it of the tubercular kind?—Ed.

* Ewell in *Sédilot's Journ. Gén. Méd.*, xlv.; Hildebrand, *id.*, xxxvi. Frequently the largest doses of opium, such as will produce great stupor, and astringents in doses that even overload the stomach, will not succeed in checking the diarrhœa. Frequently there is ulceration of the intestines, and then the sulphate of copper is recommended by Dr. Elliotson. It has a tendency to produce sickness; but this may be subdued by hydrocyanic acid. In the event of this not answering, we may try ipecacuanha in small doses joined with opium, as already mentioned.—Ed.

already observed, that the system is usually, and particularly in the beginning and at the height of the disease, in too high a degree of irritation for a convenient use of any medicines of this kind; though where the complaint has lasted for many months, and appears to be rather of the tubercular or catarrhal, than of the apostematous variety, these may sometimes be employed with great success. The Angustura bark generally agrees better than the cinchona; and to this myrrh and iron may at such times be added in increasing doses, and particularly as prepared in the *mistura ferri composita* of the London College. In the tubercular variety, the cinchona seldom agrees in any stage: Dr. Cullen conceives never; and tells us that, even where the disease has assumed something of an intermittent character, quotidian or tertian,—and he has, on this account, been tempted to try it in free doses,—he has in no instances succeeded so as to establish a complete cure. “For in spite,” says he, “of large exhibitions of the bark, the paroxysms, in less than a fortnight or three weeks after they had been stopped, always returned, and with greater violence, and proved fatal.” In the latter stages of the apostematous variety, and especially where the vomicae are small and in perpetual succession, he thinks, however, it may be of service in restoring a healthy action, and promoting a secretion of genuine pus.

In this last case, and here perhaps only, we may venture with success on the use of the cold bath. In a more irritable state or stage of the complaint, the tepid bath may occasionally prove serviceable; and, where it does so, should be repeated three or four times a week, or even oftener. Of the effect of the *baños de tierra* of the once-celebrated Solano de Luque, I cannot speak from personal knowledge. It consists in burying the patient up to the chin in fresh mould. It would be most obvious to suppose that this was designed to act as a tonic, and check the undue tendency to perspiration by a protracted chill, but that Van Swieten tells us the smell of fresh earth is serviceable, and approves of it on this account. It has since been recommended by Dr. Simmons and M. Pouteau.

Before, however, the hectic, or the general irritability of the system, has so far subsided as to render tonics advisable, our chief dependence for giving support to the system must be upon diet and regimen.

The diet should be of the lightest kinds, and in very small proportion, and with long intervals of rest; for some degree of exacerbation, in the stage of the disease we are now contemplating, is always produced by the process of digestion. Under *limosis exers* we have already seen how very small a portion of food is necessary for the support of life, when neither mental nor muscular exercise is made use of; and though hectic fever itself is a source of very great exhaustion, this exhaustion will be less in proportion as we produce less excitement, whether from eating or any other cause. And hence the most cautious physicians, from the time of the Greeks to our own day, have concur-

red in recommending food in small quantity, as well as of the lightest materials. It is not merely the stomach and its collatitious organs that are hereby put at rest, but the circulating system, the assimilating powers, the brain, and the intestines.

The food itself should consist principally of milk and the farinaceous parts of plants, if it be not limited entirely to these: and upon a diet of this kind, in conjunction with temperate air and exercise, the Greek physicians placed their only hopes of a cure. Whether it be necessary to pay that strict attention to the different kinds of milk which we find inculcated by many writers of established reputation, I cannot fully determine. Galen recommends woman's milk as lightest of all, then ass's, next goat's or ewe's, and lastly cow's (*Opp.*, tom. vi., 130, 131, edit. Basil., 1542); and Van Swieten adopts the recommendation of Galen.—(*Comment.*, tom. iv., sect. 1211, edit. Lugd. Bat., 1764.) Mare's milk has since been proposed as preferable to all these: but the analyses published by different chymists vary so much from each other, that it is difficult to come to a conclusion. If the experiments of Stipriaan may be depended upon, mare's milk contains most sugar, and least cream, butter, or caseous matter; and woman's milk most sugar, and least butter and caseous matter, next to mare's, with most cream, next to sheep's.—(*Crell's Chemische Annales*, sect. viii., p. 138, 1794.) Whence mare's milk should be the lightest of the whole, but less nutritive than woman's. According to Parmenier, however, ass's milk contains less proportion of caseous matter than any of the rest.

Peculiar properties may sometimes be given to milk by the food fed upon; and hence Galen endeavoured to render it more astringent, by placing the animal that was to furnish it in pasturage enriched for the purpose with agrostis, lotus, polygonum, and melysophyllum. And as the patient became convalescent, and could bear a richer nutriment, he was allowed to sail down the Tiber and use the cow's milk of Stabia, which was peculiarly celebrated for its excellence.

When ass's milk cannot conveniently be obtained, its place may be supplied with what has been called artificial ass's milk; which is a mixture of cow's milk and animal mucilage, diluted in a farinaceous apozem, rendered slightly sweetish and aromatic by eryngo. The ordinary form consists in boiling eighteen contused snails with an ounce of hartshorn shavings, of eryngo-root, and pearl-barley, in six pints of water, to half its quantity, and then adding an ounce and a half of sirup of Tolu. Four ounces of this are usually taken morning and evening, with an equal quantity of fresh milk from the cow.—(*Med. Trans.*, vol. ii., p. 341.)

The chief foods which have been allowed in the general treatment of consumption in its earlier and middle stages, in conjunction with milk and the farinacea, are the vegetable and animal mucilages, but particularly the former. And of these, that obtained from the Iceland liverwort has been held, and deservedly so, in

the highest degree of estimation; for, to an aliment of sufficient nourishment, it adds a tonic power by its bitterness; yet a power that, so far from increasing vascular action, seems rather to quiet it; as though the bitter principle were itself in possession of something of the sedative quality of the hop, Ignatius's bean, or some other plant that decisively unites the two.

In supporting or recruiting the strength, a due attention to air and exercise is also of high importance. The advantages offered by the first are those of a mild, dry, and equable atmosphere; and, probably, these are the whole. If the patient's own country give him these, he need not wander from home. If it do not, he must create an artificial atmosphere in his own chamber, or set of chambers, by keeping the thermometer at from 60° to 65° of Fahrenheit, and confining himself to this temperature; or he must seek the atmosphere he stands in need of in a foreign climate. The disadvantage of the former is, that though he may support the requisite temperature, he cannot conveniently obtain a sufficient change of air, nor so well avail himself of the various exercises that might be useful to him, as if he were at liberty to go abroad.

Hence a change of abode has been recommended in all ages to those whose native soil is subject to considerable and sudden atmospheric variations, though pathologists have by no means agreed upon a meteorological standard. For the patient's residence in our own country, the southwestern boundary of the Cornish coast, and particularly Penzance, seems to offer the best asylum: and where a foreign climate is recommended, it should lie between thirty and forty degrees of latitude: if lower than this, the disease, and especially where ulceration has taken place, seems to be exacerbated instead of diminished, and, consequently, its fatal issue to be quickened (Sir G. Blanc, *Observations on the Diseases of Seamen*, 8vo., 1785); notwithstanding that to the natives consumption is little known within the tropics.

In Great Britain, the annual mortality from this disease in 1811, when the population was calculated at 23,353,000, seems to have amounted to 55,000, being a proportion of 1 in 224. In Geneva, from a very exact register, M. Prevost Moulton estimates it at 1 in 521.—(*Chisholm, on Tropical Climates*, p. 234.)

Generally speaking, however, a change of climate or of local situation has been determined upon too late; and hence has not been attended with all the benefit that might otherwise have been reasonably hoped for. On which account many pathologists have considered it as of little importance, if not more injurious than staying at home, though the most celebrated spots should be selected.

Thus Dr. Carmichael Smyth asserts, that Madeira is unfavourable to the consumptive when the lungs are materially injured, notwithstanding the mildness and equability of its climate.* Nice and Naples are said to be equally

unfriendly from the neighbourhood of mountains; and Dr. Southey's inquiry has led him to conclude that, in Malta, Sicily, and other islands in the Mediterranean, phthisis, though a rare disease among the natives, does not appear to be retarded in those who visit them for a cure.* M. Portal dissuades from all such trials by affirming that there is no dependance to be placed upon them, since he has seen the disease accelerated in Englishmen, or those of other northern nations, by a visit in quest of milder air to the south of France; while, in the natives of Languedoc or Provence, it has been restrained by a removal to Paris.—(*Obs. sur la Nature et le Traitement de la Phthisie Pulmonaire*, ii., p. 358.) Nor are the observations of M. Fodéré much more encouraging to a trial of any part of France: as he expressly tells us that, in the provinces on the borders of the Mediterranean, phthisis commits the most horrible ravages; while, out of 62,447 deaths which took place at Paris in the years 1816, 1817, and 1818, thirteen thousand eight hundred and eighteen fell victims to diseases of the chest.—(*Leçons sur les Epidémies et l'Hygiène Publique*, tom. ii., 1813.)

The whole of this, however, only shows us that very great care is necessary in ascertaining the state and stage of the disease, the patient's constitution, and the local features of the situation that may be proposed for his residence: and we have already shown how it is possible for a mild and relaxing climate to prove remedial to strangers, while it may even become a predisponent cause of phthisis to natives. Where, in the commencement of the disease, there is great irritability or an inflammatory diathesis; or, in its advance, the strength of the constitution is greatly reduced; and especially where an obstinate diarrhœa has supervened, the fatigues of journeying and of a sea-voyage, and the necessary relinquishment of many of those minuter, but still important conveniences, to which the patient has been accustomed at home, will more than counterbalance all the advantages he might derive from the possession of a milder and more equable atmosphere.

The topography of the situation about to be chosen is of equal importance; for if it be strongly marked by lofty cliffs or mountains,† the air will seldom circulate freely, but rush in currents in some parts, and be obstructed and become stagnant in others. Such is the state of Hastings on the Sussex coast of our own country,

monary Consumption, &c., 8vo., 1787. In Madeira the thermometer commonly ranges from 60° to 75°; and, in the greatest extremes, seldom exceeds these limits by more than 5°.—See *Journ. of Morbid Anatomy, Ophthalmic Medicine, &c.*, vol. i., p. 103.—Ed.

* *Obs. on Pulmonary Consumption*, 8vo., 1814. Phthisis was common enough among the inhabitants of Malta and Minorca when the editor formerly visited those islands as an army surgeon.—Ed.

† Laennec observes that, though phthisis is unfrequent in mountainous countries, it runs a very rapid course when it does occur in them.—On *Diseases of the Chest*, p. 368, 2d edit. by Forbes.

* Account of the Effects of Swinging in Pul-

which would otherwise form an excellent asylum for those who are subject to pulmonary affections, and cannot remove far from their native abodes. The shore is skirted by two enormous cliffs of sandstone, that rise between two and three hundred feet in perpendicular height. The old town is built in a deep ravine opening towards the northeast, that lies between them, and the new town immediately under the cliffs, fronting south and west; and hence, while the air is rushing in a perpetual current through the former, it becomes stagnant, heated, and suffocative in the latter.* On this account, it has been uniformly found that small islands, without any great boldness of feature, enjoy the most equable temperature, and, when within the range already pointed out, form the most favourable situations for consumptive cases. Madeira, in some of its positions, is one of the best foreign stations in the winter season; but from its mountainous face, and the snow, sleet, and cold winds to which it is occasionally liable, catarrhal affections, and even genuine consumption itself, are, according to Dr. Gourlay, not uncommon to the natives; and in removing to it, therefore, it will be necessary to select a spot of sufficient elevation, and equally sheltered from the meteorological evils of currents, tempests, and suffocative heat. And, however fortunate a patient may be in procuring such a residence at Madeira, he will, in all probability, succeed still better, and obtain a greater choice of desirable situations, at Nice, Pisa, or even Hières; and might be more comfortable at Villa Franca than even at any of these, if the town were now of sufficient extent and population to offer him the conveniences he will always want, and especially that of a roomy and excellent lodging-house, which, in the present decayed state of this town, is not a little difficult to be obtained. The depth of the bay, and the very abrupt elevation of the hills that rise in a most beautiful and romantic amphitheatre behind it, enable the patient to make a considerable range without exposure to sudden currents. The east is its only unsheltered quarter, and, from the evils attendant on occasional chills, he must sedulously avoid this.

But we have already shown that a high degree of heat habitually applied to the body, as in intertropical regions, as a source of debility and irritation, may itself call forth a latent con-

sumptive predisposition into action, and become a source of phthisis, as well as a temperature of unfriendly cold. The variety in this case, as we have already observed, is almost always the tubercular, and often combined with a strumous diathesis, if it do not originate from it. The change must here, therefore, be to a cooler instead of to a warmer temperature; to an atmosphere of a more refreshing and invigorating power; to a climate still mild, but less exciting, equable in its thermometer, and tonic in its general influence.*

After all, the most equable of temperatures is that of the sea itself: and hence many patients who feel inconvenience from a residence on the seaside, are almost instantly relieved by sailing a few miles distance from it. This has often been resolved into the exercise of sailing, or the sea-sickness which in many instances is hereby excited. It is, nevertheless, a distinct advantage from either, and resolvable into the explanation just stated.

Sea-sickness, however, is of unquestionable service in many cases, and particularly in those in which a protracted nausea by other means has already been recommended. The exercise of sailing is useful on another and a very different account. All motion without exertion, or with no more exertion than gives a pleasurable feeling to the system, which the Greeks expressed by the term *xōra*, instead of exhausting, tranquillizes and proves sedative. It retards the pulse, calms the irregularities of the heart, produces sleep, and even costiveness. Hence sailing on the Tiber was a common prescription among the Roman physicians, and many consumptive patients have found great benefit from long voyages, in which they have suffered no sea-sickness, and have been exposed to many varieties of atmospherical temperature. Hence, too, the well-known advantage of exercise in a swing, or in a carriage, on horseback, or even on foot, as soon as these can be engaged in with comfort; the organs of respiration, like those of every other kind, deriving strength, instead of weakness, from a temperate use of them.

Gymnastic medicine, however, seems by many pathologists to have been carried to an extreme; and especially by Sydenham, who employed horse-exercise in all stages of the dis-

* For a more inviting account of Hastings, as a place of resort for invalids, see Harwood's *Curative Influence of the Southern Coast*: or the *Journal of Morbid Anatomy, &c.*, by Dr. Farre, vol. 1., p. 121. Laennec considered maritime situations as exhibiting a less prevalence of consumption; but Dr. Forbes, who has resided long on the southern coast of England, deems the opinion unestablished by proof. During a residence of five years at Penzance, Cornwall, a place much frequented by consumptive patients on account of the mildness and equability of its temperature, Dr. Forbes had extensive opportunities of observing the effect of change of climate on phthisis; and he says, that, in the greater number of cases, the change was not beneficial.—*Transl. of Laennec*, 2d edit., pp. 324 and 367.

* The following remarks by Dr. Clark deserve attention:—"A change of climate having been decided on, the particular situation to be selected becomes a question. Professor Laennec's decided preference of a maritime residence is not, perhaps, founded on very extensive experience. Certain it is, however, that as well in this country as on the continent, the places usually resorted to by consumptive invalids are on the seacoast, or at no great distance from it. In almost every case, when the removal to a milder climate can be effected by sea, this means is much preferable to a journey by land. In some cases, the good effects produced by a voyage are very remarkable."—(See *Laennec*, by Forbes, 2d edit., p. 368.) No doubt, as Dr. Forbes has explained, change of climate often fails, because tried too late; and some deception prevails respecting such cases as are benefited, and which are frequently only specimens of chronic catarrh, or chronic bronchitis.—*Ed.*

ease, and roundly affirms, that neither mercury in syphilis, nor bark in intermittents, is more effectual than riding in consumptions.—(*Opp.*, p. 629.) Nor is carriage-exercise, says he, by any means to be despised, though not equal to that of the saddle. Hoffmann and Baglivi adopted the same opinion, and laid it down in terms nearly as unqualified. Where phthisis is a secondary disease, and dependant upon some obstruction of the digestive viscera, exercise of this kind may, in many instances, be employed as in important co-operation with other means, even from the beginning; and to such cases of consumption Desault judiciously limits it. In the present day, it has been revived by Dr. Stewart under a variety of ingenious modifications, and appears in many cases to have afforded relief: but the constitutions of mankind must strangely have altered since the days of Sydenham, if the severity of horse-exercise could at that period have been employed as a specific remedy in consumptions of every kind. Stoll did not find it so in the middle of the last century; for he tells us, that, if a consumptive patient mount his horse, he will ride to the banks of the Styx as surely as if he were in a pleurisy.—(*Rat. Med.*, i.) And Stoerck died consumptive, though in the habit of riding, killed by an hæmoptysis apparently produced by this exercise.—(*Quarin*, pp. 162, 163.)

IV. Another part of the curative process in the disease before us has consisted in endeavouring to subdue the local irritation, and improve the secretion from the lungs. This has been chiefly attempted by fumigations, medicated airs, expectorants, and sedatives.

Bennet was strongly attached to the first of these, and thought they proved peculiarly detergent, and enabled the patient to throw up a more laudable discharge with increased facility. He sometimes employed aromatic herbs immersed in hot water, over which the patient held his head, surrounded with cloths to confine the vapour, which was thus inhaled with every inspiration. But he seems to have placed more dependance on an inhalation of the fumes of various terebinthinate resins, as frankincense, styrax, and turpentine itself, mixed into a powder or troche with a few other ingredients, and burnt on coals: to which he sometimes added a considerable proportion of orpiment. And such was the success ascribed to this practice, that Willis, not many years after, resolved the greater exemption of certain parts of England and Holland from coughs and consumptions, to the turf and peat fires which the inhabitants were in the habit of using, and the arsenical principle which was intermixed with the material. In our own day, terebinthinate fumigations have been very extensively tried, in consequence of the warm recommendation of Sir Alexander Crichton,* who thought he had perceived great and decisive advantage from the aroma of pitch

and tar diffused through rope manufactories, ships, and other places where these articles are in perpetual use. I have tried this repeatedly by heating a tin vessel of tar over an oil or spirit-lamp, and thus impregnating the atmosphere of the chamber with the powerful vapour that arises. In doing this, however, we must be careful not to burn the tar; for in such case the room will be filled with an empyreumatic smoke, that will greatly augment the patient's cough instead of diminishing it: and it will be also advisable, as recommended by Dr. Paris (*Pharmacologia*, vol. ii., p. 339, edit. 1822), to add about half an ounce of subcarbonate of potash to every pound of tar, for the purpose of neutralizing its pyroligneous acid, the fume of which will otherwise ascend and prove irritating.

In those states of the disease in which terebinthinate, as myrrh, benzoin, or copayva, may be taken internally with a prospect of success, this kind of fumigation will sometimes prove useful also, and it is hence far better adapted to the tubercular and catarrhal than to the apostematous variety. In a chronic state of the first two I have sometimes thought it serviceable, but I have more frequently used it without any avail. The experience of Dr. James Forbes, who has tried this remedy upon an extensive scale, very closely coincides with these remarks. Of nineteen cases of phthisis, of which he has given us an account, it neither cured nor improved any; on eight it had no effect; and mischievously suppressed the secretion, injured the breathing, and increased the disease in eleven. In cases of chronic catarrh, where the secretion constitutes the disease, and tonics and astringents are useful, it often succeeded. Of thirty-two cases narrated, it had no mischievous effect on any; no effect whatever on eighteen; improved six, and cured eight.—(*Remarks on Tar-Vapour*, by James Forbes, M. D., 8vo, 1822.)

Pneumatic medicine, which about thirty years ago was in the highest popularity, does not appear, when candidly examined, to have been more successful. Oxygen gas has, in almost every instance, proved so stimulant, and so much increased the signs of inflammatory action, that, though it has seemed occasionally to afford a momentary relief in a few cases, it has rarely been persevered in more than a fortnight, by which time it has often suppressed the usual expectoration, and produced an hæmoptysis.—(*Fourcroy, Annales de Chim.*, iv., p. 83, 1790.)

There was much more reason and ingenuity in recommending an inhalation of hydrogen intermixed with common air than of oxygen, since the effect of this gas in destroying the irritability of the living fibre is known to every one; and it was hence a plausible conjecture, that, by being applied immediately to the seat of the disease, it might sufficiently subdue the inflammatory impetus, change the action of the ulcerated surface, improve the secretion, and annihilate the hectic. The experiment has been tried at home and abroad upon a pretty extensive scale, by employing different proportions of hydrogen, so that the patient has twice a day

* Practical Observations on the Treatment and Cure of several Varieties of Pulmonary Consumption; and on the Effects of the Vapour of Boiling Tar in that Disease, Lond., 8vo., 1823.

breathed from a pint to a quart of gas at a time, diluted with from twelve to six times its measure of common air; and, making every allowance for an exaggeration of statement in those who have most warmly engaged in the practice, it seems difficult not to concede that it has proved serviceable in various cases.

A combination of hydrogen with common air seems, indeed, to be beneficial in various other modes of application; but whether by lowering the ordinary stimulus of common air, or by directly diminishing and exhausting the nervous influence communicated to the lungs, it is not easy to determine. In either way, however, it has an equal tendency to indispose them to inflammatory action. Thus Clapier relates a case of confirmed consumption cured by an habitual residence in a coal-mine (*Journ. Méd.*, xviii., 59), and expressly states that the matter expectorated soon began to assume a more healthy appearance, and was excreted more freely. It is, in like manner, a common remark, that the miners of Cornwall are more generally exempt from phthisis than most other persons (*Southey, Observations on Pulmonary Consumption*, 8vo., 1814), and that butchers, who are perpetually engaged in slaughter-houses, and surrounded by a vapour impregnated with hydrogen, possess an equal emancipation. It is probably to this cause, if to any, we are to ascribe the benefit which Bergius found consumptive patients derive from a residence in cow-houses (*Neue Schwed. Abhandl.*, 1782, part iii., p. 298), and which was, not long since, a fashionable mode of practice in our own country.*

Expectorants and demulcents have also very generally been employed for the same purpose—that of subduing the disease by exciting a healing action in the tubercles or ulcerations, indicated by improvement in the expectoration.

Of the general nature and mode of action of these classes of medicines, we have already spoken at large in discussing the treatment of cough and asthma: and our remarks, therefore, upon the present occasion, will be but few.

Where the irritation is considerable, and accompanied with much increase of vascular action, as in the commencement of the apostematous and catarrhal varieties, the best demulcents, and, indeed, the only medicines of this

kind we can employ as palliatives, are the vegetable mucilages, as of tragacanth, quince-seeds, or gumarabic. Where it is necessary to diminish the general action, these may be united with small doses of ipecacuanha, or of squills, which have the double power of exciting nausea, and unloading the mucous follicles of the bronchiæ as expectorants. And, where the cough is very troublesome and the pain acute, they should be united with narcotics, as opium or hyoscyamus.

In a more advanced stage of the disease, and through the entire course of the tubercular variety, except where hæmoptysis is present, the expectorants, more properly so called, have often been employed with advantage. One of the oldest of these is sulphur, and, perhaps, one of the best: from its not readily dissolving in the first passages, it is carried to the rectum, and skin sometimes, with little alteration, and hence gently stimulates both extremities, loosens the bowels, and excites a pleasing diaphoresis on the surface.* It is in this way it appears to be serviceable in an inflammatory or tubercular state of the lungs. It was in high repute among the Greek and Roman physicians, who, when employing it as an expectorant, usually combined it with yolk of egg; and it has maintained its character to the present day. In the tubercular or scrofulous variety, as it is often called, it has frequently been united with some other preparation, as diaphoretic antimony, with which it was joined by Hoffmann, dulcamara by Videt (*Médecine Expectante*, tom. iii., p. 237, 8vo., Lyons, 1803), and cinchona by Dr. Trotter.—(*Medicina Nautica*, vol. iii., p. 325.)

The vulnerary balsams and resins, however, have been more generally had recourse to, but ought rarely, perhaps never, to be employed in an early stage of the disease. Their action is common, and depends upon their possession of a terebinthinate principle, and hence they might be used indiscriminately, but that some of them are less stimulant and heating than the rest. Myrrh and camphire are among the least irritant, and may often be employed when we dare not trust to any other. Copayva, though of somewhat greater balsamic pungency, has often been found essentially useful. Marryatt was peculiarly attached to it: he gave twenty drops of it night and morning upon sugar, and asserts that, when an ulcer has been formed, it ought never to be omitted (*Therapeutica*, Lond., 1758); and Dr. Simmonds appears to hold it in nearly as high an estimation.—(*Pract. Obs. on the Treatment of Consumption*, Lond., 1780.)

Many of the remedies already enumerated under the present head act with a sedative influence, and of opium we have already spoken. But there is a medicine which immediately belongs to the present place, not yet noticed, that has of late years been strongly urged upon the public in the warmest terms of panegyric, and by many celebrated writers been regarded as a specific in consumption; and that is, the prussic or hydrocyanic acid. M. Magendie has been highly sanguine concerning it in France.—(*Recherches sur l'Emploi de l'Acide Prussique*, &c.,

* Of late years the inhalation of iodine and chlorine has been extensively tried. When iodine is employed, it is only in a minute quantity, and mixed with hydriodate of potassa. Dr. Elliotson informs us, that he has seen more mitigation from the chlorine than the iodine; but he has never seen a case cured by either of them. He has known a single drop of tincture of iodine, put into a pint of fluid, produce great irritation; but chlorine is borne much better: the mitigation afforded by it, however, is but temporary. The following is the mode of using it recommended by Dr. Elliotson:—Into three quarters of a pint of water, drop four or five minims of a saturated solution of chlorine; but he considers it best to begin with one or two minims, and to increase the quantity gradually, in proportion as the patient can bear it.—See Lect. at Lond. Univ., as published in *Med. Gaz.* for 1833, p. 236.—Ed.

par F. Magendie, D. M., &c., 8vo., Paris, 1819.) MM. Brera, Manzoni, and Borda (*Storia della Febbre Petecchiale di Genova*, &c.) in Italy, and Dr. Granville in our own country (*Observations on the Internal Use of the Hydrocyanic Acid in Pulmonary Complaints*, &c.); yet not a single case of actual cure in confirmed phthisis has hitherto been advanced by any of them. We have already noticed this powerful medicine as a most valuable subduer of nervous irritation in periodic nervous cough and whooping-cough, and there can be no question that it will often be found capable of acting in the same manner in phthisis. But, from the greater degree of debility and relaxation in this last than in the preceding diseases, we have more to fear from the mischievous effects of the prussic acid, which cannot always be guarded against, and which M. Magendie admits to have taken place occasionally with very fearful apprehensions, such as vomiting, diarrhoea, great depression of spirits, prostration of strength, and even syncope. And hence, if it be employed as a palliative at all, it should be in the earlier stages of the disease; for, in the latter, where it is most wanted, it is altogether unsafe, and must yield to most of the forms of opium. And the same remark may be made concerning aconite, another of the famous counter-stimulants of the present Italian school of medicine, and with which M. Borda tells us he has sometimes snatched the patient from the jaws of death.

V. The last part of the general therapeutic process, which has been attempted in most ages, has consisted in endeavouring to diminish or carry off the local affection by a transfer of action.

Blisters have very generally been applied for this purpose to the back or the chest. Their service is temporary, but often very efficacious, and they ought never to be neglected. It was formerly the custom to render them perpetual by the use of savin ointment or some other escharotic. But it is less painful and more beneficial to let the skin heal, and renew them after short intervals.

Setons, issues, and caustics, however, where the constitution is not very delicate, nor the habit very irritable, have proved far more powerful revellents, on account of their more violent stimulus and greater permanency of action. The actual cautery, though much abstained from in modern practice, from its apparent, and, indeed, real severity, was in almost universal use in ancient times; and, in the mode described by Celsus, was undoubtedly a very formidable operation. When the disease, says he, has taken a deep root, the cautery must be applied under the chin, in the throat, twice on each breast, and under the shoulder-blades; and the ulcers must not be healed as long as the cough continues.

The obvious intention is to produce a revulsion, and hence, by transferring the morbid action to a part of less importance, to allow the lungs to return to a healthy condition. Such transfer may, by these means, in some cases be rendered total, though, in general, the morbid

irritation is only partially, instead of entirely, carried off. There are other means, however, by which it seems to be removed altogether, although they are seldom put into our hands.

Thus M. Bayle's fifty-third case is that of a medical man who was fully prepared to meet his fate, and resolved to take no medicine whatever. At this time a severe rigour from an unknown cause attacked him, succeeded by a sweating-fit so profuse, that his linen was changed two-and-twenty times in a night, and even this was not sufficient. The paroxysm proved critical, and the disease was thus carried off by an ephamera.

Sir Gilbert Blane gives an account of a like singular and salutary change excited by a hurricane at Barbadoes in 1780, which produced such an effect on the air or on the nerves of the sick, that some who were labouring under incipient consumption were cured by it: while others who had reached a more advanced stage were decidedly relieved, and freed for a time from many of their symptoms.—(*Observations on the Diseases of Seamen*, 8vo., Lond., 1785.)

No affection seems to keep a consumptive diathesis in so complete a state of subjugation as pregnancy. Most practitioners have seen cases in which a female has dropped all the symptoms of phthisis upon conception, and has continued free from the disease till her delivery. Suckling does not seem to continue the truce; but, if she conceive again shortly afterward, she renews it: and there have been instances in which, from a rapid succession of pregnancies, the suspension has been so long protracted, that the morbid diathesis has run through its course and entirely subsided, leaving the patient in possession of firm and established health.

As one disease, therefore, or state of body, is well known to have a frequent influence upon another, and consumption is found to be thus influenced by various affections, it is a question well worth inquiring into, whether there be any malady of less importance, which, like cowpox over smallpox, by forestalling an influence on the constitution, may render it insusceptible of an attack of phthisis? Dr. Wells, not many years ago, very ingeniously engaged in an inquiry of this kind, and, finding that it was common for the consumptive in Flanders to remove to the marshy parts of the country where agues were frequent, began to think, not indeed that agues might give an exemption from consumptions, but that the situation which produced the former might prove a guard against the latter. And, so far as his topographical investigations have been carried, and they have extended over some part or other of all the quarters of the globe, this opinion has been countenanced; for he has discovered that, wherever intermittents are endemic, consumption is rarely to be met with, while the latter has become frequent in proportion as draining has been introduced.—(*Trans. Medico-Chir. Soc.*, vol. iii., p. 471.) The later inquiries of Dr. Southey do not support this hypothesis, but the question is yet unsettled, and well worth pursuing; and Mr. Mansford, who practises in the interior of Som-

ersethshire, has still more lately published a work, which, though not written as a defence of Dr. Wells's opinion, indirectly confirms it, by endeavouring to prove that a low, inland situation, like the vales of his own country, is far better calculated as a residence for consumptive patients than the air of mountains, or of the seacoast.—(*Inquiry into the Influence of Situation on Pulmonary Consumption*, by J. G. Mansford, &c., 8vo., 1818.)*

* As the pathology of consumption is not yet fixed, so too the treatment of this disease varies with different physicians: the assumption that the forming stage of phthisis is, in many cases, of an inflammatory character, has led the profession in the U. States to a more active method of relief in early periods, than is sanctioned by the practice of Europe: phthisis has generally been considered in this country as allied to pneumonitis, bronchitis, &c., and as requiring the use of the lancet, purgatives, antimonials, &c., during the first stage, which practice is warmly advocated by Dr. Hosack (Essays, vol. ii.): few however would imitate the extreme depletory practice of Rush; bloodletting has its limits. In regard to purgatives, morbid anatomy has so often shown an inflammatory condition of the mucous membrane of the alimentary canal, that the milder cathartics seem more appropriate than drastic purgatives.

Antimonials, in the earlier stages of the disease, are almost universally recommended, and Dr. Balfour's practice of tartar-emetic ointment is extremely popular. Practitioners differ widely as to the remedial powers of digitalis: while it is much extolled by some as lessening the activity of the heart and arteries, it is rejected by others as increasing the debility and irritability. Dr. Eberle's estimate of its value seems to us to be just: "that under careful management, and in conjunction with a well-regulated diet and proper attention to the cutaneous functions, much good may be derived from its employment in incipient phthisis." "Tar fumigations, employed as directed in the text, have been found highly serviceable by American practitioners. In regard to iodine, a gentleman of ample experience, Dr. Morton of Philadelphia, remarks (*Illustrations of Pulmonary Consumption*), that "in a large number of instances, it has appeared, especially in incipient consumption, to arrest or suspend the tubercular secretion, and with it the hectic, marasmus, cough, dyspnoea, and other urgent symptoms;" and again, "in a majority of cases, even in the second stage of phthisis, I have been much gratified with the results; thus, it often relieves the dyspnoea, improves the complexion, and restores the appetite, even when the advanced progress of the disease precludes all hope of recovery." Dr. Rush urges salivation as important in treating pulmonary consumption; we are aware that the American journals contain some interesting reports in which this plan of treatment has been successful, but there are habits of body, peculiarities of temperament, and other circumstances, which, in some cases of phthisis, would forbid it.

The respiration of cold air was proposed as a remedy in pulmonary diseases by the late Dr. C. Drake, of New-York. He states, "that its sensible effects were tolerably uniform. The most constant effect on the pulse was to render it fuller: when it was preternaturally frequent, it commonly rendered it slower; it very generally mitigated the cough, diminishing its frequency, and rendered the expectoration freer and easier." For a view of the

GENUS IV.

MELANOSIS.*

MELANOSE.

SECRETION OF A BLACK MATERIAL, MORE OR LESS INSPISSATED; STAINING OR STUDDING THE VISCERAL AND OTHER ORGANS.†

THE tubercles and tubers of struma chiefly originate in the texture of the glands, especially the lymphatic, and are often confined to them. There are other tubercles, as those of mesenteric tabes, that spread rapidly into different textures, and sometimes originate in them. But there are none that seem to commence or extend over so large a field as those we are now about to describe, or so seriously to affect the constitution.‡ There is not, indeed, a single organ of the simplest or most complicated kind, from the cellular texture to the unravelled elaboration of the brain, which is not occasionally loaded with them; while, in various parts, the black pigment, which gives them their hue, is found diffused in extensive sheets, without tubercles, or the pulpy matter that fills their cysts; transforming the natural colour of the organs, to which it is conveyed, into its own morbid jet. [The most frequent seat of true melanosis, however, is found by Dr. Carswell to be the serous tissue, more especially where this tissue constitutes the cellular element of organs. Here the melanotic matter accumulates in the cells, and forms tumours of various sizes. Its formation, as a secretion, is still more conspicuous in the loose cellular tissue, and especially on extensive serous surfaces.]

The last change has hitherto been found chiefly in the bones, but sometimes also in the membranes, and even the parenchyma of organs, constituting, in the language of M. Breschet, a false membrane or membranous expansion on the surface of the mucous and other textures; and it is hence possible that examples may hereafter be met with of a generally DIFFUSED, as well as a generally TUBERCULAR, form of the disease. But as the second, with a few local exceptions, is the only mode under which it has hitherto appeared,§ we have at present but one

apparatus employed by Dr. Drake, see the Am. Journ. of Med. Sc., vol. iii., p. 53.—D.

* Melanose, Laennec; Melanoma, Dr. Carswell; Black Cancer, Baron Dupuytren.

† "True melanosis consists in the formation of a morbid product of secretion of a deep brown or black colour, of various degrees of intensity, unorganized, the form and consistence of which present considerable variety, solely in consequence of the influence of external agents."—(Dr. Carswell, in *Illustrations of Elementary Forms of Disease*, fasc. iv.)—Ed.

‡ If we advert to tubercular diseases of the lungs, peritoneum, spleen, and some other organs, and at the same time recognise them, with many of the best modern pathologists, as scrofulous affections, some of our author's doctrine, as here laid down, will appear incorrect.—Ed.

§ Since the period when this was written melanosis has been investigated with considerable attention, and our knowledge of its nature has been

species of the genus, which we shall proceed to describe under the name of

Melanosis Tubercularis. Tubercular Melanose.*

SPECIES I.

MELANOSIS TUBERCULARIS. TUBERCULAR MELANOSE.

THE BLACK SECRETION PULTACEOUS, IN ENCYSTED† TUBERCLES, PEA-SIZED OR WALNUT-SIZED, SCATTERED IN GROUPS OVER MOST OF THE ORGANS; CHIEFLY BELOW THE SURFACE, SOMETIMES UPON IT: FEVER MOSTLY A HECTIC: GREAT DEBILITY.‡

It is singular that this very striking disease should not have been traced, or rather, perhaps, not have attracted much of the attention of

much extended. We are now aware that it presents itself in various forms, which have been treated of with great ability and discrimination by Professor Carswell, in his *Illustrations of the Elementary Forms of Disease*, fasciculus iv., Lond., 4to., 1834. He divides melanotic formations into two kinds, the *true* and *spurious*. Thus, when these formations or products depend on a change taking place in that process of secretion, whence the natural colour of certain parts of the body is derived, or, in other words, when they constitute what is called an idiopathic disease, he considers them as belonging to the first kind; and, when they originate in the accumulation of a carbonaceous substance, introduced into the body from without, the action of chymical agents on the blood, or the stagnation of this fluid, he includes them in the second kind.—Ed.

* Four varieties, or species, are described by Professor Carswell, namely,—1. Punctiform. 2. Tuberiform. 3. Stratiform. 4. Liquiform. The tuberiform, which is by far the most common, corresponds to Dr. Good's melanosis tubercularis, or the *melanose en masse* of French pathologists. Tuberiform melanosis agrees with the "concrétions mélaniques;" punctiform with the "mélanose infiltrée;" stratiform with the "mélanose membriforme;" and liquiform with the "mélanose liquide" of Laennec, Breschet, Andral, and other writers. It was Breschet who applied the term liquid melanosis to one of the varieties.—Ed.

† "Tantôt la matière est enkystée, tantôt elle n'est contenue dans aucun réservoir; et elle paroît être exhalée à la surface des tissus, ou épanchée dans une cavité."—(Breschet.) "La mélanose en masse peut être entourée d'un kyste, ou en être dépourvue. Le premier cas est infiniment plus rare que le second."—(Andral, *Précis d'Anat. Pathol.*, tom. i., p. 451.) Laennec's distinctions of encysted and unencysted melanosis are of much less importance than similar distinctions in relation to cancer; in fact, cysts are rarely met with, and, when they are present, consist of such a cellular loose tissue, that they have little effect as boundaries to melanotic humours.—(Blandin, *Dict. de Méd. et de Chir. Pratiques*, art. MELANOSE.) According to Dr. Carswell, melanosis is perhaps never found encysted in compound tissues or organs, as the brain, lungs, liver, or kidneys; whereas it is always so in the cellular and adipose tissues, and sometimes also on the surface of serous membranes.—See *Illustrat. of the Elementary Forms of Disease*, fasc. iv.—Ed.

‡ In the majority of cases, melanosis does not produce great constitutional disturbance. We find it sometimes attaining considerable magni-

tude in the liver, and in the common cellular tissue, without giving rise to any functional derangement sufficient to excite the suspicion of its existence; it may merely occasion a degree of uneasiness by its mechanical effects on the contiguous parts.—Ed.

pathologists, till a few years back, at least in the nosology of man. For it has been long observed in many kinds of quadrupeds, as the dog, cat, hare, but especially the horse, and, among the veterinary surgeons of France, has obtained the name of charbon, or *maladie charbonneuse*. It is, however, to the ingenious anatomical researches of MM. Laennec and Bayle (See *Journ. de Méd. de Corvisart*, &c., tom. ix., p. 368) that we are indebted for our first knowledge of the disease as it exists in man,* and for the very appropriate generic name of MELANOSIS,† or MORBID DENIGRATION, by which it is now generally distinguished.

[The colour of melanosis varies from dark yellow to brown, deep blue approaching to black, and to complete black, which is the most common. It is readily detected by its peculiar shades of colour in any organ containing it; more especially as the surrounding tissues are lighter coloured, and form a contrast with it. No smell proceeds from it, a circumstance distinguishing it from gangrene, which always emits a very offensive odour; nor has it any particular taste, a character which belongs to it in common with most other morbid formations. The minute texture of melanosis is little known: if we except the cyst, no vessels nor nerves have been discerned in it; and it seems as if it were an inorganic substance deposited in or upon various parts. The melanosis described in the definition prefixed to this article by Dr. Good, is the most common or the tubercular va-

tude in the liver, and in the common cellular tissue, without giving rise to any functional derangement sufficient to excite the suspicion of its existence; it may merely occasion a degree of uneasiness by its mechanical effects on the contiguous parts.—Ed.

* Breschet assigns the honour of having first described this organic affection to Dupuytren, who declared, when MM. Bayle and Laennec (*Bulletins de la Soc. de l'Ecole de Méd.*, No. ii., 1806) published their observations, that he had for several years described the disease in his lectures. Some controversial papers on this point may be seen in Corvisart's *Journ.*, tom. ix., p. 360 and 441, and tom. x., p. 89 and 96. An allusion to the disease, however, may be traced in the writings of Morgagni, Bonetus, and Haller. In *Epist. iv.*, No. iv., De Sedibus et Causis Morb., Morgagni informs us, that in one body which he opened, the lungs looked as if they had been stained with ink; and in another place, he describes the lungs as having been found indurated and black. In a dropsical patient, the liver, after death, was also black.—(*Epist. vii.*, No. xi.) In Haller's *Opuscula Pathol.*, obs. xvii., notice is taken of an example in which the lungs were found not filled with pus, but with a matter as black as ink; and of another case, in which the author met with black matter in the cavity of the chest.—Ed.

† Breschet says, however, "Cette désignation ne se trouve ni très-rigoureuse ni très-exacte, car on voit plus souvent ces matières être jaunes-brunes, couleur de suie ou de bistre, que véritablement noires. Cependant j'en ai rencontré, qui étoient parfaitement noires, et qui coloroient les tissus de lin et le papier, comme le fait la solution aqueuse de l'encre de la Chine."—See *Journ. de Physiol.*, tom. i., p. 354.—Ed.

riety of it, but it presents itself in other shapes.* The melanotic deposit takes place in three distinct forms: 1st, Very much divided and suspended in liquids; hence the black tinge of the serous fluid of certain cavities, and especially as frequently presented by the serosity of the peritoneum, when the liver, bowels, stomach, or uterus, are the seats of cancerous disease.† Breschet, Andral, and Cruveilhier, describe a melanotic secretion from the surface of a mucous membrane, or the cavity of the stomach; but, in doing so, it seems to Professor Carswell that they have mistaken the black discoloration of the blood, produced by the action of the gastric juice on this fluid, when effused, for true liquiform melanosis.—(Op. cit., fasc. iv.) 2dly, As a very thin layer spread over serous membranes, the stratiform or membraniform melanosis. In this case it sometimes exhibits a fine glossy black colour, resembling that of Indian-ink. The layers are more or less extensive; and M. Méral has seen the whole of the peritoneal coat of the intestines covered with them. The matter is adherent to the serous membranes, which are almost the only ones upon which it assumes this form; but they are not at all altered by it, being neither thickened nor otherwise affected; and it is remarked, that individuals who die with this modification of melanosis do not fall victims to it, but to other organic changes. Layers of black matter are noticed on some portions of the mucous system, as on the tongue in typhoid and other fevers; and Méral even conceives that such appearance is a specimen of one kind of melanosis. 3dly, Melanosis most frequently assumes a globular shape, or the form of a tubercle, varying from the size of a millet-seed to that of an egg, or even a larger body. Its shape is moulded by the containing parts; and hence it is in general less symmetrically spherical in soft parts, and more regularly globular

in such as are firm. 4thly, A fourth variety is that in which the disease is diffused through certain tissues, the “*mélanoze infiltrée*” of Laennec, the “*punctiform melanosis*” of Carswell.*]

The cause, progress, diagnosis, and mode of treatment of tubercular melanosis, are at present obscure and unsatisfactory. The individual labouring under it frequently exhibits, when he first applies for help, a considerable degree of febrile excitement, debility, and oppression in the thorax or abdomen; most commonly about the pleura or in the loins.

Every case of melanosis that came under the observation of Dr. Armstrong was accompanied by more or less chronic bronchitis, which, however, he admits, is not sufficient of itself to produce melanosis, as numerous examples of it take place without any traces of the latter affection.—(*Morb. Anat.*, &c., p. 25.) [Melanosis is alleged to be more frequently combined with carcinoma than with any other disease; but, as Dr. Carswell observes, there is no similarity between these two diseases, their anatomical, physical, and chymical characters being totally different. Several varieties of the former (regarded as such in Dr. Carswell's classification) are highly organized, while melanosis itself is an unorganized substance, injurious only from its quantity, the number of organs which it affects, its situation, and mechanical operation. In Dr. Carswell's work may be seen representations of melanosis, combined with fibrous, carcinomatous, and erectile tissues.]

The above, however, are not always the introductory symptoms; for the disease sometimes commences with catarrhal or rheumatic affections after exposure to cold, succeeded by shivering fits.† The patient seems generally unwell for the first five or six weeks after this attack; but when it has once firmly established itself, and evinced the thoracic or abdominal signs just adverted to, it proceeds with a rapid

* This form is exemplified occasionally in most of the organs of the body, and also sometimes on serous surfaces, as the pleura and peritoneum. In compound organs, the disease is generally a single swelling; but in the cellular and adipose tissues there is an aggregation of tumours, producing tuberculated masses. In the liver, lungs, and kidneys, according to Dr. Carswell, the tuberiform melanosis is always combined with the punctiform.—Ed.

† Breschet, in Magendie's Journ., tom. i., p. 359. Laennec takes no notice of the fluid variety. Indeed, as he describes melanosis as a *tissue*, he could not regard a liquid as meriting the name. But other pathologists, who look upon melanosis as a simple deposit of unorganized colouring matter, have no more difficulty in conceiving its fluid than its solid state. The liquiform variety of true melanosis has in general been confined to natural or accidental serous cavities. Dr. Carswell has never seen it in man, as a product of secretion, but has met with it in consequence of the destruction of melanotic tumours, and the effusion of their contents into the serous cavities, the walls of which they had perforated. The accidental serous cavities in which it is found are those which constitute cysts, particularly in the ovaries.—Ed.

* The punctiform melanosis appears in minute points or dots, grouped together in a small space, or scattered irregularly over a considerable extent of surface. Such appearances are most frequently seen in the liver, the cut surface seeming as if it had been dusted over with soot or charcoal powder. When examined with the aid of a lens, the black points sometimes present a stellated or penicillated arrangement, which, in some cases, can be distinctly seen to originate in the ramiform expansion of a minute vein, filled with melanotic matter. At other times, this matter appears to be deposited in the molecular structure of this organ, consisting of the most minute points disseminated throughout the acini of the liver, of various depths of shade, terminating in black.—See Carswell's *Illustrations of the Elementary Forms of Disease*, fasc. iv.—Ed.

† Melanosis often produces, at its first formation, no disturbance of the health, and the existence of the disease is frequently not suspected previously to dissection. However, several patients were cut off by the disorder who had a sallow complexion, excessive debility, and more or less oedema, being in a state very similar to the advanced stage of scurvy.—See Magendie's Journ., tom. i., p. 365.—Ed.

and fatal step, and in about a fortnight, he falls a victim to the hectic fever, perspiration, emaciation, and debility by which he is jointly assaulted: the prodromi or incursive symptoms, whether affecting the loins or chest, usually giving way before the closing scene arrives, and deceiving the sufferer, and sometimes even his medical attendant, into a belief that he is improving; when he suddenly sinks from debility alone.

If the patient be examined accurately at this time, a few tubercles or clusters of tubercles may occasionally be felt under the skin, especially that of the abdomen or of the breasts. And sometimes also a cyst, much larger than the rest, may be found projecting, and even forcing its way externally through the integuments. In a few instances this larger cyst ulcerates, of which a striking example occurred to M. Breschet in 1821, and is particularly noticed by Mr. Cullen. In the right groin of the patient, who was a female, an ulcerative surface was perceived about as large as a crown piece, the bottom of which consisted of the ordinary black material of the disease before us, jetty as China ink, of the consistence of cream above, but much more inspissated below, where it was in contact with the cellular texture. There were sufficient proofs that it was not a mere sloughing sore; among which it may be observed that it was destitute of fetor, and that in its immediate vicinity, as well as in other parts of the body, as was afterward ascertained by opening into them, there was a crop of defined melanotic tubers of different forms and diameters.

One of the best marked instances upon record is the following, which occurred to Professor Alison in the Royal Infirmary, Edinburgh. The patient's name was Rachael Bruce, and she was admitted on the third of June.—(*Trans. of the Medico-Chir. Soc. of Edin.*, vol. i., p. 275, 1824.) She complained of severe pains shooting down from the loins to the inferior extremities, and to the abdomen. She had similar pains in the right shoulder and arm, increased in the night-time, or by motion. She had become weak and emaciated since her complaints began, and was liable to shivering, followed by flushing and profuse perspiration, which increased her debility without relieving her pains. The abdomen was swelled, but did not fluctuate upon percussion, and the distention varied in degree at different hours of the day. She had thirst, with scanty, high-coloured urine, not coagulating by heat. The integuments of the abdomen were flaccid; and a hard, moveable tumour could be felt in the iliac and hypogastric regions. She was also liable to paroxysms of dyspnoea during the night. Her appetite was impaired. She had a bad taste in the mouth, with white and dry tongue. Her bowels were reported to be regular; but she had occasional nausea.

She stated her complaints, which were of five or six weeks standing, to have commenced, after exposure to cold, with shivering and pain, and stiffness of the loins, and of the hip and

knee-joints of the left side. The enlargement and induration of the abdomen had been remarked only during the last fortnight.

Up to June the 20th, being seventeen days from the time of admission, the symptoms continued with little variation. On the 21st were perceived several small painful tumours on the integuments of the abdomen, which she declared to have existed from the commencement of her illness. She was on this day examined by a skilful accoucheur, who reported the tumour felt in the hypogastric region to be unconnected with the uterus. On the 24th a copious sweating, with involuntary discharge of urine, was added to the other symptoms. From this moment there was great debility, with decided hectic fever; and a tendency to sloughing of the sacrum. On the evening of the 7th she had vomiting of a dark-coloured matter, and soon afterward died.

The course is usually more rapid: and in the case of John Houston, a shoemaker, admitted into the same infirmary under the care of Dr. Home, extended only to thirteen days. His chief symptoms at the time of admission were those of pleurisy, with a severe cough and difficult expectoration. The bladder was also affected; and on the eighth day he was troubled with painful hemorrhoidal tumours, probably produced by the action of repeated purgatives. The other symptoms gradually diminished, but the debility increased. On the twelfth day, as we learn from a diary of the symptoms and treatment, furnished us by Sir Andrew Halliday, his pulse was 112; heat 98½ Fahrenheit; he was allowed a beefsteak, and a quarter of a pint of sherry. On the ensuing night he made complaint of great weakness; his pulse quickened to 140, and he died at four in the morning.—(*London Medical Repository*, vol. xix., p. 442.)*

The treatment is yet to be learned; and the cases before us afford little instruction upon the subject. The first was resisted by little more than palliatives, as leeches, laxatives, anodynes, and Dover's powder. The second unfolds a bolder plan, though the patient still sooner reached his end. It consisted in venesection to sixteen ounces, two days in succession, and powerful purgatives, at first often repeated, of calomel, jalap, and sulphate of magnesia, &c.

* A case of melanosis, affecting the parotid gland, is recorded by Dr. Valentine Mott, in the *Am. Journ. of Med. Sc.*, vol. x., p. 16. The description is accompanied with a coloured engraving of the melanotic body, which was extirpated. On dividing the tumour longitudinally, not a vestige of the original organization of the gland could be observed. The inner surfaces had the appearance of firm tar, and imparted a black colour to the fingers when touched. After the operation, the patient seemed to do well; but in about a month several tumours appeared on the scalp, a dark spot showed itself in the integuments of the diseased side of the face, the knee swelled, and hectic supervened. The patient died fifty-three days after the operation. No examination of the body could be made, but Dr. Mott is confident that the disease was constitutional melanosis.—D.

But this was not long continued, no benefit appearing to issue from it; and it yielded to sedative mucilages and a tonic diet.

In reasoning speculatively, we should speak with great modesty. But admitting the material which forms the tubercles to be a peculiar secretion, and that the constitutional excitement consists mainly in this new and stimulant action, perhaps it may, in future cases, be found useful to combine the two intentions of allaying the peculiar irritation, and, at the same time, urging the secretions to a renewal of their proper action; or, in other words, to employ the conjoint force of sedatives and counter-irritants; which may be effected by a union of opium, or Dover's powder, with the tincture of iodine. The great and beneficial influence which the latter is well known to exercise in many cases over strumous tubercles, should indicate its use on the present occasion. And it is also not improbable, from the approach which the disease seems occasionally to make to the more irritant cases of phthisis, in its excitement of the chest and its hectic fever, that the hydrocyanic acid might at times, with great advantage, take the place of all other sedatives. Such coincidences of symptoms, moreover, show us clearly the place which melanosis should occupy in a general nosological arrangement.*

Before hazarding a syllable upon the physiology of this very extraordinary disease, it is requisite to put the reader into possession of the general appearances afforded by post-obit examinations; and the case already alluded to, as under Professor Alison's care, is admirably adapted to this purpose, if put into an abridged form.

The body evinced great and general emaciation, and various small dark-coloured tumours, perceptible during life, were still distributed over it. In the mammae, these were largest and most numerous: they were traced in cysts, and imbedded in the cellular substance; and when cut into were found to contain a deep black-coloured matter, of a soft and pulpy consistence. Within the abdomen, most of the cellular and adipose textures had disappeared. The peritoneum lining the parietes was of a blackish colour, and the black matter was irregularly deposited in striae and spots upon the inner side of the membrane, which had lost much of its natural transparency. The omentum presented a similar appearance, and several globular shining tumours of a black colour were appended to it, which, when cut into, poured out a similarly coloured fluid. Spots and tubercles of a like kind were traced in the serous or outer membrane of the intestines, and between the folds of the mesentery. The ovaria were several times as large as their natural size, seated in front of the uterus, and occupying the lateral iliac regions.

* When a melanotic tumour is so situated as to admit of being removed with a knife, this is the proper practice. In the human subject such an operation has been done for the extirpation of the eye affected with this extraordinary disease. Melanotic tumours have often been successfully removed from horses.—See *Archiv. Gén. de Méd.*, Juin, 1828, p. 180.—Ed.

Their external surface had a dark, shining, lobulated appearance, with numerous ramifications of vessels upon the peritoneal covering; beneath which black matter was irregularly deposited in spots, giving a mottled appearance to the whole. When cut into, their substance was uniformly black. The cellular texture still retained its consistence, and vessels containing red coagulated blood could be traced through it. Several distinct cysts or cavities were found in their substance, which poured out a black liquid when opened. The kidneys, liver, spleen, and the mucous or interior membrane of the stomach and intestines, were all free from black matter, although it was deposited in the cellular tissue connected with these organs. On uncovering the breast-bone and skull-cap, it was observed that the whole texture of the sternum, the anterior portion of the ribs, and a great part of the parietal and occipital bones, were black, more brittle, and of softer consistence than natural, but without enlargement or ulceration. The periosteum was nearly natural, but the whole inner table of the skull, when removed from the dura mater, was of a darker hue than natural, and in some places where the black matter was deposited in irregular patches of the bone, there were corresponding stains on the surface of the dura mater. The substance of the brain was healthy, but a few black striae were discernible in the membranes, and the tunics of several of the vessels. A large quantity of serum was effused under the arachnoid membrane and in the ventricles. Within the thorax, the costal pleura and surface of the lungs were studded with black tubercles like those of the integuments, while some of them were larger. The substance of the lungs was dark, and some minute tubercles were imbedded in it, and like spots were noticed beneath the pericardial coverings of the heart, which contained some coagulated blood in its cavities, and was softer than usual.

It should further be observed, that in a few places in the present subject, but more generally in others, the black material varied considerably from its ordinary degree of consistence, and instead of being pulpy or nearly solid, was a fluent liquid; and that several of the tubercles were filled with a white and brain-like substance, while those that surrounded them were of a deep jet.

The first opinion formed respecting the nature of these enlargements by MM. Breschet and Laennec was, that the dark material was congested blood that had escaped from the capillary vessels into the cellular substance by a rupture of their coats, or by anastomosis from relaxation. But this conjecture was soon found untenable, as it was sufficiently ascertained that the material is a distinct secretion, and is now supposed to be a secretion *sui generis*. Nor is another opinion of M. Laennec's much more tenable, which advances that the black material evinces different stages of elaboration; that when first thrown forth it is pultaceous or nearly solid, and in a state of crudity, but that it gradually matures, and advances to a state of ramollissement or fluidity. For it is well observed

by Dr. Cullen, that, were this true, we should expect to find the largest cysts or reservoirs in the highest state of liquefaction, and the smallest in the highest state of solidity; the contrary of which is usually the course pursued. [Mr. Fawdington (*Case of Melanosis, with General Observations on the Pathology of this interesting Disease*, 1826), however, follows Laennec in placing the stage of fluidity posterior to that of solidity. At first it seems difficult to conceive how the melanotic matter can be originally deposited in any other than a liquid form; and if in a solid state, how from its organic nature it can undergo the process by which it is afterward softened. Yet, that tubercles of the lungs are first solid and afterward soften, though their substance has no organization, is the general belief.*]

It is also justly remarked by Dr. Cullen of Edinburgh, that the characters of tubercular melanosis completely distinguish it from cancer and fungus hæmatodes; since it is well known to exist without local pain,† and to propagate itself by cysts and boundary lines, while both the others are accompanied with severe lancinating pains, and burst through every bond, and extend their ravages in every direction.

[Dr. Armstrong, in noticing the opinion that melanosis, like tubercle, scirrhus, and fungus, is associated with an organized affection *sui generis* of the solids, takes the opportunity to remark, that in all the cases examined by him, the disease seemed to be nothing but a secretion, sometimes occurring in textures otherwise apparently natural, sometimes in those chronically inflamed, and sometimes co-existent with either scirrhus or fungus.—(*Armstrong's Morbid Anatomy, &c.*, p. 24, 8vo., London, 1828.) It is a peculiar feature in the nature of melanosis, that the animal textures are never, strictly speaking, converted into it, unless it be proved that the oily matter of the cellular tissue undergoes this change; and even on this supposition

it would be the conversion of an inorganic secretion rather than of an organic issue, into melanosis. On the contrary, the new matter is deposited in the substance of the textures or organs, or between their component fibres. These circumstances, together with its appearance in several of the bones, where it seems to have occupied the situation of the marrow,* would give some countenance to the notion that melanotic matter was a diseased modification of the adipose secretion. To this idea, however, an objection is presented in the melanotic masses found occasionally in the liver, spleen, and substance of the kidneys. Its occurrence in the pancreas forms little or no valid objection; for the quantity of adipose cellular substance with which the portions of this gland are connected, might be regarded as the primary matrix of the morbid deposition.—(*Edin. Med. Journal*, No. xc., p. 162.) All this, however, is only conjecture; but the following observations respecting the anatomical distribution and preference to certain textures exhibited by melanosis, seem to be founded upon the careful consideration of facts.

First, The cellular tissue and adipose membrane are both most abundantly and most generally the seat of the melanotic deposition; that is to say, of the tubercular melanosis. The subcutaneous and intermuscular cellular tissue is a common situation of it; as well as other parts of great laxity, where the cellular membrane is abundant, as in the genital organs, around the rectum, within the pelvis, and on the forepart or at the sides of the spine.

Secondly, The delicate cellular tissue which connects the serous membrane to contiguous parts and to the enclosed organs, presents this melanotic deposit nearly in the same, if not in a greater degree, than the common cellular membrane. This was particularly noticed in the case recorded by Mr. Fawdington. In Dr. Home's patient, though the pleura was studded with melanose tubercles, no mention is made whether they were upon or under it; but as the lungs are described as extensively occupied by melanotic masses, there is reason to infer that this is meant of the cellular tissue beneath the pleura, and connecting that membrane to the pulmonary lobules. In like manner, when, in the same case, the substance of the heart is said to be affected; when, in the case of Rachael Bruce, spots are said to have been noticed beneath the pericardiac coverings of the heart; and when, in Mr. Fawdington's case, the surface of the heart is described as covered with melanose spots, chiefly subjacent to the pericardium; little doubt can be entertained that the tissue of melanotic infiltration is the subserous and intermuscular structure. Infiltration of the abdominal subserous cellular tissue is particularly remarked in the case of Rachael Bruce, related by Dr. Cullen and Dr. Carswell, and also in Mr. Fawdington's examples. Next to the cellular

* M. Blandin supports Laennec's view by observing that melanotic tumours may change into a softened state, particularly when they are situated near the surface; the skin becomes thin and ulcerates, and from the surface of the sore is discharged a glutinous black matter, which is characteristic of the disease. A case exemplifying these changes was seen by M. Blandin in the Salpêtrière, and the particulars of it were published by Bîschet.—(*See Journ. de Physiol. Expériment.*, tom. i., p. 351.) The old woman, the subject of it, and who is referred to in our text, had melanotic tumours in the right groin, thigh, and breasts. It seems that the part, after having ulcerated, will sometimes form granulations and heal. This fact was illustrated in a horse, from which M. Damoiseau removed a melanotic tumour, as related by M. Trousseau.—*Archives Gén., &c.*, Juin, 1828, p. 180.—Ed.

† "Comme elle (la mélanose) paroît être absolument insensible, les viscères où elle existe ne manifestent aucune douleur, même à la pression; s'il y a de la douleur, on peut affirmer, que cette lésion organique n'y est pas seule. La mélanose seroit entièrement sans inconvénient, si elle ne gênait pas par son volume des viscères essentiels."—*Dict. des Sciences Méd.*, tom. xxxii., p. 185.—Ed.

* Breschet states, however, that he has never seen melanosis in the central cavities of the bones, in the synovial membranes, nor in cartilages.—*See Magendie's Journ.*, tom. i., p. 364.

and adipose tissue, several of the internal organs, termed parenchymatous, are most frequently the seat of the disease. Thus, not only the lungs (which, indeed, by the French writers are deemed the most common situation*), but the liver, the spleen, and the kidneys, are stated, in the case of Houston, to have been occupied with melanotic masses. In Mr. Fawdington's case, the liver, pancreas, spleen, and kidneys, were extensively affected; while in Dr. Alison's case, though the substance of both mammae and of both ovaries was completely melanosed, the liver, spleen, and kidneys were exempt from the disease. When melanotic tubercles take place in the liver, they are frequently of considerable size, and sometimes as large as an egg.

Lastly, it is to be observed, that, in the case of Houston, one of the ribs and a part of the clavicle were melanosed. In that of Rachael Bruce, a part of the inner table of the scull was darker than natural, and the surface of the bone was stained with particles of black matter. A great part of the parietal and occipital bones was black, less consistent and more brittle than natural; and similar changes were observed in the sternum and sternal ends of the ribs. According to Breschet, the parts of bones connected with the muscles are most commonly affected. Some textures seem either quite exempt from melanosis, or only to be very slightly affected by it. Thus the nerves, the proper arterial tissue,† and muscular fibre, are scarcely ever the seat of it; and it is doubtful whether the serous and mucous membranes ever become penetrated by the melanotic deposition.‡ The above critic errs, however, in setting down the skin as rarely or never affected. In the cutaneous texture, says Breschet, melanoses are common; and he has found an infinite number of small black tumours, resembling grains of cassia, situated in the skin, and appearing to originate from the rete mucosum. An example of this kind, which was seen by Breschet, is recorded by Alibert, who denominates it *cancer mélané*.—(Magendie's Journ., tom. i., p. 361; and Alibert, *Nosologie*, &c.) It ought to have been mentioned, that melanosis often attacks the lymphatic glands, the eye, and fat of the orbit; and that traces of it are frequently met with, as Dr. Armstrong confirms, in various diseased structures.]

We have reason to conclude that the disease before us is at first local, or commences in a particular organ; and that, from the general sympathy of the secretory system with the part where it first appears, it ramifies in every direction, over the most solid and compact, as well as over the most loose and yielding tex-

tures; accumulating and forming reservoirs where there are cells or other hollows for its reception, and spreading as a jet, die, or sheath on the surface, or through the parenchyma, where these are not.

[The doctrine of the disease being at first local, is liable to several objections: first, the great disorder of the health frequently preceding the melanotic formation;* secondly, the great extent of the affection, and the many internal organs found after death studded with melanotic tubercles; thirdly, some peculiarity of constitution appears requisite, from the curious circumstance that the disease, when it occurs in horses, is chiefly observed in such as have a white or gray coat.†]

What is the nature of the black die or pigment, and by what means is it produced? Much more attention to the subject is necessary, before any satisfactory reply can be given to this question. The material to which it seems most nearly to make an approach, in temperate climates, is the black pigment of the choroid membrane, and perhaps that which is supplied from the rete mucosum as a colouring matter for black hair. Both these are evidently productions of the secretory system. They are indeed small in quantity; but if we turn our eyes to the intertropical climates, we shall find the same, or a like jet pigment, thrown forth over the entire surface, and continued by a permanent supply, as the die antecedently furnished is carried off. And if we attend to the curious economy which takes place in this subject respecting the children of negroes, we shall also find this material produced in very large abundance in a short time: for the infants

* This is not, however, a constant circumstance: many patients with melanosis have not suffered at first much constitutional disturbance; and Dr. Carswell, we know, ascribes the injurious effects of melanotic formations principally to their mechanical pressure on the neighbouring parts: they are not themselves organized.—Ed.

† See G. Breschet, in Magendie's Journ. Expér. de Physiologie, tom. i., p. 355. "The much greater frequency of melanosis in the gray and white than in the bay, brown, or black horse, is a circumstance which may be noticed here as favourable to the theory which ascribes the origin of this disease to the accumulation in the blood of the carbon which is naturally employed to colour different parts of the body, as the hair, rete mucosum, choroid, and other parts."—(See Carswell's Illustrations of the Elementary Forms of Disease, fasc. iv.) Remarkable examples of melanosis in the horse are recorded by MM. Goyer and Rodet (Journ. de Méd. Vétérinaire, tom. ii., p. 273); and MM. Trouseau and Le Blanc relate other interesting facts of the same kind.—(Archiv. Gén. de Méd., Juin, 1828.) Speaking of the melanosis being principally seen only in white or gray horses, M. Blandin observes:—"On dirait que chez eux la matière colorante s'est, pour ainsi dire, réfugiée dans ces tumeurs."—(Dict. de Méd. et Chir. Pratiques, art. MELANOSE.) Occasionally, however, melanosis is met with in horses of other colours, and both Rodet and Andral have noticed it in those of a bay colour. In the horse, melanotic tumours are most liable to form under the tail, whence they extend into the pelvis.—Ed

* "Le poulmon est, de tous les viscères, celui où on les voit le plus fréquemment."—Dict. des Sciences Méd., tom. xxxii., p. 185.

† This is true, notwithstanding, as Breschet remarks, "les vaisseaux sanguins sont parfois entourés de ces tumeurs, et le vaisseau est caché au milieu de la matière mélanique."

‡ See Edin. Med. Journ., No. xc., p. 157; also Dr. Cullen and Dr. Carswell, in Edin. Med. Chir. Trans., vol. i.; and Fawdington's Case of Melanosis, 1826.

of negroes, as we shall have occasion to observe more at large when treating of EPICHRYSIS or MACULAR-SKIN,* are nearly fair when first born, and only become coloured with the black effusion a few weeks afterward; which at first gives little more than a tawny hue, but gradually advances to a jet.

We shall also have occasion to notice, in the same place, that this black die, like the pigment in melanosis, is on some occasions secreted in the form of a finer and more fluent liquid, and in others in a more inspissated state, and united with a coarser material, constituting the rete mucosum of Malpighi; who, moreover, gave it the name of rete from a belief that he was able to trace in it something of a fibrous structure; an idea that has not been realized by Cruickshank or any later anatomist. And it is not a little singular, that as in melanosis we sometimes meet with a few patches or tubercles of the preternatural secretion destitute of its colouring die, and presenting a variegated appearance of black and white mosaic, so, in the distribution of the natural pigment of the negro over the surface, we sometimes meet with the same casual obstruction to the flow of the black die, producing that marbled skin which gives the individuals the name of piebald negroes.

[According to the researches of Breschet and Cruveilhier, when the black matter of melanosis is not concrete, but liquid, or when it is deposited in layers on the surface of a serous or mucous membrane, the minute bloodvessels are filled with a black of precisely the same kind as that exhaled.†

Dr. Armstrong suggests, that as melanosis is frequently combined with chronic bronchitis, the venous character imparted to the whole mass of blood by this last disease may facilitate the dark and peculiar secretion of the first disorder. He observes, that the secretion peculiar to melanosis varies in colour from a dark brown to a deep blue or green black. It is sometimes spread, like so much paint, under the serous membrane of the intestines, for instance, or diffused through the substance of the spleen; while, in other cases, it is circumscribed in distinct patches, as in the parenchyma of the lungs, liver, or kidneys; in short, being occasionally found thus diffused or limited in most organs.—(*Morbid Anatomy of the Bowels, &c.*, p. 24.)]

The chymical analyses of MM. Barruel and Lassaigue show that melanotic tumours consist, first, of coloured fibrin; secondly, of a blackish colouring matter, soluble in weak sulphuric acid, and in a solution of subcarbonate of soda, which become reddish; thirdly, of a small quantity of albumen; and, fourthly, of a chloruret of

sodium, subcarbonate of soda, phosphate of lime, and oxyde of iron. The principles of melanosis, therefore, nearly resemble the constituent elements of the blood.* It is homogeneous, opaque, and destitute of any particular smell or taste. Thénard ascertained that it contains a very large proportion of carbon. When exposed to the air, it putrefies slowly.†

GENUS V. STRUMA SCROFULA.

INDOLENT, GLANDULAR TUMOURS, FREQUENTLY IN THE NECK; SUPPURATING SLOWLY AND IMPERFECTLY, AND HEALING WITH DIFFICULTY; UPPER LIP THICKENED; SKIN SMOOTH; COUNTENANCE USUALLY FLORID.

THE Greeks denominated this disease XOIPAZ, the nosologists of recent times SCROFULA, thus literally translating the Greek, and importing *swine-evil*, *swine-swellings*, or morbid tumours to which swine are subject. Celsus employs STRUMA, which was common in his own day, and has well described the complaint under this name, which is therefore selected on the present occasion. It is probably derived from στρώμα, "congestion," or "coacervation," as of straw in a litter, feathers in a bed, or tumours in a body; in which last sense Cicero elegantly employs the metaphor in the phrase "struma civitatis," "the scrofula or king's evil of the state." The medical dictionaries and glossaries concur in deriving struma from the Latin *struo*, but the terminating syllable of the noun should rather prove it to issue from a Greek source.

Other animals are subject to this disease besides man. It is, as already observed, from the frequency of its appearance among swine, that the Greek name, as well as the more recent one of scrofula, is derived. Among horses we meet with it at least as often, when it is called farcy; under which modification it is propagable by transfusion of blood from the diseased horse, not only to other horses, but to asses also, as

* Dr. Foy instituted a comparative analysis of medullary, scirrhus, and melanotic substances, and found them to contain albumen, fibrin, and salts, having for their basis soda, potash, and lime; also oxyde of iron, which was in rather greater proportion in the first two diseases than in melanosis; and in this latter alone he detected a highly carbonized principle, probably altered carbon, which constituted nearly a third of the morbid mass.—(*See Archives Gén. de Méd.*, Juin, 1828.) The colouring matter of melanosis is generally thought to bear a considerable analogy to the colouring matter of the blood.—Ed.

† A singular appearance lately presented itself to the American editor, who, in company with Dr. Benj. Drake of New-York, examined the body of a rhinoceros to ascertain the cause of its decease, which was found to be pulmonary congestion. The small intestines, which were thirty feet in length, presented in nearly their whole course, minute black dots, resembling what is termed punctiform melanosis. Whether this appearance was natural or the result of disease, we are not prepared to say.—D.

* Vol. ii., Cl. VI., Ord. III., Gen. X., Spe. 2, 6, and comp. with the introductory note to Gen. IX., Trichosis.

† When melanotic matter is found in bloodvessels, it is chiefly in the venous capillaries, and "under circumstances which show that it must have been formed in these vessels."—See Professor Carswell's *Illustrations of the Elementary Forms of Disease*, fasc. iv.—Ed

has been lately proved by Professor Coleman at the Veterinary Institution. Sauvages, who has many species under the generic character, has two for the forms now referred to. The porcine species he denominates *scrofula Chalcid*, and the equine s. *Farcimen*.

As it is not the intention of the present work to notice the diseases of other animals, otherwise than by an occasional and incidental glance, we shall proceed to a contemplation of the present genus under the single species of

1. Struma Vulgaris. King's Evil.

The strumous and mesenteric decline, in the present classification *atrophia strumosa*, is often introduced as a second species; but, though nearly allied to the present genus, it has so much closer a connexion with all the subdivisions of the genus *MARASMUS*, and especially with that of *atrophia*, that the former is evidently its proper place, and we have accordingly treated of it under that genus.*

SPECIES I.

STRUMA VULGARIS.

KING'S EVIL.

TUMOURS CONFINED TO THE EXTERNAL CONGLOBATE GLANDS;† PEA-SIZED OR CHESTNUT-SIZED; APPEARING IN INFANCY OR YOUTH; SUBSIDING ON MATURE AGE; HEREDITARY.

SCROFULA, though not a contagious disease, is unquestionably hereditary,† and hence very generally dependant upon a peculiar diathesis. Yet, like many other hereditary diseases, it is also occasionally generated as a primary affection, without any hereditary taint that can be discovered. I had very lately a gentleman under my care, who has been greatly afflicted with it for many years, and is now chiefly labouring under its sequelæ; for the sores, which are in different glands and joints, and some of which have affected the bones, are healing; yet, of eight brothers and sisters who have reached the middle of life, he is the only one who has discovered any tendency to such complaint, nor is it to be traced through any part of the family lineage as far as it can be ascended.

* Tubercular diseases of the lungs, spleen, and peritoneum, are regarded by many pathologists of the present day as scrofulous affections: so are particular diseases of the eyes, bones, and joints, and likewise some chronic abscesses, of which one of the most remarkable examples is the psoas, or lumbar abscess. A tendency to the formation of abscesses in a very slow and sometimes hardly perceptible manner, unpreceded by any very obvious exciting cause, is a common occurrence in scrofulous individuals. We see, then, how imperfect is Dr. Good's definition of scrofula, and how much more comprehensive it might have been made.—ED.

† The editor is at a loss to understand why the deep-seated lymphatic glands, which are often the seat of scrofulous disease, should be excepted.

‡ Kirkland, On the Present State of Surgery, vol. ii. Kortum, Comment. de Vitio Scrofuloso, Lemgovia, 1789. Baumes, sur le Virus Scrofuloux, &c.

When it occurs as a primary or ingenerated affection, it is by no means always limited to any particular temperament or habit of body. The individual just noticed is of moderate stature, brown complexion, dark brown hair, and ruddy face: and I am still occasionally attending a lady who has long been subject to the same complaint, without any trace of hereditary predisposition, of a sallow countenance, dark eyes and hair, and of rather tall and slender make. But, where scrofula appears hereditary, and especially where it does not show itself very early, it is often accompanied with a peculiar constitution.* "It most commonly," says Dr. Cullen, "affects children of soft and flaccid flesh, of fair hair and blue eyes, smooth skins and rosy cheeks: and such children have frequently a tumid upper lip, with a chop in the middle of it; and this tumour is often considerable, and extended to the columna nasi and lower part of the nostrils." And it is a further remark of Dr. Cullen, but which I have not found to hold very generally, that, where it takes place in children whose parents have given no signs of it, the latter have nevertheless evinced much of the habit and constitution by which the disease is ordinarily characterized.

From all this we have a clear proof that king's evil is a disease of debility, operating by a specific influence on the circulation, and particularly on the lymphatic system.—(Garn, *Kranken geschichten*, p. 121.) Whether this influence be the result of a specific matter is by no means so clear, however common the opinion. It is also a general belief that this specific matter is, from the first, a specific irritant or acrimony. But this, at least, is a mistake; for the disease is accompanied throughout with diminished, instead of with increased irritability (*Richter, Chir. Bibl.*, band viii., p. 501); and hence the power producing it must be of a sedative, rather than of an exciting or acuating quality. And it is in this diminution of irritability that scrofula differs from all other atonic diseases, since the debility and irritability generally augment in like proportion, and maintain an equal march.

Early life is peculiarly characterized by an abundance of albumen, as its maturity is by an abundance of fibrin. Dr. Parr ascribes the scrofulous diathesis to a redundancy of albumen at this period, together with an excess of oxygen and a deficiency of azote, evidenced by the florid hue of the countenance. By this hypothesis he obtains a sort of lentor in the circulating system, and accounts for the origin of scrofulous tumours by arguing that, since the mobility of the lymphatic system is peculiarly affected and diminished, the viscid fluids will be most disposed to stagnate there, and particularly in the lymphatic

* The numerous disordered conditions of the function of nutrition evinced in scrofulous persons, are certainly independent of one another: all of them proceed from a cause that is manifested to us by the existence of those modifications of nutrition and secretion, the assemblage of which makes what is termed a scrofulous constitution.—See Andral, *Anat. Pathol.*, tom. i., p. 5, Svo. Paris, 1829.—ED.

glands, as they must necessarily stagnate most where the impelling power is least.*

It is here, indeed, rather than in any other modification of tubers or tubercles, that we find most to oppose to the opinion of those physiologists, as M. Broussais and Dr. Alison, who ascribe the origin of all tubercles to the existence of a higher or lower degree of inflammation. Yet it is singular that, at the same time, we here meet with proofs of the most advanced state of a living action in the morbid growths themselves, the most perfect specimens of vascularity and sensation, and particularly where they originate in a glandular texture, which is their proper seat. This living property, however, they do not seem capable of retaining long; for they soon run through their career of vitality, and become decomposed. Such was the short-lived date, according to the first physiological poet of Rome, of those monster-growths which sprang in the infancy of the world, but were soon cut off by Nature, as incongruous with her laws and hateful to her survey.

"Cætera de genere hoc monstra, ac portenta,
creabat:
Nequidquam; quoniam Natura absterruit auctum;
Nec potuere cupitum ætatis tangere florem,
Nec reperire cibum, nec jungi per Veneris res."†

These sprang at first, and things alike uncouth:
Yet vainly; for abhorrent Nature quick
Check'd their vile growth; so life's consummate
flower
Ne'er reach'd they, foods appropriate never
cropp'd,
Nor tasted joys venereal.

As occurring in early life, when, as we have already observed, there is a peculiar abundance of albumen, with a comparatively less portion of fibrin or coagulable lymph, it is highly probable that a morbid deposition of albumen forms the commencement of the strumous tuber. And such, indeed, seems to be proved by the chymical tests to which Dr. Abercrombie has put them.—(*Trans. Medico-Chir. Soc. Edin.*, vol. i., p. 686.) It is at first, perhaps, deposited in a soft state, and involved in the structure of the gland, the part being in other respects vascular and organized, and probably capable of performing its functions. As the disease advances the proportion of albumen seems to increase, while, at the same time, it assumes a more concrete and structural figure, and evinces a vascular and sensitive character. "In this first state of enlargement," says Dr. Abercrombie, "these glands

* The doctrine of Andral is exactly the reverse of this: a morbid state of the lymphatic glands is most frequent at the period of life when the nutrition of these organs is most active. This, says he, affords a confirmation of the general law, in virtue of which the frequency of the disease of every organ is in a direct ratio to the development of its structure and action.—(*Anat. Pathol.*, tom. ii., p. 449, 8vo., Paris, 1829.) Then, what are we to think of the hypothesis of stagnation in the lymphatic glands, when we find, from the experiments of Becker, that when they are diseased, quicksilver pervades them in the freest manner?—Ed.

† Lucret., *De Rer. Nat.*, v., 845.

present, when cut into, a pale flesh-colour, and a uniform, soft, fleshy texture. As the disease advances, the texture becomes firmer and the colour rather paler. In what may be regarded as the next stage, we observe portions that have lost the flesh-colour and have acquired a kind of transparency, and a texture approaching to that of soft cartilage. While these changes are going on, we generally observe, in other specimens, the commencement of the opaque white structure, which seems to be the last step in these morbid changes, and is strictly analogous, in its appearance and properties, to the white tubercle of the lungs.* In a mass of considerable size we can sometimes observe all these structures, often in alternate strata; some of the strata being composed of the opaque white matter; others presenting the semi-pellucid appearance; while in other parts of the same mass, we find portions which retain the fleshy appearance. In the most advanced stage, the opaque, white, or ash-coloured tubercular matter is the most abundant, and this afterward appears to be gradually softened, until it degenerates into the soft cheesy matter or ill-conditioned suppuration so familiar to us in affections of this nature." The morbid growth, therefore, as it recedes from its more vascular and vital elaboration, gradually subsides into the simple pretension of coagulated albumen, of which it consisted at first. In the second stage, the part is probably susceptible of active inflammation and healthy suppuration, or suppuration making a near approach to that of a healthy character. In its closing stage it seems incapable of healthy action, and only passes into that peculiar state of softening which arises from a simple decomposition of the tubercular organization.

We have already described at some length the probable origin of tubercles in other textures, chiefly in the serous and mucous membranes of organs, and in the structure of the lungs. The remarks now offered will enable us in some degree to judge in what respect the tubercles of proper glands, as those of the lymphatics and the mesentery, are assimilated to these, and in what respects they differ from them. The subject, however, is still open to inquiry, and

* In the section on tubercular phthisis, reference has been made to Dr. Carswell's observation that the same kind of substance as constitutes tubercles in the lungs has been traced in scrofulous lymphatic glands. According to Andral, the latter organs rank as parts of the body in which tubercular matter is most commonly detected. At present this deposit is supposed to take place in the substance of these organs; but Andral conceives it probable that future researches may trace its seat to be within the lymphatic vessels which communicate together in these organs. In fact, cases have come under his notice, where tubercular matter was found in the thoracic duct, and in several of the absorbent vessels.—(*Anat. Pathol.*, tom. i., p. 451.) This view seems, however, to disagree with the assertion, that mercury will readily pass through the vessels of diseased lymphatic glands. We are yet in want of precise information respecting the state of the absorbent vessels in the glands, when these latter are in various conditions of disease.—Ed.

much remains to be accomplished before a full and satisfactory result is likely to be obtained.

Be the proximate cause of scrofula, however, what it may, as the remote cause is of a debilitating kind, we can readily see what are likely to prove occasional and co-operative causes, or those calculated to call the remote cause into a state of activity. They must consist of every thing that directly lowers and reduces the tone of the living fibre, and puts the system out of that state of firm and vigorous elasticity which is the best prophylactic against the disease, and keeps the scrofulous diathesis most effectually in a state of subjection. And hence we find the common debilitating powers of cold, damp, meager or unwholesome food, want of cleanliness, and a close and suffocating atmosphere, the most usual incidental sources of strumous affections.—(*E. A. Lloyd's Treatise on Scrofula*, &c., 8vo., Lond., 1821.)

But for these, a scrofulous predisposition might remain dormant in the constitution through the whole of life; and descend to and disorder the next generation, without having in the least disturbed the present. But the moment any of these occasional causes become adjuncts with the scrofulous diathesis, scrofula, rather than any other disease they are also calculated to promote, will make its appearance and commence its ravage. And hence the frequency of this disease in large manufacturing towns, and in higher and colder latitudes than 45°.

Heat, as a relaxing and debilitating power, tending to produce languid action, is also a frequent cause whenever applied in excess and habitually; and particularly where, like cold, it is combined with sudden variations of temperature. Scrofula is known to be particularly frequent in Hindoos, Hottentots, and negroes, when they come to temperate climates; and especially in the children of settlers in intertropical regions, upon their quitting such regions for countries of a milder temperature.

[The unusual frequency of phthisis among negroes and Hindoos, and even among mulattoes and half-caste people, in this climate, is, as Dr. Alison observes (*Edin. Med. Chir. Trans.*, vol. i., p. 399), generally admitted. At the same time he grants, that, as the black population of tropical countries have other peculiarities besides that of being brought up in hot climates, we are not entitled to ascribe their scrofulous tendency exclusively to this circumstance. Yet, says he, when we connect the facts above stated with the enervating influence produced by long residence in hot climates on European constitutions, so strikingly shown in the different forms assumed by fever and by hepatitis in the old settlers and the newly-arrived Europeans; and this, again, with the facts already adduced to show the connexion of general debility with scrofula; it seems to Dr. Alison extremely probable, that this part of the constitution of negroes and Hindoos is very much owing to the long-continued application of heat in early life, and particularly to this cause acting on many generations in succession.]

The influence of excessive cold, however,* is

much more rapid than that of excessive heat, and far more obvious to the sense. Yet it is often sustained with impunity where the constitution is firm, and the cold rarely subject to vicissitudes; and especially where there is no other debilitating cause to contend with, as the depressing passions, a sedentary occupation, scanty and innutritive diet, damp and impure air, or any kind of personal neglect or uncleanness. And it is on this account, we meet with a far smaller proportion of scrofula in early life among the peasantry of higher latitudes and mountain scenery, as that of Scotland and Switzerland, than among the mechanics of crowded and warmer cities. "I was told," says Dr. Alison, "by one of the physicians of the Hôpital des Enfants Malades, at Paris, where upwards of five hundred children die annually, whose bodies are almost uniformly opened, that he believed nearly one half of the bodies he saw opened had scrofulous tubercles in some part or other." This is indeed a higher aggregate than is to be found in the metropolis of our own country, and obviously includes mesenteric or strumous tubers, of which we have treated already, as well as every other modification of scrofula. But the same writer calculates, from data furnished by Dr. Perceval, that the proportion of scrofulous fatal cases among children at Manchester, at the time Dr. Perceval wrote, generalizing them as above, could not be less than a third of the whole infantine mortality; while at Waverton, a country parish near Chester, it appears from the same documents that the deaths from scrofula in children under five years of age, did not amount to a fourth part of this proportion. In the bordering village of Reyton, the difference appears to have been still greater; for the whole mortality of children under five years of age in this last parish, compared with the same period of parallel mortality at Manchester, was only as two to seven; not more than one seventh part of the children born in this village appearing to die before they had attained their fifth year. "I examined lately," says Dr. Alison, "a register, which I know to have been kept with great accuracy for nearly four years, of the deaths of a country parish in Scotland, that of Rafford, near Forres, the population of which parish is almost exactly a thousand persons. Of forty-two deaths that had occurred in that time, two only, or one in twenty-one, were below the age of two; and three only, or one in fourteen, below that of five years;" while in the town of Manchester, to which we have just referred, Dr. Perceval assures us, on an average of twenty years, that the proportion of deaths under two years to the whole deaths was 1 to 2.9.—(*Perceval's Works*, vol. iii., p. 107.)

To add any thing further is unnecessary. Scrofula is manifestly a disease of weak vascular action, and is sure to be found in abundance with other diseases, issuing from the same soil, consociate, to whose fatality it largely adds. Extreme heat and cold, though powerful predisponents, are far more injurious when flowing in irregular vicissitudes, than when in a uniform tenour; and the mischievous effect of the latter

is often counteracted where combined with the tonic powers of a pure and dry atmosphere, a regular plan of diet and exercise, the salubrious exhalations from growing vegetables, and the grateful stimulus of their odours in village scenery.

[And, as Dr. Alison has judiciously remarked, those who suffer most from the agency of cold, as a cause of disease in general, are by no means those who are most frequently exposed to it; but those whose previous condition is such as to favour its operation on the body, and particularly those in whom the circulation, either from the state of the constitution or accidental circumstances, is feeble and easily depressed. The same well-informed physician elsewhere observes, that what is true of the production of disease in general by exposure to cold, seems to be true of the production of scrofulous diseases in particular; but with these limitations:—

1. That scrofulous action appears to be excited almost solely in the earlier periods of life.
2. That, for the production of this kind of diseased action, there appears to be required, besides other conditions, a certain peculiarity of habit, not understood, but, manifestly, in Dr. Alison's opinion hereditary.
3. That the constitutional debility which disposes to scrofulous disease from cold, appears to be more permanent and habitual than that which disposes to other diseases resulting from this cause.]

For the reasons just urged, scrofula has at times been called into activity by local injuries, the depressing influence of severe grief, or a sudden reverse of worldly prosperity. It is also sometimes joined with or follows rickets; and is frequently a sequel of severe febrile disease, smallpox, yaws, measles, syphilis, scarlatina, several obstinate cutaneous affections, and the long use of mercury.

But though scrofula usually commences in the lymphatic glands, it often extends beyond them: as gout, that ordinarily shows itself at first in the small joints, and rheumatism, that begins in the large joints, spread not unfrequently to the membranes and the muscles. I have said that, under the influence of the scrofulous diathesis, the circulating system is weakened generally; and hence also we frequently find the eyes, the mucous glands of the nose, the tonsils, and even the joints and bones, successively yielding to its influence.*

The disease for the most part shows itself early in life, though rarely before the second,† and commonly not till the third year of infancy; from which period it continues to prey on the

system till the seventh, when, in ordinary cases, it gradually subsides and disappears. If the predisposition be not considerable, the attack is sometimes postponed till after the seventh year, and has occasionally been retarded till the age of puberty, after which, however, we have very seldom any first manifestation of the disease.

The first tumours we meet with are usually upon the sides of the neck, below the ears, or under the chin; and confined to the lymphatic glands in these parts. The tumours are, perhaps, two or three in number, moveable, soft, and slightly elastic, of a globular or oval figure, without pain or discoloration of the skin. In this state they continue for a year or two; after which they grow larger and become more fixed, and acquire a purplish redness. They then give that feeling of greater softness, and at length of fluctuation, to which we have just adverted; after which the skin, in one or more of them, becomes paler, and a peculiar liquid is poured forth at several small apertures, apparently like immature pus, but growing daily less purulent, and at length assuming a cheesy or curd-like form.* The tumour, or cluster of tumours, then subsides, but others rise in the neighbourhood; and in this manner the disease proceeds, fresh tumours forming, chiefly in the course of the spring, as the older disappear, and the same process is continued for several years; after which the ulcers heal spontaneously, with puckered and indelible indentations, provided the disease terminates favourably; but if not, other parts of the system, as we have already observed, become tainted with the morbid influence, and add to the sum of distress. If the attack fall upon the eyelids, they become inflamed, are swollen and red, and pour forth from their minute glands an erosive but viscid secretion, which glues them together at night, so that in the morning they are opened with difficulty. The adnata partakes of the irritation, which is at length communicated to the whole globe of the eye, and not unfrequently to the cheek, from the acrid discharge that flows down. An unsightly lippitude, and eversion of the lower eye-

* According to Mr. Wardrop, "the matter has at first a firm curdy consistence, and, as the process advances, some portions become more fluid; until, ultimately, the suppurative cavity contains a matter partly curdy, partly puriform, and partly serous. When this matter is removed by ulceration of the parietes of the cavity containing it, an irregular-shaped cavity remains in the substance of the gland. While the swelling of the part diminishes, the sides of this cavity become covered with a curdy yellow incrustation, more or less firm, and from its surface a puriform matter is secreted. This incrustation prevents the formation of granulations, and is the cause of scrofulous cavities not healing up; while it is by the separation of this crust, in consequence of laying open these abscesses, that granulations form and heal up the cavity.

"The incrustation covering the internal surface of the scrofulous abscess, when of very long standing, acquires a surface which resembles a mucous membrane, from which the puriform fluid is secreted."—Baillie's Works, by Wardrop, vol. ii Preliminary Obs., p. 33.

* Sometimes the disease commences in the eyes, joints, spleen, lungs, peritoneum, or other organs, and the lymphatic glands may either escape, or be affected only secondarily. For this and other reasons, the editor regards the definition at the head of the present section as liable to objections.—Ed.

† When the mother has been scrofulous, tubercles in the lungs, and strumous disease of the kidneys, have been sometimes, though rarely, noticed in the fetus or stillborn infant.—See Lloyd, op. cit., p. 23.—Ed.

lid are hence a very common result of a scrofulous attack on this organ.

In like manner the disease, in this unfavourable and aggravated state, often makes its assault on the limbs, and fixes on the ligaments, cartilages, or even the bones themselves; and particularly whenever any injury occurs to a joint. An indolent tumour first shows itself, which tardily advances in magnitude with a kind of smothered inflammation, and at length opens on the surface from one or more minute ulcerations, which discharge the sanious kind of fluid we have already noticed. And it is here we perceive how nearly scrofula is related to hydarthrus, or white swelling; and how readily the former may become a cause of the latter, as already observed under that species. If the strumous diathesis be excited by the fracture of a bone, the broken ends unite with great difficulty, and sometimes not at all. A specific tumour forms in the seat of the injury, the soft parts are often affected with a weak inflammation, and ulcerate slowly, and the bone is rendered carious. If the injury occur in the middle of a cylindrical bone, an exfoliation may take place in a long course of time; but if at its extremity, it will become spongy, enlarged, and disorganized. If a cure be at length effected, the enlargement will remain and the articulation be lost; yet amputation will be of no use while the part continues under the influence of the scrofulous taint.*

[The susceptibility of scrofula, inherent in different parts, is said to be altered by age: "Thus, in children, the upper lip, eyes, glands of the neck, and those of the mesentery, are generally the parts first affected; the lungs, bones, and other parts being subsequently attacked.—(Lloyd on Scrofula, p. 5.)]

In the worst and severest stage of the disease, the entire system appears to be contaminated; hectic fever ensues, and sometimes tubercular phthisis, which gradually puts an end to the contest.

[The urine of scrofulous subjects is said to contain less phosphoric acid than the urine of healthy persons, and an increased quantity of phosphate of lime. This earth is also sometimes found after death in the lymphatic glands, in the thoracic duct, and in the substance of the viscera.†]

In attending to the cure, we must not be unmindful of the principle we have endeavoured to establish, that scrofula is a disease of debility, principally affecting the lymphatic system, ac-

companied with diminished irritability.* And it hence follows that our chief dependance must be upon a tonic and stimulant plan, so modified as to meet the patient's age, idiosyncrasy, and manner of life.

An old hypothesis is, that scrofula depends upon an acrimony in the system, and hence sedatives and narcotics have found a place among the most celebrated of its remedies; while, as the chymical character of the acrimony has been also pretended to be developed, and has been declared to be a specific acid, another class of remedies had recourse to has been the alkalis.

That the latter are often of considerable service, ought I think freely to be admitted; but we have assuredly no proof that they become beneficial as correctors of acidity. They are gentle stimulants, admirably adapted to the debilitated and indolent condition of the vascular system they are intended to excite; and hence, in whatever form they are given, have a chance of doing good. And it is to this principle we are, perhaps, to resolve all the advantage that has been stated by different writers, and in different ages of the world, to have resulted from the use of burnt sponge, burnt cuttlefish, shells of all kinds, burnt hartshorn, and even burnt secundines, which last were at one time in high request, and are to be found as a sovereign remedy in Schroeder's Pharmacopœia.—(Lib. v., p. 288.) All these have in our own day deservedly yielded to the carbonate of soda and subcarbonate of ammonia; which, in a more elegant and concentrated form, offer whatever virtues may be contained in the older medicines: and still more lately to iodine, not long ago detected by M. Courtois in kelp and other salt-works; for a more particular account of which medicine the reader may turn to the treatment of BRONCHOCELE.—(Vol. ii., Cl. VI., Ord. I., Gen. II., Spe. 1, *Emphyema Sarcoma Bronchocele*.) The author has, at this moment of

* How contrary this theory is to that entertained by some other writers, may be seen by a reference to Crowther's work on white swelling, &c., ed. 1808. A still later author remarks:—"In scrofulous disease there is generally what is termed a delicate state of the health, great nervous irritation, greater susceptibility than natural; so that certain external agents, as cold, &c., applied to the body, produce unusual effects; and there is always more or less disorder of the digestive organs; and, upon accurate investigation, this state of the system will always be found to have existed for some time previous to the appearance of the disease in any particular part."—(Lloyd on Scrofula, p. 32.) The editor believes that we know nothing about the proximate cause of scrofula; and that the digestive organs cannot be essentially concerned in the production of the disease, is as clear as the fact pointed out by Mr. Lloyd, that scrofula sometimes affects the fœtus in utero. The disorder of these organs, in many examples, is certainly only an effect; yet it is not here intended to deny the possibility of the origin of scrofula being promoted by derangement of the functions of the digestive organs. But that something else is requisite appears certain, as these organs are frequently disordered without a single symptom of scrofula showing itself.—ED.

* This is not quite correct, as no stumps generally heal more favourably than those resulting from the amputation of scrofulous joints.—ED.

† Pinel, Nosogr. Philosophique. We know from the researches of Dr. Carswell, that tubercular matter, the same kind of unorganized deposit as is found in tubercles of the lungs, is also sometimes detected in scrofulous glands; and, as these are sometimes cured, the fact has been adduced as an argument in favour of tubercular phthisis not being absolutely incurable.—See Dr. Carswell's Illustrations of the Elementary Forms of Disease.—ED.

writing, among other patients who have been benefited by this plan, a lad about thirteen years of age, with weak eyes, inflamed and irritable conjunctiva, and such an enlargement of the parotid glands* as to make them nearly meet, so that the mouth opens with uneasiness. He has now applied the ointment of iodine for three weeks, and at the same time taken half a grain twice a day in the form of a pill, and is essentially improved in every respect. [Iodine may be said to be the medicine to which the generality of medical practitioners are turning their attention as a means of curing various forms of scrofulous disease. Its extraordinary power in dispersing many strumous swellings cannot be doubted; but whether it possess any specific power for the correction of the scrofulous diathesis, still remains to be proved.†]

Lime-water and the muriate of barytes,‡ which last was thought by Dr. Adair Crawford to be nearly a specific, if they have any pretensions whatever, can only derive them from the general principle of their being stimulants, and especially of the lymphatic system. And the same may be observed of petroselinum, sarsa, meze-reon, balsam of sulphur, and calamus aromaticus.

Muriate of soda, or common sea-salt, possesses a like character, and has undoubtedly been found of far more use in many cases. It has hence been employed very freely, both internally and externally. In the latter case generally through the medium of the bibulous marine plants, which contain it in a larger proportion, and have been applied to the strumous tumours in the form of epithems, as sea-wrack (*fucus vesiculosus*), sea-tang (*alga marina*), and sea-oak (*quercus marina*).

The mineral waters of every description have in like manner been had recourse to, chalybeate, sulphureous, and saline; and perhaps, as Dr. Cullen observes, with nearly a like reputation and success; though it is by no means improbable

that some waters may prove a more remedial stimulant or alterant to some constitutions, and others to others. And we thus possess a more plausible reason for their being advantageous than that offered by Dr. Cullen; namely, that, "if they are ever successful, it is the elementary water that is the chief part of the remedy" (*Practice of Physic*, vol. iv., 1752); which, he tells us in another place, "may be of use by washing out the lymphatic system."

Stimulant external applications, besides sea-water, have also been tried, and undoubtedly been often found serviceable; as a long continued friction of the hand over the scrofulous protuberances, mercurial or ammoniacal plasters, or the convenient form in the London Pharmacopœia that combines both these ingredients; irritant ointments, especially those containing iodine, the aura of voltaism, or moderate shocks of electricity.

The means of this kind, however, to which we have recourse, whether external or internal, should always be gentle at first, however we may venture upon augmenting them afterward. If we stimulate violently, we shall do mischief rather than good, and add to the debility instead of diminishing it. Scrofula is a strictly chronic disease; it never has been, and never can be cured rapidly; and wherever any beneficial influence has been produced upon it, it has always been, as in the use of alkalis and of mineral waters, by lenient means and patient perseverance.

But we have to increase the power as well as to take off the irritability; and hence tonics seem to be as much demanded as stimulants, and have in fact been as generally made use of.

It is very singular, that, of this class of medicines, the only two which Dr. Cullen has thought it worth while to notice, are bark and coltsfoot; of the first of these he speaks very doubtfully; while he seems to depend more on the second than on any other remedy whatever. This opinion he expresses in his *Practice of Physic*, published in 1783; but in his *Materia Medica*, published six years afterward, he gives it the same high character, and tells us that he was induced to try it in scrofulous cases upon the testimony and recommendation of Fuller. He employed both an expressed juice of the fresh leaves, and a decoction of the dry; but preferred the former, of which he gave "some ounces every day," and affirms that "in several instances it had occasioned the healing up of scrofulous sores." He admits, however, that neither of them was, in some trials, sufficiently effectual.

The metallic salts have been more generally used, and have at least acquired a higher reputation; though, with the exception of calomel, I do not know of any of them that can appeal to any decided testimonies in proof of their success; and even calomel may perhaps be regarded rather as an alterant or mild stimulant, than as a tonic. Salivation has always done harm; and, on this account, mercury in every form must be given in minute doses. Combined with some preparations of antimony, and partic-

* The editor believes that this case must have been either a bronchocele, or a general enlargement of the lymphatic glands on each side of the neck and behind the jaw; for, besides the fact that the parotid gland is seldom or never the seat of scrofula, the extension of the disease under the chin seems to prove that the disease could not have consisted in the parotid.—Ed.

† The strongest facts on record proving the usefulness of iodine in scrofulous diseases, are those published by Dr. Lugol (*Mém. sur l'Emploi de l'Iode dans les Maladies Scrofuleuses*, 8vo., Paris, 1829), who employs this medicine, however, in a greater variety of ways and forms than we have taken the trouble to do in this country. Instead of the tincture, he prescribes an aqueous solution of iodine of different strengths, with a proportion of the hydriodate of potash in them. He also applies iodine in the form of baths, lotions, and collyria; sometimes also as a stimulating or rubefacient application; and, in particular cases, as an escharotic. Whoever wishes to give iodine a fair trial in scrofula, should prescribe it in Lugol's manner, whose formulæ may be seen in his work.—Ed.

‡ This article is highly recommended by Dr. Williamson.—See *Potter's Med. and Phil. Lyceum*, Baltimore, 1811.—D.

ularly with the precipitated sulphuret, as in Plummer's pills, it is said to have been chiefly serviceable. But in my own practice, I have not found this medicine of any manifest service in the present disease.

The acids have also been tried, but are of little or no avail.

Upon the whole, however, the tonic class of medicines has thus far proved considerably less decisive and important, in the treatment of scrofula, than we might fairly have conjectured. Yet a tonic regimen of sea-air, sea-bathing, liberal exercise, and a diet somewhat generous, is of the highest consequence in promoting improvement, and ought by no means to be dispensed with. The infirmary at Margate is on this account a noble institution, and cannot be too liberally supported.

Of the specific benefit of narcotics, as hemlock, henbane, foxglove, solanum, asclepias, vinetoxicum, and many others, I have yet to be persuaded. They may possibly be of some use in quieting the irritation occasionally produced by congestion and mechanical pressure where the tumours are peculiarly indurated and large, and in such cases may assist in softening and diminishing them. And they may, perhaps, operate in the same way where, in the latter and more malignant stages of the disease, the secretion is become virulent, the open ulcers irritable, and a foundation is hereby laid for hectic fever. But I can conscientiously say, with Dr. Cullen, that they have often disappointed me, and have not seemed to dispose scrofulous ulcers to heal.

The local applications, like the internal remedies, should be slightly stimulant; and, where the tumours have broken, usually consist of digestive ointments combined with the caustic metallic salts of mercury, zinc, or copper, and of digestive lotions of a dilute solution of alum or nitrate of silver. These are well calculated to coincide with the general intention; but we must not expect a sound cure till the morbid impression is set at rest in the constitution, or utterly extirpated from it.

[Those who espouse the hypothesis that in scrofula there always is more or less disorder of the functions of the digestive organs, and primarily of no other important function, of course renounce all faith in specifics, and consider the principal indication to be that of improving the state of those functions by attention to diet, and by keeping the bowels regular, and the hepatic secretions natural. The editor believes that more good may be effected in scrofulous cases by endeavouring to rectify any obvious defect in the constitution, or, in other words, to improve the health in general, than by trying the effect of various medicines, supposed to have a specific power over the disease. On this very principle, however, iodine, carbonate of soda, blended with rhubarb or columbo powder, and other alteratives and tonics, will frequently be proper, as well as small doses of the blue-pill, the compound calomel pill, and the compound decoction of sarsaparilla; with occasional mild purgatives, so much confided in by those prac-

tioners who believe the cause of scrofula to be essentially connected with disorder of the digestive organs.]*

GENUS VI. CARCINUS. CANCER.†

SCIRRHOUS, LIVID TUMOUR, INTERSECTED WITH FIRM, WHITISH, DIVERGENT BANDS, FOUND CHIEFLY IN THE SECERNENT GLANDS; PAINS ACUTE AND LANCINATING; OFTEN PROPAGATED TO OTHER PARTS; TERMINATING IN A FETID AND ICHOROUS ULCER.

Of this genus there is but one known species: for the division into occult and open, or

* Struma is comparatively of rare occurrence in the more northern portions of the United States; the official report of deaths by this disease in the city of New-York for the past five years, amounting only to sixty-five; but in the southern country the case is far different, and there this malady proves a complete scourge to the black population, who in the northern states also appear more disposed to it than do the whites; among the latter, it seems to affect foreigners rather than Americans, and to be often called into action by the confined air of narrow and dirty habitations, by unwholesome diet, &c.

The treatment of scrofula is conducted on the principle that the disease is often constitutional; the popular idea that the muriate of barytes was useful, has led many to our mineral springs, and more particularly to that of Ballston in the state of New-York, inasmuch as chymical analyses had shown that this compound of barytes was a constituent part of these mineral waters. Chalybeates, more particularly the carbonates and phosphates of iron, are now commonly prescribed, attention being previously paid to the digestive organs. Iodine, also, has many firm friends with us.—D.

† One of the heterologous formations, as they are termed by Professor Carswell, in his Illustrations of the Elementary Forms of Disease. The essential character of the heterologous formations, he founds on the presence of a substance which does not enter into the original composition of the body. When the heterologous deposit is collected at numerous points, in the shape of a hard, gray, semitransparent substance, intersected by a dull-white, or pale straw-coloured, fibrous, or condensed cellular tissue, the disease is usually termed *scirrhous*. When it assumes a regular lobulated arrangement, so as to present an appearance similar to a section of the pancreas, it constitutes the *pancreatic sarcoma* of Abernethy. For other varieties, named by the French *tissu lardacé*, *matière colloïde*, and *cancer gélatiforme*, or *aréolaire*, consult Dr. Carswell's work. In order to trace the precise seat, origin, and mode of formation of cancer, it is necessary, as this excellent pathologist observes, "to catch the disease, as it were, at the earliest period of its formation; that is to say, when the heterologous substance of which it consists has just been deposited, and has not effaced the particular texture or structure of the part in which it is contained. Investigated in this its first stage, we ascertain, with greater or less facility, that this substance becomes manifest to our senses, either as a production of nutrition or secretion. In the former case, it is deposited in the same manner as the nutritive element of the blood enters into the molecular structure, and assumes

indolent and ulcerative, introduced by Hippocrates, and continued to the time of Boerhaave, is unnecessary in pathology, and incorrect in a nosological arrangement; as the distinctions it contemplates are nothing more than so many stages or modifications of the same disease in different habits, or affected by different concomitants. This species is what is generally described under the name of

1. *Carcinus vulgaris*. Common cancer : and it is not necessary to alter the term.

SPECIES I.
CARCINUS VULGARIS.
COMMON CANCER.

TUMOUR BURNING, KNOTTY; WITH DARK, CANCRIFORM VARICES; ULCER, WITH THICK, LIVID, RETORTED LIPS.

THERE is a soft, fungous, and bleeding ulcer, possessing the name of fungus hæmatodes, which has by many writers of celebrity been supposed to be of a cancerous origin; and, under their authority, it has been so regarded in the author's volume on Nosology: but as it seems to differ from cancer in its constitutional influence, and in some of its local characters,* it is better to contemplate it as a malignant ULCER of a peculiar kind; and in the present work it is referred to that genus accordingly.†

The term *carcinus* (καρκίνος) is Greek, and imports a crab; the disease being thus call-

the form and arrangement of the tissue or organ into which it is thus introduced. In the latter, it makes its appearance on a free surface, after the manner of natural secretions, as on serous surfaces in general. Proceeding still further in our researches, we find this substance existing not only in the molecular structure, and on the free surface of organs, but also on the blood of the venous and capillary divisions of the vascular system."—Professor Carswell, *op. cit.*—Ed.

* One fact, mentioned by Dr. Carswell, is exceedingly curious and important in relation to these malignant diseases:—"Numerous examples," says he, "might be given of scirrhus, medullary sarcoma, and fungus hæmatodes, originating in the same morbid state, and passing successively from the one into the other, in the order in which I have named them. Indeed, we often meet with all the varieties which I have enumerated of both species, not only in different organs of the same individual, but even in a single organ."—(See Illustrations of the Elementary Forms of Disease, 4to., fasc. ii., Lond., 1833.) One evening, at the London University, Sir Astley Cooper lately mentioned to Dr. Carswell and the editor, that he knew of a case in which a lady, whose breast had been removed, and was found to have the true scirrhous texture, afterward died of fungus hæmatodes in the same situation.—Ed.

† The fungus hæmatodes of Hey, is the *medullary sarcoma* of Abernethy, the *matière cérébriforme*, or *encéphaloïde* of Laennec, the *spongoid inflammation* of John Burns, and the *soft cancer* of several other writers. As it is not till an advanced stage of the disease that any fungus or ulceration occurs, medullary sarcoma is one of the best of these terms. Fungus hæmatodes is, at all events, totally inapplicable, until the morbid mass projects through the skin and bleeds; and even then it is not truly a fungus, but a soft medullary substance.—Ed.

ed from the cancriform or crab-like ramifications of the dark distended veins of the cancerous tumour. The question is of some consequence, whether cancer be a constitutional or a local, whether an hereditary or merely an occasional disease. Much has been said, and well said, on both sides. Till of late years, the disease was generally regarded as a constitutional affection, and will, for the most part, therefore, be found in the division of cachexies, from Sauvages to Macbride, though Dr. Cullen has introduced it into his class *locales*; and since his time, many of the best writers of the present day, among whom are Dr. Baillie and Mr. Abernethy, concur in regarding it as local alone. If the disease be merely local, it is difficult, and perhaps insuperably difficult, to say why a blow on a conglomerate gland, as the breast for example, should sometimes produce a cancer, but more generally not; or what that power is that excites the cancerous action in one person, from which another, or perhaps a hundred others, remain free upon an application of the very same injury to the same organ. A blow on the knee often produces a white swelling, but ten thousand children receive blows on the knee without any such effect following. In this case we resolve the difference of result, without a controversy, into the presence or absence of a scrofulous constitution; and without this view of the subject we should find ourselves at a loss for an answer. And unless we apply the same reasoning to cancer, we shall ever, I fear, remain at an equal loss. The cases, moreover, in which cancerous tumours are found in other parts of the body, after one or more than one has been extirpated, lead us by an easy thread to the same conclusion, provided the tumour has been removed in an early stage of the disease, and before ulceration has taken place; for it is possible that the specific matter of a cancer, generated and matured locally, may be absorbed and deposited on the organs which are afterward affected.* But if the extirpation have taken place before the formation of the specific matter, it is not easy, except by a constitutional diathesis, to account for any subsequent appearances.†

* The impossibility of communicating cancer from one person to another by inoculation with the matter of cancerous ulcers, is a strong fact in opposition to this last hypothesis. The existence of a specific cancerous matter, or virus, is denied by M. Roux, as the editor conceives, upon very sufficient grounds.—Ed.

† Dr. Carswell joins our author in considering cancer as a constitutional disease:—"It may," says he, "be regarded as a law, that the speciality of a morbid product, of the nature of those I am now treating of (carcinoma, &c.), is entirely independent of any local agency whatsoever. The trite, but important remark, that hundreds and thousands of individuals are daily affected, for example, with inflammation, without this local disease being followed by any other than its usual effects, places in the clearest light the necessity of a previously existing modification of the economy, as the immediate and essential condition of the speciality of the heterologous formations, when they occur in conjunction with inflammation."—See Illustrations of the Elementary Forms of Disease, fasc. ii.—Ed.

It is still stronger in proof of an hereditary predisposition, that various members of the same family have exhibited the same disease, either simultaneously or in succession; and that the descendants of those who have been afflicted with it, seem to have more frequently suffered from it than others. It is not necessary to advance individual instances in support of these positions, though it may be noticed, in passing, that Bonaparte died of a cancer in the stomach, his father of a scirrhus pylorus.—(*Account of the last illness, decease, &c. of Napoleon Bonaparte, by Archibald Arnot, 1822.*) The same remarks have been made upon a general survey of the disease in most ages; and the doctrine of an hereditary influence, in consequence, descended to us as a result of such remarks from the time of the Greeks and Romans.

Since the first and second editions of the present work, in which these remarks occur as now again presented to the reader, they have received no inconsiderable degree of confirmation by the publication of Sir Astley Cooper's Lectures on Surgery, in which the same line of pathology is pretty closely adopted. With respect to the constitutional character of the disease, he tells us, from numerous dissections, that "it seldom happens, when a tumour of this kind exists in the breast, that only one is found, for there are generally several smaller, in different parts of the glandular structure," and that not only the glands in the axilla, but those above the clavicle are changed in their internal appearance from the deposit of a scirrhus secretion resembling that in the breast, and that most of the viscera, in different cases, participate in the same morbid change, especially the lungs, the liver, the uterus, the ovaria; while in proof of its hereditary influence, he observes as follows:—"There are sometimes several persons in the same family who will be affected with this disease. A physician had three relations, sisters; the first of whom had a scirrhus tubercle of the breast, of which she died. A second had the disease, which was removed by Mr. Lucas senior; the disease returned, and she died. The third had applied to me, for a very painful swelling in the breast. They were unmarried. Therefore," continues he, "in a family in which one is affected, the first dawn of complaint should be carefully watched, and the general health be well attended to in others."—(*Tyrrel's edition, vol. ii., pp. 183, 186, 189, 8vo., 1825.*)

How far a predisposition to cancer, whether original or derived, may manifest itself by external signs, I am not able to determine. Such an outward character is by no means constant in the list of hereditary diseases. It is, perhaps, generally visible in those that affect the mind, but far less so in those that affect the body. In phthisis, the predominant diathesis has a striking exterior; in scrofula, the outward and visible sign is far less distinct, though such a sign seems to prevail generally: in gout, there is no specific exterior that we can depend upon. Dr. Parr, however, has conceived that cancer has its outward character as well as phthisis, and that it is indelibly marked in the complexion:

"for we have found," says he, "cancers more frequent in the dark cadaverous complexions, than in the fairer kind. The complexion we mean is distinct from the darkness of the atrabilious or melancholic habits: a blue tint seems mixed with the brown, and is chiefly conspicuous under the eyes, or in the parts usually fair. This may, perhaps, be a refinement without foundation, but we think we have often observed it. There is certainly no constitutional symptom by which it can be predicted, if, in women, a scanty and a dark-coloured catamenial discharge be not a prognostic of the future disease. Cancer has certainly been traced in females of the same family; and those who have escaped suffer from irregular anomalous pains, and different, often unaccountable complaints."—(*Medical Dict. in verbo.*) The picture thus ingeniously drawn is worth bearing in mind, but I have never been able sufficiently to appropriate it; and, in the last two or three cases of cancerous breasts that have occurred to myself, the patients have been of fair complexion, and light hair; one of them, indeed, peculiarly so; the lady was about fifty, and had a large and very handsome family, all of whom were so fair as to make a near approach to the phthisical exterior, though none of them have ever exhibited its pathognomonics.

Cancer has also been imagined by many practitioners of high respectability to be contagious, of whom we may mention Bierchen, Sinnert, and Gooch; but there seems no sufficient ground for the continuance of such an opinion. Inoculation has been said to have produced the complaint: but this is contrary to the results of later investigations; for M. Alibert inoculated both himself and several of his pupils, without any other effect than that of local inflammation, and even this did not always ensue.—(*Maladies de la Peau, &c.*) The discharge from cancers has been swallowed by dogs without any mischief.

The parts most usually affected by cancer are the excretory glands, and especially those that separate the fluids to be employed in the animal economy, rather than those that secrete the excrementitious parts of the blood. The lymphatic glands are seldom primarily affected, though they may become so secondarily, that is to say, in consequence of the effect of a neighbouring cancerous tumour or ulcer upon them; but whether this is on the principle of irritation or absorption, is not quite clear. "I never yet," says Mr. Pearson, "met with an unequivocal proof of a primary (cancerous) scirrhus in an absorbent gland."—(*Principles of Surgery, &c., vol. i., p. 209, &c.*) And hence we behold a striking difference between the nature of cancer and scrofula. But, though the secretory glands are most open to the attack of cancer, any part of the body may become its seat. We meet with it, however, chiefly in the breasts of females, the uterus, the testes, the glans penis, the tongue, stomach, cheeks, lips, and angles of the eyes. The diseased action commences in the minuter vessels, and the adjacent parts are affected in consequence.

Women are more subject to cancer than men,

and in these the mammae and the uterus are the organs most predisposed to its influence. Celibacy, as well as the cessation of the menses, conduces to its production or appearance, and hence antiquated maids are mostly affected with it, and, next to these, mothers who have not suckled their children; for we may lay it down as an axiom, in the language of Dr. Parr, that a milk abscess never becomes a cancer. Then follow women who are past child-bearing, and, lastly, women who have borne children, and suckled them with their own milk, and males incidentally exposed to its occasional causes. To which we may add that, when cancer occurs in men, it is chiefly in the lips, and, when in children, in the eyes.*

Of the remote cause of cancer we know nothing. While scrofula has been supposed by some to be the result of an acid acrimony, cancer has by others been supposed to be produced by a peculiar alkali. Dr. Crawford, from a series of very curious experiments upon the matter of cancer, thought he had ascertained this to consist principally of hepatized ammonia, and found that this matter effervesced with sulphuric acid.—(*Phil. Trans.*, vol. lxxx., 1791.) Ploucquet, however, affirms that it sometimes effervesces with alkalis as well.—(*Init. Biblioth.*, tom. ii., p. 202.) The taste discovers nothing; for to the tongue it is insipid and mawkish rather than acid or alkaline. Yet Parr, laying hold of Crawford's experiments, has boldly ventured to assert that the remote cause, or rather the cause of the cancerous diathesis, consists in an excess of ammonia, with a redundant development of sulphur.

When it was popular in the Linnæan school to resolve almost all diseases into the irritation of worms, grubs, or insects existing parasitically in different organs of the body, cancer was by some theorists supposed to depend upon a like cause; and the hypothesis has been since adopted by several writers in our own country, as Mr. Justamond, who ascribed it to the larvæ of a particular species of insects, and Dr. Adams, who referred it to hydatids.—(*Observations on Morbid Poisons*.) Vermicles, or the larvæ of insects, have at times been found in the open ulcer of a cancer, as in the fetid discharge of many other malignant ulcers. These, as in other cases, have undoubtedly proceeded from eggs deposited in the sore as a nidus, though the worm or insect that has so deposited them has never been detected.† Such appears to be the

foundation of this hypothesis, which we have no authority for carrying further, and which is rarely advocated in the present day.

The occasional or exciting causes are numerous, but to account for their efficiency, it seems indispensable, as we have already observed, to suppose the existence of a cancerous predisposition or diathesis, since we see the same causes acting in innumerable instances daily without betraying any tendency to such a result. Where this is present, it may be produced by an external injury upon any of the parts most susceptible of cancer; by an indurated and chronic tumour incidentally inflamed or irritated; an accumulation of acrid filth in the rugæ of the skin, which is a frequent cause of cancer in the testes, and particularly among chimney-sweepers; the hard and pungent pressure of a wart or corn in an irritable habit, of which the medical records offer various examples; the general disturbance produced in the system by a severe attack of smallpox, or several other exanthems; a sudden suspension of a periodical hemorrhoidal flux, and a cessation of the menses; and, when in the stomach, by a previous life of ebriety or irregular living. With these, severe cold seems also to co-operate, as the disease is generally admitted to be both more frequent and more virulent in the high northern latitudes than in the southern regions of Europe.

When cancer takes place in the breast, it usually commences with a small indolent tumour that excites little attention. In process of time this tumour is attended with an itching, which is gradually exchanged for a pricking, a shooting, and at length a lancinating pain, a sense of burning, and a livid discoloration of the skin. And however difficult it may be to determine the precise point of time in which the scirrhus first becomes converted into a cancer, where these symptoms are united there can be no risk in calling the tumour by the latter name. Adhesive bands are now formed in the integuments, which become puckered, while the nipple is drawn inwards by suction, and, in some instances, completely disappears; the tumour rises higher towards the surface, and feels knotty to the finger, at the same time that the subcutaneous vessels are distended with blood, and show themselves in dark, cancriform varices. The march of the disease may be slow or rapid, for it varies considerably in its pace; but at

with as an anatomical element of the disease; but the serous tissue is frequently present, and may form either a capsule or interior cyst, filled with gelatinous, albuminous, or other fluids. However, in the molecular structure, the quantity of cellular and fibrous tissues which intersect a scirrhus in various directions may be very considerable. In dense organs, like the breast, uterus, ovaries, liver, walls of the stomach, &c., these tissues are often very abundant.—(See Dr. Carswell's *Illustrations of the Elementary Forms of Disease*, fasc. iii.) According to this author's investigation, the blood-vessels seen in scirrhus are only branches belonging to the neighbouring tissues, and which have become enclosed within the morbid substance.—Ed.

* The cases which used a few years ago to be set down as cancers of the eyes of children, are now well ascertained to be in reality examples of fungus hæmatodes.—Ed.

† The great attention now paid to morbid anatomy has dispelled for ever these sports of the imagination. In cancer there is a deposit of what is termed heterologous matter, quite different from any of the normal tissues. The carcinomatous substance may exist in the molecular structure of organs or on free surfaces, and in the blood, and it always forms by far the greater bulk of the disease. When the carcinomatous matter is deposited on free surfaces, the fibrous tissue is not often met

length the integuments give way in a few points to the ulcerative process, and a small quantity of caustic ichor, or of lymphatic fluid tinged with blood from eroded vessels, is thrown forth, sometimes with a short and deceitful relief (*Prysschriften Uitgegeven door het Genootsch. ter bevordering der Heelkunde*, Amsterdam, 1791): the ulcerative process in the meantime advancing and spreading more widely and deeply, till a considerable extent of surface becomes exposed, and a broad excavation is scooped out, with a discharge of a peculiar and most offensive fetor.* Here again the ulcer sometimes affords a delusive hope of recovery by its granulating; but the granulations are soft and spongy, and not unfrequently bleed, from the loose texture of the new vessels, or their erosion by the cancerous matter. It is rarely, moreover, that they extend over the entire surface of the sore; for, more generally, while one part is covered with them another part is sloughing, and each of the parts runs alternately into the action of the other.† And, not unfrequently, the lymphatic vessels become affected as high up as the axilla, and in their course betray a few smaller tumours. But whether this be a mere result of contiguous sympathy or of cancerous taint is uncertain. Cancer, as we have already observed, rarely, if ever, commences in lymphatic glands, but they, at length, partake of the disease in the course of its ravages; and hence all such suspected tumours are prudently removed when the knife has been resolved upon. Where the disease has spread widely or continued long, some of the muscles of respiration participate in the irritation, and the breathing is performed with difficulty.‡

When cancer attacks the uterus, it is known by tense lancinating pains in this organ shooting through the region of the pelvis, indurations in the part sensible to the touch, a preceding and immoderate leucorrhœa or menstruation,

* C. Bell on the Diseases comprehended under the name of Carcinoma Mammæ.—See *Medico-Chir. Trans.*, vol. xii.

† Both in cancer and fungus hæmatodes sloughing is a common occurrence, and arises from various causes, such as the pressure of the morbid substance on the veins, the irritation of it on the neighbouring tissues, or even the constriction of a portion of the disease by a narrow opening in a fascia, through which it protrudes. "Congestion, hemorrhage, softening, and sloughing," as Dr. Carswell observes, "take place in both cases of carcinoma. In scirrhus, however, they originate in the vascular system of the tissues included within the carcinomatous matter; but are not, on that account, less frequent and destructive than those which arise in the proper and collateral circulation in cephaloma (fungus hæmatodes). In general the softening is less complete, the hemorrhage not so considerable, and the sloughing more extensive in the former than the latter."—(See Dr. Carswell's *Illustrations*, fasc. iii., 4to., Lond., 1833.) Nerves, he says, have never been detected in either of these diseases, as a new formation.—Ed.

‡ This probably depends on the absorbent glands under the sternum becoming diseased. Hence likewise the cough that usually takes place in the advanced stage of cancer of the breast.—Ed.

sometimes both. The ulcerative process, as far as we are acquainted with it, is the same as already described; and as soon as it has worked to the surface of the organ, there is a sanious, or bloody, or mixed discharge, characterized by the peculiar stench of the disease. By degrees the labia swell and become œdematous, and if, as sometimes happens, the inguinal glands be obstructed, the œdema extends down the thigh, and the ulceration proceeds often to the bladder and rectum.—(*Clarke, Obs. on the Diseases of Females*, &c., 8vo., 1821.)

Cancer in the vagina, which, however, rarely takes place, can easily be felt; and in the rectum, the distinction is not difficult. The nature of the discharge, and the other symptoms just noticed, are sufficient to decide its existence. It is still more obvious in the penis.

None of these symptoms assist us in determining its presence in the stomach: and hence, how confidently soever it may be conjectured from the marks of an acute and burning pain, tenderness of the epigastrium upon pressure, nausea, and rejection of food, and even an offensive fetor in the breath, the disease can seldom be completely ascertained till after death. It is sometimes accompanied with vomiting, and sometimes not; and ordinarily the absence of vomiting is an unfavourable sign, as it has often been found to proceed from an induration of the coats of the stomach generally, which has rendered it incapable of contracting, or from a cancerous ulceration and enlargement of the pylorus (*Mém. sur le Vom.*, par M. Piedagnel, &c.; *Journ. de Phys. Exp.*, par M. Magendie, 1821, Paris), which, upon the slightest pressure, readily admits the contents of the stomach into the duodenum. There is here, however, usually habitual nausea, though without vomiting.

The progress of cancer in the testicle is often slower than in many other parts. In chimney-sweepers we can trace an obvious cause, which is that of soot lodged in its rugæ, and irritating as well from its own acrimony, as from that of the perspiratory fluid with which it comes in contact and forms a union. A painful ragged sore, with hard rising edges, is first produced; or sometimes a little indurated wart; which, from inattention, increases in size, is repeatedly rubbed off by the exercise of climbing, enlarges and deepens its sphere of irritation, grows more malignant, and at length is converted into a real cancer, and affects the whole scrotum, or the body of the testis. In whatever part of this complicated organ, however the disease commences, it is progressively communicated to the rest; the scirrhus increases in size and hardness, till the tumour often acquires an enormous and irregular magnitude, studded externally with numerous protuberances, and the shape of the testis, even before ulceration, is entirely lost. In the progress of the disease the spermatic cord becomes affected, and the taint or irritation is communicated more or less to the viscera and lymphatic glands of the abdomen.

From the cancerous effect of a highly irritable wart or crack on the scrotum of chimney-sweep-

ers and smelters of metals, we may derive some idea of the formation of cancers on other superficial parts of the body from a similar beginning. These most frequently occur on the lips, nose, or eyelids; and oftener from a crack than from a wart. The edges of the sore become hard, and one or more tumours issue from them, which increase in size, and gradually evince a cancerous character.

On the tongue the same disease sometimes shows itself, and more usually commences with a small wart or pimple near the tip, which hardens by degrees, grows highly irritable and malignant, and spreading its influence through the entire organ, swells it to a prodigious size, and renders it of a scirrhus induration.

These local tumours are seldom entitled to be called cancers on their origin. They are almost always produced, as Mr. Earle has justly observed, by local irritation, and exacerbated by a continuance of the same cause; and hence they rarely give much trouble on extirpation, and perhaps never endanger the constitution. A chronic malignancy may, however, convert them into genuine carcinomata.—(*Medico-Chir. Trans.*, vol. xii., art. xxii.)

Cancer is said, in a few instances, to have terminated spontaneously. De Haen gives us one example of this (*Epist. De Cicutâ*, p. 43), and Parr affirms that he has seen six cases of the same in his own practice. But he adds, in proof of its being a constitutional affection, that in every case the cure was followed by some other disease, as an enteritis, fixed pains in the limbs, a sciatica, or an apoplexy; in one of these cases the apoplectic attack occurred twice, and the last was fatal.*

In general, however, a cure is rarely affected but with the knife or caustic, the use of which it does not belong to the present course of study to explain. Yet the progress of the complaint may perhaps be arrested; and we are often able, without cutting, to render it at least tolerable for a series of years. In an early stage of the disease relief may often be obtained by topical bleeding, as with leeches; and topical refrigerant applications, as saturnine lotions, or sheet lead in very thin layers, as the linings of tea-packages, an application which has of late been brought forward as something new, but which was employed long ago, and may be found recommended in many of the older journals of established reputation.† The diet should be limited to the mildest nutriment, and wine be sedulously avoided. At this period, indeed,

whatever can prevent or lessen inflammation should be seriously studied and adhered to.

Pouteau relates the particulars of a cure produced by rigid abstemiousness alone, the patient taking nothing whatever but water for a period of two months.—(*Nuovo Metodo per curare sicuramente ogni Cancero coperto*, &c., Venezi, 1750; *Œuvres Posthumes*, tom. i.)

As, however, the disease advances, and assumes more of a chronic character, the activity of the smaller vessels may be gently urged, in order to relieve or prevent congestion. And, where the irritation is not great, we may by degrees apply gentle stimulants also externally, and let the saturnine lotion be superseded by the acetated solution of ammonia, tar-water as recommended by Quadri, or the application of mercurial ointment, combined with a small portion of camphire, to the surrounding parts.

The internal medicines which have been chiefly trusted to for the cure of cancer, are the lurid and umbellate narcotics and the mineral tonics: the former apparently for the purpose of taking off irritation, and in some instances correcting the specific acrimony; and the latter for supporting the living power, and thus enabling the system to obtain a triumph over the disease by its own instinctive or remedial energy.

Of the first class, the chief have been the belladonna and hemlock, and particularly the latter, which appears to have been most promising. When Dr. Stoerck of Vienna published his work upon the successful exhibition of hemlock in cases of confirmed cancer, many of which were vouched for by the Baron Van Swieten, every practitioner was eager for examples upon which to try the experiment for himself. Solanum had been in vogue, but was just sinking into disrepute from its numerous failures; and corrosive sublimate was the medicine chiefly confided in at St. Thomas's Hospital. Dr. Akenside, who was at this time prescribing the corrosive sublimate in the hospital with what he thought a gratifying success, immediately exchanged it for the conium, or cicuta, as it was then called. He tried it upon a large scale in every stage and modification of the disease, and at first with the most sanguine expectations; but his hopes gradually failed him as he advanced in the career of his experiments, and he was compelled to make very great drawbacks upon Dr. Stoerck's commendation of the medicine. He allows it, however, a certain portion of merit, and his account is drawn up with a degree of candour which entitles it to the fullest confidence, and appears to deal out the real truth. In recent states of the disease, where there was no ulceration, or none of any depth, he asserts that it often produced a favourable termination, and gives numerous examples to this effect. But in inveterate cases, where the cancerous ulcer had made considerable progress, its benefit was very questionable: it operated often for a very few days like a charm, diminished the pains, and improved the discharge; but suddenly it failed to do the slightest good any longer, unless the

* Dict. in verb., vol. i., p. 329. The termination of carcinoma in mortification, from obliteration of veins, is stated by Professor Carswell as far from being a rare occurrence.—Ed.

† Eph. Nat. Cur., dec. i., ann. iv., v., obs. 161. It is on the principle of diminishing the supply of blood for the nutrition and growth of cancerous tumours, that the frequent local abstraction of this fluid, the application of cold, the use of the ligature and compression, have been recommended as the most effectual means of arresting or retarding their progress.—Professor Carswell, op. cit., fasc. iii.—Ed.

dose was very largely increased, upon which a like beneficial effect followed, but unfortunately of equally transient duration. The dose was in many instances again increased, and continued to be so, till at length the symptoms produced by the cicuta were as mischievous as those of the cancer itself, and Dr. Akenside was compelled to abandon it.—(*Transact. of the Coll. of Phys. of Lond.*, vol. i., art. vi., p. 64.)

We are hence in some degree prepared for the contradictory accounts of its effects. De Haen asserts that it affords neither cure nor relief of any kind (*Rat. Med.*, ii., 37); Bierchen, that it aggravates real cancer, though sometimes serviceable in scrofula; and Lange, that it is altogether inefficacious.—(*Diss. dubia Cicuta rextata*, Helmst., 1764.) Fothergill is friendly to its use (*Works*, vol. ii., passim); and Bell (*On Ulcers*, part ii., sect. viii.) and Fearon (*On Cancers*, passim) recommend it both externally and internally, alone or in combination with opium.

For this discrepancy of judgment, we have in some measure endeavoured to account. Yet the advocates of the medicine have doubtless, in some instances, suffered themselves to speak of it in exaggerated terms; and it is highly probable that in others, where it has seemed altogether inefficacious, the hemlock, whether in powder or extract, was administered in an imperfect state. Dr. Cullen gives a striking example of this last fact in a lady, who, being very particular in the use of this medicine, employed the powder as mostly to be depended upon, and weighed out her own doses, beginning with a small quantity at a time, and proceeding gradually till she took sixty grains at once. By this period her parcel of the powder was exhausted, and she had derived no beneficial effect. She supplied herself, however, with another parcel, and being warned that different samples were rarely of the same strength, she reduced her first dose of the new plan to a scruple: yet even this nearly killed her; for in ten or fifteen minutes she was affected with sickness, tremour, giddiness, delirium, and convulsions. Happily, the sickness proceeded to a vomiting, and the poison was rejected. But of the fresh supply she was never afterward able to take more than five or six grains at a dose, notwithstanding she had taken sixty grains of the preceding without any mischief.—(*Mat. Med.*, vol. ii., part ii., ch. vi., p. 264.)

Yet the quantities pretended to be given by some practitioners are far beyond this last amount. Thus, Dease informs us that he gave AN OUNCE AND A HALF of the powder every twenty-four hours (*Introduct. to the Theory and Pract. of Surg.*, i.), and performed a cure; and Rostard, that his ordinary allowance was six drachms of the extract for the same period, which is a still higher proportion.—(*Journ. de Méd.*, tom. xxxviii., p. 36.) Warner gave a drachm and a half, and thought it an enormous quantity, without mischief.—(*Treatise on the Eyes*, passim.)

Upon the whole, the balance of experiments

seems very much to confirm the candid report of Dr. Akenside. Schaeffer and many others contend, that even its beneficial influence is nothing more than a result of its narcotic power; but it does seem, in some instances, to act as a discutient, and to improve the quality of the secretion as well as to relieve the pains. Dr. Cullen advances further, and tells us that he has found it, in several cases, make a considerable approach towards healing the sore; "Though I must own," says he, "that I was never concerned in a cancerous case, in which the cure of the sore was completed."—(*Mat. Med.*, loco citat.)

Of the other narcotics, chiefly of the solanaceous order, that have been employed, it is hardly worth while to speak particularly. The same uncertainty has accompanied their use: and some of them, as aconite and dulcamara, have been rather supposed to effect whatever temporary benefit has flowed from their employment by the general disturbance they produce in the system, whereby a transient stop is put to every other anomalous action, than by their sedative power.

Of the metallic oxydes that have been brought into use, the only ones it is necessary to notice are those of mercury, iron, and arsenic. The first has been uniformly found mischievous when carried to the extent of salivation. Loss asserts, that by this means he cured a cancer of the nose and face (*Observ. Med.*, b. iv., Lond., 1672); but this was probably a spurious disease of zaruthan, as it has been called by some writers. It has more generally been employed as a gentle stimulant or alterant. Many practitioners have preferred the corrosive sublimate in small doses, but the submuriate is a far better preparation. And even this is given with more advantage in the form of Plummer's or the compound calomel pill, than alone; a form that conveniently unites a mild stimulant with a mild relaxant. To this, if the pain be acute, should be added a small quantity of opium; at the same time carefully guarding the bowels against constipation by any convenient aperient, if the pill itself should not prove sufficient.

Iron has been tried in almost every state of combination. The ferrum ammoniatum appears to have been the most successful, and is still the most popular. Under the name of flores martiales, it was introduced for this purpose before the public as far back as the middle of last century, by Francis Xavier de Mars, obtained, however, by a very uncouth and operose process. Dr. Denman was particularly attached to this metal, in whatever form administered; and broadly affirms that, after having employed almost all the medicines recommended for this disease in every different stage, he has never found any of them possess the pretensions of iron; and that the rest may be generally regarded as totally unavailing.—(*Observations on the Cure of Cancer*, p. 77.) Its greatly stimulant power rather recommends it to us on the present occasion, than proves an objection; for it is the kind of stimulus we stand in need of to

excite a new local action. It is said to produce a very speedy mitigation of pain, an improved discharge, and a less fetid smell; and, even in hopeless cases, to render the disease less malignant and distressing: unfortunately, however, its effects, like those of conium, have rarely been found permanent; and it has closed its career as a palliative, rather than as an antidote.

But of all the medicines of this class, arsenic has acquired the highest and most extensive reputation. This is a strictly oriental remedy, employed, as we shall have occasion more fully to observe when treating of elephantiasis, for every impurity of the blood. Who first ventured upon it in Europe for the disease before us, is not very satisfactorily known. It was common in the time of Hildanus, who ascribes its introduction into practice to the monk Theodoric, who flourished about the beginning of the eleventh century.—(Cent. vi., obs. 81.) It has formed the basis of almost all the secret remedies for cancer which have at any time been current, whether external or internal, from that of Fuschius, in the fourteenth century, who united it with soot and serpentary, to that of Richard Guy, who wrote upon the disease (*Essay on Scirrhus Tumours and Cancers*, 1759) in the middle of the last century, and whose boasted arcanum was found to be a composition of arsenic, sulphur, hogsfennel (*peucedanum officinale*), and crows-foot (*ranunculus sylvestris*).—(Richter, *Chir. Bibl.*, band v., p. 132.)

Of the real effects of arsenic, as of several of the preceding medicines, we labour under great obscurity from the discrepant reports which have been communicated. Le Febure, with a host of practitioners antecedent to and contemporary with himself, employed it both externally and internally, and regarded it as a specific.—(*Remède éprouvé pour guérir radicalement le Cancer occulte, et manifeste ou ulcéré*, 8vo., Paris.) Smalz thinks it serviceable.—(*Seltene chirurgische und medicinische Vorfälle*, Leips., 1784, 8vo.) Schneider (*Chir. Geschichte*, Theil. v.) and Justamond declare it to be useless, though the latter employed it locally as an escharotic. Hildanus (*Account of the Methods pursued in the Treatment of Cancerous and Scirrhus Disorders*, Lond., 1780) and Delius (*Dissert. Observat. et Cognit. nonnulla Chirurg.*, fasc. vi.) assert it to be injurious; and Schenck (*Observ.*, lib. ii., N. 304) and Meibom (*Blumenbach, Bibl.*, band viii., p. 724) give examples of fatal effects from its employment.

Fatal effects, indeed, it is easy to produce, provided a sufficient degree of caution be not employed in experimenting upon it. And, in truth, it is not till lately that any very convenient form has been devised for trying its virtues without a risk of mischief; but the arsenical solution of the London College, for which we are indebted to Dr. Fowler, has given us a preparation of this kind. Yet, even with this advantage, we cannot boast of any certain success in the use of arsenic. It acts very differently on different constitutions, though, generally speaking, it proves beneficial, and in some cases may produce a radical cure. But more

commonly, like the preparations of hemlock and iron, it unfortunately loses its effect as soon as the habit has become accustomed to its influence, and the cancerous action resumes its victorious career. And perhaps the only power that is capable of neutralizing cancer, or keeping it permanently in subjection, is the existence of a predominant diathesis of some other kind. How far the remark may have been made antecedently I know not, but from a pretty close attention to the subject within my own sphere of observation, I have been led to conclude that cancer does not often make its attack upon those who are constitutionally subject to gout, and seems to be restrained by its influence.

The list of external applications is still more numerous than that of internal. We have already glanced at the local treatment before ulceration has taken place. After this period sedative applications do not succeed, and moderate stimulants alone seem to afford any material degree of relief. In fact, the inflammation has now acquired much of the character of a malignant erythema, and requires warmer applications than phlegmonic sores.* Yet a cure is rarely to be effected, except by the caustic or the knife. When the poison was supposed to be of an acid character, a solution of the alkalis was employed to correct it. It was afterward conceived to be of an alkaline nature; and various acids, and particularly the carbonic acid gas, were regarded as the best antagonists. Who first employed it for the present purpose is not known; but it stands recommended as early as 1776, in an article of Magellan, inserted in Rosier's Journal; and an easy and convenient mode of application has lately been contrived by Dr. Ewart of Bath. Dr. Crawford, however, for the same purpose, preferred a lotion of muriatic acid diluted with three or four times its weight of water. Carminati and Senebier applied the gastric juice of animals; but poultices of carrots or charcoal have been in more general reputation. [A solution of the chlorides of lime or of soda, has also been of late years employed.]

All these have a considerable influence in correcting the oppressive fetor, and keeping the sore clean; but whether they go beyond this has been doubted. Yet even this is of great importance, since such an effect must necessarily give some check to the spread of the ulceration, afford solace to the patient, and probably improve the nature of the discharge itself. And hence many writers have been sanguine enough to expect an entire cure from such processes; and others have given accounts of such cures nearly accomplished, but which seem seldom, if ever, to have been rendered complete.

Fomentations of hemlock and various other narcotics have been also had recourse to, and sometimes tepid baths of the same, in which

* The editor has known the liquor opii sedativus preferred, in some instances, to every other dressing; and, on other occasions, nothing was found to afford so much ease as the simple ung. cetacei.—Ed.

the patient has been ordered to sit for twenty minutes at a time; and temporary benefit has sometimes followed the use of these means; but they have often been tried with as little avail as the suckling of toads, which was at one time a fashionable remedy, and esteemed of great importance, the animals being feigned to expire in agonies as the poison of the ulcer was drawn out, and its surface assumed a better aspect. Bouffey, who was a witness to their use, tells us, and probably with some truth, that they did more harm than good (*Journ. de Méd.*, tom. lxii.), and dealt out more poison than they took away. The era of this invention is unknown, but it was still in use about half a century ago in our own country, if we may judge from one of the private letters of Junius to Woodfall, who, alluding to the princess dowager of Wales, at that time afflicted with a cancer that destroyed her in January, 1772, asserts that "she suckles toads from morning till night."—(*G. Woodfall's edition*, vol. i., p. *241.)

One of the best detergents appears to be arsenic* finely levigated, and sufficiently reduced in strength by a union with calamine or some other ingredient. It is also one of the best caustics, in a simple or more concentrated state, and was freely employed as such by Mr. Justamond. Guy's powder, which we have already noticed, is used externally for the same purpose.†

[Mr. Carmichael some years ago strongly recommended the application of preparations of iron to ulcerated cancers, and gave a very interesting account of the good effects which he had seen arise from them. The plan has been repeatedly tried in this country, but its success here has not corresponded with that stated to have resulted from it in Ireland. When a medicine or application proves successful in the hands of one surgeon, and unsuccessful in those of another of equal skill, the inference is, that, if the medicine or application in each case be undoubtedly of similar qualities, but its effects different, the cases themselves cannot precisely correspond in their nature. No doubt, many alleged specifics for cancer have obtained their repute by the circumstances of their having

cured tumours and ulcers which only somewhat resembled, but were not really cancers.]

We have already observed that sheets of lead, among other preparations of this metal, were applied to the cancer about forty or fifty years ago, and bound over it with some degree of pressure. But a pressure of a much severer kind, together with the use of the same metallic sheeting, was employed a few years ago by Mr. Young, a fair and impartial trial of whose plan, however, by other surgeons, has completely proved that it is generally more hurtful than beneficial.

After all, when the cancerous character of the tumour is once decidedly established, little dependance is to be placed upon any plan but that of extirpation with caustic or the knife. The actual cautery, as employed by M. Mau noir, of which we shall have to speak more at large when discussing the genus *Ulcus*, may, perhaps, be most advantageously made use of in small cancers of the face; but the knife is the preferable instrument where the organ is large and extensively affected. Mr. Bell advises an early performance of the operation; Mr. Pearson, that we should wait till the extent of the disease has fully unfolded itself, so that no morbid part may be left behind.* Yet some parts may be doubtful even at last, and, wherever there is the least suspicion of this, they should unquestionably be removed along with the more decided portion of the morbid structure.

Even this remedy, however, can only apply to exterior organs, or to organs that can be brought down to the surface; for the uterus has been occasionally extirpated with success, but, far more frequently, without any benefit, perhaps from the operation having been postponed till too late.† In all other instances, the practice is melancholy from the first. The die is cast; and all we can hope to accomplish is to postpone the fatal result, to mitigate the sufferings of the day, and soften the harsh passage to the tomb.

GENUS VII

LUES.

VENEREAL DISEASE.

ULCERS ON THE GENITALS, INGUINAL RUBOES, OR BOTH, AFTER IMPURE COITION; SUCCEED-ED BY ULCERS IN THE THROAT, COPPER-COLOURED SPOTS ON THE SKIN, BONE-PAINS, AND NODES.

THE term LUES is derived from the Greek λύω, "solvo, dissolvo"—"to macerate, dissolve, or corrupt;" and, agreeably to the common rule

* The maxim of every surgeon of judgment in the present day, is to recommend the removal of every truly cancerous disease as soon as its nature is manifest. This proves the general inefficiency of all medicines and local applications, and the dangers resulting from delay.—Ed.

† In cancers of the rectum Lisfranc has succeeded in extirpating the diseased structure with perfect relief to the patient. In a memoir read by

* In consequence of many patients having fallen victims to the absorption of arsenic from the surface of cancerous and other anomalous sores, few modern practitioners now venture to apply powdered arsenic to carcinomatous ulcers.—Ed.

† Baron Dupuytren uses arsenical applications, prepared so as to modify the diseased surface, without acting as a caustic. The formula of the powder which he applies is 4 parts of arsenical acid and 96 of the submuriate of mercury in every 100. Occasionally the proportion of arsenic is increased to 5 or 6 in 100. When the baron uses a liquid, or paste, he merely blends the above powder with distilled water, or gumarabic powdered and moistened. When, however, the lotion is employed, 6, 8, 10, or even 12 parts of arsenic may be the proportion of it to the calomel. It is chiefly for phagogenic or inveterate ulcerations about the nose, lips, and face, that Baron Dupuytren has recourse to this heroic remedy, as he calls it.—See *Leçons Orales de Clinique Chirurgicale*, tom. iv., p. 471, et seq., 8vo., Paris, 1834.—Ed.

of expressing the power of the Greek ν by a Roman y , should be written *LYES*, as in the case of *Lyssa* and *Paralysis*, both of which are derived from the same root; but *lues* has been employed so long and so generally, that it would be little less than affectation to attempt a change, and in allucinatio, or hallucinatio, from the Greek $\alpha\lambda\upsilon\omega$, or $\alpha\lambda\upsilon\sigma\tau\iota\varsigma$, we are supported by a similar example of deviation from the common rule.

It appears to have been known to the world from an early age, as I have remarked in the running comment to the volume of *Nosology*, that acrimonious and poisonous materials are at times secreted by the genitals, capable of exciting local, and, perhaps, constitutional affections, in those who expose themselves to such poisons by incontinent sexual intercourse. Celsus enumerates various diseases of the sexual organs, most of which are only referable to this source of impure contact; but the hideous and alarming malady which was first noticed as proceeding from the same source towards the close of the fifteenth century, and which has since been called almost exclusively *VENEREAL DISEASE*, has suppressed, till of late, all attention to these minor evils, in the fearful contemplation of so new and monstrous a pestilence, to various modifications of which most of the anterior and slighter diseases of the same organs seem to have been loosely and generally referred, as though there were but one specific poison issuing from this fountain, and consequently but one specific malady. On which account, much confusion has arisen in the history and description of the disease; and syphilis, its most striking species, though commonly admitted, as we shall see presently, to be comparatively of recent origin, is by Plenck (*Beobacht.*, &c., ii.), Richter (*Chir. Bibl.*, band i., sect. ii., p. 163), Stoll (*Praelect.*, p. 94), and other writers of considerable eminence, regarded as of far higher antiquity: asserted by Lefevre de Villebrune (*Retz. Annales*, iv.) to have existed eight centuries before the expedition of Columbus to America, and by De Blegny (*L'Art de guérir les Mal. Vén.*, &c.) to have been extant in the Mosaic age.

The keen and comprehensive mind of Mr. John Hunter first called the attention of practitioners to the idea of different poisons and different maladies; and the subject has since been pursued by Mr. Abernethy with a force of argument, and illustrated by a range of examples, that seem to have put the question at rest. Mr. Abernethy has sufficiently established that, independently of the specific disease now generally recognised by the name of syphilis, there are numerous varieties of some other disease, perhaps other specific diseases, which originate from a distinct, possibly from several distinct, poisons secreted in the same region from pecu-

him to the Royal Acad. of Medicine at Paris, he gives the details of a case in which three inches of this intestine were successfully removed.—See his memoir on Excision of the Rectum, trans. by Doane, in the U. S. Med. and Surg. Journ., vol. i., p. 294.—D.

liarity of constitution or causes hitherto undiscovered, and which are accompanied with primary and secondary symptoms that often vary in their mode of origin, succession, and termination, from those of genuine syphilis, though, in many instances, they make a striking approach to it, and to which, therefore, Mr. Abernethy has given the name of pseudo-syphilitic diseases.*

The approach, indeed, is often so close as to render it difficult, and occasionally, perhaps, impossible, to decide between them; and hence, whether these really constitute distinct species, issuing from distinct sorts of infection, or are mere varieties or modifications of one common species produced by one common morbid secretion, has not yet been sufficiently determined. In this ignorance upon the subject, it is better, for the present, to regard them in the latter, as being the more simple view; and, with this preliminary explanation, the expediency of allotting the two following distinct species to the genus *lues* will, I think, be obvious to every one.

|-------------------|--------------|
| 1. Lues Syphilis. | Pox. |
| 2. — Syphilodes. | Bastard-pox. |

SPECIES I. LUES SYPHILIS. POX.

ULCERS ON THE GENITALS CIRCULAR, UNGRANULATING, THICKENED AT THE EDGE; THOSE OF THE THROAT DEEP AND RAGGED; SYMPTOMS UNIFORM IN THEIR PROGRESS; SPEEDILY AND UNIFORMLY YIELDING TO A COURSE OF MERCURY WHERE IT AGREES WITH THE CONSTITUTION; LESS CERTAINLY AND WITH MORE DIFFICULTY YIELDING WITHOUT IT.

THE vulgar term for the ulcers is *Chancres*, and the vulgar name for the disease is *Pox*, formerly *Greatpox*,† as contradistinguished from *VARIOLA* or *SMALLPOX*, on account of the larger size of its blotches. It was also very generally called *French pox*, as being supposed to be a gift to Europe from the French nation.

There is some uncertainty concerning the

* Had Dr. Good taken a correct view of the facts, disclosed in the paper on syphilis, inserted by the late Mr. Rose in the Medical and Chirurgical Transactions of London, he would have perceived that nothing could be more conducive to error, than the circumstances which Mr. Abernethy regarded as tests of the true venereal disease. One notion which he adopted was, that the venereal disease always became progressively worse, unless mercury were prescribed; and, consequently, another part of his creed was, that if a sore or other complaint got well without the aid of the specific, fancied to be quite essential to the cure of every real form of the venereal disease, the fact was an adequate proof that the case could not have been of the latter nature. All these, and several other doctrines formerly entertained, have been annihilated by the plain and impartial details published by Mr. Rose. Most of Mr. Abernethy's syphiloid cases are now generally believed to have been truly syphilitic ones.—Ed.

† De Henry, *La Méthode curative de la Maladie Vénérienne*, vulgairement appelé la Grosse Vérole, &c., Paris, 8vo., 1552.

origin of the specific term *SYPHILIS*, which Swediaur ascribes to Fernelius, but which assuredly existed long before his day; and was probably invented by Fracastorio about the close of the fifteenth century, from the Greek *σφίλω*, and *φίλω*, importing "mutual love;" for such is the title by which he has designated his celebrated and very elegant poem upon this very inelegant subject.

There is an equal uncertainty as to the quarter in which the disease originated. It is usually ascribed to the American continent, and believed to have been imported into Europe by the crews of Columbus on his first or second return home in 1493 and 1496; a belief, however, which seems to be altogether without foundation, for, at the period even of the first return of this celebrated circumnavigator in March, 1493, it seems to have preceded his return by some weeks; since, on his reaching Seville in the ensuing month of April, in order to join the Spanish army, it had already arisen, and was spread over Auvergne, Lombardy, and various other parts of Italy; as, in the course of the summer months, it was observed in Saxony, Brandenburg, Brunswick, Mecklenburg, and especially Strasburg, as all the German writers concur in admitting;* and even at Cracow, in Poland, according to Strykowski's Chronicle of Lithuania; while Fracastorio, who was an eyewitness of the entire progress of the disease, and, from his high medical reputation, and residence almost on the spot of its first appearance, more largely engaged in the cure of it than any physician of his day, asserts, that it was even ravaging a considerable part of Asia and Africa, as well as of Europe; "Europam," says he, "ferè omnem, Asiæ verò, atque Aphricæ, partem non parvam occupavit."—(*De Contag. Morbis.*) The writer proceeds to notice the dispute that was then hotly engaged in, as well concerning the nature as the origin of the disease, and again expresses his disbelief in its having been imported from America by the crews of Columbus. On this account he feels himself at liberty to give it a very early origin in his poem upon the subject, and describes his fictitious hero Syphilus as having brought down the disease upon himself and the world at large as a curse for having insulted Apollo, while tending the flocks of King Alcithous.

"Protinus illuvies terris ignota profanis
Exoritur: primus, regi qui, sanguine fuso,
Instituit divina, sacrasque in montibus aras,
SYPHILUS; ostendit turpes per corpus achores,
Insomnes primus noctes, convulsæque membra
Sensit, et à primo traxit cognomina morbus:
SYPHILIDEMQUE ab eo labem dixere coloni."

One of the earliest German writers who ascribed the disease to the return of Columbus, is Leonard Schmauss, a physician of Strasburg, whose works were published in 1518; but neither his history nor his arguments are in any degree satisfactory: while his countryman,

* See especially Meiner, *Sitten des mittel Alten. Stumpf, Schweitzer Chronik*, lib. xiii. Stettler, *Schweitzer Chronik*, lib. vii. Sprengel, *Geschichte der Arneykunde*, theil. ii.

Matern Berlen, a clergyman of Ruffach, and an eyewitness of the disease on its first appearance, assigns it a very different origin; and, in his history of the Italian expedition of Charles VIII., declares it to have been a punishment inflicted by the Almighty on this monarch and his subjects, in consequence of his having carried off the Dutchess Anne of Bretagne from the Emperor Maximilian, to whom she had been betrothed.

Among the Spanish writers, there are two chiefly who ascribe the origin of syphilis to an American source; while others, by their silence upon the subject when detailing the particulars of the return of Columbus, give sufficient evidence that they disbelieved the report. Of the two who thus contributed to spread it, one of them, Gonçalvo Hernandez de Oviedo, affirms that it was conveyed into Italy by Cordova's fleet, which, however, did not arrive in Italy (Messina) till May 24, 1495, and, consequently, not till two years after the disease had existed there. The other is Sepulveda, who, in a history of America, written in a good Latin style, towards the middle of the sixteenth century, roundly asserts that "*ex Barbaricarum mulierum consuetudine Hispani morbum contraxerunt.*" But as this writer does not, like his contemporary Fracastorio, enter into the particulars of the controversy, his assertion can go no farther than to the weight of his own individual opinion in a controverted case.

Among those who have been most full in their accounts of the voyages of Columbus and the discovery of America, we may certainly reckon Antonio de Herrera. He fixes the return of Columbus at the period above specified; and is very particular in detailing the order sent to Lisbon to him, on the moment of his arrival, to follow the Spanish court to Barcelona, to which city it was then removed; the highly honourable reception the great navigator received; the preparations which were immediately made for his second voyage; the speed with which these preparations were accomplished; and the instructions given to him on the occasion. Yet not a hint is added that his crews were unhealthy, that the new recruits had any dread of the plague, to which, had he brought it home, they must have known they were about to be exposed, nor a single instruction to be provident of their health in this respect. He took leave of the royal pair with every mark of distinction, the whole court accompanying him to his house, as well at the time as when he quitted Barcelona. "*Despidóse,*" says Herrera, "*de los Reyes, y aqual dia le acompañó toda la corte de palacio á su casa, y tambien quando salió de Barcelona.*"—(*Hist. Gen. de las Ind. Occ.*, decad. i., lib. li., ch. v.)

Linnæus stands alone in arranging syphilis as an exanthem, along with smallpox and measles. He thought himself justified, from the fever which occasionally accompanies the copper-coloured spots on the skin, in an advanced stage of its secondary symptoms; or perhaps from the fever which, on the first appearance of the disease, unquestionably accompanied it, and uni-

formly preceded the eruptions. For it is an extraordinary fact, to which all the contemporaneous writers bear witness, that syphilis, when it first broke forth upon the world, and, indeed, as it is described in Fracastorio's poem, was not only called the plague, but was, in truth, a specific fever, attended with most violent putrid symptoms, together with carbuncles, buboes, and other glandular abscesses, which discharged a malignant sanies often fatal, and even when recovered from, leaving the most melancholy marks of its ravages.

And hence, in many places, the infected were as much exiled from the community by a line of circumvallation drawn around them, as in the case of plague. In Scotland, indeed, they were strictly prohibited all medical assistance, and inhumanly left to the effects of their own licentiousness: for Mr. Arnot gives the copy of an order from the privy council of Edinburgh, which equally banished to the Island of Inchkeith those who were affected with the disease, and those who undertook to cure it.*

By degrees, however, the disorder appears to

* History of Edinburgh, by Hugo Arnot, Esq., 4to., 1789. With reference to the origin of syphilis, the editor is skeptical about the correctness of the doctrine which attempts to refer the first commencement of the complaint only to one source. Is it rational to believe that all the syphilitic mischief that has scourged the various cities, kingdoms, and generations of the world, has arisen from the amours of a single unfortunate individual in whom the virus was first produced? Are we to fancy that the disease never had but one primary source? and that it is to the mysterious concoction of the poison in one individual alone, that all quarters of the world are under obligations for the gift of the venereal disease? No doubt syphilis must have had a beginning, like every thing else; but probably it has had numerous beginnings. Various considerations would lead us to expect (what is, indeed, the fact), that in every country where the population is numerous, and promiscuous sexual intercourse exists, the venereal disease would be prevalent. Mr. Travers has consequently declared it to be his belief, that if all the syphilis in the world were to be now annihilated, a never-failing source of the disease would still remain, in the action of the matter of superficial or gonorrhœal ulcers of the penis on the human constitution.—(See his Pathology of the Ven. Disease.) In relation to this part of the subject, Mr. Wallace also considers it not in opposition to the general laws of nature, that the venereal disease may have arisen on different occasions spontaneously.—(See Treatise on the Ven. Disease and its Varieties, p. 8, 8vo., Lond., 1833.) At the same time he adds:—"No cases have occurred to me, nor have I heard or read of any, in which the evidence was quite satisfactory, that a deranged state of general health, or simple local irritation, or other accidental causes, either local or constitutional, ever produced by their influence on the system any effects which resembled in their series or order the constitutional symptoms of the venereal poison."—(P. 12.) The question, however, more immediately under our consideration is, not whether this poison exists at all, but, admitting the reality of its existence, whether it has had one or numerous origins? and whether it can originate under the circumstances adverted to by Mr. Travers?—Ed.

have assumed a chronic form, and at length so far changed its nature, as to make its attack without fever, and to remain local except from absorption. It seems still, indeed, to be continuing its course of melioration, notwithstanding the assertion of Dr. Swediaur (*Beobachtungen, &c.*, p. 172), that it has not assumed a more mitigated character at present than in former times; for very severe cases are now much rarer, not only in private practice, but even in public hospitals, than they were thirty or forty years ago.

It is possible that this change may have been produced by two causes; firstly, by the virus wearing out its own strength and becoming milder as it descends to different individuals and generations, and has to cope with the force of sound constitutions, and, perhaps, also, with a perpetual instinctive power or vis medicatrix naturæ, constantly labouring to subdue it: of which we shall hereafter have occasion to offer other examples than the present. And, secondly, it is also highly probable, that the frequent and indeed universal use of mercury for its extermination has succeeded, as a specific, in softening its violence, in the same manner as we know the virus of cowpox succeeds in giving a milder character to smallpox, even where it does not altogether answer as a prophylactic.

Syphilis shows itself under two distinct sets of symptoms, local and constitutional, the latter of which is commonly, but not always, a sequel of the former.

In which way soever it is produced, it is usually by means of impure coition; though we shall have occasion to show presently, that syphilitic matter coming in contact with any part of the surface of the body, where it is capable of burrowing and meeting with a little mucus, sweat, or, perhaps, any other natural secretion, is capable of assimilating it to its own nature, and hence of introducing the disease into the system by absorption, and consequently without any breach of surface. And hence, as other parts than the sexual organs may be a medium of communication, no local symptoms may in some instances ensue, and the constitutional signs be the first to manifest themselves.

The earliest ordinary mark, however, that infection has taken place, is the appearance of one or more minute pimples of a peculiar kind, which are called chancres; having a hard inflamed base, of a pale red hue, and irritable apex, which next opens with a small eyelet, becomes ulcerated, and discharges a small portion of limpid virus, that produces fresh chancres wherever it spreads. In the common mode of infection, the chancre shows itself on the prepuce, glans, and orifice of the urethra in men, and about the labia, nymphæ, clitoris, and lowermost part of the vagina in women. This mark sometimes appears as early as the third or fourth day after coition, more generally, however, a few days later; and in some instances, where the cutaneous absorbents possess little irritability, not till a lapse of several weeks. The chancre occasionally degenerates into a hard and irritable wart, with which the genitals are

frequently studded, sometimes as low down as the anus.

Another local symptom is the formation of a bubo in one or both groins, evidently produced by an absorption of the virus first deposited, or, as is more commonly the case, multiplied in the ulcerated chancre, communicated to the lymphatics, and hence to the inguinal glands, which, in consequence, become inflamed and tumefied. The tumour, when first perceived, is small, but hard, fixed, and diffused, with a somewhat obtuse pain. It enlarges gradually, and becomes more acutely painful, so as to render walking troublesome; and, if not opened by the lancet, generally bursts by the time it has reached the size of a pullet's egg, and discharges a copious quantity of pus from a single hollow. In a few instances the suppurative inflammation does not follow, and the tumour, as it augments, acquires considerable induration.

Sometimes, also, the inflammation extends by sympathy to the spermatic cord, which is inflamed and rigid through a great part of its course, while the testes themselves are tender and considerably swollen.

And occasionally, from sympathy also, or an entrance of a part of the received virus into the urethra, its mucous membrane becomes inflamed, and pours forth a considerable secretion of pus or purulent mucus, resembling that of blennorrhœa, or gonorrhœa, as it is commonly called, or the discharge from the eyes in purulent ophthalmia.

This was at one time mistaken for a genuine gonorrhœa, and the two diseases were very generally regarded as only different modifications of one and the same species. And some practitioners continue to be of the same opinion still, notwithstanding all the facts that have been adduced in proof of their being distinct maladies, produced by distinct kinds of contagion.* The local symptoms of syphilis, chancres, and buboes, are perpetually occurring without gonorrhœa, and gonorrhœa without chancres and buboes. Insomuch that there are not wanting practitioners who affirm that they never occur together, unless the two venoms are received simultaneously. And there is no doubt that this assertion is true in regard to a genuine gonorrhœa; but, from the cause already stated, a large flow of pus or purulent matter, and a general irritation and enlargement of the body of the penis, in appearance strongly resembling the symptoms of a genuine gonorrhœa, sometimes coincide with the primary signs of a syphilis, of which a very marked case occurred to the author not long ago, which he showed to an eminent surgeon of the metropolis, who had antecedently been incredulous upon this point. And hence a like admission of Professor Frank, who, however, does not speak very decidedly

* Thus, in an enumeration of the morbid states or actions produced by the direct application of the venereal poison, we find included, by one of the latest writers on the subject, "an increased and morbid secretion from the diseased surface of the urethra, constituting the state commonly called gonorrhœa."—Wallace, on the Ven. Disease, p. 45, 8vo., Lond., 1833.—Ed.

upon the subject; and has strangely placed syphilis not only with gonorrhœa, but with leucorrhœa, mucous piles, hernia humoralis, and a variety of other diseases, under one and the same indistinct genus, to which he has given the name of medorrhœa.—(*De Cur. Hom. Morb. Epit.*, tom. v., p. 149, Mannh., 8vo., 1792.) But the clearest and most incontrovertible proof of distinction between the two complaints immediately before us is, that in no instance whatever has a simple gonorrhœa, unconnected with bubo or chancre, produced those secondary or constitutional symptoms to which the proper local signs of syphilis are sure to lead, if not corrected in their progress.*

These symptoms are, a progressive soreness and ulceration of the tonsils, uvula, palate, and tongue; the voice being rendered hoarse, and the swallowing difficult. The ulcers about the fauces are of a distinctive character, being foul and rugged, with an excavated centre covered with a brown or whitish slough, and surrounded with a hard, red, elevated, and erythematous outline.

Sometimes the mucous membrane of the conjunctive tunic of the eyes next suffers in the same way, and displays an inflamed surface, with ulcerations on the eyelids and angles of the eyes.† The skin is in various parts covered over with copper-coloured spots, which at first desquamate in scurfs, afterward in scales, and still later in scabs; each of which leaves a foul ulcer, that gradually grows deeper, and discharges an offensive fluid.

As the disease advances, irregular pains shoot through the limbs, and are felt so severely at night as to prevent sleep. By degrees they strike into the bones, which become diseased, and in many places swell into nodes, which at length grow carious: while the ulcerations about the fauces spread at the same time, or even before this, to the adjacent bones of the palate and nostrils, which are gradually eroded and carried away; so that the speech is rendered nasal and imperfect, and the nostrils are flattened to the level of the cheeks.

Finally, the countenance grows sallow, the hair falls off, the appetite is lost, the strength decays, and a low hectic preys upon the system, and at length destroys it.

It is not easy to say how long the matter of syphilis, when once communicated, may remain limited to the local symptoms of chancres or

* The earlier American physicians generally believed that gonorrhœa and lues syphilis arose from two distinct poisons, and necessarily demanded different modes of treatment; that mercury was indispensable to cure the latter, while it was unnecessary, if not pernicious, in treating the former. This opinion, however, was somewhat questioned when the treatise of John Hunter was published in this country; and his authority is so great, that some still maintain the identity of all venereal poisons.—D.

† Among the secondary symptoms Dr. Good should have mentioned iritis, which is a far more unequivocal effect of syphilis than the affections of the conjunctiva and eyelids, to which he has alluded.—Ed.

buboes, or continue inert in the system where no local symptoms have taken place; or what period must intervene before a patient may be pronounced safe after having exposed himself to contamination. We have already seen that the primary or local signs generally manifest themselves within four or five days; and, where the constitution has become infected without them, we have reason to expect the appearance of the secondary symptoms soon after three weeks, or from this time to six months: and if this latter interval have passed without the slightest manifestation of mischief, locally or generally, we have little reason to fear for the issue. It has been said, however, that the poison has lurked unperceived for several years; yet it is rarely that such an assertion is made, except for the purpose of excusing some fresh infection. I should, indeed, have been disposed to think it had never been made otherwise, but that Dr. Hahnemann has referred to an instance or two to the contrary, in which he places full confidence (*Unterricht für Wundärzte über die Venerischen Krankheiten*, 8vo., Leips., 1789); and particularly that the late Mr. Hey of Leeds, whose authority is indisputable, has offered it as his opinion, formed from a variety of cases that had occurred to him during an extensive practice of nearly threescore years, that a man may communicate the disease after all the symptoms have been removed, and he is judged to be in perfect health; and that a mother who has been once affected may convey it, notwithstanding an apparent cure, to two, three, or four children in succession, each of whom he supposes will have it in a milder form than the preceding one; as though it were gradually ceasing in the constitution, though it still continues to show some degree of activity.*

* Facts illustrating the Effects of the Venereal Disease, by William Hey, Esq., F. R. S., 1816. The doctrines here adverted to, particularly that of the poison *lurking* unperceived in the constitution for many years, and that of a man in perfect health, or without any perceptible ailment about him, being able to communicate the disease to a woman, may be considered as now having few advocates. As the disease may be transmitted from the mother to the fetus through the medium of the blood, a suspicion has frequently been entertained that it is likewise communicable through the medium of the natural secretions, the saliva, milk, semen, &c. With respect to the fetus, we may infer that it receives the infection by means of the circulating blood, in the same manner as the mother herself receives her secondary symptoms; but, with regard to the saliva, semen, and milk, it is difficult to pronounce how far these secretions will serve as means for the transmission of the disease, till the power of the secondary symptoms in general to do so is better made out. The editor believes with Mr. Travers, that none of the natural secretions of a contaminated individual can communicate the disease to other persons. The following statement in this gentleman's work (*Pathology of the Ven. Disease*) is interesting: a man who has syphilis in the secondary form, provided he be free from all affections of the genitals, will communicate no taint to his progeny any more than to his wife; but a healthy wet-nurse, getting a sore nipple, in consequence of suckling a

It is obvious, however, that in syphilis, as in various other diseases produced by the absorption of a specific virus, different constitutions are differently affected, and that some are far more susceptible of the morbid action than others. In many instances it is received by simple contact alone, and through an unbroken skin. It is generally, perhaps, thus received in the ordinary course of connexion; but still more evidently thus in other cases, and by other organs: for it has been very frequently caught by sucking the nipple of an infected wet-nurse; by infected saliva communicated in kissing; by drinking out of a cup that has previously been used by a syphilitic patient (*Reid, Diseases of the Army, &c.*; *Grüner, die Ven. Anst. durch gemeinschaftl. Trinkge., Weissenfels*, 1787); and it is said to have been produced by receiving infected breath, and lying in a bed which had been antecedently occupied by a person labouring under the disease (*Horstius*, opp. ii., p. 315): in some of which cases, however, it seems necessary to suppose the existence of a cut or crack, or some other breach of surface in the skin, and particularly about the lips, with which the syphilitic virus must have come into union. And it is hence easy to conceive how much more readily it may be communicated by the insertion of an exotic tooth (*Watson, Medical Transactions*, vol. iii., p. 325), by bleeding or scarification with an infected lancet (*Girtanner, die Venerischen Krankheiten, &c.*, p. 165), or by the attendance of an infected midwife (*Act. Nat. Cur.*, vol. vii., obs. 75; vol. ix., obs. 94),* who has sometimes given the complaint both to the mother and the child.†

A very melancholy instance of infection is related by Dr. Barry of Cork, communicated by a woman who was in the habit of drawing the

pocky child, and having secondary symptoms, will communicate the disease to the fetus of which she may become pregnant. This, we see, is agreeable to the usually received opinions, that the blood will contaminate the embryo though all genital sores may be absent, and though the party cohabiting with the woman is actually beyond the sphere of the influence of the disease in her. As far as the present state of our knowledge of the subject reaches, we may conclude that the disease is only communicable through the medium of a purulent fluid, and not an ordinary secretion, with the exception of the mode of its transmission to the fetus, which receives the infection through the circulation, and may therefore be regarded as under the same circumstances with respect to the secondary effects of the disorder as the mother herself.—Ed.

* In the *Westphälischer Anzeiger*, a case is stated where leeches, having been applied to a syphilitic patient, and afterward to an infant, the latter was affected with lues.—D.

† The faith to be put in several of these alleged modes of infection must be regulated by the well-established fact, that the venereal disease cannot be communicated unless the infectious matter be directly applied and lodged upon some part of the body of the person who catches the disease. The communication of the disorder through respiration, or by sleeping in a bed in which a venereal patient has previously lain, would not generally be credited by surgeons of the present time.—Ed.

breasts of puerperal patients; and who, upon examination, was found to have chancres on the lips and roof of her mouth, probably caught from some impure person in the course of her vocation. From the numerous engagements of this woman, the disease had spread very widely; and the rapidity of its progress was as striking as the manner of its communication. "The nipple," says Dr. Barry, "first became lightly inflamed, which soon produced an excoriation, with a discharge of a thin liquor; from whence red spreading pustules were dispersed round it and gradually spread over the breast, and, where the poison remained uncorrected, produced ulcers. The pudenda soon after became inflamed, with a violent itching, which terminated in chancres that were attended with only a small discharge; and in a short time after, pustules were spread over the whole body. It finished this course, with all these symptoms, in the space of three months. The disorder made a quick and rapid progress in those who first received it, they not being apt to suspect an infection of this nature in their circumstances. The husbands of several had chancres, which quickly communicated the poison, and produced ulcers in the mouth, and red spreading pustules on the body. But some of them escaped, who had timely notice of the nature of the disease, before the pudenda were affected. Some infants received it from their mothers, and to the greatest part of them it was fatal."*

* Edin. Med. Essays, vol. iii., art. xxi., p. 297. The real nature of the disease here spoken of is very ambiguous, and much doubt must be entertained respecting its syphilitic character; for, according to received opinions, it is not the ordinary course of the venereal disease to be communicated through the medium of any other secretion than the matter of a chancre, nor to attack the pudenda secondarily, after the infection has been originally communicated through some other quarter. According to Mr. Hunter, the matter of secondary venereal sores cannot impart the disease. However, it should be noticed, in opposition to the doctrine of the venereal disease being only communicable by the application of the matter of a chancre to the body of the person who catches the disease, that many cases are recorded of infants contracting the complaint, as was supposed, through the milk of infected nurses; and that other examples are related, in which most severe effects, resembling those of the worst forms of syphilis, have followed the transplantation of a tooth. In such instances, if the disease communicated were truly venereal, they were of course transmitted through the medium of the milk and the secretions of the mouth; but it is not a view in which the editor places any confidence. Various statements in the writings of Mr. Evans and the late Dr. Hennen, tend also to prove that the matter of true chancre in one person does not always communicate to another individual a sore of the same character; that the common secretions of the genitals, in unclean females, will cause in other persons who have connexion with them, sores of a very anomalous and infectious nature; and that several individuals who cohabit with a particular female that has, perhaps, merely a discharge, as ascertained by careful examination, may have, in one example, a true chancre; in a second, a superficial ulcer with elevated edges; in a third a clap, without any

Where a wet-nurse and the infant she suckles are both affected, and there is a doubt which has communicated it to the other, collateral circumstances will assist us much: but where the one, as is usually the case, has constitutional symptoms, and the other only local, the former must have had the disease the longest, and consequently have been the source of contamination.*

Such, however, is the insusceptibility of some idiosyncrasies, that the matter of syphilis, like that of smallpox, seems to have no effect upon them, and they are proof against its activity. I once knew a young physician, who, finding himself to be thus naturally protected, fearlessly, and for the sake of experiment, associated himself with females in the rankest state of the disease, and escaped in every instance. In like manner, Schenck (*Obs.*, lib. vi., N. 21) gives us a case of an infant rendered syphilitic through a diseased father, while the mother remained unaffected; and Mauriceau and other writers give cases of infants which have been fortunate enough to avoid infection, though born of syphilitic mothers (*Mauriceau*, ii., p. 100, 377; *Eph. Nat. Cur.*, cent. iii., iv., obs. 18); while Pallas asserts that the Ostiacks have a general immunity from the disease, under whatever form it offers itself.—(*Reisen*, iii., p. 50.)

sore; and in a fourth, no ulceration, discharge, nor any complaint whatever. These facts certainly tend to prove that the nature of the complaint may be very considerably modified by some inexplicable peculiarity, either in the constitutions of different individuals, or in the state of the parts to which the infectious matter is applied.—Ed.

* The hereditary transmission of lues will hardly be questioned, even by the most skeptical; and clinical practice might controvert the opinion of Mr. Travers, that none of the natural secretions of a contaminated individual can communicate the disease to other persons. We have good authority for stating the following case, which occurred in the practice of the late Dr. Post, of New-York. A gentleman, who deemed himself cured of syphilis, married: his child exhibited the disease soon after birth, and imparted it to the wet-nurse, whose character was beyond suspicion; the wet-nurse infected another female who drew her breasts, in consequence of which she was treated by mercurials, and was subjected to a surgical operation for an affection of her upper lip. The vision of the wet-nurse was impaired by the disease. In Dr. Hosack's Medical Essays, vol. ii., several cases are recorded of the communicability of syphilis to the fetus in utero. In speaking of the remarkable fact that Dr. Denman never saw a decided instance of a child born with venereal disease, Dr. Francis remarks, "The diseased mother may affect the fetus while in utero; the diseased infant may, by sucking, infect the nurse; the infected nurse may, in turn, communicate the complaint to the infant suckling at her breast. All this has occurred where the organs of generation, both male and female, were unaffected." "I have had under my care three cases of the venereal disease communicated to the fetus in utero: two of these cases occurred where the genital system appeared in a perfectly sound state; in the other, there were ulcers of the labia and constitutional disease."—See Francis's Denman, 3d edit., New-York.—D.

And, after all, the symptoms that characterize the disease, as well in its first as its second stage, are at times so nearly approximated by those which are occasionally traced in the second species of this genus, syphiloid lues or spurious syphilis, that it is often extremely difficult to distinguish them, and we are obliged to enter minutely into the history of the case, in order to assist our decision.

It was regarded by Mr. Hunter as a pathognomonic character of syphilis, firstly, that it never ceases spontaneously; secondly, that it is uniform and progressive in its symptoms; and thirdly, that it is only to be cured by mercury. And such were the doctrines of a few of his warmest advocates, almost down to the present time.*

How far these characters may have applied to it on its first appearance in Europe, under the influence of European excitements, and when the general constitution of European nations was fresh to its virus; or how far such characters may have descended to the middle of the last century, not long after which Mr. Hunter was so deeply engaged in drawing up those masterly views of this disease which he at length gave to the public in 1786, it may be difficult to determine. But to maintain any one of these doctrines without much modification, and especially as criteria of genuine syphilis in the present day, after the wide field of experiments which has been opened to us, both at home and abroad, would be the height of incredulity. For we have hundreds and perhaps thousands of proofs, that instead of "never ceasing spontaneously," it has occasionally disappeared without any other care than that of cleanliness and a reducent diet; that instead of being uniform and progressive in its symptoms, it has occasionally retrograded, or disguised itself under a variety of peculiarities, according to the influence of habit, climate, or idiosyncrasy; and that, instead of being only to be cured by mercury, various other modes of treatment have been quite as successful; while, in numerous cases, mercury has added to the virulence of the disorder, and introduced many of those very symptoms which have usually been regarded as indicative of its secondary stage. Insomuch that it has been almost as seriously made a question in France, whether there is any such disease as syphilis,† as it has been in our own country, whether there ever was such a disease as plague: the former being as much resolved into local uncleanness or constitutional irritation, as the latter has been into some modification of typhus with incidental influences.

This, however, is to run from one extreme of opinion to another; and all we can fairly collect from such a collision of facts and opinions, is a confirmation of the conjecture I have already

ventured to throw out, that syphilis, like many other diseases, is capable of being greatly modified by contingent or habitual concomitants, or that it has actually changed its character, and is in a progressive course of melioration.

In truth, it is well known that Mr. Hunter himself found at times the secondary symptoms of syphilis intractable to a mercurial course, and had the candour to acknowledge as much. Dr. Adams, indeed, with all his warmth of attachment to the Hunterian code of doctrines, has given an impressive case of this very kind, in which, in spite of the mercury, the disease carried its assault from the first to the second order of parts, by which is meant the bones. But then this anomaly is accounted for by their ingeniously telling us, that if a constitutional disposition to the disease be formed, the mercury cannot cope with it till such disposition comes into action; which seems, as Mr. Guthrie has justly observed, to mean nothing more, in plain language, than that "the disease cannot be prevented in certain constitutions from running its own course, when it may at last be cured."

Of all the profession, the medical officers of the British army seem to have been first impressed with the expediency of re-examining and revising the established doctrines upon the subject before us, from having observed that mercury is little used in Southern Europe, especially in Spain and Portugal, and that syphilis is there suffered in a very considerable degree to take its natural course; or at most to be treated locally as ordinary sores, and constitutionally with only herbaceous diluents or diaphoretics; while the primary symptoms evidently vanish under this simple remedial course, and secondary symptoms are at times not more common than where mercury is had recourse to and solely depended upon. Mr. Rose, surgeon to the Coldstream regiment of guards, was determined to put the question to a test, and upon such a scale as might lead to something of a decisive result. He forbore, in consequence, about the year 1815, to employ mercury for the cure of any case of syphilitic affection, or suspected to be such, among the soldiers of his own regiment; and soon sufficiently perceived, that though the cure did not advance so rapidly as under a judicious use of mercury, it nevertheless in every instance did advance; that it was not more severely followed by secondary symptoms or a syphilitic dyesthesia, than where mercury is trusted to as a specific; and that, of course, it was without the risk of those mischiefs to the general health, which mercury is so well known to introduce where it disagrees with the constitution.*

Having persevered in this mode of treatment, in his own opinion very successfully, for a period of nearly two years, he communicated its

* The late Mr. Rose had the merit of establishing more accurate views of the nature of this Protean disorder, especially with regard to the points which are here specified.—ED.

† See the anonymous but ingenious pamphlet, "Sur la Non-existence de la Maladie Vénérienne," Paris, 8vo., 1811.

* Many facts tending to show that syphilis is curable without mercury, might be seen in the large work entitled the *Aphrodisiacus* of Lusitanus and others, edited by Boerhaave, and published more than a century ago. The voyages of Don Ulloa contain evidence of the kind influence of climate in this disease.—D.

result to the public (*Med. Chirurg. Trans.*, vol. viii., p. 349, 1817), with a long list of well-diversified cases and observations that cannot fail to make an impression on every one who reads them.

The experimental course laid down by Mr. Rose was soon adopted by others, and, on various occasions, carried into establishments which afforded ample space for a satisfactory examination. It was tried in other battalions of the guards, as well in France as at home; was introduced into the York Hospital at Chelsea, and various other hospital establishments, as at Dover, Chatham, and Edinburgh. "From these hospitals," says Mr. Guthrie, "I have seen the reports of nearly four hundred cases which have been treated with the same result, as far as regards the cure of primary ulcers; each ulcer appears to have run a certain course, which, as to extent, was much the same as in one of the same appearance where mercury was supposed to be necessary, and, at an indefinite period of time, to have taken on a healing action, and, in the greater number of instances, skinned over rapidly, leaving a mark or depression showing a loss of substance. With us, where the ulcer had the characteristic appearance of chancre, dry lint alone was generally applied to it. Where these signs were less prominent, a variety of applications were used. But there were a great number of sores, both raised and excavated, on which no application made the least favourable impression for many weeks. They did, however, yield at last to simple means, after remaining for a considerable time nearly in the same state, several of them having become sores of a large size previous to or in the first days of their admission. If they were ulcers without any marked appearance, and did not amend in the first fortnight or three weeks, they generally remained for five or seven weeks longer; and the only difference, in this respect, between them and the raised ulcer of the prepuce was, that this often remained for a longer period, and that ulcers possessing the true characters of chancre required in general a still longer period for their cure, that is, from six or eight, to ten, twenty, and, in one case, to twenty-six weeks, healing up and ulcerating again on a hardened base. Those that required the greatest length of time had nothing particular in their appearance that could lead us to distinguish them from others of the same kind that were healed in a shorter period. Neither were any of these ulcers followed by a greater number of buboes, nor did they suppurate more frequently than in the same number of cases treated by mercury. On the contrary, the ulcers were not so frequently, on the average, followed by them, neither did they so often suppurate. But this may also be attributed to the antiphlogistic means employed both generally and locally for their relief."—(*Medico Chirurg. Trans.*, vol. viii., p. 557.)—And to this it may be added, that M. Cullerier, the first surgeon in the Venereal Hospital at Paris, has been for years in the habit of demonstrating to his pupils the possibility of curing every kind of ulcer that

falls under his notice without mercury. He usually, indeed, has recourse to this medicine *afterward*, but for the mere purpose of guarding against secondary symptoms.

It is very candidly admitted, however, by Mr. Guthrie, that although these experiments give the strongest proof of the possibility of curing venereal ulcers without mercury, yet that a much longer period of time is required for the cure. "I have every reason," says he, "to be certain, from former experience, that almost all these protracted cases would have been cured in one half or even one third of the time, if a moderate course of mercury had been resorted to after common applications had been found to fail."

The result of this inquiry therefore should by no means induce us to relinquish the use of mercury as of specific influence in general practice; but it is of great importance as offering solid consolation to those who may be labouring under the disease with an idiosyncrasy or acriditude of constitution that forbids the use of this specific, and converts it into a poison, instead of receiving it as a remedy.

It is admitted, also, that the cases of secondary symptoms occur more frequently in the cure of primary symptoms without mercury than where the last has been had recourse to. Upon the former plan of treatment, Mr. Guthrie calculates the secondary symptoms to occur about once in ten times; in the latter, once in about fifty-five times. But it is singular that, in the former case, the secondary symptoms are for the most part far milder than in the latter, the bones being rarely if ever affected. "Inso-much," says Mr. Guthrie, "that some of my friends, of great talents and experience, have been induced from this to suppose, that the greater severity of symptoms which are frequently met with have been caused by the exhibition of mercury in the first instance, which aggravated the constitutional disease." Mr. Guthrie, however, ascribes this more lenient show and course of the symptoms to the stricter antiphlogistic means resorted to in the simple than in the mercurial treatment, and endeavours to prove that mercury has no tendency to produce any such aggravation, except when injudiciously employed, or it does not harmonize with the idiosyncrasy, or actual state of the constitution.

It has been asserted, indeed, that in Portugal, where, as we have already observed, mercury is rarely had recourse to, both the primary and the secondary appearances are much more virulent than in England, or under a course of mercury: that the local ulcers are far more apt to slough and become gangrenous, and to run into that encircling phagedænic sore about the glans which has been vulgarly denominated *black lion*, and that a greater proportional number of British soldiers, and even officers, suffered irremediable injury from syphilis during the Peninsular war than are in the habit of suffering in this degree at home. These facts have been especially noticed by Dr. Fergusson in a valuable paper on the subject (*Med.-Chir. Trans.*, vol. iv.), and they are virtually admitted by Mr. Guthrie, who, however, ascribes the

malignity, in every instance, to the accidental circumstances of change of climate and intemperance of habit, rather than to the absence of mercury. "I do not think," says he, "the disease which the troops contracted in Portugal was in the slightest degree more violent than the same kind of complaint at home, neither do I place the least reliance on what has been said by others about a distemper called the black lion of Portugal, which I do not believe exists. But I perfectly coincide with him (Dr. Ferguson) in opinion that the change from the climate of Great Britain to that of Portugal in the summer, with the different mode of life, does act most powerfully on our northern constitutions, and disposes strongly to inflammatory affections. It is this that rendered the same kind of wounds more dangerous to the British soldiers than to the natives, and it was to this disposition, increased by the greatest irregularity of conduct and often by intemperance, a vice the natives are not addicted to, that we were indebted for the mutilations which ensued from the venereal disease."

The following calculation of results seems to be a fair expression of the general facts, and, in the present state of the question, they are too important to be omitted. They comprise the conclusion of the same able writer's remarks upon the subject.

1. "Every kind of ulcer of the genitals, of whatever form or appearance, is curable without mercury. This I consider to be established as a fact, from the observations of more than five hundred cases which I am acquainted with, exclusive of those treated in the different regiments of guards, and which occurred in consequence of promiscuous intercourse.

2. "Secondary symptoms (and I exclude trifling pains, eruptions, or sore throats), that have disappeared in a few days, have seldom followed the cure of those ulcers without mercury, and they have, upon the whole, more frequently followed the raised ulcer of the prepuce, than the true characteristic chancre of syphilis affecting the glans penis.

3. "The secondary symptoms in the cases alluded to, amounting to one tenth of the whole, have hitherto been nearly confined to the first order of parts, that is, the bones have in two instances only been attacked, and they have equally been cured without mercury.

4. "As great a length of time has elapsed in many of these cases without the occurrence of secondary symptoms, as is considered satisfactory where mercury has been used, viz., from six to eighteen months.

5. "The primary sores were of every description, from the superficial ulcer of the prepuce and glans to the raised ulcer of the prepuce, the excavated ulcer of the glans, and the irritable and sloughing ulcer of these parts. In the inflammatory stage, attended by itching, scabbing, and ulceration, they were treated, for the most part, by antiphlogistic and mild remedies; in the latter stage, when the ulcers were indolent, whether raised or excavated, by gentle stimulants.

6. "The duration of these stages is very different, is often increased by caustic and irritating applications, and is much influenced by surgical discrimination in the local treatment.

7. "The last or indolent stage often continues for a great length of time, especially in the excavated chancre and raised ulcer of the prepuce. And it appears to me that in these particular cases, a gentle course of mercury, so as slightly to affect the gums, will materially shorten the duration of it, although in others it is occasionally of no service.

8. "Although the secondary symptoms do for the most part yield to simple remedies, such as venesection, sudorifics, the warm bath, sarsaparilla, &c., without much loss of time, that is, in the course of from one to four or six months, yet, as in the primary ulcers, a gentle course of mercury will frequently expedite, and in particular persons and states of constitution is necessary to effect a cure; and that a repetition of it will even in some cases be requisite, to render it permanent."

There is yet one singular feature which remains to be noticed before we close the history of syphilis, and which, so far as I know, has never yet been fully brought before the public eye, although established by many of the best reports in the possession of the Army Medical Board; and that is, the great difference which exists in the facility with which syphilis, and, I may add, the affections that make a near approach to it, as bastard syphilis and gonorrhœa, are propagated in the East, compared with their propagation in the West Indies. These reports have been submitted to me by the friendship of the director general; and the chief conclusion I have been able to draw from them—and it is a conclusion that Dr. Gordon, who was kind enough to go over these reports with me, has long since arrived at from the same documents—is, that every two regiments in the East Indies furnish, at least, as many cases of both genuine and doubtful syphilis, as are furnished by the whole army in the West Indies.

But the following tables will give the reader an opportunity of calculating for himself, and will show that the difference is sometimes much greater. The report from the whole of the West Indies for the year 1823 is as follows:—

Cases of syphilis unaccompanied with	
secondary symptoms	16
Doubtful or bastard syphilis	15
Simple buboes	5
Annual number of cases for the	—
whole of the West Indies in 1823	36

Now, the report from the 1st or royal regiment alone, for the same year, stationed at Trincomalee, gives 177 cases of syphilis, without any subdivision into genuine and doubtful.

In like manner, during a preceding year, while the 12th regiment of light dragoons furnished the following report—

From the uncertainty which still prevails respecting the specific nature of several of the above affections in the minds of many practitioners, they are returned as of a common family; and however unscientific such an arrangement may be in itself, it at least enables us to draw a more satisfactory general conclusion, as showing that none of the forms of disease which, in the widest latitude of the term, can be referred to a syphilitic origin, are here kept back.

I was, in effect, not a little surprised at finding how few reports respecting syphilis have been sent home from the West Indies, compared with those from the East, till Dr. Gordon convinced me, from the nature of those which have been received, of the difficulty of making out any such reports whatever in particular years; and pointedly directed my attention to a remark in one of them, transmitted by Mr. Tegart, a highly intelligent inspector of hospitals at Barbadoes, as though offering an apology for the scantiness of his returns upon this subject. "One gentleman, Mr. Taylor, of much learning, and great experience in this island, who has resided here nearly thirty years, says that in that long period he has only seen two cases of primary disease. The fact is," continues Mr. Tegart, "that syphilis is almost unknown in this country:" alluding to the West Indies generally.

To what then are we to ascribe the wonderful contrast presented to us in these two colonies of the same empire? Is syphilis regulated by some such law as that of plague, which, as we have already observed, seems incapable of existing in an atmospheric temperature above 80°, or much below 60°; and hence has never been able to obtain a footing in Abyssinia or the south of Arabia, while it has rarely appeared earlier, as an epidemic, than June or July, in our own country? or is it affected by any other meteorological influence? The question is of no small moment: for if it be either the atmospheric temperature or temperament of the West Indies that produces so striking and beneficial an effect upon the specific poison of syphilis, it may be found that the best asylum we can provide, even for those who are actually labouring under the disease, and in its rankest form, is the same quarter: so that Barbadoes

and Jamaica may in process of time become as general a resort for syphilitic patients, as Madeira or the south of France for consumptive.

Till we are further acquainted, however, with the cause and nature of these discrepancies than we are at present, we must continue to provide for syphilis the best means of cure we may be able to do at home. And in pursuing this object it is not to be wondered at, from the observations already offered, that plans of very different kinds, and medicines of very different classes, should not only be had recourse to in our own day, but should have been adventured upon at all times, even when the disease may be supposed to have raged with a far greater degree of malignity than at present.

From the number and repugnance even of those that have acquired any considerable degree of reputation, there is no small difficulty in reducing them to any thing like an intelligible classification. Yet, upon the whole, we may observe that the medicines which have been chiefly had recourse to, or have been found most serviceable in curing syphilis or arresting its progress, are narcotics, diluent diaphoretics, diuretics, drastic purgatives, and those which introduce a large portion of oxygen into the system.

Of the narcotics, recourse has been chiefly had to opium, conium, solanum, and belladonna, manifestly upon the principle of their being sedatives, and hence rendering the system intractable to the syphilitic virus. This some of them accomplish in a very considerable and desirable degree; and particularly opium, which has been mostly trusted to, and tried upon a wider scale than any of the rest. It moderates and alleviates every symptom; and, from a cause not well ascertained, may be taken in very large doses with less inconvenience in syphilis than in almost any other disease. From its palliative effects, it has been supposed by many practitioners capable of producing a radical cure; and numerous histories to this purpose have been published by those whose judgments have been unduly prejudiced in its favour. On these histories it is not necessary to enlarge: they have been long before the world, and have called forth other trials, which have not proved equally successful. Narcotics in general, and opium beyond the rest, add considerably to the efficacy of other means, and particularly of mercury; but of themselves they are not competent to remove the complaint, and consequently are not to be depended upon.*

The list of warm and diluent diaphoretics

* As, from what has been said in the foregoing pages, every form of the venereal disease seems to admit of a spontaneous cure, without the specific influence of any medicine whatsoever, the question about opium should rather relate to its useful or injurious effects on the disease than to its power of curing it; and if the disorder will get well of itself when no opium is given, and will not do so when this medicine is exhibited, the conclusion must absolutely be that opium is injurious, and prevents the cure. No doubt our author did not mean to maintain this doctrine.—Ed.

that have been employed as remedies in syphilis are very extensive; but it may be sufficient to enumerate the following: mezereon, guaiacum, sarsaparilla, saponaria, bardana, similax, and one or two species of asclepias, or swallow-wort.

All these are supposed to be serviceable by exciting a determination to the skin, and throwing off the syphilitic poison, as various other poisons are thrown off, from the surface; and in very warm climates many of them are said to operate a radical cure, though the statements to this effect are rarely such as we can depend upon.*

They have all had their day, and the only one at present in much request is sarsaparilla, of the actual amount of whose virtues it is difficult to speak with precision. Like the *lobelia syphilitica*, or blue cardinal-flower, which is a purgative plant, it owes its earliest reputation to the American tribes; and when first imported into Europe by the Spaniards, about the year 1563, it had the character of being a specific for the venereal complaint. From being extolled, however, too highly,—for it never fulfilled this character in the old world,—it has since sunk, like many other useful medicines, into a very unmerited contempt, inasmuch that Dr. Cullen allows but eight lines to its history and qualities, in the course of which he tells us that if he were to consult his own experience he would not give it a place in the *Materia Medica*, as he has never found it an effectual medicine in syphilis or any other disease.—(*Mat. Med.*, part ii., chap. v., p. 200.) The London College, however, have evinced a different opinion, for they have adopted it under various forms: and Professor Thomson, of Edinburgh, has been so highly satisfied with its antisyphilitic powers, that he has for some years relinquished the use of mercury altogether, in favour of a mode of practice which consists chiefly in the employment of sarsaparilla.—(*Edin. Med. and Surg. Journ.*, No. liii., p. 84.) Upon a very large scale, he has met with very great success; though, like Mr. Rose, he candidly acknowledges that the secondary symptoms of the disease have required a longer time to be overcome under the new treatment than they would under a mercurial.

There is also a much more powerful objection to its use; namely, that the secondary symptoms are in many cases apt to return soon after the new treatment has been relinquished, or other symptoms not essentially different. The fair pretensions of sarsaparilla appear to be those of a mild stimulant and diaphoretic. It is hence in many cases a useful auxiliary to mercury:

* Now, however, that the curableness of the venereal disease without any medicine, or with only such as are quite inert, and destitute of any specific power, is considered to be an established fact, the doubts here expressed concerning the subsidence and effectual dispersion of venereal complaints under a course of warm diaphoretic medicines, are quite inconsistent with the view which the author has taken of what was made out by Mr. Rose's investigations.—Ed.

but I have chiefly found it succeed in chronic cases, where the constitution has been broken down, perhaps equally, beneath a long domination of the disease, and a protracted and apparently inefficient mercurial process. In connexion with a milk diet and country air, and with a total abandonment of mercury, I have here often found it of essential importance, and have seen an incipient hectic fall before a free use of it in a week. Its best form is the old one of the decoction of the woods, of which three or four pints should be taken daily.

In France the same plan has been long in general use, and has been found equally successful. On account of the dearness of sarsaparilla, when genuine, M. Etienne Sainte-Marie has been induced to try the *carex arenaria*, or German sarsaparilla of our old dispensaries, as Gleditch of Berlin had done before him; and though he does not, like Gleditch, regard it as more efficacious, he affirms, after employing it for ten years, that it is at least of equal value.—(*Méth. pour guérir les Mal. Vén. invét.*, &c., Paris, 1818.)

The syphilitic poison has also been often attempted to be thrown out of the body by exciting the excretories of some other organ than those of the skin, or in conjunction with them. Thus the *flammula Jovis*, or upright traveller's joy, the *clematis recta* of Linnaeus, which acts powerfully both on the surface and on the kidneys, is said to have been employed with great advantage, and was at one time in high and extensive estimation. It was given in the form of an infusion of the leaves; and Dr. Stoerck, with his usual liberality, assigns it an extravagant praise, informing us that it effectually subdues all the secondary symptoms of inveterate headaches, bone-pains, nodes, ulcerations of the throat, and cutaneous eruptions.—(*Libell. quo demonstr. herb. vet. dict. flamm. Jovis posse tutò exhiberi*, Vienna, 1769.)

The *lobelia syphilitica* of the American Indians has a still fairer claim to notice. It is a drastic purgative, uniting something of the stimulant and narcotic powers of tobacco, to which it has some resemblance in its taste. In the simple life and inirritating diet of the American tribes, it is possible that it may have proved as successful as it is stated to have been; but it has completely failed in Europe.*

Of the antisyphilitics whose influence seems to depend on their being loaded with oxygen, the principal are the mineral acids and the metallic oxides.

Of the first, the nitric has chiefly been made a subject of experiment in our own country, though the sulphuric has been employed abroad.—(*Crato.*, epist. v., p. 293.) Its general effects are, as we might expect them to be, tonic and sedative; whence the appetite is increased, a greater rigidity or firmness is given to the liv-

* According to the best information, the *lobelia* is still used by the Indians. The ravages of this disease among them, however, have recently led them to employ mercury. Barton says (*Veg. Mat. Med.*), that the antisyphilitic powers of *lobelia* are no longer credited.—D.

ing fibre, and a greater density to the coagulable lymph: the action of the bowels, and even of the bladder, being diminished. Besides these, it has a particular effect on the mouth, approaching to that of ptyalism, for the gums are rendered slightly sore, the mouth and tongue become moist, and in India and other warm climates a real salivation is said to ensue. Under this change, the syphilitic symptoms assume a better appearance, and especially those that belong to the primary set; but we have no decided case in which a perfect cure has been accomplished in our own country,* though Dr. Scott affirms that in India this has been common. The acid he was in the habit of employing was a direct aqua regia, as already noticed in the treatment of jaundice (Cl. I., Ord. II., Gen. I., p. 205. ;) and with the internal use of this he combined that of the acid bath, as there also particularly specified. His object was to effect a cure without incurring any of the evils so frequent upon a mercurial course; and to this object the proposed plan has, in his opinion, given complete success. It would have been happy for the world if this success had been permanent and universal; but the plan has since fallen in its reputation, not much less in India than in Europe.

The metallic oxydes have offered a large field for experiment; and almost all the metals have been had recourse to in rotation, as copper, iron, antimony, mercury, arsenic, and even gold.

The pretensions of arsenic are certainly considerable: it forms the ordinary medicine employed in syphilis by the cabirajahs or native Indian physicians, who depend upon it as a specific. They give it in the form of white arsenic, in combination with black pepper, as we shall notice more at large when treating of elephantiasis, for which also it is esteemed a powerful remedy. The only auxiliary is a cathartic of manna dissolved in a decoction of *nymphaea Nelumbo*.

Of the effects of any of the preparations of gold, we know but little. Many of them were in high repute formerly as a cure for various cachexies, and are said to have been used with success in syphilis.—(*Agricola, Comment. in Pappium*, Nürn., 1643.) They have since been tried in France,† and also in this country.‡

Antimony, and perhaps a few other metals, are useful auxiliaries: but, in fact, the only

metal, and I may add the only medicine, on which we can confidently rely for a general cure of syphilis in all its stages, in our own climate, is MERCURY.*

This has been tried from an early period in almost every variety of preparation; and, provided a sufficiency of it is introduced into the system, in every variety it has been found to succeed; so that, in the present day, the peculiar form is regarded of less importance than on its first use; though we may observe, that it seems to be most rapidly efficacious in those forms that introduce the largest proportion of oxygen into the system. And as it operates chiefly, like most other medicines, through the medium of the circulation, when it once becomes mixed with the current of the blood, it is equally efficient in the cure of a recent chancre and a chronic ulceration of the throat.

Mercury is a universal stimulant, and increases the action of all the secretories at one and the same time; for it operates simultaneously on the intestines, the skin, the salivary glands, and even the bladder; though it displays itself chiefly by its action on the salivary glands. It has also, when given in moderate doses, considerable pretensions to a tonic power, though this is overwhelmed by its stimulant effects when the dose is considerably increased. It seems, therefore, to unite most of the virtues of the preceding remedies, excepting the sedative; and hence it is greatly improved by the addition of opium and camphire, which give it the quality it stands in need of.

Independently, however, of its combining in itself many of the virtues of the preceding remedies, mercury seems also to possess some specific virtue unknown to the rest; for we can associate all the general qualities by a combination of different medicines without producing the same result. Mercury, indeed, to these general qualities adds that of peculiarly stimulating the salivary glands, which the other remedies employed in syphilis do not at all, or never in an equal degree; but that its specific power as an antidote does not depend upon its being a sialagogue is clear, because, while it has sometimes excited salivation without effect, it has at other times produced a perfect cure without any salivation whatever; for, in some idiosyncrasies, the salivary glands are not affected by its irritation.

Dr. Cullen, however, who had a mortal aversion to considering any medicine in the character of a specific, denies that mercury is a specific in syphilis, as he does also that it is an antidote to the disease. It is in vain to point out to him its specific influence upon the salivary glands, or its specific action upon the mouth;

* The preparations of gold and platina have been tried with perseverance by M. Cullerier, but without success. They are difficult to manage on account of their activity, and also of the facility with which they are decomposed. In this country, too, results have not warranted the reliance placed on them by Chrestien.—See Eberle's Am. Med. Review, vol. i.; also Dyckman's edition of the Edinburgh Dispensatory.—D.

* As syphilis in most of its forms, if not all, has been fully proved to admit of a spontaneous cure, we should be obliged to suppose the nitric acid to be not only useless, but an impediment to the cure, if our author's statement were substantially true. This is not, however, suspected; nor can there be any foundation for the suspicion, while Mr. Rose's facts continue to dispel various prejudices concerning the incurable nature of the disease without the aid of mercury.—Ed.

† See the Report of A. S. Duportal, M. D., and Th. Pelletier, Apoth. Annales de Chimie, tom. lxxviii., p. 38. Delpech, Chir. Clin., 4to., 1823.

‡ See a paper by Mr. R. D. Forster, on the Employment of the Chloride of Gold and Soda in Syphilis, published in Lancet for Feb., 1834.—Ed.

he denies the whole, and contends that mercury might travel, and perhaps would travel for ever in some other direction, were it not for the friendly interposition of the ammoniacal salts of the blood, which he fancies to have a close affinity with mercury, as he supposes they have also with the salivary glands; in consequence of which, they take the mercury by the hand, and introduce the one stranger to the other (*Mat. Med.*, part ii., chap. xvii., p. 443-450); thus solving the difficulty like divinity in the catastrophe of a drama. The result of the whole, in the opinion of Dr. Cullen, is, that mercury cures the venereal disease, not by producing any change in the state of the fluids, but entirely by giving a stimulus to the excretories at large, by whatever contrivance it reaches them, and thus increasing the excretions, and washing out the poison from the body.

That it does this is highly probable; but this alone is not sufficient, for fresh poison is continually forming by the process of assimilation, or the conversion of some part of the fluids it comes in contact with into its own nature; since, if it were not so, and the minute drop of virus that excited the disease at first remained without any increment, there can be no question that such a general scouring of the system would be unnecessary, and that the ordinary evacuations would be sufficient to throw it off. And hence we have not only to carry away the poison that is actually present in the vessels, but to prevent the formation of new.

Now it is in this power of prevention that the specific virtue of mercury seems to consist; and this it is that renders it paramount to all other remedies in the cure of syphilis. It is not only an evacuant, but an antidote: for, as we have already seen, it quickens the action of other remedial means when united with them, and far more speedily effects a cure even by itself than any of them. By what means, however, it becomes an antidote, or exerts its specific power, we know not. The matter of a chancre, mixed up with a quantity of Plenck's gummy solution of mercury, has been applied to a sound person without occasioning either a chancre or any other syphilitic symptoms. And it has hence been supposed that mercury neutralizes the syphilitic virus, and produces a third and harmless substance; as it has been further supposed, that it is by the disengagement of the oxygen which the various preparations of mercury introduce into the system, that this effect is accomplished. All this is ingenious, and may be true; but the evidence does not come home to the conclusion. Even the experiment with chancrous matter and the mercurial solution has not been satisfactorily performed; and if the result were as here stated, the matter, while it has no power of assimilating the solution into its own nature, as it has the fluids of the human body, may only have been rendered inert by simple dilution.

[Instead of these chymical hypotheses, the belief most commonly adopted by modern practitioners is, that mercury excites a new and peculiar action in the system, whereby the syphilitic action is destroyed. This, however, is only a

theory; and though it originated with Mr. Hunter, it should be regarded rather as an attempted than a well-proved explanation of the *modus operandi* of mercury.]

We have said that, provided a sufficient quantity of mercury be introduced into the system, the particular preparation is of no great importance. Van Swieten preferred the oxymuriate, and every one followed his example. The calcinated mercury came next into popularity, and triumphed over every other form. It was the leading article of most of the secret remedies that were sold for the complaint, and especially of Keyser's pills; the receipt for which was purchased with great formality by the French government, with an express provision not to make it public till the inventor's death.* These pills, however, which consisted of nothing more than mercury calcined by needlessly operose elaboration and mixed up with manna, were found in many cases to irritate the bowels, even when united with aromatics and opiates; and hence they gradually yielded on the continent to Plenck's solution, which still holds a considerable sway.

In our own country it is now most usual to employ the mercurial pill, or calomel, either alone or together with mercurial ointment. Yet, whatever plan is preferred, much caution is necessary in carrying it into effect; for the older practitioners, who employed larger doses, frequently did as much mischief to the constitution by the antidote as it had received by the infection. If calomel be employed, about two grains a day will commonly be found sufficient, guarded when necessary by a grain of opium; and if the ointment be preferred, half a drachm of the strong mercurial ointment may be rubbed in night and morning. If the disease be not severe or of long standing, it will not be necessary, with a little management, to produce salivation, which in most instances may be regarded only as a test that the system is thoroughly impregnated with the medicine; but, in chronic cases, we ought not to be satisfied without it.

In the course of the present work—and the observation is applicable to other doctrines than those of medicine—we have often seen that extremes lead to extremes: and hence, while many practitioners have been reviving the attempt to cure syphilis entirely without mercury, others have revived that of attacking it with very large doses. The last has chiefly been confined to those who have been employed in warm climates, and been friendly to the same practice in dysentery and yellow fever. In syphilis, however, they seem to have been somewhat more successful than in the other diseases, doubtless from the more decidedly specific influence of mercury over the former. The dose, with these gentlemen, is the usual one of a scruple, which in our own climate is repeated daily for three or four days in succession; but in warmer climates, four or even five times in

* Des Dragées, ou Pilules de M. Keyser, par Richard de Hautesierck. Recueil d'Observations de Médecine des Hôpitaux Militaires, &c., Paris, 1766.

twenty-four hours. In various cases the effects on the stomach and bowels are severe, and in all cases a considerable degree of nausea is excited, and the appetite is entirely suppressed. But, upon the whole, the bowels and general system are for the most part less affected than might be supposed; ptyalism is often excited in two or three days, and a constitutional improvement speedily shows itself. So that, where the treatment does not disagree with the idiosyncrasy, the cure is rapid and perhaps radical; the individual being usually set at liberty in a fortnight or three weeks.* But such a practice must not be attempted indiscriminately, and should indeed be used with great caution: for it has fallen to the author's lot to know of not a few instances, in which the constitution has been so completely broken down by the very onset of this energetic plan, as to require not two or three weeks, but many months, before the patient was re-enabled to take his station in society; to say nothing of the virulence which has been added to all the symptoms of the case, whether primary or secondary, in dyscrasies or idiosyncrasies which are hostile to the use of mercury. There can be no doubt, indeed, that a long perseverance even in small doses, under like circumstances, will not unfrequently produce as lamentable an effect. But, in this case, we can hold our hand much more easily on the first appearance of mischief.

In all cases of the use of mercury, but particularly in cases of salivation, care should be taken to avoid cold, and flannel should be worn next the skin. It is also of importance that the diet should be light and simple, as the pulse is usually accelerated, and, by a stimulating regimen, would be so much quickened as to do serious mischief. Mr. Hunter lays no stress on this point, but it ought by no means to be neglected.

If a bubo have formed in the groin, the mercurial ointment is best rubbed in a little below it, as it would increase the inflammation if applied to the tumour itself. In about a week or ten days the mouth will become slightly sore, when the further use and proportion of the ointment or other preparation must be regarded by the violence or duration of the complaint.

An injudicious use of mercury, or indeed any use of it in highly irritable habits, will sometimes excite a very troublesome erythema, that spreads itself in trails or patches over the whole surface; commonly, however, commencing about the genitals and lower limbs. It is accompanied with a painful tenderness and itching of the skin, and as the erythema meanders onward, the trails or patches first observed heal as new ones make their appearance. We have already glanced at this affection under the vesicular species of ERYTHEMA. Mercury must in this case be desisted from, the bowels be loosened with some gentle aperient, and the irritability opposed by

* Dr. S. A. Cartwright of Mississippi has employed calomel in this manner in many cases of syphilis, where small doses of mercury had been used without success.—See his Essay on Syphilis in the Am. Med. Recorder, vol. viii.—D.

sedative and mild cardials, as camphire, guaiacum, and sarsaparilla; and particularly by the mineral acids.*

SPECIES II. LUES SYPHILODES. BASTARD-POX.

THE GENERIC ULCERS INDETERMINATE IN THEIR CHARACTERS; SYMPTOMS IRREGULAR IN THEIR APPEARANCE; USUALLY YIELDING SPONTANEOUSLY; VARIOUSLY AFFECTED BY A COURSE OF MERCURY.

I HAVE already observed, at the opening of the present genus, that the species before us is designed to include a multiplicity of affections, which, in many of their signs, have a close resemblance to syphilis, but differ from it in the progress of the symptoms, as well as in the means that are necessary for a cure.†

Such affections are of high antiquity, far higher, indeed, than those of syphilis, and some of them appear to be glanced at in the sacred records. A few of them may perhaps have arisen in much later times, and may be arising at present.—(Pearson, *Obs. on the Effects of var. art. of the Mat. Med. in the Cure of L. Ven.*, 2d ed., p. 53.) By Celsus the subject is touched upon scientifically: it has been taken up in modern times by Mr. Hunter with that spirit of inquiry which peculiarly distinguished him, and has since been pursued by Mr. Abernethy (*Surg. Obs. on Dis. ressemb. Syphilis*, Lond., 1810), Mr. Carmichael, and various other surgeons and physiologists, with a kindred comprehension and genius: and the track which they have traced out in England is precisely parallel with the march which M. Etienne Sainte-Marie has of late years pursued in France, conceiving himself, according to his own account, to have been the original discoverer of these distinctions; which is the more extraordinary, since this writer, as we have already had occasion to observe, believes in the exploded doctrine of the identity of syphilis, and what is commonly called gonorrhœa.—(*Méth. pour guérir les Mal. Vén.*, &c., Paris, 1818.) The subject, however, is still in its embryo. Mr. Hunter considered his own remarks rather as hints for others to prosecute than as a com-

* In the U. States, syphilis is generally treated by mercurials; and although some practitioners believe that it can be cured without this class of medicines, but very few have adopted the non-mercurial practice. The preparations of mercury most used are calomel, blue-pill, and corrosive sublimate. The latter remedy, notwithstanding the violent opposition of Mr. John Pearson of the Lock Hospital, London, is too well known, and has proved too efficacious, to be invalidated even by him. An able view of the Medical History and Curative Action of Mercury, by Dr. J. W. Francis, will be found in the Am. Med. and Phil. Register, vols. iii. and iv.—D.

† Many of these cases would be arranged by Mr. Wallace as degenerations of syphilis.—See his Treatise on the Venereal Disease and its Varieties, p. 60, where he enters into the consideration of what he terms the "degenerations of primary syphilis."—Ed.

plete account of it. And though Mr. Abernethy has accumulated facts and cases, and ably illustrated them with observations that sufficiently establish these hints, and give something of a body to the outline, we are still in want, as we have already seen, of distinctive characters, and cannot determine with any degree of accuracy, whether the wide group of complaints that fall within the present range of contemplation are mere varieties of a common species produced by a common poison, or distinct species dependant upon distinct poisons, as discriminable from each other as all of them are from proper syphilis.

Under the last species, we had occasion to notice Mr. Hunter's pathognomonic criteria of genuine syphilis: first, that it never ceases spontaneously; secondly, that it is uniform and progressive in its symptoms; and thirdly, that it is only to be cured by mercury.

Could this view of the disease be strictly supported, we should have a tolerably distinctive character by which to discriminate the preceding from the present species; but sufficient proof has been offered, that not one of the three points holds good with a considerable degree of modification, whether in respect to the primary or secondary symptoms of these maladies.

Very ingenious attempts have since been made to distinguish these diseases, not by their general march and mode of cure, but by their immediate and prominent signs; that of the true syphilitic chancre in the first stage, and those of the peculiar nature of the spots, the nodes, or the ulcers, in the second. But the close approach to syphilis, at times, of misaffections, whose history, when minutely investigated, has clearly proved them to have issued from other sources than syphilis, has in a great measure levelled all such landmarks, and nearly left us in extreme cases without a clew.

It is after all, therefore, rather from the general history of the different examples in all their bearings, than from the individual symptoms, that we can alone arrive at any sound or satisfactory means of referring them to a syphilitic or a different origin. If we can strictly rely upon the assertion, or know, as a fact, that there has been no impure connexion; if we cannot perceive that there has been any primary ulcer; if we find that the symptoms, whether primary or secondary, readily give way spontaneously, or by other remedies than mercury; or if we have proof from the first that they are exasperated by this last medicine, whatever be the approximation of such symptoms to those of genuine syphilis, we may rest pretty well assured that the disease is syphilitic, rather than syphilitic lues. In the first case, indeed, unquestionably so, and nearly unquestionably so in the second and third.

It is well known that constitutional derangement, in an irritable habit or idiosyncrasy, will often follow from other local causes of various kinds, and often from what is ordinarily of very slight import. It is hence that the general health in some persons suffers from such cutaneous eruptions as rose-rash, herpes, or itch. Gonorrhœa has perhaps at times, as we have already remarked, affected the constitution in

like manner, and even thrown over the skin spots that have been mistaken for those of genuine syphilis. And there is hence reason for believing, that even an incidental and unspecific irritation of the prepuce or the glans may, in the same way, occasionally so far simulate the march of the same disease, as to exhibit a very close semblance to the raised ulcer, or the excavated chancre, or even the phagedænic slough; or, passing by these first symptoms, that it may mimic as closely those of the second stage of the disease. And as it is now pretty generally admitted on all hands, that morbid and irritative secretions of various kinds, independently of those of syphilis or even gonorrhœa, are thrown forth and accumulate in the sexual organs of contact, we can trace a variety of sources of both local and constitutional affection, which, issuing from the same seat, may assume something of a family character; to say nothing of those more wonderful resemblances of the secondary symptoms of syphilis which have sometimes been found to occur without any previous local contagion, and in the most unspotted purity of single life.

A consideration, therefore, of such diseases, or varieties of diseases, as are thus found to approximate the general character of syphilis, though issuing from sources widely distinct, and possessing, in the midst of such approximation, a few discriminative marks, perhaps at all times, and under all circumstances, however they may hitherto have eluded the prying eye of the pathologist, is evidently called for, and it is the object of the present subdivision to embody them, as far as the footsteps of observation will at present allow.

We have thus far, however, followed them into their extremes, in which alone their symptoms appear merged in those of syphilis; for, in the greater number of cases, a distinction is not very difficult, either in the local or the constitutional attack.

In illustration of these remarks I might refer to the observations of those who have been attentive to the subject on a large scale, but I refer more particularly to the collection of cases which Mr. Abernethy has printed in the work already alluded to.

The disease ordinarily commences with local symptoms, though not always; but the local symptoms have a less resemblance to those of genuine syphilis than the constitutional by which they are succeeded. A few foul and highly irritable sores are unexpectedly discovered on the genitals, commonly larger than chancres, and less thickened and indurated, about the size of a sixpence, and frequently sprouting with fungous granulations. Rarely, but very rarely, they have the guise of a true chancre; so rarely, indeed, that of the twenty cases contained in Mr. Abernethy's book, the fifth is the only one that answers to this description. These are sometimes succeeded by buboes and sometimes not. And where buboes take the lead, they run their course more rapidly, and with more violent inflammation, than in the true disease, and spread to a greater number of circumjacent

glands. These mostly, if not always, heal by the ordinary means without mercury, or constitutional symptoms of any kind. But, not unfrequently, in a few weeks or months, they are followed by a soreness and ulceration of the tonsils, copper-coloured spots over the body, and nodes or swellings of the periosteum in various bones; and sometimes these symptoms change their order of succession, or appear single.

In a few instances the constitutional symptoms take the lead and the local follow, of which Mr. Abernethy's fourth case affords an example. The patient here perceived first of all a small ulcer on the breast near the nipple, after having suckled a nurse-child about four months. It was of the size and shape of an almond, and was ascribed to the child's having a sore nose and lips. A gland in the axilla soon swelled and subsided, but, in about two months, the patient had a severe febrile attack, accompanied with a sore throat; from this she soon recovered, but had shortly afterward a copper-coloured eruption scattered over the body, and upon the disappearance of this, white blisters about the pudenda, which gave her pain in walking. About a week afterward her husband found a sore on the penis, covered by a black scab, of about the size of a sixpence, with a base neither hard nor thick, but with the surrounding skin much inflamed. Another formed in the course of the lymphatics towards the groin; the inguinal glands enlarged, and one of them suppurated; and an eruption of a papulous erythema, ushered by a few febrile symptoms, followed in about three weeks. The sores were twice touched with lunar caustic, and, as well as the bubo, were afterward washed with calomel in lime-water: they gradually healed. Both patients recovered, the wife with little assistance from mercury, having taken only a few compound calomel pills with small doses of nitric acid; the husband without mercury altogether, except that a dose of calomel was once administered with other aperient drugs as a purge.*

* These cases resemble some others quoted by the author under the preceding species as syphilitic; but against which inference the editor has mentioned a few considerations which occurred to him at the time of reading them. With regard also to the present examples, set down as syphilitic, the conclusion that they were not venereal cannot be maintained by the mere fact that they got well with little or no mercury, for, as already explained, all forms of the venereal disease are generally curable without mercury, though this often accomplishes the cure with greater expedition, and diminishes the frequency of secondary symptoms. When we read in Mr. Abernethy's *Observations on Diseases resembling Syphilis*, p. 44, that "the fictitious disease, in appearance, so exactly resembles syphilis, that no observation, however acute, seems to be capable of deciding on its nature;" and when we find him admitting, at p. 54, that all his reasoning is founded "upon the presumption that diseases which spontaneously get well are not syphilitic," we are compelled, in the present more accurate state of our knowledge upon the latter point, to confess that Mr. Abernethy completely failed in making out

In all these cases we meet with a virus that seems to be more active and irritating than that of genuine syphilis, but which, while it pursues, though with much irregularity, the same general path, runs through its course much more quickly, and is more effectually coped with by the natural strength or remedial instinct of the constitution. And hence, all that we are here called upon to do in the way of treatment is to support the general vigour and second the instinctive effort. This is best to be accomplished by tonics and gentle stimulants, and, where necessary, by sedatives. The mineral acids are the best means of supplying the first intention; camphire, the decoction of the woods, and the compound calomel pill, where small doses of mercury do not irritate, the second; and opium the third, though to this last it will rarely be necessary to have recourse at all.

The distinction between these affections and genuine syphilis is frequently difficult, but of importance; since, as a full use of mercury seldom seems to do good, and often does serious mischief in the former, such a plan has a chance of overwhelming the constitution with a second disorder instead of freeing it from a first.

To this family of maladies we are probably to refer the disease which, for a century or two, has been known in Scotland by the name of *SIBBENS*, or *SIVENS*, literally *rubula*, or *raspberry eruption*, and which seems to be a variety of lues, rendered hybrid by passing through a constitution already contaminated with genuine *RUBULA* or *yaws*.* The local symptoms have a much nearer resemblance to those of *bastard-pox* than of genuine syphilis, but in its constitutional progress, after the ordinary affection of the fauces, the disease has a tendency to throw forth over the surface an eruption of tubercles, which speedily degenerate into fungous ulcers resembling *yaws*, rather than an eruption of copper-coloured spots; which tubercles sometimes show themselves also in the throat itself. The constitutional disease spends itself chiefly on the surface, and the bones are rarely affected. With these exceptions we may agree with Dr. Gilchrist (*Account of a very infectious Distemper*, &c.) and Mr. Hill, of Dumfries (*Cases in Surgery*), that it has not a symptom which does

any peculiarities in his cases to justify their being denominated *pseudo-syphilitic*. When we are told of a disease being exactly like syphilis in appearance, we ought first to be informed what is the precise appearance of syphilis itself; for it presents itself in so many shapes, and has so many varieties, or degenerations, as Mr. Wallace terms them, that they form a very obscure and complex subject. Frequently no judgment of any value can be given about the nature of a sore, suspected to be venereal, merely from the look of it, without any reference to other particulars in the history of the case. On this point there are some interesting remarks in Mr. Wallace's *Treatise on the Venereal Disease*, p. 84, et seq.—Ed.

* Some few cases of *sibbens* occurred in 1819-20 among the ditchers employed on the grand canal between lake Erie and the Hudson. The persons affected were last from Canada, and were natives of Scotland or Ireland.—D.

not accompany the lues venerea (meaning syphilis) through all Europe; that both are equally infectious; both only communicated by sexual intercourse or other familiar contact; and both beneficially treated by mercury, which, they affirm, is the only remedy to be depended on. Mr. Hill tells us that it was introduced into the vicinity of Dumfries about the year 1772, "by some pocky soldiers, who, to prevent their debauching in town, were disposed through the neighbouring villages." Even upon his own showing, however, a much looser and blander exhibition of mercury than is sufficient for the cure of a confirmed syphilis,* will effect this in sibbens; for he adds, that "by the employment of a mild preparation of this metal he has cured numbers without confining them to their houses, even in frosty or snowy weather." It is probable, therefore, that sibbens might be eradicated by other means as well; but these gentlemen, notwithstanding the peculiarity of many of its symptoms, regarded it as a genuine syphilis, and, in consequence, did not direct their attention to any other mode of treatment.†

GENUS VIII.

ELEPHANTIASIS.

ELEPHANT-SKIN.

SKIN THICK, LIVID, RUGOSE, TUBERCULATE;
INSENSIBLE TO FEELING; EYES FIERCE AND
STARING; PERSPIRATION HIGHLY OFFENSIVE.

THE Greeks denominated this disease ELEPHAS, or ELEPHANTIASIS, because the skin of persons affected with it resembles that of the elephant in thickness, ruggedness, insensibility, and dark hue. Thus applied, therefore, the term imports *elephant-skin*, in the same manner as the same national school denominated dandruff pityriasis, or *bran-skin*, from the skin, under this disease, resembling branny scales; and another sort of scaly malady, ichthyiasis, or *fish-skin*, from the resemblance of the skin when thus affected to the scales of fishes. There are, however, two diseases of a very different kind, which occur in the translations of the Greek and Arabic writers under the name of elephas, elephantia, or elephantiasis; that immediately before us, and the thick leg of Barbadoes and other hot climates: and as the former of these has also, by many of the Arabian writers, been called lepra, or leprosy, and especially black leprosy, though as distinct from genuine leprosy as it is from the thick leg; and as the common term lepra has been continued

* When it is recollected that the venereal disease does not absolutely require mercury for its cure, but may be cured without it, the criterion here adverted to must be extremely fallacious.—ED.

† In the treatment of syphiloid affections, and in cases where mercury, through injurious management or peculiarity of constitution, has proved detrimental, Plummer's pill will be found an effectual alterative. Carmichael's Essays on the Venereal Disease contain satisfactory evidence of the valuable properties of antimonials in managing syphiloid disorders.—D.

in the translations of such writers, and copied from them by writers of our own times, an almost impenetrable confusion has been thrown around the whole of these diseases; and they have, even by modern writers, been strangely huddled together, and contemplated as mere modifications of one and the same malady, or as having some other connexion which does not in reality exist.

My attention was particularly called to this subject several years ago by an application from Dr. Bateman, who was then preparing his work on Cutaneous Diseases for the press, to assist him in unravelling it from the thorny maze in which it was at that time enveloped; and as the following letter from him, written in consequence of my acceding to his request, shows the real difficulty of the case, and is highly creditable to the activity of his mind, the reader will be obliged to me for introducing it.

"In order to give you the least trouble possible in the research which you were good enough to promise to make for me this morning, I wish to state, in a few words, the object of my inquiry. I believe the proper tubercular *elephantiasis* of the Greeks was called *juzam* or *aljuzam* by the old Arabians (*dsjuddam* and *madsjud-dam* by the moderns, according to Niebuhr.)—(See *Avicen.*, quart. iii., or lib. iii., fen. iii., tract. iii., cap. i.)

"If so, do the other Arabian writers also designate the proper elephantiasis by the same appellation?—For instance, is it used by Haly Abbas?*

"Again, what is the Arabic term applied to the THICK LEG (which most of the translators call *elephantiasis*, but which the translator of Haly Abbas calls *elephas*, thus distinguishing it from *elephantia*)?—The *thick leg* is described by Haly Abbas (*Theoricè*, lib. viii., cap. xviii.), by Avicen (*Lib. ii.*, fen. xxii., tract. i., cap. xvi. or xviii.), by Rhazes (*Ad Almanzor*, lib. ix., cap. xciii.), and by Avinzoar.—(*Lib. ii.*, cap. xxvi.) The translators of the other works in these places used the word *elephantia*.

"Thus, the proper *elephantiasis* is called *elephantia* by (the translators of) Haly Abbas, and *lepra* by (the translators of) Avicen, Rhazes, and Avinzoar. And the *thick leg* is the *elephas* of the former, and the *elephantia* of the latter. My chief inquiry is, whether the difference is only among the translators, or whether there is likewise a want of uniformity in the nomenclature of the original writers.

"En passant, I may observe, that some farther confusion has arisen among the translators respecting another *leprous* disease, as it has been called, which the Arabians seem to have considered as having some affinity with the proper elephantiasis (*juzam*), but yet is materially different in its symptoms; and which they have denominated *baras* or *barras*, and *albaras*, and which appears to accord accurately with the *leuce* of the Greeks, and the *vittiligo* (species

* *Theoricè*, lib. viii., cap. xv., and *Practicè*, cap. iv. In which passages the translator has used the word *Elephantia*, and not *Lepra*, like the other translators.

3) of Celsus. If the Hebrews did not apply the term (translated) *leprosy* to several affections of the skin (such as the scaly *lepra Græcorum*, the psoriasis of Dr. Willan, and the *leuce*, which I suspect they did), this *leuce* or *baras* would seem to be the *unclean leprosy* described in Leviticus, chap. xiii.*

"If your knowledge of the oriental languages will enable you, together with your knowledge of these diseases, to disperse some of the thick mist in which the translators have enveloped them, I should be exceedingly glad to partake of a little of your light."

The substance of the author's reply to this letter, already given in a note to the volume of Nosology, but which ought not to be omitted on the present occasion, was as follows:—

The Greeks became first acquainted with the elephantiasis from their casual intercourse with Egypt. To this quarter Lucretius, adopting the common opinion, ascribes its origin:—

"Est ELEPHAS morbus, qui propter flumina Nili, Gignitur Ægypto in mediâ, neque præterea usquam."†

High up the Nile, mid Egypt's central plains,
Springs the BLACK LEPROSY, and there alone.

Arabia, however, seems rather to have been the prolific source of this terrible scourge than Egypt; if we may judge from what seems highly probable, namely, that this is the disease with which Job was afflicted in Idumea, a part of Arabia, as described in the sacred poem that bears his name under the appellation of צרעת נגע, "the stroke of the scourge," and which affords, without question, the most ancient record in the world, composed in a mixed language of Arabic and Hebrew; and if we add to this the still more powerful argument, that the Arabic name of the disease has extended itself all over the east, and is almost the only name by which it is known in Egypt, Persia, and India, in all which regions the disorder is about equally common. Yet the Arabic name is not *elephas* or *elephantiasis*, but *juzam* جزام, literally "disjunction, amputation," vulgarly indeed, and more generally pronounced and written *judam* جدام, from جد, a root which imports "erosion," "truncation," "excision;" evidently referring to the destructive character of the disease, and the spontaneous separation of the smaller members, as the fingers and toes, when severe in its progress.

The Arabians, however, have a malady, but of a very different kind, to which they also give the name of *elephas*, or *elephant affection*, in their own language داء الفيل *dal fil*,

which is literally *morbus elephas*, and which they sometimes contract to *نيل* *fil*, or *elephas*, alone.

It is the "swelled, tumid, or Barbadoes leg of modern writers, the *bucnemia tropica* of the present system." And, on this account, when learning, and especially medical learning, found an asylum during the dark ages at the splendid courts of Bagdat, Bassorah, and Cordova, and the best Greek writers were translated into Arabic, or the best Greek and Arabic into Latin, two different diseases were found to possess a like name; for the Greeks, notwithstanding that they had elephantiasis to signify *juzam*, could only translate *dal fil* by *elephantiasis* also. And hence arose that confusion of the two maladies which has continued to the present moment, notwithstanding the wide distinction between them, the one being a tubercular affection of the whole body, while the other is a scaly affection of only particular parts, and commonly of not more than a particular limb.

The leprosy, properly so called, the *leuce* (λευκή) of the Greeks, and the *baras* or *beras*

برص of the Arabians, was by many of the Arabian physicians, and very generally among the people, supposed, in various cases, to terminate in *juzam* or *elephantiasis*, as though this also was nothing more than a different stage or degree of the same disease. And hence another error and perplexity in medical study. *Alsahavari* thus unites them, and they are jumbled together or explained alike in nearly all the oriental dictionaries; in which *beras* or *leprosy*, and *juzam* or *elephant-skin*, are, almost without an exception, regarded as convertible terms. This oriental confusion of two very different diseases was readily copied by the Latin translators, till at length both in the east and west, *beras* or *leprosy*, though literally *scale-skin*, became a sort of family name for almost every disfigurement of the skin, whether tubercular or scaly, cutaneous or constitutional. And on this account, *elephantiasis* and *leprosy*, and several other diseases even in the nosology of Linnæus, are included under the term *lepra*; all which the disciples of this school, extending a principle very widely adopted by them, ascribe to animalcules drunk in with the common beverage of water, especially the *gordius marinus*.

The author ought not to conceal Dr. Bate-man's acknowledgment of this communication, and his assent to its explanation, contained in the following opening of a letter received a few days afterward:—

"I thank you sincerely for your ready and interesting communication, which satisfactorily explains the point respecting which I was the least able to obtain satisfaction from the translators, viz., that the Arabians had applied the term *elephant* (*elephas*, according to the able translator of Haly Abbas), or *fil*, as you state, to the swelled leg. This is some apology for the appropriation of the Greek term *elephantiasis* (though it actually denoted a different disease) to the Arabian thick leg; but the appropriation of *lepra*, which is never mentioned by

* This is the opinion of two learned old Germans, Leon. Fuchs, in his *Paradoxa Medicinæ*, lib. ii., cap. xvi.: and Gregor. Horst, in his *Epist. to Hopner*, inserted in his *Observationes Medicinales*, lib. viii., obs. xviii. And Sennert seems to be of the same opinion, *Pract. Med.* lib. v., part i., cap. xl.

† De Rer. Nat., vi., 1112.

the Greeks but as a 'superficial, rough, and scaly affection,' to the tubercular *juzam*, has unfortunately misled and confused us for a thousand years."

Dr. Bateman adds, that he apprehends the term *elephantiasis* had also a reference to the *magnitude* and *DURATION* of the disease, independently of the appearance of the skin. And it is very probable, as the malady was likewise sometimes denominated *leontiasis*, that the formidable and frightful aspect of the patient labouring under it may have been hereby compared to the general exterior of both the elephant and the lion: for while *Arctæus* tells us, in describing it, that "it is disgusting to the sight, and in all respects terrible like the elephant," *Avicenna* affirms, "it renders the countenance terrible to look at, and somewhat of the form of the lion's visage."

The necessity of that stricter investigation into the nature of genuine *elephantiasis*, thus anxiously desired by Dr. Bateman, will be the more obvious when the reader learns, that in the classical work of Professor Frank it is arranged as a species of *lepra*; as are also *ichthyiasis*, and various other cutaneous affections, that should take their station in distinct quarters.—(Op. cit., tom. iv., p. 211, 1792.)

Besides the *elephantiasis* of the Arabians, we have a disease of the same kind, or which seems to be of the same kind, common to some parts of Italy, and another common to some parts of Spain; both which seem, indeed, to have issued from the Arabian stock. And hence *elephantiasis*, as a genus, offers us the three following species:—

1. *Elephantiasis Arabica*. Arabian *elephantiasis*.
2. ————— *Italica*. Italian *elephantiasis*.
3. ————— *Asturiensis*. Asturian *elephantiasis*.

SPECIES I.

ELEPHANTIASIS ARABICA.

ARABIAN ELEPHANTIASIS. BLACK LEPROSY.

TUBERCLES CHIEFLY ON THE FACE AND JOINTS :

FALL OF THE HAIR EXCEPT FROM THE SCALP :

VOICE HOARSE AND NASAL : CONTAGIOUS AND HEREDITARY.

This species, which is the oldest of the three, is also the most inveterate: for we do not know that the Italian species is contagious, though, like the Arabian, it appears to be hereditary; while the Spanish is, perhaps, neither contagious nor hereditary.

In some parts of the world, indeed, even the present species is said not to be contagious, though all the writers concur in its being hereditary in every quarter.* Thus Dr. Schilling,

* Dr. Kinnis mentions two patients whom he saw in the Isle of France, and who "stood in the relation of mother and daughter. The husband of the former had been dead eight or nine years: he had long been afflicted with palsy and dropsy, to which, only two years before he died, was su-

while he admits the latter effect, asserts that it is not contagious in Surinam, and Dr. T. Heberden asserts the same of this disease in Madeira. "I not only," says he, "am a daily witness of communication between lepers and other people without the least ill consequence, but know several instances where a leprous husband (afflicted with the Arabian leprosy or *elephantiasis*), married to a sound wife, has cohabited with her for a long series of years, and had several children by her, without her having contracted the least symptom of the disorder, although the children have inherited it; and vice versa between a leprous wife and sound husband."—(*Med. Trans.*, vol. i., p. 35.)

That the disease, however, is contagious as well as hereditary in India and Arabia, we have the concurrent testimony of all the medical writers of both countries, native as well as foreign; so that there can be no doubt upon the subject. And hence the Madeira and Surinam *juzam* should seem to be a variety of the oriental, influenced by peculiarity of climate or some other incidental cause.

This severe malady, wherever it shows itself, is sometimes slow in its growth, and continues many years without deranging the functions of the patient, yet great deformity is advancing upon his external make. The *alæ* of the nose become swelled and scabrous, and the nostrils are preternaturally dilated; the lips are tumid; the external ears, particularly the lobes, are enlarged and thickened, and beset with tubercles. The skin of the forehead and cheeks grows dense and hard, and forms large and prominent rugæ, especially over the eyes; the hair generally, except on the head, falls off; the voice becomes hoarse and obscure; the external sensibility is obtunded or totally abolished, so that pinching or puncturing gives no pain. The tubercles at length begin to crack and ulcerate; ulcerations appear in the throat and nostrils; the breath is intolerably offensive; the palate destroyed; the nose falls off; the fingers and toes, from the increased depth and virulence of the ulcerations, become gangrenous, and separate, and drop off one after another. [In the cases noticed in the Isle of France, the palms of the hand were seldom tuberculated, but had a dry, smooth, shrivelled appearance, as if the fat had been absorbed from under the skin. The backs of the hands, and more particularly

peradged *elephantiasis*. Her daughter was attacked about the time of her husband's death; she herself about two years afterward; and one of her sons had since fallen a victim to the disease. Her father was a Frenchman, her mother and maternal grandfather Creoles, and none of them was ever affected." Another patient is stated to have inherited the predisposition from the family of his maternal grandmother, who was never attacked herself, but lost two sisters and three nieces from the disease. None of his other relations, for three generations back, were ever known to have been affected. Dr. Kinnis saw his mother, with three other children, in the best health. She and her mother were Creoles, her grandparents Europeans.—See *Edin. Medical Journal*, No. lxxxi., p. 290.—Ed.

of the fingers, were swollen, thickened, flabby, and beset with oblong tubercles, impeding the motion of the joints. One patient had lost four toes of the right foot, excepting a single phalanx, which three of them still possessed; and another had lost two phalanges of the little finger. In one case the terminal bone of the great toe was exposed and dry; in another there was a circumscribed gangrenous spot on the fourth toe; and in most of the cases there were open indolent sores on the backs of the fingers, the bend of the ankle joints, the soles of the feet, or about the toes; sometimes superficial, and of a red colour; sometimes foul, discharging little, surrounded with hard, irregular edges, or overgrown with morbid cuticle.—(*Dr. Kinnis, Edin. Med. Journ.*, No. lxxxi., p. 288.) The mental powers suffer less than in the two other species; the dreams, however, are greatly disturbed, the manners, for the most part, morose and melancholy, and sometimes there is an inextinguishable desire of sexual intercourse.*

The disease is also known in the high northern latitudes of Norway and Iceland. In the last place it is peculiarly prevalent, produced, as Dr. Henderson justly observes, by the rancidity of the food usually fed on, wet woollen clothes, an insalubrious air, and want of cleanliness. It is called "Likhra," or "Putrefaction;" and an hospital is established for it in each of the four quarters of the island. It seems to be here both infectious and hereditary. "In its primary stage," says Dr. Henderson, "its symptoms are inconsiderable. A small reddish spot, scarcely larger than the point of a needle, breaks out at first about the forehead, nose, corner of the eyes, and lips; and in proportion as it increases, other pustules make their appearance on the breast, arms, armpits, which generally dry up in one place and break out in another without pain, till the disease has considerably advanced, when they cover almost the whole body, give the skin a scabrous appearance, stiffen it sometimes in shining scales, which fall off like dust, sometimes in malignant tumours and swellings. The patient in the meantime labours under lassitude of body, anæsthesia, and lowness of spirits." The miserable progress is nearly a transcript of the description just given. The patient is so worn out with fatigue and melancholy as to be often tempted to make away with himself. He sur-

renders one part of the body after another to the insatiable malady, "till at length," says Dr. Henderson, "death, the long wished-for deliverer, comes suddenly and puts an end to his misery."—(*Iceland, or the Journ. of a Residence in that Island*, vol. i., p. 295, 8vo., Edin., 1818.)

Mr. D. Johnson, of the Bengal establishment, ascribes the disease in India to nearly the same causes as Dr. Henderson in Iceland. It is found principally among the poorer castes, and "attacks chiefly such people as have their feet and hands frequently in cold water or earth, such as the peasants in the low marshy countries of Bengal and Orissa, Dobys (washerwomen) and Mollies (gardeners) in the upper provinces of India; and I conceive that cold and poorness of blood cause the circulation in the extreme capillary vessels to become too languid; the consequence is, a gradual decay or depolution of these parts." This writer admits that the disease appears in hereditary descent, but, as the different trades and occupations of the natives descend hereditarily also, he has some doubt whether the latter may not be the sole cause of its appearing in successive generations, instead of a family taint.—(*Misc. Obs. on certain Indigenous Customs, Diseases, &c. in India*.)

There seems to be a variety of this disease, in which a tumour of a larger size than the rest seats itself in the inguinal glands, sometimes in both groins, and is subject to a regular paroxysm of inflammation once in about every fourth month, preceded by shivering, and accompanied with a smart febrile excitement. These symptoms usually subside in three or four days, and leave the tumour as before. But, not unfrequently, that on the one side or on the other, rarely or never on both sides, advances to supuration, and produces a troublesome sore. Dr. Adams met with cases of this kind in Madeira, and Dr. Kinnis has since observed the same in the Isle of France (*Obs. on Elephantiasis as it appears in the Isle of France*, Edin. Med. Journ., Oct., 1824, p. 289): thus giving the disease an approach towards BUCNEMIA TROPICA.

The cure is extremely difficult, but a course of warm diaphoretics succeeded by tonics, and especially the metallic tonics, seems to have constituted the most successful plan. Hence a free use of sarsaparilla, mezereon, or guaiacum, has been found beneficial, and mercurial alteratives still more so, though salivation appears to have

* According to Dr. Kinnis, who has given an interesting description of elephantiasis as it appears in the Isle of France, the wasting of the genitals, represented by Dr. Adam as attending the disorder in Madeira, did not take place in a single individual of the other island; "the testicles in males, and the breasts in females, being constantly of their natural size. With regard to the functions of these organs," says Dr. Kinnis, "neither the wonderful salacity ascribed to the miserable victims of this loathsome disease by some authors, nor the utter extinction of the venereal appetite said to characterize them by others, existed in any case. One of the female patients, who had been affected with the disease only two years and a half, affirmed, that though she had ceased to menstruate from its commence-

ment, or to experience her former sexual propensities, she had yet suffered a miscarriage about twelve months before I saw her, and continued to cohabit with the person by whom she was kept. Another was the mother of two young children, one of whom I saw at the breast: she cohabited with a black," &c.—(*Dr. Kinnis, in Edin. Med. Journ.*, No. lxxxi., p. 289.) In an example detailed by Mr. Lawrence, in the *Med. Chir. Trans.*, the testes were unnaturally small and soft; and in four cases seen by Dr. Bateman, the venereal desire was lost. From the evidence collected on this point, we may conclude with Dr. Joy (*Encyclop. of Pract. Med.*, art. ELEPHANTIASIS), that the affection of the mammary and seminal glands, like the femoral tumour, is at most only an occasional complication.—ED.

been uniformly mischievous. Even the lobelia has had its advocates, and, upon the ground of its proving salutary in syphilis, it has probably also been sometimes serviceable in elephantiasis. Dr. Schilling endeavours to increase the determination to the skin, by advising the use of the warm bath and gentle exercise, and embrocating the body with spirits of wine or rum, or exposing it to a vapour-bath of mastic, olibanum, benzoin, or lavender.

In India the cabirajahs, or native physicians, after bleeding and purging, immediately apply to the metallic tonics, and particularly to the white oxyde of arsenic, which they give, as in the case of syphilis, and indeed of various other impurities of the blood, in the form of pills; mixing the arsenic, which, in Hindostanee, is sané hya, and in Arabic, shucc, with six times its weight of black pepper into a mass with a little water; so that each pill may contain about two thirds of a grain of arsenic and four grains of pepper, which is to be taken twice a day: and this medicine is regarded almost as a specific antidote. It has no doubt proved often successful: and I have known various cases in our own country in which it has been found equally so in the form of the arsenical solution.

In this quarter of the globe, however, Mr. Playfair has of late years revived the use of one of the species of asclepias or swallow-wort. In Europe, the *a. Vincetoxicum* was formerly in high favour as an alterant and alexipharmic, and was often denominated contrayerva Germanorum: but its virtues were not sufficient to support its character. The swallow-wort employed by Mr. Playfair is the *a. gigantea*, a native of the east, and appears, from an account lately published by Mr. Robinson (*Medico-Chirurg. Trans.*, vol. x.), to be possessed of more active and possibly more salutary qualities. It is the *mudar* or *midaur* of Hindostan, a shrub not yet systematically arranged, but found on all the uncultivated plains of India, producing a milky juice, which is the part employed medicinally, not only in this complaint, but in various herpetic affections, by being applied to the skin.—(*Misc. Obs.*, &c., by Daniel Johnson, Esq.)

The tonic found most useful by Dr. T. Heberden in Madeira was bark, which, however, has not proved of equal success in other places, or in the hands of other practitioners; but he employed it in connexion with that course of external stimulants which has been found generally serviceable, and probably not a little contributed to its wonderful efficacy in the various cases he refers to, and particularly one of a confirmed and chronic attack. "I have," says he, "in this island experienced the use of the bark in four or five leprous patients with success. One had a confirmed elephantiasis; the others were only incipient, having no other symptoms than florid or livid tubercles in the face and in the limbs. The confirmed elephantiasis was attended with livid and scirrhous tubercles, which had overspread the face and limbs; the whole body was emaciated; the eyebrows inflated; the hair of the eyebrows fallen off entirely; the bones of the nose depressed; the *alæ nasi* tumefied, as

likewise the lobes of the ears; with a suffusion in both eyes, which had almost deprived the patient of his sight. There was a want of sensation in the extremities, and a loss of motion in the fingers and toes."

For upwards of seven years, Dr. Heberden had used every medicine he could think of to relieve this patient, but in vain. Antimonials and mercurials of almost every kind, neutral salts, the warm diaphoretics, as sassafras and sarsaparilla, warm baths and medicated baths, were alike fruitless. On May 2d, 1758, he made his patient commence an electuary of powder of bark, with a third part bark of sassafras root, inspissated with sirup; and of this the quantity of a large nutmeg was ordered to be taken twice a-day. The patient at the same time had his arms and legs bathed with an embrocation, consisting of an ounce of lixivium of tartar and two drachms of spirit of sal-ammoniac, intermixed with half a pint of proof spirit. By the latter end of May the tubercles were considerably softened; by June 28th, they were dispersed; a red scurfy efflorescence alone remaining behind, which in ten days lost its florid hue and peeled off, leaving the cuticle sound and clean. "The patient," says he, "gradually recovered the sensation in his legs and arms, and the use of his toes and fingers; the hair has grown again on his eyebrows; and the only remainder of the distemper which I can perceive is, that the nose continues somewhat flatter, from the depression of the bones. The suffusion is quite cured, and the patient is *εὐσαρκός καὶ εὐχρῶος*,* of a healthy skin and colour."

SPECIES II.

ELEPHANTIASIS ITALICA.

ITALIAN ELEPHANTIASIS.

TUBERCLES CHIEFLY ON THE BODY AND LIMBS, SOMETIMES DESQUAMATING: GREAT TENSION OF THE SKIN: VERTIGO: BURNING, LANCINATING PAIN IN THE HEAD: MELANCHOLY, AT FIRST REMITTING, AFTERWARD FIXED, TERMINATING IN ALIENATION OF MIND: HEREDITARY.

For a knowledge of this species we are almost exclusively indebted to the Italian physi-

* *Med. Trans.*, ut *suprà*. Mr. Robinson represents the disease as presenting itself under two forms in Hindostan; one characterized by the dropping off of the fingers and toes, the insensibility of the skin, and the extreme torpor of mind and body; the other by tubercles, ulceration of the palate, and affections of the cartilages and bones of the face, together with the frequent occurrence of the oblong glandular tumour in the groin. The *mudar*, so useful in the first variety, is injurious in the second, which is benefited by arsenic.—(*See Med. Chir. Trans.*, vol. x.) Iodine might be tried both externally and internally. Rayer recommends exciting a slight degree of inflammation in the diseased skin with ammoniacal liniments, tincture of cantharides, or ointment of the hydriodate of potass. If they produce too much irritation, they are to be used alternately with the warm bath.—*Ed.*

cians, who have generally given it the name of pellagra or pelagra. The first writer upon the subject appears to have been Francis Frapolli, a physician of Milan, whose work, "In morbum vulgò Pelagram dictum," was published at Milan in 1771, and who expresses himself doubtful whether the disease, though not antecedently described, is not referred to occasionally by earlier writers, although he does not think that the pilarella, as the syphilis was called when it proved depilatory to the chin and eyebrows, was the disease in question, notwithstanding this seems to have been an extensive opinion at the time. The next tract of any note upon the subject was published at Venice in 1784, by G. M. d'Oleggio, under the title of "A Theoretical and Practical Treatise on the Diseases of Vernal Insolation, commonly called Pellagra."* But the best account we have received of this complaint is from the pen of Dr. Jansen, of Leyden, which appeared in 1788, and asserts that it is endemic in the Milanese territory.—(*De Pellagra morbo in Mediolanensi Ducatu endemio*.) It is, in truth, common to both the Milanese and Venetian territories, as well as to other districts widely differing in soil and temperature; and can scarcely therefore be referred to either of these sources. There is little doubt of its being hereditary, but not contagious; and it does not seem to have existed earlier than the middle of the last century.† It is commonly ascribed, as we have observed above, to the heat of the sun's rays (*J. P. Frank*, op. cit., tom. iv., p. 43) after the chill of winter, and is hence called *mal del sole*, which we have just seen was the view taken of it by D'Oleggio; while by Odoardo it is attributed to a scrofulous habit (*D'una spezia particolare di Scorbuto*, Venet., 1776), and by Videmari and others, who have too much limited themselves to the nature of the eruption, to an impetiginous impurity.—(*De quâdam Impetiginis specie*, Svo., 1790.) But none of these explanations seem to rest on any very solid foundation; and, upon the whole, we have more reason for regarding it as produced by the debilitating causes of hot, confined air, want of cleanliness, and bad diet, operating in many cases upon a diathesis hereditarily tainted. It is found chiefly among the Milanese and Venetian peasantry, whose hovels are full of wretchedness, and rarely makes its appearance till after the age of puberty. Alibert, in his "Diseases of the Skin," has denominated it, but with little accuracy, Ichthyosis Pellagra.—(*Desc. des Mal. de la Peau*, p. 175.)

The first symptoms of the disease are general languor, listlessness, gloom, feebleness, and stupor in the legs, and hence unsteady walking, vertigo, and confusion of ideas. Domeier, another writer upon the subject, extends the stupor of the legs to the entire frame, and asserts that anæsthesia is a characteristic symptom of

this species.—(*Baldinger, Journ.*, vol. xxvi., p. 9.) But this assertion is not confirmed by the history of other pathologists, though the languor and inertness are often very great, as well as universal.

These symptoms usually take place in the spring; and as the summer approaches, a sense of tension, burning, and itching is felt in every external organ except the head, followed by an eruption of rosy papulæ, scattered over the skin generally,* which terminate in tubercles of a shining red colour. After some days the tubercles desquamate, and the skin appears at first red, but soon recovers its natural colour. As the summer, however, advances, every symptom commonly subsides, and the strength is renewed with the winter; but the symptoms return with increased violence with the return of the spring, and this for several years in succession. But if the symptoms do not thus subside, they soon become even on the first attack considerably exasperated, and form a second stage of the disease, in which the itching grows more pungent; the heat more fiery; the skin harder, cracked, and chapped; the debility is greater; the mental functions are disturbed generally; the appetite is irregular; the sleep broken with acute pain in the head and spine, soon followed by delirium. The cutaneous affection now diminishes, but the nervous symptoms are greatly augmented. The vertigo increases; the patient is sad and loves solitude, and melancholy delirium alternates with furious mania. The *tædium vitæ* is insupportable, and self-murder is a frequent consequence. Strambi remarks, that those who labour under this disease have the greatest tendency to drown themselves, "as by a hallucination," says he, "opposite to that of hydrophobia."—(*De Pellagra, Obs.*, ann. i., ii., iii., Mediol., 1785.) Coercion is at last necessary; and a diarrhœa, dysentery, or dropsy, closes the dreadful scene, if the patient do not sink earlier from corporeal and mental exhaustion.† Dr. Holland tells us that at one time

* Dr. Holland says:—"The local symptoms very generally show themselves, in the first instance, early in the spring, at the period when the mid-day heat is rapidly increasing, and when the peasants are most actively engaged in their labours in the fields. The patient perceives on the back of his hands, on his feet, and sometimes, but more rarely, on other parts of the body exposed to the sun, certain red spots or blotches; which gradually extend themselves, with a slight elevation of the cuticle, and a shining surface, not unlike that of lepra in its early stage."—See *Med. Chir. Trans.*, vol. viii., p. 321.

† Besides exhibiting, at different periods in the same individual, many varieties in the appearances of the skin, as erysipelas, lepra, psoriasis, elephantiasis, and ichthyosis, it is liable to terminate in the production of several constitutional or general derangements of the system,—tetanus, chorea, epilepsy, convulsions, dropsy, melancholia, mania, marasmus, &c. "Hence," as Dr. James Johnson has observed, "we see written over the beds in the Milan Hospital the various diseases to which pellagra forms the adjective, as atrophica pellagrina, phthisis pellagrina, hydrops pellagrinus, paralysis pellagrina, mania pellagrina, &c."—

* *Tratto teoretico-pratico delle malattie dell'isolato di primavera volgarmente dette della Pellagra.*

† *Paralleli fra la Pellagra ed alcuna malattie, che più lo rassomigliano, del F. Fanzago. Padova, 1792.*

in the lunatic hospital at Milan, of five hundred patients more than one third were *Pellagrosi* (*Medico-Chir. Trans.*, vol. viii., part ii., p. 326); and he also informs us, that morbid dissections have thrown little light on the pathology of this disease; that the liver and spleen have at times evinced indurations and enlargements; and traces of disease have been occasionally seen in the intestines and mesenteric glands; but by no means constantly, and rather as effects than causes of the disorder.

The treatment needs not essentially differ from that of the preceding species. Pure air, habitual cleanliness, warm bathing, and a nutritious diet, with such tonics, whether vegetable or mineral, as best agree with the constitution, have proved most successful where the disease has not advanced beyond the reach of recovery. At Milan, the lichen *Islandicus* is one of the most popular remedies.

[Antimonials are also in repute, and attention is paid to the diarrhoea with which the disease is frequently accompanied. Bloodletting is rarely practised, except when mania or some local inflammation comes on. In some instances, according to Dr. Holland, the cutaneous affection forms the principal indication of the complaint for several successive years; being renewed every spring, and disappearing again in the autumn. In other cases, he says, where it has been found possible to remove the patient to a new situation and mode of life, the disease is still further arrested in its progress. "It rarely happens, however, that these means can be practically adopted; and the constitutional malady is generally so far established in the third or fourth year, that little hope remains of benefiting the patient, either by medicine or change in the mode of life."]

SPECIES III.

ELEPHANTIASIS ASTURIENSIS.

ASTURIAN ELEPHANTIASIS.

TUBERCLES CHIEFLY ON THE HANDS AND FEET; CRUSTACEOUS, DESQUAMATING: CONTINUAL TREMOUR OF THE HEAD AND UPPER PART OF THE TRUNK: BALDNESS OF THE SCALP, AS WELL AS OF OTHER PARTS: GLOOM AND TERROR OF MIND.

This species agrees in many of its symptoms with the Italic, and it is only worth while to notice the points in which they differ. Upon the whole, we may observe, that all the species coincide in being founded on an exhausted constitution, in the general character of the tubercles, and in their fatal termination by dropsy, atrophy, or some other asthenic disease. The Arabian species attacks the face, the roots of the hair, and the palate-bones, before the remaining parts on which it preys are diseased, and the affection of the skin increases with the increase of the other symptoms. In the Italian species, the affection of the skin diminishes as the nervous and mental commotion augments.

Change of Air, or the Pursuit of Health, p. 75.—EDITOR.

The pellagra also is distinguished by thick urine, double vision, and a peculiar mouldy smell of the sweat. In the Asturian species the crustaceous tubercles are peculiarly painful, highly fetid, more deeply furrowed with cracks, and more disgusting to the sight; attacking the head as well as other parts indiscriminately, and destroying the roots of the hair. The mind is less affected than in the last, and with melancholy and terror rather than with raving delirium.

This species constitutes the Asturian leprosy of Thiery, Vandermonde, and Sauvages; but genuine leprosy is rarely a constitutional complaint; and the present is its proper place. As the tubercles desquamate, the skin appears of a glossy leprous red, and the disease is hence called by the Spaniards *Mal de la Rosa*.

The causes are, extreme poverty and its attendants, filth, bad diet, and crowded unventilated rooms in the deep and swampy valleys of the country, almost impervious to the rays of the sun; and hence the medical treatment and general regimen recommended under the preceding species, will here afford the fairest promise of success.

GENUS IX.

CATACAUSIS.

CATACAUSIS.

GENERAL COMBUSTIBILITY OF THE BODY.

The peculiar state of the constitution which lays a foundation for the present genus of morbid affections, is of a very singular and mysterious kind; and the only medical work that has referred to it in our own country, antecedently to the author's own system of Nosology, is Dr. Young's Medical Literature, in which it is noticed under the Greek name here applied to it, derived from *κατακαίω*, "exuro." One species only has hitherto been discovered as belonging to it; which, from the peculiar habit under which it occurs, may be distinguished by the name of

1. *Catacausis Ebriosa*. Inebriate Catacausis.

SPECIES I.

CATACAUSIS EBRIOSA.

INEBRIATE CATACAUSIS.

THE LIVING BODY INFLAMMABLE IN CONSEQUENCE OF A LONG AND IMMODERATE USE OF SPIRITUOUS LIQUORS: THE COMBUSTION EASILY EXCITED, OR SPONTANEOUS.

In this wonderful malady, the art of medicine can be rarely of any avail; since the mischief is, in almost all instances, only to be discovered after a cessation of life, and the destruction of some part of the body by an actual flame or fire, in many instances spontaneously issuing from its surface. There may be some difficulty in giving credit to so marvellous a diathesis; yet examples of its existence, and of its leading to a migratory and fatal combustion, are so numerous and so well authenticated, and press upon us from so many different countries and eras, that it would be absurd to with-

hold our assent. In almost every instance, the combustion seems to have taken place in females, advanced in life, and immoderately addicted to spirituous liquors.—(*Bartholin, Act. Hafn.*, i., obs. 118.) In some cases, the heat that has set them on fire appears to have originated in themselves; in others, to have been communicated by a stove, or a candle, or a stroke of lightning (*Fouquet, Journ. de Méd.*, tom. lxxiii.); but in no case has the fire or flame hereby excited in the body been so powerful as essentially to injure the most combustible substances immediately adjoining it, as linen or woollen furniture. The body, in several instances, has been found actually burning, sometimes with an open flame flickering over it; and sometimes with a smothered heat or fire, without any open flame whatever: while the application of water has occasionally seemed rather to quicken than to check the igneous progress.

This is the more extraordinary, as the human body, in every other state we are acquainted with, whether of health or disease, is scarcely at all combustible of itself, and cannot be reduced to ashes without the assistance of a very large pile of fagots or other fuel, as universal experience in this very ancient mode of sepulture, and the history of martyrs who have been condemned to the flames, abundantly testify.

The event has usually taken place at night, when the sufferer has been alone; and has commonly been discovered by the fetid, penetrating scent of sooty films, which have spread to a considerable distance; the unhappy subject has in every instance been found dead, or more or less completely burnt up; the burnt parts being reduced to an oily, crumbly, sooty, and extremely offensive matter. "I confess," says M. Pierre-Aime-Lair (*Journ. de Physique*, an. viii.), "that these accounts at first appeared to me to be worthy of very little credit; but they are presented to the public as true, by men whose veracity is unquestionable. Bianchini, Maffei, Rollin, Le Cat, Vicq d'Azyr, and other men distinguished by their learning, have offered certain testimony of the facts. Besides, it is not more surprising to meet with such incineration, than a discharge of saccharine urine, or an appearance of the bones softened to a state of jelly."

Those who are desirous of pursuing this curious subject farther, and of entertaining themselves with the very extraordinary histories connected with it, as also of examining the various hypotheses by which they have been accounted for, may consult the Philosophical Transactions (see especially vols. xliii., xlv.), which contain numerous examples; as also a variety of foreign journals of established reputation, referred to and cited in the running commentary to the author's volume of Nosology.—(*Ploucquet, Littérat. Méd.*; *Dupont, de Corporis Hum. Incendii Spontaneis.*) We have not space to enter into these separate cases, though many of them are highly interesting; but in a general course of medical study, the phenomenon ought not to be passed by: it forms one of

VOL. II.—H

the most curious links in the long chain of morbid affections, and equally demands our attention as pathologists and physiologists.*

GENUS X.

PORPHYRA.

SCURVY.

LIVID SPOTS ON THE SKIN FROM EXTRAVASATED BLOOD: LANGUOR, AND LOSS OF MUSCULAR STRENGTH: PAINS IN THE LIMBS.

PORPHYRA is in Greek what purpura is in Latin, literally, "the purple or livid disease." The latter has been very generally made use of; but the former is here preferred on two accounts. First, that of technological simplicity,—the names of the genera under the present system being uniformly of Greek origin. And secondly, because the Latin purpura has been used in senses so numerous, so vague and unconnected, that at this moment it conveys no definite idea whatever. "The term purpura," observes Dr. Bateman, most correctly, "has been employed by different writers in so many acceptations, that some ambiguity would perhaps have been avoided by discarding it altogether; for some authors have used it as an appellation for measles, others for scarlet fever, for miliaria, strophulus, lichen, nettle-rash, and the petechiæ of malignant fevers; while formerly it was applied to petechial spots only by Riverius, Diemerbroeck, Sauvages, Casson, and some others."—(*Synopsis of Diseases*, p. 102.)

The usual synonyme for purpura is *scorbutus*; but to this there are still stronger objections. For, as a term, it is neither Greek nor Latin, nor any language whatever; but an intolerable barbarism, derived, as is commonly supposed, from the German compound *schar-bocke*, literally "aggregate-pox," "cluster-pox;" but more likely from *scharf-pocke*, "violent," or "vehement-pox;" or *schorf-pocke*, "scurf," or "scurvy-pox," to which the inventor has endeavoured to give a sort of Latin termination. Independently of which, *scorbutus*, as employed at present, only indicates a particular species of scurvy; and could not, therefore, without imprecision, be used in a generic signification.

The sense here expressed by porphyra, runs, as nearly as possible, parallel with the range assigned by Dr. Willan to purpura. "With Riverius and some other authors," says he, "I propose to express by the term *purpura* an efflorescence consisting of some distinct pur-

* Cases of catacausis ebriosa are recorded in several American periodicals. A paper on the subject may be found in the *Am. Med. Recorder*, vol. v. The author of it, Dr. J. K. Mitchell of Philadelphia, maintains "that combustible gases are generated in the systems of drunkards by the decomposition of alcoholic potions; that these gases, and even the identical spirituous liquors, are distributed to every part of the system, and that these gases inflame spontaneously, just like gases out of the body, without the aid of fire."—See also the *Elements of Med. Jurisprudence*, by Prof. J. R. Beck and Trotter on Drunkenness,—D.

ple specks and patches, attended with general debility, but not always with fever." And again: "Cases of the purpura seem to have been studiously multiplied in periodical publications, and in medical or surgical miscellanies. I consider it under all the forms described as pertaining to the scurvy, though it is *not always* attended with sponginess of the gums, and a discharge of blood from them, according to the definition of scorbutus in nosology."—(*On Cutaneous Diseases*, Ord. III., p. 453.)

Porphyra, in its present signification, is intended to include every description of petechial eruption and spontaneous ecchymosis, not dependant on fever as their cause, in which case these affections are only symptomatic.

The genus, thus explained, will associate under its banners the three following species:—

- | | |
|----------------------|-------------------|
| 1. Porphyra Simplex. | Petechial Scurvy. |
| 2. ——— Hæmorrhagica. | Land Scurvy. |
| 3. ——— Nautica. | Sea Scurvy. |

SPECIES I.

PORPHYRA SIMPLEX.

PETECHIAL SCURVY.

SPOTS NUMEROUS, BUT SMALL AND FLEABITE-SHAPED: CHIEFLY IN THE BREAST, ARMS, AND LEGS: PALENESS OF VISAGE.

PULICOSE or petechial spots were at one time supposed to be, in every instance, the result of debilitating and putrid fevers. Riverius is perhaps the earliest author who distinguishes between simple petechiæ and petechial fevers. Vascular debility or relaxation is, however, the predisposing cause in both cases.—(*Plumb, Practical Treatise on the Diseases of the Skin*, p. 100, 8vo., 1824.) They necessarily, indeed, accompany each other, and, wherever they exist in any considerable degree, they lay a foundation for those minute extravasations which constitute the present species; and which may take place either from occasional ruptures of the weakened coats of the minute subcutaneous bloodvessels, in consequence of their being incapable of resisting the impetus of the blood that flows through them; or from the mouths of many of them, which should give forth only the finer and limpid particles of the blood, yielding and allowing an exit to the red globules.

Both these may follow atonic fevers; but the usual remote causes, in the species before us, are severe labour with innutritious or spare diet, and especially with impure air; an impoverished state of the system from a sudden and profuse loss of blood; a sedentary and inactive life, or some chronic and exhausting disease, by which the general strength has been broken down. To these Riverius adds suppression of the catamenia, and a certain mild ebullieny of the blood in boyhood—*levem quandam sanguinis ebullitionem*—a phrase, apparently importing an excess of sanguineous temperament; from both which, he tells us, he has frequently seen the disorder originate. And he is confirmed in the last by a case hinted at by Dr. Perceval in his manuscript comment on the author's *Nosology*,

in which he observes, under the present species, that "in a young lady of a full habit and florid complexion, if the skin of the face or neck were touched, even slightly, blood oozed from the pores."

The disease seems also to be produced at times by some unknown cause; of which Cullen has given a striking instance in his *Materia Medica*. "The patient," says he, "was a woman who had lived very constantly upon vegetable aliment, and had not been exposed, so far as could be judged, to any febrile or putrid contagion; and yet, without a feeling of any other disorder, was affected with numerous petechiæ over the whole surface of her body. After these had continued for some days, without any symptoms of fever, she was affected with swelled and bleeding gums, with fetid breath, and much thirst; and, in the course of a week or two more, almost every symptom of a putrid fever came on, and in a few days proved fatal."

It is possible in this case, that the brain may have lost its energy, and the blood become impoverished by too low a diet, though the history is not given with sufficient fulness to speak with much decision upon this point. The fever was evidently produced by the irritability of weakness, and necessarily ran into a typhous type from the same cause.

The disease, as it commonly shows itself, appears under two forms, which may thus be described as varieties:—

- | | |
|--------------------|-----------------------------|
| α Pulicosa. | Exhibiting from the first a |
| Simple pulicose | pulicose or fleabite ap- |
| scurvy. | pearance. |
| β Urticaria. | The fleabite spots preceded |
| Nettle-wheal | by reddish, rounded, and |
| scurvy. | nettle-sting wheals, but |
| | without the nettle-sting |
| | itching; fugacious and |
| | migratory. |

THE FIRST VARIETY is not only produced by debility, but attended with languor and pains in the limbs, and chiefly affects women and children, in consequence of their greater laxity of fibre.

THE SECOND VARIETY may possibly be accompanied with more constitutional affection; for there is usually a loss of appetite, and an œdematous swelling of the hands and ankles, while the spots are brighter at night and darker in the day, evidently proving great irritability in the capillaries, and especially towards the period of the natural evening paroxysm of fever. This variety often continues for five or six weeks.

Better diet, freedom from hard labour, pure air, sea-bathing, the mineral acids, and other tonic medicines, afford a pretty certain process of cure.

SPECIES II.

PORPHYRA HÆMORRHAGICA.

LAND SCURVY.

SPOTS CIRCULAR, OF DIFFERENT SIZES; OFTEN IN STRIPES OR PATCHES, IRREGULARLY SCATTERED OVER THE THIGHS, ARMS, AND TRUNK;

OCCASIONAL HEMORRHAGE FROM THE MOUTH, NOSTRILS, OR VISCERA: GREAT DEBILITY AND DEPRESSION OF SPIRITS.

THIS species, the morbus maculosus Werlhofii of the German writers (*Gesch. eines glücklich geheilten Morbus Maculosus Werlhofii, von Dr. Marquett, &c., Magdeburg*), is sometimes marked by febrile paroxysms, with variable intervals, but usually occurring in the evening. It has no regular or stated termination. Dr. Willan has found it run on, in different cases, from fourteen days to a twelvemonth and upwards. It is met with at every period of life, but chiefly affects persons of a weak and delicate habit, often children, principally women.

The precursive symptoms are lassitude, faintness, and pains in the limbs, so that business, or even company, is found fatiguing. After this, there are often shiverings, nausea, and vomiting. The purple eruption, for the most part, appears first on the legs, and afterward, at irregular periods, on the thighs, arms, and trunk of the body; the hands and face generally remaining free. The spots, however, are frequent on the interior of the mouth, and particularly the tonsils, gums, and lips, where they are sometimes raised or papulated. It is here the first hemorrhage commonly issues, though, as the disease advances, blood flows also from the nostrils, lungs, stomach, intestines, and uterus; all which organs, together with the heart, are sometimes found studded with spots on their surface, on examination after death.—(*Edin. Med. and Surg. Journ.*, July, 1822.) The hemorrhage is often profuse, and cannot easily be restrained, and is accompanied with anasarca swellings. It sometimes precedes the purple spots, but more commonly takes place a few days afterward. It is this rapid erosion or ulceration of the bloodvessels, and consequent discharge of blood, often accompanied with diarrhoea or dysentery, where the intestines associate in the complaint, by which land scurvy is chiefly distinguished from sea scurvy, and acquires the distinctive name of *hemorrhagic*; since, though these symptoms may also occur in the latter, they do so rarely, except in the last stage of the complaint.*

* There is no sponginess of the gums, as in common scurvy, nor are the limbs affected in the manner often exhibited in the latter disease. Rayer, in his *Traité des Maladies de la Peau*, tom. ii., has described purpura under the name of *hémacélinose* (derived from *αἷμα*, blood, and *κέλες*, a spot, and *νόσος*, disease), and arranged it with cutaneous and subcutaneous diseases. But, as Dr. Watson has justly observed, purpura cannot be regarded merely as a cutaneous disease; for the effusion of blood is not confined to the skin or subcutaneous textures, but may happen likewise on internal surfaces, and in the parenchymatous texture of the viscera.—(*See Med. Gaz.*, vols. vii. and x.) Frequently, as Dr. Elliotson remarks, there is a bleeding from the mucous surfaces, bleeding from the mouth, from the stomach, and from the intestines. There is no inflammation nor tenderness of the particular parts. The white of the eye and inside of the mouth are often spotted. The disease occurs under the most op-

[In the dissection of a highly interesting case recorded by Dr. Fairbairn, the sides of the neck and upper parts of the chest were found swollen and livid, with a feeling of crepitus and considerable œdema over the trunk. In some places the cellular and muscular textures of the neck and chest were injected with blood, and emphysematous. The thorax contained about a pound of a fluid resembling blood, of a very dark colour and viscid consistence. The lungs, bronchial tubes, and trachea, contained a large quantity of bloody, serous fluid, and, beneath the internal coat of the latter, there was a slight effusion of dark venous blood. Between the folds of the anterior mediastinum and of the pericardium, a considerable quantity of very dark blood was effused in the cellular texture. Under the lining of the cavities of the heart, and under that of the aorta, there was a large bloody effusion. The floating abdominal viscera presented a dark leaden colour, and on the intestines were a few petechiæ. The inner coat of the stomach, towards the pylorus, was also thickly studded with them. The liver, spleen, and right kidney were softer than natural.—(*See Edin. Med. Chir. Trans.*, vol. ii., p. 161.)]

The most usual remote causes of the present, as of the preceding species, are poor diet, impure air, anxiety of mind, and a sedentary mode of life: and if women under these circumstances and affected with this complaint be wet-nurses, their infants participate in the disease from the milk not being sufficiently nutritious. It is also produced by habitual gluttony, and particularly by an habitual and immoderate use of spirits, which have the strongest tendency to render torpid the collatitious organs of digestion, and especially the liver, whence congestions and other obstructions, and whence, too, the larger and more dangerous hemorrhages that occur in this species.

[The causes of purpura, and its pathology, are not well ascertained. In the very remarkable example of the disease recorded by Dr. Fairbairn, the blood drawn presented a striking peculiarity in colour and consistence: it was florid like arterial blood, slow in coagulating, and the coagulum soft and tremulous, without separation of serum. What was drawn, however, at the third bleeding, coagulated more firmly, and showed a small portion of serum.*]

posite circumstances; occasionally with great debility, weakness of the pulse, exhaustion, and sometimes with an inflammatory state of the system, the blood being buffy and cupped, and the patient greatly relieved by venesection. In some other examples of the disease, such treatment would be death. In severe cases, the patient looks as if he were in a state of anæmia. On the other hand, Dr. Elliotson informs us that he has seen children with many hundreds of purpurul spots upon them, running about perfectly well. Frequently no cause whatever can be assigned for the disease, and the pathology is a perfect mystery.—*See Dr. Elliotson's Lect. at Lond. Univ.*, as published in *Med. Gaz.*, vol. xi., p. 342.—Ed.

* *See Edin. Med. Chir. Trans.*, vol. ii., p. 163. Some of the best arguments in favour of the doctrine that purpura is dependant upon changes in

As these causes are widely different in their mode of action, though they concur in producing the same effects, the treatment must vary in like manner.

Where the source of the disease is poverty, with its miserable train of attendants, poor diet, impure air, hard labour, grief of mind, the mode of cure recommended for the preceding species will be found equally serviceable: but the tonic and stimulant plans may be carried to a higher range: the bark should be freely administered, wine be liberally allowed, and lemons, or citric acid in any other form, be used to an extent of three or four ounces of lemon-juice daily; which, however, is the smallest quantity from which any essential benefit may be expected. Of all the antiscorbutics, this is by far the most effectual, and by some writers is regarded as a specific. [In Dr. Fairbairn's case, fifteen drops of diluted sulphuric acid were frequently given in cold water.] And, as the weak action of the vessels is extreme, the terebinthinate stimulants, as camphire and the rectified oil of turpentine, are often peculiarly advantageous. The last has been strongly and judiciously recommended by Dr. Whitlock Nichol; and other practitioners have fully confirmed his views.*

The worst symptom is the tendency to hemorrhage, which is sometimes profuse, and restrained with great difficulty, and has been known to prove fatal. Occasionally, however, an accidental hemorrhage has had a contrary effect, and carried the complaint away; and hence Dr. Parry of Bath, and Dr. E. Gairdner of Edinburgh (*Edin. Med.-Chir. Trans.*, vol. i., p. 671, &c.), have found venesection serviceable. In some of these cases we may reasonably suspect visceral congestion, and especially that of the liver, to lie at the foundation; and dissections have proved this to be no uncommon cause of the disorder.—(*Plumbe on Diseases of the Skin*, p. 108, 8vo., 1824.) The symptoms of visceral obstruction, indeed, are often sufficiently clear; and where these occur antecedently to the tonic plan, we must freely and repeatedly evacuate the bowels, and may advantageously have recourse to the lancet:† and the more so, as this form of the disease is sometimes accompanied with inflammatory action, and is chiefly what is referred to by Dr. Stoker under the name of dynamic purpura.—(*Path. Obs.*, &c., p. 110, Dublin, 1823, 8vo.)

the composition and properties of the blood, may be found in Dr. Watson's *Lecture on Purpura*.—See *Med. Gaz.*, vol. x., p. 498.—Ed.

* See Dr. Magee's case of purpura hæmorrhagica successfully treated with spirit of turpentine; *Edin. Med. and Surg. Journ.*, No. lxxxv., p. 307. He prescribes for an adult half an ounce, with an equal quantity of oleum ricini, and a little peppermint or cinnamon water. Rayet applies to the petechiæ and ecchymoses on the surface of the body, linen wetted in spirituous lotions, a solution of the chloride of soda, or vinegar and water.—See *Traité des Mal. de la Peau*, tom. ii.—Ed.

† One of the most severe and successful cases that Dr. Elliotson ever saw treated, was under Dr. Roots, in St. Thomas's Hospital. There were petechiæ, vibices, and ecchymoses, in every part

[The case attended by Dr. Fairbairn, led him to consider it as having a striking resemblance to active hemorrhage; and hence, he is an advocate for the depleting system.]

In some cases, the disorder appears to be relieved by metastasis. Willan has related a singular case, which it is difficult to account for otherwise. A lady, aged thirty-six, of the sanguine temperament, after experiencing for several days a painful inflation of the stomach, was seized, on the 17th of June, 1792, with violent vomiting, which continued almost incessantly through the 18th and 19th, and was accompanied with excruciating pains in the bowels. The fluid discharged was clear, strongly tinged with green bile, and amounted to three or four quarts a day. The vomiting abated about the 20th, and she had loose stools of a green colour, intermixed with black coagulated blood. This kind of discharge continued till the 25th, producing great languor and faintness, thirst and restlessness, with a cool skin and remarkably slow pulse. On the evening of the 25th her extremities became suddenly cold, the pulse scarcely discernible, a cold sweat trickled from every part of the body, her voice was indistinct, and her breathing laborious. From this alarming state she recovered in the course of the night; and, on the following day, a rash appeared over the whole body in small and circular patches, confluent on the neck, shoulders, and nates, but in other places distinct. The eruption diminished in two or three days, and assumed a livid colour; and the discharge of blood ceased from this time. She improved generally, but for two months suffered greatly from languor and debility: the extremities were for a long time anasarctous, and two of the spots became gangrenous. In the *Trans. of the Medico-Chirurgical Society of Edinburgh*, vol. i., p. 680, is a brief history of a case that proved fatal in less than forty-eight hours. The patient was a strumous child; on dissection, the pericranium and dura mater were found covered with petechial spots. Blood was also effused on the brain; and the serous membranes in the chest and abdomen were universally studded, like the dura mater, with dark livid spots.*

The account now given of the causes of this

of the body; great congestion of the liver, so that the right hypochondrium was distended; and blood was poured forth from different cavities. The patient was bled, and took oil of turpentine, and he got rapidly well. In another case, under Dr. Elliotson himself, treated in the same way, the patient became apoplectic, and a clot of blood was found on the brain. In proof that the disease may be inflammatory, it is alleged that the blood is sometimes buffy and cupped. In such cases, Dr. Elliotson finds that purging the patient with colchicum is a good practice. Where the pulse is strong, he approves of bleeding; but would in each case adapt the mode of treatment to the particular circumstances of it; and he admits the frequent necessity for bark, wine, and good nourishment.—See *Med. Gaz.*, vol. xi., p. 343.—Ed.

* Similar pathological appearances are recorded by Rayet, *Traité des Mal. de la Peau*, tom. ii., obs. 174, &c.—Ed.

species, corresponds to such as we usually meet with in the present day. But if we look back into the history of this disease as far as the seventeenth century, and especially to the state of this metropolis, we shall find hemorrhagic or land scurvy making a much nearer approach to sea scurvy than in our own time; not only in its symptoms, but from the peculiar causes that seem to have given rise to it, and which are now, for the most part, removed. The population within the walls of the old city was at that period far greater than at present, since the streets have been very extensively widened, and many of them entirely pulled down; and fashion, which does not always operate so usefully, has led all who are capable of following its steps into the more salubrious air of the neighbouring villages. Independently of this, the supply of fresh vegetable food for man, and of winter-fodder for cattle, was, at the period before us, so scanty as to render it necessary to salt a great quantity of the cattle that was killed in the summer season for winter use. To which we have to add a far greater degree of dampness and uncleanness, not only in the public streets, but also in private houses.

All these are also causes of sea scurvy; and we find from the description of Willis and others, that they produced conjointly very similar effects; and that the mortality hence ensuing was very great. The monthly deaths, according to the bills of mortality, occasioned by what is there called scurvy, were seldom less than fifty, and frequently as high as ninety. In the period of the plague, they are only set down at a hundred and five from this last cause for the year. It was not, indeed, till the beginning of the sixteenth century, that any great progress was made in the art of kitchen-gardening in our own country. At this last period, so low was the knowledge of this art, that Queen Catharine of Aragon could not procure a salad till a gardener was sent for from the Netherlands to raise it: nor were the most common articles of the kitchen-garden, such as cabbages, cultivated till this reign.—(*Anderson's History of Commerce*; *Sir G. Blane's article, Med.-Chir. Trans.*, vol. iv., p. 96.) And such was the prejudice at one time entertained against pitcoal, from its being supposed to load the atmosphere with unhealthy fumes, but which is now become one of our most powerful ventilators, and consequently one of our most active agents in promoting the general health of the city, that a law was formerly in existence which made it a capital offence to burn it within the city walls; so that it was only allowed to be used in the forges of the environs. Sir Gilbert Blane informs us that the late Mr. Astle, keeper of the records in the Tower, told him that he had there discovered a document importing that, under the operation of this law, a person had been tried, convicted, and executed for this offence in the reign of Edward the First. We learn also from Davenant (page 351, ed. 1673), that heaps of the most noisome filth were suffered to accumulate in consequence of the imperfection of the public sewers; and that particular places were marked

out and assigned for such accumulations, which were called lay-stalls; and hence the name of Lay-stall-street, which exists in one or two parts of the metropolis even in the present day.

The same happy causes, therefore, which have delivered us so generally from dysentery, remittent fevers, and even the plague itself, have freed us also from land scurvy. And it has operated over all the other large cities of England as well as over the metropolis; and over the open country as well as over the towns. Even the remote districts of Somersetshire, not more than a century ago, formed a striking theatre for the exhibition of this tremendous scourge, as we learn from Dr. Musgrave's work (*De Arth. Sympt.*), published in the year 1703. "Agri Somersettenses, uliginosi magnâ parte et depressi, aërem crassum et humidum trahentes, incolæ, maculis subnigris, ulceribus malignis, crurum dolore, respiratione difficili, lassitudine spontaneâ, nervorum debilitate, hydrope, gangrænâ, et istiusmodi aliis scorbuti exquisiti signis CREBERRIME divexantur."

The picture is strongly and fearfully sketched, and precisely corresponds with the definition just offered. How then comes the country, as well as the town, to be so wonderfully and beneficially changed in our own day! "The same spirit of improvement," says an admirable writer (*Dr. Heberden, Med. Transact.*, vol. iv., art. vii.), from whom I have often had occasion to quote, and whose words I would always give rather than my own, "which has constructed our sewers, and widened our streets, and removed the nuisances with which they abounded, and dispersed the inhabitants over a larger surface, and taught them to love airy apartments, and frequent changes of linen, has spread itself likewise into the country; where it has drained the marshes, cultivated the wastes, enclosed the commons, enlarged the farmhouses, and established cottages. Few, perhaps, even among physicians, are aware of the extensive influence of these measures. Few have adverted, with the attention it deserves, to the prodigious mortality occasioned formerly by annual returns of epidemical fevers, of bowel complaints, and other consequences of poor and sordid living, to which we are now entire strangers."

In consequence of this extraordinary improvement in the best branch of physical philosophy, the same attentive pathologist tells us, that "for ten years, during which time he was one of the physicians to St. George's Hospital, the cases of genuine scurvy that were brought into this establishment, and fell under his care, did not amount to more than four, not one of which was severe. In St. Bartholomew's Hospital, however, about the year 1795, owing to the very great severity of the preceding winter, various poor patients were received with all the characters of true porphyry; which, in one man, were carried to such a height, that he died in a most offensive state the day after he was admitted."

We have lately, however, and to the astonishment of every one, witnessed a most severe and even fatal renewal of this disease, in the Penitentiary prison for convicts, established on the

side of the Thames at Milbank : and this to such an extent, that at one time there were not fewer than about four hundred and fifty on the sick-list, out of a prison population of about eight hundred and fifty (*Report of a Select Comm. of the House of Commons, 1823, p. 242*), chiefly labouring under dysentery or diarrhoea, from the effects of the disease on the stomach and intestines, which, on post-obit examinations, were generally found to be pulicose or ulcerated in various parts; the complaint being at length apparently propagated by contagion.

The cause of this disease has hitherto been involved in much doubt. The prison was throughout ascertained to be cleanly, and, for the most part, well warmed, the cells lofty and unobjectionable, and the courts airy and paved with flagstone. The original soil was swampy, but it is generally believed at present to be free from damp, in consequence of the enormous expense of draining and other means of exsiccation that have been bestowed upon it: and the surrounding neighbourhood is undoubtedly healthy. It was at first mainly attributed to a reduced scale of diet, and particularly of animal food, which had been suddenly laid down for the prison; but a return to a richer scale produced no advantage; and was accompanied with an extension rather than a diminution of the diarrhoea or dysenteric form of the disease. So that at the end of six months, after every remedial plan which the physicians to the establishment could devise in succession, that of mercury being the chief, at first given in small and alternate doses, and afterward more freely, and for the express purpose of producing salivation, the whole prison population, as well male as female, was removed from the Penitentiary, and transferred to the hulks at Woolwich.

The real cause of this mischief has hitherto puzzled the ablest and most acute physiologists, and is supposed to bid defiance to all conjecture.—(*An Account of the Disease at the General Penitentiary, by P. M. Latham, M.D., &c., p. 217, 8vo. 1825.*) Yet I think it is by no means impossible to follow it up, and drag it from its obscurity.

In a population so large as that we are now considering, it is not enough that the courts should be airy, and the air not manifestly loaded with moisture; but it is equally necessary that such air should be free from confinement; that it should be in a constant state of perfusion, and refreshed and purified by renewal: for without this, large as the courts are, the air they contain must equally be drained of its vivifying power, and tainted with the azotic vapour that every individual is perpetually pouring forth from his skin and his lungs: and consequently must tend in a greater or less degree to a generation of the disease before us, or rather to all those morbid effects which the Milbank Penitentiary has so strikingly unfolded.

Now it appears to me almost impossible to take a survey of this prison, without coming to an admission that it is, with respect to ventilation, in the very condition just described. The inhabitants of the neighbourhood are healthy,

because, notwithstanding the lowness and original swampiness of the ground-soil, and its exposure to exhalations, the fanning breezes which are daily playing around them carry off the rising moisture, and supply them with a perpetual current of pure air. But the height of the terminal and intersecting walls of the prison, with only a few small openings for doors, and no opposite outlets, effectually prevent this within its limits. Air will here, indeed, find its way, as it will everywhere else, unless opposed by an hermetical seal; but as soon as it enters the courts of the Penitentiary, it is almost as much imprisoned as the convicts themselves: it is in a considerable degree bottled up; and the only change it can undergo is that of parting with its vivifying principle, and receiving a mischievous principle in return. Were it indeed entirely bottled up in the manner here spoken of, the result would be obvious instantaneously: but this is not the case, for a part of it must necessarily fly off in consequence of its higher temperature and greater specific levity, and its place be supplied with air from without. But the supply does not seem to be in proportion to the demand; the balance is not duly preserved, and the expired and tainted air is not sufficiently carried off. It is very possible, also, that some degree of humidity, though not manifest to the senses, is perpetually ascending from the low and once swampy soil beneath, which should be swept away by the winnow of a stirring breeze. Where a large population is immured in a boundary of any extent, if the supply of pure air be in the least degree below the supply of foul air, the health of such population must be encroached upon: and the less the difference, the more insidious the effect, because the more invisible. It is, however, an effect that must go on: its influence must at length become obvious, and challenge attention; and the result, as already observed, must be, if I mistake not, a combination of symptoms more or less approaching to those which have of late been exhibited at the Penitentiary before us.

If the real cause be thus correctly traced out,* the remedy will not be difficult in the hands of an able pathologist, and a skilful architect.†

* The difficulty of acceding to the author's views arises from the fact that other prisons, quite as much crowded as the Penitentiary, less dry, and not so well ventilated, have not been visited by the disease in question.—ED.

† This form of porphyria sometimes attends intemperance in ardent spirits, as well as the circumstances connected with indigence, bad food, vitiated air, &c. In many instances the epidemic termed spotted fever, which prevailed so extensively in the United States a few years since, exhibited in some individuals the characteristics of porphyria, and, as our author admits, cases of the complaint occasionally appear in jails, hospitals, &c. Mr. Eddy, in his account of the State Prison of New-York, has mentioned many instances of it, arising from errors in diet and confinement in impure air. Porphyria hæmorrhagica, though often marked by great debility, is sometimes relieved by venesection and purgatives, followed by tonics and stimulants.—D.

SPECIES III.
PORPHYRA NAUTICA.
SEA SCURVY.

SPOTS OF DIFFERENT HUES INTERMIXED WITH LIVID, PRINCIPALLY AT THE ROOTS OF THE HAIR; TEETH LOOSE; GUMS SPONGY AND BLEEDING; BREATH FETID; DEBILITY UNIVERSAL AND EXTREME.

THIS species is denominated SEA SCURVY, not from its being exclusively limited to mariners and extensive fleets, but from its being most common to persons thus occupied, and raging in such situations with the most fatal havoc. For the peculiar, as well as the general causes which produce it at sea, may also operate on shore, and have at times operated with merciless ravage in besieged garrisons, and among armies reduced to short provisions, or of unwholesome kinds, and worn down by fatigue, anxiety, and exposure to a damp atmosphere. Such seems to have been the condition of the Roman army under the command of Germanicus, as related by Pliny; whose account of the disease that preyed upon it, though vague and unsatisfactory, coincides with the general appearance of sea scurvy. We have similar descriptions in several of the expeditions that took part in the Holy Wars, and particularly that of St. Louis, as related by Joinville. We may hence conclude that sea scurvy is not a disease of recent times alone (*Richter, Pr. Disquisitio in Hippocraticas Scorbuti antiquitates, &c.*); though it does not appear to have attracted any very general attention till the melancholy result of the famous voyage of Vasco de Gama in 1497. The spirit of maritime discovery was at this time in full vigour and activity: the Portuguese, the Spaniards, the Dutch, and the English, vied with each other in their efforts to explore remote and unknown countries; the means of providing suitably for voyages of so great length were little understood; and hence the disease frequently made its appearance during the progress of the next half century, and raged with tremendous violence. It is well known, indeed, that so late as 1741, the fleet under Captain (afterward Lord) Anson, lost half its crew in the space of six months from the time it left England.

The diagnostics and progress of the disease are neatly and accurately concentrated by Dr. Parr. Its first appearance is evinced by a pale, bloated complexion, lassitude, and a disinclination to motion, with diminished energy in the muscular fibres: to which may be added, some degree of stiffness or induration, and an intumescence of the lower limbs. If the gums, even in this early stage, be examined, they will be found spongy and apt to bleed on being touched, while the teeth are loosened in their sockets. The skin is sometimes rough, but more generally smooth and shining, covered with bluish or livid spots, which do not rise above it; and these spots often coalesce in large blotches, particularly in the legs and thighs. About the same period, old ulcers often break out again, and the slightest mercurial preparation quickly produces

salivation. The ulcers discharge often a fetid sanies, or are covered with a coagulated crust, which is renewed whenever it is separated. The edges are livid, with irregular granulations, which sometimes run into a bloody fungus. During the whole of this period the appetite continues good, and though tensive pains arise, and are necessarily distressing, yet, on the whole, the patient feels little inconvenience.

The state of the bowels is very various. The stools are often frequent and offensive; but there is sometimes an obstinate costiveness. The urine is commonly high-coloured and fetid; the pulse feeble, but rarely quick. A weakness in the joints appears early, and increases with the disease; and a shrinking of the flexor muscles renders the limbs useless: producing the scorbutic paralysis of Dr. Lind. The calves of the legs fall away, with sometimes an irregular hardness, and at length become œdematous, while the bones themselves, no longer supplied with a sufficiency of calcareous earth, give way at the callus of fractures; and those which have been formerly broken and re-united, become again separate at the line of re-union.*

The last stage is truly distressing. Blood is frequently discharged from the intestines, bladder, and other organs. The slightest motion brings on faintness, and often immediate death. Catchings of the breath and syncope, sometimes slightly experienced, indeed, at an earlier period, are now frequent and dangerous; yet the sense of weakness is so much less than its real amount, that the patient often attempts exertion, and dies in the very effort: though, more frequently, he survives the attempt for a short time, and especially when animated by any powerful and pleasant motive, as the hope of getting on shore, or even of engaging in fight with an enemy.

The most obvious of the remote causes of sea scurvy is salt provisions; and, perhaps, the most obvious of its proximate causes is a putrescent state of the blood: and hence these are the causes that have been commonly assigned, from the time of Sir John Pringle to the present day.

That an excess of salt, and particularly of salted meat, is a powerful cause in the production of scurvy, is unquestionable; yet not more perhaps from its tendency to dissolve the fluids,—for the blood retains a buffy crust even to the last,—than from its rendering the salted meat less nutritious. But it is by no means the only

* Aitken, *Essays on several Important Subjects in Surgery, &c.*; Lord Anson's *Voyage, &c.* Scorbutic ulcers have the following character:—Instead of pus, they excrete a thin, fetid, sanious fluid, mixed with blood. Their edges are generally of a livid colour, and swollen; a coagulum is soon formed on their surface, which can with great difficulty be wiped away, or separated from the subjacent parts. These are soft, spongy, and putrid. When, however, the removal of the coagulum is effected, another shortly afterward forms again, followed by a soft bloody fungus of considerable size, termed by sailors bullock's liver. According to Lind, it is as difficult to repress almost as fungus hæmatodes, and, when destroyed by the cautery or the knife, is reproduced again in a few hours.—Ed.

cause. In the preceding varieties, we have already seen it produced on land as well as at sea, and in some cases where there was no employment of salt provisions. And even sea scurvy itself has occasionally been found to arise where the diet has by no means been saline; and in damp situations, whatever have been the diet, unless where peculiarly generous and stimulating; and we have one instance of its having occurred in a young woman who had subsisted almost wholly on tea.

In like manner, though the fluids of the body are loose and incoagulable, the muscular fibres are equally loose and incontractile; so that the latter, as justly observed by that excellent practical writer, Dr. James Lind (*Treatise on the Scurvy*, &c., p. 277), are as much affected as the former: and, if we attend to the course of the symptoms as they arise, we shall find that they are affected soonest; for the earliest signs of the disease are those of languor, debility, and dejection; though, upon the whole, the mental depression is less considerable than in land scurvy; and, as we have already observed, there is a sense of mental energy to the last, which is far more than commensurate with the actual strength of the body.

How far salt provisions alone might produce sea scurvy, is scarcely worth while to inquire; for there is no extensive history of the disease in which they have acted solitarily; having always been more or less united with a cold or damp atmosphere, great fatigue, or a want of proper and invigorating exercise, want of ventilation, neglect of cleanliness, and very generally short rations, or an unwholesome diet of other aliments besides salt meat.*

Now these are causes which must have a direct influence on the fibrous structure, and consequently on the whole organization of the body, before the fluids can become affected; and it is easy to trace the changes which occur in them subsequently to, and through the medium of this influence.

Under the circumstances we are now contemplating, the digestive organs suffer first; they become weakened in their power, and for the reasons already stated when treating of MARASMUS, the weakness will extend through the whole range of the digestive chain, and influence all the organs of assimilation; while the lungs, the brain, the heart, and the skin, unite in the general debility. Hence none of the secretions will be sufficiently elaborated, or, perhaps, in sufficient quantity; there will be a less supply of sensorial energy, and a less vigorous action of the vascular system: a smaller formation of gluten, and elimination of carbon from the lungs. And hence, as a necessary consequence, the looser texture and deeper hue of the blood.

On this account Girtanner (*In Blumenbach, Bibl.*, band iii., p. 527) and other pathologists, who refer sea scurvy exclusively to a looseness of the solidum vivum, have more to advance in

their behalf than those who refer it exclusively to a looseness of the fluids. But both are affected, and affected equally, though the former takes the lead. Sea scurvy is therefore a disease, whose proximate cause is a putrescent, though not a putrid state of the animal solids and fluids, produced by an assemblage of antecedents co-operating to a common effect.*

It is assuredly, however, not necessary that all the causes we have adverted to should operate at the same time. But it is of the utmost importance, both in preventing the appearance of the disease, and effecting its cure where it is present, to have the eye cautiously directed to every one of them, and to destroy its agency as far as we are able. And it is owing to the unremitting attention which is paid to these points in the navy of our own country, that sea scurvy has long been rarely heard of in English fleets or English merchant ships; and that the globe is perpetually sailed over, and the highest as well as the hottest latitudes coasted and cruised in, without the generation of this destructive plague. And thus it has been ever since the celebrated and extraordinary circumnavigation of Captain Cook in the *Resolution*; in which, by first laying down a code of regulations for the government of his crew, founded on the soundest judgment, and afterward persevering in them with an unremitting spirit, directed to all the subjects before us, he was enabled to fulfil his voyage of three years and eighteen days, with a company of a hundred and eighteen men, traversing all climates, from fifty-two degrees north to seventy-one south, with the loss of only one man by disease, and that man apparently labouring under a consumption before he left home.

The regulations and management adopted by Captain Cook, are contained in his paper communicated to the Royal Society.—(*Phil. Trans.*, vol. lvi., year 1776, p. 402.) It is a production of the highest merit, and was justly honoured with the Copley medal for the year. In conjunction with Sir John Pringle's additional remarks upon it,† it has laid the chief foundation for the present mode of treating this disease, and particularly of providing against its attack. The principles it unfolds should be canvassed by the nautical student in the communications themselves, in conjunction with the later works of Sir Gilbert Blane (*Treatise on the Diseases of Seamen*) and Dr. Trotter.—(*Medicina Nautica*.)

With the auxiliaries of cleanliness, proper ventilation, a dry atmosphere, and fresh provisions, the medical treatment of sea scurvy is

* That scurvy is a disease of the whole system is now universally believed. In post-mortem examinations, pathologists find extravasations of dark-coloured blood, not merely in the sub-cutaneous cellular membrane, but in several of the viscera, and also between the fibres of the muscles. Some interesting specimens of the latter fact may be seen in the Museum of the London University.—Ed.

† A Discourse upon some late Improvements of the Means for preserving the Health of Mariners, &c., 4to., London.

* An insufficient supply, or total want of fresh succulent vegetables, might here have been noticed among the exciting causes of scurvy in long voyages.—Ed.

sufficiently simple, and the disease is found to yield easily. The means more immediately effectual are the native vegetable acids, and above all that of lemons, upon which we shall speak more at large presently; all sorts of fermented liquors; the alkaline plants, as garlic, scurvy-grass, water-cress, garden-cress, brook-lime, which, notwithstanding their alkaliescence, contain a great quantity of acrescent matter, and by their acrid property promote the excretions of urine and perspiration; and the spruce-fir,* as well as other plants of the coniferous tribe that contribute to the same purpose.

The fruit of the *rubus Chamæmorus*, or cloud-berry, found on boggy mountains in our own as well as in more northern countries, is also a cheap and valuable antiscorbutic. In Sweden, from the recommendation of Linnæus principally, the berries are eaten very largely as a confection; the Laplanders, in whose gloomy region the plant grows in great abundance, preserve considerable quantities of the fruit in snow, and export them to Stockholm in casks.

The burdocks were formerly very much extolled in scorbutic and almost every other disease of the present order, and especially the *arctium Lappa*, clotbur, or great burdock, common to the wastes of our own country, which was supposed to possess all the powers of the China and sarsaparilla roots. The root, given in decoction, is certainly a diuretic and diaphoretic; but, as an antiscorbutic, it is of far inferior merit to the plants already mentioned.†

The infusion of malt, as recommended by Dr. Macbride, does not seem to have answered all the expectations entertained concerning it. Dr. Trotter never saw it do good; and Dr. John Clark affirms freely and candidly, that in various cases in which he tried it, with all the concomitants of pure air and good nutriment, it had no influence either in removing the disease or in checking its progress; in consequence of which he preferred Dr. Silvester's antiscorbutic drink, which is made by boiling three ounces of cream of tartar, four ounces of juniper-berries, two drachms of ginger in powder, and five pounds

* The essence of spruce, or rather spruce beer, is admitted by Sir Gilbert Blane to possess antiscorbutic virtues, as well as beer or porter; but the great remedy on which he insists is lemon-juice. The essence of spruce, a little diluted, produced surprising benefit in the West Indies. It acted as a purgative, and remained on the stomach when every thing else was rejected.—See Trotter's Med. Naut., vol. i., p. 349.—Ed.

† Sugar has sometimes proved useful in cases of scurvy. The following instance is recorded, and deserves notice:—

“A vessel came from the West Indies heavily laden with sugar. A calm that had not been foreseen, prolonged the passage till all their provisions were exhausted. The sugar was the only resource left to the crew, and, nourished by it, they at length arrived safely in port. Some sailors had died of scurvy during the voyage, and many were threatened with death from the same cruel malady. The scurvy ceased when its victims were from necessity reduced to the sugar diet, and the remedy was at the same time an agreeable aliment.”—D.

of coarse sugar, in six gallons of water. After boiling half an hour, the whole is poured into a tub and allowed to ferment. It may be drank as soon as the fermentation commences, from one to three pints daily.—(*Obs. on Diseases in Long Voyages*, &c., 8vo.)

Captain Cook, however, thought very highly of malt sweetwort, and esteemed it one of the most powerful antiscorbutics. The Russians, for want of sweetwort or table-beer, employ a brisk acidulous liquor called quas, formed by fermenting small loaves made of ground malt and rye meal. Dr. Mounsey tells us, that this is the common drink of both the fleets and armies of the Russian empire. Oatmeal is also occasionally used for the same purpose, in the form of an acidulated gelatinous food denominated *soins*; made by infusing the meal in water till a fermentation commences and the liquor grows sourish, which in a moderate temperature will take place in about eight-and-forty hours. The liquor is then poured off from the grounds, and boiled to the consistence of a jelly, which, sweetened with sugar and mixed with a little wine, yields an aliment not less palatable than medicinal.

Pure fresh water is also another material of great importance, not only in curing this disease, but in guarding against it: and of so much moment did Captain Cook esteem its purity, as well as its freshness, that he had the old stock poured away, though procured only a few days before, whenever he had an opportunity of obtaining a new supply. And at a time when it was universally conceived that the frozen water of the icebergs consisted of salt water, or was unwholesome, as formed of frozen snow, it was matter of most agreeable surprise to him to find that the melted ice of the sea, from whatever quarter derived, is not only sweet, but soft, and as wholesome as the purest spring or river water; thus affording him a supply he had no expectation of finding.

The best means of preserving water pure, is by keeping it in casks charred for the purpose on their inner surface; and the best means for restoring it to purity when it has become foul and offensive, is by mixing a little fresh powdered charcoal with every cask before it is tapped, and in drawing it off through a stone filtering-cistern, containing a bed of the same material.

As fermented liquors have been found serviceable, many of the gases have been tried in their simple form, and some of them have been thought serviceable; but their carriage, or the means of obtaining them extemporaneously, is highly inconvenient: and it was well observed by that excellent navigator La Pérouse, that seamen may be gorged with bottles of them without deriving a thousandth part of the benefit produced from a good slice of fresh meat, fruits, and herbs.

Of all the antiscorbutics, however, that have thus passed under our survey, the citric acid, or that of lemons, is the only one that can make an approach towards the character of a specific for sea scurvy; and how well entitled this

medicine is to the maintenance of such a claim, now that the mode of preserving it in a state of activity, first suggested by Dr. Lind, has been fully established, the following brief but triumphant narrative of Dr. Baird will sufficiently evince:—"The next time I saw this disease in a very spreading degree, so as to affect the whole fleet, at a period when the existence of the country depended upon that fleet keeping the sea, was in the year 1801, when my Lord St. Vincent took the command of the Channel fleet. A short time after we sailed, and in not more than a fortnight, the scurvy made its appearance, and spread very rapidly through the fleet. Fresh provisions were not then supplied to it as now, nor vegetables. Being aware that lemon-juice was then in store, and could be drawn for the fleet, I expressed to the commander-in-chief my great anxiety that a fresh supply should be had as fast as possible. The fleet was then blockading Brest: a cutter was despatched to communicate the state of the health of the fleet; a supply of lemon-juice came out, and we gave it freely to those labouring under the disease, and daily, mixed with water and sugar, to the whole of the crews of the ships, and continued its use during the time we were at sea, which was nearly seventeen weeks; during which time the fleet had not, as a fleet, a single fresh meal, nor any thing in the shape of an antiscorbutic, but lemon-juice. The disease under the use of this totally disappeared; we returned with twenty-four sail of the line into Torbay, out of which number there must have been ten or twelve three-deckers; and I think, estimating fairly, there could not, upon an average, have been less than seven hundred men in each. When we arrived, the surgeons of the fleet were desired to make a return of the number of patients fit for the hospital. They made a return of twenty-four. I was directed by the commander of the fleet to examine them, to see whether they were subjects for the hospital. I found eight of them were cases of hernia, or surgical cases, that could not be benefited by the hospital. I selected sixteen from them. Out of twenty-four sail of the line, there was not a single case of scurvy; and, what was extraordinary, to such a state of health was that fleet brought by the use of lemon-juice, that the *Glory* had only four men on her sick-list; so that out of fifteen or sixteen thousand men, there were only sixteen subjects for the hospital; and some of the ships had not lost a man at that time."—(*Report of the Committee of the House of Commons upon the Penitentiary at Milbank, 1823, p. 199.*)*

As the vessel of a tainted crew approaches

* This form of disease seldom prevails in the United States Navy, doubtless on account of the liberal supply of fresh vegetables, the use of citric acid, and the free employment of the chlorides of soda and lime. The temperance observed in dispensing stimuli to the seamen, is also attended with advantages; and the practice of commuting, when possible, for their daily allowance of ardent spirits, as recently recommended by the Secretary of the Navy, deserves imitation.—D.

land, nothing is more common, or apparently more reasonable, than for those that are most affected to be the most anxious to be put on shore at the moment. Yet, for reasons we have already urged, this should rarely be complied with; for the real debility is so much greater than the apparent, or, in other words, the energy of the mind is so much greater than that of the body, that they often sink under the labour of the removal, and sometimes die before they reach the asylum provided for them. In cases of extreme weakness, the external air alone, and especially when sharp or in a current, is sufficient from its pressure and stimulus to puff out the little flame that flickers in the vital lamp; a fact which, to adopt the words of Dr. Trotter, "has been long observed, and recently confirmed by five men dying in the boat belonging to the Prince of Wales ship-of-war, between the Downs and Deal hospital."

GENUS XI. EXANGIA.

ENLARGEMENT, BREACH, OR OTHER MORBID PERFORATION OF A LARGE BLOODVESSEL, WITHOUT EXTERNAL OPENING.

THE expediency of placing this genus in its present situation, among diseases dependant on a "morbid state of the blood or bloodvessels," would be obvious to every one, even though the maladies it embraces were in every instance local. This, however, is rarely the fact; for the first two species included under it result commonly from a peculiar diathesis; and the last is productive of severe, and often fatal constitutional disorder. These species are as follow:—

- | | |
|-----------------------|------------|
| 1. Exangia Aneurisma. | Aneurism. |
| 2. ——— Varix. | Varix. |
| 3. ——— Cyania. | Blue-skin. |

SPECIES I. EXANGIA ANEURISMA. ANEURISM.

PULSATING TUMOUR OF AN ARTERY.

THE disease of aneurism, which consists in a permanent dilatation or breach of the coats of an artery, may be produced by external violence, as a strain or puncture, or by arterial debility. The last is the more common cause, and it may be local or general: it may be limited to the part in which the aneurismal swelling occurs, or it may extend through the whole range of the arterial system, which is sometimes found to be universally though irregularly feeble, and consequently feebler in some parts than in others. It is this last condition of the arteries which constitutes what has been called the aneurismal diathesis; and, under its influence, aneurismal tumours not unfrequently occur in different arteries of the same individual simultaneously or in succession. De Haen gives a singular example of this in a boy of seventeen.—(*Rat. Med., iv., 2, § 7.*)

[Sir A. Cooper has seen seven aneurisms in one person: one in each ham; one in the bifurcation of the aorta; one at the origin of the arteria profunda; one in the middle of the thigh; and two between the popliteal and the femoral.—(*Lectures on Surgery*, vol. ii., p. 37, 8vo., 1825.) But Pelletan the enormous number of sixty-three, from the size of a filbert to that of a hen's egg.—(*Clinique Chir.*, tom. ii., p. 1.) It is an observation made by the former experienced surgeon, that when aneurisms occur opposite a joint, a partial disease of the artery often gives rise to them; but that, when they are seated in other parts of the body, there is usually a disease in the arteries, which produces a general disposition to their formation; in other words, there is an aneurismal diathesis. The ultimate success of operations, he says, will depend very much upon the disposition to the disease being partial or general.—(*Lect.*, vol. cit., p. 40.) With respect to the cause of aneurism, which our author ascribes to what he terms arterial debility, if we exclude those cases which arise from the wound or rupture of an artery, it is certain that the generality of instances are preceded either by a steatomatous thickening, with ulceration of the internal coats of the artery, or by calcareous deposition between the middle and internal coats, attended with loss of elasticity in the affected part of the vessel, and a disposition to crack or give way. The blood then comes in contact with the external elastic coat, which is raised into an aneurismal swelling. At length, more or less of this coat is removed by absorption, or bursts, and the blood then receives a covering from the arterial sheath. As the disease advances, it presses upon and causes the absorption of all the surrounding parts, and is more or less diffused and circumscribed, according as it may happen or not to be confined or bounded by an entire cyst, formed by the adhesive inflammation, the remains of the original sac, or any ligamentous expansion.—(*First Lines of Surgery*, p. 255, 5th edit.)]

Aneurism is ordinarily represented as appearing under only two forms: the true, or, as Mr. B. Bell more particularly denominates it, the encysted (*Syst. of Surg.*, vol. i., ch. iv., p. 196), and the false or diffused. To these it is necessary to add the varicose of Dr. Hunter, and the cardiognmus of the Greek writers; thus presenting us with the four following varieties:—

- | | |
|----------------|----------------------------|
| α Cysticum. | Encysted aneurism. |
| β Diffusum. | Diffuse aneurism. |
| γ Varicosum. | Varicose aneurism. |
| δ Cardiognmus. | Aneurism of the præcordia. |

The TRUE OR ENCYSTED variety, forming the aneurism by dilatation of M. Petit (*Mémoires de l'Acad. des Sciences*, 1736), is characterized by the tumour being circumscribed or having a defined outline; and is produced by a yielding or dilatation of the coats of an artery so as to form a sac, which constitutes the sphere of the arterial enlargement. Where it does not occur suddenly from external violence, it is commonly the

result of a diseased state of the arterial coats, by which the artery becomes changed in its general character, and especially thinner in its texture. This morbid condition sometimes extends to a considerable range, and the artery is in consequence dilated through its whole circumference, and, where the aorta has suffered, has been found to occupy its entire curvature, and even to extend beyond it. At times, indeed, and not unfrequently, as we have already observed, it is a constitutional affection, and various arteries fall a prey to its influence simultaneously or in succession. And hence Sir Astley Cooper has wisely cautioned his pupils never to operate upon an aneurism till they are satisfied that no others exist.—(*Lectures*, &c., ut supra, vol. ii., p. 29.) The period of life at which they most usually occur is between thirty and fifty years of age, when the muscular system is yet strong, but the strength of the arterial tissues is beginning to be impaired. And we can hence readily perceive why males should be more subject to the disease than females; as also why persons in very advanced life, like the young, should less frequently suffer from its attacks. One man of eighty, and one boy of eleven years of age, form the extremes on which Sir Astley Cooper tells us he has ever had to perform the operation;—in the first the aneurism was popliteal; in the second, tibial; and both appear to have done well.—(*Id.*, vol. ii., p. 46.)

The tumour, when first observed, is small, and excites little attention; for there is no pain, the skin is of its natural appearance, and the tumour vanishes when pressed upon by the finger. But during the pressure a pulsation is clearly distinguishable, corresponding with that of the subjacent artery. As the disease advances, the tumour increases; and when it has gained considerable magnitude, the skin becomes pale, and even œdematous; the pulsation still continues, though the tumour yields less regularly to the pressure of the finger than heretofore, being soft and fluctuating in some parts, but, from coagula lodged and hardened in the sac, firm and resisting in others. The seat of the aneurism at length becomes distressingly painful from the increased coagulation and swelling; the skin assumes a livid hue, and seems verging to a gangrenous state; the bloody serum oozes from it, and it often ulcerates; when the walls of the arterial sac, meeting with less support than hitherto, give way, the blood bursts forth with violence, and, if the artery be large, soon produces death by inanition.

In an early stage of the disease, it cannot easily be mistaken for any other; for the signs of a regular pulsation, absence of pain, and disappearance of the tumour on pressure, are sufficient to distinguish it. But when in the progress of the complaint the pulsation becomes almost imperceptible, and the tumour hard, it has been confounded with other encysted tumours, scrofulous swellings, and abscesses. The last is the most common error, and by leading to an injudicious opening, has sometimes proved a fatal one.—(*Reincsius, Schola Ictorum Med.*, p. 321.)

Pressure, under favourable circumstances, has

sometimes produced changes leading to a cure of the disease. Dr. Albers of Bremen gives an instance of this even in an aneurism of the femoral artery.—(*Trans. of Medico-Chirurg. Soc.*, vol. ix.) It has commonly been said that the compress should never amount to more than an easy support to the weakened and enlarged organ (*Desault, Journ. de Chirurg.*, tom. ii.): and it is very probable that tight bandages, by impeding the circulation in the adjoining veins, as well as arteries, have often proved injurious. Dr. Perceval, however, in the manuscript comment with which he has enriched the author's volume of Nosology, has the following notice under the present head; seeming to show that even a tight compress has at times been of the highest advantage; and a like success is related by Acrel in an aneurism of the aorta.—(*Chirurgische Vorfälle*, band i., 44.) "In the rebellion of 1798, an officer received a wound from a bayonet which grazed the left carotid artery and produced a pulsatory tumour; this was kept down by a spring-collar, and at length disappeared. Many years after, having lived rather freely, he died dropsical. Previous to his death he had a most violent palpitation of the heart, and discharged by stool immense quantities of blood. The heart was not found enlarged, but the cavity of the left carotid was almost entirely obliterated."

In connexion with pressure, great benefit has also frequently resulted from keeping the amount of the circulating fluid in a diminished state by occasional venesections, purgatives, and a spare diet. Morgagni relates a case in which such a regimen alone effected a cure when commenced early.—(*De Sed. et Caus.*, ep. xvii., art. 30, 31.) Yet it is obvious that in some habits a cure, even of the same artery, is obtained much more easily than in others: and hence it seems sometimes to have taken place spontaneously; of which an example is given by Mr. Crampton (*Med.-Chir. Trans.*, vol. vii., p. 341), and by Mr. Ford in a journal of an earlier date.*

[Although it is the common course of aneurisms, when they are left to themselves, to increase in size, and at length to burst and destroy the patients by hemorrhage, sometimes things happen otherwise, and, in consequence of certain changes taking place, a spontaneous cure is the result. There are four modes in which this desirable event may be produced. 1. Sometimes the whole aneurismal swelling suddenly inflames and sphacelates; in this state, if the inflammation extend its effects to a sufficient depth, the sac in the vicinity of the artery, and a portion of the canal of this vessel itself, may become completely blocked up by coagulating lymph, so that no more blood can get into the tumour, the pulsation of which is

extinguished. The mortified parts, together with the mass of congealed and sometimes putrid blood in the sac, are cast off; and, if the patient's constitution holds out, the ulcer left by the detachment of the sloughs heals up, and the cure is completed. When, however, the inflammation and sloughing are confined to the skin and superficial portion of the sac, the patient bleeds to death on the separation of the dead parts. 2. The second process by which the spontaneous cure of an aneurism may be produced, is the increase of the lamellated coagula in such a degree within the sac as completely to fill it, in which case the blood also coagulates in the adjoining portion of the artery, which becomes impervious for a certain extent above and below the communication which it had with the aneurismal cavity. Similar changes happen when the cure is accomplished by pressure. 3. Until lately, it was believed by Scarpa and other eminent pathologists that no aneurism could be cured, unless the sac and an adjoining part of the artery were thus obliterated; but the facts collected by Mr. Hodgson leave no doubt that when an aneurism of the aorta undergoes a cure, the sac alone may be filled up with coagula, while the vessel itself remains pervious. 4. The last manner in which a spontaneous cure may be brought about, is by the pressure of the sac itself upon the artery.*]

Every palliative means should be had recourse to before an operation is resolved upon; for, even under the most favourable circumstances, such a step is hazardous, and it is peculiarly so when the aneurism is connected with a diseased state of the arterial trunk, or the whole arterial system, of which it is seldom possible for us to form a correct judgment. To describe the nature of the operation would be to travel into the province of surgery. I may, however, observe that, in cases of necessity, it has often been performed with full success, and even a perfect use of the affected limb, in trunks of a very large calibre. Sir Astley Cooper has given an account of two cases in which the operation was effected on the carotid artery. The first proved unsuccessful from the long standing and size of the sac, which pressed with perpetual irritation on the larynx and pharynx, exciting frequent fits of coughing, and preventing deglutition. The second case terminated favourably, but the tumour was smaller and of more recent growth.†

In the SECOND VARIETY, OF DIFFUSE ANEURISM,

* See Sir A. Cooper's Lectures, &c., vol. ii., p. 47. The pressure of one aneurism on the artery leading to another aneurism, has sometimes cured the latter. Thus, Mr. Liston records one example, in which the pressure of an aneurism of the arteria innominata on the subclavian artery cured an aneurism in the axilla.—Ed.

† When the simultaneous existence of several aneurisms, the state of the health, or other particular circumstances, do not forbid the operation, the maxim of the best modern surgeons is to operate, if possible, before the aneurismal tumour has attained a large size, which always renders the cure more remote and uncertain.—Ed.

* London Medical Journal, vol. ix. Other instances have occurred to Dr. Baillie and to Sir Astley Cooper. "I have seen," observes the last writer, "spontaneous cures of aneurism produced without any circumstance which would readily explain the cause."—Lectures, &c., vol. ii., p. 48, 8vo., 1825

the aneurism by infusion of M. Petit (*Desault, Journ. de Chirurgie*, p. 321), the coats of the artery, instead of being dilated into a sac, are divided, and the blood flowing at large into the cellular or other surrounding parts, the tumour is extensive and undefined.

This is usually the result of external violence; the swelling often spreads to an unlimited range, and the progress towards a rupture of the integuments is more rapid than in the last. Here pressure is of no avail, and even mischievous, since it will more effectually obstruct the course of the blood in the surrounding veins than in the divided artery, and increase the chance of mortification. The cure should be conducted on the same principles by which the treatment of a wounded artery is regulated. Sometimes, however, a single ligature above the wound or rent in the vessel will suffice and does generally suffice in the false aneurism at the bend of the arm, not unfrequently occasioned by the unskilful use of the lancet.

The THIRD VARIETY, OF VARICOSE ANEURISM, OR ANEURISMAL VARIX, was first distinctly pointed out by Dr. Hunter, who characterized it by this name. It is produced by puncturing an artery through a vein that lies immediately above it and upon it, as in bloodletting at the arm, so that the arterial blood flows from the arterial puncture, not through the cellular substance, but into the superincumbent vein through the corresponding venous puncture. In this case the tumour is elongated, taking the course of the vein, which is hereby distended and rendered varicose. Sometimes, indeed, where the venous communications are frequent, all the adjoining veins participate in the distention, and are equally affected. The tumour, as in the first variety, disappears upon pressure, and as soon as the pressure is removed, the blood issues from the arterial puncture with a whizzing sound and a tremulous motion, rather than a distinct pulsation.*

This is the least dangerous of all the varieties of aneurism, and that in which pressure may be most successfully applied. It has sometimes produced a radical cure; but generally so far succeeded as to render the operation unnecessary, provided the patient passes a quiet and unfatiguing life; for it has been known to exist twelve, twenty, and even thirty years without any serious injury to the general health.†

* The varicose aneurism does not always correspond to this simple account of its nature; for, not unfrequently, between the vein and artery an aneurismal sac is produced, out of which the blood passes into the vein. This complication materially influences the principles of treatment, because the sac may enlarge to a considerable size, more particularly if its communication with the vein happen to be obliterated, while its communication with the artery remains free.—Ed.

† The simple form of aneurismal varix, left to itself, usually attains the size of a pigeon's egg, and then continues stationary. In consequence of a good deal of the arterial blood, destined for the supply of the hand and forearm, passing directly into the vein, those parts are weakened, and sometimes colder than natural

The FOURTH VARIETY is distinctly a constitutional affection, and usually of considerable distress and oppression. It is characterized by an obtuse intumescence and constant disquiet of the præcordia, with a sense of internal weight and pulsation, increased on the smallest motion; according to Corvisart, the carotids throb, the pulse is strong, hard, and vibrating. It is the CARDIOGNUS* of Galen and Sauvages; the aneurisma præcordiorum of many authors, and the polypus cordis of others. The symptoms are usually found on dissection to proceed from an aneurismal enlargement of some part of the substance of the heart, or the larger vessels in its immediate neighbourhood; but whether, as Corvisart affirms, the enlargement be more common to the left than the right ventricle (*Sur les Maladies et les Lésions Organiques du Cœur*, &c.), is not satisfactorily determined.† It is sometimes accompanied with, and perhaps produced by, a polypous concretion; and sometimes without any such substance whatever: and, where the larger vessels are affected, they are here, more than in any other variety, thickened and rendered rigid by irregular deposits of calcareous or ossific matter. [Two remarkable examples of blood in the heart having become vascular, were published by M. Bouillaud in his

and the pulse at the wrist enfeebled or imperceptible.—Ed.

* Cardiognus is used by some medical writers in two senses:—1. That of a partial enlargement of the heart, forming a sac in which coagulable lymph is deposited, and which is sometimes called an aneurism of the heart. 2. That of a general dilatation of the natural cavities of this organ.—(Bateman, *Rees's Cyclopædia*.) In the present work the term is more comprehensively employed, as under this head we find arranged dilatations of the cavities of the heart, aneurisms of the great vessels near it, and a thickening of the substance of the heart (hypertrophy), just as if they were only modifications of the same disease, and were marked by no material difference of symptoms. Now, although practitioners, even with the aid of the stethoscope and percussion, are not familiar enough with the pathognomonic symptoms of dilatations of the natural cavities of the heart and of hypertrophy to be able to give such a delineation of them as can be fully depended upon, yet it may be confidently asserted, that a dilated ventricle with an attenuation of its parietes, cannot present the same kind of pulse, and cause the same general effects on the circulation, respiration, and system at large, as a ventricle the muscular substance of which is enormously thickened. This must be perfectly obvious, notwithstanding the fact remarked by Andral (*Anat. Pathol.*, tom. ii., p. 283), that the strength and hardness of the pulse do not depend altogether upon the greater or lesser thickness of the parietes of the left ventricle. The two diseases, in fact, are quite as different from one another as they are from aneurism of the arch of the aorta, with which they are classed.—Ed.

† A thickening of the parietes of the heart, when partial, mostly affects the left ventricle (see Andral, *Anat. Pathol.*, tom. ii., p. 284); but the walls of all the four cavities may be similarly changed. An attenuation of the parietes, with dilatation of the cavities, forming the passive aneurism of Corvisart, is more common on the right than on the left side of the heart.—Op. cit., p. 289.—Ed.

valuable memoir on the obliteration of veins. In one, the right auricle was occupied by a coagulum, in which were an infinite number of red vessels. In the other, the right cavities of the heart contained masses of organized, albuminous, fibrinous matter, adherent to the parietes of the heart by means of filaments, and inseparable without breaking them. The patient died of symptoms resembling those of aneurism of the heart. Another case has been published by Dr. Rigacci.—(*Bulletin des Sciences Méd.*, Sept., 1828.)]*

Cardiognmus is sometimes a result of violent exertion; and is then mostly an affection of the young and the strong, of those who engage in manly exercises, or are subject to violent passions. But it is more frequently a result of debility, and chiefly to be met with in persons of advanced age. It is well observed, indeed, by M. Rostan, that a dilatation and thickening of the walls of the heart are not a consequence of great power or strength of constitution with energy of healthy action; but are generally caused by that state of the arteries which is an ordinary consequence of old age, in which they lose their natural elasticity, and become ossified, thick, inorganic tubes.—(*Nouveau Journ. de Médecine*, tom. i., p. 367.) This ossification affects the valves of the heart as well as the vessels in its neighbourhood, whence the heart is perpetually oppressed, and called upon for increased action; which increased action itself is another cause of increased thickening in the cardiac coats.†

* Laennec (*De l'Auscultation Médiate*, vol. ii., p. 244) relates several cases of this kind; he terms them globular excrescences of the heart. Breschet thinks that their organization takes place in the same manner as those of the false membranes, and depends on the same cause.—See note to Doane's translation of Meckel's Anatomy, vol. ii., p. 217.

† Hypertrophy is not always the original cause of palpitations of the heart, but often the effect of them. They take place in three very different states of the animal economy, which Professor Andral advises to be carefully discriminated, as they call for different methods of treatment. The first is a state of plethora, that makes the heart beat with too much violence, giving rise to dizziness, vertigo, &c. Here low diet and copious bleeding are indicated. The second condition promoting the occurrence of palpitations, is that in which there is a deficiency of blood; and in a person thus circumstanced, the palpitations and dyspnoea cease as soon as he is fed well, and more blood has entered the system. In a third condition, the centres of the nervous system are primarily disordered; and then palpitations may be the only indication of the diseased modification of the nervous action; or sometimes merely a secondary effect, among many others, of which most organs may be the seat, as in hysteria. Here neither bleeding nor tonics will answer; but the patient must be submitted to such treatment as will bring about some change in the state of the nervous system. Thus, as Andral explains, there are many affections of the heart which morbid anatomy only shows us, as it were, the terminations of; and what is observed in the dead body is not always the original cause of the symptoms. It is not hypertrophy of the heart that has at first oc-

This, however, is the *passive* enlargement of M. Corvisart; who gives us also a thickening and enlargement which he calls *active*; in which the increased action of the heart, instead of being confined to itself, is extended to its parietes, to the vessels that issue from it, and, consequently, to the pulse generally. Laennec has acceded to this last form of disease (*De l'Auscultation Médiate*, &c., Paris, 1819), and it constitutes his *hypertrophie*.* In this case, the stethoscope, of which we have spoken under *marasmus phthisis*, may often be advantageously employed as a diagnostic.—(Suprà, p. 523.)

The disease not unfrequently proceeds from a distinct cyst, sometimes traced in the substance of the heart, as that of the right auricle, of which an example is given by Bartholin (*Act. Hafn.*, iv., obs. 47); or of the left ventricle, as stated by Dr. Douglas (*Phil. Trans.*, vol. xxix., p. 1414–1416); but more usually in the arch of the aorta.

And in some instances this cyst, or some other morbid structure, has been found to become so much enlarged as to encroach in a

casioned the palpitations, but these have often been the cause of the hypertrophy. Moreover, although in the enlarged heart it seems as if a more active vitality existed, since there is an excess of nutrition, this local condition of the heart does not always prove the condition in which the constitution was at the period when merely an increase of pulsations existed, without any augmentation of nutrition. Here morbid anatomy might lead to error, if the inference were made, that because the heart is thickened and enlarged, debilitating treatment was indicated in the commencement of the disorder. The therapeutic means must often be determined by the states of the nervous and sanguiferous systems then existing.—See Andral, *Anat. Pathol.*, tom. ii., p. 346.—Ed.

* Hypertrophy of the left ventricle has several degrees. Thus, it may be quite restricted to the *carneæ columnæ*, or merely affect the pillars of the mitral valve. In some instances it is only the septum ventriculorum that is thickened; while in others, the whole of the parietes of the left ventricle may be in this condition. It is particularly in cases where the septum is in a state of hypertrophy, that the capacity of the right ventricle is singularly lessened, this cavity seeming, indeed, sometimes like a small appendage, of very narrow dimensions, attached to the left ventricle. The same effect, however, now and then proceeds from hypertrophy affecting only its fleshy pillars. The right ventricle seldom attains a considerable thickness, though Laennec has seen it five times thick, and MM. Bertin and Bouillaud fifteen. Hypertrophy of the auricles is rare, and when it happens, it is almost always accompanied by the same affection of the ventricles. In hypertrophy of the parietes of the heart, its substance may either retain its natural consistence, which is most common; or it may be indurated, which is very unusual; or softened, which is still less frequent. In hypertrophy of the parietes of the heart, its cavities may continue of their natural size; be dilated, constituting the active aneurism of Corvisart, the eccentric hypertrophy of MM. Bertin and Bouillaud; or, lastly, they may be diminished, so as to form the concentric hypertrophy of the two latter pathologists.—Andral, *Anat. Pathol.*, tom. ii., p. 284.—Ed.

very considerable degree upon the natural capacity of the heart. And hence, though the general substance of the organ, with its diseased increase of growth, has weighed upon dissection fifteen pounds, the cavity, in a few rare instances, has hardly equalled that of a walnut. Portal, who is disposed to admit of Corvisart's division of the disease into active and passive, seems chiefly to object to the term dilatation as applied to the heart in this state of engorgement.*

In many of these cases, we can trace the cause; for the aneurismal artery is at times as contracted in the vicinity of the sac, as if it had been tied by a ligature. The aorta has occasionally, in this manner, been rendered altogether impervious, the circulation being continued by an enlargement of the anastomosing vessels.—(*Cooper and Travers's Surgical Essays*, i., p. 125.)

On this account, Morgagni ascribes the disease before us to a narrowness of the larger arteries as its common cause; and hence explains why it is so frequently found among tailors and other sedentary workmen.—(*De Sed. et Caus.*, Ep. xxi., 49; xxvi., 31–33.)

The medical treatment can be rarely more than palliative. Fatigue and great exertion must be sedulously avoided, together with keen mental excitement. The diet should be light, the meals and hours of rest regular, and the exercise should be that of a carriage. The bowels must be attended to; and, where the palpitation or other distress is peculiarly troublesome, it may sometimes be relieved by camphire, ammonia, and tincture of hyoscyamus.

We may observe, before quitting the subject, that the largest aneurisms have been those of this quarter, and particularly of the aorta, as there is here the greatest force of action. Litre gives a description of one of the superior trunk, that ascended as high as the maxilla (*Mém. de l'Acad. Royale des Sciences à Paris*, Ann. 1707), and Teichmeyer of another that burst into the pericardium.—(*Dissert. de Stupendo Aneurysmate Brachii*, &c., Jen., 1734.) From their extent and pressure, they often erode the cartilaginous and even bony substance of the ribs; and La Faye relates a case in which a part of the sternum, as well as two cartilages of the ribs, was hereby destroyed.—(*Phil. Trans.*, N. 287.) In an enormous aneurism of the abdominal aorta, Morgagni mentions that the pos-

terior wall of the artery itself was destroyed, the neighbouring parts supplying the place of a wall (*De Sed. et Caus. Morb.*, Ep. xl., 26): and, in a like aneurism of the thoracic aorta, he found the bones in the vicinity broken and demolished by the force of its pressure.—(Ep. xvii., 25–27.)

SPECIES II.

EXANGIA VARIX.

VARIX.

SOFT, LIVID TUMOUR OF A VEIN.

This disease is to veins what the true or encysted aneurism is to arteries. The coats of the veins are preternaturally dilated, and more in some parts than in others, so that a vein thus enlarged to any considerable extent often appears to be a chain of venous cysts; and as contiguous veins often communicate, the enlargement is not unfrequently extended from one to another, till the whole forms a plexus of varices, and every part seems ready to burst. In some instances, they do actually burst.

This affection mostly occurs in the veins of the lower extremities, in consequence of their being the most dependant part. They often arise spontaneously in persons of lax fibres; but are far more frequently a consequence of undue fatigue, strains, cramps, or pressure. The most frequent cause is a pressure of the fœtus in pregnancy against the external iliac veins, in consequence of which the blood ascends with difficulty from all the inferior veins, which become distended and weakened by its accumulation.

From strains and other causes, however, varices have been occasionally traced in other large veins than those of the extremities. Thus Tozzetti discovered one after death in the *vena azygos* (*Prima Raccolta di Osservazioni Medice*, Firenze, 1752); and Michaelis describes another, that terminated fatally, in the jugular vein.* They are also met with in the spermatic veins; and, in this position, have very generally been described under the incorrect name of circocele or varicose rupture. Morgagni asserts that the spermatic varix appears more frequently on the left than on the right side, from the insertion of the spermatic vein into the emulgent.—(*De Sed. et Caus. Morb.*, Ep. xliii., art. 34.) They are often possessed of considerable irritability in themselves, and almost always add in a high degree to the irritability of diseased

* *Mémoires sur la Nature et le Traitement de plusieurs Maladies*, tom. iv., 8vo., Paris, 1819. The cysts or partial dilatations of the heart here spoken of vary in size, from that of an almond to that of a hen's egg. Sometimes the parietes of the heart around them are thickened, sometimes remarkably attenuated. These pouches contain very solid layers of concrete fibrin, just as a common aneurismal sac does, to which they correspond in more than one point. M. Breschet, who has drawn up an interesting memoir on this form of disease, names it *false consecutive aneurism* of the heart; an appellation disapproved of by M. Andral, because dissection does not always exhibit a laceration of the lining of the heart.—*Anat. Pathol.*, tom. ii., p. 290.—Ed.

* See Richter's *Chirurgische Bibliothek*, in loco. The best modern pathologists make a distinction between simply enlarged and tortuous veins, and those which are varicose. The former are not attended with any disease of their coats, or with any changes disqualifying them for the due conveyance of the blood; whereas true varicose veins are accompanied with disease of their coats, and more or less obstruction of their canals. In Cruveilhier's *Anat. Pathol.*, livr. xvi., may be seen an interesting representation of an enormous enlargement and tortuosity of all the subcutaneous veins on the forepart of the abdomen, causing a swelling, which he compares to a Medusa's head; the case was simple dilatation, not varix.—Ed.

parts in the vicinity, so that if an ulcer take place contiguously, it will rarely admit of a cure till the varix be first removed.—(*Mém. de l'Acad. Royale des Sciences à Paris*, Ann. 1707.)

The best remedy, in all cases where it can be applied, is a moderate, steady, and continued pressure, which, where the varix occurs in the legs, is easily accomplished by an elastic stocking, or, which is preferable, a circular bandage of fine elastic flannel. Daute's plan of using cold water is also a very simple, and, where the varix is fresh, not unfrequently a very efficacious remedy (*Von dem äusserlichen örtlichen Gebranche des Kalten Wassers*, &c., Leips., 1784, 4to.); but how far a solution of mineral acids or metallic salts may add to its virtue, as recommended by some practitioners, the author cannot affirm from his own practice.

[In cases which resisted compression, and were attended with a painful ulcer that would not heal, Sir Everard Home tied the trunk of the vena saphena, as it passes over the knee-joint. Many severe and fatal consequences, however, having resulted from this practice, Mr. Brodie conceived that it would be safer to cut the vein completely through, leaving the superincumbent skin undivided, a plan easily accomplished with a narrow, sharp-pointed, slightly-curved bistoury.*] The attempt to cure varices by the knife or ligature has succeeded where there is neither local nor constitutional irritability, but it has more frequently failed, and the inflammation hereby produced has occasionally proved fatal.† Yet, where the effect is less extensive, it is apt to be followed by a serious and far more diffuse enlargement of the vein, with varicose prominences, similar to that which sometimes occurs in drawing blood from the arm, of which, till of late years, no very intelligent explanation has been given, and which I shall, therefore, endeavour briefly to illustrate.

This singular and painful line of swelling was at first supposed to arise from the prick of a nerve, and it is perfectly clear that the tingling and shooting pains which succeed venesection are sometimes produced by a partial division of a nerve, from an interesting case of Mr. Sherwen, of Enfield, that only yielded to an entire division of the nerve by a transverse section above the orifice, after every other attempt had been tried in vain.‡ But the nerves of the arm liable to be wounded in bleeding are mostly small and unimportant; while others are often pricked and wounded in many of the common operations of surgery, without any serious consequence whatever. The mischief has by other writers, as Heister, Garengot, and Haller, been ascribed to wounding a tendon or its aponeurosis, but, unluckily for such physiologists, tendons in other

places are often torn or wounded with very little inconvenience. Even the Achilles tendon, the largest in the body, is frequently broken without any of the severe symptoms that sometimes arise from bloodletting. Besides which, the accident from bleeding occurs as frequently when a person has been bled in a vein which has no tendon near it, as where there is reason to expect that a tendon may have been wounded. It happens as often that a swelled arm is the consequence of bleeding in the cephalic or cephalic-median vein as of bleeding in the basilic or basilic-median.

Mr. J. Hunter was the first physiologist who ascertained the real cause of the mischief before us, and traced it to a general principle, which he laid down as applicable to all internal cavities, namely, that when injured or rendered otherwise imperfect, they are often apt to inflame at the injured part, and to have the inflammation spread rapidly over their whole extent, as I have already had an opportunity of observing under peritonitis, puerperal fever, and on various other occasions. He was first led to this view of the cause in the case of veins from noticing what occasionally happens to horses. It is no uncommon thing for hostlers, out of an unnecessary or ill-judged care, to bleed these animals in the neck, even when in perfect health; and, in several instances of this kind, Mr. Hunter had observed that the neck swelled and the horse died; and, on examining the nature of the disease by dissection, he found that the cavity of the vein was inflamed, and that the inflammation had spread along its internal surface to the chest, sometimes even to the heart itself. And he afterward found a like effect produced in the veins of the human arm, where inflammation had succeeded to bleeding, and particularly in one case that occurred in St. George's Hospital, being that of a man who died suddenly on the eighth day after having been bled in the basilic vein of the right arm, and having suffered from inflammation as a consequence. On dissecting the arm, he found not only that the cavity of the vein had inflamed, but that the inflammation had extended from the puncture which had been made by the lancet in bloodletting, as high as the axilla, proceeding also to some distance below the puncture. About the middle of the arm the vein had suppurated, and, from the ulceration or absorption of parts which attends abscesses, the vein was divided into two, and each extremity, like the internal surface of the abscess, was irregular and jagged.

Mr. Hunter was disposed to think that the principal cause which produces the inflammation of a vein after bleeding is the want of a disposition to heal, arising either from its being exposed, or in consequence of the lips of the orifice in the skin not being properly brought together. And he hence strongly advises that the sides of an opened vein should at all times be made to approximate as accurately as possible, and that the orifice in the skin should be drawn to one side of that in the vein, so as to make the skin do the office of a valve to the venal opening.—(*Edin. Med. Com.*, vol. iii., p. 430.)

* See *Med. Chir. Trans.*, vol. vii., p. 195. Mr. Mayo obliterates varicose veins by applying a caustic paste over them.—Ed.

† *Observations on Varix*, &c., by Richard Carmichael, &c., *Trans. King's and Queen's Coll.*, Dublin, vol. ii., p. 345, 1824.

‡ *Edin. Med. Comment.*, vol. v., p. 430.—See also *Stud. of Med.*, vol. i., Cl. III., Ord. II., Gen. VI., Spe. 5.

There seems, however, in this explanation, to be a something wanting, and I cannot avoid thinking, as in the case of puerperal fever, that there must be, at the same time, some peculiar local or constitutional irritability predisposing the injured part to run into an inflammatory action; a striking instance of which, already slightly alluded to, occurs in a case communicated by Dr. A. Duncan. The patient, himself of the medical profession, twenty-eight years of age, had opened a boil on his hand with a lancet which had been applied to an obscure sore on the back of another person about a month previously, but against which no proof of being either poisoned or unclean could be brought forward. The inflammation, instead of subsiding after opening the tumour, increased, and spread up the arm to the axilla; but the swelling was attended with little redness, and no acute pain, though with considerable fever and restlessness. The affected arm, three days afterward, exhibited one or two red streaks running up from the elbow to the shoulder, in the course of the cephalic vein; the breathing was much affected, quick and short, but without pain in the chest; there was a troublesome cough, and the expectoration, though small in quantity, was tinged with blood. The countenance was anxious, depressed, and of a leaden hue; the features sharpened; the eyes sunk and dull; tongue foul; pulse a hundred and ten strokes in a minute. These symptoms increased in violence, with transient fits of delirium and subsultus tendinum; the intumescence of the arm, however, remaining to the eye much the same, with little complaint of pain. The patient sunk gradually in just a week from the first appearance of local affection, and ten days after using the lancet.

On examining the body, much chronic disease was found in the chest; the cartilages of the ribs on one side were slightly ossified: there was a general adhesion of the lungs to the costal pleura, pericardium, and diaphragm, with a recent effusion of coagulable lymph; in some places a little coloured, and occasionally evincing a few fibrous shreds. The substance of the lungs appeared also generally unsound, and in some parts contained tubercles and calculi, one of the tubercles being as large as a nut, and filled with a yellow, purulent-looking fluid.

The general health had borne up under all these chronic sappings, undisturbed, to the time of the local affection of the hand, as also under a protracted fatigue, through the whole of the preceding winter, from a course of hard professional study, augmented, still more lately, by great mental anxiety and disappointment. All these seem to have produced a morbid excitement of habit, which, though not fatal of itself, gave a fatal tendency to the inflammation on the hand, or rather to the irritation of the cephalic vein, which was probably pricked on opening the bile, as will be sufficiently obvious from the appearances of the limb on dissection. Many livid spots were observed externally: the opened and unhealed ulcer was found to be accompanied with a swelling of the cellular substance, extending, more or less, up the whole arm: and,

Vol. II.—I

on making a long incision from this ulcer to the top of the shoulder, a small abscess was accidentally entered into at the bend of the arm, which proved to be the cephalic vein accidentally divided, and unfolded the immediate seat of mischief. The vein appeared full of purulent matter, and, in consequence, was carefully traced through its entire range. "The disease of the vein consisted in external redness, arising from the increased size of the vasa vasorum; thickening of all its coats, so that it remained, like an artery, round without collapsing; increased size, especially in the forearm; its containing no blood in any part of its course, and being generally filled with purulent matter, except in a few places where it seemed empty; and in the inner coat being everywhere red and thickened. The veins coming from the back of the forefinger, middle, and ring-finger, were all diseased, but that from the little finger was healthy."*

PHLEBITIS is far more easily produced than ARTERITIS, as veins are more irritable than arteries; but we hence learn that even the former is occasionally influenced by constitutional excitements

SPECIES III.

EXANGIA CYANIA.

BLUE-SKIN.

SKIN MORE OR LESS BLUE; LIPS PURPLE;
GENERAL HEBETUDE AND INACTIVITY.

THIS species is designed to express that singular appearance and diseased state of the entire system, produced mostly by a connate communication of the two ventricles of the heart, and consequently, an imperfect discharge of the carbon of the blood at the lungs, which constitute the proper organ of its elimination. From the Greek *κύανος*, or "blue," Sir Alex-

* At the present day, our knowledge of the frequency and nature of phlebitis has been much increased. We are now aware that it may arise not merely from the puncture or mechanical irritation of a vein, but may arise as a consequence of any surgical operation or accidental injury, and of any suppurative disease. Cruveilhier seems to the editor to claim the merit of having given the most rational explanation of the cause of its severe and often fatal character. When a vein inflames and suppurates, or pus is introduced into it, this fluid circulates with the blood, and reaches the venous capillaries, in which it excites obstruction, inflammation, and abscesses. Cruveilhier found, that when he introduced any extraneous fluid or matter into veins which communicate with the vena portæ, abscess in the liver was excited; but if the veins so treated were of the system more directly connected with the vena cava, the abscess often formed in the lungs, joints, serous cavities, &c. If it be asked why the absorption of pus from common abscesses has no such effects, the answer which Cruveilhier would make is, that here the pus is so altered or modified by the action of the organs of absorption upon it, that the evil is thus prevented. Some of the best observations on phlebitis are contained in Cruveilhier's *Anat. Pathol.*—Ed.

ander Crichton, in allusion to the colour of the skin by which it is peculiarly distinguished, has elegantly named it CYANIA, and the term has been adopted as a specific appellation on the present occasion.*

Antecedently to birth, the lungs are of small comparative importance to the functions of life and growth, and hence no more blood seems to circulate through them than is necessary for their development and health. The florid or decarbonated blood, instead of being received from the lungs by the pulmonary veins, is received from the placenta by the venæ cavæ, and passes for the most part at once into the general circulation, chiefly by means of the foramen ovale, by which the two ventricles communicate, and partly by means of the ductus arteriosus, by which the pulmonary artery at this time anastomoses with the aorta; that portion of blood only which escapes through this canal flowing forward into the collapsed substance of the lungs; amounting probably to not more than a third or a fourth part of the whole.

Immediately on birth, however, the plan of decarbonization is immediately changed. The fetal duct and foramen are closed, and the whole mass of blood flows, black instead of florid, from the venæ cavæ into the heart, and is sent by the pulmonary artery to the lungs for ventilation, instead of to the placenta, in which organ, by the disengagement of the carbon with which it is loaded, and partly perhaps by the absorption of oxygen from the respired air (for the subject is still open to controversy), it acquires its perfect elaboration and florid hue.

Hence if, in consequence of any aberration from the common law which regulates the wonderful change that thus takes place in the infantine heart and its attached vessels at the time of birth, either of these communications should remain open, the venous or black blood must wholly, or in a very considerable degree, be thrown back again into the general circulation, instead of passing to the lungs: and the minute arteries on the surface, which give to the complexion its tinge, being filled with the same, the general hue must be changed from a florid to a blue or purple, more or less deep, according as the pulmonary circulation is more or less impeded. This natural defect constitutes the disease before us. In the varicose aneurism, a small part of the florid or arterial blood flows through an accidental opening into the veins, but never in such a quantity as to disturb the economy of general health. In cyania a much larger, but variable proportion, of the black or venous blood, flows by a physical opening into the arteries; and usually with serious inconvenience to the general health, most commonly indeed with fatal effects.

* A variety of cyania, not noticed by the author, is found to result occasionally from the internal use of the nitrate of silver. This fact was known to Fourcroy.—(See *Médecine éclairée par les Sciences Physiques*, tom. i., p. 342.) The cases detailed by Drs. Albers and Roget are highly interesting and curious.—See *Med. Chir. Trans.*, vol. vii., p. 284, et seq.—Ed.

How far the ordinary disengagement of carbon from the blood may be dispensed with, or, in other words, to what extent these connate communications may remain, and the present disease take place, without endangering the life, we have no exact means of ascertaining. Dissections have shown us that the foramen ovale has continued partially open to old age, without much or even any interference with the common functions of health (*Geschichte einer Chirurg. Privatgesellschaft in Kopenhagen; Bertholin, Anal. Reform.*, lib. li., cap. 8): but we may confidently assert that, whenever so large a portion of venous blood is thrown into the arterial circulation as to give a blue or purple tinge to the lips or the skin generally, all the functions will be performed feebly, and there is great danger that the infant will never reach the age of puberty. There may be living power enough in the blood to support the growth of the frame during the retired and quiet tenour of infancy, in which there are no sudden exertions or calls for a more than ordinary expenditure of sensorial power; and hence it is no uncommon thing for a child to survive the first three or four years of life with a skin completely blue, and consequently with a full proof that the foramen ovale, or the ductus arteriosus, or both, are open to a very considerable extent, and that not more than perhaps a third or fourth part of the general current of the blood passes into the lungs and undergoes the process of ventilation. But as soon as a more active period of life commences, and the child is trusted to its feet, and engages, or should engage, in the pursuits or even amusements of boyhood, with all its physical and moral excitements, the living power is not adequate to the demands made upon it, and he sinks beneath their oppression, and generally expires in a fainting fit. There is commonly, moreover, through the short and pitiable term of his existence, the clearest proof of general torpitude and deficient energy; every exertion is a trouble, every stimulus produces fatigue; the muscles enlarge, but they want vigour and elasticity; and so far as I have seen, the faculties of the mind are equally blunted. The celebrated blue-boy, described by Dr. Sandifort, advanced farther towards an adult age than is by any means common. Here the aorta took its rise from both ventricles; the pulmonary artery was scarcely pervious to a small probe, and the difficulty of passing the probe from the heart to the lungs was greater than in the contrary direction. The patient was affected with an asthma from his second year, and terminated the miserable series of his sufferings in his thirteenth.—(*Observationes Anatomico-pathologicae*, Lugd. Bat., 1777, 4to.) In the case of a young female, related by Morgagni, the term of life was protracted to the sixteenth year; but there appears to have been a somewhat freer communication with the lungs, notwithstanding that the foramen ovale was wide enough to admit the little finger. The patient, however, was sickly from her birth, and laboured under great general debility; her respiration was difficult, and her whole skin of a livid colour.—(*De Caus. et Sed. ep. xvi.*) Dr. Holmes has lately com-

municated a similar case, but where the passage was somewhat more free; the patient in consequence reached the age of twenty-one, and then died of dropsy.—(*Trans. of the Medico-Chir. Soc. of Edin.*, vol. i., art. vi., 8vo., 1824.)

Life, however, for a short time, has been maintained under still more complicated misformations of the heart and adjoining arteries. Mr. Standert gives the case of a blue-child, that lived ten days, in which the two ventricles communicated; there was no pulmonary artery, but its place was supplied by an artery that branched off to the lungs from the aorta in the situation of the ductus arteriosus, the blood from which was returned by four small pulmonary veins.—(*Phil. Trans.*, 1805, p. 228.) And, in Dr. Baillie's *Morbid Anatomy*, is a still more complicated case of a child that lived about two months, in which the two ventricles communicated, but seemed to change their respective offices; the aorta arising from the right ventricle, and the pulmonary artery from the left. The arterious duct was also open.—(Plate vi., p. 21.) Richerand, however, gives an example, and it is the only one I am acquainted with, of a man who, under this disease, reached the age of forty-one: his flesh was of a relaxed fibre, his colour uniformly blue; and he could only sleep in a sitting position.—(*Physiology*, &c.)*

In a few instances this disease has been suspected to arise subsequently to birth, from some injury or diseased condition of the heart. Corvisart has related a case of this kind, that terminated fatally, in a boy twelve and a half years old, and who had manifested no symptoms of the disease till five months before he saw him, which was on his admission into the Clinique Interne, April 21, 1797. His countenance was puffed, his lips violet, his restlessness extreme. He died on the 25th of the same month. On dissection, a foramen was found between the two ventricles, capable of admitting the little finger.†

* In the Archives Générales de Médecine, Sept., 1827, a still more curious case is mentioned. The subject lived till he was 35 years of age, was married, and was the father of five children. He had been affected with extreme agitations, palpitations, paroxysms of asthma, and even syncope. On dissection, it was found that the septum between the ventricles of the heart was deficient.—D.

† Cyania may occur, however, without any open communication between the right and left cavities of the heart; a fact particularly pointed out by Corvisart. On the other hand, such communication may exist without cyania being produced. Dr. Crampton has seen several cases of this description. In one the communications were so capacious, that the heart might have been regarded as consisting of only one auricle and one ventricle.—(*Med. Trans. of Dublin College*, vol. i., new series.) Breschet met with an instance in which the subclavian arose from the pulmonary artery, and yet there was no blue nor purple discoloration of the parts supplied by the ramifications of that vessel. Cyania of the face sometimes originates, as Corvisart explains, from the influence of organic disease in the right cavities of the heart upon the whole venous system. Under the same circumstances, the mucous tissues

In distressing affections of this kind the art of medicine is unavailable, and all we can advise is perfect tranquillity, a light diet, and attention to the state of the bowels. In one instance, and only one, I have seen the blueness of the skin gradually disappear a few months after birth, and the child grew stout; evidently proving that the morbid communication, whether in the foramen or the arterious duct, was closed by a natural process.*

GENUS XII.

GANGRÆNA.

GANGRENE.

THE DEATH OF A PORTION OF THE BODY, WHILE THE REST CONTINUES ALIVE, OFTEN IN A SOUND STATE.

GANGRÆNA, sphacelus, and necrosis, have been hitherto used in very indefinite senses, sometimes as synonymes, and sometimes as different stages of a common disease. And even in this last view they have rarely preserved their gradations with any thing like a uniform consent; the whole of them sometimes expressing the highest, and sometimes an inferior degree of the malady they equally import. For reasons stated in the volume of Nosology, the first of these terms is here employed in a generic sense, and the two latter as subdivisions or species included under it: sphacelus importing mortification, as it occurs in its ordinary form, with lividity, vesication, ulceration, and fetor; and necrosis, that insensibility and shivering of the flesh which occasionally occur in paralytic limbs. The genus will also extend to two other species: as the gangrene which commences in a bone, and is usually called a caries; and that peculiar form of the disease which begins insensibly in the extremities, and spreads without fever in an ascending direction, till the affected limbs drop off in succession.

All these will therefore be treated of in the following order.

1. Gangræna Sphacelus. Mortification.
2. ——— Ustilaginea. Mildew mortification.

are liable to become injected, in old persons, with dark blood. Obstruction to the free passage of blood through the aorta, joined with hypertrophy of the heart, retardation of the pulmonary circulation, and plethora of the right ventricle and auricle, may likewise bring on cyania, or, as it is more frequently named, cyanosis.—ED.

* The details of fifty-six cases of cyanosis may be seen in Gintrac, *Observations et Recherches sur la Cyanose*, Paris, 1824; and Meckel, in *Archiv. f. d. Physiol.*, vol. i., p. 221, has given a table of seventy-seven separate observations. Cases of the same have been recorded by American writers, as Jackson, Dorsey, and Thaxter, in the *N. E. Journ. of Med. and Surg.*, vols. i., iii., and v.; by Perkins and Hoffman, in *New-York Med. and Phys. Journal*, vols. ii. and vi., and by Coates and Mauran, in *Phil. Journ. of the Med. and Phys. Sc.*, vols. ix. and xiv.—See likewise *Blue Disease*, in a *Dict. of Pract. Medicine*, by James Copland, Boston, 1834.—D.

SPECIES I.
GANGRÆNA SPHACELUS.
MORTIFICATION.

THE DEAD PART SOFT, MOIST, CORRUPT, AND
HIGHLY OFFENSIVE.

MORTIFICATION signifies the death of a portion of the soft parts, sometimes including also the bones, as when the whole limb mortifies. It is not, however, simply the death of parts occasioned in any kind of way, for when a piece of flesh is removed from the body by excision, its vital principle soon ceases; yet this is not mortification in the technical sense of the term. On the contrary, mortification is preceded by certain changes in the parts about to perish, which are generally converted into a brown or black, fetid, cold, insensible mass, with which the general nervous and vascular systems have no longer any organic connexion. The parts thus altered and deprived of vitality are called sloughs. In consequence of the discontinuance of the living principle, the laws of animal chymistry, previously held in subjection by its superior sway, acquire an ascendancy; a play of chymical affinities takes place; and putrefaction, or a decomposition of the organized substance, and a restoration of its constituent parts to their elementary forms, necessarily ensue.

It is from this cause the affected part becomes soft, corrupt, and offensive, and is called *moist gangrene*; and not from an accumulation of animal juices, as stated by Professor Frank; "*ob succorum stantium aut corruptorum abundantiam.*"—(Op. cit., tom. ii., p. 18.)

The total debility, insensibility, or torpidity, attending gangrene, may be produced by too much or too little action or excitement; for the vital flame may be supplied so rapidly as to destroy by its own violence, or there may be no supply whatever. And we are hence furnished with the two following varieties of the disease:

- | | |
|-------------|-----------------------------|
| α Inductus. | Superinduced mortification. |
| β Atonicus. | Atonic mortification. |

The ordinary causes of the first are fever, inflammation, local violence, or severe cold. Those of the second are old age, impure air, scanty or innutritious food; and for the same reason, as Sir Clifton Wintringham has observed, ossification in the arteries of the part affected; which is, indeed, chiefly a consequence of old age.—(Comment. de Morbis quibusdam, &c., No. liv.)

Where mortification originates from a severe contusion or other injury, in a person of florid

and vigorous health, and in the prime of life, we have an example of the FIRST VARIETY. There is in this case high inflammatory action, great heat, swelling, and pulsation; the vessels are supplied with a superabundance of living power (the excitability of the Brunonians), and are in consequence excited beyond their strength; they are hence worn out by the impetuosity of the toil, lose their tone, and the parts become torpid and insensible from the vehemence of their own exertion.*

The SECOND VARIETY may be illustrated by the mortification which so frequently takes place in the extremities of persons already exhausted by hard labour, intemperance, or advanced years, and whose extremities are bloated and anasarous. In this case, instead of a superabundant supply of living power, there is little or no power whatever; for the whole circulation is languid, and the nervous energy now scarcely reaches the extremities, and particularly the lower limbs, the muscular fibres of which, however, are in themselves so irritable, that a more than ordinary excitement is scarcely capable of rousing them; and hence they yield to the process of putrefaction from a cause the very reverse of what operates in the preceding case.†

Under the first form there is more pain and fever, as there is more sensibility and violence, than under the second; and, on this account, the destructive march is more rapid; but, with these exceptions, the symptoms, which are the ordinary ones of putrefaction, are the same. The colour of the skin changes to a dark red or livid hue; the cuticle is separated from the true skin by the interposition of an ichorous fluid, contained in vesicles, or bullæ, or diffused generally; it bursts by degrees; and the subjacent integuments are cold, black, flaccid, sloughy, and insensible; with a sanious or bloody discharge of a most offensive smell.—(Frank, De Cur. Hom. Morb., class ii., sect. 130.)

* The mere torpidity or insensibility of parts would not amount to sphacelus, or complete mortification, or even to any degree of it whatever; for, as the editor has elsewhere explained, the entire and unalterable cessation of every action and function in the part is absolutely essential to what is understood by sphacelus. Sensibility and power of motion may be annihilated, and yet the part affected continue to live, as is daily exemplified in cases of paralysis. In a palsied limb, the temperature of the parts and the force of the circulation are also lessened; yet the fluids pursue their usual course, nutrition and absorption are carried on, and the parts continue to retain, for an indefinite length of time, an inferior degree of vitality. *Gangrene*, however, in the sense in which it was used by Galen, and is still often used by the moderns, signifies the first stage of mortification, when there seems to be a partial but not total destruction of the parts, when the blood still circulates through some of the larger vessels, and the nerves retain a portion of their sensibility.—See First Lines of the Practice of Surgery, p. 37 and 39, 5th edit.

† "Mortification always spreads more extensively in cellular membrane than in the skin and muscles; a fact particularly worthy of recollection when amputation is to be performed."—Op. cit., p. 39.

* The sense of the term *necrosis*, as employed by the author, does not coincide with that commonly assigned to it by modern writers, and which is a mortification of a more or less extensive portion, or even of the whole of a bone; while *caries*, instead of being promiscuously used to denote either the mortification of bone, or the process in this structure analogous to ulceration of the soft parts, is now restricted by many judicious pathologists exclusively to the latter affection.—ED.

[One remarkable circumstance always attending sphacelus, but not noticed by the author, appears to merit attention, as it demonstrates the friendly effort made by nature for the preservation of the patient: when a limb sphacelates, the blood coagulates in the large arteries leading to the parts affected, and this for some distance from the line which marks the extent of their destruction. Now if this were not the case, the patient would inevitably bleed to death as soon as the process takes place by which the sloughs are thrown off; but, except in hospital gangrene and phagedænic sloughing, hemorrhage is rarely to be feared in mortification.]

If the sphacelus meet with no check from art or nature, it spreads rapidly in every direction, particularly under the first variety; and more especially when aided by an impure or unventilated atmosphere, of which the hospital gangrene, as it is called, furnishes us with a fearful example. "I have seen," says Dr. Hennen, "the external ear and the palpebræ destroyed in this manner, as if in a series of concentric circles. Even upon surfaces barely contiguous, as the fingers and toes, it generally spreads in a similar way; so that the sore which might have been on the middle finger or toe, and confined entirely to it in the morning dressing, by night engaged the adjoining sound ones, and in less than twelve hours more embraced the whole foot or hand. The gangrene still advancing, fresh sloughs* were rapidly formed, the increasing cup-like cavity was filled up and overtopped by them, and the erysipelatous livor and vesication of the surrounding skin gained ground, while chains of inflamed lymphatics could be traced from the sores to the adjoining glands; thus exciting inflammation and suppuration, which often furnished a new nidus for gangrene. The face of the sufferer assumed a ghastly, anxious appearance; his eyes became haggard, and deeply tinged with bile; his tongue loaded with a brown or blackish fur; his appetite entirely failed him; and his pulse was considerably sunk in strength, and proportionably accelerated."

During this state Dr. Hennen adds, that the bravest soldiers betrayed "the greatest imaginable impatience of pain and depression of spirits. Men who had borne amputation without a groan, shrunk at the washing of their sores, and shuddered at the sight of a dead comrade; or even, on hearing the report of his death, predicted their own dissolution, and sunk into sullen despair. The third and last stage was now fast approaching. The surface of the sore was covered with a bloody oozing; and on lifting up

* In hospital gangrene the sloughs are not like those of common sphacelus; but the disease is attended with a rapid and singular mode of decomposition in the mortified parts, of which hardly any vestiges appear. No ordinary sloughs are seen; but, in lieu of them, the surface of the diseased part is covered with a whitish or ash-coloured viscid matter, which exhibits at particular points specks of blood.—See First Lines of the Practice of Surgery, p. 40, 5th edit.; Delpech, Précis des Maladies Chirurg., tom. i., p. 75; R. Welbank, in Med. Chir. Transact., vol. ii.; and Blackadder on Phagedæna Gangrænosa, Edin., 1818.

the edge of the flabby slough, the probe was tinged with dark-coloured grumous blood, with which also its track became immediately filled: repeated and copious venous bleedings now came on, which rapidly sunk the patient; the sloughs, whether falling off spontaneously or detached by art, were quickly succeeded by others, and discovered on their removal small thickly-studded specks of arterial blood. At length an artery sprung, which, in the attempt to secure it, most probably burst under the ligature: the tourniquet or pressure was now applied, but in vain; for while it checked the bleeding it accelerated the death of the limb, which became frightfully swelled and horribly fetid. Incessant retchings soon came on, and with cauma, involuntary stools, and hiccough, closed the scene."—(*Principles of Military Surgery*, 2d edit., 8vo., Edin., 1810.)

In this severity of attack and debility of the system, the most compact parts of the solids fall a prey, as well as those that are more loose; but when the atmosphere is purer or more bracing, and the strength firmer, the cellular texture first and chiefly suffers. And we are hence able to understand the meaning of Dr. Riberi, of Turin, who, in describing a similar gangrene in the hospital of San Giovanni in that city, during the years 1817–1820, tells us that it often alternated from a sphacelating to an erysipelatous inflammation, the latter appearing as the former began to cease, on the return of a cooler or drier air; or, where both co-existed, the slighter erysipelatous affection being limited to the more robust patients, or those who were fortunate enough to lie in the best ventilated parts of the sick wards.—(*Sulla Gangrena Contagiosa o Nosocomiale*, Turin, 8vo., 1821.)

In this extreme form of gangrene a septic principle appears to be developed, capable of propagating the same disease by contagion; for not only "upon surfaces barely contiguous" was it found to obtain an existence, but "the skin of other persons, although perfectly sound, which had been touched with a sponge employed in washing the gangrenous sores, ulcerated, and soon became itself a slough. This," adds Dr. Hennen, "was often observable among the orderlies and nurses;" and the description of Riberi does not essentially differ.

The treatment belongs rather to the department of surgery than that of medicine. It is obvious, however, that, under the above two varieties, it must be greatly varied to meet the variety of cause and constitution. Where an inflammatory diathesis is present, evacuations of every kind must be had recourse to, as venesection, purging, and relaxants, while the local applications should consist of refrigerant epithems till the entonic action is completely reduced; after which, bark and the mineral acids, with a nutritive, but not a stimulant diet, should be chiefly relied upon; and if the fetor be considerable, powdered charcoal, or the yeast or carrot poultice, should be applied topically. But where, on the contrary, the mortification is that of atony, the warmest tonics and stimulants are demanded, both locally and generally, from the first.

If the limb be frostbitten, and there be danger of mortification from this source, a plan of treatment will be requisite, different from both the above, the advantage of which is known to every one, though the principle upon which it acts has never been clearly explained.

The torpidity or insensibility of the part affected is in this case evidently produced by the exhausting power of the cold, which destroys or extinguishes the irritable and sensorial principle as rapidly as it is supplied. Putrefaction, however, or a decomposition of the organic structure, does not readily ensue, because the auxiliaries of this change, and which are absolutely necessary to its production, such as heat, air, and moisture, are not present; for, as the parts become frozen, they lose their moisture or fluidity, and as there is no breach of surface, there is no communication with the external air. When a limb in this state is suddenly brought before the fire, it becomes gangrenous almost instantly; for, by this means, putrefaction obtains possession of these auxiliaries, and, in its process, gains the start of the remedial or restorative power of nature. And hence it is well known, that the worst thing that can be done to a frozen limb is to bring it into such a situation. On the contrary, if we give time to this restorative power to exert itself, while we prevent the process of putrefaction from taking place, by keeping the limb very nearly in the same condition of freezing, or rather by raising it out of this condition by slow and imperceptible degrees, we shall have the best chance of recovering it to life; since we hereby afford an opportunity for the warm and circulating blood and the active principle of irritability to push forward once more into the vessels of the frozen structure, which, however weakened and insentient, have not yet become decomposed.

The advantage of plunging a frozen limb first into ice-water, and afterward into water raised just above the freezing point, and in this manner advancing it gradually to a common temperature, is of general notoriety; and it is this plan which forms the usual treatment. In what way the benefit is accomplished has been a frequent subject of inquiry; the remarks just offered may perhaps afford a satisfactory explanation of the subject.

[The treatment of hospital gangrene differs very materially from that of other cases of mortification; but, as the subject is strictly surgical, all that need be mentioned in the present place is, that the local applications by which it is most effectually checked, are the undiluted mineral acids, strong arsenical lotions, and, according to Delpech, the actual cautery.]

SPECIES II.

GANGRÆNA USTILAGINEA.

MILDEW MORTIFICATION.

GANGRENE DRY, DIFFUSE, DIVERGENT, COMMENCING IN THE EXTREMITIES, WITHOUT FEVER OR INTUMESCENCE, AND SPREADING TILL VARIOUS LIMBS DROP OFF IN SUCCESSION:

GREAT HEBETUDE OF MIND AND BODY; OFTEN WITH VIOLENT SPASMS.

THIS is the *necrosis ustilaginea* of Sauvages, the specific epithet being derived from the cause to which it has commonly been ascribed, and from which, in various cases, it seems to take its rise; I mean the use of grain vitiated or poisoned by the growth of parasitic plants in the interior of the culm or straw, chiefly the "ustilago," "blight or mildew;" whence the name of "*mildew mortification*" among ourselves, as that of *ergot*, or *spur*, among the French, from the resemblance which the mildewed or blighted corn bears to the spur of a cock, in Latin *clavus*, which is the name borne by this parasitic plant in the language of many botanists.

Grain, thus injured by some fungus or other, has been found, when employed as food, productive of two dreadful diseases, to both of which, indeed, the French have given the name of *ergot*, as occasioned by a common cause; as they have also that of *mal des ardens*, from the burning internal heat which is felt in either case. The one of these disorders is a typhus fever, with the general character of *pestis*, or what Sauvages calls *erysipelas pestilens*, which is synonymous with the third variety of *PESTIS* in the present work: the other is the migratory gangrene before us, which commences without fever in the hands and feet, with a sense of numbness and external coldness, a dusky or livid cuticle, great debility of mind and body, often violent spasmodic contractions (*Morgagni, De Caus. et Sed. Morb.*, Ep. lv., art. xxiv.; *Bresl. Sammlung.*, 1724, i., p. 643); and spreads rapidly over the system, till the fingers, arms, nose, legs, or thighs are affected, and some of them drop off spontaneously.

Mr. Pott has described a variety of dry or chronic mortification often met with in practice, but without appearing to satisfy himself with any particular cause. "Beginning," says he, "at the extremity of one or more of the small toes, in more or less time it passes on to the foot and ankle, and sometimes to a part of the leg, and, in spite of all the aid of physic and surgery, most commonly destroys the patient. It is very unlike to the mortification from inflammation, to that from external cold, from ligature or bandage, or to that which proceeds from any known and visible cause, and this as well in its attack as in its process. In some few instances it makes its appearance with little or no pain; but in by much the majority of these cases, the patients feel great uneasiness through the whole foot and joint of the ankle, particularly in the night, even before these parts show any mark of distemper, or before there is any other than a small discoloured spot on the end of one of the little toes.* Each sex is

* In a remarkable case of this species of mortification which the editor attended in the summer of 1828, with Mr. Hughes, of Newman's Row, Lincoln's Inn Fields, and which was also visited by Sir Astley Cooper, both feet and legs were attacked, and gradually destroyed, nearly up to the knees. The pulse varied from 100 to 130;

liable to it: but for one female in whom I have met with it, I think I may say that I have seen it in at least twenty males. I think, also, that I have much more often found it in the rich and voluptuous than in the labouring poor; more often in great eaters than free drinkers. It frequently happens to persons advanced in life, but is by no means peculiar to old age. It is not in general preceded or accompanied by apparent distemperature either of the part or of the habit."

In its severer attacks, however, the constitution seems to be generally contaminated, the mind and body become equally debilitated, there is great irritability, and a tendency to convulsive action.

According to some statements, this singular disease is connected with a diseased state of the digestive organs, from excess of living, deleterious food, or some other cause in connexion with great nervous debility (*Home, Facts and Experiments*, p. 18; *Ludwig, Adversar.* i., i., 7, p. 188); and the tendency to gangrene proceeds rather from a deficiency of sensorial power than from any morbid condition of the circulating system,† whether atonic or entonic. And hence we find it best relieved by

and the stomach was so little disturbed that the patient used generally to eat a mutton chop for dinner until the last two or three days preceding his death, which took place about a month from the commencement of the disease. Until the final stage the patient had but little delirium. Two circumstances were particularly remarked: first, that the disease never extended itself without being preceded by violent pain in the part about to be destroyed, so that a judgment could always be formed beforehand, from the degree of suffering, whether the spreading of the disorder would be considerable or not; secondly, that the process of mortification, and its appearance in one leg, were totally different from those exhibited in the other. In the left, the disorder began on the inside of one of the toes, and followed the course described by Pott; in the right, a general diminution of the temperature of the foot and leg occurred, without any discoloration of the skin, or any vesications, or particular affection of the toes. The coldness was followed by total loss of sensibility in the parts, and cessation of the circulation and every other action in them; the flesh was, in short, little more altered in appearance than that of the limb of a dead subject. It was a specimen of the *gangræna necrosis albida* of the present system.—Ed.

† An ossified state of the arteries leading to the mortified parts, and organic disease of the heart, have been detected in some examples of this species of chronic mortification; but not so constantly as to appear to be an unequivocal cause of the disorder, especially as this is frequently not present where they exist. Yet, with old age and an impaired constitution, it is often suspected that they are capable of bringing on, or having some share in the production of this kind of mortification. Such were the ideas prevalent in this country about the causes of *gangræna senilis*; but, of late, a new doctrine has been promulgated by the Baron Dupuytren, namely, that this variety of mortification is dependant upon arteritis, or inflammation of the small arteries leading to the parts affected.—(See *Leçons Orales de Clinique Chirurgicale*, tom. iv., p. 481, &c., 8vo., Paris, 1833.)

free doses of opium, in conjunction with a generous and even stimulant diet. Bark is of no avail, and the local use of spirituous fomentations and cataplasms, warm pungent oils and balsams, of as little. Mr. Pott tried them in every form, but without the smallest success; and at length employed no other topical application than smooth, soft, unirritating poultices, and confined himself to the use of opium alone, of which he sometimes gave a grain every three hours. And under the influence of this medicine the progress of the gangrene has often become checked in a few days, and a line of separation distinctly marked; soon after which the mortified parts have sloughed away, the diseased bone dropped spontaneously from the affected joint, healthy granulations succeeded, and in due time a cure has been effected.

SPECIES III.

GANGRÆNA NECROSIS.

DRY GANGRENE.

THE DEAD PART DRY, SHRIVELLED, HARD, AND DUSKY.

THIS singular species of gangrene seems to proceed from a marasmus or atrophy of the affected limb, in consequence of which, as in the atrophy of the body at large, the animal oil, flesh, and fluids also, are gradually absorbed, and the limb becomes emaciated and withered: "*mummia instar pars affecta*" (*De Cur. Hom. Morb. Epit.*, tom. ii., p. 18, 8vo., Mannh., 1792), says Professor Frank. During the progress of this change it necessarily grows feebler and more torpid, till at length it is no longer capable of receiving the nervous energy, and its different parts turn dead and rigid. In palsied limbs a termination of this kind is by no means uncommon.

In some instances of this affection the blood-vessels have collapsed, perhaps become obliterated, without a retention of any of the constituent principles of the circulating fluid, and consequently the withered limb has preserved something of the natural colour of the skin. In others, the red particles of the blood, changed, as in the veins, to a dark or livid hue, have, to a certain degree, remained in the vessels and given to the limb a purple or variegated die. And hence the species has laid a foundation for the two following varieties:—

- a* Albida. Retaining something of the White gangrene. natural colour of the skin.
- β* Discolor. The natural colour changed
- Black gangrene. to a livid, or a mixture of hues.

In consequence of such inflammation they are rendered impervious, and mortification is the result. The baron alleges that this view has been confirmed by *post-mortem* examinations, and, what is important to be taken into the account, he declares that, by having recourse to bleeding as well as opium, he stops the disorder, and saves not less than two thirds of his patients. When the notorious ill success with which this species of mortification is treated in Great Britain is recollected, we are bound to put Baron Dupuytren's statements to the test of experience.—Ed.

It has never hitherto been satisfactorily explained how it happens that, under this kind of mortification or death, the parts should not, as in the preceding species, fall a prey to putrefaction. Perhaps the following remarks may afford some clew to this singular exception.

We have already had occasion to observe, under the first species, that a frostbitten limb does not putrefy so long as it continues frozen, because the accessories or co-operative powers of putrefaction, without which this process cannot take place, are not present, such as warmth, moisture, and a free influx of air. Now none of these are present in the species before us; for the limb is cold, completely emptied of its fluids, and impervious to atmospheric influence; and, consequently, there are the same obstructions to putrefaction in dry gangrene as in a limb killed by the biting power of frost.

So in the burning sands of Egypt, a buried corpse is often found, if dug up a month or two after interment, with as few marks of putrefaction. I have said that warmth is a necessary auxiliary, but it must be warmth to a certain degree only; for if it exceeds this, all the interior fluids will by the heat itself be raised towards the surface, and pass off rapidly in the form of vapour; in consequence of which the animal substance whence they issue will be as destitute of moisture as if it were frozen, and hence as incapable of putrefying. Now this is the case with a body interred in the sultry sands of the Delta: all its fluids are so highly rarefied as to evaporate and be drunk up by the bibulous soil by which it is surrounded, before any organic decomposition takes place: and hence the buried corpse, instead of crumbling into dust, is converted into a kind of natural mummy, some parts of which exhibit proofs of that waxy fat to which the French chymists have given the name of adipocire; but no part of which undergoes the decomposition of putrefaction. I do not mean that this is always the case, but that it has occurred in a variety of instances where the antiseptic incidents have been peculiarly favourable to such an effect.

And hence Dr. Frank tells us, that the dry gangrene sometimes changes to what is called humid, and, at others, converts the parts affected into a kind of mummy.—(*De Cur. Hom. Morb. Ep.*, class ii., § 130.)

Dr. Alix, of Altenburg, gives a singular example of the second variety of this species, in a man seventy-two years of age, which commenced, contrary to its usual course, with inflammatory symptoms. The back of the left hand was attacked with heat, swelling, and pain, accompanied with thirst, a smart fever, and delirium. At the time Dr. Alix saw him a blackness had spread over all the hand and part of the forearm, which were of a gangrenous hue, but without pain, and as hard as wood. The pulse was small and the spirits low. Amputation was advised, but not agreed to. About six months afterward he saw the patient again accidentally: the gangrene had spread up the elbow-joint, the limb was still without pain, the pulse was better, and there was no want of ap-

petite. As it was not supposed the man could live long, no further inquiries were made about him till a full year afterward, when he was found to be as firm and stout as ever, although he at this time laboured under a tertian intermittent, and had lost one of his eyes. The gangrene had spread over the whole arm up to the shoulder-joint; the limb still continued hard, and as black as smoked meat, but did not emit any cadaverous smell. In about a month from this time the arm dropped off spontaneously, without the least hemorrhage; the exposed surface of the shoulder dried without any discharge whatever, and the old man, at the time of publishing the case, four years afterward, was in the enjoyment of a very good share of health.—(*Matthæi Francisci Alix, Med. et Chir. Doct., &c., Observat. Chirurg.*, fasciculus i., Svo., Altenburg, 1778.) In this instance the small proportion of living power, which continued after the inflammation had subsided, preserved the limb from putrefaction, aided by the hard and shrunk condition into which it had fallen from absorption, and a paralysis of the secretions.

Where there is no inflammation, topical stimulants, and especially of the oleaginous kind, as camphorated oils and warm balsams, with persevering friction, are sometimes found useful in the commencement of this disease. Repeated blistering and setons have also proved serviceable, and the voltaic trough still more so, in conjunction with a nutritive and generous diet. But when the gangrene has established itself, medical skill can do nothing more than look on and lament its want of power.

SPECIES IV.

GANGRÆNA CARIÆ.

CARIÆ.

THE DEAD PART ORIGINATING IN A PORTION OF THE SUBJACENT BONE: PAIN DEEP-SEATED, SUPERJACENT INTEGUMENTS FLACCID AND DISCOLOURED.

BONES, notwithstanding their solidity, possess the same living power, and are subject to the same diseases, as are the soft parts. Like these, they are subject to a cessation or loss of this living principle, and the disease is in this case usually called a CARIÆ,* a Latin term, probably derived from the Hebrew כרה "*careh*," "to dig into, penetrate, or erode," "to scoop, or hollow out." It may originate in a bone itself, which constitutes a proper caries; or it may be communicated from a superjacent ulceration, in which form it is more correctly denominated a carious ulcer.

The history and treatment of caries belong rather to the department of surgery than that of medicine, and are to be learned from writers on this branch of the profession who have expressly

* More frequently at the present day a *necrosis*, as already mentioned; while the word caries is used by the best surgical writers to signify ulceration of bone.—See Dr. Cumin's Arrangement, &c., of Diseases of the Bones, in *Edin. Med. Journal*, No. lxxxii., p. 6.—ED.

treated of it, among whom may especially be mentioned Wiseman (*Surgery*, book ii., ch. 7), Petit (*Maladies des Os.*, tom. ii., ch. 16), and Monro;* particularly the last, as his learned and ingenious essay on this subject ought to engage the attention of every one. The remarks, therefore, to which the author will limit himself, will be general and pathological, and as summary as possible.

Most of the causes that produce a gangrene in the soft parts, may produce a caries or gangrene in the bones: as external injuries, cold, and a deficiency of nutrition in consequence of old age or deleterious food. It is also not unfrequently produced by lues, porphyra, or scrofula.

It is usually first ascertained, where there is no external ulcer, by an obtuse and deep-seated pain, which appears to issue from the bone; an exostosis or protuberance of the bone or periosteum in the part affected, tenderness to the touch, a loose and flabby feel of the superincumbent integuments, and a discoloration of the skin. On being laid bare it evinces all the different modifications of sphacelus, which we have just noticed in the soft parts: for it is sometimes moist and wormeaten, forming the *caries vermoulée* of M. Petit, the cells being filled with a corrupt sanies or spongy caruncles, so that the whole assumes a quaggy appearance; and sometimes dry and wasted; and the dry variety, as in necrosis, is sometimes of a pale white, and sometimes of a black or livid hue. And hence M. Petit has subdivided the disease into four distinct species or varieties, founded on these remarks, but into which we have not space to follow him. The dry caries is generally the most superficial, and consequently exfoliates most easily; the history and laws of which very curious process we have already pointed out under the genus *APOSTEMA*; for the economy pursued by nature in the separation and removal of a dead soft part, is precisely the same as that pursued in the separation and removal of a dead portion of bone. The ancients attempted to expedite this by various means; some of which were puerile, but others certainly calculated by their power to do either much good or a great deal of mischief; particularly the destruction of the integuments by the potential cautery, and afterward an application of the actual cautery to the dead bone itself. Celsus gives a detailed account of this operation, which, when the caries was deep, was accompanied with numerous perforations into the bone, into each of which the hot iron was passed in succession.

[Instead of these formidable measures, which would destroy the bone if it were not already destroyed, and which are calculated to extend the destructive process in it farther than would otherwise be the case, modern practitioners are generally content either with simple unirritating applications, and awaiting the completion of ex-

* Edin. Med. Essays, vol. v., p. 279. Besides these works, the valuable treatise of F. P. Weidmann, *De Ossium Necrosi*, fol. Francofurti ad Mœnum, 1793, deserves particularly to be consulted, as being more modern, and comprising the most approved doctrines.—ED.

foliation; or, where this is too tedious and hopeless, they sometimes cut down the diseased portion of bone, and remove it by manual operation. Many surgeons are also in the habit of applying to dead and carious portions of bone the mineral acids, more or less diluted, with the view of expediting the exfoliation, and exerting a healthy action in the carious part; but the practice should be adopted with caution, because such applications, if they do not fulfil the object proposed, will certainly increase the mischief. Mr. Nicol, of Inverness, has published some observations, recommending the external use of the nitrate of silver, and the internal exhibition of sarsaparilla, in the treatment of caries: his remarks deserve attention.—(See *Edin. Med. and Surg. Journ.*, No. xciv., art. 1.)]

When the restorative power of art or of nature has succeeded in forming a healthy line of separation, and detaching the dead part from the living, the former is usually thrown off in a cylindrical plate; and before the exfoliation is accomplished, we are able to hear, as Severinus has justly remarked, a shrill sound whenever the carious plate is struck with a probe, as if it were hollow. Soon after this the edges of the exfoliating part rise a little, and a little pus, or even blood, is easily pressed out at the margin. Here also granulations begin at this time to appear, which spread over the sound bone underneath, and seem to assist the separation of the dead plate above; so that it gradually becomes loose, and can soon afterward be taken away without violence.

The dead part of a bone is sometimes detached and thrown off to a very great extent, and especially in the cylindrical bones.—(*Bartholin, Act. Hafn.*, obs. 1; *Nicholai, Diss. Observ. quædam Medic.-Chir.*, Jen., 1786.) The whole body of the tibia has in this manner been occasionally detached by nature from its extremities, and its place supplied by a vicarious callus, which has run down the whole of the interior groove hereby produced, and acquired the hardness of bone. Several cases of this kind are given in the *Edinburgh Medical Essays* (vol. i., p. 192–194; vol. v., p. 370); in one of which the caries appeared in both legs: the total tibia of one limb, as the writer, Mr. W. Johnson of Dumfries, informs us, being separated and thrown off at once; while that of the other was detached in small pieces, and thrown out gradually. In five months from the removal of the entire tibia, the patient, a boy of eleven years of age, was able to walk without crutches, continued well afterward, and was fit for any country work; the legs being straight, with only a little thickness at the ankles. Justamond gives a similar case of the humerus, and Sherman of the thigh-bone. I have occasionally seen this natural process initiated successfully, both in the tibia and the bones of the forearm, and the diseased part taken out by a saw, by which process a very long period of pain and confinement has been saved to the patient.

If the caries commence in the internal lamina, the superjacent sound part has sometimes been opened through its whole length by the trephine applied in a line of succession: the carious part

has thus obtained an easy exit as soon as detached, and the entire bone has soon been renewed. The humerus was thus treated successfully in the case of a negro boy, as related by Mr. Walker.*

A caries of the spine, from the tumid, and, so to speak, *inflated* appearance of the superincumbent integuments, was formerly denominated *spina ventosa*: and the term has, with great inconsistency, been since applied by many writers to all bones whatever affected in the same manner, and particularly those of the tarsus and carpus; as it has by others been applied, with equal incorrectness, to a general softness or flexibility of the bones, as in *perostia flexilis*, or *cyrtosis*.

Of vertebral caries, Mr. Brodie has given cases which make it probable that here also the disease sometimes commences in the bones, and sometimes in the intervertebral cartilages; for in various instances the loss of substance was greater in the former, and in others in the latter.†

* Med. Trans., vol. iii., p. 27. In a work devoted to medicine, a minute account of the process by which the dead bone, or sequestrum, as it is termed, becomes included in a new bony tube, may not be expected; but it is right to mention, that the mode hinted at by Dr. Good does certainly not generally take place; that is to say, the new shaft is not produced by a separation of the external laminae of the original bone. Numerous preparations in almost every museum prove, that at all events, in many instances, the sequestrum actually consists of the whole thickness of the original shaft, from which the periosteum has separated, assumed increased vascularity, and been converted into the organ for the new bony formation. After the osseous tube has been produced, a highly vascular substance begins to line its interior, lying between it and the outer surface of the sequestrum, and seemingly possessing a considerable absorbent power, which it exerts on the dead bone in contact with it. Under favourable circumstances, the greater part of the sequestrum will sometimes be gradually removed. The new osseous shell always has one or several apertures in it, termed *cloaca*, through which any purulent matter and small particles of dead bone find their way to the outside of the new bony formation, whence they pass through the fistulae, and are discharged.—Ed.

† Pathological and Surgical Obs. on the Diseases of the Joints, 2d ed. Caries, in the sense of ulceration of bone, is, as Dr. Cumin has correctly observed, of two kinds. In the *first*, a process of destruction is going forward, without any attempt to repair the injury. In the *second*, the process of absorption of the osseous substance is accompanied by the formation of a new bony deposit, which is much more irregular in its arrangement, and imperfect in its organization, than the original bone. The first is named by Dr. Cumin *caries expedens*; the second, *caries ossificans*. A simple absorption of bone, unaccompanied with the secretion of pus, he terms *osteo-anabrosis*. "Instances of this affection are presented by bones which have suffered from the pulsating action of aneurismal tumours; and remarkable examples of the disease have been occasionally met with in the bones of the cranium. Mr. Russell has detailed several cases, in which portions of bone were separated by this process of erosion. He has also seen the absorption proceed in such a manner as to leave an aperture in the cranium, without the separation of any bone, or any appearance of ulceration.—

GENUS XIII.

ULCUS.

ULCER.

A PURULENT OR ICHOROUS SORE, PRODUCED BY THE SEPARATION OF A DEAD PART; BY THE BURSTING OF AN ABSCESS; BY A WOUND THAT HAS SUPPURATED; OR BY THE PROCESS OF ULCERATION.

THIS genus of diseases is, in every species, a subject of manual attention, and chiefly to be remedied or cured by external means. Its mode of treatment, therefore, must be learned under a course of surgical lectures; and it is only noticed in the present place, to show the exact station which it ought to bear in a general system of nosology founded on a physiological basis. *Ulcus* is, strictly speaking, a Greek term, with a mere change of one convertible vowel for another, to give it more of a Latin form: the derivative noun being *ἔλκος*, probably, as conjectured by Eustathius, from *ἐλκω*, "traho," in the sense of "distraho," hereby producing what the Greeks called a *λῶσις συνεχέλης*, which is, literally, a "solution of continuity."

Ulcers have been treated of by different writers under a great variety of divisions and subdivisions; sometimes as being connected with the state of the constitution, or as being a mere local disease; sometimes as recent or chronic; and sometimes as mild or malignant: but, as local ulcers may become constitutional, the constitutional may assume various forms, the recent be rendered chronic, and the mild and the malignant change places, none of these characters are calculated for clear or permanent distinction. And hence another principle has been appealed to in the volume of Nosology, derived from the variety of their external form, and they have been contemplated under the following species:—

1. *Ulcus Incarnans.* Simple Healing Ulcer.
2. — *Vitiosum.* Depraved Ulcer.
3. — *Sinuosum.* Sinuous Ulcer.
4. — *Tuberculosum.* Warty Excrescent Ulcer.
5. — *Cariosum.* Carious Ulcer.

SPECIES I.

ULCUS INCARNANS.

SIMPLE HEALING ULCER.

THE DISCHARGE PURULENT, THE SURFACE HEALTHY AND GRANULATING.

WHEN an ulcer assumes this form, it is hardly

(Edin. Med. Chir. Trans., vol. i., p. 74.) A remarkable instance of the same disease is given by Mr. Wilmer from the practice of Mr. Harrold. —(Cases and Remarks, p. 40.) It is by the process of *osteo-anabrosis*, that nature produces the removal of the milk teeth; and a corresponding disease is sometimes met with in the adult, where the teeth become loose, and, when extracted, their fangs are found extensively absorbed, although by no means in a state of ulceration.—(Cumin, in Edin. Med. Journ., No. lxxxii., p. 8.) When a fungous tumour grows from the dura mater, the superincumbent part of the skull is generally absorbed without suppuration, and the swelling projects under the scalp.—Ed.

to be called a disease; being nothing more than the ordinary process of the remedial power of nature to restore the substance that has been lost by external violence, or some internal morbid action, and to endow it with the same attributes of vascularity, feeling, and motion. It is to this form that all the other species of ulcer must be reduced, before a cure can be accomplished or hoped for. Even the surgeon has here little upon which to employ himself; for with cleanliness, a light and easy dressing, plain, unirritating diet, and regular hours, the processes of incarnation and cicatrization, which we have already explained under the genus *APOSTEMA*, will proceed spontaneously and without obstruction, and a cure be speedily completed.

SPECIES II.

ULCUS VITIOSUM.

DEPRAVED ULCER.

WITH A VITIATED SURFACE AND SECRETION.

THIS degenerate condition exhibits itself under various forms, and results from various causes. The modifications most worthy of notice are the following:—

- α Callosum. The edges indurated and retracted.
Callous ulcer.
- β Spongiosum. With fungous or spongy excrescences, often from a medullary base.
Fungous ulcer.
- γ Cancrosum. With a hard, livid, lancinating, irregular, and frequently bleeding tumour at its base.
Cancerous ulcer.

The causes in each of these may be constitutional or local; and, in managing the ulcer, it is of great importance to determine this point; for the patient may otherwise be put very needlessly upon a long course of alterants, or may omit such a course when absolutely necessary. If there be a cancerous, a scrofulous, a scorbutic, a venereal, or any other constitutional disorder, it will be imperative upon us to pursue the respective modes of treatment already laid down for these several complaints, since otherwise no topical applications can be of the least avail.

There may be also a considerable degree of constitutional debility and relaxation, to which the depraved state of the ulcer is owing; and, in truth, this is the most common of all the constitutional causes, and one which demands quite as much attention as any of the rest. In treating of abscess, we endeavoured to show that one of the uses of pus is to promote the formation of healthy granulations; and in treating of inflammation, we observed that a certain degree of vigorous and entonic, as well as inflammatory action, is necessary for the secretion of that fluid. And hence, if the system be without this condition, the ulcer cannot heal; and, instead of genuine pus and healthy granulations, we shall find a watery, ichorous fluid poured forth, of no advantage whatever, and often of an acrimonious quality, that irritates and thickens, and sometimes erodes and extends the edges of the ulcer; or a thin imperfect pus, accompanied with flabby

and fungous granulations, that sprout up, indeed, rapidly and luxuriantly, but want firmness of texture, show a weak and morbid sensibility, and bleed and die away almost as soon as they are formed.

Where this is the case, the ulcer, whatever modification it assumes, can only be brought into a healing train by increasing the health and vigour of the constitution. This, however, it is often difficult to accomplish; for, in very numerous instances of obstinate ulcers, we find the constitution has been exhausted and worn out by hard labour, hard drinking, or protracted exposure to a tropical sun, and is labouring under a long train of dyspeptic, hepatic, or podagral symptoms. It is not necessary to repeat the plan it will be incumbent upon us to pursue under these circumstances, as we have already detailed it under the constitutional affections themselves. And if, by persevering in such general treatment, we can give to the constitution a sufficient degree of vigour, the only difficulty we shall have to encounter is the vitiated state, and perhaps habit, to which the ulcer has been reduced in consequence of the constitutional affection.

We hence come to the local treatment of ulcers, which forms a direct branch of surgical, and even manual attention. And I shall hence only further observe, that the principles which seem to have been productive of the best success, are those of changing the nature of the vitiated action, by a local application of irritants;* and increasing the tone of the vessels by warm suppuratives and astringents, and the pressure of elastic bandages, which should be made of calico or the finest flannel. Mr. Baynton preferred the former on every occasion, as less cumbrous and more cleanly, and as being "a better conductor of that morbid heat which so constantly affects inflamed parts." In many cases, however, and particularly in cold, œdematous limbs, it is rather desirable to accumulate than to carry off heat; and here the use of flannel will be preferable to that of calico: it possesses, moreover, more elasticity, and, when thin and fine, is neither more cumbrous nor more uncleanly.

Formerly, the actual cautery was frequently used in this country, as it is now abroad, as the most effectual as well as the shortest means of extirpating cancerous scirrhusities about the lips and other parts of the surface. And it is sometimes considered peculiarly calculated for radically destroying many of those irregular and spongy excrescences, which have a tendency to bleed freely from the slightest cause.

Fungus hæmatodes, classed in the present system with ulcers, has been regarded by some writers, and especially by M. Roux, as a soft and fungous cancer; but it seems to be without any of the pathognomonic signs by which cancers are distinguished. It is not known to be hereditary, nor to become scirrhus in any

* Extensive experiments with kreosote have proved this agent to be very valuable for this purpose.—D.

stage,* nor does it chiefly affect a glandular situation.

[Although fungus hæmatodes was in former days generally confounded with cancer, it is a disease of a very peculiar nature. Instead of being hard and unyielding, like a scirrhus tumour, it is generally soft and elastic. Instead of being intersected by the same kind of ligamentous fibres or bands which exist in a scirrhus, fungus hæmatodes consists of a soft pulpy matter, which mixes readily with water, and is hardened by acids or by being boiled in water. When the skin gives way, instead of the morbid growth being destroyed by ulceration, as in cancer, a quick-growing fungus arises from it, and the tumour increases with augmented rapidity. Fungus hæmatodes, instead of having a firm texture like the fungus of a cancerous ulcer, is a dark-red or purple mass, of an irregular shape and of a soft texture, easily torn, and bleeding profusely when slightly injured. A cancer, in its primary form, seems to be confined to certain organs and textures; and, while in some of these fungus hæmatodes, in its primary state, has not been seen, it has been detected in other parts where no truly cancerous disease has ever been noticed. While cancer is also rather a disease of advanced life, many of the patients attacked by fungus hæmatodes are young.—(See *Wardrop on Fungus Hæmatodes*, chap. xii., and *First Lines of the Practice of Surgery*, p. 215, 5th edit.) No remedy, external or internal, seems to have the power of checking this formidable disease. Abroad, the actual cautery has indeed been alleged sometimes to have answered; but in this country, all escharotics, and even concentrated sulphuric acid, have been found incapable of destroying the fungus as fast as it is regenerated. The only chance of cure depends upon the early removal of the whole of the disease by amputation or excision; but even this is frequently impracticable, in consequence of the particular seat of the disease; and often unavailing, on account of so many parts being affected, that the disease may be said to pervade the system.†]

In the treatment of depraved ulcers, some practitioners depend almost entirely for the cure on a restoration of the constitutional health; and contend that, with the accomplishment of this, the remedial power of nature is adequate to all the rest, with local cleanliness, rest, and the use of warm or cold water, according to the nature of the case. Such especially is the practice of

* These observations are partly incorrect. Sir Astley Cooper mentioned a case to the editor a little while ago, where a lady, after having had a scirrhus breast removed, died of a fungus hæmatodes. Professor Carswell, as already noticed in the section on Carcinus, regards fungus hæmatodes as a species of carcinoma; and he speaks of the two diseases as occasionally met with together, not only in the same individual, but in the same organ.—See his *Illustrations of the Elementary Forms of Disease*, 4to., Lond., 1833.—Ed.

† The material deposited in scirrhus is not disposed to become organized, and vessels are rarely perceptible in it; but the brain-like substance of fungus hæmatodes abounds with them.—Ed.

Professor Kern in the Imperial Hospital at Vienna, who makes a boast of proscribing ointments, plasters, lotions, charpie, caustics, and even bandages themselves, except in a few cases, trusting entirely to the use of water and a simple covering of linen, and this too even in gangrenous, scrofulous, and venereal ulcers.—(*Ann. der Chirurg. Klinik*, 2 vols., 8vo., Wien., 1809.) This practice is too simple to become very popular, but his success is undisputed.

SPECIES III.

ULCUS SINUOSUM.

SINUOUS ULCER.

COMMUNICATING WITH THE NEIGHBOURING PARTS BY ONE OR MORE CHANNELS.

We have already seen that inflammations of every kind propagate themselves by continuous sympathy, and hence one cause of the spread of those that are ulcerated. But ulcerative inflammations do not spread equally; for those parts are most subject to their action, and consequently give way soonest, where the living principle is weakest, or the structure is most loose and cavernous. And hence a more frequent origin of hollows and sinuses in the cellular substance, particularly in the more dependant parts, as about the rectum and the urethra.

When these sinuosities are first formed or scooped out, their walls are soft, irritable, and of the common cellular web; but when they have remained for a considerable period of time, they become callous and insensible, forming the two following varieties, noticed in the volume of Nosology:—

- | | | |
|---|------------------|------------------------------------|
| a | Recens. | The channel fresh and yielding. |
| | Recent sinus. | ing. |
| β | Fistulosum. | The channel chronic and indurated. |
| | Fistulous sinus. | durated. |

The form assumed by a sinus is determined by the course of the probe; its capacity, by the quantity of water or any other fluid it will contain, when injected by a syringe.

Three modes of cure have been attempted: that of incarnation, or filling up the hollow by sound granulations issuing from the bottom; that of coalition, or a union of the walls of the sinus; and that of destroying it, by an opening down its entire length. The first is sometimes accomplished by warm lotions, where the sinus is shallow. The second is more usually had recourse to where it is deeper; and attempted first by irritant and even erosive injections, so as to excite a new inflammation down the whole course of the canal; and afterward by pressure, applied at first to its lowest part, and advanced gradually to its mouth; or, which is better, by a seton passed from the orifice of the ulcer to the utmost depth of the sinus, leaving here an opening sufficiently large for the escape of whatever matter might otherwise collect and become stagnant. The third mode of cure is effected by the knife; and where unaccompanied with danger or inconvenience from the vicinity of large bloodvessels, is by far the speediest and most decisive of the whole.

SPECIES IV.

ULCUS TUBERCULOSUM.

WARTY EXCRESCENT ULCER.

WITH TUBERCULOUS EXCRESCENCES, AND RAGGED AND SPREADING EXULCERATIONS.

THIS is the *NOLI ME TANGERE* (*Dartre Rongeante* of M. Alibert) of many writers, and the *LUPUS* of others; evidently referring to its unmanageable character, and the ravenous or wolf-like ferocity with which it preys on the neighbouring organs, spreading in ragged and fungous lobes, or with cracking and callous edges, and destroying the skin through an extensive range, and sometimes even the muscles, to a considerable depth.

A valuable practical paper upon this disease (*Phil. Trans.*, vol. xlix., year 1755) was addressed to the Royal Society by M. Daviel, surgeon to Louis XV. of France; who describes it as a cancer, to which, indeed, from its tendency to ramify, and the virulence of its discharge, it has some resemblance; and whence Sauvages denominates it *cancer lupus*. [The disease generally commences on the alæ of the nose, with small tubercles, which gradually change into ulcerations. These throw out a discharge, which dries and produces scabs, under which the sores are sometimes much concealed, and burrow more deeply into the part. In general, a portion of the disease will be healing, while another is extending itself; and afterward, the parts previously healed break out again. In this manner all the skin of the nose suffers, and sometimes other parts of the face: in bad cases, even the cartilages are destroyed, and little of the nose is ultimately left but its bridge. According to Dr. Bateman, the disease sometimes appears on the cheek, in the form of a sort of ringworm, destroying the substance, and leaving a deep and deformed cicatrix; and he had seen a similar circular patch of the disease dilating itself at length to the extent of a hand-breadth or more over the pectoral

muscle.—(*Bateman's Cutaneous Diseases*, p. 296, 3d ed., 1814.)]

When the case is recent, and there is no morbid irritability in the habit, the diseased action has yielded to a skilful application of counter-stimulants, as a dilute solution of the nitrate of silver or aromatic vinegar; after which the tar ointment has been found most serviceable.

[In particular examples, the most successful local applications have been solutions of arsenic or sulphate of copper, and the unguentum hydrargyri nitratis. Frequently, however, nothing will avail without internal alterative medicines, such as the compound decoction of sarsaparilla, nitrous acid, the muriate of barytes; and, above all, the liquor arsenicalis. In obstinate cases, the practice of dissecting away all the diseased parts has sometimes been adopted.]

SPECIES V.

ULCUS CARIOSUM.

CARIOUS ULCER.

THE ULCER EXTENDING INTO THE SUBSTANCE OF THE SUBJACENT BONE

WHEN a portion of a bone is killed by an ulcerative process commencing in itself, it forms, as we have already observed, a *CARIES* properly so called. When it is destroyed by the spread of a sore commencing in the integuments or muscles above it, the disease is called a *CARIOUS ULCER*; and when the ulceration extends to the medulla of the bone, it is often denominated an *arthrocace*.

Upon this subject, however, it is not necessary to enlarge in the present place, as we have already discussed the general nature and the ordinary forms of ulceration under the *SECOND SPECIES* of the genus before us; and the mode by which the death and separation of one portion of bone from another are effected, under the *FOURTH SPECIES* of the preceding genus.

CLASS IV. NEUROTICA.

DISEASES OF THE NERVOUS FUNCTION.

ORDER I.

PHRENICA.

AFFECTING THE INTELLECT.

" II.

ÆSTHETICA.

AFFECTING THE SENSATION.

" III.

CINETICA.

AFFECTING THE MUSCLES.

" IV.

SYSTATICA.

AFFECTING SEVERAL OR ALL THE SENSORIAL
POWERS SIMULTANEOUSLY.

CLASS IV.

PHYSIOLOGICAL PROEM.

THE numerous and complicated train of diseases we are now entering upon, appertains to the highest function of visible beings: the possession of which emphatically distinguishes animals from plants, and the perfection of which as emphatically distinguishes man from all other animals: these are diseases of the NERVOUS FUNCTION; which, in the sphere of its activity, embraces the powers of intellect, sensation, and muscular motion. Each of these powers evinces diseases of its own, and will consequently lay a foundation for a distinct order under the class before us. While, as there are also other diseases that affect several of them simultaneously, we become furnished with a fourth order, which will complete the series.

All these diversities of vital energy are now well known to be dependant on the organ of the brain,* as the instrument of the intellectual powers, and the source of the sensific and motory. Though, from the close connexion and synchronous action of various other organs with the brain, and especially the thoracic and abdominal viscera, such diversities were often referred to several of the latter in earlier ages,

and before anatomy had traced them satisfactorily to the brain as the fountain-head. And of so high an antiquity is this erroneous hypothesis, that it has not only spread itself through every climate on the globe, but still keeps a hold on the colloquial language of every people; and hence the heart, the liver, the spleen, the reins, and the bowels, generally, are among all nations regarded either literally or figuratively as so many seats of mental faculties or moral feeling. We trace this common and popular creed among the Hebrews and Arabians, the Egyptians and Persians, the Greeks and Romans; among every savage as well as every civilized tribe; nor is there a dialect of the present day that is free from it: and we have hence an incontrovertible proof that it existed as a doctrine of general belief at a time when mankind, few in number, formed a common family, and were regulated by common notions.

The study of anatomy, however, has corrected the loose and confused ideas of mankind upon this subject; and while it distinctly shows us that many of the organs popularly referred to as the seat of sensation do and must, from the pe-

* Perhaps, instead of the expression, "organ of the brain," it would be more correct to say, "nervous system;" for it is not every animal that has a brain, and certain functions of the nerves, even in the human subject, seem to be independent of this organ. "A nervous system appears essentially composed of two parts: of a central organ, consisting of two cords; one corresponding with either half of the body, upon which nodular masses

are generally placed; and secondly, of other cords, called nerves, derived from the central organ to the sentient surfaces, or contractile parts of the animal. In the star-fish, a radiated animal, the central organ consists of a ring of white nervous matter, which surrounds the orifice of the stomach, and gives off opposite to the centre of each ray nerves for its supply."—See Mayo's *Outlines of Physiology*, p. 252, 2d edit., 1828.—Ed.

cularity of their nervous connexion with the brain, necessarily participate in the feelings and faculties thus generally ascribed to them, it also demonstrates that the primary source of these attributes, the quarter in which they originate, or which chiefly influences them, is the brain itself.

We are speaking, however, of man and the higher classes of animals alone: for, as the scale in animal life descends, the organ of a brain is perpetually diminishing in its bulk, till at length it totally disappears, and its place is supplied by other fabrications, as we shall have occasion to observe in the sequel of this introduction: which will lead us to take a brief notice of the following subjects:—

- I. The General Nature of the Brain, its Ramifications and Substitutes.
- II. The Principle of Sensation and Motion.
- III. The Intellectual Principle.

I. In man, and those animals whose encephalon approaches the nearest to his in form, the brain is of an oval figure, surrounded by various membranes of different firmness and density, and consists of three principal divisions: the cerebrum, or brain, properly so called, the cerebellum, or little brain, and the oblongated marrow. The first forms the largest and uppermost part: the second lies below and behind; the third lies level with the second, and in front of it; it appears to issue equally out of the two other parts, and in turn to give birth to the spinal marrow; which may hence be regarded as a continuation of the brain, communicating with its different parts by the aid of numerous commissures, the *quærbänder* of the German writers, and extended through the whole chain of the back-bone. They are similarly accompanied with a cineritious or ash-coloured substance, which forms the exterior of the three first divisions, but the interior of the spinal marrow, and appears to derive its hue from the great number of minute vessels that appertain to it.

It is still, however, a contested opinion, as it was among the Greek physiologists, whether the brain or the spinal marrow be the parent organ. Vesalius, Fallopius, Winslow, Haller, and Portal, concur with Galen in regarding the spinal marrow as an appendix of the brain. Malpighi, Reil, Tiedemann, and Gall, contend, on the contrary, as Plato and Praxagoras contended formerly, that the brain is an efflorescence of the spinal marrow, which takes the lead in the process of organization: while M. de Serres has still more lately thrown out a third hypothesis, and derived not only each of these organs from a different source, but even the cerebellum as well: the spinal marrow issuing from the intercostal arteries, the cerebellum from the vertebral, and the proper brain from the carotids. Time alone, and more minute examination, must settle these discrepancies.*

According to Mr. Bauer's very delicate microscopic experiments, when the substance of

the brain is made a subject of examination immediately after death, "abundance of fibres," to adopt the words of Sir Everard Home in relating these experiments, "are met with in every part of it; indeed, it appears that the whole mass is a tissue of fibres, which seem to consist entirely of an accumulation of globules, whose union is of so delicate a nature, that the slightest touch, even the mere immersion in water, deranges and reduces them to that mass of globules of which the brain appears to be composed, when examined with less accuracy, or under less favourable circumstances." Mr. Bauer found that the globules of the brain, as well as those of pus, are exactly of the same size as those of the blood when deprived of their colouring matter.—(See Sir Everard Home's *Croonian Lecture*, *Phil. Trans.* for 1818.) And hence the doctrine of Prochaska (*Op. Min.*, tom. i., p. 342) and the Wenzels (*De Structurâ Cerebri*) respecting the globular form of the ultimate particles of the brain, seems sufficiently confirmed.*

[When we cut into the interior of the brain, we find it to be composed of two substances, which differ in their colour and consistence, and are named the *cortical* or *cineritious*, and the *medullary*. The cortical, as its name imports, is on the outside, and is of a reddish-brown colour; and is softer than the medullary, and considerably more vascular. The medullary matter is, both from its aspect and relative position, generally considered as constituting the nervous substance in its most perfect state: and Gall and Spurzheim conjecture, that the use of the cineritious is to form or secrete the medullary part.—(*Recherches sur le Système Nerveux*, § 2.) The particular facts, says Dr. Bostock, from which they derive their hypothesis, are, that the nerves appear to be enlarged when they pass through a mass of cineritious matter, and that masses of this substance are deposited on all the parts of the spinal cord, where it sends out nerves. In opposition to the above opinion, however, Professor Tiedemann states, that in the fœtus the medulla is formed before the cortex; and he limits the use of the latter to the conveyance of the arterial blood, necessary to support the energy of the perfect nervous matter.†]

Sir Everard Home, from the above-mentioned microscopic disclosures, endeavours to show that muscular fibres are minute chains, formed by an attachment of one globule of blood to an-

* According to Prochaska, the nervous pulp consists of flocculi, which are composed of globules, about eight times less than the red particles of the blood (*Op. Min.*, p. 342); and this account, in its essential parts, has been confirmed by the more recent and elaborate investigations of the Wenzels.—(*De Structurâ Cerebri*, p. 24, et seq.) Bauer, whose researches confirm the existence of globules, found them larger and in greater proportion in the medullary than in the cortical substance.—See *Phil. Trans.* for 1818 and 1821; also, Bostock's *Physiology*, vol. i., p. 234.—Ed.

† See *Anatomie du Cerveau*, traduite par Jourdan, p. 128; Bostock's *Physiology*, vol. i., p. 223; Magendie, *Physiologie*, tom. i., p. 162, &c.

* Paragraph found among the author's MSS. subsequently to the publication of the third edition.

other; and that vascularity in coagula or extravasated blood, or in granulations produced by pus, is effected by the escape of minute bubbles of carbonic acid gas from the living fluid; which hereby opens a path to a certain extent into the tenacious blood or pus that is extravasated or secreted.

From the lower part of the brain, or, according to the latest researches, rather from the medulla oblongata, and also from the spinal cord, arises a certain number of long, whitish, pulpy strings, or bundles of fibres, capable of being divided and subdivided into minuter bundles of filaments or still smaller fibres, as far as the power of glasses can carry the eye. These strings are denominated nerves; they are enclosed in sheaths of membrane; and, by their various ramifications, convey different kinds or modifications of living power to different parts of the body, keep up a perpetual communication with its remotest organs, and give motivity to the muscles. [The nerves are most copiously distributed to the organs of sense and voluntary motion; the viscera are much more sparingly supplied with them; the glands have still fewer nerves; and some of the membranous parts are sometimes conjectured to be destitute of them. Generally speaking, the nerves which supply the organs of sense proceed immediately from the base of the brain, or rather from the medulla oblongata; while most of the muscles (but not all) receive their nerves from the spinal cord. As Dr. Bostock has observed, there is more irregularity with respect to the course of the nerves which go to the viscera; they generally derive their immediate origin from some of the ganglia and plexuses forming part of the great sympathetic nerve, and they are connected with each other in a great variety of ways. The nervous system, viewed as a whole, however, and comprising the brain, spinal cord, and all their ramifications, is in general so symmetrical, that if the body were longitudinally divided into two equal halves, the arrangement of the brain and nerves in each half would, with the exception of a few deviations from this rule, caused by the situations of particular viscera, precisely correspond.—(*Bostock's Physiology*, vol. i., p. 228.)

In various examples, the fibrils of which adjacent nerves are composed are reciprocally thrown across from one to the other, forming what is termed a *plexus*. As Mr. Mayo has explained, the nerves which proceed from the further side of a plexus may be more numerous or fewer than those which enter it; but the essential result is, that nervous fibrils from different sources are brought together to form new trunks.* A ganglion is a small nodule, usually

flattened, of an oval or circular shape, and of a reddish-gray colour, which is found either on the trunk of a single nerve, or where two or more branches coalesce. Sir Charles Bell's opinion respecting the ganglions will be presently noticed. Scarpa supposes that a ganglion is but a bed of gelatinous membrane, in which the smallest fibrils of the nerves are arranged in new combinations. Others believe that nervous filaments originate in the gray matter of ganglions.—(*Mayo's Physiology*, p. 324, 2d edit.)†

As the brain consists of three general divisions, it might at first sight be supposed that each of these is allotted to some distinct purpose; as, for example, that of forming the seat of intellect or thinking; the seat of the local senses of sight, sound, taste, and smell, and the seat of general feeling or motivity. The investigations and experiments of Sir Charles Bell and M. Magendie, to which we shall presently advert, pave the way to some important doctrines in respect to a few of these points, but leave us quite in the dark with respect to various others; and particularly as to the source of intellect: while it is difficult to reconcile even the doctrines which have been thus fairly deduced with the motific, and even with the sentient powers that must exist in numerous cases of an extensive disorganization of the brain, and in acephalous animals. The first and second nerves, and the portio mollis of the seventh, sufficiently attest their exclusive uses as nerves of the special senses; while the distribution of the greater part of the third, of the fourth, and of the sixth nerve to voluntary muscles, which receive fil-

plexus is intricate in proportion to the number of muscles to be supplied, and the variety of combinations into which the muscles enter, while the filaments of nerves, which go to the skin, regularly diverge to their destination. The nerves on the face and those on the side of the neck form plexuses; but the grand plexuses are near the origins of the nerves of the upper and lower extremities. By the interchange of filaments, the combination among the muscles is formed.—See *Med. Gaz.* for Feb., 1834, p. 777; also, *Exposition of the Natural System of the Nerves of the Human Body*, 8vo., 1824.—Ed.

* "The most probable conjecture as to the use of the ganglia seems to be that they are points of nervous communication, in some respects similar to the arterial communications, as they serve to diffuse more equally the nervous influence; or to lymphatic glands, which collect parts and change their mode of distribution."—See *A Comparative View of the Sensorial and Nervous Systems in Men and Animals*, by John C. Warren, M. D., Prof. of Anat. and Surg. in Harvard University, Boston, 1822.—D.

† It is a remark made by Sir Charles Bell, that the principles and facts unfolded in his views of the nervous system, lead us to understand the "use of all the intricate nerves of the body, with the exception of the sixth. The sixth nerve stands connected with another system of nerves altogether; I mean the system hitherto called the sympathetic, or sometimes the ganglionic system of nerves; and of this system we know so little, that it cannot be matter of surprise if we reason ignorantly of the connexion of the sixth with it."—*Natural System of the Nerves of the Human Body*, p. 64.—Ed.

* In explaining the cause of the complexity of the nerves, Sir Charles Bell remarks, that some degree of irregularity in their distribution must arise from their being compound; but, says he, the principal cause is the necessity of arranging and combining a great many muscles in their different offices. Wherever we trace nerves of motion, we find, that before entering the muscles they interchange branches, and form an intricate mass of nerves, or what is termed a *plexus*. This

aments from no other source, proves clearly that these nerves are voluntary nerves, as well as conducive to muscular sensation. "Perhaps," says Mr. Mayo, "it is not unfair to argue analogically from the preceding instances, that the same surface of the brain or spinal cord furnishes to each voluntary muscle of the body its voluntary and sentient nerves, if the two are not identical."—(*Anat. and Physiol. Commentaries*, No. ii., p. 1., 8vo., Lond., 1822.) There is in like manner reason for believing that the fifth nerve, which at its origin consists of two portions, is not only a nerve of voluntary motion, but furnishes branches to the special senses, and even communicates general sensation to the muscular fibres; and that its gustatory twig is a nerve of both touch and taste at the same time.*

The remarks of Sir Charles Bell upon this subject are well entitled to attention. "The trigeminus, or fifth nerve," says he, "bestows upon all the surfaces of the head and face, external and internal, that sensibility which is enjoyed by the rest of the body through the spinal marrow" (*Phil. Trans.*, 1823, pp. 289, 290); and, in proof of this, he describes various experiments which show that, on dividing its branch to the cheek and lips, or on its destruction by disease, insensibility instantly takes place in these organs. Yet some of its branches prove motific as well as sensific, and draw the muscles of the eye into a state of mutual action to expel offensive particles that have found admission to its surface: while, of the nine nerves that proceed from the brain, constituting the whole number that thus originate, six of them are distributed in a greater or less proportion to the single organ of vision, and co-operate in giving perfection to its powers; as the third, fourth, part of the fifth, sixth, and seventh.

Several of these phenomena may indeed be resolved, though not the whole, into that close interunion which some parts of the brain maintain with other parts by means of ganglions, commissures, and decussations of nerves; whence injuries on one side are often accompanied with loss of motion or feeling in the organs of the other side. So the curious and ingenious experiments instituted by Dr. Philip (*Phil. Trans.*, 1815, pp. 5-90), and to which we shall have occasion to return presently, sufficiently prove, that stimuli of a certain kind, as spirit of wine, applied to the posterior part of the naked brain

of an animal, produce the same effect on the heart, and equally increase its action, as if applied to the anterior part. To affect the heart, however, it seems necessary that the stimulus should spread over a pretty large extent of the brain; so as to take in, by the range of its excitement, some of the ganglions of the brain, whose office, as Dr. Philip conceives, is "to combine the influence of the various parts of the nervous system from which they receive nerves, and to send off nerves endowed with the combined influence of those parts."* He hence accounts for some organs of the frame being affected by every part of the nervous system, and others by only certain small parts of it; and the wide influence possessed by the great sympathetic nerve, which is less a single nerve than a string of ganglions. We are also hereby shown why the intestines, like the heart, sympathize with every portion of the nervous system.

From all this, however, it is clear, that there, is much yet to be learned concerning the actual arrangement of the brain, or of its partition into three divisions, and of the respective shares which the different parts take in producing a common effect: and consequently it seems to be altogether a wild and idle attempt to subdivide these perceptible regions of the brain into still smaller and merely imaginary sections, and to allot to each of them a determinate function and faculty.

That a sensorial communication, however, is maintained between some part or other of the brain and every part of the body, and that this communication is conducted by the nerves, is unquestionable from the following facts:—If we divide, or tie, or merely compress a nerve of any kind, the muscle with which it communicates becomes almost instantly paralytic; but upon untying or removing the compression, the muscle recovers its appropriate feeling and irritability. If the compression be made on any particular part of the brain, that part of the body becomes motionless which derives nerves from the part compressed. And if the cerebrum, cerebellum, or medulla oblongata be irritated, excruciating pain or convulsions, or both, take place over the whole body; though

* *Phil. Trans.*, 1815, p. 436. An opinion formerly prevailed, that ganglia were intended to cut off sensation; but Sir Charles Bell noticed that every one of the nerves, which he took to be instruments of sensation, had ganglia on their roots. "Some very decided experiment," he says, "was necessary to overturn this dogma. I selected two nerves of the encephalon; the fifth, which had a ganglion, and the seventh, which had no ganglion. On cutting across the nerve of the fifth pair on the face of an ass, it was found that the sensibility of the parts to which it was distributed was entirely destroyed. On cutting across the nerve of the seventh pair on the side of the face of an ass, the sensibility was not in the slightest degree diminished. By pursuing the inquiry, it was found that a ganglionic nerve is the sole organ of sensation in the head and face; and thus my opinion was confirmed, that the ganglionic roots of the spinal nerves were the fascies or funiculi for sensation."—C. Bell's *Nat. Syst. of the Nerves*, p. 34.—Ed.

* The fact of the same nerve seeming to answer both for motion and sensation, is accounted for by the important discoveries of Sir Charles Bell and M. Magendie. Mr. Mayo's experiments and arguments tend to prove that "the ganglionic portion of the fifth, and the hard portion of the seventh nerve, are voluntary nerves to parts, which receive sentient nerves from the larger or ganglionic portion of the fifth." By the expression *sentient nerves*, Mr. Mayo means those, the division of which is followed by instantaneous loss of sensation in a part; by *voluntary nerves*, he means those upon the division of which the will ceases to influence the muscles they supply.—*Outlines*, &c., p. 331, &c.—Ed.

chiefly when the irritation is applied to the last of these three parts.* For, according to the laws of the nervous action, as collected from a variety of experiments by Dr. Philip (*Phil. Trans.*, 1815, p. 444), and stated in a subsequent paper to that just referred to, "neither mechanical nor chymical stimuli (irritating the brain by a knife, or pouring spirits of wine upon it) applied to the nervous system excites the muscles of voluntary motion, unless they are applied near to the origin of the nerves and spinal marrow." It is from the medulla oblongata that all the nerves of respiration take their rise; and hence, any sudden injury or accident that interrupts its course, by putting a close to the respiration, induces death instantly.—(*On the Nerves, &c.*, by Sir Charles Bell, *Phil. Trans.*, 1822, p. 284.)

The nerves issue in pairs, one of each pair being allotted to either side of the body. The whole number of pairs is forty, of which nine rise immediately from the great divisions of the brain under which we have just contemplated it, and are chiefly, though not wholly, appropriated to the four local senses; and thirty-one from the spinal marrow.

We have thus far represented the spinal marrow as issuing from the brain, in conformity with the general doctrine that has hitherto been held upon the subject. It has of late years, however, been contended by various physiologists (*Tiedemann, Anatomie du Cerveau, trad. par A. J. Jourdan, &c.*, Paris, 1823; *Serres, Anat. Comparée du Cerveau, &c.*), and particularly by Drs. Gall and Spurzheim, that the spinal marrow itself is the origin or trunk of the nervous system, and that, instead of issuing from the brain, it gives birth to it. The argument is derived from the existence of a spinal marrow alone in acephalous monsters, and a nervous cord without a brain, answering the purpose of a spinal marrow, in most invertebral animals. Whence it is inferred that the nervous column is the radical part of the system, and that the brain is an increment from it in the more perfect classes.†

The question is not of much importance, though there is something ingenious in thus tracing animal life from its simpler forms. Yet the opinion seems to be in direct opposition to a well-ascertained fact we shall have to advert to presently, namely, that the magnitude of the brain and the extent of its intellectual powers hold an inverse proportion to the size of the spinal marrow, and consequently, upon this hypothesis, to their apparent means of supply. Nor

is it the mode of induction usually adopted by physiologists on like occasions; since they generally describe the arteries as issuing from the heart, instead of giving rise to it, notwithstanding that the heart, like the brain, has been found totally wanting in some monsters, and the circulation carried on by an artery and a vein alone, of which Mr. Hewson gives a very singular instance (*On the Lymph. Syst.*, part ii., p. 15); and that most of the worm genera are equally without a heart, though they are in possession of circulatory vessels. We only see in these arrangements, that neither a brain nor a heart is essentially necessary to animal life: and that the great Author of nature is the Lord, and not the slave of his own laws; and is capable of effecting the same general principle by a ruder, as well as by a more elaborate design.

There is one part, however, of the system of nervous power, in the more perfect classes of animals, that is particularly worthy of our attention, as furnishing a rule peculiar to itself, and being without a parallel in any other part; and that is, the origin, structure, and extensive influence of the great sympathetic or intercostal nerve, which forms a kind of system in itself, an epicycle within the two cycles of cerebral and vertebral influence. It is connected both with the brain and spinal marrow, and may be said to arise from either. Admitting the brain to be its source, it is an offset from the sixth pair of nerves on either side, and in its course receives a small tributary twig from the fifth, and branches from all the vertebral, from whose union and decussation it is studded with numerous ganglions or medullary enlargements, of which there are not less than three in the neck alone, tinted by an addition of cineritious substance, a larger number in its line through the chest, and others as it descends still more deeply, independently of various confluences of smaller branches that unite and form extensive networks. Having reached the hollow of the os coccygis, it meets its twin from the opposite side, which has pursued a similar course, and been augmented by similar contributions.

Thus equally enriched with the nervous stores of the brain and the spinal marrow, it sends off radiations, as it takes the course of the aorta, to all the organs of the thoracic, abdominal, and hypogastric regions, to the lungs, the heart, the stomach and intestines, the bladder, uterus, and testes; and thus becomes an emporium of nervous commerce, and an instrument of general sympathy: and, what is of infinite importance in so complicated a frame as that of man, furnishes to the vital organs streams of nervous supply from so many anastomosing currents, that if one, or more than one, should fail or be cut off, the function may still be continued. To this it is owing, in a very considerable degree, that the organs of the upper and lower belly exhibit that nice fellowship of feeling which often surprises us, and that most of them are apt to sympathize in the actual state of the brain.

There is no animal whose brain is an exact counterpart to that of man: and it has hence been conceived, that by attending to the dis-

* Some of the observations of Flourens and Hertwig on this subject will be presently noticed.—ED.

† *Anatomie et Physiologie du Système Nerveux, &c.*, par. F. J. Gall et G. Spurzheim, 4to., Paris, 1810. The later investigations of Tiedemann and Serres into the development of the nervous system of the human foetus, represent the spinal cord, the medulla oblongata, the cerebellum, and the cerebrum, as formed in the succession here specified.—Béclard, *Additions à Bichat*.—ED.

inctions between a human brain and that of other animals, we might be able to unfold a still more mysterious part of the animal economy than that of sensation or motion, and account for the superior intellect with which man is endowed.

But the varieties are so numerous, and the parts which are deficient in one animal are found connected with such new combinations, modifications, and deficiencies in others, that it is impossible for us to avail ourselves of any such diversities.

[The principle of improvement in the nervous system, throughout the ascending scale of animals, is the progressive accumulation of nervous matter in larger masses upon that part of the central organ which is nearest the head or mouth. In proportion as this alteration from the simplest type of organization is effected, the animal becomes more and more individualized, portions separated from it are found to be less capable of independent existence, and the destruction of one organ is observed to produce more derangement of the rest.—(See *Mayo's Outlines of Human Physiology*, p. 257, 2d ed.)]

Aristotle endeavoured to establish a distinction, by laying it down as a maxim that man has the largest brain of all animals in proportion to the size of his body; a maxim which has been almost universally received, from his own time to the present period. But it has of late years, and upon a more extensive cultivation of comparative anatomy, been found to fail in various instances: for, while the brain of several species of the ape kind bears as large a proportion to the body as that of man, the brain of several kinds of birds bears a proportion still larger. Söemmerring has carried the comparison through a great diversity of genera and species: * but the following brief table will be sufficient for the present purpose. The weight of the brain to that of the body forms

In man from	1-22 to 1-33 part.
Several simiæ	1-22
Dog	1-101
Elephant	1-500
Sparrow	1-25
Canary-bird	1-14
Goose	1-360
Turtle (smallest)	1-5688

Söemmerring has hence endeavoured to correct the rule of Aristotle by a modification under which it appears to hold universally; and, thus corrected, it runs as follows: "Man has the largest brain of all animals in proportion to the general mass of nerves that issue from it." Thus, the brain of a horse gives only half the weight of that of a man, but the nerves it sends forth are ten times as bulky. The largest brain

* Diss. de Basi Encephali, Götting., 1778, 4to. G. R. Treviranus has given the results of a series of observations on the relative weight and breadth of the brain to that of several of its parts in different mammiferous animals; also a table of the proportion of the several parts of the brain to the greatest breadth of the spinal cord. The particulars may be found in the *Edin. Med. and Surgical Journ.* for January, 1829.—Ed.

which Söemmerring ever dissected in the horse kind weighed only 1 lb. 4 oz., while the smallest he has met with in an adult man was 2 lb. 5½ oz.

But the remark applies farther than to man: for this acute physiologist has been able to trace a direct proportion between the degree of intelligence in every class of animals and the bulk of the brain, where the latter bears an inverse proportion to the nerves that arise from it. And we may hence observe, in passing, as, indeed, we have already hinted, that the nerves seem rather to be a product of the brain, than the brain of the nerves: for it is much more easy to conceive how a fountain may become exhausted in proportion to the magnitude of its streams, than how a reservoir can be augmented in proportion to the minuteness of its channels.*

Upon a general survey I may observe, that the nervous structure of all vertebral animals, comprising the first four classes of the Linnæan classification, mammals, birds, amphibians, and fishes, is characterized by the two following properties:—Firstly, the central organ of the nervous system consists of a brain, with a long cord or spinal marrow descending from it; and, secondly, that both are securely enclosed in a bony case or covering.

In man, as I have already observed, the brain is (with a few exceptions) larger than in any other animal in proportion to the size of the body; and, without any exception whatever, in proportion to the size of its dependent column.

In other animals, even of the vertebral classes, or those immediately before us, we meet with every variety of proportion, from the ape, which in this respect approaches nearest to that of man to tortoises, and fishes, in which the brain does not much exceed the diameter of the spinal marrow itself.

It is not, therefore, to be wondered at, that animals of a still lower description, and without a vertebral column, should exhibit proofs of a nervous cord or spinal marrow, without a brain of any kind at the top; and that this cord should even be destitute of its common bony defence. And such is actually the conformation of the nervous system in insects, and, for the most part, in worms; neither of which are possessed either of a cranium or a spine; and in none of which we are able to trace more than a slight enlargement of the superior part

* The doctrine that the nerves arise from or are a production from the brain, has of late years been considerably weakened, if not quite refuted, by various facts, among which it is only necessary to mention here the existence of nerves in acephalous monsters. One of the most interesting cases of this kind formed the subject of a memoir, published not long ago by M. Spessa, surgeon of Treviso. A female infant was born totally destitute of brain, cerebellum, and medulla oblongata. It was not at all under the ordinary full size of a child at birth, being a foot in length; and, notwithstanding its acephalous condition, it exhibited, directly after birth, manifest signs of life, for it breathed, cried, and moved its limbs. The heart and arteries pulsated in the usual manner. The infant suddenly ceased to live at the end of eleven hours.—See *Lond. Med. Gaz.*, vol. xi., p. 559.—Ed.

of the nervous cord, or spinal marrow, as it is called, in animals possessing a spine; often consisting of one, and sometimes of two ganglions, designed, apparently, to correspond with the organ of a brain; the descending column chiefly taking the course of the œsophagus, and surrounding it. The nervous cord however, in these animals, is proportionally larger than in those of a superior rank; and though sometimes simple, as in molluscous worms, in other cases, as in insects, is possessed at various distances of minuter ganglions, or little knots, from which fresh ramifications of nerves shoot forth like branches from the trunk of a tree, and which have sometimes been regarded as so many distinct cerebels, or little brains: having a close resemblance to the subordinate system of the intercostal nerve in man, as we have already traced it in its various ramifications and connexions.*

In worms of apparently the simplest make, as zoophytes and infusory animals, no distinct structure can be discerned, and particularly nothing like a nervous system. The hydra, or nearly transparent polypus, found so frequently in the stagnant waters of our own country, with a body of an inch long, and arms or tentacles in proportion, seems, when examined by the largest magnifying glasses, to consist of a congeries of granular globules or molecules, not unlike boiled sago, surrounded by a gelatinous substance; in some tribes solitary, in others catenated. And hence, whatever degree of sensation or voluntary motion exists in such animals, can only be conceived as issuing from these molecules acting the part of nervous ganglions, detached or connected. And on this account M. Virey has elegantly divided all animals into three classes, according to the nature of their nervous configuration; as, first, animals with two nervous systems, a cerebral and sympathetic, including

mammals and birds, amphibians and fishes. Secondly, animals with a sympathetic nervous system alone, surrounding the œsophagus, as mollusca and shellfishes, insects and proper worms. And, thirdly, animals with nervous molecules, as echini, polypes, and infusory animalcules, corals, madrepores, and sponges; all which, in M. Virey's classification, are included under the term zoophytes.*

The only sense which seems common to animals, and which pervades almost the whole surface of their bodies, is that of general touch or feeling; whence M. Cuvier supposes that the material of touch is the sensorial power in its simplest and uncompounded state, and that the other senses are only modifications of this material, though peculiarly elaborated by peculiar organs, which are also capable of receiving more delicate impressions.† Touch, however, has its

* When the nerves, the spina marrow, and medulla oblongata (as Mr. Mayo observes) are proved to be sufficient for the continuance of sensation, volition, and the commonest instincts, we naturally suppose that the cerebral masses which seem to grow in the scale of animals with their approximation to reason, are the seat of the higher affections of the mind. When, indeed, we read over an enumeration of the different affections of consciousness, and compare the phenomena of the mind with the anatomy of the brain, we see not the most remote correspondence between the structure of the organ and the mutual dependance of the mental phenomena. When, again, we compare the brain in man with the brain in the higher animals, we are surprised to find exactly the same complexity of structure, the same series and order of internal parts, the same general exterior structure in both. The brain, however, in the higher animals (contrasted with their other organs in general, and their spinal cord and medulla oblongata in particular) is relatively smaller than in man, and its external structure much less complicated. The brain of the monkey, for example, has the internal parts of the same general form with those of the human brain; but the surface of the hemispheres, instead of the numerous intricate furrows and sinuosities, by means of which the quantity of cineritious matter upon the cerebrum and cerebellum in man is so prodigiously increased, exhibits but a few straight depressions, and has proportionately a vastly less extent of the cortical superficies, and of the immediate medullary substratum. "It is here, then, that we are tempted to place the seat of reason; and, as it appears that the human brain excels that of the monkey by the number and intricacy of its folds and convolutions, so should we analogically be led to suppose, that the difference in mental endowments between one man and another may be connected with a greater amplitude of the surface of the brain in those who are most highly gifted."—*Outlines of Physiology*, p. 298, 2d edit.

* See Sir E. Home's Croonian Lecture on the Internal Structure of the Human Brain, when examined in the microscope, as compared with that of fishes, insects, and worms.—(Phil. Trans., 1824, p. 1.) On this part of the subject, Sir Charles Bell has presented some different, but very ingenious views. In animals which do not breathe by a uniform and general motion of their bodies, he observes, there is no spinal marrow, strictly speaking, but only a long compound and ganglionic nerve, extending through the body for the purpose of sensation and motion. In such creatures, the cord does not actuate the animal machine with alternate dilatation and contraction. There may be a motion of some part which admits and expels air from a cavity, or agitates the water, and which motion is subservient to oxygenation of the blood; and there may be a nerve supplied to that apparatus, with sensibility and power suited to the function thus to be performed, and resembling our par vagum in office; but there is no regular and corresponding distribution of a respiratory system of nerves to both sides of the body, and no arrangement of bones and muscles for a general and regular motion of the frame, like that which takes place in vertebral animals, and which is necessary to their mode of existence.—Sir Charles Bell's *Exposition of the Natural System of the Nerves of the Human Body*, p. 23, London, 8vo, 1824.—Ed.

† *Anatom. Comparat.*, i., 25. In the writings of Sir Charles Bell will be found many interesting observations against the doctrine of *common sensibility*. "The sensibility of the skin," says he, "is one thing; the sensibility of the surface of the eye is another; the sensibility of a third part (as the throat) differs again from these; the sensibility of internal parts differs from the sensibility of external parts; and each degree and kind of sensibility is benevolently bestowed for a definite purpose. When you compare the external and

peculiar local organ, as well as the other senses, for particular purposes, and purposes in which unusual delicacy and precision are required: in man, this peculiar power of touch is well known to be seated in the nervous papillæ of the tongue, lips, and extremities of the fingers. Its situation in other animals I shall advert to presently.

The differences in the external senses of the different orders and kinds of animals consist in their number and degree of energy.

All the classes of vertebral animals possess the same number of senses as man. Sight is wanting in zoophytes, in various kinds of molluscs and articulated worms, and in the larvæ of several species of insects. Hearing does not exist, or at least has not been traced to exist, in many molluscs and several insects in a perfect state. Taste and smell, like the general and simple sense of touch, seem seldom to be wanting in any animal.

The local sense of TOUCH, however, or that which is of a more elaborate character, and capable of being exercised in a higher degree, appears to be confined to the three classes of mammals, birds, and insects: and, even in the last two, it is by no means common to all of them, and less so among insects than among birds.

In apes and macaques, constituting the quadrumanæ of Blumenbach, it resides partly in the tongue and tips of the fingers, as in man, but equally, and in some species even in a superior degree, in their toes. In the racoon (*ursus lotor*) it exists chiefly in the under surface of the front toes. In the horse and cattle orders, it is supposed by most naturalists to exist conjointly in the tongue and snout, and in the pig and mole, to be confined to the snout alone: this, however, is uncertain; as it is also, though there seems to be more reason for such

the internal parts, you find that it is not a common sensibility which they partake of. What would be your condition, were the parts within and around the knee-joint, or the ankle-joint, as sensitive as the surface of the body? You would be creeping home as if you had inflammation in the joints. You could not walk, if the parts that were bruised in the motions of the body possessed sensibility like the integuments. On the other hand, what would be the consequence if there were no sensibility there? You would have no guidance in the measure of your exertions; you would have nothing to tell you how much power in using the limbs was compatible with the texture of your body; you would be subject to injury, not from without, but from within, to rupture and to laceration. Thus, you will ever find, that the sensibility which is to guard the body is suited to the particular part." Sir Charles Bell afterward adverts to another illustration of his doctrine, afforded by that delicate organ the eye; the sensibility of whose surface has a relation to the protecting apparatus, so that the fine structure and transparency of the globe may be preserved; while the sensation of the retina is adapted to the varieties of light and colour only. In the operation of couching, the pain from the passage of the needle through the retina is not so great as that which proceeds from a particle of sand under the eyelid.—See Clinical Lecture in Med. Gaz. for Feb., 1834, p. 760.—Ed.

a belief, that in the elephant it is seated in the proboscis. Some physiologists have supposed the bristly hairs of the tiger, lion, and cat, to be an organ of the same kind, but there seems little ground for such an opinion. In the opossum (and particularly the Cayenne opossum) it exists very visibly in the tail; and M. Cuvier suspects that it has a similar existence in all the prehensile-tailed mammals.

Blumenbach supposes the same sense to have a place in the same organ in the platypus, or ornithorhynchus, as he calls it, that most extraordinary duck-billed quadruped which has lately been discovered in Australasia, and, by its intermixture of organs, confounds the different classes of animals, and sets all natural arrangement at defiance.

The local organ of touch or feeling in ducks and geese, and some other genera of birds, appears to be situated in the integument which covers the extremity of the mandibles, and especially the upper mandible, with which apparatus they are well known to feel for their food in the midst of mud, in which they can neither see nor perhaps smell it.

We do not know that amphibians, fishes, or worms, possess any thing like a local sense of touch: it has been suspected in some of these, and especially in the arms of the cuttlefish, and in the tentacles of worms that possess this organ; but at present it is suspicion, and nothing more.

In the insect tribes, we have much reason for believing such a sense to reside in the antennæ or in the tentacles; whence the former of these are denominated by the German naturalists, *fühl-horner*, or feeling-horns. This belief has not been fully established, but it is highly plausible from the general possession of the one or the other of these organs by the insect tribes, the general purpose to which they apply them, and the necessity which there seems for some such organ from the crustaceous or horny texture of their external coat.

The senses of TASTE and SMELL in animals bear a very near affinity to the local sense of touch; and it is difficult to determine whether the upper mandible of the duck tribe, with which they distinguish food in the mud, may not be an organ of taste or smell as well as of touch: and there are some naturalists that in like manner regard the cirrous filaments or antennules attached to the mouths of insects as organs of taste and touch equally. Taste, in the more perfect animals, resides jointly in the papillæ of the tongue and the palate; but I have already had occasion to observe that it may exist, and in full perfection, in the palate alone, since it has been found so in persons who have completely lost the tongue from external force or disease.*

* The brilliant discoveries of Sir Charles Bell, with respect to the Nervous System, prove very clearly that the fifth pair is not only the nerve of sensibility to the head and to the tongue,—not only the *gustatory nerve*,—but has branches which go to the muscles, and those muscles are connected with the act of mastication.—Ed.

In animals that possess the organ of nostrils, this is always the seat of smell; and in many quadrupeds, most birds, and perhaps most fishes, it is a sense far more acute than in man, and that which is chiefly confided in. For the most part it resides in the nerves distributed over the mucous membrane that lines the interior of the bones of the nostrils. Generally speaking, it will be found that the acuteness of smell bears a proportion in all animals to the extent of surface which this membrane displays, and hence, in the dog and cattle tribes, as well as in several others, it possesses a variety of folds or convolutions, and in birds, is continued to the utmost points of the nostrils, which, in different kinds, open in very different parts of the mandible.

The frontal sinuses, which are lined with this delicate membrane, are larger in the elephant than in any other quadruped, and in this animal the sense is also continued through the flexible organ of its proboscis. In the pig the smelling organ is also very extensive; and in most of the mammals possessing proper horns, it ascends as high as the processes of the frontal bone from which the horns issue.

It is not known that the cetaceous tribes possess any organ of smell: their blowing-holes are generally regarded as such, but the point has been by no means fully established. We are in the same uncertainty in respect to amphibians and worms: the sense is suspected to exist in all the former, and in several of the latter, especially in the cuttlefish; but no distinct organ has hitherto been traced out satisfactorily.*

In fishes there is no doubt: the olfactory nerves are very obviously distributed on an olfactory membrane, and, in several instances, the snouts are double, and consequently the nostrils quadruple, a pair for each snout. This powerful inlet of pleasure to fishes often proves fatal to them from its very perfection; for several kinds are so strongly allured by the odour of marjoram, asafoetida, and other aromas, that, by smearing the hand over with these substances, and immersing it in the water, they will often flock towards the fingers, and in their intoxication of delight may easily be laid hold of: and hence the angler frequently overspreads his baits with the same substance, and thus arms himself with a double decoy.

* According to the researches of Sir Charles Bell, the act of smelling is not simply the exposure of the odoriferous particles floating in the atmosphere to the olfactory nerve; but they must rush with a certain violence over it. "There is," says he, "a sort of double or internal nostril; and a change is produced in the figure of the passage when you breathe simply, and when you smell. This configuration of the tube is that which, in the act of taking snuff, gives force to the stream of air upwards. If a man were putting his nose to his snuff-box, and simply breathing, all the snuff would go into the throat; but when he snuffs with the nostril it goes upwards, and stimulates the higher part of the Schneiderian membrane. This is effected by the action of the muscles of the nostril, which depends upon the portio dura. Hence, when the influence of this nerve is lost, there is an imperfection in the act of smelling."—Sir Charles Bell, in *Med. Gaz.* for Feb., 1834, p. 701.—*Ed.*

There can be no doubt of the existence of the same sense in insects, for they possess a very obvious power of distinguishing the odorous properties of bodies, even at a considerable distance beyond the range of their vision; but the organ in which this sense resides has not been satisfactorily pointed out. Reimar supposes it to exist in their stigmata, and Knoch in their anterior pair of feelers.

The general organ of HEARING is the ear, but not always so; for in most of those who hear by the Eustachian tube only, it is the mouth: in the whale tribes, it is the nostrils or blow-hole. It is so, however, in all the more perfect animals, which usually for this purpose possess two distinct entrances into the organ; a larger and external surrounded by a lobe, and a smaller and internal opening into the mouth. It is this last which is denominated the Eustachian tube. The shape of the lobe is seldom found even in mammals similar to that in man, excepting among the monkey and the porcupine tribes. In many kinds there is neither external lobe nor external passage. Thus in the frog, and most amphibious animals, the only entrance is the internal or that from the mouth; and, in the cetaceous tribes, the only effective entrance is probably of the same kind; for, though these may be said to possess an external aperture, it is almost imperceptibly minute. It is a curious fact, that among the serpents, the blind worm or common harmless snake is the only species that appears to possess an aperture of either sort; the rest have a rudiment of the organ within, but we are not acquainted with its being pervious to sound.

Fishes are well known to possess a hearing organ, and the skate and shark have the rudiment of an external ear; but, like other fishes, they seem chiefly to receive sound by the internal tubule alone.

That insects in general hear is unquestionable; but it is highly questionable by what organ they obtain the sense of hearing. The antennæ, and perhaps merely because we do not know their exact use, have been supposed by many naturalists to furnish the means: it appears fatal, however, to this opinion to observe, that spiders hear, though they have no true antennæ; and that other insects which possess them naturally, seem to hear as correctly after they are cut off.

The sense of VISION exhibits perhaps more variety in the different classes of animals than any of the external senses. In man, and the greater number of quadrupeds, it is guarded by an upper and lower eyelid, both of which in man, but neither of which in most quadrupeds, are terminated by the additional defence and ornament of cilia or eyelashes. In the elephant, opossum, seal, cat kind, and various other mammals, all birds and all fishes, we find a third eyelid, or nictating membrane as it is usually called, arising from the internal angle of the eye, and capable of covering the pupil with a thin transparent veil, either wholly or in part, and thus defending the eyes from danger in their search after food. In the dog this membrane is

narrow; in oxen and horses it will extend over half the eyeball; in birds it will easily cover the whole; and it is by means of this veil, according to Cuvier, that the eagle is capable of looking directly against the noonday sun. In fishes it is almost always upon the stretch, as in their uncertain element they are exposed to more dangers than any other animal. Serpents have neither this nor any other eyelid, nor any kind of external defence whatever but the common integument of the skin.

The largest eyes, in proportion to the size of the animal, belong to the bird tribes, and nearly the smallest to the whale; the smallest altogether to the shrew and mole, in the latter of which the eye is not larger than a pin's head.

The iris, with but few exceptions, partakes of the colour of the hair, and is hence perpetually varying in different species of the same genus. The pupil exhibits a very considerable, though not an equal variety in its shape. In man it is circular; in the lion, tiger, and indeed all the cat kind, it is oblong; transverse in the horse and in ruminating animals; and heart-shaped in the dolphin.

In man, and the monkey tribes, the eyes are placed directly under the forehead; in other mammals, birds, and reptiles, more or less laterally; in some fishes, as the genus *pleuronectes*, including the turbot and flounder tribes, both eyes are placed on the same side of the head; in the snail they are situated on its horns, if the black points on the extremities of the horns of this worm be real eyes, of which, however, there is some doubt; in spiders the eyes are distributed over different parts of the body, and in different arrangements, usually eight in number, and never less than six. The eyes of the sepia have lately been detected by M. Cuvier; their construction is very beautiful, and nearly as complicated as that of vertebrated animals.—(*Animal Kingdom*, trans. by H. M. Murtrie, M. D., New-York, 1833.) Polypes and several other zoophytes appear sensible of the presence of light, and yet have no eyes; as the nostrils are not in every animal necessary to the sense of smell, the tongue to that of taste, or the ears to that of sound. A distinct organ is not always requisite for a distinct sense. In man himself we have already seen this in regard to the sense of touch, which exists both locally and generally: the distinct organ of touch is the tips of the tongue and of the fingers, but the feeling is also diffused, though in a subordinate and less precise degree, over every part of the body. It is possible, therefore, in animals that appear endowed with particular senses without particular organs for their residence, that these senses are diffused, like that of touch, over the surface generally; though there can be no doubt that, for want of such appropriate organs, they must be less acute and precise than in animals that possess them.

Whether there be any other than the five senses common to man and the higher classes of animals, may be reasonably doubted; but we occasionally meet with peculiarities of sensation that can hardly be resolved into any of them.

Thus the bat appears to be sensible of the presence of external objects and obstructions that are neither seen, smelt, heard, touched, or tasted; for it will cautiously avoid them when all the senses are purposely closed up. And hence many naturalists have ascribed a sixth sense to this animal. It is equally difficult, by any of the known senses of fishes or of birds, to account for the accuracy with which their migratory tribes are capable of steering their annual course through the depths of the ocean or the trackless regions of the atmosphere, so as to arrive at a given season on a given coast, or in a given climate, with the precision of the expertest mariner. While, with respect to mankind themselves, we sometimes meet with persons who are so peculiarly affected by the presence of a particular object that is neither seen, smelt, tasted, heard, or touched, as not only to be conscious of its presence, but to be in great distress till it is removed. The presence of a cat not unfrequently produces such an effect; and the author has himself been a witness of the most decisive proofs of this in several instances. It is possible that the peculiar sense may, in such cases, result from a preternatural modification in some of the branches of the olfactory nerve, which may render them capable of being stimulated in a new and peculiar manner; but the individuals thus affected are no more conscious of an excitement in this organ of sense than in any other; and, from the anomaly and rare occurrence of the sensation itself, find no terms by which to express it.

In Germany it has of late been attempted to be shown that every man is possessed of a sixth sense, though of a very different kind from those just referred to; for it is a sense not only common to every one, but to the system at large; and consists in that peculiar kind of internal but corporeal feeling respecting the general state of one's health, that induces us to exult in being as light as a feather, as elastic as a spring, or to sink under a sense of lassitude, fatigue, and weariness, which cannot be accounted for, and is unconnected with muscular labour or disease. To this sensation M. Hubner has given the name of *cænesthesia*, and several of his compatriots that of *selbstgefühl*, and *gemeingefühl*, "*self-feeling* or *general-feeling*;" and its organ is supposed to exist in the extremities of all the nerves of the body, except those that supply the five external senses.* I scarcely know why these last should have been excepted; for the sensation itself is nothing more than a result of that general sympathy which appears to take place between different organs and parts of the body, expressive of a pleasurable or disquieting feeling, according as the frame at large is in a state of general and uninterrupted health, or affected by some cause of disquiet.

II. As the nerves thus generally communi-

* Comment. de Cænesthesi; Dissert. Aug. Med. Auct. Chr. Fred. Hubner, 1794. This is totally different from what has been termed *common sensibility*, the objections to which expression, as brought forward by Sir Charles Bell, have been alluded to in a previous note.—Ed.

cate with each other, and with the brain where this organ exists, it has been a question in all ages by what means they maintain this communication, and what is the nature of the communicated influence? or, in other words, what is the fabric of the nerves, and the quality of the nervous power!*

Upon these points, two very different opinions have been entertained from an early period of the world, which, under different modifications, have descended to our own times: for by many physiologists, both ancient and modern, the nerves have been regarded as solid capillaments, or tense and elastic strings, operating by tremours or oscillations, like the chords of a musical instrument; and by others, as minute and hollow cylinders conveying a peculiar fluid. The word NERVE, which among the ancients was applied to tense cords of every kind, and especially to bow-strings and musical strings, affords a clear proof how generally the former of these hypotheses prevailed among the Greeks. It was not, however, the hypothesis either of Hippocrates or Galen: for by them, while the nerves were regarded as the instruments of sensation and motion, the medium by which they acted was supposed to be a fine ethereal fluid, elaborated in the organ of the brain; to which they gave the name of animal spirit, to distinguish it from the proper fluid of the arteries, which was denominated vital spirit. "Not," says Galen, "that this animal spirit is of the substance of the soul, but its prime agent while inhabiting the brain."—(*De Hippocratis et Platonis Decretis*, lib. vii., A, tom. i., p. 967, ed. Basil, 1542.) But, with respect to the manner in which the animal spirit operates upon the nerves, they spoke with great modesty; for though they thought they had been able to trace a tubular form in some of the nerves, and particularly those of vision, they had not been able to succeed in others. "And hence," says Galen, "it is impossible for us to pronounce absolutely, and without proof, whether a certain power may not be transmitted from the brain through the nerves to the different members; or whether the material of the animal spirit may not itself reach the sentient and moving parts; or, in some way or other, so enter into the nerves as to induce in them a change, which is afterward extended to the organs of motion."—(*Id.*, sect. C, p. 969.)

In a state not much less unsettled remains the subject at the present moment. Dr. Hartley, in the beginning of the seventeenth century, revived the hypothesis, that the nerves are bundles of solid capillaments conveying motion, sensation, and even perception, by a vibratory power, and supported his opinion with great in-

genuity and learning (*Observations on Man, his Frame, &c., his Duty and his Expectations*, 2 vols., 8vo., 1749); but the opposite hypothesis, that they are minute tubes filled with the animal spirit of the Greek physiologists, had acquired so extensive a hold ever since the discovery of the circulation of the blood, which presupposes the existence of tubular vessels too subtle to be traced by the senses, that it never obtained more than a partial and temporary assent; and hence, from the times of Sydenham and Boerhaave almost down to our own day, the last has been the popular doctrine.

In effect, no fibres of the animal frame can be less adapted to a communication of motion by a series of vibrations than those of the nerves, since none exhibit a smaller degree of elasticity; and though we have little reason to confide in their tubular structure, or to believe that any kind of fluid is transmitted in this way, the close affinity which the nervous power is now known to hold with several of the gases that chymistry has of late years unfolded to us, and the wonderful influence which some of them possess over the moving fibres of the animal frame, seem to leave no question that the nervous power itself is a fluid,* though not, perhaps, of their precise nature, yet resembling the most active of them in its subtilty, levity, and rapidity of movement. Nor is there, upon this supposition, any difficulty in conceiving its transmission by solid fibres or capillaments of a particular kind, the *neurilemma* of Bichat, while we behold the ethereal fluids now referred to transmitted in the same way by substances still more solid and unporous.

But there is another question, closely connected with the present subject, that has also greatly interested physiologists both in ancient and modern times, and is not yet settled in a manner altogether satisfactory.

It has appeared that the nerves are instruments both of sensation and motion. Are these two effects produced by the same nervous fibres, or by different? or by the same fluids, or by different? That there must be two distinct kinds of fibres or of fluids is clear, because, as we shall have more particularly to observe when we come to treat of paralysis, the muscles of a limb are sometimes deprived of both sensation and motivity at the same period, sometimes of sensation alone while motivity continues, and sometimes of motivity alone while sensation continues. And hence Hippocrates and Galen, the last of whom has treated of the subject with great minuteness in many of his writings, while they speak of only one kind of animal spirit, speak of two kinds of nerves, those of sense and of motion; equally issuing from the brain, and mostly accompanying each other, and forming parts of the same organs.†

This distinction is supported by the concurrent observations and experiments of physiolo-

* "The question," says Dr. Bostock, "may be thus stated in direct terms:—When an impression made upon an organ of sense is transmitted by a nerve to the brain, or when the exercise of volition is communicated to the nerve, so as to produce the corresponding effect upon the muscle, what change does the nerve experience, or in what way is it acted upon so as to admit of this transmission?"—*Elem. Syst. of Physiology*, vol. i., p. 250.—Ed.

* The editor's opinion of this hypothesis will appear in the sequel.

† The curious fact of most of the nerves of motion (though not all) originating from the spinal marrow, has been already stated.—Ed.

gists, and especially by the curious investigations of many of those of our own day, among whom should be particularly noticed the names of Flourens, Rolando, Charles Bell, Magendie, and Shaw. M. Rolando attempted to show, by a long train of interesting but very painful experiments, carried on through animals of almost every kind, that the cerebrum is the ordinary source of sensation, and the cerebellum of motion: for, according to his observations, in every instance in which the former is much broken down, or in any other way injured, drowsiness, stupor, or apoplexy is sure to follow; the animal being still capable of exercising locomotive power, but without any guidance or knowledge of what it is about, or where it is moving to. But the moment the cerebellum is wounded, the locomotive power is instantly lost.—(*Saggio sopra la vera Strutt. del Cervello*, &c., e sopra le Fonz. della Sist. Nervosa, Sassari, 1809.) These investigations were valuable, as leading on to others more accurately conducted, and followed up by more correct conclusions. That these distinct portions of the brain are endowed with separate powers, as observed by Rolando, has been sufficiently ascertained by other pathologists; and especially by M. Flourens (*Arch. Gén. de Méd.*, i., ii.; also, *Recherches Exp. sur le Syst. Nerveux*, Paris, 1824), who does not seem at the time to have been acquainted with Rolando's experiments, and consequently gives us the weight of an unconnected testimony. But it seems to M. Magendie (*Exp. sur les Fonctions*, &c., *Journ. de Physiologie*, tom. ii., iii., passim, 1822, 1823) to be now better established, that the converse of M. Rolando's constitutes the law and order of nature: sensation appearing to be dependant upon the cerebellum instead of upon the cerebrum; while motivity takes its rise from the cerebrum instead of from the cerebellum.

[If, however, the researches and experiments of Magendie oppose those of the foregoing physiologists, let it be remembered that the results of his investigations disagree with many observations made on this subject by physiologists of high reputation. According to Sir Charles Bell, the nerves of the greatest number of the voluntary muscles are derived from the medulla spinalis, and the best modern anatomists trace the origins of most of the other nerves to the medulla oblongata. If, therefore, the origins of the nerves could be taken as a criterion, Magendie's views would not be at all tenable. But it is not by this test that the question can be settled, because the inquiry here refers, not to what nerves are concerned in sensation and voluntary motion, but to what part of the brain or cerebellum the power of regulating the voluntary action of the muscles is to be ascribed. It is a question, therefore, that can only be settled by experiment.

In order to determine the exact uses of particular parts of the brain and its appendages, numerous experiments have been performed, which consisted in observing very carefully the effects resulting from the injury of definite portions of those organs. The first researches of

this description were those of Molinelli (*Comment. Bononiens.*, p. 130), and they have been followed up by the more important experiments of Boerhaave, Haller, Zinn, Zimmermann, Fodera (*Magendie, Journ. de Physiologie*, vol. i., 1823), Legallois (*Exp. sur le Principe de la Vie*), Krauss (*Diss. de Cerebri læsi ad motum Volunt. relatione*, Vratisl., 1824), Hertwig (*Hecker's Litterarische Annalen*, &c., May, 1826), and those of the physiologists already enumerated. Of all the experiments made on this subject, those of Flourens are perhaps the most valuable. From them, which, indeed, confirm earlier observations, it results that each strongly developed part of the brain is intended for the performance of particular functions, the hemispheres of the cerebrum being the organ of the mental faculties (understanding, memory, and will), and the centre of all the perceptions;* while the cerebellum is the organ in which the different muscular motions are regulated and directed to one common object. In the corpora quadrigemina is seated the original active principle of the iris, the retina, and optic nerves. Irritation of the corpora quadrigemina, medulla oblongata, and medulla spinalis, shows that these are the only parts of the nervous system connected with muscular contractions. Another inference is, that the power of sensation is a single one, and resides in a single organ.

According to Hertwig's still more recent investigations, although the substance of the hemispheres is the centre of all the perceptions, it is insensible of external irritations. Irritations and even injuries of the hemispheres, he found, produce no involuntary motions of the muscles, merely weakness and paralysis of them; and always on the side of the body opposite to that on which the injury was inflicted. Hertwig's experiments also confirm the doctrine that the operation of the hemispheres is in a crossed direction, that the *consensus communis* is not dependant on them alone, since it remains after they have been destroyed; and that the respiration and circulation are also independent of them.

With respect to the cerebellum, Dr. Hertwig found that its substance was not sensible to immediate external irritations, by which also no motions of the muscles were excited; but that the undisturbed operation of this organ is necessary to the production and co-operation of the muscles for a particular purpose, as flying, walking, &c. His experiments likewise tend to prove that the action of the cerebellum on the voluntary muscles takes place in a cross direc-

* The following criticism is entitled to consideration:—"One of the most important points which M. Flourens attempts to establish is, that the lobes of the cerebrum are the exclusive seat of sensation and volition; yet it seems quite evident, from the result of the experiments, that, after the removal of these lobes, sensation, although rendered feeble or obtuse, was by no means extinguished; while the functions which depend upon volition, such as the various kinds of locomotion, were still executed by the animal, although it was difficult to excite them into action."—See Bostock's *Physiology*, vol. iii., p. 374.

tion; and that the uses of the senses and all the other functions depend very little on the action of the cerebellum.

According to Dr. Hertwig, a superficial irritation or wound of the pons varolii produces in animals some pain and temporary convulsions; but deep, penetrating injuries cause, independently of the other effects, a permanent irregularity in the voluntary motions of the body, arising from a disturbance in the balance of the powers between the two sides of the body, or between its anterior and posterior parts. The pons exerts considerable influence over the voluntary locomotive organs for the preservation of the balance between them. Another conclusion to which Dr. Hertwig's experiments led him is, that the pons varolii has little influence over the senses and consciousness. With regard to the medulla oblongata, Dr. Hertwig's experiments corroborate the opinion that it has great influence over respiration, and also partly over the circulation. Hence its complete division destroys life by interrupting respiration. The same experimenter infers, that, as injuries of this organ do not disturb the senses, the intellectual functions can have no dependence upon it.*

Sir Charles Bell has successfully followed up

* According to the learned Professor Jackson, of Philadelphia, "the cerebrum is the seat of the organs of the intellectual, and affective or moral faculties. The cerebellum is the organ for co-ordinating or combining the muscular contractions required to produce locomotive motions and equilibrium or station. The ash or gray substance, the most vascular portion of the nervous structure, is that which is active in the production of the nervous phenomena. It originates the power or agent, the cause of the sensations and voluntary movements, that excites the muscular contractions requisite to the performance of respiration, the expressions, &c., and which would appear to be generated by this substance in the medulla oblongata; and finally, in the cerebrum it constitutes the organs exercising the intellectual and moral faculties, &c. The white medullary or fibrous substance is subservient to the offices of the ash or gray substance, conveying to it impressions excited on the external and internal surfaces of relation by the nervous cords composed of this substance, and reconducting from the ash substance the nervous force, agency, influence, or whatever name may be given to this unknown principle or agent, into the different organs and tissues, and probably fluids of the organism. The white medullary or fibrous substance of the cerebrum and cerebellum is encephalic nerves, executing the same office as the same substance has been shown to perform in nerves and the spinal marrow; and it transmits the actions excited in the medulla oblongata, by sensible impressions proceeding from the senses, to the gray substance composing the intellectual and affective organs in the cerebrum constituted for that purpose; and reconveys the actions of these organs into the medulla oblongata, whence they are directed into the organism, causing locomotions, the expressions, and even disturbances, when violent, of the organic and functional actions of the viscera."—See the Principles of Medicine, founded on the Structure and Functions of the Animal Organism, by Samuel Jackson, M. D., &c., Philadelphia, 1832.—D.

the distinct and established powers of the two departments of the brain (*Idea of the Anatomy of the Brain*, 1809) into the spinal marrow, which he has sufficiently proved to consist of a double cord;* an anterior connected with the crura of the cerebrum and productive of locomotion, and a posterior connected with the crura of the cerebellum, productive of sensation.† And he has further shown, that these two distinct powers are communicated to every part of the body by nervous fibres, according as they issue from the one or the other of these respective channels: that, for the most part, every nervous fascicle distributed over the body and limbs has a double origin, and issues equally from both the anterior and posterior trunk of the spinal medulla, and is, consequently, alike sensitive and modifiable; while those which proceed from one alone are limited in their power to the peculiar property of their source,‡ of which the

* The following is Sir Charles Bell's description: "Different columns of nervous matter combine to form the spinal marrow. Each lateral portion of the spinal marrow consists of three tracks or columns; one for voluntary motion, one for sensation, and one for the act of respiration. So that the spinal marrow comprehends in all six rods, intimately bound together, but distinct in office; and the capital of this compound column is the medulla oblongata. No doubt," he adds, "these grander columns contain within them subdivisions; for if we lift up the medulla spinalis from the cerebellum, and look at its back part, we shall see more numerous cords, the offices of which will one day be discovered."—See Exposition of the Natural System of the Nerves, p. 20, 8vo., London, 1824.

† "The anterior column of each lateral division of the spinal marrow is for motion, the posterior column is for sensation, and the middle one is for respiration. The two former extend up into the brain, and are dispersed or lost in it, for their functions stand related to the sensorium; but the latter stops short in the medulla oblongata, being in function independent of reason, and capable of its office independent of the brain, or when separated from it.

"It is the introduction of the middle column of the three, viz., that for respiration, which constitutes the spinal marrow, as distinct from the long central nerve of the animals without vertebræ, and which is attended with the necessity for that form of the trunk which admits of the respiratory motions."—Op. cit., p. 22.

‡ The following observations were published by Mr. Mayo:—"When a spinal nerve is divided in its course through the body, the parts supplied by it beyond the division are paralyzed: they lose sense and motion. If the two origins of the spinal nerves be exposed in a young animal, and separately divided, different effects are produced. The section of the anterior root deprives of voluntary motion the part supplied by the nerve; the section of the posterior root deprives the corresponding part of the body of sensation, voluntary motion being left." These experiments were made by M. Magendie, and published by him in his Journal of Physiology. But many years earlier, Mr. Bell had made experiments upon the spinal nerves, some account of which had been printed and circulated among his friends, as well as delivered in his lectures. The following is an extract from this account:—"On laying bare the

portio dura of the seventh nerve affords a striking example: being, when uncombined, simply a nerve of motion, without the attribute of sensation, but exercising motion over all the organs of the face that are connected with the function of respiration, whether in the cheeks, lips, or nostrils; and hence operating equally in the acts of speaking, singing, sucking, drinking, spitting, coughing, and sneezing. And he has confirmed these discoveries by the striking fact, that the nerves of the head, which issue, like the spinal medulla, from both departments of the brain, possess the same double power, and are, in like manner, nerves of sensation and motion; of which the fifth pair offers a notable example, bestowing at the same time sensibility on the head

roots of the spinal nerves," observes Mr. Bell. "I found that I could cut across the posterior fasciculus of nerves, which took its origin from the posterior portion of the spinal marrow, without convulsing the muscles of the back; but that, on touching the anterior fasciculus with the point of the knife, the muscles of the back were immediately convulsed." Mr. Bell was carried by these experiments, says Mr. Mayo, very near to the truth, but he failed at that time to ascertain it: he inferred from his experiments, indeed, that the anterior and posterior roots of the spinal nerves have different functions; but in the nature of these functions he was mistaken. Upon the anterior root he supposed both sensation and motion to depend; the posterior he considered an unconscious nerve, which might control the growth and sympathies of parts. When Mr. Bell published a further account of the functions of these nerves, M. Magendie had already given to the world the true theory of their uses.—(See Mayo's *Outlines of Physiology*, p. 325, 2d edit., 1828.) However this may be, the editor believes that if it had not been for the original train of experiments instituted by Sir Charles Bell, we should yet have remained ignorant of the distinction between nerves of sense and nerves of motion. Nor does Sir Charles Bell admit some part of the foregoing statements. As for Magendie, his claim is also put in a different light by certain important explanations recently published. In the tract printed long before 1811, Sir Charles Bell declares that he distinctly inculcated the great principle, "that a nerve, whatever its nature may be, cannot perform two functions at once; it cannot convey sensation inwards to the sensorium, at the same time that it carries outwards a mandate of the will to the muscles, whether it be through the means of a fluid, or an ether, or a vibration, or what you will, that it performs its functions. Two vibrations cannot run counter through the same fibre, and at the same instant. Two undulations cannot go in different directions through the same tube at the same moment; and therefore," says Sir Charles Bell, "I conceived that the nerves must be different in their kind. This led me to experiment upon the nerves of the spine; for, I said, where shall I be able to find a nerve with the roots separated? where shall I be able to distinguish the properties of a compound nerve? By experimenting upon the separate roots of the spinal nerve. So then, taking a fine instrument, the point of a needle, and drawing it along one set of roots, and then along another, I found that as I touched one set, the anterior roots, it was like touching the key of a piano-forte—all the chords, as it were, the muscles, were in vibration; and when I touched the other, there was pain and struggling. That would not do; the

and face, and performing various muscular motions common to all animals, so as to be analogous to a double spinal nerve, or rather to the spine itself, and enriched, like the spine, with ganglions in particular parts. Many of these experiments have since been repeated, and the results to which they have thus led, though in some respects opposed by other experiments of M. Fodera (*Rech. Exp.*, &c., *Journ. de Physiologie*, Juillet, 1823), have generally been confirmed by M. Magendie, Mr. Shaw, Mr. Broughton, and various other anatomists; and we hence see the reason of those frequent decussations and other interunions of nerve with nerve, by which those possessing a single origin, and consequently a single property, hereby exchange

animal being alive to sensation, there was confusion; and therefore I struck the animal on the head, and then I made my experiments clearly; by which it was shown that the roots of these nerves were of different qualities: one obviously bestowing motion; and, by inference, the other bestowing sensibility." Having come to the conclusion that the roots of the spinal nerves were double, that each might have a double function, he inquired of himself, How is the head supplied? Is there any nerve in the head that has a resemblance to the nerves of the spine, one root of each of which nerves has a ganglion, and the other not? Then, he said, what nerve of the head has a ganglion? The fifth has a double root, with a ganglion on one of these roots, like a spinal nerve. Now the function of the posterior root of the spinal nerve, or that which did not excite motion when irritated, he thought might be illustrated by considering the fifth pair as nerves of the same class. Experiments were made upon the three branches of the fifth pair in the face; and what was incomplete in the experiments upon the spinal nerves was made perfectly clear by them. It was established, that branches proceeding from a ganglion, in all respects the same in structure as the ganglions of the spinal nerves, were the only nerves which bestowed sensibility on the head. "It has been said," observes Sir Charles Bell, "that I gave out that sensation and motion belonged to the anterior roots. How could that be? The principle upon which I proceeded, the idea which I entertained for many years, that which forced me on to all my experiments, was, that one filament could perform only one function; and for me to say that the anterior roots performed two functions, was just giving the whole matter up. It has been my misfortune to put all these things down in a large, heavy, dear book: were it generally read, which I learn from my bookseller that it is not, I should have no occasion at any time to vindicate the originality or correctness of my observations. When M. Magendie took up this subject he had in his hands my original paper, in which the classification of the nerves, and the principles on which that classification is founded, 'that nerves arising from distinct roots are endowed with distinct functions,' are all stated. He had copies of these plans which are now hung up beside me. The experiments upon the fifth nerve, which are detailed in that paper, and which were suggested to me by my previous experiments upon the roots of the spinal nerves, were repeated before him in Paris by Mr. John Shaw, who had on various occasions made the experiments on the spinal nerves before my pupils in Great Windmill-street, previously to visiting Paris."—See *Medical Gazette* for February, 1834.—Ed.

filaments, and become enriched with a new power, the respective filaments being enveloped in the same sheath.

[In elucidating the uses of the fifth pair of nerves and the *portio mollis* of the seventh, Mr. Mayo merits considerable honour. From a series of experiments detailed by him (*Anat. and Physiol. Commentaries*, 1822), the conclusion is made, that the *portio dura* of the seventh nerve is a simple voluntary nerve, and that the facial branches of the fifth are exclusively sentient nerves. In pursuing this subject, Mr. Mayo was led to observe that there are muscles which receive no branches from any nerve but the fifth: these muscles are the masseter, the temporal, the two pterygoids, and the circumflexus palati. These muscles, he further remarked, are supplied with branches from the third division of the fifth, that is to say, from the particular division of the fifth with which the *smaller fasciculus* or root of the nerve is associated. After some careful dissection, in the greater part of which he found that he had been anticipated by Palletta, he made out that the *smaller fasciculus* of the fifth is entirely consumed upon the supply of the above-mentioned muscles, to which it is to be borne in mind that twigs from the ganglionic portion are likewise distributed. "But," says Mr. Mayo, "I had already ascertained by experiment, that almost all the branches of the larger or ganglionic portions of the fifth were nerves of sensation. I proved this point in the ass, the dog, and the rabbit, respecting the second and third divisions of the fifth; in the pigeon, respecting the first division. It was therefore thoroughly improbable that the twigs sent from the same part of the nerve to the muscles of the lower jaw should have a different quality, and be nerves of motion. For this function it was reasonable to look to the other nervous fibrils which the masseter, and temporal, and pterygoid muscles receive; in other words, to the branches of the *smaller fasciculus* or root, or ganglionless portion of the fifth. All this was made out before the publication of M. Magendie's discovery of the parallel functions of the double roots of the spinal nerves."—(*Mayo's Physiology*, p. 331, et seq., 2d edit.)

At the same time that praise is due to others for what they have done on this intricate subject, the world and posterity will never forget the matchless claims of Sir Charles Bell to the glory of having first pointed the path that led to all the success with which the nervous system has been examined in latter times. It is not fair that his merit should be lost sight of, and even his originality questioned, because other physiologists have contributed to establish and perfect the system which he first suggested. Sir Charles Bell has most ably explained, that the great error which misled anatomists in their conceptions concerning the nerves, consisted in following, though with some license, the old hypothesis, that the nerves receive their influence from the brain, and confer it on remote parts of the body, and that they are endowed with the same powers. For (says he) whether we look upon the intricacy of the parts

on dissection, or attempt to unravel the mystery of sensation and voluntary and involuntary motion performed by a single nerve, there is a complete discrepancy between the fact and the hypothesis. In the view which Sir Charles Bell takes of the nerves of the human body, there are, besides the nerves of vision, smell, and hearing, four systems combined into a whole. Nerves, entirely different in function, extend through the frame: those of sensation; those of voluntary motion; those of respiratory motion; and lastly, nerves which, from their being deficient in the qualities that distinguish the three others, seem to unite the body into a whole, in the performance of the functions of nutrition, growth, and decay, and whatever is directly necessary to animal existence. These nerves, Sir Charles Bell remarks, are sometimes bound together; but they do not in any case interfere with or partake of each other's influence. A nerve is seen to consist of distinct filaments, but there is nothing to distinguish them or indicate their offices. One filament may be for the purpose of sensation, another for muscular motion, a third for combining the muscles in the act of respiration; but the subserviency of any particular filament to its proper office can only be made out by tracing it and observing its relations, and especially its origin in the brain and spinal marrow.

The key to Sir Charles Bell's system is in the simple proposition, that *each filament has its peculiar endowment, independently of the other filaments bound up along with it; and that it continues to have the same endowment throughout its whole length.* Thus, if its office be to convey sensation, that power shall belong to it in all its course, wherever it can be traced; and at whatever point, whether in the foot, leg, thigh, spine, or brain, it may be bruised, pricked, or otherwise injured, sensation, and not motion, will result; and the perception arising from the impression will be referred to that part of the skin where the remote extremity of the filament is distributed.

There is much, however, in this recondite subject, that still requires elucidation; and particularly in regard to that continuation of sense and motion in many cases which we shall hereafter have to notice, in which the brain, through a very considerable extent, both in its white and cineritious substance, has been found in a mollescent or pulpy state; often, indeed, entirely disorganized, and as soft as soap: while, in other instances, the spinal marrow, through an extent of six or seven inches in length, has been found equally dissolved, and its chain completely destroyed; * one set of limbs being rendered

* This point requires further investigation. When the spinal cord is divided in experiments upon warm-blooded animals, or is compressed or lacerated, the lower part of the body is totally paralyzed. This result, as Mr. Mayo observes, is so uniform, that we are bound to suppose an error in the narrative of two well-attested cases, on record, of sensation and voluntary motion continuing after the division of the spinal marrow. Some violence is scarcely avoidable in opening the spinal canal;

rigid and motionless, with an augmented sensibility, at the same time that the sensation and mobility of the rest have been scarcely interfered with. And hence a separate and specific power has, from an early age, been ascribed to the nervous fibres themselves, while the brain has been contemplated as their radix. This, in truth, was the peculiar hypothesis of Glisson, and nearly so of Haller, with respect to the motory power; and Girtanner, who trod in the same footsteps, with a clear and comprehensive mind, considerably enlarged upon it, and gave to the moving energy the name of *vis insita*, as, by way of distinction, he applied that of *vis nervea* to the energy or power of feeling.* And as he believed that other organs besides muscles, and indeed plants† as well as animals, are possessed of fibres endowed with the same power, and that a brain is by no means essential for their production, he in like manner changed the name of muscular to that of irritable fibre; and contended that a principle of irritability is common to fluids as well as to solids, and co-extensive with organized nature.—(*Mém. sur l'Irritabilité, Journ. de Phys.*, 1790.)

By what means these fibres unite into solid masses or hollow coats, and what are their respective powers when thus complicated, shall be glanced at hereafter;‡ at present we must confine ourselves to their actuating principle, whatever that may consist in.

Oxygen was at this time the popular aura of the philosophers, as caloric had been a short time before. Lavoisier had just proved its close connexion with several of the vital functions, and hence the chymical divinity of Girtanner was oxygen. He paid unbounded homage to its influence; attempted to show that irritability

and if the spinal cord be already partially divided, the operation of exposing it may easily complete the rupture. How slight a continuity of nervous fibre is sufficient to sustain the communication between parts of the medulla spinalis, must be known to those who have attempted to destroy animals by pithing: a very slender layer of nervous substance will enable the animal to continue breathing, which, however, ceases instantly on its division.—See Mayo's *Outlines of Physiology*, p. 285, 2d edit.—Ed.

* The doctrines involving the respective properties of the *vis insita* and *vis nervea* formerly attracted much attention, and the views of Whytte and Haller were treated with some severity. The happy manner in which Mr. Abernethy has discussed many topics connected with the intricate questions of human physiology and comparative anatomy, will always recommend his writings, and more particularly his lectures delivered before the Royal College of Surgeons in 1817, as worthy of an attentive perusal.—D.

† The seeming analogy between the life of animals and that of plants has led vegetable physiologists to a comparative investigation of the subject. Besides light, heat, and oxygen, the common stimuli of plants, electricity has been mentioned as an official agent by which plants are excited to increased development. De Candolle remarks that the discharge of electricity is one of the most powerful stimulants to the vital action of plants.—D.

‡ See the introductory remarks to Order III. of the present Class, *NEUROTICA, CINETICA*.

ty, and even life itself, are dependant upon it; and that in the animal system it is distributed to every part by means of the circulating blood.

But the still more striking properties of the galvanic fluid began now to be discovered, and to captivate the general attention; and the time drew nigh in which oxygen was doomed to fall as prostrate before the shrine of galvanic aura, as caloric had fallen before that of oxygen. And it is curious to remark how nearly this discovery was not only made but completed in all its bearings, and by the very same means, about fifty years before the attention of Galvani was directed to the subject; for we are told in the *Philosophical Transactions* for 1732 (vol. xxxvii., p. 324), that the queen's physician, Dr. Alexander Stuart, being engaged in a course of experiments upon the frog, observed, upon thrusting the blunt end of a probe into the spinal marrow after decapitation, that the muscles of the animal's body were thrown into convulsive contractions; and that the same happened to the muscles of the head when the probe was thrust into the brain. And by additional experiments he advanced so far as to infer that what the nerves contribute in muscular motion cannot be produced by oscillations or elasticity, but must be owing to a fluid contained in them: but which fluid he was unfortunate enough to conceive was a pure and perfectly defecated elementary water; using the word water, however, in a general sense, as merely opposed to sal volatile or fermented spirits, which he thought the term animal spirits was calculated to import.

Whatever be the nature of the active and ethereal fluid which was thus supposed to exist by Stuart, and has since been attempted to be established by Galvani, it is presumed to have a powerful influence upon many branches or divisions of the nervous system, though not upon all.* Its effects upon the muscles of an animal for some hours after death are too well

* Although our author, as we shall presently find, makes the judicious distinction between the hypothesis of galvanism and electricity being identical with the imaginary nervous fluid, and the doctrine of their being only stimulants, by which the secretion of this fluid may be excited, and the action of the nerves continued, he does not seem to entertain the slightest doubt of the actual existence of a nervous fluid, and of its being a secretion, as if these circumstances had been satisfactorily proved and demonstrated. The editor often regrets that Dr. Good should have assumed these hypotheses as positively established facts, and that he did not rest satisfied with the less objectionable expressions, nervous power, nervous energy, or nervous influence, instead of the phrases, more frequently introduced into the second edition than the present, of "secretion of sensorial power, of the nervous fluid," &c. &c., involving him in the most visionary speculations. The hypothesis of a nervous fluid, the product of secretion, is not essentially different from the notion of the existence of animal spirits. The principal ground of the latter, as Dr. Bostock remarks, "seems to have been the idea that the brain is a secretory organ; an idea which was suggested by the great quantity of blood sent to it, and by some supposed resemblance in its structure to other secreting glands.—(Descartes, *Tractus de Homine*, § 14.)

known to be particularized; and Dr. Philip seems to have shown, by various trains of experiments (*Phil. Trans.*, 1814, pp. 5-90), that it is equally capable of maintaining respiration, and the operation of several of the animal secretions, especially those that induce digestion, for as long a period. But in drawing from such facts the corollary, that the "IDENTITY of galvanic electricity and nervous influence is established by these experiments," he seems, like those who have anticipated him in the same doctrine,* to proceed farther than he is warranted: for we have no right to say more than that galvanic electricity is a stimulus exciting the nervous influence into a state of continued secretion or continued action, which may possibly

Yet, as nothing cognizable by the senses is produced by it, it was concluded that it must secrete something of a subtile or ethereal nature, peculiarly suited to the performance of the functions which belong to the brain, and which are so unlike those of other material substances. It must be recollected that about two centuries ago, every thing that could not be otherwise explained was referred to the agency of some kind of refined spirit; an idea which appears to have been originally derived from the alchemists; and after being incorporated with the metaphysics of the age, gave rise to a long train of mysticism. Almost every philosopher of that period adopted more or less of these notions. Newton's ether is well known to have proved an abundant source of speculation to multitudes of those who called themselves his followers, and who seem unfortunately to have copied almost the only error which this great man committed. Upon this slender foundation was built the hypothesis of the nervous fluid, or the animal spirits, as they have been termed; yet their existence was assumed as an ascertained fact, and even their different affections and diseases were spoken of with as much confidence as if the authors had been treating upon something which was the immediate object of their senses, and with which they were perfectly familiar. The doctrine of the animal spirits has likewise become a subject of popular belief, and has given rise to a variety of expressions that are every day employed in our common language. There does not, however, appear to be the least shadow of proof of their existence, either from experiment or observation; there is no analogy in their favour; the structure and physical properties of the nerves do not seem adapted to the office that has been assigned them; and, in short, the whole is an hypothesis entirely unfounded and quite gratuitous."—See Bostock's *Physiology*, vol. i., p. 253.

* The researches of Valli led him also to conclude that electricity and the nervous fluid were identical.—(*Journ. de Phys.*, tom. xli.) And, as is remarked by Dr. Bostock, Mr. Abernethy goes still further; for he regards some subtile fluid, analogous to electricity, not merely as the prime agent in sensation, but even as constituting the essence of life itself. "Singular as it may appear, we find this highly respectable and intelligent writer sliding into materialism at the very time when he is directing the force of his genius against this doctrine.—(See *Lect. on Hunter's Physiology*, pp. 26, 30, 35, 80, &c.) It is scarcely necessary to observe, that, metaphysically speaking, the subtile or ethereal agents that are called in to aid in our explanation of the vital phenomena, are as truly material as the densest stone or metal."—See Bostock's *Physiology*, vol. i., p. 256.

be done by various other stimuli as well as by that of galvanism. M. Rolando, however, has proceeded farther than this; for while he regards the nervous fluid and that of galvanism as identic, he contemplates the cerebellum and its appendages as a galvanic machine, in which the cerebellum itself constitutes the formative pile, the medulla oblongata the conductor in which the fluid is accumulated, and the spine and nerves the channels through which it is conveyed to the muscles for the purpose of exciting *voluntary motion*. But this puts us into possession of only one half of the powers of the brain,—the *motific*. For the *sensific* powers, M. Rolando has revived the old doctrine of vibrations already noticed, and conceives that all sensations are commenced at the extremities of the nerves, and are conveyed from the circumference to the centre of the system by vibrating cords.—(*Coster, Archives Gén. de Méd.*, Mars, 1823.)*

Upon the whole, the nervous system seems to present itself, in the different classes of ani-

* Messrs. Dumas and Prevost have made some curious observations on the part taken by the nerves in muscular contraction. Their experiments, as stated by Prof. Dunglison (*Human Physiology*, by Robley Dunglison, vol. i., p. 313, Philadelphia, 1832), are as follow:—"By a microscope magnifying ten or twelve diameters, they first of all examined the manner in which the nerves are arranged in a muscle; and found, as has been already observed, that their ramifications always entered the muscle in a direction perpendicular to its fibres. They satisfied themselves that none of the nerves really terminate in the muscle; but that the final ramifications embrace the fibres like a noose, and return to the trunk that furnishes them, or to one in its vicinity: the nerve setting out from the anterior column of the spinal marrow and returning to the posterior. On farther examining the muscles at the time of their contraction, the parallel fibres composing them were found by the microscope to bend in a zigzag manner, and to exhibit a number of regular undulations: such flexions forming angles, which varied according to the degree of contraction, but were never less than fifty degrees. The flexions, too, always occurred at the same parts of the fibre, and to them the shortening of the muscle was owing, as MM. Dumas and Prevost proved by calculating the angles. The angular points were always found to correspond to the parts where the small nervous filaments enter, or are fixed into, the muscle. They therefore believed that the filaments, by their approximation, induce contraction of the muscular fibre: and this approximation they have ascribed to a galvanic current running through them, which, as the fibres are parallel and very near each other, ought to cause them to attract each other, according to Ampere's law, that two currents attract each other when they move in the same direction. The living muscles are consequently regarded by them as galvanometers of an extremely sensible kind, on account of the very minute distance and tenuity of the nervous filaments.

"They moreover affirm, that by an anatomical arrangement, the nerve is fixed in the muscle in the very position required for the proper performance of its function; and they esteem the fatty matter which envelops the nervous fibres, and which was discovered by Vauquelin, as a means of insulation, preventing the electric fluid from passing from one of the fibres to the other."—D.

mals, under various scales of elaboration; but, in every scale, to be a secernent organ through its entire range; operating by means of two or more different sets of fibres, which may be secretories or conductors of as many different fluids, or modifications of the same fluid.*

In the higher and more complicated classes of animals it consists of a cylindrical cord or spinal marrow, a central or ganglionic compages, and a brain, all communicating and acting in harmony.—(*De Nervi Symp. hum. fabricâ, usû, et morbis*, &c., Auctore, J. Lobstein, Paris, 1823.) In some of the inferior classes we find the cylindrical cord alone, and in others the ganglionic compages; while, in the lowest of all, we trace a variety of distinct and granular molecules, which seem to act the part of nervous ganglions, though we cannot discover their connexion.

The brain has so much of the general structure and character of a gland, as to be admitted by many to be an organ of this kind.† This is a point conceded even by Dr. Cullen, notwithstanding that, by supposing the energy of the brain to be a mere quality rather than a specific essence, and to be incapable of undergoing any change of recruit or exhaustion, he finds no adequate use for its glandular conformation. As we are justified, however, by all the force of analogy in regarding it as a gland, though unquestionably a gland of a peculiar kind, and as we are equally justified, on the same ground of analogy, in regarding the nervous power or energy by which it maintains a communication with every part of the system as a fluid of a peculiar kind, we are almost driven to the necessity of contemplating it as the source from which this fluid issues, and by which it is supplied as it becomes exhausted: and more especially when we reflect upon the enormous proportion of blood which is sent from the heart to the head, as the

most extensive laboratory of the entire frame, and which, according to Haller (*Elem. Physic.*, x., v., 20), amounts to one fifth, or, on the lower estimate of Monro (*On the Nervous System*, p. 3), to one tenth* of the entire current poured forth from the left ventricle of the heart, while it is well known that the weight of the human brain is not more than one fortieth part of the entire body.

It is probable that the nervous fluid, on its first secretion and in its simplest state, is as homogeneous as that of the blood; but that, like the blood, it becomes changed by particular actions, either of the particular parts of the brain, or of particular nerves themselves, into fluids possessing different powers, and capable of producing very different effects. And as modern experiments have induced us to believe, with Galen, that the nerves are a continuation of the matter of the brain (*Hippocr. et Plat. Decret.*, lib. iii., tom. i., p. 921), it is not improbable that many or all of them are endowed with something of its secernent power, and are capable of assisting in the secretion of the same fluid in its simplest state, or in some of its simpler modifications. And we may hence see the reason of that complicated mechanism which distinguishes the higher classes of animals, and how it is possible for a nervous system to exist, though with inferior powers, under a less composite fabrication.

This, however, is not mere conjecture; for in acephalous and anencephalous monsters we are compelled to admit it as a fact; and in different ramifications of the nerves we can trace such different effects actually produced: and as it has sufficiently appeared that the operative power is a quick and subtile fluid, we are directly led to conclude that such difference of effects must depend on a diversity of fluids, or on various modifications of a common fluid in different trunks or ramifications; the last of which explanations is by far the simplest and easiest.‡ And hence, in certain parts of the system, the nervous influence becomes capable of producing the effect of sensation; in others, of motion. And hence, again, the sensific influence is rendered capable of exciting in one set of organs a sense of sight; in others, of hearing, smell, or taste; while that of touch is diffused over the surface generally.

This last, by its extensive diffusion, is by Mr. Hunter called *common sensation*; and his view of the subject is in perfect consonance with the present. "It is more than probable," says he, "that what may be called organs of sense (local

* One objection to this hypothesis depends upon the fact, that, if it were admitted, we should not then have any clearer notions of the mode in which the brain and other parts of the nervous system perform their functions, than if no such hypothesis had ever been started. As Mr. Lawrence has observed, "who understands muscular contraction better by being told that an Archeus or subtile matter sets the fibres at work?"—Ed.

† This doctrine, though adopted by some physiologists, is not espoused by others. When the comparison of the brain to a gland is made, we may inquire whether it be intended to assume that the nervous fluid is secreted by the brain, and thence transmitted through the nerves? or whether the brain only secretes its own nervous fluid, and the nerves theirs? Lastly, we may ask, who has ever seen this wonderful fluid? and how many kinds of it are fancied to exist? for the several parts of the brain have different functions; and some nerves are for sensation, and others for motion. In short, it is better to confess that we know nothing of the way in which the brain and other parts of the nervous system execute their functions; and, instead of talking about the secretion of the nervous and sensorial fluid, it may be wiser to rest satisfied with the less objectionable phrases of nervous action, nervous energy, nervous influence, sensorial power, &c.—Ed.

* Boerhaave's estimate of the proportional quantity of the blood sent to the head is greater even than that named by Haller.—D.

‡ These hypotheses are at once refuted by the consideration that the different attributes of different nerves or nervous filaments are ascertained by the best modern physiologists, and particularly by the important experiments of Sir Charles Bell and those of M. Magendie, to depend upon the nature of their origin or roots, and the particular manner in which they are connected with certain portions of the brain, spinal cord, &c. Their connexion or not with ganglions, is another circumstance seeming to have much influence.—Ed.

organs) have particular nerves, whose mode of action is different from that of nerves producing common sensation, and also different from one another; and that the nerves on which the peculiar functions of each of the organs of sense depend, are not supplied from different parts of the brain. The organ of sight has its peculiar nerve: so has that of hearing; and probably that of smelling likewise: and, on the same principle, we may suppose the organ of taste to have a peculiar nerve, although these organs of sense may likewise have nerves from different parts of the brain; yet, it is most probable, such nerves are only for the common sensations of the part, and other purposes answered by nerves."—(*On the Animal Economy*, p. 261.)

We see farther, that, for the purpose of elaborating the exquisitely fine and active fluid that, differently modified, excites the local organs of sense, and excites* them in perfection, it is necessary that the nervous system should exist in its highest scale of fabrication, and be crowned with the apparatus of a brain, though this is not the only use to which the brain is subservient: and hence it was long ago pointed out by Galen, that it is from the brain alone the nerves appropriated to the local senses take their rise (*De Instrumentis Odoratibus*, edit. Basil, tom. i., p. 381); for though we have instances of the existence of a few of these senses where the nervous system is found in a much less finished form, they are never complete in number, nor apparently in acuteness.

The sense of touch, on the contrary, which, as we have already observed, is regarded by Cuvier as produced by the sensific fluid in its simplest and least compounded state, or, as Galen has it, "is the duldest and rudest of all the sentient powers," flows, for the most part, as the latter has also remarked, from the spinal marrow alone, since it is from this column that the nerves of touch almost exclusively arise. And hence we have little difficulty in conceiving how a sense of this kind may exist in mollusca, shellfishes, and the larvæ of insects, which have no other nervous system than a medullary column, with a slight increment at the upper extremity, or no increment whatever; and have no other sense, or none but in a very imperfect degree.

The nervous power producing motion, and which has properly been denominated irritative, appears to be of a still lower description than that of touch. It is hence common to the great

* Here it is to be observed that the author speaks of the "fine and active fluid" as merely exciting the organs of sense, and not as the means by which the impressions received by those organs are communicated to the sensorium. But if we ask whether vision is excited by this imaginary fluid, or by the rays of light impinging upon the retina, the invalidity of the hypothesis, even in this shape, is immediately self-evident. On other occasions the nervous fluid is used in a different meaning, being nothing less than synonymous with nervous or sensorial power itself. In all this a great want of precision attends the hypothesis, which, to increase the confusion, extends itself also to the explanation of muscular action.—ED.

mass of muscular fibres, and is probably capable of being secreted by these fibres generally; so that every fibre supplies itself where it receives no supply from any other source. Yet the proper source or reservoir of this modification of nervous fluid seems to be a ganglionic system; that which, in the higher classes of animals, we have already noticed as formed by the curious structure and ramifications of the intercostal nerve, and that which appears to be a copy of it in worms and zoophytes, which have no other nervous organization whatever. From the copiousness with which this central system furnishes a recruit to the involuntary organs, with which it is peculiarly connected in mammals, we may see why these organs are able to persevere in one uninterrupted train of action, without exhaustion or weariness, from the beginning to the end of life; and why several of them, as the heart, the lungs, and the stomach, should be able to exhibit proofs of irritative power for a considerable period of time after the death of the system, and especially when roused by particular stimulants. Fishes in general have few pretensions to this structure, and hence they die sooner than most other animals, and exhibit little muscular irritability afterward. Yet it is remarkable, that in those genera which make the nearest approach to a ganglionic system, as the cod and carp, we have examples of a like power. The fishmongers of the metropolis have taken advantage of this endowment in the cod-kind, and introduced the fashion of crimping or corrugating the flesh by the stimulus of transverse incisions; and in some curious experiments on the carp, lately instituted by Mr. Clift, he found its heart leaping, when out of water, four hours after a separation from the body.—(*Phil. Trans.*, 1815, p. 90.) If the apparently isolated molecules found in the make of the polype and various worms are ganglions of nervous irritation, extending their vital influence through certain ranges or peripheries, we are also hence enabled to account for the peculiar tenacity with which the principle of life adheres to them, and the wonderful power of reproduction which belongs to detached segments.

The curious and striking experiments which have lately been made upon animals by Dr. Philip and M. le Gallois, confirm the general view now offered so far as they bear upon it. These have consisted in an examination into the different effects produced on the heart and lungs by suddenly destroying or cutting off the communication of the whole brain; by slowly destroying it; by destroying it in the posterior part alone, and in the anterior part alone; and by destroying, in like manner, the spinal marrow at the neck, or where it unites with the brain; in its middle or dorsal, and in its lumbar region. The animals operated upon were chiefly rabbits.

According to the experiments of M. le Gallois (*Exp. sur la Principe de la Vie, &c.*), after the destruction of the brain, the action of the heart still continues for a considerable period of time unimpaired; while, on the destruction of

the spinal marrow at its upper or cervical extremity, this action becomes instantly so debilitated as to be no longer capable of supporting the circulation. Whence he infers that it is from the cord of the spinal marrow, and not from the brain, that the heart derives the principle of its life and motions.

The experiments of Dr. Philip (*Phil. Trans.*, 1815, pp. 15 and 444) are at variance with the above of M. le Gallois, and his conclusions are therefore somewhat different. They seem to show that both the brain and spinal marrow may be destroyed, and yet the heart continue to act forcibly and steadily, provided the lungs be excited by the artificial breath of a pair of bellows.

The brain and spinal marrow were destroyed by a hot wire, the animal being first stupified by a blow on the occiput. Frogs and a few other animals were here employed, as well as rabbits. It is not exactly stated how long, under this process, the heart continued to beat. Yet, contrary to what Dr. Philip seems to have expected, but in perfect concurrence with the hints I have just thrown out, he found that certain stimuli applied to the brain, whether in the anterior or posterior part of the head, increased very sensibly the action of the heart, the animal being still prepared as just stated. The same effect ensued when the same stimuli were applied to the cervical and even the dorsal part of the spinal marrow, but not when applied to the lumbar.

Dr. Philip hence concludes that there are three kinds of vital power:—muscular, possessed by the lowest kinds of animals that are destitute of both the others; nervous, or that which is here denominated the medium of touch or simple feeling, chiefly derived from or dependant upon the spinal marrow, and possessed by animals somewhat more advanced in the scale of life; and sensorial, constituting what we have just regarded as the medium of the local senses, and appertaining to the higher classes. He adds, that each of these may exist alone, and consequently independently of the rest; but admits that where the nervous principle co-exists with the muscular it exerts an influence over it, so that the latter may even be overborne or destroyed by such influence; and that when the sensorial co-exists with both, it exercises over both an equal degree of control.

III. But the nervous organ in its most elaborate and perfect state, as in man, is not only the seat of sensation and motion, but of intelligence; it is the instrument of communication between the mind and the body, as well as between the body and the objects by which the body is surrounded. And as a failure or irregular performance of its functions in various ways lays a foundation for an extensive division of corporeal diseases, so a like failure or irregularity of performance in other ways lays a foundation for as numerous a train of mental maladies.

Of the nature of the mind or soul itself, we know little beyond what REVELATION has informed us: we have no chymical test that can reach its essence; no glasses that can trace its mode

of union with the brain; no analogies that can illustrate the rapidity of its movements. And hence the darkness that in this respect hung over the speculations of the Indian gymnosophists and the philosophers of Greece continues without abatement, and has equally resisted the labours of modern metaphysicians and physiologists. That the mind is an intelligent principle, we know from nature; and that it is a principle endowed with immortality, and capable of existing after death in a state separate from the body, to which, however, it is hereafter to be reunited at a period when that which is now mortal shall put on immortality, and death itself be swallowed up of victory—we learn from the God of nature. And, with such information, we may well rest satisfied; and, with suitable modesty, direct our investigations to those lower branches of this mysterious subject that lie within the grasp of our reason.

I cannot, however, drop the subject altogether, without observing that the discussion concerning the particular entity of the mind seems to have been conducted with an undue degree of heat and confidence on all sides, considering our present ignorance of whatever substance has been appealed to as constituting its specific frame.

Is the essence of the mind, soul, or spirit, material or immaterial? The question, at first sight, appears to be of the utmost importance and gravity; and to involve nothing less than a belief or disbelief, not, indeed, in its divine origin, but in its divine similitude and immortality. Yet I may venture to affirm that there is no question which has been productive of so little satisfaction, or has laid a foundation for wider and wilder errors, within the whole range of metaphysics: and for this plain and obvious reason, that we have no distinct ideas of the terms, and no settled premises to build upon. Corruptibility and incorruptibility, intelligent and unintelligent, organized and inorganic, are terms that convey distinct meanings to the mind, and impart modes of being that are within the scope of our comprehension. But materiality and immateriality are equally beyond our reach. Of the essence of matter we know nothing, and altogether as little of many of its more active qualities; insomuch that, amid all the discoveries of the day, it still remains a controvertible position, whether light, heat, magnetism, and electricity are material substances, material properties, or things superadded to matter, and of a higher nature.

If they be matter, gravity and ponderability are not essential properties of matter, though commonly so regarded. And if they be things superadded to matter they are necessarily immaterial, and we cannot open our eyes without beholding innumerable proofs of material and immaterial bodies co-existent and acting in harmonious union through the entire frame of nature. But if we know nothing of the essence, and but little of the qualities of matter, of that common substrate which is diffused around us in every direction, and constitutes the whole of the visible world, what can we know of that

which is immaterial? of the full meaning of a term that, in its strictest sense, comprehends all the rest of the immense fabric of actual and possible being, and includes in its vast circumference every essence and mode of essence of every other being, as well below as above the order of matter, and even that of the Deity himself!

Shall we take the quality of extension as the line of separation between what is material and what is immaterial? This, indeed, is the general and favourite distinction brought forward in the present day: but it is a distinction founded on mere conjecture, and which will by no means stand the test of inquiry. Is space extended? every one admits it to be so. But is space material? is it body of any kind? Descartes, indeed, contended that it is body, and a material body; for he denied a vacuum, and asserted space to be a part of matter itself: but it is probable that there is not a single espouser of this opinion in the present day. If, then, extension belong equally to matter and to space, it cannot be contemplated as the peculiar and exclusive property of the former; and if we allow it to immaterial space, there is no reason why we should not allow it to immaterial spirit. If extension appertain not to the mind or thinking principle, the latter can have NO PLACE of existence: it can exist NOWHERE; for WHERE or PLACE is an idea that cannot be separated from the idea of extension. And hence the metaphysical immaterialists of modern times freely admit that the mind has NO PLACE of existence; that it does exist NOWHERE; while, at the same time, they are compelled to allow that the immaterial Creator, or universal Spirit, exists EVERYWHERE, substantially as well as virtually.

Nor let it be supposed that the difficulty is removed by adding to matter the quality of solidity in conjunction with that of extension, and hence distinguishing it as possessed of SOLID EXTENT; for the quality of solidity is less characteristic of it than any we have thus far taken notice of, and is perpetually fleeing from us as we pursue it. That matter is infinitely divisible we dare not say, because we should hereby reduce it to mathematical points, and because, also, there would in such case be no certain or permanent basis to build upon, and to ensure a punctuality of material cause and effect; and hence Sir Isaac Newton was obliged to suppose that it is possessed of ultimate atoms which are solid and unchangeable. But of these the senses can trace nothing, and our admission is nothing more than conjectural.

Let not the author, however, be misunderstood upon this abstruse and difficult subject. That the mind has a DISTINCT NATURE and is a DISTINCT REALITY from the body, that it is gifted with immortality, endowed with reasoning faculties, and capacised for a state of separate existence after the death of the corporeal frame to which it is attached, are, in his opinion, propositions most clearly deducible from revelation, and, in one or two points, adumbrated by a few shadowy glimpses of nature. And that it may be a substance strictly IMMATERIAL and ESSEN-

TIALLY DIFFERENT from matter is both possible and probable, and will hereafter, perhaps, when faith is turned into vision, and conjecture into fact, be found to be the true and genuine doctrine upon the subject. But till this glorious era arrive; or till, antecedently to it, it be proved, which it does not hitherto seem to have been, that matter, itself of divine origin, gifted even at present, under certain modifications, with instinct and sensation, and destined to become immortal hereafter, is physically incapable, under some still more refined, exalted, and spiritualized modification, of exhibiting the attributes of the soul; of being, under such a constitution, endowed with immortality from the first, and capacised for existing separately from the external and grosser frame of the body; and that it is beyond the power of its own Creator to render it intelligent, or to give it even brutal perception, the argument must be loose and inconclusive: it may plunge us, as it has plunged thousands already, into errors, but can never conduct us to demonstration. It may lead us, on the one hand, to the proud Braminical and Platonic belief, that the essence of the soul is the very essence of the Deity, and consequently a part of the Deity himself; or, on the other, to the gloomy regions of modern materialism, and to the cheerless doctrine that it dies and dissolves in one common grave with the body.

It is no fair objection, however, against the immaterialist, that, by contemplating the mind as a distinct essence from that of the body, man is hereby rendered a compound being, possessing at one and the same time two distinct lives mysteriously united in an individual frame, and running in parallel lines till the hour of death. For while the known and obvious laws and faculties of the mind and body are so widely different as they are acknowledged to be on all hands, some such composite union has been and must be allowed under every hypothesis whatever. And least of all have the skeptical physiologists of the present day any right to triumph upon such an objection; who, drawing no light from nature, and rejecting that of sacred writ, contemplate the mind as formed of the same gross modification of matter as the body, and doomed to fall with it into one common and eternal dissolution. For even these acute materialists, with all the aid of physiological, anatomical, and chymical research, instead of simplifying the human fabric, have made it more clumsily complex, and represented it sometimes, indeed, as a duad, but of late more generally as a triad, of unities, a combination of a corruptible life within a corruptible life two or three deep, each possessing its own separate faculties or manifestations, but covered with a common outside.

This remark more especially applies to the philosophers of the French school, and particularly to the system of Dumas (*Princ. de Physiol.*, 4 tomes, 8vo., Paris, 1800-3) as modified by Bichat; under which more finished form man is declared to consist of a pair of lives, each distinct and co-existent, under the names

of an organic and an animal life; with two distinct assortments of sensibilities, an unconscious and a conscious. Each of these lives is limited to a separate set of organs, runs its race in parallel steps with the other, commencing coetaneously and perishing at the same moment. This work appeared at the close of the past century, was read and admired by most physiologists, credited by many, and became the popular production of the day. Within ten or twelve years, however, it ran its course, and was as generally either rejected or forgotten even in France; and M. Richerand first, and M. Magendie since, have thought themselves called upon to modify Bichat, in order to render him more palatable, as Bichat had already modified Dumas. Under the last series of remodelling, which is that of M. Magendie, we have certainly an improvement, though the machinery is quite as complex. Instead of two distinct lives, M. Magendie presents us with two distinct sets or systems of action or relation, each of which has its separate and peculiar functions; a system of nutritive action or relation, and a system of vital. To which is added, by way of appendix, another system, comprising the functions of generation.—(*Physiologie*, 2 tomes, 8vo., Paris, 1816, 1817.) Here, however, the brain is not only the seat, but the organized substance of the mental powers; so that we are expressly told a man must be as he is made in his brain, and that education, and even logic itself, is of no use to him. "There are," says M. Magendie, "justly celebrated persons who have thought differently, but they have hereby fallen into grave errors." A Deity, however, is allowed to exist, because, adds the writer, it is comfortable to think that he exists, and on this account the physiologist cannot doubt of his being. "L'intelligence de l'homme," says he, "se compose de phénomènes tellement différens de tout ce que présente d'ailleurs la nature, qu'on les rapporte à un être particulier qu'on regarde comme une émanation de la Divinité. Il est trop consolant de croire à cet être, pour que le physiologiste mette en doute son existence; mais la sévérité de langage ou de logique que comporte maintenant la physiologie, exige que l'on traite de l'intelligence humaine comme si elle était le résultat de l'action d'un organe. En s'écartant de cette marche, des hommes justement célèbres sont tombés dans des graves erreurs; en la suivant, on a, d'ailleurs, le grand avantage de conserver la même méthode d'étude, et de rendre très-faciles des choses qui sont envisagées généralement comme presque au-dessus de l'esprit humain."—"Il existe une science dont le but est d'apprendre à raisonner justement, c'est la logique; mais le jugement erroné ou l'esprit faux (for judgment, genius, and imagination, and therefore false reasoning, all depend on organization) tiennent à l'organization. Il est impossible de se changer à cet égard; nous restons tels que la nature nous a faits."—(*Précis Élémentaire*, &c., ut supra, passim.)

Dr. Spurzheim has generally been considered, from the concurrent tenour of his doctrines, as belonging to the class of materialists; but this

is to mistake his own positive assertion upon the subject, or to conclude in opposition to it. He speaks, indeed, upon this topic with a singular hesitation and reserve, more so perhaps than upon any other point whatever; but as far as he chooses to express himself on so abstruse a subject, he regards the soul as a distinct being from the body, and at least intimates that it *may be nearer* akin to the Deity. Man is with him also possessed of two lives, an AUTOMATIC and an ANIMAL: the first produced by organization alone, and destitute of consciousness; the second possessed of consciousness dependant on the soul, and merely manifesting itself by organization. "We do not," says he, "attempt to explain how the body and soul are joined together and exercise a mutual influence. We do not examine what the soul can do without the body. Souls, so far as we know, may be united to bodies at the moment of conception or afterward; they may be different in all individuals, or of the same kind in every one; they may be emanations from God, or something essentially different."—(*Physiognomical System*, &c., p. 253, 8vo., London, 1815.) The mind of this celebrated craniologist seems to be wonderfully skeptical and bewildered upon the subject, and studiously avoids the important question of the capacity of the soul for an independent and future existence; but, with the above declarations, he cannot well be arranged in the class of materialists.

The hypothesis adopted by Mr. Lawrence (*Introduction to Comp. Anat. and Phys.*, &c., 8vo., 1816), and which is nearly the same as that of Bichat* and Cuvier,† is altogether of a different kind; and, though undoubtedly much simpler than any of the preceding, does not seem to be built on a more stable foundation. According to his view of the subject, organized differs from inorganic matter merely by the addition of certain PROPERTIES which are called vital, as sensibility and irritability. Masses of matter endowed with these new PROPERTIES become organs and systems of organs, constitute an animal frame, and execute distinct sets of PURPOSES or FUNCTIONS, for functions and purposes carried into execution are here synonymous. "Life is the assemblage of ALL the functions (or purposes), and the general result of their exercise."—(*Ibid.*, p. 120.)

Life, therefore, upon this hypothesis, instead of being a twofold or threefold reality, running in a combined stream, or in parallel lines, has no reality whatever. It has no ESSE or independent existence. It is a mere assemblage of PURPOSES, and accidental or temporary PROPERTIES: a series of phenomena (*Ibid.*, p. 122), as Mr. Lawrence has himself correctly expressed it;—a name without a thing. "We know not," says he, "the nature of the link that unites these phenomena, though we are sensible that a con-

* "La vie est l'ensemble des fonctions qui résiste à la mort."—*Recherches Physiologiques sur la Vie et la Mort*, art. 1.

† "Dans chaque être, la vie est un ensemble qui résulte de l'action et de la réaction mutuelle de toutes ses parties."—*Le Règne Animal*, tom. i.; *Introd.*, p. 16.

nexion must exist; and this conviction is sufficient to induce us to give it a NAME, which the VULGAR regard as the sign of a particular principle: though in fact that name can only indicate the ASSEMBLAGE OF THE PHENOMENA which has occasioned its formation."—(Ibid.)

The human frame is, hence, a barrel-organ, possessing a systematic arrangement of parts, played upon by peculiar powers, and executing particular pieces or purposes; and life is the music, produced by the general assemblage or result of the harmonious action. So long as either the vital or the mechanical instrument is duly wound up by a regular supply of food or of the winch, so long the music will continue: but both are worn out by their own action; and when the machine will no longer work, the life has the same close as the music; and in the language of Cornelius Gallus, as quoted and appropriated by Leo X.,

"—redit in nihilum, quod fuit ante nihil."

There is, however, nothing new, either in this hypothesis or in the present explanation of it. It was first started, in the days of Aristotle, by Aristoxenus, a pupil of his, who was admirably skilled in music, and by profession a physician. It was propounded to the world under the name of the system of HARMONY, either from the author's fondness for music, or from his comparing the human frame to a musical instrument, and his regarding life as the result of all its parts acting in accordance, and producing a general and harmonious effect.

How far Mr. Lawrence's revised edition of this hypothesis may prove satisfactory to other classes of materialists I cannot tell: but if he should succeed he will be more fortunate than Aristoxenus, who pleased neither the other materialists nor the immaterialists of his day. From the latter, indeed, he could expect no countenance: but even the Epicureans, though they held that the mind was corruptible, as formed of matter, which they had no reason to believe was then or ever would be otherwise than corruptible under any modification whatever, held, at the same time, that it had a substantive existence, distinct from that of the grosser frame of the body, and possessed of other and far higher properties; being formed of the finest, lightest, smoothest, and most moveable material elements, and hence exquisitely etherealized and volatile:

"—est animi natura reperta

Mobilis egregie, perquam constare necesse est.
Corporibus parvis, et lævibus, atque rotundis."*

The atomic philosophers, therefore, joined with the Platonists and Stoics in opposing the system of harmony, and that chiefly upon the two following grounds, which will apply with as much force to its present as to its primary form. First, admitting that an assemblage and exercise of ALL the functions of the machine are necessary to maintain the phenomena of life, we are left as much in the dark as ever concerning the nature of the principle by which this harmonious instrument becomes gradually developed, and is

kept in perpetual play. And next, that the life or wellbeing of the animal frame does not depend upon an assemblage and exercise of ALL its functions or purposes; since the mind may be diseased while the body remains unaffected, or the body may lose some of its own organs, while the mind, or even the general health of the body itself, may continue perfect.—(Ibid., iii., 105-266; *Lactant. in Vit. Epicur. Polignac. Anti-Lucret.*, lib. v., 923.)

In the darkness, therefore, which continues to hang over the mysterious subject before us, I feel incompetent to enter into the question concerning the actual essence of the mind, and am perfectly content to take its general nature, powers, and destiny, from the only volume which is capable of giving us any decided information upon the subject; to follow it up as far as that volume may guide us; and to stop where it withdraws its assistance.

Closely connected with the present question is another of nearly as much perplexity, and the consideration of which has not been attended with much more success, but which must not be passed by on the present occasion without being glanced at.

Whatever be the nature or substance of the mind, the brain is the organ in which it holds its seat, and whence it maintains an intercourse with the surrounding world. Now it must be obvious to every one who has attended to the operation of his senses, that there never is nor can be any direct communication between the mind, thus stationed in the brain, and the external objects the mind perceives; which are usually, indeed, at some distance even from the sense that gives notice of them. Thus, in looking at a tree, it is the eye alone that beholds the tree, while the mind only perceives a notice of its presence, by some means or other, from the visual organ. So, in touching this table, it is my hand alone that comes in contact with it, and communicates to my mind a knowledge of its hardness and other qualities. What then is the medium by which such communication is maintained? which enables the mind to have a perception of the form, size, colour, smell, and even distance of objects, correspondent with that of the senses which are seated on the surface of the body? and which, at the same time that it conveys this information, produces such an additional effect, that the mind is able, at its own option, to call up an exact notion or idea of those qualities at a distant period, or when the objects themselves are no longer present? Is there, or is there not, any resemblance between the external or sensible object, and the internal or mental idea or notion? If there be a resemblance, in what does that resemblance consist? and how is it produced and supported? Does the external object throw off representative likenesses of itself in films, or under any other modification, so fine as to be able, like the electric or magnetic aura, to pass without injury from the object to the sentient organ, and from the sentient organ to the sensory, or mental presence-chamber? or has the mind itself a faculty of producing, like a mirror, accurate countersigns, intellectual

* Lucret., *De Rer. Nat.*, iii., 204.

pictures or images correspondent with the sensible images communicated from the external object to the sentient organ! If, on the contrary, there be no resemblance, are the mental perceptions mere notions, or intellectual symbols excited in the mind by the action of the external sense; which, while they bear no similitude to the qualities of the object discerned, answer the purpose of those qualities, as letters answer the purpose of sounds! or are we sure that there is any external world whatever; any thing beyond the intellectual principle that perceives and the sensations and notions that are perceived; or even any thing beyond those sensations and notions, those impressions and ideas themselves?

Several of these questions may perhaps appear in no small degree whimsical and brain-sick, and more worthy of St. Luke's than of a work of physiological study; but all of them, and at least as many more, of a temperament as wild as the wildest, have been asked and insisted upon, and supported again and again in different ages and countries, from the zenith of Grecian science down to our own day, by philosophers of the clearest intellects in other respects, and who had no idea of labouring under any such mental infirmity, nor ever dreamed of the necessity of being blistered and taking physic.

The nature of the questions themselves, therefore, when put by the characters referred to, sufficiently manifests the obscurity of the subject to which they relate: and to enter into the discussions to which they have given rise, would lead us to an irrecoverable distance from the path before us. Those who are desirous of following them up, and of witnessing an exposure of their absurdity, cannot do better than apply themselves to the metaphysical writings of Dr. Reid, Dr. Beattie, Dr. Campbell, and Professor Stewart; who if, on the overthrow of so many Babel-buildings, they have not been able to raise an edifice much more substantial in their stead, have only failed from the insuperable difficulty of the attempt.

No man was more sensible of this difficulty than Mr. Locke, nor has taken more pains both to avoid what is unintelligible and unprofitable, and to elucidate what may be turned to a good account and brought home to an ordinary comprehension. It was his imperishable *Essay on Human Understanding* that gave the first check to the wild and visionary conceits in which the most celebrated luminaries of the age were at that time engaged; recalled mankind from the chasing of shadows to the study of realities, from a pursuit of useless and inexplicable subtleties to that of important and cognoscible subjects: or rather to the only mode in which the great inquiry before him could be followed up with any reasonable hope of success or advantage.

To this elaborate and wonderful work, which has conferred an ever-during fame, not only on its matchless author, but on the nation to which he belonged, and even the age in which he lived, the physiologist cannot pay too close an attention. It is, indeed, of the highest importance to every science, as teaching us the elements

of all science, and the only mode by which science can be rendered really useful, and carried forward to ultimate perfection; but it is of immediate importance to every branch of physical knowledge, and particularly to that which is employed in unfolding the structure of the mind, and its connexion with the visible fabric that encloses it. It may, perhaps, be somewhat too long; it may occasionally embrace subjects which are not necessarily connected with it: its terms may not always be precise, nor its opinions in every instance correct; but it discovers intrinsic and most convincing evidence, that the man who wrote it must have had a head peculiarly clear, and a heart peculiarly sound: it is strictly original in its matter, highly important in its subject, luminous and forcible in its argument, perspicuous in its style, and comprehensive in its scope. It steers equally clear of all former systems: we have nothing of the mystical archetypes of Plato, the incorporeal phantasms of Aristotle, or the material species of Epicurus; we are equally without the intelligible world of the Greek schools, and the innate ideas of Descartes. Passing by all which, from actual experience and observation, it delineates the features and describes the operations of the human mind with a degree of precision and minuteness which has never been exhibited either before or since; and stands, and probably ever will stand, like a rock, before the puny waves of opposition by which it has since been assailed from various quarters. The author may speak of it with warmth, but he speaks from a digested knowledge of its merits: for he has studied it thoroughly and repeatedly; and there is, perhaps, no book to which he is so much indebted for whatever small degree of discrimination or habit of reasoning he may possibly be allowed to lay claim to.

Upon one point he is perfectly clear; namely, that the chief objections at any time urged against this celebrated production have proceeded from an utter mistake of its meaning, of which he could give numerous instances, if such a digression were allowable, from the writings of many who have the credit of having studied it profoundly. The remark applies to several of the most popular psychologists of both North and South Britain, but especially to those of the continent, and more particularly still to M. Condorcet, from whom the French in general have received an erroneous idea of several of its leading doctrines. It is to this book the medical student ought to turn himself for a knowledge of the laws that regulate the development and growth of the mind, as he should do to the labours of Haller or Hunter for a knowledge of those that regulate the development and growth of the body; and I shall hence draw largely upon it through the remainder of this introduction.

The whole, then, of the metaphysical rubbish of the ancient schools being cleared away by the purging and purifying energy of the *Essay on Human Understanding*, mankind have since been enabled to contemplate the body and mind as equally, at birth, a *tabula rasa*, or unwritten sheet of paper; as consisting equally of a blank or vacuity of impressions; but as

equally capable of acquiring impressions by the operation of external objects, and equally and most skilfully endowed with distinct powers or faculties for this purpose: those of the body being the external senses of sight, hearing, smell, taste, and touch; and those of the mind, the internal senses of perception, reason, judgment, imagination, and memory.

It is possible that a few slight impressions may be produced a short time antecedently to birth; and it is certain that various instinctive tendencies, which, however, have no connexion with the mind, are more perfect, because more needful, at the period of birth than ever afterward; and we have also frequent proofs of an hereditary or accidental predisposition towards particular subjects. But the fundamental doctrine before us is by no means affected by such collateral circumstances.

External objects first impress or operate upon the outward senses; and these senses, by means hitherto unexplained, and perhaps altogether inexplicable, immediately impress or operate upon the mind, or excite in it perceptions or ideas of the presence and qualities of such objects; the word idea being here employed, not in any of the significations of the schools, but in its broad popular meaning, as importing "whatever a man observes, and is conscious to himself he has in his mind" (*Locke, on Human Understanding*, b. i., ch. i., § 3), whatever was formerly intended by the terms archetype, phantasm, species, thought, notion, or conception, or whatever else it may be which we can be employed about in thinking.—(Id., b. i., ch. i., § 8.) And to these effects Mr. Locke gave the name of *ideas of SENSATION*, in allusion to the source from which they are derived.

But the mind, as we have already observed, has various powers or faculties as well as the body, and they are quite as active and lively in their respective functions; in consequence of which the ideas of external objects are not only perceived, but retained, thought of, compared, compounded, abstracted, doubted, believed, desired; and hence another fountain, and of a very capacious flow, from which we also derive ideas; viz., a reflex act or perception of the mind's own operations, whence the ideas derived from this fountain are denominated *ideas of REFLECTION*.

The ideas, then, derived from these two sources, and which have sometimes been called *OBJECTIVE* and *SUBJECTIVE*, constitute all our experience, and, consequently, all our knowledge. Whatever stock of information a man may be possessed of, however richly he may be stored with taste, learning, or science, if he turn his attention inward, and diligently examine his own thoughts, he will find that he has not a single idea in his mind but what has been derived from one or the other of these two channels. But let not this important observation be forgotten by any one; that the ideas the mind possesses will be fewer or more numerous, simpler or more diversified, clear or confused, according to the number of the objects presented to it, and the extent of its reflection and examination.

Thus a clock or a landscape may be for ever before our eyes; but unless we direct our attention to them, and study their different parts, although we cannot be deceived in their being a clock or a landscape, we can have but a very inadequate idea of their character and composition.

The ideas presented to the mind, from which soever of these two sources derived, are of two kinds—*SIMPLE* and *COMPLEX*.

SIMPLE IDEAS consist of such as are limited to a single notion or perception; as those of unity, darkness, light, sound, simple pain or uneasiness. And in the reception of these the mind is passive; for it can neither make them to itself, nor can it, in any instance, have any idea which does not wholly consist of them; or, in other words, it cannot contemplate any one of them otherwise than in its totality.

COMPLEX IDEAS are formed out of various simple ideas, associated together or contemplated derivatively. And to this class belong the ideas of an army, a battle, a triangle, gratitude, veneration, gold, silver, an orange, an apple; in the formation of all which it must be obvious that the mind is active, for it is the activity of the mind alone that produces the complexity out of such ideas as are simple. And that the ideas I have now referred to are complex, must be plain to every one; for every one must be sensible, that the mind cannot form to itself the idea of an orange without uniting into one aggregate the simple ideas of roundness, yellowness, juiciness, and sweetness; and so of the rest.

Complex ideas are formed out of simple ideas by many operations of the mind; the principal of which, however, are some combination of them, some abstraction, or some comparison. Let us take a view of each of these.

And first of complex ideas of *COMBINATION*. Unity, as I have already observed, is a simple idea; and it is one of the most common simple ideas that can be presented to the mind; for every object without, and every notion within, tend equally to excite it: and being a simple idea, the mind, as I have also remarked, is passive on its presentation: it can neither form such an idea to itself, nor contemplate it otherwise than in its totality; but it can combine the ideas of as many units as it pleases, and hence produce the complex idea of a hundred, a thousand, or a hundred thousand. So beauty is a complex idea; for the mind, in forming it, combines a variety of separate ideas into one common aggregate. Thus Dryden, in delineating the beautiful Victoria in his *Love Triumphant*,

"Her eyes, her lips, her cheeks, her shape, her features,
Seem to be drawn by Love's own hand; by Love Himself in love."

In like manner the mind can produce complex ideas by an opposite process; and that is by *ABSTRACTION* or separation. Thus chalk, snow, and milk, though agreeing, perhaps, in no other respect, coincide in the same colour; and the mind, contemplating this agreement, may abstract or separate the colour from the

other properties of these three objects, and form the idea which is indicated by the term *whiteness*; and having thus acquired a new idea by the process of abstraction, it may afterward apply it as a character to a variety of other objects; and hence particular ideas become general or universal.

Other complex ideas are produced by COMPARISON. Thus, if the mind take one idea, as that of a foot, as a determinate measure, and place it by the side of another idea, as the idea of a table, the result will be a formation of the complex idea of length, breadth, and thickness. Or, if we vary the primary idea, we may obtain, as a result, the secondary ideas of coarseness and fineness.

And hence complex ideas must be almost infinitely more numerous than simple ideas, which are their elements or materials; as words must be always far more numerous than letters. I have instanced only a few of their principal kinds, and have applied them only to a few of the great variety of subjects to which they are referable, and by which they are elucidated in the great work on Human Understanding.

It must, however, from this imperfect sketch, appear obvious, that many of our ideas have a NATURAL CORRESPONDENCE, congruity, and connexion with each other; and as many, perhaps, on the contrary, a NATURAL REPUGNANCE, incongruity, and disconnexion. Thus, if I were to speak of a cold fire, I should put together ideas that are naturally disconnected and incongruous; and should consequently make an absurd proposition, or, to adopt common language, talk nonsense. I should be guilty of the same blunder if I were to talk of a square billiard-ball, or a soft reposing rock; but a warm fire, on the contrary, a white or even a black billiard-ball, and a hard rugged rock, are congruous ideas, and consequently consistent with good sense. Now it is the direct office of that discursive faculty of the mind which we call reason, to trace out these natural coincidences or disjunctions, and to connect or separate them by proper relations: for it is a just perception of the natural connexion and congruity, or of the natural repugnance and incongruity of our ideas, that shows a sound mind, and constitutes real knowledge. The wise man is he who has industriously laid in and carefully assorted an extensive stock of ideas; as the stupid or ignorant man is he who, from natural hebetude, or having had but few opportunities, has collected and arranged but a small number. The man who discovers the natural relations of his ideas quickly, is a man of sagacity; and in popular language is said, and correctly so, to possess a quick, sharp intellect: the man, on the contrary, who discovers these relations slowly, we call dull or heavy. If he rapidly discover and put together relations that lie remote, and perhaps touch only in a few points, but those points striking and pleasant, he is a man of wit, genius, or brilliant fancy, of agreeable allusion and metaphor: if he intermix ideas of fancy with ideas of reality, those of reflection with those of sensation, and mistake the one for the

other, however numerous his ideas may be, and whatever their order of succession, he is a madman; he reasons from false principles, and, as we say in popular language, and with perfect correctness, is out of his judgment.

Finally, our ideas are very apt to ASSOCIATE or run together in trains; and, upon this peculiar and happy disposition of the mind, we lay our chief dependance in sowing the seeds of education. It often happens, however, that some of our ideas have been associated erroneously, and even in a state of early life, before education has commenced; and hence, from the difficulty of separating them, most of the sympathies and antipathies, the whims and prejudices, that occasionally haunt us to the latest period of old age.

Such, then is the manner in which the mind, at first a sheet of white paper, without characters of any kind, becomes furnished with that vast store of ideas, the materials of wisdom and knowledge, which the busy and boundless fancy of man paints upon it with an almost endless variety. The whole is derived from experience, THE EXPERIENCE OF SENSATION OR OF REFLECTION; from the observations of the mind employed either about external sensible objects, or the internal operations of itself, perceived and reflected upon by its own faculties.

These FACULTIES are to the mind what organs are to the body; they are its ministers in the production, combination, and resolution of different trains of ideas, and in supplying it with the results of its own activity. We sometimes, however, are apt to speak of them as distinct and separate existences from the mind, or as possessing a sort of independent entity, and as controlling one another by their individual authorities, and occasionally, indeed, as controlling the mind itself: for we accustom ourselves to describe the will as being overpowered by the judgment; or the judgment as being overpowered by the imagination; or the mind itself as being carried headlong by the violence of its own passions. By all which, however, we only mean, or should only mean, that the mind does not, on such occasions, exert its own faculties in a fitting or sober manner, or that from some diseased affection it is incapable of doing so. For the faculties of the mind are so many powers; and, as powers, are mere attributes of the being or substance to which they belong, and not the being or substance itself. These, therefore, being all different powers in the mind or in the man to do several actions, he exerts them as he thinks fit; but the power to do one action is not operated upon by the power to do another action: for the power of thinking operates not on the power of choosing, nor the power of choosing on the power of thinking; any more than the power of dancing operates on the power of singing, or the power of singing on the power of dancing (*Locke*, p. 129), as any one who reflects on these things will easily perceive.

The body has its feelings, and the mind has its feelings also; and it is the feelings of the latter which we call PASSIONS, a mere Latin term for the feelings or sufferings of colloquial

language. The feelings of the body are numerous and diversified, as those of simple ache or ease, hunger, thirst, heat, cold, and a multitude of others. Those of the mind are still more numerous and more diversified, for they comprise the multifarious train of grief, joy, love, hatred, avarice, ambition, conceit, and perhaps hundreds more: all which, whether of body or mind, Mr. Locke has endeavoured to resolve into different modifications of pleasure or pain, according as they are productive of good or evil.

But the analogy we are thus conducting between the mind and the body holds much farther; for as the latter is subject to DISEASES OF VARIOUS KINDS, so also is the former. The body may be enfeebled in all its powers, in only a few of them, or in only a single one. So also may the mind:—"The powers of perception and imagination," observes M. Pinel, "are frequently disturbed without any excitement of the passions. The functions of the understanding, on the other hand, are often perfectly sound, while the man is driven by his passions to acts of turbulence and outrage." And these infirmities, whether of body or mind, may be constitutional and permanent, periodical or recurrent, or merely incidental and temporary. The body may be of a sanguineous temperament, of a plethoric temperament, of a nervous or irritable temperament; and the mind may, in like manner, possess an overweening confidence and courage, be characteristically dull and inactive, or be ever goaded on by restlessness and eager desire: it may be quick in apprehension and taste, but weak in memory; strong in judgment,

but slow in imagination; or feeble in judgment, but rapid in imagination: its feelings or passions may be sluggish, or all alive; or some passion may be peculiarly energetic, while the rest remain at the temperate point.

When the corporeal deviations from the standard of high health are but slight, they are scarcely entitled to the name of diseases; but when severe or extreme, they become subjects of serious attention. It is the same with the different states of the mind, with which I have just contrasted them. While several, or even all the mental faculties are slightly weak or sluggish, or inaccordant with the action of the rest, they are scarcely subjects of medical treatment—for otherwise half the world would be daily consigned to a strait waistcoat: but when the same changes become striking and strongly marked, they are real DISEASES OF THE INTELLECT; and, in the ensuing order, the genera will be found taken from the peculiar faculties of the mind that chance to be thus affected.

The mind and the body bear also, in many cases, a reciprocal influence on each other; which is sometimes general, and sometimes limited to particular faculties or functions. It is hence that fever or cephalitis produces delirium, and vapours or low spirits dyspepsy.

The mind, therefore, like the body, becomes an interesting field of study to the pathologist, and opens to his view an additional and melancholy train of diseases. It is these which will constitute the subject of the first order of the class we have now entered upon, and which are entitled to a deep and collected attention.

CLASS IV.

NEUROTICA.

ORDER I. PHRENICA.

DISEASES AFFECTING THE INTELLECT.

ERROR, PERVERSION, OR DEBILITY OF ONE OR MORE OF THE MENTAL FACULTIES.

THE word PHRENICA is Greek, from the Greek noun φρήν, "the mind" or "intellect." The diseases comprised in the order are so closely associated with each other, that, however the ordinal names may differ in different systems of nosology, they are for the most part grouped in some form or other under a correspondent division. And hence the present order will be found to run nearly parallel with the Deliria of Sauvages, the Mentales of Linnéus, the Paranoïæ of Vogel, the Vesaniæ of Cullen, and still more with those of Crichton, and the Aliénation mentale of Pinel: although the generic divisions are widely different from all of them, and are attempted to be rendered something clearer and more exact. The order comprehends the six following:—

I. Ecphronia.	Insanity.
II. Empathema.	Ungovernable Passion.
III. Alusia.	Illusion.
IV. Aphelxia.	Revery.
V. Paroniria.	Sleep-Disturbance.
VI. Moria.	Fatuity.

Each of these will be found to include various distinct species of disorder, proceeding from a morbid condition of one or more of the mental faculties or feelings, or an irrespondence of them to others; sometimes originating in a diseased state of the body, and sometimes producing such a state as has already been explained in the preceding poem.*

* The different forms of madness, or insanity, are classified by Dr. Prichard under the following divisions:—1. *Moral insanity*, or madness consisting in a morbid perversion of the natural feelings, affections, inclination, temper, habits, and moral dispositions, without any notable lesion of the intellect, or knowing and reasoning faculties, and particularly without any maniacal hallucination. 2. *Intellectual insanity*, or madness attended with hallucination; in which the insane person is im-

GENUS I. ECPHRONIA.

INSANITY. CRAZINESS.

DISEASED PERCEPTION, WITH LITTLE DERANGEMENT OF THE JUDGMENT, OCCASIONALLY SHIFTING INTO DISEASED JUDGMENT WITH LITTLE DERANGEMENT OF THE PERCEPTION; DISTURBING THE MIND GENERALLY; DIMINISHED SENSIBILITY; IRREGULAR REMISSIONS.

THE generic term ECPHRONIA, in the Greek writers *ἐκφρων* or *ἐκφροσύνη*, is derived from *ἐκφρων*, "extra mentem"—literally "out of one's

pressed with the belief of some unreal event, as of a thing which has actually taken place, or in which he has taken up some notion repugnant to his own experience and to common sense, as if it were true and indisputable, and acts under the influence of this erroneous conviction. 3. Another well-marked variety, *incoherent madness*, as it was called by Dr. Arnold, in which the whole mind seems to be equally deranged. The most striking phenomena of this case are the rapidity and disorder with which the ideas follow each other, almost without any discoverable connexion or association, in a state of complete incoherence and confusion. It is impossible to fix the attention of the patient long enough to obtain a reply to the most simple question. His understanding is wholly lost in the constant hurry of ideas which crowd themselves upon him, and which appear to exceed the power of distinct utterance, while his habits betray a corresponding degree of restless activity and extravagance.—See Cyclop. of Pract. Med., art. INSANITY.

In the truth of the following observation we must all concur:—"The interests of the public greatly require that medical men, to whom alone the insane can ever properly be intrusted, should have opportunities of studying the forms of insanity, and of preparing themselves for its treatment, in the same manner in which they prepare themselves for the treatment of other disorders. They have at present no such opportunity. During the term allotted to medical study, the student never sees a case of insanity, except by some rare accident. While every hospital is open, every lunatic asylum is closed to him: he can study all diseases but those affecting the understanding—of all diseases the most calamitous."—(See Dr. Conolly's Inquiry concerning the Indications of Insanity, 8vo., Lond., 1830, Introd.) No doubt, it was the consideration of the necessity of making some attempt to remedy this defect in medical education now spoken of, that induced the governors of Guy's Hospital to attach a lunatic establishment to it. Dr. Conolly admits, however, that insane patients are not always in a state to be visited by pupils, and that a very strict discipline would be necessary to prevent disorder or impropriety; but he argues that such arrangements might be made as would at once guard those patients from disturbance whom it might injure, and present a sufficient number of instructive examples to the student.—Ed.*

* The various forms of insanity have been treated with much learning by Dr. Rush in his work on the diseases of the mind; he there considers derangement of the intellect under several heads: as *hypochondriasis*, or *tristi-mania*; *amano-mania*, or partial intellectual derangement, accompanied with pleasure, or not accompanied with distress: *mania*; *manicula*; which, according to Dr. Rush, is a second grade of general mad-

mind," as *ἐκφρων* is "mentis compos," or "in one's mind." It is here used, as among the Greeks, generically alone, in the ordinary sense of insanity; and is designed to include the two following species:—

1. Ecphronia Melancholia. Melancholy.
2. ——— Mania. Madness.*

Each of these species has been regarded by many nosologists as forming a *genus* of itself, for which there seems to be no just reason. Dr. Cullen has thus arranged them in his Synopsis; but has given them a different arrangement and a very subordinate place in his Practice of Physic, so that, in the two works, he is in this respect altogether at variance with himself. In both, his order is entitled *vesaniæ*, which, in the first, includes fatuity, mania, melancholy, and sleep-disturbance (*oneirodynia*), as distinct genera; but, in the last, takes for its genera de-

ness, and differs from mania, as chronic rheumatism varies from that which is acute, that is, in being accompanied with a more moderate degree of the same symptoms: *manalgia*; the symptoms of which are taciturnity, downcast looks, a total neglect of dress and person, and insensibility to heat and cold. Dr. Rush treats also of derangement of the memory, fatuity, incubus, somnambulism, illusions, reverie, the derangement of the passions, the morbid state of the sexual appetite, and of the disorders of the moral faculties.

Dr. T. Y. Simons (Observations on Mental Alienation, &c., Charleston, 1828) considers insanity under various grades, as, 1st, *Mania*, a total hallucination on all subjects, or a total perversion of the intellectual faculties, accompanied with furor. 2. *Melancholia*, a total or partial hallucination, accompanied with extreme dejection, fear, and false apprehensions. 3. *Monomania*, a false reasoning or conception on one subject, which, when it completely overcomes the other operations of the mind, produces either melancholia or mania, according to the cause and the temperament of the individual. 4. *Hypochondriasis*, a continued apprehension of the physical health, regardless of worldly affairs, connected with dyspeptic symptoms.—D.

* The word *mad* is stated by Dr. Armstrong to be derived from the Gothic word *mod*, which signifies rage; and the word *mania*, which the Greeks apply to madness, has the same signification. Melancholy etymologically signifies black bile. Hence, in the ancient writers, the term *mania* is applied to that form of madness in which there is excessive excitement of the system, with violent emotions of the mind; and the term *melancholia*, to that form in which the body and mind are depressed. Hence, also, the terms high madness and low madness. Insanity, from *insanus*, *unsound*, and derangement, from the French *dérangement*, signifying disorder, are common names for madness. The word *lunatic* was originally applied only to patients who had lucid intervals, and who were supposed to be under the influence of the moon. Idiocy signifies the condition of those who are imbecile from their birth, or become so in consequence of injury or disease of the brain. Delirium, derived from the Latin words *de lirâ*, out of the track, is now generally restricted to the wanderings attendant upon fever.—See Armstrong's Lectures on the Morbid Anatomy, Nature, and Treatment of Acute and Chronic Diseases, edited by Joseph Rix, p. 703, 8vo., Lond. 1834.—Ed.

lirium, fatuity, and oneirodynia. He contemplates delirium, moreover, as of two kinds; one combined with fever, and one without: the latter, he tells us, is what we name insanity; and under this latter kind alone, the apyretic delirium or insanity, running synonymously with the present genus *ecphronia*, he proceeds to treat of melancholy and mania as species or subdivisions of it: throwing back the other kind of delirium to the class of fevers, as unconnected with the subject before him. So that, properly speaking, Dr. Cullen's order of *vesaniæ* should run parallel with the present order *phrenicæ*; the genera of which should be delirium and fatuitas; while mania and melancholy should be the species of delirium or the first genus.

Crichton, Parr, Young, Pinel, and most of the German writers, contemplate these diseases under the same sort of specific subdivision. Parr, indeed, in his article *MANIA*, asserts that both constitute nothing more than *VARIETIES* of one common species: yet, with an inconsistency which, among much that is excellent, is too frequently met with in his Dictionary, he changes his opinion in the article *NOSOLOGY*, makes *vesania* the genus, and arranges melancholia, mania, and even oneirodynia, as separate species under it.

The distinguishing characters, as the two species are contemplated by the generality of nosologists, are clear. In melancholy the alienation is restrained to a few objects or trains of ideas alone; in madness it is general; in reference to which distinction M. Esquirol has exchanged the term *MELANCHOLY* for that of *MONOMANIA*. And it hence follows, that gloom, gayety, and mischievousness may equally exist under both species; according as these propensities are limited to a single purpose, or are unconfined and extend to every thing. Occasionally, however, among ancient writers, we find melancholy insanity limited to insanity accompanied with gloom or despondency, without any attention to the universality or partiality of the disease: for an undue secretion of melancholia, which is only a Greek term for black bile or choler, was supposed to be a common cause of mental dejection, and where it became habitual, to produce a low or gloomy temperament; to which the term melancholic has continued to be applied to the present day. And hence the vulgar sense of the term, which is in unison with this view, is at variance with the technical and pathological. Yet the pathologists themselves have not been uniformly true to their own import: for even Dr. Cullen, who has followed the technical signification in his *Synopsis*, by defining melancholy as "*insania partialis sine dyspepsia*," sometimes adopts the colloquial meaning in his *Practice of Physic*, and hereby betrays a confusion which rarely belongs to him; while Sir Alexander Crichton has given himself over completely to the popular, or, as he would perhaps call it, the ancient interpretation of the terms; distinguishing mania, not by the generalization of the delirium, but by its raving fury or elevated gayety; and melancholy, not by a limitation of the delirium to single objects or

trains of ideas, but by its concomitant dejection and despondency.

There seems to be an equal incorrectness, though of a different kind, in M. Pinel, whose book is, nevertheless, of great merit. Delirium or wandering is made a pathognomonic symptom in his definition of the genus; in other words, a want of correspondence between the judgment and the perception: and consequently this symptom should be found in every species which he has arranged under it. M. Pinel, however, has given us one species which has no such symptoms, and which is purposely intended to include cases of what he calls mania without any such discrepance; on which account he has denominated it *mania sans délire*. All such cases, however, are reducible to modifications of rage or ungovernable passion, and ought by no means to be confounded with mania; the judgment being, in these instances, not at variance with the perception, but overpowered by the predominant fury or passion that has been excited. They all belong properly to our next genus; under which they will be considered.

Much difficulty has also been felt in defining *ecphronia* or insanity, so as to draw the line between real disease and habitual waywardness or oddity;* and hence, while some definitions are so narrow as to set at liberty half the patients at Bethlem or the Bicêtre, others are so loose and capacious as to give a strait waistcoat to half the world.

M. Dufour undertook, with great learning and ingenuity, to prove that, as all our knowledge of an external world is derived from the action of the external senses, while mental sanity depends upon the soundness of these senses, mental insanity is alone to be referred to a diseased condition of one or more of them. And, in proof of this, he gives the case of a person who lost his senses because he could not be persuaded that the objects he saw in consequence of an incipient cataract arose entirely from that complaint. "When he found that he could not remove the dark web which appeared to him to be constantly floating before his eyes, he fell into such frequent fits of violent passion that he became quite insane. But as soon as the disease was completed he became more tractable, and submitted to the operation like a reasonable man."

* The following are distinctions insisted upon by Dr. Conolly, between eccentricity and insanity:—"The man who is merely eccentric can, if he exert himself, act rationally, and leave off his eccentricity; the lunatic cannot. The eccentric man also commonly justifies his eccentricity more speciously and more calmly; or perhaps laughs at it himself; the madman seldom justifies his peculiarities with much skill, is provoked by contradiction, and is very seldom capable of joining in a laugh which is raised against himself."—(*Inquiry concerning the Indications of Insanity*, p. 139.) Dr. Conolly acknowledges, however, that there are cases on its boundary-line, between eccentricity and madness, which seem to bid defiance to all definition; but generally resolvable into the effects of habit in confirming trifling actions, at first performed on some insufficient ground of reasoning.—Ed.

But this only shows us that

"Ira furor brevis est,"

or else that the insanity was caused, not by the cataract, but by the frequent fits of violent passion. Thousands of persons have had cataracts in every form, and other external senses than the eye diseased in every form, and have been born defective in several of these senses, without the least mark of insanity; while other persons, apparently in the most perfect possession of all the five senses, have been stark mad. Hence, the doctrine of M. Dufour boasts of few advocates in the present day.

In insanity or delirium without fever, it is far more obvious that there is a morbid condition of the judgment, or of the perception, or of both. Mr. Locke, and after him M. Condillac, refers it to the former alone, and characterizes madness, in the general sense of the term, by *false judgment*; by a disposition to associate ideas incorrectly, and to mistake them for truths; and hence, says Mr. Locke, "madmen err as men do that argue right from wrong principles."—(B. ii., ch. xi., § 13.) Dr. Battie, on the contrary, refers madness to the latter faculty alone, and characterizes it by *false perception*; but the perceptions in madness seem, for any thing we know to the contrary, to be frequently as correct as in health, the judgment or reasoning being alone diseased or defective.*

It is difficult to say which of these two explanations of madness is most imperfect. It is sufficient to observe, that neither of them, taken alone, describes a condition of the faculties strictly morbid, and consequently neither of them defines madness. For we are daily meeting with thousands of mankind who are under the influ-

* Of those lunatics whose intellectual faculties are manifestly disordered (says Dr. Prichard), there is always a considerable proportion in whose minds it is impossible to trace any particular hallucination, or erroneous perception, or recollection. The rapid succession of thoughts, the hurried and confused manner in which ideas crowd themselves into their mind in a state of incoherence, or without order or connexion, is in very many instances among the most striking phenomena of madness. There are likewise cases of a different description, in which the intellectual faculties appear to have sustained but little injury, while the feelings and affections, the moral and active principles of the mind, are strangely perverted and depraved; the power of self-government is lost or greatly impaired; and the individual is found to be incapable, not of talking or reasoning upon any subject proposed to him, for this he will often do with great shrewdness and volubility, but of conducting himself with decency and propriety in the business of life. His wishes and inclinations, his likings and dislikings, have all undergone a morbid change; and this change appears to be the originating cause, or to lie at the foundation of any disturbance, which the understanding itself may have sustained, and even in some instances to form throughout the chief character or constituent features of the disease.—(See Cyclop. of Pract. Med., art. INSANITY.) Whether these morbid changes, however, in the inclinations and wishes, likings and dislikings, are strictly the originating cause, may very well be disputed.—Ed.

ence of false judgments, who unite incongruous or discrepant ideas, and draw from false associations right conclusions, yet whom we never think of regarding as out of their senses. While, on the contrary, if false perceptions be sufficient to constitute madness, every man is insane who mistakes at a distance a square for a round tower, the bending azure sky that terminates an extensive landscape for the sea, or the distant rumbling of a heavy wagon over the streets for a peal of thunder: and we should none of us be safe from such a charge for a single day of our lives.

Dr. Cullen seems to have embraced Mr. Locke's view of the subject; for his definition of insanity (*vesaniæ*) in the latter editions of his Synopsis is, "injured functions of the mind in judging (*mentis judicantis*) without pyrexia or coma." Dr. Crichton, on the contrary, seems rather to adhere to Dr. Battie's view, though he enlarges and improves upon it; and hence his definition is, "general derangement of the mental faculties, in which *diseased* perceptions are mistaken for realities; with incoherent language and unruly conduct."

Diseased is certainly a better term than *false*, which is that of Dr. Battie; but "unruly conduct" does not essentially belong to madness, even under this excellent writer's own explanation; for of the three species which he comprehends under this disease as a genus, viz., *mania furibunda*, *mania mitis*, and *melancholia*, while the last, as he afterward illustrates it (*Of Mental Derangement*, book iii., ch. iii., vol. ii.), evinces these symptoms only occasionally, he expressly tells us of the second, that the diseased are "all happy, gay, and cheerful; that good-humour characterizes this insanity, and hence the patients are in general very tractable."—(Id., book i., ch. v., pp. 181, 182, vol. i.)

But the chief objection to Sir A. Crichton's definition of insanity, is his limiting it, in respect to the mental faculties, to the power of perception, while the judgment remains totally unaffected. "In regard to lunatics," says he, in another place, "and men who are of a sound mind, the faculty of judging is the same in both; but they have different perceptions, and their judgments therefore must be different."

Now, if the faculties of perception, attention, and memory be liable to derangement, as the same writer admits, and there be "a general derangement of mental faculties in insanity," there seems no sufficient ground for exempting the faculty of judgment. And a little attention to the history of an insane patient will, I think, sufficiently support the opinion of Mr. Locke and Dr. Cullen upon this point, and show that this, if not the faculty chiefly diseased, labours under at least as much disease as that of perception.

We have already observed, in the proem to the present class, that all the powers of the mind are as liable to be affected with diseases, and diseases of various kinds, as those of the body; and that either the body or the mind may be enfeebled at the same time in the whole of its powers, a few of its powers, or in a single

power. A sound mind supposes an existence of all the mind's feelings and intellectual powers in a state of vigour and under the subordination of the judgment, which is designed by nature to be the governing or controlling principle. And, thus constituted, the mind is said to be in a state of order or arrangement. It often happens that this order or arrangement is slightly broken in upon by natural constitution or some corporeal affection; but, so long as the irregularity does not essentially interfere with the mental health, it is no more attended to than slight irregularities or disquietudes of the body. Yet, whenever it becomes serious and complicated, it amounts to a disease; and the mind is said, and most correctly so, to be deranged or disordered.

This derangement may proceed from a morbid state of any of the intellectual or any of the impassioned faculties of the mind; for the perception may not correctly convey the ideas we receive by the external senses, or the judgment may lose its power of discriminating them, or the memory may not retain them, or the imagination or the passions may be in a state of unruly excitement—all which will lay a foundation for different kinds or genera of diseases, and, in fact, form the foundation of those appertaining to the present order.

Now, an attentive examination into the habits of an insane person will show, first, that the judgment and the perception are both injured during the existence of insanity; and next, that though, from a violent or complicated state of the disease, the morbid condition often extends to some other, or even to all the other mental faculties, yet it does not necessarily or essentially extend to them; for a madman may be furious or passionate, yet every madman is not so; his memory may fail, or his attention be incapable of fixing itself, or his imagination be wild and extravagant, but these do not always occur. The faculties, however, of the judgment and the perception are affected in every case, though they are not always equally affected at one and the same time; for the morbid power seems, for the most part, unaccountably to shift in succession from the one to the other, so as alternately to leave the judgment and the perception free, or nearly free, from all estrangement whatever; the disease being, however, always accompanied with irregular remissions, and often with such a diminution of sensibility that the patient is uninfluenced by the effects of cold and hunger, and very generally insusceptible of febrile miasm.

Thus, a madman will often mistake one person who is introduced to him for another, and, under the influence of this mistake, will reason correctly concerning him; and although he may have been for years his next neighbour, will ask him when he came from China or the East Indies, by what ship he returned home, and whether his voyage has been successful—in all of which the error may be that of the perception alone. But if, as is frequently the case, the patient address his visiter by his proper name, he gives a ground for believing that he perceives him aright, and that the error is that of the judgment,

which thus unites incongruous ideas, applying a visionary history to a real and identified person. At another time, he may from the first perfectly recognise the individual so presented to him, and, to prove his recollection and the correctness of his perception, may rapidly run over a long list of his relations, and a long string of anecdotes respecting his former life; after which he may suddenly start, and, looking at the visiter's walking-stick, tell him that that drawn sword will never save him from destruction, nor all the men that slept with him in the same bed the night before—that his rival is now pushing forward with all speed on a black horse with a large army behind him, and that to-morrow he will fight and lose his crown.*

In such a case, and it is by no means an extreme one, the perception and the judgment travel soundly and in harmony at the outset of the interview, but they soon separate and abandon each other as far as the east and west. It is not always easy to say whether the first paroxysm of insanity that thus suddenly displays itself is limited to the one faculty or the other, or is common to both. For, if the perception suddenly wander, the judgment has a new train of ideas presented to it, and must necessarily take a new direction. Yet it is difficult to conceive how the judgment can be thus abruptly led astray, if it continue sound; and hence it is more probable that the judgment itself is at

* The definition of madness adopted by Dr. Conolly is, "a loss or impairment of one or more of the mental faculties, accompanied by the loss of comparison."—(*Inquiry concerning the Indications of Insanity*, p. 114.) The cases of Nicholai and Dr. Bostock prove that persons may be conscious of the appearance of phantoms and other illusions, and know them to be false. If the foregoing gentlemen, as Dr. Conolly remarks, had for one moment lost the power of comparing, they must have believed the illusions to be real; and "from the moment of such belief they must have been mad, and the same so long as the belief remained." Dr. Conolly introduces the following observations in his illustration of his theory:—"In a fever, the patient's bed will seem in flames; or voices will whisper in his ear; or the smell of a banquet assail him; or his sense of touch seem opposed by moving bulky bodies; or the sense of sight will be harassed by the rapid succession of imaginary faces, already spoken of, appearing and disappearing in endless trains and variety. If we talk with patients thus affected, some will tell us, in a very quiet way, that they are thus tormented. Others will seem confused, and make a visible effort of sight and hearing before they tell us how they are troubled; and others will tell us what they see and what they hear, with an expressed belief, on their part, of the reality of what we know to be delusions. Of these three classes of patients," says Dr. Conolly, "the last are in a state of delirium; the second are approaching to it; the first are in a state of sound mind."

In another part of his interesting publication (p. 123), Dr. Conolly admits that it is not always easy to determine, in the case of the insane man, whether his sensation or his attention be impaired; but the effect remarked, which may arise from either impairment, is the want of power of comparing one object with another, and this, in such cases, produces the insanity.—Ed.

fault, and admits a train of ideas which, however congruous to themselves, are incongruous to those furnished by the faculty of perception; or both may equally wander and accompany each other in the visionary scene, as they at first associated in the real. It is obvious, however, if I mistake not, that both faculties are affected in the derangement of insanity, jointly or in irregular succession.*

How far a morbid state of the mental faculties may in any case depend upon the mind itself, as distinct from the sensorium or instrument by which it is connected with the body, it is impossible for us to know till we become acquainted with the nature of this connexion, and perhaps also with the essence of the mind, which, in our present state of information, seems to be a hopeless subject of inquiry. But we may possibly obtain some insight into the manner in which correct ideas of perception are changed in their nature and rendered incorrect or incongruous by a diseased judgment, by attending to a process of variation that is frequently occurring in perfect sanity and acuteness of mind. "The ideas we receive by sensation," says Mr. Locke, in adverting to this process, "are often in grown people altered by the judgment without our taking notice of it." And he explains this position by observing that, when a ball of any uniform colour, as of gold, alabaster, or jet, is placed before the eye, the idea thereby imprinted in the mind is that only of a flat circle variously shadowed, with different degrees of light and brightness coming to the organ of

sight. "But, having by use been accustomed to perceive what kind of appearance convex bodies are wont to make in us, what alterations are made in the reflections of light by the difference of the sensible figures of bodies, the judgment presently, by an habitual custom, alters their appearances into their causes; so that from that which truly is variety of shadow or colour, collecting the figure, it makes it pass for a mark or figure, and frames to itself the perception of a convex figure and a uniform colour."—(*Human Underst.*, book ii., ch. ix., § 8.) And the same change occurs still more conspicuously in looking at an engraving or a picture, in which the only idea presented by the eye to the perception is that of a plane variously shaded or coloured, but which the judgment immediately changes and multiplies into other ideas of life and motion, and running streams, and fathomless woods, and cloud-capt mountains. And if in a sane state we find the judgment capable of thus varying the ideas of perception presented to it, we can have no great difficulty, I think, in conceiving by what means such a variation may be produced, and may ramify into incongruities of great extravagance in a judgment deranged by disease.

Nor is there much difficulty in conceiving how the paroxysm should be subject to remissions or even intermissions more or less regular, or the derangement be limited, as we frequently find it, and especially in melancholy, to particular subjects or trains of ideas. For, first, all diseases have a tendency to remissions or in-

* According to Dr. Conolly's views and arguments, which are replete with truth, each of the faculties of the mind may be impaired, and impaired without insanity; at the same time, when the impairment of them, or any one of them, is such as to bring on inability to perform the act of comparison, or is accompanied by the loss of this faculty, insanity is the direct and inevitable result. The decisions are then no longer correct, the judgment no longer sound, and the actions no longer rational.—(See Inquiry concerning the Indications of Insanity, p. 170.) And, in a subsequent part of the work, when speaking of cases in which the sensations are morbid, Dr. Conolly justly observes, that, in numerous instances, the hallucination of the sense arises from an imagination previously over-excited; that over-excitement is disease, but not madness; it produces a hallucination, but, if the hallucination is known to be a hallucination, still there is no madness; if it is mistaken for reality, then the man is mad.—(P. 307.) Dr. Conolly gives from Shakspeare a fine illustration of the struggle between sanity and insanity. When the dagger first appears to Macbeth, although apparently sensible that it is a delusion, he attempts to seize it; and failing to do so, says,—

"I have thee not, and yet I see thee still.
Art thou not, fatal vision, sensible
To feeling, as to sight? or art thou but
A dagger of the mind, a false creation,
Proceeding from the heat-oppressed brain?"

"The exercise of one sense to correct the suspicious evidence of another, the comparison, and the questioning which follows, are very striking. As Macbeth proceeds, it will be observed that he is struggling to exercise the comparison, which will prevent his belief in the delusion; and that

when he becomes fully able to do it, he triumphs over the delusive appearance. The struggle is begun in the lines already quoted; it is continued in the following:—

"I see thee yet, in form as palpable
As this which now I draw.
Thou marshall'st me the way that I was going;
And such an instrument I was to use.
Mine eyes are made the tools o' the other senses,
Or else worth all the rest."

"Here we observe that the delusion is powerful, but that Macbeth compares it with the reality of his own dagger; he is evidently connecting the appearance with the cause of it; with his actual intentions, and mentally accounting for it by associating it with his hidden thoughts; yet he reasons with himself concerning the possibility of the evidence of his eyes being finer and truer than any other evidence, or the greater probability that by his state of commotion, and his disturbed feelings, his eyes are made 'the tools o' the other senses.' In this state of agitation the vision assumes some variety, while it maintains its distinctness; but the words which follow show us that the mental process, the reasonings, the comparisons which Macbeth has made, effect a triumph over the delusion:—

"I see thee still;
And on thy blade and dudgeon gouts of blood,
Which was not so before.—There's no such thing.
It is the bloody business, which informs
Thus to mine eyes."

These passages, and the comment on them by Dr. Conolly, certainly present a beautiful illustration of some of the doctrines concerning insanity contained in his valuable publication.—Ed.

termissions; but those connected with the brain or nerves more than any others, as is evident in hemicrania, epilepsy, hysteria, and palpitation of the heart. And, next, there is no man in a state of the most perfect sanity whose judgment is equally strong and exact upon all subjects, and few whose judgments are not manifestly influenced and led astray by partialities or peculiar incidents of a thousand kinds: inasmuch that we dare not, on various occasions, intrust to a man of the strictest honesty and the clearest head a particular subject for his decision, whom we should fly to as our counsellor upon every other occurrence. And it is not, therefore, very extraordinary, that in a morbid state of mind, and particularly of that faculty which constitutes the judgment, there should be an aberration in some directions or upon some subjects which does not exist upon others.

The corporeal indications differ as much as those of the mind, and generally as being governed by the latter. We have hence sometimes, as an opening symptom, an extraordinary flow of high spirits; at others extreme terror. The countenance is pale and ghastly, and strongly expressive of inward emotion; the speech hurried and tremulous; and the extremities bedewed with a cold sweat. In other instances the eye glares malignantly; the face is flushed, and evinces a dreadful ferocity; the objects of terror become objects of vengeance; and the patient is furious. In some there is an unusual degree of suspicion, and an anticipation of evil, and a belief in imaginary plots or conspiracies. In others, great irascibility and malignity, and a desire to commit some act of desperation, vengeance, and cruelty. All this is often combined with headache, giddiness, throbbing of the temples, or impaired vision. There is little or no sleep, for the mind is in a state of too much excitement; though at times the patient lies listless, and refuses to be roused.—(*Annual Report of the Glasgow Asylum for Lunatics, 1821.*)

Concerning therefore the remote or even the proximate cause of the disease, we have yet much to learn. From the view we have taken in the poem of the close connexion between the mind and the brain, it seems reasonable to conceive that the remote cause is ordinarily dependant upon some misconstruction or misaffection of the cerebral organs; and hence every part of them has been scrutinized for proofs of so plausible an hypothesis, but hitherto to no purpose whatever. The form of the cranium, its thickness, and other qualities; the meninges, the substance of the brain, the ventricles, the pineal gland, the commissures, the cerebellum, have all been analyzed in turn, by the most dexterous and prying anatomists of England, France, Germany, and Italy, but with no satisfactory result. The shape or thickness of the skull has been started, indeed, as a cause, by many anatomists of high and established reputation; but the conjecture has been completely disproved by others, who have found the very structures supposed to be most certain of pro-

ducing madness, exist in numerous instances with perfect soundness of intellect. A particular shape of the skull seems, indeed, to be often connected with idiotism from birth or soon after birth, but with no other species of mental derangement whatever.

Morgagni engaged in an extensive course of dissections upon this subject, and pursued it with peculiar ardour; and his results are given in his eighth epistle, from the second to the eighteenth article. In some cases the brain was harder, in some softer, than in a healthy state; occasionally the dura mater was thicker, and was studded with soft, whitish bodies on the sides of the longitudinal sinus. This sinus itself sometimes evinced polypous concretions; and the pineal gland, or several of the glands in the plexus choroides, were in a diseased state. Dr. Greding (*Vermischte Medicinische und Chirurgische Schriften*, Altenb., 1781), with a like spirit of investigation, arrived at a like diversity of facts. Meckel found the brain denser and harder than usual (*Hist. de l'Acad. Royale des Sciences*, &c., Ann. 1760, Berol., 4to., 1761); Dr. Smith (*Med. Observ. and Inquir.*, vol. vi.) described a bony concretion, and Plenciz and several others represent the brain as bony or calculous in various parts; while Jones, in the *Medical Commentaries*, found it softer than usual, with a thickening of the membranes and a turgescence of the ventricles. From all which, nothing precise or pathognomonic can be collected, since all such morbid appearances have been traced under other diseases as well as under insanity.

M. Pinel is firmly decided upon this point; and after a very extensive course of investigations, he asserts, with respect to the cranium, that there are no facts yet clearly established which prove the faculties of the mind (except in the case of idiotism) to be in any degree influenced by its size, figure, or density: while with respect to the contents of the cranium, "I can affirm," says he, "that I have never met with any other appearances within the cavity of the skull, than are observable on opening the bodies of persons who have died of apoplexy, epilepsy, nervous fevers, and convulsions:" and his successors M. Esquirol and M. Georget concur in the same remarks. The last, after having examined three hundred lunatics on their decease, to settle the point before us, thus concludes: "Toutes les altérations que nous avons observées sur les aliénés de la Salpêtrière sont consécutives au développement de la folie, excepté celles des cerveaux d'idiotés, qui sont primitives et liées à l'état intellectuel."

The observations of Haslam are nearly to the same effect: for they concur in showing that, except in so considerable a misformation of the skull or its contents as to induce idiotism from an early period of life, as in the case of cretinism, nothing decisive can be obtained in reference to insanity from any variations of appearance that have hitherto been detected.*

* From the dissections recorded by Dr. Haslam, his own inference is, that madness is always con-

The dissections of Greding extended to not fewer than two hundred and sixteen maniacal patients, the whole of whom, however, died of disorders unconnected with their mental ailments: three of the heads were exceedingly large, two exceedingly small; some of the skull-bones extremely thick, others peculiarly thin; in some, the frontal bones were small and contracted; in others, the temporal bones compressed and narrow.

In a table containing an aggregate of the patients received into the lunatic asylum at Bicêtre during a considerable part of the French revolution, from 1784 to 1792, by far the greatest number admitted were between the ages of thirty and forty: next, those between forty and fifty; next to these, patients between twenty and thirty; then those from sixty to seventy;

connected with disease of the brain or its membranes. Indeed, he expresses a decided opinion that insanity is not a *disease of ideas*, and is among the first who in modern times have regarded it as connected with disease of the brain or its membranes.—(See Obs. on Madness and Melancholy, &c., p. 238, &c.) A similar opinion had been previously delivered by Dr. Marshall.—(See Morbid Anatomy of the Brain in Mania, &c.) According to Greding, the pia mater and arachnoid membrane were hardly ever sound. The same fact was noticed by Dr. Haslam in thirty-seven out of thirty-eight dissections; also by J. Werzel, of Mentz (Obs. sur le Cervelet, &c., trad. par M. Breton, Paris, 1811); and Chiarugi, of Florence (Della Pazzia, &c., in Firenze, 1794). M. Bayle considers *chronic meningitis*, a form of meningeal inflammation essentially and primarily chronic, as the most frequent pathological cause of mental derangement.—(Traité des Maladies du Cerveau, &c., Paris, 1826.)

The frequency of disease of the brain in insane persons is confirmed by the researches of M. Calmeil.—(De la Paralyse considérée chez les Aliénés, &c., Paris, 1826.) Dr. Conolly also agrees in "ascribing mental disorders to corporeal disease; not to any specific corporeal disease, but to any disease capable of disturbing the functions, or impairing the structure of the nerves:" yet he adds, "we do not find in insanity, as in consumption, such invariable disorganization or impairment as would account for the long continuance of the malady, or for the small proportion of cures."—(An Inquiry concerning the Indications of Insanity, p. 14.) When insanity proceeds from adversity, domestic calamity, and other external influences on the mind, and especially when the alteration of the mind is suddenly produced by such causes, the connexion of the mental change with any organic or visible disease must be, at least in the first instance, beyond all suspicion, unless disturbance of the innervation and circulation, and other functional disorders, not necessarily accompanied by change of structure, be comprehended under the denomination of corporeal diseases. As Dr. Uwins observes,—"Who shall pronounce upon the precise nature of that change in the sentient organization, when unexpected intelligence instantaneously destroys a keen appetite? when madness occurs as the immediate result of some heart-rending disappointment? when the whole man is thoroughly and in a moment revolutionized by a change of scene and circumstance? or when faith in a physician at once breaks down the strongholds of hitherto confirmed disease?"—On Disorders of the Brain and Nervous System, p. 11, 8vo., Lond., 1833.—Ed.

and lastly, those from fifteen to twenty; below which we have no account of any admission whatever. Hence different stadia of life seem to exercise some control, and the period most exposed to the disease is that in which the influence of the passions may be conceived to be naturally strongest and most operative. "Among the lunatics confined at Bicêtre," says M. Pinel, "during the third year of the republic, and whose cases I particularly examined, I observed that the exciting causes of their maladies, in a great majority of instances, were extremely vivid affections of the mind; as ungovernable or disappointed ambition, religious fanaticism,* profound chagrin, and unfortunate love. Out of one hundred and thirteen madmen, with whose histories I took pains to make myself acquainted, thirty-four were reduced to this state by domestic misfortunes; twenty-four by obstacles to matrimonial unions which they had ardently desired to form; thirty by political events connected with the revolution; and twenty-five by religious fanaticism." Those were chiefly affected who belonged to professions in which the imagination is unceasingly or ardently engaged, and not controlled in its excitement by the exercise of the tamer functions of the understanding, which are more susceptible of satiety and fatigue. Hence the Bicêtre registers were chiefly filled from the professions of priests, artists, painters, sculptors, poets, and musicians: while they contained no instances of persons whose line of life demands a predominant exercise of the judging faculty: not one naturalist, physician, chymist, nor geometer.

But there are other organs that also betray very prominent signs of diseased action in insanity as well as the brain, as those of the epigastrium and the adjoining regions: and hence other physiologists have sought for a remote or even a proximate cause of the malady in these, rather than in the encephalon. This was the case among several, though not the majority, of the Greek physicians, as we have seen already; and it is to this quarter that M. Pinel refers the proximate cause in almost every instance in our own day. It is here he supposes the disease to commence, and contends that the affection of the brain and of the mental faculties is subsequent to the abdominal symptoms, and altogether dependant upon them; and, in proof of this, he adverts to various dissections which have shown a considerable derangement, not only in the function, but even in the structure of one or more of the abdominal organs, and particularly a displacement of the transverse colon.

But this is to give a weight to the morbid appearances occasionally manifested in these organs, above what is allowed to like misformations in the cranium. Yet there can be no doubt that, in most cases of insanity, the brain

* According to Dr. Burrows, there are five times as many females insane from this cause as males.—See Commentaries on the Causes, Forms, Symptoms, and Treatment, moral and medical, of Insanity, 8vo., 1828.—Ed.

and epigastrium suffer jointly; and that the disease may, and often does, commence in some structural or functionary affection of the abdominal organs, is perfectly clear from the frequency of this complaint during pregnancy and in childbed: its being connected with a peculiar state of the genital organs, as we shall presently have occasion to show, and its following upon a sudden suppression of the menstrual or hemorrhoidal discharge.

Nor is it difficult to account for this association of influence from the extensive distribution of the par vagum, and more particularly of the intercostal nerve over the abdominal viscera: on which account a like sympathy is by no means uncommon in various other disorders. Thus, while a concussion or compression of the brain produces nausea, sickness, and constipation, worms are frequently found to excite convulsions or epilepsy.

The fair result of the whole inquiry appears to be, that insanity, in every instance, to adopt the language of Sir A. Crichton, "arises from a diseased state of the brain or nerves, or both" (*Of Mental Derangement*, vol. i., p. 138); but that in many instances this diseased state is a primary affection, and in others a secondary, dependant upon a morbid condition of the epigastric or some other abdominal organ: for, in whatever this morbid condition may consist, and whatever symptoms it may evince, it is not till the sensorium has by degrees associated in the chain of unhealthy action, that the signs of insanity are unequivocal. And, in like manner, dyspeptic and other abdominal symptoms are not unfrequently brought on by a previously diseased state of the mind: and it is hence peculiarly difficult, and perhaps in some cases altogether impossible to determine, where we are not acquainted with the incipient symptoms, whether melancholy or hypochondrias has originated in the state of the abdominal viscera or of the cranium; or, in other words, whether the one or the other be a primary or a secondary affection.

* The ensuing passage conveys Dr. Conolly's mode of viewing one part of this mysterious subject, which has defied, and, as Dr. Good states, will continue to defy, all attempts at a satisfactory explanation:—"The manifestation of the mind must depend upon, and be modified by, the development of the brain in each individual. The same intellectual light may be given to all; but, in some, obscured by a gross organization; and in others, more happily organized, shining forth more brightly. Itself out of the reach of physical injury, it works by physical instruments; and the exactness of its operations depends on the growth, maturity, integrity, and vigour of its instruments, which are the brain and nervous system. If the nervous agents of sensation are unfaithful, the mind receives false intelligence, or transmits its orders by imbecile messengers; if the seat of thought, the centre of intellectual and moral government, is faultily arranged, the operations of the understanding are impeded and incomplete."—(See *An Inquiry concerning the Indications of Insanity*, p. 62.) The editor cannot discover the agreement between the tenour of these observations, and the doctrine to which the author of the

When, however, we are made acquainted with the history of the incipient symptoms, we have a tolerable clew to guide us; and for the most part may safely decide, that the region primarily affected is that which first evinces morbid symptoms; and hence, while we shall have little scruple in assigning the origin of most cases of hypochondriacism to a morbid condition of one or more of the digestive organs, we need have as little in assigning the greater number of cases of mania to a primary misaffection of the brain or the nerves.

In what that misaffection consists is a question that has never been settled to the present hour; and from our total unacquaintance with the nature of the connexion between the brain and the mind, it never will be in any very satisfactory manner.* The morbid changes, indeed, which we have already seen are frequently to be traced in the structure of the brain, show very sufficiently that a considerable degree of diseased action has been taking place there; but as these changes are often found in other disorders of the head as well as in mania, and more especially as we cannot tell whether they have preceded or been produced by such action, they give us little information as to the nature of the diseased action itself.

Dr. Cullen has offered a series of ingenious arguments to prove that mania consists in some inequality in the excitement of the brain (*Prac. Phys.*, vol. iv., Aph. 1562), or of the nervous power (Id. 1544), and, in most cases, in an increased excitement. Dr. Cullen's idea of the nervous power, as we have already had occasion to observe, is very far from being explicit: for he defines it "a subtile very moveable fluid, included or inherent in a manner we do not clearly understand, in every part of the medullary substance of the brain and nerves." While, in other parts of his writings, he represents it as never either recruited or exhausted, and thus conceives it to possess qualities beyond the ordinary endowments of living matter. Yet his general principle appears to be well founded, and Sir Alexander Crichton has availed him-

foregoing excellent work inclines, that mental disorders may be ascribed to any corporeal disease capable of disturbing the functions, or impairing the structure of the brain. The incongruity which is here manifest, depends upon the term *mind* being made to signify also the *soul*. But the intellectual organization and functions certainly constitute a very different subject from that of the theological doctrines of our immortal nature. Hence, also, the following passage cannot be correct:—"Nay, so dependant is the immaterial soul upon the material organs, both for what it receives and what it transmits, that a slight disorder in the circulation of the blood through different portions of nervous substance, can disturb all sensation, all emotion, all relation with the external and living world; can obstruct attention and comparison; can injure and confound the accumulations of the memory, or modify the suggestions of imagination." The statement is not accurate in relation to the soul; but unobjectionable, perhaps, if applied to the mind. Our souls, it is to be hoped, will exist, when our brain, nerves, circulation, &c., are no more.—ED.

self of it in giving a fuller explanation of this highly probable hypothesis: and, after appealing to the doctrine which has already been advanced and supported in the preceding pages of the present work, that the nervous power is a peculiar fluid secreted in the medullary substance of the brain or the nerves, he endeavours to show that the cause of insanities is a specific morbid action of the vessels which secrete the nervous fluid in the brain (*Of Mental Derangement*, vol. i., p. 174); and which may hereby be altered not only in quantity but in quality.*

From the quickness of the external senses, the irascibility, heat of the skin, flushed countenance, and uncommon energy which maniacs evince, we have reason to believe this morbid action to be, for the most part, a preternaturally increased action; and we are hence able to account for the various exacerbations and remissions which it evinces, sometimes periodically, and sometimes irregularly. Yet as the health of the faculties of the mind must depend upon a healthy energy of the vessels, too scanty a secretion of nervous fluid must be as effectual a cause of mental derangement as too copious a flow; and hence torpor of the vessels of the brain may prove as certain a cause of a wandering mind as antony, and, consequently, typhus fever may become a source of delirium as well as inflammatory. And as the various secretions can only be elaborated from the blood, and are often affected by its condition, we may see also how madness may be a result of acrid narcotics and other poisons introduced into the blood by absorption, or a transfusion of blood from animals of a different nature, of which Dionis has given some very striking examples.

That there is a tendency not only to an increased secretion of sensorial power in the head in most cases of insanity, but to an accumulation of it from all parts of the body, and especially from the surface, is clear from the patient's

diminished sensibility to external impressions, and his being able to endure the severest winter's cold, and a fasting of many days, without inconvenience or indeed consciousness. But that there is, in some cases, a diminished secretion of this fluid, producing a general debility of the living fibre, is also clear from the great tendency manifested by some maniacs, whose brain gives no proof of increased excitement, to a gangrene in their extremities, and, where they are unclearly, about the buttocks. The insensibility from this cause is sometimes so considerable as to affect not only the diffuse organ of feeling, but some of the local senses as well. And hence some patients lose their hearing, and others are capable of staring at the meridian sun without pain, or any change in the diameter of the iris.—(*Blumenb.*, bibl. i., p. 736.) Sometimes, however, the increased secretion of sensorial power is so considerable as not only to affect the head, but to augment the corporeal sensibility generally. And hence Hoffmann makes accumulated sensation an ordinary symptom of this disease (*Opp.*, Suppl. ii., 2), mistaking the exception for the general rule: and Riedlin gives us an instance of a maniac, who, instead of calling for and being able to endure large quantities of snuff, sneezed and was convulsed on smelling the mildest aromatics.*

It is a melancholy reflection, that insanity is often the result of an hereditary predisposition. This, indeed, has been denied by a few writers, but their opinion has unhappily been confuted by the concurrent voice of those who have thought differently, and the irresistible evidence of daily facts. Mysterious as the subject is, we have perpetual proofs that a peculiarity of mental character is just as propagable as a peculiarity of corporeal; and hence wit, madness, and idiotism, are as distinctly an heirloom of some families, as scrofula, consumption, and cancer of others.† In most of the latter we have already observed that something of a constitutional make or physiognomy is often discernible; and the

* *Id.*, vol. i., p. 169. With respect to the hypothesis here laid down, the editor has already delivered his opinion in the *Physiological Proem*. That the brain is an organ receiving a very great supply of blood; that its vessels are large and numerous; that an increased determination of blood to the brain, or, on the contrary, a diminution of the quantity conveyed to it, must have an effect upon the cerebral functions; that the vessels secrete from this blood the medullary and cortical substances, the fluid in the ventricles, and every kind of matter composing the various tissues of the brain; and that the perfect or imperfect state of the intellectual and nervous powers is intimately dependant upon the condition of the circulation within the head, are facts of which no doubt can be entertained. But when the venturesome physiologist proceeds farther, and first assumes the existence of a nervous fluid as synonymous with sensorial or nervous power, represents it as a secretion, and mental derangement as arising from its altered quality or quantity, he is getting out of his depth, and only contenting himself with an hypothesis, which, if it were admitted, would, after all, not render the subject at all more intelligible. Instead of the "secretion of the nervous fluid," it might be better, therefore, to read, "the production of nervous or sensorial power."—*Ed.*

* *Lin. Med.*, 1696, p. 29. Such occurrences are only accidental accompaniments of insanity, by no means essential to it, or even indicative of its existence. Were the contrary view adopted, the modern Romans, who are greatly annoyed by a perfumed handkerchief, might be set down as lunatics, as well as others whose sense of smell is so inconveniently acute, that they almost "die of a rose in aromatic pain."—*Ed.*

† In six sevenths of the cases which have come under the observation of Dr. Burrows, hereditary predisposition was traced. He does not consider that the several forms of insanity tend to transmit each its own kind from one generation to another; but, on the contrary, that they mutually transmit one another, so that mania, melancholia, and hypochondriasis, may be all remarked in different individuals of the same family. He admits, however, one exception to this rule in the instance of suicidal insanity. Probably, hypochondriasis may be another exception. Dr. Burrows does not consider hereditary insanity more difficult to cure than other forms of it, which statement disagrees with what is commonly believed.—*See Commentaries, &c.*, and *Edin. Med. Journ.*, No. xcvi., p. 123.

same is contended for by many authorities in the disease before us. Yet, if we examine the marks accurately, we shall find that they merge, for the most part, into the common symptoms of a sanguineous or melancholic temperament: either of which constitutions exercises such a control over the disease as to give it a peculiar modification, whatever be the nature of the exciting cause, which is, in truth, of little importance to the constitutional turn the malady may take, though well worth attending to in the moral treatment. "The violence of the maniacal paroxysm," observes M. Pinel, "appears to be independent of the nature of the exciting cause; or, at least, to be far more influenced by the constitution of the individual, and the peculiar degree of his physical and moral sensibility. Men of a robust constitution, of mature years, with black hair, and susceptible of strong and violent passions, appear to retain the same character when visited by this most distressing of human misfortunes. Their ordinary energy is augmented to outrageous fury. Violence, on the other hand, is seldom characteristic of the paroxysms of individuals of more moderate passions, with brown or auburn hair. Nothing is more common than to see men with light-coloured hair sink into soothing and pleasurable reveries; while it seldom or never happens that they become furious or unmanageable. Their pleasing dreams, however, are at length overtaken by and lost amid the gloom of an incurable fatuity. Those of the greatest mental excitement, of the warmest passions, the most active imagination, the most acute sensibility, are chiefly predisposed to insanity. A melancholy reflection!—but such as is calculated to call forth our best and tenderest sympathies."

It has long been a current opinion, that insanity is a disease more common to our country than to any other: and this opinion has of late been rendered more seriously alarming by the following assertion of Dr. Powell, secretary to the commissioners for licensing lunatic establishments, and which is given as the result of his official tables of returns from 1775 to 1809 inclusive, divided into lustra or periods of five years each. "Insanity appears to have been considerably upon the increase: for if we compare the sums of two distant lustra, the one beginning with 1775, and the other with 1809, the proportion of patients returned as having been received into lunatic-houses during the latter period, is to that of the former nearly as 129 to 100."—"The facts also," says he, "which present themselves to the observation of the traveller, whatever direction he may take through this country, and all the local information which we receive upon the subject, supply us, as I am led to think, with sufficient proof, that the increase must actually have been very considerable, though we cannot ascertain what has been its exact proportion."*

The first part of this opinion, or that which

regards insanity as a disease PECULIARLY PREVALENT in England, does not seem to rest on any established basis; for, calculating with Dr. Powell, that the number of lunatic paupers, and those received into public hospitals, which, under the act of parliament, are not cognizable by the commissioners, together with those neglected to be returned, compared with the returns entered into the commissioners' books, bear the proportion of three to two, which is probably far above the mark, still the aggregate number of insane persons for the year 1800, contrasted with the general census for the same year, will only hold a ratio of about 1 to 7300; while if we take with Dr. Burrows the proportion of suicides committed in foreign capitals as a test of the extent to which insanity is prevalent in the same towns, which is nevertheless a loose mode of reckoning, though it is not easy to obtain a better, we have reason to conclude that insanity is comparatively far less frequent among ourselves than in most parts of the continent: the suicides of Paris, Berlin, and Copenhagen, as drawn from tables collected by Dr. Burrows for this purpose, being, in proportion to the relative population of London, as 5 to 2 for the first, 5 to 3 for the second, and 3 to 1 for the third.—(*Inquiry into certain Errors relative to Insanity, &c.*, p. 93, 8vo., 1820.)

Nor does the idea that insanity is an INCREASING DISEASE in our own country appear to rest on a stabler foundation. Taking Dr. Powell's result as drawn from full and incontrovertible data, and comparing the supposed march of the disease with the acknowledged march of the population, although the former may possibly be said to have overstepped the latter by a few paces, the difference will hardly justify the assertion, that "insanity is considerably upon the increase." And if we take into view the intensity of interest with which this subject has, for the last twenty years, been contemplated by the public, the operation of those feelings of humanity which have dragged the wretched victims of disease from the miserable abodes of prisons and neglected workhouses, and placed them under the professional care of the superintendents of licensed establishments, and, above all, the augmented number of such establishments in consequence hereof, and the great respectability of many who have the management of them, thus giving the commissioners returns which, by the power of the act of 26 Geo. III., they could not otherwise have been in possession of, we may, I think, fairly conclude, that this apparent overstep, be it what it may, in the march of insanity beyond that of the population of the country, is a real retrogression.

At this conclusion we might, I think, fairly arrive, even if the data selected by Dr. Powell were full and incontrovertible; but he himself has candidly admitted that, instead of being full and incontrovertible, they "are subject to numerous inaccuracies, and that any deductions which may be made from them must be imperfect." It is still more consolatory to learn, that the direct deductions from the parochial and district establishments are not only in accordance

* Med. Trans., vol. iv., p. 131, art. Observations on the Comparative Prevalence of Insanity at different Periods.

with Dr. Powell's, but such as seem to show that a retrogression, instead of an advance, has actually taken place. Dr. Burrows has industriously collected many of these, and, as far as they go, they lead to such an inference almost without exception.—(*Inquiry*, &c., ut supra, p. 66; et alibi.) Yet it is probable that even this inference does not give us the precise fact, and that it is as chargeable with an error on the favourable side, as the opposite account is on the unfavourable; since the increase of licensed houses, whose returns seem to have swelled the list of the commissioners beyond its proper aggregate, has been considerably supported by a transfer from the establishments which have thus fallen off. And hence, allowing the error on the one side to compensate that on the other, we are brought to the conclusion which, after all, appears more natural, that the career of insanity is only varied in its uniformity by temporary contingencies, but that it is by no means a prevalent disease in our own country.*

* Dr. Burrows thinks that climate does not appear to be an exciting cause of insanity; but it cannot be denied, he adds, that the seasons are so; and that, when the thermometer is highest in temperate regions, the number of insane is greatly augmented. Thus, in Paris, on taking the average of nine years, the number of insane increased in May, arrived at its maximum in July, and gradually decreased till January, when it was at its minimum. Dr. Burrows also remarks, that the species of insanity termed suicidal always prevails most in the hottest season. From registers published in the cities of Westminster, Paris, and Hamburgh, suicides are most frequent in June and July; in short, whenever the thermometer ranges near 84° F. Hence, he concludes, that it is not climate, but a high temperature, which exposes the intellectual functions to derangement.

It would seem, at first view, from many circumstances, that females are more liable to insanity than males. Dr. Rush remarks, that women, in consequence of the greater predisposition imparted to their bodies by menstruation, pregnancy, and parturition, and to their minds by being much alone in their families, are more predisposed to madness than men. Yet, according to the statistics given by Dr. Burrows (if we except large cities, as Paris, Lyons, Milan, &c., where immorality and habits prejudicial to the female prevail), the majority of the insane are men. In the Royal Asylum at Charenton in France, from January 1, 1815, to January 1, 1823, 1453 lunatics were admitted; of these there were 847 males, 606 females. Of 2507 insane admitted to the Parisian hospitals, 1095 were men, and 1412 were women. At Lyons, the proportion was, men 60, women 150. In England, the number of lunatics confined in private houses from 1812 to 1824, was 7804: of these, 4461 were males, and 3343 females. But, according to an analysis published of the Pauper Lunatic Asylum in the county of Middlesex, including the metropolis, in 1827, the proportion was stated to be, men 307, women 546. In Scotland, in 1818, the proportion was, men 2311, women 2339. In the Dublin House of Industry in 1824 and 1827, nearly the same number of both sexes were admitted. The same was true of Zurich in 1823. In Germany, the men exceed. In Vienna, in 1812, the number of men insane was 177, of women 94. In Berlin, in 1816, the number of insane males was 242, of females 177.—

M 2

SPECIES I.

ECPHRONIA MELANCHOLIA.

MELANCHOLY.

THE DISCREPANCY BETWEEN THE PERCEPTION AND THE JUDGMENT LIMITED TO A SINGLE OBJECT, OR A FEW CONNECTED OBJECTS, OR TRAINS OF IDEAS: THE WILL WAYWARD AND DOMINEERING.

We have already stated, that whatever be the exciting cause of mental alienation, the symptoms are in every instance greatly modified by the prevailing idiosyncrasy; and hence, though a love of solitude, gloom, fear, suspicion, and taciturnity, are the ordinary signs of the present species, these signs often yield to symptoms widely different, and sometimes even of an opposite character; and we hence become possessed of the four following varieties:—

- | | |
|---------------|---|
| α Attonita. | Mute, gloomy, retiring melancholy. |
| β Errabunda. | Roving, restless melancholy, evincing a constant desire to change the abode. |
| γ Malevolens. | Morose or mischievous melancholy, occasionally terminating in suicide, or the injury of others. |

(Burrows's Comment on Insanity, p. 241, London, 1828.) We must regret the imperfect statements of the number of insane in the United States. Dr. A. Brigham of Hartford, taking the ascertained number of insane in Connecticut as the basis of his calculation, estimates the whole number in the United States to be 50,000; which is certainly very large, and probably exceeds the true amount.—(See Remarks on the Influence of Mental Cultivation on Health, by Amariah Brigham, Hartford, 1832.) According, however, to the reports of the Bloomingdale Asylum, New-York, the number of insane in that institution, including those remaining at the end of December, 1830, and those admitted and discharged during part of 1831, was 98; in 1832 and 1833, 216; of whom 145 were males, and 73 females; in 1834, 103; of whom 67 were males, and 36 females.

Dr. Burrows asserts that indulgence in ardent spirits is the cause why insanity prevails most among males, and in the U. States we have unfortunately too many instances of this truth. Dr. Rush remarks, that on inquiring in regard to the insane confined in the Pennsylvania Hospital, he found that one third of the whole number had become deranged from intemperance. The most frequent cause of insanity, says the report of Dr. Woodward, the able superintendent of the Lunatic Asylum at Worcester, Mass., is intemperance; and we have reason to think the same is true as respects the inmates of the Lunatic Asylum at Bellevue and at Bloomingdale.

If these facts be well founded, and there is reason to think they are, philanthropists have cause to be gratified with the salutary results which must follow from the extension of the temperance system in the United States; an abstinence from alcoholic drinks would diminish the number of the insane at least one half: hence, with the present exertions of the friends of temperance, insanity must be comparatively on the decrease in this country.—D.

δ Complacens. — Self-complacent and affable
Self-complacent melancholy; occasionally
melancholy. rejoicing in a visionary
superiority of rank, station, or endowment.

The same variety of symptoms, as chiefly modified by the prevailing temperament, are noticed by Fracastorio. "The phlegmatic," says he, "are heavy; the sanguine lively, cheerful, merry, but not witty; the choleric are in rapid and perpetual motion, impatient of dwelling upon any subject. An acuteness of wit belongs to most of the varieties, but not to all."—(*De Intellectione*, lib. ii.) And hence Diocles, in opposing Galen for holding, after Hippocrates, that gloom and terror are pathognomonic signs of melancholy, observes, "Upon serious consideration I find some patients that have nothing of these qualities, and others that exhibit every diversity of feeling; for some are sad without being fearful, others fearful without being sad; some neither, and some both."

Besides these modifications there is another of a very peculiar kind, noticed by Dr. Spurzheim, in order to show that the faculties of the mind are double, and that each hemisphere of the brain contains a distinct set. As I have never met with an instance of this variety, I must describe it in his own words. "Tiedemann," says he, "relates the example of one Moser, who was insane on one side, and who observed his insanity with the other. Gall attended a minister who, having a similar disease for three years, heard constantly on his left side reproaches and injuries, and turned his head to that side in order to look at the persons. With his right side he commonly judged of the madness of his left side, but sometimes, in a fit of fever, he could not rectify his peculiar state. Long after being cured, if he happened to be angry, or if he had drunk more than he was accustomed to do, he observed in his left side a tendency to his former alienation."—(*Physiognomical System*, &c., p. 144, 8vo., 1816.)

It may appear strange to those who have not studied the subject with much attention, that persons who are possessed of a diseased, or even defective judgment, should at any time be of quick and lively apprehension, and thus be witty without being wise. But the faculty of wit is dependant not so much on the judgment as on the imagination, and particularly on the memory; on the possession of a large stock of ideas stored up for ready use, and brought forth with rapidity. "And hence," says Mr. Locke, "some reason may perhaps be given of that common observation, that men who have a great deal of wit, and prompt memories, have not always the clearest judgment or deepest reason. For wit lying most in the assemblage of ideas, and putting those together with quickness and variety, wherein can be found any resemblance or congruity, thereby make up pleasant pictures and agreeable visions in the fancy; judgment, on the contrary, lies quite on the other side; in separating carefully, one from another, ideas wherein can be found the least

difference, thereby to avoid being misled by similitude, and by affinity to take one thing for another."—(*On Human Understanding*, book ii., chap. xi., sect. 2.) And hence we may easily account for that gayety and those ebullitions of a vivid fancy, which so often assume the character of wit in persons whose minds are deranged, and especially in the sober faculty of the judgment.

Mirth and wit, however, though sometimes found in the present species of insanity, are by no means its common characters: but, on the contrary, as we have already observed, a love of solitude, gloom, and taciturnity, and an indulgence in the distressing emotions of the mind. And hence, whenever hypochondriacism merges into actual insanity, it almost always takes this form; as melancholy, from a sort of natural connexion between the two, often assumes many of the symptoms that essentially appertain to the hypochondriac disease; the morbid state of the brain influencing the abdominal organs in the latter case, as the morbid state of the abdominal organs influences the brain in the former.

The disease shows itself sometimes suddenly, but more generally by slow and imperceptible degrees. Among the earliest symptoms may be mentioned headaches, frequent attacks of giddiness, sudden confusion of ideas, a great disposition to anger, violent agitations when irritated, and an uncommon sensibility of nerves, whereby the patient is apt to be carried to as great excesses from causes of joy as from those of grief. There is a desire of doing well, but the will is wayward and unsteady, and produces an inability of firmly pursuing any laudable exertion, or even purpose, on account of some painful internal sensation, or the perverseness of the judgment, led astray by false or erroneous ideas which command a firm conviction in the mind.—(*Crichton, of Mental Derangement*, passim.) And if the disease occur in a person possessing that temperament which has been conceived to predispose to it, and was by the Greeks denominated melancholic, the external signs become peculiarly marked and prominent: "the patient," says Hippocrates, in his book on insanity, "is emaciated, withered, and hollow-eyed, and is at the same time troubled with flatulence and acid eructations, with vertigo and singing in the ears, gets little sleep, and when he closes his eyes is distracted with fearful and interrupted dreams."

The FIRST VARIETY most commonly commences with this character, and creeps on so gradually that it is for some time mistaken for a mere attack of hypochondriacism or lowness of spirits (*Falret, de l'Hypochondrie et du Suicide*, passim, 8vo., Paris, 1822), till the mental alienation is at length decided by the wildness of the patient's eyes, the hurry of his step whenever he walks, his extraordinary gestures, and the frequent incongruity of his observations and remarks. The first stage of the disease is thus admirably expressed by Hamlet:—"I have of late, but wherefore I know not, lost all my mirth, foregone all custom of exercise; and, indeed, it

goes so heavily with my disposition, that this goodly frame, the earth, seems to me a steril promontory; this most excellent canopy, the air, look you, this brave o'erhanging firmament, this majestical roof, fretted with golden fire, why it appears no other thing to me than a foul and pestilent congregation of vapours."

But while the external world is thus in general falsely recognised by the perception, or falsely discriminated by the judgment, the mind is so completely possessed by some particular trains of imaginary ideas, that the attention is perpetually turned to them, and the judgment mistakes them for substances; and, so far as it is sensible of surrounding objects or scenery, is perpetually blending the vision with the reality. It is not that the patient's ideas are incongruous with themselves, but with the world around him; for the remarks of the melancholy man, when his attention is once correctly fixed, are for the most part peculiarly shrewd and pointed. But in the gloom that hangs over him under the variety we are now contemplating, he can rarely be brought into conversation, seeks for solitude, sits moping in one continued posture from morning till night; or, if he walk at all, seeks for orchards, back lanes, and the gloomiest places he can find. "One of the chief reasons," says Hippocrates, in his epistle to Philippones, "that induced the citizens of Abdera to suspect Democritus of craziness, was, that he forsook the city and lived in groves and hollow trees, upon a green bank by a brook-side, or by a confluence of waters, all day and all night."*

Sauvages, under the variety of *melancholia attonita*, gives an extreme case of the present modification, though not from personal knowledge. "The patient," says he, "never moves from place to place, nor changes his posture; if he be seated, he never stands up; if standing, he never sits; if lying, he never rises. He never moves his feet unless they are pushed aside by a by-stander; but he does not shun

the presence of man; if asked a question he does not answer, and yet appears to understand what is said. He does not yield to admonition, nor pay any attention to objects of sight or touch; he seems immersed in profound thought, and totally occupied by foreign matters. Yet at times he is more awake; if food be put to his mouth, he eats; if liquor be presented, he drinks." M. de Sauvages then adds, that this rare modification of the disease occurred once to Dr. James, physician to the Elector of Saxony, in a man about thirty years old, who was terrified with the thought that the Deity had condemned him. It continued for four months, during the autumn and winter, but the patient was at length restored to his right understanding.—(*Nosol. Med.*, class viii., ord. 3.)

Grief, and particularly for the loss of friends, discontent, severe disappointment, the dread of some real or imaginary evil, a violent and long-continued exertion of any of the passions, and deep uninterrupted study, have frequently proved accidental causes or accessories of this variety of melancholy, where the peculiarity of the constitution has formed a predisposition, and have sometimes produced it even where no such predisposition can be traced. M. Magendie met with a singular exemplification of this from a cause few would expect, though not difficult of solution. The patient, an intelligent and agreeable man, though of a highly nervous temperament, had the misfortune, at the age of thirty-six, to meet with various crosses in business, and to have his wife become deranged in her confinement with her first child. All his energies were devoted to the recovery of his wife, whom he accompanied in travelling, which was recommended to her; he nursed her with tender assiduity, and was a witness to all her sufferings of body and mind. In time she recovered; but he himself, instead of giving way to joy, fell into a state of the most distressing melancholy—believed himself ruined, pursued by the officers of police, and about to take his trial for some heinous offence. Upon every other subject his mind was sound. We have already observed that the sudden cessation of any habitual drain, or other corporeal irritation, has occasionally proved a cause of melancholy; and we here find that there is at times as much danger in a sudden cessation of mental as of corporeal irritation; the excited mind being as little capable of bearing the change in the one instance as in the other. And hence, whenever such an effect occurs in an irritable frame, the individual should be instantly roused to some new pursuit, that may swallow up, though more agreeably, the whole of the surplus of sensorial power that has habitually been produced. In the state above described M. Magendie's patient continued many months, when, from some unknown cause, the disease upon the mind was thrown upon the motific fibres, and he was attacked with a chorea; the intellect recovering its powers as the muscles of locomotion were more and more thrown into the most ridiculous but involuntary gesticulations. He was restored from this, and to perfect health, by the use of

* A gentleman residing in a part of the country with which Dr. Conolly is well acquainted, easy in his circumstances, and not unhappy in his family, conceived an aversion to interchanging a word with anybody whatever. He would avoid people whom he saw approaching, or leave the room when they entered it. He generally had his hands clasped before him, and used to deal much in short exclamations, such as "Lord have mercy upon us!" "What a wicked world this is!" and so forth. Yet this man, when circumstances compelled him into conversation, wanted none of the powers, and had lost none of the information requisite for performing his part in it with credit. His aversion to meeting or speaking to people was a mere aggravation of what nervous persons are very subject to: but there appeared also to be in him an inaptitude of the nervous system to be so acted upon by ordinary impressions as to attend to them; but when the impression was increased, his faculties, and especially his attention, were roused into healthy action, and consequently he was not insane, according to the principles laid down by Dr. Conolly.—See Inquiry concerning the Indications of Insanity, p. 124.—Ed.

tonics, and especially the sulphate of quinine.—(*Magendie, Journal de Physiologie, Avr., 1822.*)

Other excitements by which the present species is produced, are immoderate exercise, insolation, or long exposure to the direct rays of the sun, sudden transitions from heat to cold, powerful stimuli applied to the stomach.

In the case related by Sauvages, the disease appears to have proceeded from a heated imagination exercised upon false views of religion: and perhaps there is no cause more common or more operative, especially in timid minds; and more particularly still where the conscience is alarmed by a review of a long catalogue of real delinquencies, and a dread of eternal reprobation.

Few persons have given a more striking example of this than the Abbé de Rancé when first touched with remorse for the enormity of his past life, and before the disturbed state of his mind had settled into that turn for religious seclusion and mortification which produced the appalling austerities of La Trappe. "To this state of frantic despair," says Dom Lancelot in his letter to La Mère Angélique of Port Royal, "succeeded a black melancholy. He sent away all his friends, and shut himself up in his mansion at Veret, where he would not see a creature. His whole soul, nay, even his bodily wants, seemed wholly absorbed in a deep and settled gloom. Shut up in a single room, he even forgot to eat and drink: and when the servant reminded him that it was bedtime, he started as from a deep revery, and seemed unconscious that it was not still morning. When he was better, he would often wander in the woods for the entire day, wholly regardless of the weather. A faithful servant, who sometimes followed him by stealth, often watched him standing for hours together in one place, the snow and the rain beating on his head; while he, unconscious of them, was wholly absorbed in painful recollections. Then, at the fall of a leaf, or the noise of the deer, he would awake as from a slumber, and wringing his hands, hasten to bury himself in a thicker part of the wood; or else throw himself prostrate, with his face in the snow, and groan bitterly."

The same causes operate in the production of ROVING OR RESTLESS MELANCHOLY, forming the second variety, and exhibiting a modification which often depends obviously upon a difference of idiosyncrasy, though the cause is not always to be explained, and under the operation of which the patient has a constant desire to change his pursuit or his residence. And hence, while Albert Durer is entitled to the approbation he has so long received for his admirable picture of melancholy, under the guise of a pensive female leaning on her arm with fixed looks and neglected dress, Shakspeare has equally copied from nature in his description of the beautiful and interesting Ophelia, who, instead of shutting herself up from the world, and seeking silence and solitude, is represented as peculiarly busy and talkative, and unwittingly divulging the fond secret of her distraction to every one she meets, as well in verse as in prose. Sadness is the prevailing colour of the mind; but it is often,

as Jaques expresses it, "a most humorous sadness," so blended with sallies of pleasantry and wit, that it is impossible to listen to them without smiling, notwithstanding the gravity of the occasion. "Humorous they are," says Burton (and, unhappily for himself, no one knew how to describe the disease better), "beyond all measure; sometimes profusely laughing, extraordinarily merry, and then again weeping without a cause; groaning, sighing, pensive, and almost distracted. Multa absurda fingunt et à ratione aliena (*Frambes. Consult., lib. i., 17*); they feign many absurdities, void of all reason: one supposeth himself to be a dog, cock, bear, horse, glass, butter. He is a giant, a dwarf, as strong as a hundred men, a lord, duke, prince. Many of them are immoveable and fixed in their conceits; others vary upon every object heard or seen. If they see a stage-play, they run upon that for a week after; if they hear music or see dancing, they have naught but bagpipes in their brain; if they see a combat, they are all for arms; if abused, the abuse troubles them long after. Restless in their thoughts and actions, continually meditating,—

—'velut ægri somnia, vanæ
Finguntur species;'

more like dreamers than men awake, they feign a company of entire fantastical conceits: they have most frivolous thoughts, impossible to be effected; and sometimes think verily that they hear and see present before their eyes such phantasms or goblins they fear, suspect, or conceive; they still talk with and follow them. 'They wake,' says Avicenna, 'as others dream.' Though they do talk with you, and seem to be very intent and busy, they are only thinking of a toy; and still that toy runs in their mind, whatever it be; that fear, that suspicion, that abuse, that jealousy, that agony, that vexation, that cross, that castle in the air, that crochet, that whimsey, that fiction, that pleasant waking dream. If it be offensive, especially, they cannot forget it; they may not rest or sleep for it; but still tormenting themselves, *Sisiphi saxum volvunt sibi suis.*"

How melancholy a reflection, that the writer of this spirited description should have drawn many of its features from himself; and that the work from which it is copied, engaged in for the purpose of diverting his thoughts, and replete with genius, learning, and the finest humour, should only have exasperated the disease, and urged the pitiable patient, as there is too much reason to fear, to an untimely end! "He composed his book," says Mr. Granger, "with a view of relieving his own melancholy; but it increased it to such a degree that nothing could make him laugh but going to the bridge-foot, and hearing the ribaldry of the bargemen, which rarely failed to throw him into a violent fit of laughter. Before he was overcome with this horrid disorder, he, in the intervals of his vapours, was esteemed one of the most facetious companions in the university."

The THIRD VARIETY, in which the alienation assumes a morose or mischievous character, is

perhaps the most common form under which the disease makes its appearance. Sometimes the patient is extremely passionate, and will quarrel furiously with every one alike, in whatever tone or manner he is addressed, and expresses himself with great violence of language, occasionally with gross unqualified abuse, but occasionally also in a style of repartee that never was evinced in a sane state. More generally, however, he selects his objects of resentment; which are, for the most part, unaccountably taken from his nearest relations and kindest friends. Against these he harbours the blackest suspicion and jealousy, believing that they are haunting him to take away his money or his life, or to put him to torture. He loads them with every term of the deadliest hatred, or scowls at them with contempt, and denounces them as fools and idiots. Under the distressing influence of this horrid form of the disease, the mother abominates her infant family, and the wife her husband; the most chaste become lascivious; and lips which have hitherto uttered nothing but the precepts and the language of piety, become grossly profane, and are the vehicles of oaths and impudence. The unhappy individuals are, at the same time, not only sensible of what they say or do, but occasionally, sensible of its being wrong, will express their sorrow for it immediately afterward, and say they will not do so again. But the waywardness of the will, and its want of control by the judgment, urge them forward in spite of their desire, and they relapse into the same state almost as soon as they have expressed their regret. Mr. Locke has, with great ability, pointed out the proper distinction between these two faculties of the *DESIRE* and the *WILL*, and has exemplified it by the chastisement with which an indulgent father frequently finds himself called upon to visit an offending child, and which he wills to perform, though his desire is in the utmost degree reluctant. The disease before us is pregnant with examples of the same kind, and strikingly shows the correctness with which this great master of his subject analyzed the human mind.

We have already observed that the peculiar turn or modification of the malady depends in general far less upon the immediate and exciting cause, than upon the constitutional temperament, or some operative principle which we cannot always develop. And in proof of this it may be hinted that I have drawn the principal lineaments of the description just laid down from the case of a lady of about sixty years of age, respecting whom I was lately consulted, and whose exciting cause has been, manifestly, suppressed grief for the death of an only son, and separation from a daughter who was the remaining solace of her advancing years, in consequence of her having married a gentleman whose station is in a remote part of the globe. Possessed by nature of a high and commanding spirit, and of a peculiar degree of energy and activity, she effectually succeeded, by a violent internal struggle, in subduing the pangs that at first suffocated her; and has for several years talked

for the latter has since become a mother, without emotion. But with the loss of fine feeling for her daughter, she has lost, at the same time, all fine feeling upon other subjects; and her judgment has sunk amid the general wreck. The love of her nearest relations has turned to contempt or hatred; the ardour and animation of her mind, which restrain her from taciturnity and retirement, have rendered her forward and invective; rational expostulation has yielded to sudden and unmeaning fits of violence and blows, and the voice of piety to exclamations that would formerly have shocked her beyond endurance. She, too, is often sensible of her doing wrong, and, in letters of great sobriety and excellence, often complains of her own conduct, and the burden she is become to her friends; but the intervals of sanity are only of a few hours' duration, and with all her calmness, she is sure to relapse.—(Compare with the *Report of the Glasgow Asylum for Lunatics*, 1821.) For many months she was intrusted in her own house to the control of a professional female attendant, who, with great dexterity, at length succeeded in obtaining a due degree of authority over her without personal restraint; and, under the regimen of perfect quiet and seclusion from the world, she seemed to be in a fair way of recovery; but the mischievous fondness of her nearest relations has since removed this faithful watchwoman, and her senses have again been bartered for her liberty.

The symptoms most afflictive to the relations of the patient in this variety of insanity are the tendency to behold them with indifference or even violent aversion, and to utter exclamations and employ language of the most offensive kind to a serious and a delicate ear; and it is the symptom apparently most unaccountable to those who have not studied the disease with much attention. I have already remarked that, in insanity, the corporeal sensibility is greatly diminished, but it is not more so than the moral sensibility; and as the moral sensibility disappears, all moral restraint disappears also: and for the reason that the insane man has little feeling of cold or hunger, he has also little feeling of decency or religion. In the present variety, the worst passions are in a state of excitement, and the language most freely employed is the language of the passion that predominates; and there being no longer any moral restraint, it is employed in its utmost vehemence and coarseness. And as the fond affections have given way to the irascible, it should seem to follow, of course, that the greater the love or friendship formerly, the greater the hatred at present.

There is one consolation, however, though a small one, that we may reap from this distressing contemplation, and to which the friends of the sufferer should not be indifferent. It is that, with this blunted sensibility of mind, the patient has no pain from a consciousness of his degraded condition. And it is singular to observe, what may also contribute to alleviate the distress of the sympathizing heart, how completely his unconsciousness prevails even after a patient's restoration to health, so that few look

back upon what they have undergone with the horror that would be expected; while many, even in the apprehension of a relapse, contemplate it, and turn their eye to the abode of misery where they were lately inmates, without dread.

The FOURTH VARIETY, OR SELF-COMPLACENT melancholy, is perhaps less frequent than any of the rest; but it occurs occasionally, and is often accompanied with a high-coloured and ruddy complexion, and other marks of a sanguineous habit: "Such persons," says Burton, "are much inclined to laughter, are witty and merry, conceited in discourse, pleasant, if they be not far gone, and much given to music, dancing, and to be in women's company." Aristotle gives the case of an inhabitant of Abydos, who, labouring under this variety of the disease, would sit for a whole day as if he had been upon a stage, listening to visionary actors; sometimes acting himself, and occasionally clapping his hands and laughing as overjoyed with the performance.—(*Lib. de Reb. mir.*) Such persons have not unfrequently thought themselves called upon to undertake some desperate adventure, and are exquisitely elated with the new and lofty character they are about to embrace.

These stimulant feelings are not unfrequently connected with erroneous ideas of religion, and excite in the mind of the patient a belief that he is supernaturally endowed with the power of working miracles, or undergoing the severest mortifications without injury. The German Psychological Magazine is full of examples of this kind; and, among others, relates the case of a *gens-d'armes* of Berlin, whose name was Gragert, of a harmless and quiet disposition, but rather of a superstitious turn of mind. From poverty, family misfortunes, and severe military discipline, he brought on a series of sleepless nights, and a mental disquietude that, according to his own report, nothing could dissipate but a perusal of pious books. In reading the Bible, he was struck with the book of Daniel, and so much pleased with it, that it became his favourite study; and from this time the idea of miracles so strongly possessed his imagination, that he began to believe he could perform some himself. He was persuaded more especially that, if he were to plant an apple-tree with a view of its becoming a cherry-tree, such was his power that it would bear cherries. He was discharged from the king's service and sent to the workhouse, where he conducted himself calmly, orderly, and industriously for two years, never doing any thing that betrayed insanity; at which time Dr. Pike examined him, that he might be discharged and sent to his family. He answered every question correctly, except when the subject concerned miracles: in regard to which he retained his old notions; adding, however, at the same time, that if he found, upon trial, after he was at home, that the event did not correspond with his expectation, he would readily relinquish the thought, and believe he had been mistaken; and confessed that he had already removed one error in his mind in this way; for there was an old woman whom he had at

one time considered as a witch, but whom he afterward discovered, upon trial, to be no such thing.

Upon the medical treatment of diseases of this kind, we shall not have to say much; but as the plan chiefly advisable for the present species is equally advisable for the ensuing, it will be most expedient to reserve the discussion of it till the latter has been described in its order.

SPECIES II.

ECPHRONIA MANIA.

MADNESS.

THE DISCREPANCE BETWEEN THE PERCEPTION AND THE JUDGMENT GENERAL; GREAT EXCITEMENT OF THE MENTAL, SOMETIMES OF THE CORPOREAL POWERS.

This species appears under almost infinite varieties of character, of which, however, it may be sufficient to mark the following, modified for the most part by the predisposing causes that we have already noticed, as modifying the preceding species:—

- | | |
|---------------|------------------------------|
| α Ferox. | Furious and violent madness. |
| β Exultans. | Gay and elevated madness. |
| γ Despondens. | Gloomy, despondent madness. |
| δ Demens. | Chaotic madness. |

The exciting causes, like the predisposing, are chiefly those already enumerated under *ecphronia melancholia*: as sudden and violent mental emotion; bad passions indulged habitually; false views of religion, especially the dread of reprobation and eternal punishment; sudden reverse of fortune, whether from bad to good, or from good to bad; preying anxiety, or lurking discontent; deep protracted study, unrelieved from week to week by an interchange of exercise or society, and breaking in upon the hours of sleep; unkindly childbed; a suppression of various periodical evacuations; and sometimes even a virtuous restraint of sexual orgasm in a vigorous constitution, without taking purgative or other means to reduce the irritative entony.

Of these one of the most frequent causes is that of childbed, and recovery from childbed, though it is not always easy to develop the immediate mode by which this change in the constitution acts upon the brain; for it has occurred not only where there has been some organic affection from puerperal fever, a sudden cessation of the lochia, or a sudden relinquishment of nursing, but where the recovery has been unattended with a single unfavourable symptom, and the mother has ardently persevered in the office of a nurse. It shows us, however, very sufficiently, how strong is the chain of sympathy between the brain and many remote organs of the body, and especially those subservient to the function of generation.

M. Esquirol, not long ago, communicated a paper to the Société de Médecine upon this important subject, enriched with the results of the Hospital de la Salpêtrière, for the years 1811, 12, 13, and 14. During these four years eleven hundred and nineteen women were admitted, labouring under mental derangement: of whom ninety-two (nearly an eleventh part of the whole)

had become deranged after delivery, during or immediately subsequent to the period of suckling. In the higher ranks of society, the proportion of puerperal maniacs he calculates to be not less than a seventh of the whole. Of the above 92 cases, 16 occurred from the first to the fourth day after delivery; 21 from the fifth to the fifteenth; 17 from the sixteenth to the sixtieth day; 19 from the sixtieth to the twelfth month of suckling: and in 19 cases it appeared after voluntary or forced weaning.*

Of the above 92 cases, 8 were idiotic, 35 melancholic, and 49 maniacal. The respective ages were as follows: 22 from 20 to 25 years; 41 from 25 to 30 years; and 12 above 30. Fifty-six out of the ninety-two were entirely cured, and thirty-eight of these within the first six months. Fright was the most frequent cause.—(*Quart. Journ. of For. Medicine*, No. i., p. 98.)†

I have said that a virtuously restrained orgasm, in a full habit, and where no steps have been taken to reduce the tonic vigour, has occasionally induced mania. There is a curious instance of the powerful effect of such a state related by Kemnesius in his history of the Council of Trent, which, though it did not terminate in madness, proved quite as fatal. In the year 1419, Rossa, nephew to the King of Portugal, and archbishop elect of Lisbon, was taken seriously ill at Florence. His physicians told him that his disease proceeded from an excessive irritation of the genital organs, and that he would certainly die unless he committed fornication or married. With a courage worthy of a happier issue, he resolved on death, and met it without breaking his vow of celibacy.—(*Kemnes. Concil. Trident.*, part iii.; *De Calibatu Sacerdotum*.)

The following instance, however, will prove that mania itself is sometimes the consequence of the same firmness of mind. A clergyman of exemplary character, and one of the most distinguished preachers I have the pleasure of being acquainted with, was, many years ago, very unexpectedly attacked with a paroxysm of mania, the cause of which it seemed impossible to unfold. He recovered in about six months, and returned to a regular and punctilious discharge of clerical duty. He is a man of exquisite taste, warm imagination, exalted and highly cultivated

mind. With these qualifications, in less than a year after his recovery, he married his maid-servant, and the world imagined he was gone or going out of his senses a second time. A confidential statement of his situation soon proved to myself that nothing could be more prudent or praiseworthy than the step he has thus taken, and which had excited so much astonishment among his friends. He was fully convinced, he said, though he had never communicated it to any one, that the cause of his unfortunate malady was a genital irritation, exciting to a constant desire of matrimony, which he was not in a situation to comply with, and which compelled him to exercise from day to day a severe restraint upon his feelings. On being fully restored to health, he found the same morbid propensity beginning to return. I felt, said he, it would again drive me mad if I did not relieve it, and my principles forbade me to think for a moment of relieving it immorally. To what respectable family could I now offer myself, having so lately been discharged from private confinement? The servant who lived with me was a very excellent young woman; her disposition was amiable, her mind well capable of cultivation, and her form and manners by no means unpleasing; and hence, after mature deliberation, I determined upon marrying her, if she herself would venture upon so perilous a risk. He married her accordingly;—has ever since, for upwards of twenty years, enjoyed an almost uninterrupted share of health, and has been more than ordinarily happy in his family. Other examples of a like kind are to be found in Paullini (*Cent. iii.*, obs. 14), Martini (*Osservazioni*, ch. ii., 10), and Vogel (*Beobachtungen*, p. 9): but it is unnecessary to copy them. And hence, castration has been often advised and submitted to, and occasionally with success.

It is from a like sympathy of action between the brain and other parts of the body that we meet with instances of the one or the other species of disease before us, produced occasionally, and perhaps in habits of great sensibility, by suppressed irritations of much smaller moment; as cutaneous diseases,* a suppressed hemorrhoidal flux (*Santacruz, De Melancholia*, p. 29; *Lentilius, Miscell.*, i., p. 36), or an ulcer of long standing suddenly dried up.—(*Forestus*, lib. x., obs. 24.)

FURIOUS MANIA, constituting the first variety, sometimes makes it attack very abruptly, and commences with the patient's being sensible of some indescribable movement in his head, which excites him to loud and sudden shrieks, at the same time that he runs up and down the room, and mutters something to himself that is altogether unintelligible: though the symptoms, even in this abrupt and violent attack, admit of much diversity.

More commonly, however, the disease is the work of time; and its growth is thus admirably described by Dr. Monro in his reply to Dr. Battie:—"High spirits, as they are generally term-

* In the New-York Med. Journal, vol. i., p. 280, Dr. McDonald, physician to the Bloomingdale Asylum for the insane, has published some observations on puerperal mania, and concludes, "That young women are much more obnoxious to this malady than those more advanced, and that the susceptibility of females to it diminishes in about the same ratio that their years increase; that women are more liable to this disease at the first than at subsequent parturitions; that an hereditary predisposition to insanity exists in less than one sixth of the cases; that moral causes are co-operative only; that puerperal insanity is one of the most curable forms of mental disorder."—D.

† There is a greater predisposition to madness, says Dr. Rush, between twenty-five and fifty, than at any of the previous or subsequent years of human life.—D.

* Act. Nat. Cur., vol. viii., obs. 28. Descottes, *Journ. de Méd.*, tom. lxi. Petit, *Œuvres posthumes*, tom. iii.

ed, are the first symptoms of this kind of disorder. These excite a man to take a larger quantity of wine than usual, and the person thus afflicted, from being abstemious, reserved, and modest, shall become quite the contrary, drink freely, talk boldly, obscenely, swear, sit up till midnight; sleep little, rise suddenly from bed, go out a hunting, return again immediately, set all his servants to work, and employ five times the number that is necessary. In short, every thing he says or does betrays the most violent agitation of mind, which it is not in his own power to correct. And yet, in the midst of all this hurry, he will not misplace one word, or give the least reason for any one to think he imagines things to exist that really do not, or that they appear to him different from what they do to other people. They who but seldom see him admire his vivacity, are pleased with his sallies of wit and the sagacity of his remarks; nay, his own family are with difficulty persuaded to take proper care of him, till it becomes absolutely necessary from the apparent ruin of his health and fortune."

This picture is drawn from a rank of life something above that of mediocrity, but its general features of ebullient spirits, and hurry and bustle, and "much ado about nothing," will apply to every rank. Such a person, says Sir A. Crichton, in allusion to the present description, cannot be said as yet to be delirious, but that event soon follows, and he has then the symptoms common to the disease, symptoms which only differ from a difference in the train of thoughts which are represented in his mind. He begins to rave, and talk wildly and incoherently; swears as if in the most violent rage, and then immediately afterward bursts into fits of laughter; talks obscenely; directs offensive and contemptuous language against his relations and those around him; spits at them; destroys every thing that comes in his way; emits loud and discordant screams; and continues this conduct till he is quite exhausted. The state of rest which follows is generally short and sleepless; the patient is obstinate; he will not speak a word, and clinches his teeth if any thing be offered him to swallow; or else cunningly pretends to drink a little, but immediately squirts it out on the person who offers it. Instantly he again breaks out into all the wild and extravagant language and actions he committed before. If kept in strict coercion, he has often so much command over himself as to behave mildly and modestly; and were it not for the general expression of his countenance, and the peculiar glistening appearance and rapid movement of his eyes, he might impose on many of the bystanders, and make them imagine that the phrensy was over. The length of the paroxysm and of the interval varies greatly in different individuals.* But, generally speaking, the more violent the fit the sooner it ceases, from exhaustion; and hence sometimes it ceases in a day or two, and sometimes runs on to a month or

even more; returning at the distance of a few weeks, or at certain periods of the year.

In the SECOND VARIETY, OF ELEVATED MADNESS, the passions, and especially the irascible ones, are less busy, and the imagination is chiefly predominant, and at work without ceasing. It is here we most frequently trace something of the ruling pursuit of their former lives, so that the covetous man is still conversant about purchasing lands and tenements, and amuses himself with perpetually augmenting his possessions; while the devotional character is for ever engaged in a routine of prayers, fastings, and ceremonies, visions and revelations, and fancies himself to be inspired and lifted into heaven.* The phantoms are all of a pleasurable kind, and mostly such as afford the deluded sufferer a vast opinion of his own rank or talents. Donatus gives a case of a lady at Mantua, who conceited she was married to a king, and would kneel down and affect to converse with him as if he were present with his attendants; and if she found by chance a piece of glass in the street, she would hug it as a jewel sent her from her royal lord and husband.—(*De Hist. Med. Mirab.*, lib. ii., cap. i.) He relates another case, from Seneca, of Senecio, a madman of considerable wealth, who thought himself and every thing about him great; that he had a great wife, and great horses, and could not endure little things of any kind; so that he would be served with great pots to drink out of; great hosen, and great shoes bigger than his feet: "Like her," says Burton, "in Trallian, that supposed she could shake all the world with her finger, and was afraid to clinch her hand lest she should crush the world to pieces like an apple."—(*Anat. of Melancholy*, part i., sect. 3.)

Yet even here the train of thoughts or ideas which occupy the mind of the maniac, in many instances throw no light whatever on the nature or origin of the complaint; and we can still less avail ourselves of them than in various cases of melancholy.

This is particularly observable in the THIRD VARIETY, OF DESPONDENT MADNESS; for though this modification of the disease may occasionally be produced by suspicion, terror, or a guilty conscience, it is far more frequently the result of a melancholic idiosyncrasy, or a debilitated state of the constitution at the time of the attack, in consequence of which the sensorial fluid is secreted* perhaps even less freely, instead of more so, than in a condition of health; so that the patient sinks by degrees into a state of insensibility; unless he should be roused with false courage, and find means to put an end to his existence before this period arrives.

In DEMENTIA, OR CHAOTIC MADNESS, this state of sensorial exhaustion and consequent insensibility are still more obvious, though there is, perhaps, less constitutional tendency to the de-

* The paroxysm is accurately and powerfully described by Spenser, *Fairie Queen*, b. ii., cant. iv., xv.

* In some instances, the person labouring under this variety of elevated madness has imagined himself to be the Messiah.—D.

† As this expression is quite an improbable hypothesis, it would be better to exchange it for "sensorial power is generated."—Ed.

pressing passions. The judgment here is more diseased and weakened than in any other form, and none of the kindred faculties assuming a paramount power, there is a general anarchy and confusion in the ideas that flit over the sensory, without connexion or association of any kind. And hence Pinel has admirably characterized it as consisting in a "rapid succession or uninterrupted alternation of insulated ideas and evanescent and unconnected emotions; continually repeated acts of extravagance; complete forgetfulness of every previous state; diminished sensibility to external impressions: abolition of the faculty of judgment; perpetual activity without object or design, or any internal sense of its taking place."—(*De l'Aliénation Mentale*, ch. iii., iii., § 176.)

These maniacs are often ungovernable except by means of coercion; but they are more easily restrained than those who are in a state of phrensy. They are intractable, and neither listen to entreaty or to menaces. Fear of corporeal punishment, however, makes them obey. They willingly avoid the light, burying themselves under the bed-clothes, or under the straw of their cells. They are totally regardless of decency and cleanliness, and, from some strange motive, are often found smearing themselves over with their excrement. For the most part, they have little appetite, and refuse the food offered them; yet a sense of hunger seems sometimes to return with great keenness, when they will greedily devour their feces. Of the nature of the ideas that take place in the sensory, and are expressed by an unintelligible muttering, we know nothing further than that, from the screams and howlings with which their jargon is accompanied, there can be no doubt that they are often excited by painful sensations of body or mind.

It is happy for those who suffer under this as well as under the preceding form, that they rarely sustain a long conflict; the exhaustion of sensorial power by repeated paroxysms soon leading to a total torpitude, and consequently a death of the sensorial organ;* though there are instances in which a paroxysm of more violence than usual has produced a favourable change, and suddenly restored the patient to his senses.

In gloomy madness, in which there is often a chronic affection of some of the abdominal organs co-operating with a diseased condition of the brain, we find least to justify hope; the patients generally become weakened by fresh paroxysms, and often sink into a state of idiotism.

The first variety, on the contrary, if the constitution have not been seriously broken down by intemperance, or the patient be not suddenly

carried off by the violence of the attack on its commencement, will often work its own cure by its own ardour; and will gradually soften into a more sober state from simple mental fatigue. While in the milder and more pleasurable modification of the second variety, in which the production of sensorial power is upon the whole perhaps less than in a condition of sanity (since, though the stimulus of the disease may tend to increase it a little, the total privation which the patient enjoys of all the vexations, and anxieties, and wearing vicissitudes of real life, reduce it to a moderated and even tenour it could not otherwise possess), nothing is more common than for maniacs to continue to a very advanced age. I am at this moment interested in the case of a clergyman who has reached his ninety-sixth year, and has been in a state of quiet insanity for more than half a century.

For the most part, those are most easily as well as most rapidly cured, whose insanity, of whatever kind it be, has been produced by accidental causes, as intoxication, sudden transition from cold to heat, retention of habitual discharges, or a revulsion by a transfer of morbid action from other organs. And hence the comparative facility with which a cure is effected in insanity after childbirth. While, on the contrary, those are least likely to obtain a permanent recovery who possess an hereditary taint; the disease may indeed leave them for a time, but, the predisposition remaining, they commonly fall victims to fresh attacks after intervals of a year or two, or even of a few months.

"Mania and melancholy," says Dr. Greding, writing while he was physician to the workhouse at Waldheim, "have continued half a year with some, and remained forty years and upward with others, among whom one patient only in this workhouse attained the age of eighty-five."—(*Vermischte Schriften*, ut *suprà*, &c.)

The chance of recovery is considerably greater upon the first than upon any subsequent attack, and especially if the disease have not exceeded three months' duration when the patient is first put under medical treatment. If it have at this time lasted a twelvemonth, the prospect of success is diminished by half; if two years, not above a fourth part as many recover; and if more than two years, the expectation is small, though, where the second year is not much exceeded, a cure is by no means to be despaired of.*

The treatment of ecphronia has generally been discussed under the two heads of MEDICAL and MORAL. Both have undergone a very great improvement within the last twenty or thirty years: the first by being considerably simplified; the second, by being more thoroughly studied and raised to a higher degree of importance.†

* "Death of the sensorial organ" seems by no means an eligible expression, as it may be understood to signify that the brain, in the case here described, dies first, and the rest of the system perishes afterward, in consequence of the death of the sensorial organ. In the examples referred to, the violence of the paroxysms may be said to derange the functions of the whole nervous system, disturb all the operations of the animal economy, and thus bring on debility, various forms of disease, and speedy dissolution.—ED.

* The instructive volume of Dr. Rush, "On the Diseases of the Mind," mentions many cases of most of the prevalent forms of mania. Knapp's *Life of the late Thomas Eddy* contains the interesting particulars of the case of Count Renauld St. Jean d'Angély, from the pen of Mr. Colden. This distinguished French orator died of mania.—D.

† When a medical practitioner is consulted re-

Nothing can be more injudicious than the ordinary routine of MEDICAL TREATMENT, which, till within a few years, was equally employed in almost all the larger lunatic establishments in our own country and on the continent, especially at Bethlem, the Hospice d'Humanité, and the Hôtel Dieu; and which consisted in a course of venesections, emetics, and purgatives, administered in every case indiscriminately, and often, indeed, without even the personal inspection of the consulting physician or other superintending medical officer; and if, to these means of cure, we add the occasional use of bathing in various forms and various temperatures, we shall very nearly have exhausted the merely medical process that till of late was ordinarily had recourse to.

Upon the cruel and disgusting scenes which, from the late parliamentary inquiry and the report of the committee which followed, are well known to have occurred not long ago in the largest and most celebrated receptacle of lunatics in this metropolis, it is now unnecessary to dwell. But from the official communication of M. Esquirol to the French government concerning the residences for lunatics throughout France, it is perfectly clear that we have not transgressed in a greater degree than our neighbours. Filth, straw, and dirty rags, were all

specting a person suspected to be insane, his whole duty, as Dr. Conolly explains, resolves itself into two parts:—1. To determine whether the individual in question be of sound mind. 2. To give an opinion respecting the treatment required, and especially concerning the necessity of restraint, and the degree and nature of such restraint.

The aid of medicine is required in most cases of disturbed mind; personal restraint may be required in many; but the degrees of it which are required in different cases vary, as the cases themselves vary, from the slightest to the most complete; and complete restraint is very rarely required. Whether the person ought to be confined at all will rest, as Dr. Conolly very properly insists, upon the consideration, whether the degree or character of the mental disturbance is such as to make the patient dangerous to himself or others, either as regards person or property.—(See Dr. Conolly's Inquiry concerning the Indications of Insanity, pp. 365, 386, &c.) This talented writer adverts to the frequency of cases in which patients become more and more susceptible of all impressions, and more and more irritable, in consequence of habitual indulgence in diet which disagrees with them. Certain articles of food, or of drink, which produce a temporary disturbance of the whole system, are taken so frequently, that the body and mind are never left quite free from their effects. During the early stage of such cases, restraint may be productive of a complete cure; and even when insanity has become declared, but has not long existed, it will recede and disappear, if the habits which are destroying the mind are resolutely broken. The cure depends partly upon physical, and partly upon moral treatment; and Dr. Conolly gives it as his opinion, that both may often be better administered out of an asylum than in it. Long-continued superintendence and occasional restraint are necessary; but seclusion, confinement among lunatics, deprivation of property, long separation from friends, are quite uncalled for and improper.—Op. cit., p. 393.—ED.

these miserable beings possessed in many dépôts to mitigate the coldness of the air, and the dampness of their paved, crammed, and suffocating cells. And in some instances they had neither straw nor rags, and were perfectly naked, except from a layer of dirt. "J'ai vu," says M. Esquirol, with just indignation, "un malheureux imbécile, tout nu et sans paille, couché sur le pavé. Expriment mon étonnement d'un pareil abandon, le concierge me répondit que l'administration ne lui passait, pour chaque individu, qu'une botte de paille tous les quinze jours. Je fis remarquer à ce barbare que le chien qui veillait à la porte des aliénés étoit logé plus sainement, et qu'il avoit de la paille fraîche et en abondance. Cette remarque me valut un sourire de pitié. Et j'étois dans une des grandes villes de France."—(*Des Etablissements des Aliénés en France, et des Moyens d'améliorer le Sort de ces Infortunés*, Paris, 1819.) It is satisfactory, however, to know, that a more judicious and discriminative practice has in all these asylums been introduced since the above period, and that it has been followed by an abundant success.*

Admitting the proximate cause of insanity to be in most cases an increased action of the vessels secreting the nervous fluid [or supplying with blood the organs by which the sensorial power is produced], venesection and cathartics, and a general reducent regimen, seem indicated as an ordinary means of relief; and are unquestionably called for when the pulse is full and strong, and the temperament is sanguineous: and the success which has so frequently accompanied this practice, stamps it with the highest sanction it can receive. But there is great reason to believe, that even where the demand for bloodletting is unequivocal, it has been carried to a mischievous extent, and ruined its own benefit. Thus Plater made a point of repeating it once a week, and sometimes had recourse to it for seventy weeks in succession.—(*Observ.*, lib. i., p. 86.)

Much caution, however, is necessary even in the first trial; for as a sound intellect depends apparently upon a certain degree of excitement in the sensorial vessels, and a certain quantity of the fluid secreted [or intellectual power generated], derangement may take place also,

* In Dr. Conolly's Inquiry into the Indications of Insanity, many judicious reflections will be found on the disadvantages of the common system of lunatic asylums. Every humane mind will also incline to his opinion, that it is not every form of mental derangement that justifies confinement in such establishments. A man may fancy his legs to be butter, and take all due care of them; without injury to himself, his family, his property, or the property and persons of others, and no one can have a right to interfere with him.—(Op. cit., p. 305.) He may, on seeing his doctor, address him as if he were Jesus Christ; or he may fancy that a princess is in love with him, and do many extravagant things in consequence of the delusion; yet his conduct will not justify restraint, unless his mental disorder lead him to neglect his affairs and his family, or to inflict injury either on others or on himself.—Op. cit., p. 384.—ED.

as we have already observed, from diminished instead of from increased action, and diminished instead of increased secretion or production. And such we have reason to believe is the cause of delirium whenever it occurs in profuse hemorrhage and in typhus fevers: in all such instances, a reducent plan must necessarily tend to augment instead of to carry off the disease. And hence, the patient's general habit and temperament, the nature of the exciting cause, the probability of visceral congestion, the violence or mildness of the maniacal symptoms, the progress they have made, and the length of time he has laboured under them, are all to be taken into consideration before we can determine upon the expediency of bleeding even at first. And if, when we have decided upon its propriety, no benefit be produced from a second or a third repetition, we have no encouragement to proceed further, and should withhold the lancet altogether.

To a series of purgative medicines there is less objection, provided they are not rendered too violent. The abdominal viscera, it has already appeared, form in many instances an important link in the morbid chain of action, and are sometimes the primary cause of the disease: and it is hence of great moment that they should be effectually cleared of any matter that may irritate or clog them up. But beyond this, by keeping up such an increased action in the abdominal region as the organs may bear without debility, we may diminish or change the morbid action in the head by remote sympathy, or entirely withdraw it by a revulsion. A spontaneous diarrhœa has been known in various cases to carry off the disease as by a charm: and the use of this class of medicines is the more necessary, as the bowels of maniacal patients are apt to be extremely costive. If the black hellebore of the ancients, which appears to have been a different plant from that of the modern dispensatories, were ever entitled to half the antimaniacal virtues ascribed to it, it was most probably upon the obvious ground of its being a purgative attenuant and deobstruent.

Dr. Dubuisson has lately revived the use of the modern black hellebore in various species of mental alienation, as chronic mania, melancholy, and hypochondriacism: in all which he speaks of its effects, after an extensive trial, as highly successful. He has given it also in every form, as that of powder, decoction, watery extract, and tincture; but prefers the extract as least irritating.—(*Des Vésanies, ou Maladies Mentales*, Paris, 1816.) His opinion, however, is not supported by the result of general practice, and appears to be by far too sweeping and indiscriminate. Spleissius, nevertheless, affirms that in his hands, when given freely, it proved sedative and produced sleep.—(*Annotat. in Zapat. Mirabil.*, p. 136.)

Upon no other description of medicines can we place any rational dependance. Emetics, narcotics, and other sedatives and antispasmodics, have been tried for ages in every form and in every proportion; sometimes alone, and sometimes in conjunction with blisters and the warm or cold bath. There are instances in

which they have all appeared to produce some benefit; but the far greater number, in which they have failed, prevents us from placing any reliance upon them.

Of the narcotics, the chief that have been had recourse to are opium, aconite, belladonna, and the stramonium. Far more mischief than good seems to have followed from the use of all of them, with the exception of the first, which would probably be found a remedy of high value if we could duly discriminate the proper states or modifications of the disease for its use. Dr. Cullen's experience of it in mania he admits to be small, but he has correctly estimated its general effects in telling us that, in some cases, he found it useful in moderating the violence of the disease, but that in others he found it manifestly hurtful. A monographist upon this malady could not, perhaps, be engaged more usefully, than in turning his attention to the peculiarities which produce this difference. On the continent, it has also been given sometimes alone; but, more usually, in conjunction with nitre or camphire, or both; but in all these forms, also, with variable success.—(*Fribourg, Coll. Soc. Med. Hafn.*, ii., p. 176.)

Upon what ground St. John's wort was ever advanced to the rank of a powerful sedative I know not; but in this class it at one time took the lead, and held it for ages. Its antispasmodic powers were regarded of so high a character as equally to put to flight hysterics, hypochondriacism, and madness of every kind, and especially that which was formerly described under the name of *dæmonomania* (*Abrah. Mayer, Archiv. der Practischen Arzneykunde*), whence, indeed, its technical name of *hypericum*, or *fuga dæmonum*, under which it was also celebrated. It occupied a place in a late edition of the *Pharmacopœia* of the London College, and was at one time noticed as an antispasmodic even by Dr. Cullen, who rejected it, however, most deservedly, in his maturer courses of lectures. Its only sensible qualities are those of a slight resinous bitter, not worth the trouble of extracting.

Camphire is a sedative far better entitled to attention, and appears to have been tried with more extensive success than any other medicine of the same tribe. It has been given alone, and in union with other sedatives, chiefly with opium, nitre, and the mineral acids, none of which, however, seem to have improved its powers. Berger, Fischer, and Herz, speak favourably of its effects abroad; and, in our own country, it has had equal commendations from physicians of distinguished talents. Dr. Mead thought highly of it; Sir Clifton Wintringham tells us that he found it, given to the amount of half a drachm in the evening, diminish the phrensy, procure sleep, and produce perspiration. Unfortunately, however, here, as in the case of opium, we have so many proofs of its utter inefficacy, as to render us at present incapable of placing any dependance upon it in any quantity or with any auxiliary. Dr. Cullen had a patient who began with five grains for the night's dose, and advanced it gradually to thirty,

without any benefit, though without any increase of the pulse. At this time it was carried by accident to forty grains, which produced syncope, and nearly proved fatal. The patient, however, recovered from the accidental symptoms, but unhappily no impression was made on the constitutional disease.—(*Mat. Med.*, vol. ii., p. 294.)

The warm and cold bath have also had their votaries, but no certain benefit appears to have been derived from either. The last may be useful as a tonic in a state of convalescence, but has rarely produced real benefit during the progress of the disease. Weber, however, thought it useful, and published several cases to this effect.—(*Obs. Med.*, fascic. i., p. 26; see also, *Act. Med. Berol.*, dec. i., vol. vii., p. 61.)

From an idea that the disease consists in an undue determination to the head, or an undue excitement of the vessels supplying the organs of sensorial power, Wendt (*Nachricht, Von dem Klinischen Institut zu Erlangen*, 1783, 8vo.) surrounded the head with cataplasms of pounded ice in the form of a nightcap; and Daniel, with a still more ingenious spirit of adventure, applied cataplasms of the same kind to the head, while the body, with a view of encouraging a revulsion more effectually, was plunged into a warm bath. The process will be found described in his *Beyträge zur Medicinischen Gelehrsamkeit*, published in quarto at Halle in 1749. And I mention the fact as an act of justice to the author, since the same process has of late years been revived in France and in our own country as a new discovery. Daniel thought it highly beneficial; and by its recent revivers it was at one time held up as a specific; but whatever success may, in a few rare instances, have attended it, the practice has not been able to work itself into public favour; and a sober attention to its effects does not seem to justify its further continuance. M. Pinel was at one time favourable to an employment of jets of cold water directed upon the head, while the body was immersed in tepid water; but his successor, M. Esquirol, is decidedly of opinion that it is injurious; and in many cases has induced disorganization of the cerebrum, and rendered the madness incurable.*

After all, we have chiefly to depend on MORAL TREATMENT. Firmness on the part of the attendant, with conciliatory manners, has done wonders; but a sense of authority must be maintained, though occasional severity should be necessary for this purpose: yet it will rarely be needful to exceed the coercion of the strait waistcoat. It is needless to add, that the diet should be of the simplest kind, that every thing which can tend to produce excitement should

be prohibited, and that, in public institutions, the patients should be divided into proper classes. Amusements of every kind that may engage the attention and encourage exercise in the open air, without rousing the passions or producing fatigue, should be promoted by every contrivance that can be thought of. And if the turn or previous occupation of the patient point to any particular pursuit, and especially to handicraft trades, and those that employ the mind without exhausting it, as that of sawing, gardening, bookbinding, or watchmaking, he should be enabled to pursue it according to his own desire. The desire itself is a favourable symptom, and has often led to the most beneficial results.

Judicious conversation and cheering advice are also of great importance; and regular daily attendance on religious services in the bosom of a private family, or with a few patients of a like standard in a public institution, may be allowed, where the disease has assumed a convalescent shape, and the service is performed soberly and dispassionately.—(*Report of the Glasgow Asylum for Lunatics*, 1820.) This will at first, perhaps, be only of use as promoting a habit of moral order and quietism; but every good man will indulge the hope, that it may afterward introduce into the mind the higher blessing of spiritual peace and consolation. Yet the attempt must not be begun too soon, and in no case till the patient has acquired not only a spirit of subordination, but of tranquillity. Before this period, nothing can be so absurd as to attempt devotional instruction of any kind; for the subject of religion can only be addressed to the reason, or to the passions: the former of which does not exist in a state to be influenced; and the latter of which, if they could be influenced at all, would only add to the excitement and increase the disease. The clear duty of the priest and of the physician is in this case one and the same: it is to bring the mind home to the world around it; to draw it down and fix it upon things of time and sense, instead of rousing it to things invisible and eternal; to enable it to behold God in the materialities of his works, instead of urging it to a contemplation of him in the spiritualities of his word. To instigate to an abstract and elevated communion with his Creator a madman, who is incapable of holding an intercourse upon ordinary topics with his fellow-creature, is to cure a frozen limb by pouring boiling water upon it, or to teach the Optics of Newton in a nursery.

In many cases, the cure mainly depends upon withdrawing the patient's mind as much as possible from every former scene and every former companion; in setting before him a new world, and giving an entire change to the current of

* The treatment of mental disorder must be determined in a great measure by the cause of the affection. That cause will probably be found to be "one of those producing temporary qualities of mind, but the operation of which has, in the case of the insane person, more deeply affected the understanding. Some stimulus may have been withdrawn, or some emotion may have acted too much as a stimulus. Disease, or age, may have produced disturbance or debility. If

the undue exercise or the too great neglect of any one faculty, as of the attention, the memory, or the imagination, has brought on the malady, the object must be to excite or to sooth, to rouse or to restrain such faculty; or if the irregularity seems dependant on some bodily inaptness or disorder, to this, of course, attention must be immediately given."—See Dr. Conolly's Inquiry concerning the Indications of Insanity, p. 388.—ED.

his recollections and ideas. There are particular cases, however, and perhaps particular periods of the disease, if we could accurately hit upon them, in which the sudden admission of a well-known friend or relation, and a sudden recall of the mind to its former images and habits, tend to produce a most salutary excitement, and disperse the maniacal cloud like a dream. Dr. Gooch has given an interesting illustration of this remark in the case of a lady, twenty-eight years of age, of a good constitution but susceptible mind, who fell into a state of melancholy, in the ordinary sense of the term, a few months after a second childbirth, and at length became furious. "She was now," says he, "put under the care of an experienced attendant, separated entirely from her husband, children, and friends; placed in a neat cottage surrounded by agreeable country (it was the finest season of the year), and visited regularly by her physician. For several weeks she manifested no improvement; sometimes she was occupied with one notion, sometimes with another; but they were always of the most gloomy description. At length it became her firm belief that she was to be executed for her crimes in the most public and disgraceful way; every noise she heard was that of the workmen erecting the scaffold; every carriage, the officers of justice assembling at the execution. But what affected her most deeply was, that her infamy had occasioned the disgrace and death of her children and husband, and that his spirit haunted her. As soon as the evening closed, she would station herself at a window at the back of the cottage, and fix her eyes on a white post that could be seen through the dusk; this was the ghost of her husband; day and night he was whistling in her ears. Several weeks passed in this way. The daily reports varied, but announced nothing happy. At length her husband became impatient, and begged to have an interview with her, thinking that the best way to convince her he was not dead was to show himself. This was objected to. He was told the general fact, that patients are more likely to recover when completely separated from their friends; and that if she saw him, she would say it was not himself but his ghost. But the husband was obstinate, and an interview was consented to. When he arrived at the cottage he was told that she had had a tolerable night, was rather more tranquil, but that there was no abatement of her gloomy notions. 'As soon as I entered the drawing-room, where she usually spent the day' (I copy his own statement, which I have now before me, and which he wrote down at the time of the occurrence), 'she ran into a corner, hid her face in a handkerchief, then turned round, looked me in the face, one moment appearing delighted at the thought that I was alive, but immediately afterward assuming a hideous expression of countenance, and screaming out that I was dead, and come to haunt her. This was exactly what Dr. — had anticipated, and for some minutes I thought all was lost. Finding that persuasions and argument only irritated and confirmed her in her belief, I desisted, and

tried to draw off her attention to other subjects. It was some time since she had either seen me or her children: I put her arm under mine, took her into the garden, and began to relate what had occurred to me and them since we parted. This excited her attention; she soon became interested; and I entered with the utmost minuteness and circumstantiality into the affairs of the nursery, her home, and her friends. I now felt that I was gaining ground, and when I thought I had complete possession of her mind, I ventured to ask her, in a joking manner, whether I was not very communicative for a ghost. She laughed. I immediately drew her from the subject, and again engaged her attention with her children and friends. The plan succeeded beyond my hope: I dined, spent the evening with her, and left her at night perfectly herself again.' He went the next morning in a state of intense anxiety to know whether his success had been permanent; but her appearance at the window with a cheerful countenance soon relieved his apprehensions. While he was there, Dr. — came in. He went up stairs without knowing the effect of the interview, and came down, saying, 'It looks like magic!' With the view of confirming her recovery, she was ordered to the seaside to bathe. As soon as the day of her departure was fixed she began to droop again, the evening before it she was very low, and on the morning of her setting off was as bad as ever. This state continued for several weeks, in spite of sea-air and bathing; and ceased as suddenly as it had done before, apparently in consequence of interviews with friends, calculated to remove the apprehensions by which her mind was haunted. She has since then continued perfectly well, and has had another child, without the slightest threatening of her former malady."—(*Med. Trans.*, vol. vi.)*

* On the medical treatment of mania we would remark, that whether the results of American practice be more or less favourable than those abroad, yet that neither in our public nor private institutions have those afflicted with insanity ever experienced such harsh and injurious treatment as the late parliamentary reports have brought to light. The moral treatment of the insane was adopted at the Bloomingdale Asylum about twenty years since, and was warmly advocated by the late Thos. Eddy (See his *Hints and Life*, by S. L. Knapp, New-York, 1834); and if philanthropists have relied more upon it than on medical treatment, we have cause to be gratified with the benefits they have conferred on the cause of humanity. Perhaps a more active mode of medical practice is generally pursued by American physicians in the acute forms of insanity than is recommended in the text; and this would seem to be justified by the results. The following remarks, however, deserve attention. Dr. Francis observes,

"There is another circumstance I can hardly allow to be passed over on this occasion without a remark, and which, I think, has been a concurring cause of the too hasty and too general adoption of moral management, as of itself alone the essential means of cure of maniacal subjects. The delirium of inebriety, and the more advanced forms of diseased action denominated *delirium tremens*, have inadvertently been confounded with *idiopathic mania*; and inasmuch as the right use of

This was a bold venture, and the physician must be of a temper more than ordinarily sanguine who would predict a like success upon every similar attempt. Yet we have already had occasion to observe, that puerperal insanity is more easily recovered from than most other forms of the disease.*

reason is for the most part, in those cases, restored by mere abstraction from noxious potation, which is effectually secured by confinement, moral management, without other aid, has been allowed an undue weight in the curative process of genuine mania. I am aware that permanent cerebral disorganization may arise from intemperance in drink, as dissection has repeatedly shown; but the neglect of a distinct pathognomonic difference between the ravings of inebriety or delirium tremens, and mental derangement, strictly so considered, has led to gross miscalculations in our prognosis. As alcoholic insanity is engendered in every country where drunkenness prevails, it is perhaps more frequently seen in our *mixed* population than in that of Europe. Hence we have sometimes been led to pronounce hastily and erroneously that our success in the management of lunacy is greater than that of other nations. We, however, must be supplied with more extensive and more accurate tabular views of the comparative results of practice in different institutions abroad and at home, before we can come to a satisfactory conclusion on this contested head. It is cheering to the feelings of the philanthropist to know, that by remedial measures, much more is accomplished at the present day than was at a former time imagined practicable."—D.

* In the foregoing talented observations, Dr. Good has omitted to notice a subject which has been most eloquently treated of by Dr. Conolly, namely, the many circumstances which, in places for the reception of lunatics, retard or prevent the patient's return to the full enjoyment of reason. In particular, Dr. Conolly adverts to the neglect of making a proper classification of the inmates of such establishments. "There is," says he, "sometimes a mere separation of the rich from the poor; or of the noisy from the quiet; or of the paralytic and idiots, or, at the best, of convalescents from the rest. Even this case is not common. Not only so long as it is neglected, but so long as one lunatic associates with another lunatic, supposing the cases to be curable, so long must the chances of restoration to sanity be very materially diminished. Convalescents should not even associate with convalescents, except under the strict watching of persons of sound mind: they can hardly assist, and they may retard, recovery of one another."—(Inquiry concerning the Indications of Insanity, p. 28.) Dr. Conolly also points out a class of patients for whom a lunatic asylum is a most improper place, viz., those who become affected with various degrees of weakness of intellect. In such persons there is little or no extravagance, still less is there any thing in their condition to render their liberty dangerous. As this infirmity of mind is diversified by intervals of amendment, it is clear that confining such individuals with lunatics is the most likely thing both to afflict them and to shut out every hope of restoration to mental strength. The maxim which Dr. Conolly everywhere inculcates is, that restraint, with reference both to the person and to the management of affairs, can never be justified, except by probable danger to the person of the patient or to others, or to his property or the property of others.—(P. 430.)

GENUS II.

EMPATHEMA.

UNGOVERNABLE PASSION.

THE JUDGMENT PERVERTED OR OVERPOWVERED BY THE FORCE OF SOME PREDOMINANT PASSION; THE FEATURES OF THE COUNTENANCE CHANGED FROM THEIR COMMON CHARACTER.

THE term EMPATHEMA is derived from the Greek *πάθημα*, "passio," "affection," whence *ἐμπαθής*, "cui insunt affectus seu perturbationes; affectu percitus vel commotus."

We have already had occasion to observe, that the various faculties of the mind are just as liable to be separately diseased as those of the body: for, as the faculty of digestion may be impaired, while that of respiration or secretion remains in perfect health; so may the perception or the judgment be injured, while the memory or the imagination continues in its former activity. It is the same with the pathetic faculties. These, I have stated, are to the mental part of the human frame, what feelings, properly so called, are to the corporeal: and hence both may be excited pleasurable or painfully; they may be in morbid excess or in morbid diminution; and their influence may equally vary, according to the peculiarity of the passion or the sense affected. Each will therefore furnish a distinct division of diseases: the first constitutes the genus before us; the second will be found in the ensuing order.

The present genus, however, has never hitherto been properly arranged or digested. Pinel is constantly describing the species that belong to it in his general remarks and illustrative cases, but allots no place to it in his nosological arrangement, with the exception of the third species; which, as I have already observed, he has irregularly ranked as a subdivision of mania, under the name of *manie sans délire*; although he admits that the judgment and perception, and, indeed, all the reasoning faculties

"If an insane man believes that he has communication with angels, or is an emperor, or a general, his happiness may be very harmless; he may require no restraint. But, in the angelic revelations made to him, he may be ordered to kill his children; or, in his capacity of emperor or general, he may put his supposed subjects or soldiers to death. The disposition to do this may arise suddenly, and nothing but watching and superintendence can lead to a discovery of it. Yet, to restrain this poor man at all times from walking about the fields, or partaking of any of the common enjoyments of society of which he is capable, because such a thing may happen, is not to be justified. Unless he is known to be mischievous, it is unnecessary and cruel. A man must not be made a prisoner for life because he chooses to wear a coat the wrong side outwards, or a pointed hat. It may be more necessary to protect him from others, than others from him; and therefore an asylum to him may be what its name imports,—a sanctuary and a refuge; but unless he is disposed to injure others or himself, he must not be subjected to severe restraint. If he has property, and can take care of it, no one ought to touch that property on account of his peculiar dress."—Op. cit., p. 430.—ED.

of the mind, are in most cases undisturbed. In like manner, Sauvages has incorrectly merged the whole family into a single species under the genus mania, to the utter confusion of both.

It is not a little singular that Dr. Crichton, who has written so excellently on the diseases of the passions, and has illustrated his observations with such a variety of examples, should, both in his "Inquiry into the Nature of Mental Derangement," and in his "Synoptical Table," either have assigned no place to these diseases, or have transferred them, like Sauvages, to insanity, under his nomenclature, *delirium*; although, as I have just remarked, the perception and the judgment (a diseased condition of which is usually appealed to as constituting pathognomonic symptoms of insanity) are, for the most part, strikingly clear in empathema, and often peculiarly acute. This last faculty, indeed, is frequently *perverted* by the prevailing emotion or passion of the hour; as where a man, under the influence of despair, reasons himself into the lawfulness and expediency of suicide; but the argument, though deflected, runs still in a right line; or, in other words, consists of correct reasoning built on a perception of false ideas as its premises, of which we have had various examples in the philosophical suicides of Germany. In the greater number of cases, however, the judgment, instead of being perverted, is merely overpowered by the impassioned emotion; there is neither false judgment nor false perception.

Ungovernable passion, or empathema, nevertheless, though not strictly insanity, is as much a mental derangement as insanity itself.

"Ira furor brevis est,"

is as clear a truth as is to be found in the whole learning of the Roman empire; and hence the elegant and fanciful mind of the Greeks added the term mania to that expressive of any passion or emotion whatever, when in a state of violence or misrule, as doxomania, erotomania, chrysomania; and, in this sense, mania is often used in the colloquial language of our own day. For poetry or vernacular speech, mania, thus employed, is intelligible enough; but it is not sufficiently correct for medical or physiological purposes, under which predominant passion must necessarily be distinguished from delirium.

The genus EMPATHEMA has three species: the first characterized by the rousing power of the prevailing passion; the second, by its depressing power; the third, by symptoms different from both, and which will be explained in its order.

- | | |

| 1. Empathema Entonicum. | Impassioned Excitement. |
| 2. ——— Atonicum. | Impassioned depression. |
| 3. ——— Inane. | Hairbrained passion. |

SPECIES I.

EMPATHEMA ENTONICUM.

IMPASSIONED EXCITEMENT.

THE PREDOMINANT PASSION ACCOMPANIED WITH
VOL. II.—N

INCREASED EXCITEMENT, ARDOUR, AND ACTIVITY; EYE QUICK AND DARING; COUNTENANCE FLUSHED AND TUMID.

THE varieties are innumerable: the chief are as follow:—

α Lætitia.	Ungovernable joy.
β Philautia.	Self-love. Self-conceit.
γ Superbia.	Pride.
δ Gloria famis.	Ambition.
ε Iracundia.	Anger.
ζ Zelotypia.	Jealousy.

All these, and, indeed, all other passions whatever, are as much direct and indirect stimulants to the mind, as provocative foods or drinks are to the body. Employed occasionally, and in moderation, both may be of use to us, and are given to us by nature for this purpose: but when urged to excess, they throw the system off its healthy balance, rouse it by excitement, or depress it by exhaustion; and weaken the sensorial vessels by the wear and tear they produce.

As those we are now contemplating are attended with increased action, they have some few symptoms in common, how widely soever they may differ in others; of which the chief are, an augmented temperature and an accelerated pulse. If carried to such a degree that the judgment loses its power, or, in other words, the man has no longer any command over himself, they betray themselves by their effect on particular features and particular organs, according as the emotion is of a painful or a pleasurable character, or as the pain or the pleasure predominates in those cases which partake of both.

There are some organs, however, that seem to be equally affected under a vehement excitement of whatever may be the prevailing passion, as the brain, the heart, and the lungs; for headache and apoplexy, palpitation and anhelation, are alike common to sudden fits of extreme joy, terror, and rage. The thoracic effects are, indeed, the most striking; and hence it is that the præcordia has been more generally supposed in all ages and countries to be the seat of mental emotion than the encephalon; and the state of the heart as light and jumping for joy, oppressed and breaking with grief, or black and bilious with hatred, has been more commonly appealed to than that of the animal spirits; though the latter is the cause, and the former the mere effect.

It may be thought, perhaps, that the vulgar character of the heart, as indicative of hatred or revenge, is merely figurative, and has no foundation in nature. But this is not the case: for anger, when long indulged, is well known to affect the functions of the liver, and has often laid a foundation for jaundice, and consequently for a deeper colour as well as other properties of the blood that circulates through the heart; a fact so well known, that the seat of anger has, in the poetical language of most countries, been transferred to this organ, and bilious or choleric and irascible are convertible terms in the popular language of our own day.

We have endeavoured to account for the difference of effect produced by the sensorial fluid in the different organs of local sensation, by supposing some degree of change to take place in the nature of this fluid by the action of the respective sentient nerves at their origin or extremity.* It is possible that other changes may take place in the sensorium, from the influence of peculiar mental impressions, and that certain classes or ramifications of nerves may be more affected by particular impressions than others. And we may hence account, not only for the sympathy of the liver with the sensorium when urged by anger, but for that of other organs, under other impassioned excitements; and this not merely whether pleasurable or painful, but according to the peculiarity of the pleasure or the pain which forms the source of incitation. Thus, while anger stimulates the liver, fear has a tendency to produce a diarrhoea and incontinence of urine; grief disorders the stomach, and affects the lachrymal glands; sudden fright divests the muscles of locomotion, and produces palsy; while mirth throws them into involuntary action, and compels a man to leap, laugh, and sing.

This, however, is to digress; for our present business is to contemplate the mental, rather than the corporeal, effects of the passions, when urged to excess, or intemperately protracted.

The instances of derangement produced by a sudden FIT OR IMMODERATE FLOW OF JOY are numerous, and not difficult to account for. As this impassioned emotion, when indulged with a rampant domination over the judgment, is a direct stimulus of a very powerful kind, acting not only on the nerves but on every part of the body, it cannot take place without producing great sensorial exhaustion, and consequently cannot be persevered in without remissions of languor and lassitude, like the effects of intoxication from strong wine or spirits. The misfortune is, that when the elevating faculties of the mind, and especially the imagination, are once let loose by the operation of this passion, and both run wild together, the mental excitement will sometimes continue after the strength of the body is completely prostrated. And when this strength is sufficiently recruited for the external senses to convey once more to the perception true and lively impressions of the objects that surround them, the perception, which has been also morbidly affected by the violence of impassioned paroxysms, will not receive or convey them in a true state, and a permanent derangement is the consequence. Cardan (*De Sapientiâ*, lib. ii.) gives the case of an artisan of Milan, who, having had the good luck to find an

instrument that formerly belonged to Archimedes, ran mad with a fit of transport into which he was hereby thrown: and Plutarch, in his life of Artaxerxes, has a like story of a soldier, who, having had the high honour of wounding Cyrus in battle, became so overjoyed that he lost his wits from the moment. Boerhaave (*De Morb. Nerv.*, lib. ix., cap. 12) and Van Swieten (*Comment.*, tom. iii., p. 144) relate cases of epilepsy that followed from the same cause.

Occasionally, the exhaustion of sensorial power hereby produced is so sudden and total, that the whole nervous system seems instantaneously to become discharged of its contents, like a Leyden vial loaded with electricity when touched with a brass rod, and death takes place at the moment. There are various instances on record, in which a like fate has followed upon the injudicious production of a pardon to a culprit just on the point of his being turned off at the gallows. Valerius Maximus relates two anecdotes of matrons, who in like manner died of joy on seeing their sons return safe from the battle at the lake Thrasis; the one died while embracing her son; the other had been misinformed, and was at that moment lamenting his death. The power of surprise was added, therefore, in this case, to that of joy, and she fell even before her arms could clasp him.—(Lib. ix., cap. 12.) Marcellus Donatus, Pechlin, and other collectors of medical curiosities, are full of incidents of this kind: and a case not very unlike occurred a few years since to the present author, in the person of an intimate friend and most exemplary clergyman. This gentleman, who had consented to be nominated one of the executors in the will of an elderly person of considerable property with whom he was acquainted, received, a few years afterward, and at a time when his own income was but limited, the unexpected news that the testator was dead, and had left him sole executor, together with the whole of his property, amounting to three thousand pounds a year in landed estates. He arrived in London in great agitation; and on entering his own door dropped down in a fit of apoplexy, from which he never entirely recovered; for though he regained his mental, and most of his corporeal faculties, his mind was shaken and rendered timid, and a hemiplegia had so weakened his right side that he was incapable of walking farther than a few steps.

Could this passion be employed as a medicine, and administered with a due regard to time and measure, from its powerful influence on the whole system, there can be no doubt that it might be made productive of the most beneficial effects. And there is hence no reason for hesitation in admitting many of the wonderful cures which are reported to have been occasionally operated by its sudden incursion. Corineus gives the case of a tertian ague thus removed; Lory that of a stricture of the pylorus with incessant vomiting (*De Melancholiâ*, tom. i., p. 37); and Trellian, what we should less have expected, a radical cure of melancholy.—(Lib. xli., p. 17.)

In the SECOND VARIETY we have noticed the

* This and other hypotheses, founded on the presumed existence of a sensorial fluid, may satisfy readers disposed to be content or pleased with conjecture; but until the reality of such fluid be proved, they can only be regarded as sports of the imagination. It is fortunate, however, that the occasional reference made to them in the text does not impair the generally valuable character of the author's matter.—Ed.

predominance of SELF-CONCEIT. The ordinary feeling here is still of a pleasurable kind, but never amounts to the paroxysms of the preceding; its effects, therefore, on the soundness of the mind are more gradual, but in many instances quite as marked. It is a vain and preposterous estimation of one's personal powers or endowments, accompanied with so immoderate a love of one's own self on this very account, as to make the possessor blind to every instance of superiority in another person, and hence to save him in a considerable degree from the pain he would otherwise endure; for the self-conceited man is not easily mortified or humiliated, and hence not easily cured of the malady. "A wise man," says Mr. Mason in his *Treatise on Self-Knowledge*, "has his foible as well as a fool: but the difference between them is, that the foibles of the one are known to himself, and concealed from the world; the foibles of the other are known to the world, and concealed from himself. The wise man sees those frailties in himself which others cannot: but the fool is blind to those blemishes in his character which are conspicuous to every one else."—(Part i., chap. vii.) It was under the influence of this disease that Menecrates, as we learn from *Ælian*, became so mad as seriously to believe himself the son of Jupiter, and to request of Philip of Macedon that he might be treated as a god. But it is not always that the man thus deranged falls into such good hands as those of the Macedonian monarch; for Philip, humorously determining to make the madman's disease work its own cure, gave orders immediately that his request should be complied with, and invited him to a grand entertainment, at which was a separate table for the new divinity, served with the most costly perfumes and incense, but with nothing else. Menecrates was at first highly delighted, and received the worship that was paid to him with the greatest complacency; but growing hungry by degrees over the empty viands that were offered him, while every other guest was indulged with substantial dainties, he at length keenly felt himself to be a man, and stole away from the court in his right senses.—(Lib. xii., cap. 51.)

The passion of PRIDE has a close affinity to that of self-conceit: but is less confined to self-endowments, and is a relative as the former is a personal vanity. The proud man may indeed have the same preposterous estimation for some supposed gift of person, but the grasp of the passion does not terminate here; for he carries the same estimation to every thing that in the remotest degree appertains to him, and is hence as vain of his birth, or family connexions, his wealth, his estates, his country, his office, his honour, or his religion; and he is hence open to more numerous mortifications, and is in fact more frequently mortified, than the mere egotist. Examples of a deranged mind from ungovernable pride are to be found in every rank of life; but as those in the loftiest have the cup of intoxication most frequently offered to them, and drink deepest of its contents, it is here, among kings, and courtiers, and prime ministers, and

commanders, that we are to look for the most striking instances of this malady. Many a crown won by good fortune, and which might have been preserved by moderation, has been lost by the delirium of pride and vain-glory; of which the history of Demetrius of Macedonia furnishes us with one of the most memorable examples: who, in his disgraceful fall, was obliged to abandon, among the other idols of his heart, the unfinished robe which was to have hung over his shoulders, containing a magnificent embroidery of the sun, the moon, and all the stars of heaven, designed to have represented him as the sovereign lord of the whole.

There is, however, another kind of madmen, to adopt the words of Burton (*Anat. of Melanch.*, part i., sect. ii., vol. i., p. 189), opposite to these, "that are insensibly mad, and know nothing of it; such as affect to condemn all praise and glory, and think themselves most free when they are most mad: a company of cynics, such as monks, hermits, and anchorites, that condemn the world, condemn themselves, condemn all titles, honours, offices, and yet, in that contempt, are more proud than any man living. They are proud in humility, proud in that they are not proud. They go in sheep's russet, many great men that might maintain themselves in cloth of gold, and seem to be dejected; humble by the outward carriage, when as inwardly they are swollen full of pride, arrogance, and self-conceit. And therefore Seneca adviseth his friend Lucilius, in his attire and gesture, his outward actions especially, to avoid all such things as are most notable in themselves; as a ragged attire, hirsute head, horrid beard, contempt of money, coarse lodging, and whatever leads to fame that opposite way."—(*Epist. v.*)

When the passion of pride is united with that of ardent desire after something beyond us and above us, it constitutes the next feeling of AMBITION: and hence this also is an inflating emotion, a tympany of the mind, and may be called *prospective* vanity, as pride is *relative* vanity, and self-conceit *personal*. It is the more dangerous to the understanding, in consequence of the double force with which it overpowers the judgment; and hence the slave of inordinate ambition is far more restless, and in a far higher degree of excitement, than the slave of either of the other two kinds of vanity; and as, being dependant upon a greater number of contingencies, he is most of all open to reverses and downfalls.

Examples are not necessary, and would be a waste of time. Whenever the stimulant ideas or thoughts that are connected with any one of this train of passions pass over the mind, the blood, as is justly observed by Sir A. Crichton, rushes with impetuosity to the head, the sentient principle is formed in preternatural quantity, and the excitement is at last so often renewed, and increases to such a degree, as to occasion an impetuous and permanent delirium. But when the expectations and high desires which pride or vanity naturally suggests are blasted; when these passions are assailed by poverty, neglect, contempt, and hatred, and are unequal to the contest,

they now and then terminate in despondency, or settled melancholy.—(*Of Mental Derangement*, book iii., ch. ii.)

But if such be a frequent effect of the stirring passions of a pleasurable kind, it is not difficult to conceive that those accompanied with pain, as the passion of *ANGER*, and all its compounds, suspicion, revenge, and especially jealousy, must make a much wider inroad upon the domain of a well-ordered mind, and introduce confusion and derangement. Nor is the effect confined to the head; for a stimulus thus violent affects the entire system, and, as we have already observed, has a peculiar sympathetic influence on the liver; producing in many instances a diseased secretion of bile, and altering it in a very short period, not only in its quantity but in its quality. At the same time, every vessel is exhausted of its irritability, and the whole strength is so prostrated as occasionally to lead on to obstinate faintings, convulsions, and death. The expressions and gestures are always violent and offensive, and are similar to those of maniacal rage; the eyes are red and inflamed, the countenance is flushed, swollen, and distorted, and the person is ungovernable. Such was the case, in 1392, with Charles VI. of France; who, being violently incensed against the Duke of Bretagne, and burning with a spirit of malice and revenge, could neither eat, drink, nor sleep for many days together, and at length became furiously mad as he was riding on horseback, drawing his sword, and striking promiscuously every one who approached him. The disease fixed upon his intellect, and accompanied him to his death.

In *JEALOUSY*, as in ambition, there is a combination of irritating passions, and the combination is still more complicated; for it is a compound of suspicion, hatred, eager desire of revenge, occasionally intermixed with love. To hot climates it appears to be endemic; and there is not, perhaps, an eastern dynasty that does not offer numerous examples of its sanguinary phrensy and diabolical career.

It is not often, however, that any of the varieties of this species terminate in permanent insanity, although the case of Charles VI. of France forms an exception to the general rule. As moral treatment appears to be of more benefit in the preceding genus than medical, it is almost the only treatment that can be recommended in ungovernable passion; though the violence of the excitement should unquestionably be reduced by venesection and purgatives. After this, time and perfect quiet must be chiefly depended upon: yet judicious conversation, and more especially a judicious choice of subjects, may accomplish much. A deaf ear is generally turned to the precepts of the moralist; but if attention can be obtained for them, Epictetus and Mason's *Self-Knowledge*, Pascal's *Thoughts*, and Lord Bacon's *Essays*, will furnish valuable remedies; and so also, and of a much more powerful operation, will the still better penned ethics of a book, which, in every Christian country, should be uppermost in the mind without any suggestion. Moral castigation, however, if not too

sudden or severe, is that which generally works most effectually; and few madmen of this kind have been able to meet a serious reverse of fortune, or condition of life, without being the better for it, if not destroyed by its first shock. Self-conceit, which is a mere product of self-ignorance, is best removed by an acquaintance with the world, and especially with men of real talents and genius, in which sphere the man who labours under it will soonest learn his own emptiness, and the means of remedying this defect. And hence the advantage of a public education over a private one; in which talents are brought into a fair competition with talents, and every one learns to appreciate his powers, not by the standard of his own vanity, but by the stamp of merit that has passed the mint.

SPECIES II.

EMPATHEMA ATONICUM.

IMPASSIONED DEPRESSION.

THE PREDOMINANT PASSION ACCOMPANIED WITH DIMINISHED EXCITEMENT, ANXIETY, AND LOVE OF SOLITUDE: EYE FIXED AND PENSIVE; COUNTENANCE PALE AND FURROWED.

THE mental emotions productive of these effects, are at least as numerous as those which harass the frame by increased excitement. The following may serve as examples:—

α Desiderii.	Ungovernable Love.
β Auri famis.	Avarice.
γ Anxietudinis.	Anxiety.
δ Mœroris.	Heartache.
ε Desperationis.	Despondency.

As increased sensorial excitement produces various symptoms in common, whatever be the nature of the governing passion at the time, there are also various symptoms common to decreased sensorial excitement under each of these depressing passions: as a greater or less degree of torpor in every irritable part, especially in the circulating and absorbent systems; whence paleness of the countenance, coldness of the extremities, a contraction and shrinking of the skin and general surface of the body, a retardation and smallness of the pulse, want of appetite, deficiency of muscular force, and a sense of languor which overspreads the whole frame.

The ardent desire which is distinguished by the name of *LONGING*, is directed towards objects of various kinds that are absent, and equally relate to places and persons. It is a painful and exhausting emotion, as compounded of hope, love, and fear, and peculiarly agitates the præcordia; and hence the striking and beautiful apothegm of the wise man,—“Hope deferred maketh the heart sick.” It is felt by children at a distance from home, and who are eager to return to the embraces of their parents; by foreigners who have a strong and inextinguishable love for their country, and are anxious to return to the scenes and the companions of former times; and by the youthful pair who have vowed an eternal attachment, and are sure that they cannot live without each other, but whose union is opposed by bars that are felt to be insurmountable. And hence the present va-

riety includes the three modifications of HOME-SICKNESS, COUNTRY-SICKNESS, and LOVE-SICKNESS. The first is for the most part transitory; the second, the *heimweh* of the Germans, has sometimes, and especially among the Swiss, when their manners were simpler, and their domestic virtues and feelings much stronger, than they seem to have been of late years, produced not only a permanent melancholy but hectic fever. Yet it is to the third that our attention is chiefly called on the present occasion, from the greater frequency of its occurrence, and the more severe and tragic effects to which it has led, where obstacles have arisen in its progress.

We have, on the present occasion, nothing whatever to do with the gross passion of concupiscence, which is as different from that of pure and genuine love as light from darkness. The man of lust has indeed his love, but it is a love that centres in himself, and seeks alone his own gratification; while the passion we are now speaking of puts self completely out of the field, and would voluntarily submit to every pain, and sacrifice even life itself, in promoting the happiness of the beloved object. Yet, constituted as we are by nature for the wisest and best of purposes, a pure corporeal orgasm still interweaves itself with the sentimental desire, though subordinate to it in virtuous minds, and the flame is fed from a double source. "Nuptial love," says Lord Bacon, "maketh mankind; friendly love perfecteth it; but wanton love corrupteth and embaseth it."—(*Essays*, No. x.)

What it is that first lights up this flame is of no importance to the present subject. A peculiar cast of form or of features, acknowledged by all to be moulded according to the finest laws of symmetry, and productive of a high degree of external grace or beauty; or a figure, or a manner, that to the eye of the enamoured beholder gives token of a mind adorned with all he can wish for; or an actual knowledge, from long acquaintance, of the existence of such internal cultivation and excellence, may be equally causes of the same common effect. And hence this is of little or no account; for the passion being once excited, the judgment runs a risk of being overpowered by its warmth and violence; and the moment it is overpowered, the new train of ideas that are let loose upon the mind are of a romantic character; and as soon as any obstacle starts up as a barrier in the vista of hope, instead of being damped or repressed, they grow wilder and more vivid, till at length the sensorial system is worn out by the vehemence of its labour; and though the excitement is really less than at first, because there is less vascular vigour for its support, it is still greater than ever, compared with the weakened state of the sentient organ.

Yet love-sickness itself, whatever mischief it may work in the corporeal frame by sleepless nights, a feverish pulse, and loss of appetite,* and however, from the exalted state of the ima-

gination and the increased sensibility of the body, it may transpose the reality of life into a kind of visionary existence, and so far produce mental derangement, rarely leads to direct insanity, so long as there is the remotest hope of the attainment of its object. But if hope be suddenly cut off by an inexorable refusal, the intervention of a more fortunate rival, the concealment of the object of adoration, or any other cause whatever, the mind is sometimes incapable of resisting the shock thus produced by the concurrent yet opposite powers of desire and despair; and in a moment in which the judgment is completely overwhelmed, the love-sick maniac calls to his aid the demoniacal passion of revenge, and, almost at hazard, determines upon a plan of murder directed against his rival, his mistress, or himself. The story of Mr. Hackman and Miss Rae will at once, perhaps, occur to the recollection of most of the author's reader's in proof of this assertion. He himself had some acquaintance with the former; and is convinced, from what he knew of him, that nothing but a paroxysm of insanity could have urged him to so horrible an act.

The operation of the passion of AVARICE, when it has once obtained an ascendancy over the mind, is altogether of a different nature from that of the preceding variety, though it often produces a wider and more chronic alienation. It has not a stirring property of any kind belonging to it, but benumbs and chills every energy of the body as well as of the soul, like the stream of Lethe: even the imagination is rendered cold and stagnant, and the only passions with which it forms a confederacy, are the miserable train of gloomy fear, suspicion, and anxiety. The body grows thin in the midst of wealth, the limbs totter though surrounded by cordials, and the man voluntarily starves himself in the granary of plenty, not from a want of appetite, but from a dread of giving way to it. The individual who is in such a state of mind must be estranged upon this point, how much soever he may be at home upon others. Yet these are cases that are daily occurring, and have been in all ages: though perhaps one of the most curious is that related by Valerius Maximus of a miser who took advantage of a famine to sell a mouse for two hundred pence, and then famished himself with the money in his pocket.—(*Lib. vii., cap. vi.*) And hence the madness of the covetous man has been a subject of sarcasm and ridicule by moralists and dramatic writers in every period, of which we have sufficient examples in the writings of Aristophanes, Lucian, and Molière.

There is another mental feeling of a very afflictive, and too often, like the last, of a chronic kind, which is frequently found to usurp a dominion over the judgment, and to imbitter life with false and visionary ideas, and that is, a habit of ANXIETY, or PREYING CARE; which not only drives the individual who possesses it mad, but runs the risk of doing the same to all who are about him, and are harassed with his complaints and discontents. This is sometimes the effect of a long succession of misfortunes or vexatious troubles; but seems in some persons

* Schurig. *Gynealog.*, p. 94. Horstius, *An Pulsus aliquis amatorius concedendus?* Bilizer, *De Naturâ Amoris*, Giess. 1611, 4to.

to depend on a very high degree of nervous sensibility, united with a choleric or melancholic temperament.* Their age, wealth, or situation in life is of no importance; and though their digestive powers are good, and they are not hypochondriacs, they are always apprehensive and full of alarm, and flee from every appearance of joy as they would from an apparition, or even sooner. In the language of Burton, who knew too well how to describe them, "the old are full of aches in their bones, croups, and convulsions; dull of hearing, weak-sighted, hoary, wrinkled, harsh, so much so that they cannot know their own selves in a glass; a burden to themselves and others. If they be sound, they fear diseases; if sick, weary of their lives. One complains of want, a second of servitude, another of a secret or incurable disease, of some deformity of body, of some loss, danger, death of friends, shipwreck, persecution, imprisonment, disgrace, repulse, contumely, calumny, abuse, injury, contempt, ingratitude, unkindness, scoffs, scouts, unfortunate marriage, single life, too many children, no children, false servants, unhappy children, barrenness, banishment, oppression, frustrated hopes, ill success;

"Caetera de genere hoc, adeo sunt multa, loquacem,

Delassare valent Fabium."

"In the meantime," continues the younger Democritus, "thus much I may say of them, that generally they crucify the soul of man, attenuate our bodies, dry them, wither them, rivel them up like old apples, and make them as so many anatomies."—(*Anat. of Melancholy*, part i., sect. ii., subs. x.)

Nothing can be more different than this constitutional pining, and the pains produced by HEARTACHE, or the reality of severe grief. The former is talkative and querulous; the latter is dumb, and flies from company. The sensorial exhaustion is so considerable, that the mind, with its attention upon the full stretch, has scarcely strength enough to collect the train of ideas on which alone it resolves to dwell; and hence all conversation is irksome, the presence of a friend disquieting, and the deepest solitude is anxiously sought for. And not unfrequently the discharge of nervous power is so considerable and sudden as to produce a general torpor of the brain; which, if it do not happily terminate in quiet sleep, is the inlet of apoplexy. Even in the former case, the inirritability of the nervous fibres continues to such an excess, that the sufferer has no natural evacuation for perhaps several days, feels no hunger, cannot be persuaded to take food, is incapable of sighing, and sheds no tears. And hence the appearance of tears and sighing are good omens, and are correctly regarded as such; since they show that the

general torpitude is giving way in the organs that most associate with this painful emotion of the mind, to a slight return to irritability. As soon as the flow of the sensorial principle is a little increased, the præcordia struggles with great anxiety, and the heart is overloaded and feels ready to break or burst, whence the name of HEARTACHE, so appropriately applied to this variety of suffering. Sometimes, also, hysteric flatulence oppresses the respiration, and convulsions, and not unfrequently death itself, ensue. Of this last effect Erndt has given numerous instances.—(*Relatio de Morbis anno 1720 Waraviae curatis*, Dresd., 1730.) But if recovery should take place, it is usually long before the judgment re-assumes its proper sway in the mind, and the temporary derangement altogether ceases. At times, indeed, this never returns, and the pitiable sufferer only lives through the shock to endure the severer evil of confirmed insanity; of which Shakspeare has given us an admirable copy in the character of King Lear, finely imagined to be a result of filial ingratitude.

DESPAIR makes a near approach to heartache in the overwhelming agony it produces, and its pressing desire of gloom and solitude; but, generally speaking, the feeling is more selfish, and the mind more hurried and daring. Despair, as it commonly shows itself, is utter hopelessness from mortified pride, blasted expectations, or a sense of personal ruin: heartache is either hopelessness from a sense of some social bereavement, or relative ruin. The gamester, who cares for no one but himself, may rage with all the horror of despair; but the heartache belongs chiefly to the man of a warmer and more generous bosom, stung to the quick by a wound he least expected, or borne down, not by the loss of fortune, but of a dear friend or relative, in whom he had concentrated all his hopes. The well-known picture of Beverley is drawn by the hand of a master, and he is represented as maddened by the thought of the deep distress into which his last hazard has plunged his wife and family; but if his selfish love of gaming had not triumphed over his relative love for those he had thus ruined, he would not have been involved in any such reverse. While Beverley was in despair, it was his wife who was broken-hearted.

The sources of this most agonizing emotion are innumerable; and from the total shipwreck of all hope on which it is founded, there is no passion of the mind that drives a man so readily to an act of suicide. To live is horror: the infuriated sufferer feels himself an outcast from God and man; and though his judgment may still be correct upon other subjects, it is completely overpowered upon that of his actual distress; and all he thinks of and aims at is to withdraw with as much speed as possible from the present state of torture, totally regardless of the future, or falsely satisfying himself by a perversion of his judgment that there is no crime in his doing so.

One of the severest causes of despondency is a conscience labouring under a deep sense of guilt for some

"—undivulged crime
Unwhipt of justice;"

* One position maintained by one of the latest writers on mental derangement is, that mere nervousness and insanity are absolutely identical; or, in other terms, that nervous derangements differ "in measure more than in kind."—Dr. Uwins on the Disorders of the Brain and Nervous System, pp. 5, 24, &c., 8vo., Lond., 1833.—Ed.

and so severe has the anguish been in many cases, that the tormented wretch, thus haunted by himself, and hating the light of heaven, has been compelled, as the less evil of the two, to surrender himself to the laws of his country, and court the disgrace of a public execution. Yet the same miserable feeling has sometimes followed from an ideal cause, especially in a mind of natural timidity, or constitutionally predisposed to a gloomy view of nature: for such, by a mere exercise of their own meditations, but far oftener by the coarse but impassioned oratory of itinerant preachers, are induced to believe that the Almighty has shut them out for ever from the pale of mercy, and that the bottomless pit is yawning to receive them; and under the influence of such an impression, they too frequently work themselves up into a state of permanent insanity, or hurry themselves by their own hands into the horrors of a fate from which they feel assured that no repentance nor power of religion can save them.

In the midst of great public calamities, the passion of ungovernable despondency is apt to become epidemic, and particularly, as M. Falret has well observed, where the constitution of the atmosphere, from being moist and hot, and consequently relaxing and debilitating, favours its spread. In 1806 the feeling of desperation was so common at Paris, that sixty suicides occurred during the months of June and July; at Copenhagen, in the course of the same entire year, three hundred; and in 1793 about thirteen hundred at Versailles alone.—(*Falret, de l'Hypochondrie et du Suicide*, 8vo., Paris, 1822.) The sensation, however, whether general or individual, is most acute where there is little corporeal exertion, and consequently where there is time to cultivate and brood over it. Hence suicide is frequent in the distress of sieges, in the first alarm of civil commotions, or when they have subsided into a state of calmness, and the mischiefs they have induced are well pondered; but it seldom takes place in the activity of a campaign, whatever may be the fatigue, the privations, or the sufferings endured. On the fall of the Roman empire, and throughout the revolution of France, self-destruction was so common at home as at last to excite but little attention; it does not appear, however, to have stained the retreat of the Ten Thousand under Xenophon, and, according to M. Falret, was rare in the French army during its flight from Moscow.*

In all these varieties of empathema, the art of the physician can do but little; and, in many of them, nothing whatever. Yet, where the heart suffers acutely, and the mind is deeply dejected, sedatives and antispasmodic cordials may occasionally be found useful; and, as the

abdominal viscera are greatly liable to be affected, the appetite to fail, the liver to be congested, and the bowels rendered costive, these organs must be watched, and such relief be afforded as they may stand in need of. Where aperients are required, the warm and bitter resins will generally answer the purpose best, alone or combined with rhubarb. Where love is the cause of disease, and the fair patient is young and delicate, suppressed menstruation or even chlorosis is by no means unfrequent, followed by hysteria and other nervous affections that produce considerable trouble.

In all cases of mental dejection, however, a kind and judicious friend is by far the best physician. Medicines may do a little, change of scene and country, of custom and manners, a little also; but the soothing of tenderness and indulgence, and the voice of that friendship which knows how to discriminate opportunities, and seasonably to alternate admonition with consolation, will accomplish more in the way of cure than all the rest put together. The despondency produced by the real sense of a guilty conscience, or the visionary belief of eternal reprobation, may derive important and most salutary advantage from religious instruction, when conducted with a judicious attention to the exigency of the case. But much circumspection and adroitness are requisite upon this point; for, so rooted is the feeling to be extirpated, that no ordinary means will suffice for its eradication; while, if it be forcibly snapped off, it will shoot out the wider, and grow ranker than ever.

The excitement of an opposite passion or train of feelings has sometimes been accompanied with success; for there are instances in which the slave of imaginary pain and misery has for ever forgotten his sense of visionary grievances under the stroke of poignant and real affliction; and the miser, when reduced by a sudden reverse of fortune to actual beggary, and thus completely disencumbered of the load that has hitherto so much oppressed him, has returned to his sober senses, and learned a juster estimate of worldly possessions.

The same attempt has often been recommended in disappointments under the passion of love; and, according to the concurrent report of the poets of ancient and modern times, many of whom profess to be well versed in this kind of discipline, it has very generally been attended with success. Where the emotion has more of a corporeal than a sentimental origin, this may easily be conceived; and it is possible that it may also sometimes have occurred under a purer feeling; though, for the honour of the human heart, I do not think this is much to be trusted to. Where the choice between two young persons of fair character is really imprudent, yet the affections are so riveted as to bid defiance to all forcible attempts to unfetter them, a promise of consent on the part of the reluctant parent at the distance of a given period of time, as a year and a half, or two years, with an undertaking on the part of the lovers neither to see nor correspond with each other in the meantime, an engagement easily fallen into, has

* Spurzheim remarks (*Obs. on Insanity*, p. 186, London, 1817), that "there are countries and districts where suicide is endemical. In Germany, about Hamburg, Potsdam, Halle, Jena, it is much more common than in Austria; and at certain periods it is more frequent than at others; sometimes it is epidemic, so that in a short time there are a great number of instances, and then much fewer during a long interval."—D.

answered in many instances to which I have been privy. The ardour has gradually cooled on the one side or the other; the judgment has been more impressed with the nature of the imprudence; or a more attractive form has interposed, and irretrievably settled the question. While, on the contrary, if the fidelity should hold on both sides to the end, and the passion be heightened instead of depressed, as in this case there is most reason to suppose it would be, hard, indeed, must be the heart that would extend the restriction further, and that would not wish joy to so deserving a couple.

SPECIES III.
EMPATHEMA INANE.
HAIRBRAINED PASSION.

WAYWARD AND UNMEANING PASSION, URGING TO INDISCRIMINATE ACTS OF VIOLENCE: AIR HURRIED AND TUMULTUOUS; COUNTENANCE FLUSHED; EYES GLARING AND PROMINENT.

This is the *manie sans délire* of M. Pinel, a case of frequent occurrence, but incorrectly named in this manner; since, in the opinion of all other nosologists, and, perhaps, all other pathological writers, the character of delirium (that is, of diseased judgment, diseased perception, or both) is essential to mania.

M. Pinel ascribes this species principally, and with great force of reason, to a neglected or ill-directed education upon a mind naturally perverse or unruly, and gives the following striking example:—An only son of a weak and indulgent mother was encouraged in the gratification of every caprice and passion, of which an untutored and violent temper was susceptible. The impetuosity of his disposition increased with his years. At school he was always embroiled in disputes and quarrels; and if a dog or a horse offended him, he instantly put it to death. This wayward youth, however, when unmoved by passions, possessed a perfectly sound judgment. When he came of age he proved himself fully competent to the management of his family estate, as well as to the discharge of his relative duties; and even distinguished himself by acts of beneficence and compassion. But his deep-rooted propensity to quarrel still haunted him; and wounds, lawsuits, and pecuniary compensations were the general consequence. At last an act of notoriety put an end to his career of violence. Enraged at a woman who had used offensive language to him, he tumbled her into a well. A public prosecution followed, and, on the testimony of a great many witnesses, who deposed as to his furious deportment, he was condemned to perpetual confinement at the lunatic asylum of Bicêtre.

On the commencement of the French revolution, when the mob broke open the doors of the prisons and the lunatic hospitals to liberate all whom they thought unjustly confined and under restraint, a patient labouring under the present species in the Bicêtre asylum pleaded his own cause so rationally and pathetically, and so artfully accused the governor of the asylum

of cruelty, that the armed rabble commanded him to be instantly liberated, and scarce suffered the governor to escape with impunity. The patient, thus restored to freedom, was led about in triumph amid reiterated shouts of "Vive la République!" The sight of so many armed men, their loud and confused noise and tumultuous conduct, soon roused the visionary hero to a fresh paroxysm of fury. He seized, with a vigorous grasp, the sabre of his next neighbour, brandished it about with great violence, and wounded his liberators indiscriminately. Fortunately, he was soon mastered, when the savage mob thought proper to lead him back to his cell, and with shame and reluctance acknowledged their own ignorance and misconduct.

The mode of treatment may be collected from the preceding pages.

GENUS III.
ALUSIA.

ILLUSION. HALLUCINATION.

THE JUDGMENT PERVERTED OR OVERPOWERED BY THE FORCE OF THE IMAGINATION; THE SPIRITS PERMANENTLY ELEVATED OR DEPRESSED; THE FEELINGS OF THE MIND DEPICTED IN THE COUNTENANCE.

ALUSIA is here derived from the Greek *ἀλυσίς*, "aberratio," from *ἀλλέω*, "errabundā mente afficior,"—"inquietus aberro:" whence the Latin term *allucinatio* or *hallucinatio*. According to the rule which renders the Greek *α* by the Latin *y*, the name of this genus ought rather perhaps to be *alysis*; but as the Latins have themselves retained the *v* in *allucinatio*, it is here suffered to continue in *alusia*, making a similar exception to that already observed in *lues*. The Greek term is preferred to the Latin, as the name of the genus, for the sake of uniformity. Sauvages, and after him Sagar, have employed *hallucinatio* as the name of an order; Darwin and Crichton as that of a genus, and, consequently, running parallel with the genus before us. Wherever the genus exists, *hypochondrias* or *hypochondriasis* is usually placed under it. It is so by Sauvages, Sagar, and Crichton: and it occupies the same place in Linnæus, who has merely adopted the term *imaginarii* instead of *hallucinationes*.

Alusia embraces the two following species:—

1. Alusia Elatio. Sentimentalism.
Mental extravagance.
2. ——— Hypochondrias. Hypochondriacism.
Low spirits.

SPECIES I.
ALUSIA ELATIO.

SENTIMENTALISM. MENTAL EXTRAVAGANCE.

ROMANTIC IDEAS OF REAL LIFE; ARDENT AND EXALTED FANCY; PLEASURABLE FEELINGS; FREQUENT PULSE; GREAT ACTIVITY; EYE KEEN AND LIGHTED UP; COUNTENANCE CONFIDENT AND ANIMATED.

The merit or demerit of this species, named

from the rhetoricians ELATIO, and with them importing "elevated, exalted, magnificent style or imagery," must, I fear, mainly rest with the author himself. It is, however, strictly derived from nature, and is intended to fill up what has hitherto been left as a vacant niche by the nosologists. Alusia or hallucination, like ephronia or insanity, comprises a list of affections that are characterized by two opposite states of nervous action, entonic and atonic, or, in the language of Dr. Cullen, excitement and collapse: elatio is intended to include the former of these, as hypochondrias, the ensuing species, is the latter. They stand in the same relation to each other as elevated and dejected madness or melancholy. Both are united with a peculiar modification of the digestive function, but possessing opposite bearings; being in the former strikingly active and energetic, and in the latter strikingly sluggish and languid. Hence, under the first species, the patient is able to endure enormous fastings, and to support life upon the scantiest and least nutritive diet, either of which would be destructive under the second.

This species embraces the following varieties:—

- | | |
|--------------|-------------------------------|
| α Heroica. | Chivalry. Romantic gallantry. |
| β Facetosa. | Crack-brained wit. |
| γ Ecstatica. | False inspiration. |
| δ Fanatica. | Fanaticism. |

The age of the first of these varieties, that of CHIVALRY OR ROMANTIC GALLANTRY, has nearly, if not altogether, departed. It may be regarded as a generous and high-spirited flight of the imagination, that gives a visionary colouring to the external world, and combines, without a due degree of discrimination, ideas of fact with those of fancy. Like many of the varieties of empathema or ungovernable passion, it may lead to or be combined with ephronia or insanity.

I have sometimes had to attend patients who, having spent the greater part of their days and nights over the most captivating novels of the present day, had acquired so much of this falsity of perception as to startle their friends around them, and to give evident proof that they were of a mind occasionally deranged, though, when the attention could once be seriously engaged, capable of being brought down to the soberness of external objects and real life. These have commonly been ladies unmarried or without a family, about the middle or a little beyond the middle of life, of a nervous temperament, fine taste and fancy, but whose education had been directed to subjects of superficial or external ornament rather than of intrinsic excellence. Their manner has been peculiarly courteous, their conversation sprightly and figurative, and their hand ready to aid the distressed. But it has been obvious that in all they were saying or doing they had some ideal character in their minds, whose supposed air, and language, and manners they were copying; and the distressed were always most sure of relief, and of a relief often beyond the necessity of the case, whose story was combined

with some perilous adventure or sentimental catastrophe.

In former times, however, when the wild and daring spirit of romance formed the subject of popular study, and

"The spinsters, and the knitters in the sun,
And the free maids that wove their threads with
Were wont to chant it," [bones,

this bewildering triumph of the imagination over the judgment was far more common, and carried to a much higher pitch. The high-toned and marvellous stories of La Morte d'Arthur, Guy of Warwick, Amadis of Gaul, The Seven Champions of Christendom, and the Mirror of Knighthood; the splendid and agitating alternations of magicians, enchanted castles, dragons, and giants, redoubtable combatants, imprisoned damsels, melting minstrelsey, tilts and tournaments, and all the magnificent imagery of the same kind that so peculiarly distinguished the reign of Elizabeth, became a very frequent source of permanent hallucination. The historian of Don Quixote adhered strictly to the tenour of his times in representing the library of this most renowned knight as filled with romances of this description, and himself as being permanently crazed by an uninterrupted perusal of them. And that the same morbid effect was not confined to Spain, and was, indeed, common to our own country, we know from the severe but just invectives of Ascham against this class of writings, and his complaints against the disordered turn they had given to the public mind; and still more from the necessity Shakespeare felt himself under in making all his maniacal characters, whether really or but pretendedly so, deeply versed in the prose or poetical romances of the day, and throwing forth fragments of exquisite force or beauty in the midst of their wildest and most disordered ravings: Lear, Edgar, and the heart-broken Ophelia are in this respect alike gifted, and show to what sources their reading had been directed. Without an attention to these casual glances it is impossible to understand the meaning of the sentiment, and its force or feeling is lost upon us, as in the following burst of Ophelia, which consists of a string of quotations, or allusions to picturesque customs:—

"You must sing *Down a-down an you call him adown-a*. O, how the wheel becomes it! It is the false steward that stole his master's daughter."

We have not space for the explanation, but it may be found in the commentators, or in the interesting and elaborate history of "Shakespeare's Times," by my early and valued friend, Dr. Drake.

The SECOND VARIETY of the present species, that of CRACK-BRAINED WIT, is derived rather from the peculiar temperament of the individual than from any particular habit or train of reading; for, in general, few persons have given themselves less time to read, study, or even think, than those who are possessed by it. It is characterized by high spirits, a sportive and rampant imagination, and a flow of facetious ebullient wit incapable of restraining itself. It is hence

often poured forth on most improper occasions, and hesitates not to sacrifice a friend at the shrine of a jest.

There are some persons who possess by nature so perpetual a tide of excitement, that their high spirits seem seldom or never to ebb; and so irresistible a propensity to this kind of verbal merriment, that no change of circumstances can deprive them of it. Sir Thomas More, who perhaps overflowed with this disposition in a very high degree, is well known to have been facetious on his own scaffold.

It is not always, however, nor, as we have just observed, even for the most part, that the man of ready wit is, like Sir Thomas More, a man of ready judgment or sound learning. The apprehension necessary to constitute the one, is widely different from that necessary to constitute the other, as we had occasion to remark under a former genus: and hence vivacious sallies, taunts, and repartees, not only may co-exist with a deranged condition of mind, but are frequently a result of it. And on this account the court jester of former times, whose office succeeded to that of minstrel, was commonly denominated the king's fool, as uttering, from the unbridled liberty of speech that was allowed him, humorous flashes of rebuke which no man in his sober senses would have ventured upon; and which seemed, to adopt the language of Jaques, who was himself not unjustly accused of wearing the same livery, to show that

——— "in his brain,
Which is as dry as the remainder biscuit
After a voyage, he hath strange places cramm'd
With observation, the which he vents
In mangled forms."

The THIRD VARIETY, OR ECSTATIC ILLUSION, is also a pleasurable hallucination; and consists in a sense of false inspiration, or a visionary boast of some preternatural endowment, in the course of which the judgment is so far perverted as to mistake the energetic notions of the imagination for realities; so that the victim of the delusion believes in apparitions, affects an intercourse with the world of spirits, or lays claim to a power of working miracles.

This morbid afflatus has often been aped by cunning impostors, to serve their own interests with the multitude: and there is no great difficulty in conceiving that it is in many cases a real and serious hallucination, when we reflect on the ease with which such impostors themselves are capable of deluding the populace and working them up into false ecstasies, and especially of inveigling them into a hearty belief of their own miraculous powers. When the passions of men are once set afloat, and the subject presented to them is full of the marvellous and the terrible, they are too apt to confound the false with the real, and are prepared to proceed to whatever extremities the magician may choose to lead them. We are told by Lucian that when Archelaus, a celebrated Greek actor, performed the part of Andromeda in the tragedy of Euripides, several of the spectators were seized with a delirium; some at the time of performance, others a day or two afterward; during which they did

nothing but declaim in a theatrical manner, and piteously lament the fate of the persecuted princess. Burton, therefore, has some reason for remarking, that what the impostors before us, or the brain-sick enthusiasts whom they imitate, once broach and set on foot, "be it never so absurd, false, and prodigious, the common people will follow and believe. It will run like murrain in cattle, scab in sheep. Nulla scabies superstitione scabior: as he that is bitten by a mad dog bites others, and all in the end become mad. Either out of affectation of novelty, simplicity, blind zeal, hope, and fear, the giddy-headed multitude will embrace it, and without farther examination approve it."—(*Anat. of Melancholy*, part iii., sect. iv., l. 3.)

The genuine enthusiast is always possessed of a warm imagination, and generally of a nervous temperament and delicate frame; and a long series of elevated abstraction on religious subjects, combined with protracted fasting, has ordinarily been the harbinger of the fancied afflatus. Such was the discipline by which the lovely, and blooming, and sincerely devout Saint Teresa was prepared for ecstasies and visions, and led to impose upon herself and all that beheld her; and seriously to believe, in the fervour of her mind, that her body was lifted from the earth: and that she heard the voice of God, saw our Lord with St. Peter and St. Paul standing on her left hand; by the first of whom the cross which was at the end of her beads was miraculously transformed into four large gems, incomparably more precious than diamonds; with many other marvellous revelations, which we cannot find room to detail. Though it should be noticed, that devils appeared to her as well as blessed spirits, whom she always kept at a distance by sprinkling holy water; and that she was an eyewitness to the joyful escape from the flame of purgatory of the purified souls of Father Peter of Alcantara, Father Ivaguez, and a Carmelite friar.—(*Butler's Lives of the Saints*, in loco.)

It is not necessary to produce other examples, though many might be brought from our own times. A cure is extremely difficult to be obtained; and I am afraid that even Mr. Locke's admirable chapter on Enthusiasm would be read to no purpose. In one instance, the enthusiast seems to have been brought home to himself by a pleasant and ingenious stratagem of his superintendent at Venice. This visionary had conceived himself to be Elias, and, like the prophet, had determined upon fasting forty days. The keeper, fearful that he would never hold out, and that he should lose his patient, dressed up a man in the attire of an angel, who was introduced to him in no ordinary manner, and informed him that he was commissioned from Heaven to bring him food. The supposititious Elias took it, was afterward allowed to find out the trick, and thus, at the same time, found out his own imposition upon himself.

From the influence which we have seen such enthusiasts, or even pretended enthusiasts, capable of producing upon the mind of the multitude, when roused by the solemnity and awful-

ness of the revelations that are supposed to be disclosed to them, we can easily see how PANATISM, constituting the FOURTH VARIETY of the present species, may obtain an ascendancy, and even rage with all the ramifying power of an epidemic: consisting of religious flights of the imagination, predominant over the natural feelings as well as the judgment, excited by the calls or doctrines of those who affect to be preternaturally gifted, or who possess an equal influence over the mind by the high sanction of priesthood, profound learning, or any other respected authority: and often urging to a voluntary and inappropriate submission to severe privations, mortifications, and tortures; or to the torture and massacre of those who profess different creeds.

Examples, as in the last variety, may be found in every age and religion, but chiefly in times of gross ignorance and barbarism; where the general mind has been too little informed to distinguish between truth and sophistry, and the passions have been undisciplined to restraint. It is hence of no importance what religion or superstition is to be inculcated; for those that are true and those that are false have been equally laid hold of by enthusiasts and impostors to produce the same end, and effect the same triumph by means and machinery that could only be furnished from the infernal regions. Hence the blood and raving of the prophets of Baal; the Curetes or Phrygian priests, and the delirious votaries of the Indian Juggernaut; the cruel and senseless penances and punishments sustained in many of the convents and nunneries of Lamism, and still more so in those of many Catholic countries. Hence the terrible sufferings of the Waldenses, the furies of St. Bartholomew's day, the fires of Smithfield, and the dark and doleful cells, the whips, and wires, and pincers, and pulleys, and all the infernal paraphernalia of the Inquisition. Hence, in ancient times, the matrons of Canaan and of Carthage were instigated to throw their own children into the flames, and sacrifice them to the gloomy deity whose anger it was held necessary to appease; and hence, in more modern days, Philip II. of Spain was goaded to impeach a son, of whom he was little worthy, before the Chamber of Inquisitors, to bespeak their condemnation of him, and to take effectual care that he should be poisoned as soon as his sentence had been pronounced.

The cure of these diseases belongs rather to colleges of general instruction than of medicine. Individual cases of enthusiasm and fanaticism have existed, and will probably continue to exist, in all ages; but when the general mind is well informed, and the social feelings and virtues are duly estimated and widely cultivated, the wildfire will burn in vain, and meet with little or no fuel to support its rage.

SPECIES II.

ALUSIA HYPOCHONDRIAS.

HYPOCHONDRIACISM. LOW SPIRITS.

GLOOMY IDEAS OF REAL LIFE; DEJECTED

SPIRITS; ANXIETY; DYSPEPSY; LANGUID PULSE; INDISPOSITION TO ACTIVITY; EYE OBLIQUE AND SCOWLING; COUNTENANCE SAD AND SULLEN.

THE TERM HYPOCHONDRIAS is taken from the anatomical compound hypochondria, to which region the disease was formerly supposed to be altogether confined. Hypochondrias is here used instead of hypochondriasis, the common name, because, as already observed on various occasions, *iasis* as a termination is limited, nearly with this single exception, to denote in the medical vocabulary a peculiar family of cutaneous diseases, as pityriasis, psoriasis, ichthyiasis, and many others. The author has felt the less difficulty in proposing this change, as hypochondriasis is of comparatively modern invention, and is not to be met with in the Greek or Latin writers, by whom the complaint is usually alluded to or described as a species of melancholy, or rather as a disease of the melancholic temperament.

It constitutes the third sort or species of this malady described by Galen, and which he regards as connected with a peculiar state of the stomach; though, from its mental symptoms, he does not incline to contemplate it, as Dioscorides, a contemporary physician of reputation, had done in his Book on Gastric Affections, as a simple disease of this organ. The controversy has been in different times continued to our own day; and it does not seem to be even yet universally settled whether hypochondrias should be regarded as a mental or a dyspeptic malady. M. Esquirol and M. de Villermay (*Traité des Maladies Nerveuses*, &c.) contemplate it in the latter light; M. Georget (*Sur la Folie—Physiologie du Cerveau*) and M. Falret, though a pupil of M. Esquirol, refer it in every instance to the brain as its primary seat.—(*De l'Hypochondrie et du Suicide*, &c., 8vo., Paris, 1822.) In Pinel the disease seems to be included under *aliénation mentale*, and its different varieties to be distributed, though without particular remark, amid the five species into which he has divided that genus.

The present species bears so near a resemblance to several of the varieties of genuine melancholy as to be often distinguishable from them with great difficulty; and the more so as it is no uncommon thing for hypochondrias to terminate in melancholy, or for melancholy to be combined with hypochondrias.—(*Falret, de l'Hypochondrie*, &c., ut *suprà*, *passim*.) Both may be the result of a predisposing constitution, or may be primarily induced by accidental causes where no such constitution exists: and the predisposition and the accidental causes of the one may become those of the other: for the temperament known by the common name of melancholic, and characterized by a lean and dry corporeal texture, small and rigid muscles, a sallow skin, brownish-yellow complexion, little relieved by redness of any kind, deep-black and coarse hair, eyes sunk in hollow sockets, large prominent veins, especially in the hands and arms, with a tendency to solitude and private musing, is a common precursor of both. And, in like

manner, a sedentary life of any kind, and especially severe study protracted to a late hour in the night, and rarely relieved by social intercourse, exercise, or nugatory amusements; a debauched and dissolute habit, or excesses in eating and drinking, may become causes of either of these maladies, from accessory circumstances that cannot be traced out even where the predisponent temperament does not seem to exist. But it is very justly observed by Sir A. Crichton, that, even in those "whose health is much deranged, true melancholy seldom arises, except mental causes of grief and distress join themselves to the corporeal ones: and this constitutes one of the characters which distinguish *melancholia vera* from hypochondriasis. The former may be said to be always excited by mental causes, and consists in various phenomena of grief, despondency, and despair; whereas the latter most commonly arises from corporeal causes, and its mental phenomena consist of erroneous ideas entertained about the patient's own make or body."—(*Of Mental Derangement*, vol. iii., p. 235.)

The corporeal causes are usually a diseased condition of one or more of the digestive organs, and especially, as we shall presently have to observe, a displacement of some part of the colon. It is also not unfrequently a result of the sudden cessation of some periodical or other habitual discharge, as that of an issue, or of a hemorrhoidal flux, a chronic ulcer, or some external eruption.

The melancholy man seldom lives long, and his disorder often commences in the meridian of life. He frequently terminates his days by violence, or, at the utmost, never attains old age. The hypochondriac seldom becomes affected till after the meridian of life, and very generally continues to the stage of longevity.

The common corporeal symptoms are, a troublesome flatulence in the stomach or bowels, acrid eructations, costiveness, a copious discharge of pale urine, spasmodic pains in the head and other parts of the body, giddiness, dimness of sight, palpitations, general sleeplessness, and an utter inability of fixing the attention upon any subject of importance, or engaging in anything that demands vigour or courage. The mental feelings and peculiar trains of ideas that haunt the imagination and overwhelm the judgment exhibit an infinite diversity, and lay a foundation for the three following varieties:—

- a Autalgica. Vapours.
- β Pertæsa. Weariness of life.
- γ Misanthropica. Misanthropy. Spleen.

In the FIRST VARIETY, which is commonly distinguished by the name of VAPOURS, or LOW SPIRITS, the patient is tormented with a visionary or exaggerated sense of pains or some concealed disease; a whimsical dislike of particular persons, places, or things; or groundless apprehensions of personal danger or poverty.

Greding gives an account of a medical practitioner who applied to him for assistance, under an impression that his stomach was filled with frogs, which had been successively spawning ever since he had bathed, when a boy, in a pool

in which he had perceived a few tadpoles. He had spent his life in trying to expel this imaginary evil, and had travelled to numerous places to consult the first physicians of the day upon his obstinate malady. It was in vain to attempt convincing him that the gurglings or borborygni he heard were from extricated and erratic wind. "He argued himself," says M. Greding, "into a great passion in my presence, and asked me if I did not hear the frogs croak."

I have under my care a hypochondriac of about fifty years of age, who affords a sufficient proof that Molière drew his *Malade Imaginaire* from nature, and hardly added an exaggerating touch. His profession is that of the law; his life has been uniformly regular, but far too sedentary and studious. Without having any one clearly-marked corporeal affection, he is constantly dreading every disease in the bills of mortality, and complaining, one after another, of every organ in his body, to each of which he points in succession as its seat: especially the head, the heart, and the testes. He now suspects he is going to have a cataract, and now frightens himself with an apprehension of an involuntary seminal emission. It is rarely that I have left him half an hour but I have a note to inform me of some symptom he had forgotten to mention, and I have often five or six of these in the course of the day. The last was to state that, shortly after my visit, he had a discharge of three drops of blood from the nose—a change which he thought of great importance, and requiring immediate attention. His imaginary symptoms, however, soon disappear, provided they are listened to with gravity and pretended to be prescribed for, but not otherwise. Yet, in disappearing, they merely yield to others that can only be surmounted in like manner. His head is too much confused to allow him to engage in any serious study, even if it were prudent to recommend it to him: but on all common subjects he is perfectly clear, and will converse with shrewdness and a considerable extent of knowledge. His bowels are sluggish; his appetite not good, though he eats sufficiently; his sleep is unquiet, but he has enough of it without opiates; his pulse is variable, sometimes hurrying on abruptly, and without any obvious cause, to a hundred strokes in a minute, but often very little quicker than in a state of health. His tongue varies equally, and is irregularly clean, milky, and brownish, and then suddenly clean again. He is irritable in his temper, though he labours to be calm; and is so rooted to his chamber that it is difficult to drag him from it. He has now been ill about ten weeks; but it is during the winter, and the season is too severe and inclement for him to venture abroad. I look forward to his restoration in the spring from exercise, change of air, and a course of tonic medicines. I have not found him complain of *dysphagia globosa*, or that sense of suffocation from the feeling of a constricting ball in the throat which is so common to hysteric patients, and which, from its being often also traced in the present disease, has been called by Pechlin *suffocatio hypochondriaca* (Lib. i., obs.

31); but his spirits are in a state of almost perpetual depression.

A superficial and injudicious perusal of medical books addressed to those who are not of the profession has been a frequent source of this affection. M. Villermay distinctly states as one of its causes among his own countrymen a "lecture habituelle de Buchan." Rousseau admitted that this was a powerful cause of hypochondriasis in respect to himself. "Having read," says he, "a little on physiology, I set about studying anatomy; and passing in review the number and varied actions of the parts which compose my frame, I expected twenty times a day to feel them going wrong. Far from being astonished at finding myself dying, my astonishment was that I could live at all. I did not read the description of any disease which I did not imagine myself to be affected with; and I am sure that, if I had not been ill, I must have become so from this fatal study. Finding in every complaint the symptoms of my own, I believed I had got them all, and thereby added another still more intolerable—the fancy of curing myself."

The whims that are sometimes seriously entertained under this variety of the disease are so truly ludicrous, that "to be grave exceeds all power of face." One thinks himself a giant, another a dwarf; one is as heavy as lead, another as light as a feather. Marcellus Donatus makes mention of a baker of Ferrara who thought himself a lump of butter, and durst not sit in the sun nor come near the fire for fear of being melted. They are all extremely timid, and their fears are exercised upon trifles, or are altogether groundless. Some suspect their nearest and dearest friends of designing to poison them: others dare not be alone in the dark lest they should be attacked with ghosts or hobgoblins. They dare not go over a bridge, or near a pool, rock, or steep hill, lest they should be tempted to hang, drown, or precipitate themselves: and, if they come to a place where a robbery or a murder has been committed, they instantly fear they are suspected. Trincavellius had a patient that for three years together could not be persuaded but that he had killed a man, and at length sunk into a confirmed melancholy, and made away with himself for fear of the gallows.—(*Consil.*, xiii., lib. i.)

It is a melancholy reflection that the wisest and best of mankind are as open to this affliction as the weakest, and, perhaps, more so. Pascal himself was at one time so hallucinated with hypochondriacism as to believe that he was always on the verge of an abyss into which he was in danger of falling. And, under the influence of this terror, he would never sit down till a chair was placed on that side of him on which he thought he saw it, and thus proved the floor to be substantial.

It is frequently induced by too free a use of spirituous liquors, the stomach and other digestive organs being hereby debilitated and almost paralyzed; and, where this is the case, the disease is apt to terminate in that exhausted state of the nervous system generally, and delirious

condition of the brain, which by some writers has been called *delirium tremens*;* in which the mind and body exhibit equal feebleness, combined with a high degree of irritability, and the patient often falls a sacrifice in a few days; previous to which he is worn out with convulsive struggles, succeeded by a cold and general perspiration; the pulse increases in rapidity and becomes thready, and the twitching of the tendons subsides into a tremour that spreads over the whole body; the countenance is pale and anxious, the patient mutters with incessant rapidity, and the *DELIRIUM* is constant, though easily interrupted by questions addressed to him. In one case, says Mr. Blake, who has given a good description of the complaint, the mind was so diseased that the patient, after being desired to put out his tongue, continued for nearly half an hour to push it out and draw it in alternately in quick succession, whenever I looked towards him.—(*Edin. Med. and Surg. Journ.*, Oct., 1823, p. 501.) If, before this extremity takes place, a sound and refreshing sleep creep gradually over the frame, the irritability subsides, a healthful quiescence succeeds to general commotion, and the mind and the body become by degrees reinvigorated.

Under the SECOND VARIETY we meet with a totally distinct set of morbid feelings and ideas; for the patient is here oppressed with a general listlessness and disgust; an irksomeness and weariness of life, often without any specific reason whatever. This is the *melancholia Anglica* of Sauvages, who describes it as common to our own countrymen; under the attack of which, says he, "languid, sorrowful, tired of remedies of every kind, they settle their affairs, make their wills, take leave of their friends by letters, and then put an end to their lives by hanging, poison, or some other means: exhibiting a wish to die, not from insanity or severe grief, but tranquilly, from a mere *tædium vitæ*, or irksomeness of existence." This may occasionally be the case; but by far the greater number of suicides in our own country proceed, not from hypochondriacism, but a despondency produced by real losses; and belong, therefore, as I have already observed, to the genus *empathema*. Yet this miserable upshot occurs in a few instances from the feeling, or rather the want of feeling, here assigned; the perpetrators of the horrid deed being generally those who, having been actively engaged in the heyday and meridian of

* *Delirium tremens* is unfortunately very frequent in the United States. American practitioners have paid great attention to it, and have written many valuable treatises upon its nature and treatment. Our limits will not permit even an abstract of them. We would, however, refer the reader to a learned article by Dr. Coates, in the *N. A. Med. and Surg. Journal*, vol. v.; to Dr. Brown's Essay in the *Am. Med. Recorder*, vol. v.; to the communications of Dr. Drake and Dr. Klapp, in the first and second volumes of the same journal, and to a treatise on the same subject by Dr. John Ware, of Boston. Baron Dupuytren also has described the same disease in the first volume of his *Clinical Lectures on Surgery*, under the term *nervous delirium*.—D.

life, have retired upon their fortunes with a view of enjoying them in quiet, but who unhappily find themselves fitted for any thing rather than for quiet; who have no taste for reading, reflection, or domestic tranquillity, and are too proud to return to the bustle of the world and the excitement of nicely-balanced speculations. There is here a want of the habitual stimulus to a production of sensorial power; in consequence of which the individual sinks into a state of low spirits, and becomes unhappy. A like issue frequently follows upon a life devoted to all the pursuits of sensual gratification, in the course of which the individual has exhausted his stock of enjoyments, and worn out his powers of body and mind before he has reached little more than the midway of his existence. Every thing now palls upon his senses, and he has neither taste nor energy to engage in more rational pursuits. "A ride out in the morning, and a warm parlour and a pack of cards in the afternoon, are all that life affords," said a patient of Dr. Darwin to him, a man of polished manners about fifty years of age. He got tired of these in a few months, and, having no other resource, shot himself.—(*Zoonom.*, vol. iv., p. 90, edit. 8vo.)

Burton has well described the state of mind of many that are tormented with this most wretched malady (*Anatomy of Melanch.*, part i., sect. iii., i., 2), but still more so those affected with the THIRD VARIETY, which is strikingly accompanied with peevishness, general malevolence, and an abhorrence of mankind. "They are soon tired with all things: they will now tarry, now be gone; now in bed, they will rise; now up, then go to bed; now pleased, and then again displeased; now they like, by-and-by dislike all, weary of all: sequitur nunc vivendi nunc moriendi cupido, saith Aurelianus (lib. i., cap. vi.); discontented, disquieted; upon every light occasion or no occasion object; often tempted to make away with themselves; they cannot die, they will not live; they complain, weep, lament, and think they lead a most miserable life: never was any man so bad. Every poor man they see is most fortunate in respect of them; every beggar that comes to the door is happier than they are; jealousy and suspicion are common symptoms in the misanthropic variety. They are testy, peevish, distrustful, apt to mistake, and ready to snarl upon every occasion and without any cause with their dearest friends. If they speak in jest, the hypochondriac takes it in good earnest: if the smallest ceremony be accidentally omitted, he is wounded to the quick. Every tale, discourse, whisper, or gesture he applies to himself: or, if the conversation be openly addressed to him, he is ready to misconstrue every word, and cannot endure that any man should look steadfastly at him, laugh, point the finger, cough, or sneeze. Every question or movement works upon him, and is misinterpreted, and makes him alternately turn pale and red, and even sweat with distrust, fear, or anger."

As in this species the body is more affected than in any other division of mental alienation, more may often be accomplished by MEDICINE;

though we must by no means be inattentive to moral discipline. The skin is very frequently cold and without a free secretion, and hence general friction, with rubefacients and the warmer diaphoretics, have often been found serviceable. The digestive organs are almost always torpid, and several of them, especially the stomach and liver, secrete their respective fluids not only in too small a quantity, but of an unhealthy quality, so as to be too viscid, too dilute, or morbidly stimulant. Some kind of acrimony, indeed, is almost always found in the stomach, and particularly that of acidity. And hence aperients, carminatives, and particularly the tonic plan which has already been recommended under *LIPOSIS Dyspepsia*, are manifestly called for, and will often be found serviceable.

Post-obit examinations have also frequently pointed out another local cause, which otherwise we should little expect: and that is, a displacement of the transverse colon.* M. Pinel, as we have already observed, regards this as a very common cause of insanity in all its forms: but there can be no question that it is a powerful and ready cause of the present species of mental alienation. M. Esquirol, who has found it as frequently as M. Pinel, tells us that this displacement sometimes consists in an oblique, and sometimes in a perpendicular direction of the intestine, so that its sinister extremity lies behind the pubes; while it has sometimes descended into the form of an inverted aorta even below the pubes and into the pelvis. No disease of the organization has been found in any instance, and hence the change of place must proceed from relaxation and debility alone where the misposition is not connate; on which account it may in some instances be an effect, as it is certainly a cause in others. It is under these circumstances that we chiefly meet with that pain in the epigastrium to which we have already adverted, and which gives the feeling of a tight cord surrounding the body in the line of distress; and when such a symptom, therefore, occurs, we have reason to suspect the cause of the disease to be produced by some derangement of the colon in respect to position. Under the operation of such a cause, the art of medicine can do but little; temporary ease, however, may be obtained by the pressure of a belt broad enough to support the whole of the lower belly; and it is possible that the intestine may gradually right itself under a course of the warmer tonics, as columbo, canella alba, and cassum-muniar, or lose its morbid irritability by habit. But these are rare terminations; for more generally the

* The facts in support of this doctrine have not been so numerous in this country as in France; and its correctness has even been doubted. In Paris, however, the opportunities of dissecting the bodies of insane persons have been for many years much greater than in London; and when we find such authorities as MM. Pinel and Esquirol attesting, by recorded dissections, the truth of the cause here assigned for the present species of mental alienation, the fact, in relation to the natives of France, must at all events be admitted.—Ed.

displacement increases, and the disease itself gains ground and becomes more incurable.

Congestions from weakness of vascular action in one or more of the abdominal viscera are a frequent result of the present complaint, and not unfrequently a primary cause; and hence we may see why the bleeding piles should be serviceable in so many instances as to obtain from Alberti the name of *medicina hypochondriacorum* (*Dissert. de Hæmorrhoidibus*, Halle, 1716), and why leeches repeatedly applied to the anus, as recommended by Schoenhæyder, should often have a like beneficial effect.—(*Act. Soc. Med. Hafn.*, ii., p. 313.) This is of the greatest importance where the disease has been preceded by a periodical flow of blood from the hemorrhoidal veins, and should point out to us the necessity of renewing any other discharge or external irritation to which the system may have been accustomed.

Opium is a very doubtful medicine, though strongly recommended by Deidier and other respectable writers, and readily had recourse to by hypochondriacs themselves to relieve their distressful sensations. Dr. Cullen asserts peremptorily that he has always found a frequent use of opiates pernicious in hypochondriacs (*Mat. Med.*, vol. ii., p. 245, edit. 4to.); and, in many instances in which I have myself been tempted to employ it, I have been compelled to withhold its further use from its doing more mischief than good. It has often in such cases been exchanged for other sedatives, but rarely with any decided advantage.

Exercise of all kinds should be encouraged in every modification of the disease, but especially exercise on horseback, though it is seldom, in the first and third varieties, we can succeed in getting a patient to try it. The diet should be governed by the principles already laid down for treating indigestion.

In the MORAL MANAGEMENT, assiduous kindness and consoling conversation produce a deeper effect than they seem to do. Loquacity is always hurtful; but a talent for cheerful discourse, intermixed with interesting and amusing anecdotes, frequently draws away the patient's attention from himself, and becomes a most useful palliative. In the autalgic variety, in which he is perpetually haunted with a feeling of some dreadful disease which exists nowhere but in his own fancy, the hallucination, when we possess his confidence, should be removed by a candid statement of the fact, and, if necessary, friendly expostulation: but the moment we find the prepossession is too strong to be removed by argument, it is better to humour the conceit, and to pretend to prescribe for it. It is sometimes necessary, indeed, for the hypochondriac is often possessed of great cunning, to drop all pretensions whatever, and to put him in good earnest upon a course of medicines for a disease we know he is as free from as ourselves. Thus a firm belief that he has an inveterate itch is a common delusion with a patient of this kind, and it will be often found impossible to persuade him that he is cured till his whole body has been repeatedly rubbed over with sulphur or

hellebore ointment. I had lately under my care a special pleader of considerable eminence, who in the course of this affection would have it that he had the pox. I at first argued the point with him day after day, but to no purpose; he felt certain that he should never be well till he was not only salivated, but had used tonic injections for a gleet which he said accompanied it, though he had no discharge whatever. It was in vain to deceive him by supposititious medicines; for he was a man of considerable learning, and well acquainted with medical preparations; and I hence allowed him his heart's desire: he rubbed in mercurial ointment every night, and for an injection used a solution of zinc. In a week he persuaded himself he was well, and begged permission to desist from a farther use of the remedies; a permission which was readily granted him.

In the second variety, or *tædium vitæ*, where the time seems to hang intolerably heavy on the patient's hands from his having, in a mistaken search after happiness, relinquished a life of constant excitement and activity for the fancied delights of rural retirement and quiet, the best and most radical cure would be a return to the situation that has been so unfortunately abandoned; but if this cannot be accomplished, the patient must be put into a train of pursuits of some other kind. If he be fond of the sports of the country, he should weary himself in the daytime with hunting or shooting, or even horse-racing, rather than be hypochondriacal from idleness; and spend his evenings in the bustle of dinner-parties or cards. And if he be capacitated for higher and more useful occupations, let him plunge headlong into the public concerns of the parish and its neighbourhood, become a member of its select vestries, a trustee of the highways, or a magistrate of the district. The habit of excitement must for some time be maintained, though it be afterward let down by degrees: and the intermediate steps are of no great importance, so far as they answer their purpose. We are not at present arguing the case upon a principle of ethics or of religion, but merely upon a principle of moral medicine. Yet I have often known persons of the above description broken in by degrees to a love of domestic quiet for which they were by no means fitted when they first entered upon it; and who, with a love of domestic quiet, have settled also, as a more sober stage of life has advanced, and reflection has gained ground upon them, into a love of strict moral order, and the higher duties of a conscientious Christian, to which one time they seemed as little disposed.*

* The following remarks by Dr. Conolly are exceedingly just:—"So many hypochondriacal persons are known to be at large who entertain strange opinions concerning their own form and nature, that it seems hardly necessary to caution the practitioner against treating such patients as madmen are commonly treated. That the mind of these individuals is impaired, is unquestionable; but the character of the impairment is not dangerous. Yet when there is much anxiety to get rid of a troublesome member of a family, very great stress is laid on these fancies, to which,

GENUS IV.
APHELXIA.
REVERY.

INACTIVITY OF THE ATTENTION TO THE IMPRESSIONS OF SURROUNDING OBJECTS DURING WAKEFULNESS.

APHELXIA is derived from ἀφελω, "abstraho, retraho, avoco, abduco;" and is in use among the Greek writers.

The subject is almost, if not altogether, new to nosology, and has seldom been dipped into by physiologists. Dr. Darwin occasionally touches upon it in various parts of his "Zoonomia," and Dr. Crichton in his "Inquiry into the Nature of Mental Derangement;" and it is well described and illustrated by La Bruyère in his "Characters;" but it yet remains to be analyzed, and reduced to a nosological method, and examined in a pathological view. A few leading ideas on this subject have already been thrown out by the author, in his comment upon the present definition in the volume of Nosology; and of these he will avail himself in treating of it more at large.

In order to our becoming acquainted with the existence of surrounding objects, or of an external world, as it is called by psychologists, three things are necessary: sound external senses; a secretion of the nervous fluid (or, as it might be perhaps more correctly expressed, a due maintenance of the nervous and sensorial energy), apparently under different modifications, whereby they are made capable of being roused or excited by the different objects addressed to them; and an exercise of the faculty of attention to the impressions which are thus produced. The will has, or ought to have, a power of calling this, as well as every other faculty of the mind, into a state of exertion, or of allowing it to be indolent; and it is chiefly upon this want of power, or the same power intensely exerted, that the phenomenon of revery depends; thus giving rise to the three following species of mental aberration:—

1. Aphelxia Socors. Absence of Mind.
2. ——— Intenta. Abstraction of Mind.
3. ——— Otiosa. Brown-study.

In the first of these the attention is truant, and does not yield readily to the dictates of the will: in the second it is riveted, at the instigation of the will itself, to some particular theme unconnected with surrounding objects: and in the third it has the consent of the will to relax itself, and give play to whatever trains of ideas are uppermost or most vivacious in the sensory.

SPECIES I.
APHELXIA SOCORS.
ABSENCE OF MIND.

TRUANT ATTENTION; WANDERING FANCY; VACANT OR VACILLATING COUNTENANCE.

This is an absence, or vacuity of mind, too taken by themselves, the practitioner must not attach great importance."—See Inquiry concerning the Indications of Insanity, p. 405.—Ed.

common at schools and at church; over tasks and sermons; and there are few readers who have not frequently been sensible of it in some degree or other.

In reading books in which we are totally uninterested, composed in a tedious and repulsive style, we are almost continually immersed in this species of revery. The will does not exert its power: the attention is suffered to wander to something of stronger attraction; or the imagination is left to the play of its own nugatory ideas; and though we continue to read, we have not the smallest knowledge of the argument before us; and if the subject to which the train of our thoughts is really directed be of a strikingly ludicrous character, we may possibly burst into a laugh in the middle of a discourse of great gravity and seriousness, to the astonishment of those around us.

This is a common case, and may lead to great embarrassment. We have nevertheless thus far supposed that the will does not exert its power, and sufficiently rein in the attention to the subject addressed to it. It not unfrequently happens, however, that the will, for want of a proper habit, has lost its power, either wholly or in a very great degree, and cannot, with its utmost energy, exercise a due control over the attention; and it also happens in other cases, from a peculiarity of temperament or morbid state of body, that the faculty of the attention itself is so feeble, that it is incapable of being steadily directed for more than a few minutes to any object of importance whatever, with all the effort of the will to give it such direction.

The mind, under either of these conditions, is in a deplorable state for all the higher purposes of reflection and knowledge for which by its nature it is intended; since it is upon the faculty of attention that every other faculty is dependant for its vigour and expansion: without it the perception exercises itself in vain; the memory can lay up no store of ideas; the judgment draw forth no comparisons; the imagination must become blighted and barren; and where there is no attention whatever, the case must necessarily verge upon fatuity.

In early life, the attention, like every other faculty of the mind, is weak and wandering, is often caught with difficulty, and rarely fixed upon any thing. Like every other faculty, however, it is capable of being strengthened and concentrated; and may be made to dwell upon almost any object proposed. But this is a work of time, and forms one of the most important parts of education: and, in the course of this discipline, it should not be forgotten that the faculty of attention, when it first shows itself, is more readily arrested by some subjects than by others, and that it is hence of great moment to ascertain those subjects, and to select them in the first instance. The habit is what is chiefly wanted; and the quicker this is acquired, the more time we gain for transferring the same habit to other and perhaps more valuable purposes afterward.

This is a point seldom sufficiently considered in the course of education; and, for want of such consideration, far more than half the time

of many boys becomes an entire blank, and is lost; and not a few suffered to remain block-heads in the particular department to which their hours of study are directed, who might discover a considerable capacity and genius if the department were changed for one more adapted to their own taste, or, in other words, more attractive to their attention.

There is a very singular instance of habitual absence of mind related by Sir A. Crichton, in a young patient under the care of Dr. Pitcairn and himself, which, though some other circumstances appeared to have combined with it, is ascribed considerably to the error of education we are now speaking of, that of not duly studying the peculiar bent of a mind in many respects singularly constituted, and drawing forth and strengthening the faculty of attention, which was in an especial degree weak and truant, by an employment of such objects and pursuits as were most alluring. This patient was a young gentleman of large fortune, who, till the age of twenty-one (and he does not seem to have been much more at the time of describing his case), had enjoyed a tolerable share of health, though of a delicate frame. In his disposition he was gentle and calm, but somewhat unsociable. His absence of mind was extreme, and he would sometimes willingly sit for a whole day without moving. Yet he had nothing of melancholy belonging to him; and it was easy to discover by his countenance that a multiplicity of thoughts were constantly succeeding each other in his imagination, many of which were gay and cheerful; for he would heartily laugh at times, not with an unmeaning countenance, but evidently from mental merriment. He was occasionally so strangely inattentive, that, when pushed by some want which he wished to express, if he had begun a sentence, he would suddenly stop short after getting half way through it, as though he had forgotten what else he had to say. Yet, when his attention was roused and he was induced to speak, he always expressed himself in good language and with much propriety; and if a question were proposed to him which required the exercise of judgment, and he could be made to attend to it, he judged correctly. It was with difficulty he could be made to take any exercise; but was at length prevailed upon to drive his curriole, in which Sir Alexander at times accompanied him. He at first could not be prevailed upon to go beyond half a mile; but in succeeding attempts he consented to go farther. He drove steadily, and when about to pass a carriage, took pains to avoid it: but when at last he became familiarized with this exercise, he would often relapse into thought, and allow the reins to hang loose in his hands. His ideas seemed to be for ever varying. When any thing came across his mind which excited anger, the horses suffered for it; but the spirit they exhibited at such an unusual and unkind treatment made him soon desist, and re-excited his attention to his own safety. As soon as they were quieted, he would relapse into thought: if his ideas were melancholy, the horses were allowed to walk slow; if they were gay and cheerful, they were

generally encouraged to go fast.—(*Of Mental Derangement*, vol. i., p. 281.)

Perhaps, in this case, something might have been owing, as supposed by Sir A. Crichton, to an error in the mode of education; but the chief defect seems to have been in the attentive faculty itself, and its labouring under a natural imbecility, which no mode of education could entirely have removed. We have had frequent occasions to observe that the powers of the mind vary in different individuals as much as those of the body: and we have already offered examples of weak or diseased judgment, weak or diseased perception, and weak or vehement imagination. In the case before us, the mental disease seems to have been chiefly confined to the faculty of attention; and we shall presently have to notice a similar imbecility of the memory, and even of all the mental faculties conjointly.*

SPECIES II.

APHELXIA INTENTA.

ABSTRACTION OF MIND.

THE ATTENTION WOUND UP AND RIVETED TO A PARTICULAR SUBJECT; WITH SYMPATHETIC EMOTION OF THE MUSCLES AND FEATURES CONNECTED WITH ITS GENERAL DRIFT.

In this species the faculty of attention, instead of being feeble or contumacious to the will, is peculiarly strong, and vehemently excited, and acts in perfect co-operation with the will itself. And in many instances the sensorial energy maintained is so great, and demands so large a supply of sensorial power, as apparently to exhaust the entire stock, except, indeed, the reserve which is in almost all cases instinctively kept back for the use of the vital or involuntary organs. And hence all the external senses remain in a state of torpor, as though drawn upon for their respective contributions of sensorial power in support of the predominant meditation: so that the eyes do not see, nor the ears hear, nor does the flesh feel; and the muser may be spoken to, or conversation may take place around him, or he may even be struck upon the shoulders, without any knowledge of what is occurring.

Abstraction of mind may be produced by various causes, but the following are the chief, and form two distinct varieties:—

- α Aphelxia a pathe- From some overwhelm-
mate. ing passion.
- β Aphelxia a studio. From intense study.

Of THE FIRST VARIETY we have already offered abundant examples in the two preceding

* The *absent man* cannot spread his attention over many things at once: it is concentrated on one subject, or one train of thought; and the most trivial thoughts are sufficient for its exclusive occupation. He therefore commits a thousand extravagances; puts on his friend's hat; loses his way in his native town; goes to bed in the middle of the day, because he finds himself in his bedroom; or forgets his own name when he knocks at a person's door.—See Conolly on Insanity, p. 121.—Ed.

genera: and especially in the cases of ungovernable joy or rapture, grief and despondency; under the influence of which the affected person is often as much lost to the world around him, as if he were in a profound sleep and dreaming; and only hears, sees, and feels the vivid train of ideas that possess themselves of his mind, and rule it as a captured citadel. To these alone the attention is directed; here it exhausts all its power, and the will concurs in the exhaustion; inasmuch that the patient is said in some cases to have stared at the meridian sun without pain (*Blumenb.*, bibl. i., p. 736); and in others to have been undisturbed by the discharge of a cannon.—(*Darwin*, *Zoonomia*, iii., i., ii., 2.)

We meet with like proofs of this variety of revery in many cases of intense study, and especially upon abstract subjects, as those of pure mathematics, in which all the reasoning and more serious faculties of the mind, as the perception, the memory, and the judgment, as well as the attention, are jointly called into action, and kept equally upon the stretch. Of the power of this variety of revery in rendering an individual torpid and almost dead to all around him, we have a decided instance in Archimedes at the time of his arrest. When the Roman army had at length taken Syracuse by stratagem, which the tactics of this consummate engineer prevented them from taking by force, he was shut up in his closet, and so intent on a geometrical demonstration, that he was equally insensible to the shouts of the victors and the outcries of the vanquished. He was calmly drawing the lines of a diagram when a soldier abruptly entered his room, and clapped a sword to his throat. "Hold, friend," said Archimedes, "one moment, and my demonstration will be finished." The soldier, surprised at his unconcern at a time of such extreme peril, resolved to carry him before Marcellus; but as the philosopher put under his arm a small box full of spheres, dials, and other instruments, the soldier, conceiving the box to be filled with gold, could not resist the temptation, but killed him on the spot.*

SPECIES III APHELXIA OTIOSA. BROWN-STUDY.

LEISURELY LISTLESSNESS; VOLUNTARY SURRENDER OF THE ATTENTION AND THE JUDGMENT TO THE SPORTIVE VAGARIES OF THE IMAGINATION; QUIESCENT MUSCLES; IDLE GRAVITY OF COUNTEenance.

THE attention is equally summoned into action and dismissed at the command of the will. It is summoned in the last species: it is dismissed when a man voluntarily surrenders him-

* If the attention be much engrossed by one object, it is necessarily withdrawn from others; and although readily transferred in general from one set of objects and ideas to another set of objects and ideas, it is sometimes so tenacious of one set as to refuse, as it were, to turn to a succession. We

self to ease and listlessness of mind; during which period, moreover, in consequence of this indulgence in general indolence, the external senses themselves unite in the mental quiescence, and a smaller portion of nervous energy is probably generated, for the very reason that a smaller portion is demanded; and hence the active senses without are as vacant and unstrung as the active senses within, and as blunted to their respective stimuli. The first playful ideas that float over the fancy in this case take the lead, and the mind relaxes itself with their easy and sportive flow. It is the *studium inane* of Darwin (*Zoonom.*, iii., i., ii., 2; and again, iv., ii., iv., 2), who seems, however, to have in some degree misapplied the name, or to have confounded the aberration with that of *ecphronia* or *alusia*. Cowper has admirably described it in the following verses:—

"Laugh, ye who boast your more mercurial powers,
That never feel a stupor, know no pause
Nor need one: I am conscious, and confess,
Fearless, a soul that does not always think.
Me oft has fancy, ludicrous and wild,
Soothed with a waking dream of houses, towers,
Trees, churches, and strange visages, express'd
In the red cinders, while with poring eye
I gazed, myself creating what I saw.
Nor less amused have I quiescent watch'd
The sooty films that play upon the bars
Pendulous, and foreboding in the view
Of superstition, prophesying still, [proach.
Though still deceived, some stranger's near ap-
'Tis thus the understanding takes repose
In indolent vacuity of thought,
And sleeps and is refresh'd. Meanwhile the face
Conceals the mood lethargic with a mask
Of deep deliberation, as the man
Were task'd to his full strength, absorb'd and
lost."

In the indolent mind such indulgence is a disease; and, if not studiously watched and opposed, will easily become a habit. In the studious and active mind it is a wholesome relaxation; the sensory, in the correct language of the poet, "sleeps and is refreshed," grows fertile beneath the salutary fallow, and prepares itself for new harvests.

This is more particularly the case where, in conjunction with an attention "screwed up to the sticking-place," and long continued there, a spirit of ardent emulation is at the same time stirring, and distracted between the hope and fear of gaining or losing a distinguished honour or reward. I have seen this repeatedly in young men who have been striving night and day, and week after week, for the first prizes of our English universities; some of whom have indeed succeeded, but with a hectic exhaustion that has been recovered from with great difficulty; while others, in the full prospect of success, have been compelled to relinquish the pursuit, and to degrade.

read that when Sir Joshua Reynolds, after being many hours occupied in painting, walked out into the street, the lamp-posts seemed to him to be trees, and the men and women moving shrubs.—See Dr. Conolly's *Inquiry concerning the Indications of Insanity*, p. 119.—Ed.

Yet even without this conflict of feeling, where the attention alone has been too long directed to one or to a variety of recondite subjects without relaxation, the mind suffers considerably, and its powers become shaken and confused; of which we have an interesting example in the case of Mr. Spalding, a scholar of considerable eminence in Germany, as drawn by himself, and communicated to the editors of the *Psychological Magazine*.—(*Crichton's Inquiry into Mental Derangement*, i., 237.) His attention, he tells us, had been long kept upon the stretch, and had been still more distracted by being continually shifted from one subject to another, when, being called upon to write a receipt for money paid him on account of the poor, as soon as he had written the two first words, he found himself incapable of proceeding farther. He strove all he could, and strained his attention to the utmost, but to no purpose; he knew the characters he continued to make were not those he wished to write, but could not discover where the fault lay. He then desisted, and partly by broken words and syllables, and partly by gestures, made the person who waited for the receipt understand that he should leave him. For about half an hour a tumultuary disorder reigned in his senses, so that he was incapable of remarking any thing very particular, except that one series of ideas of a trifling nature, and confusedly intermixed, forced themselves involuntarily on his mind. At the same time his external senses continued perfect, and he saw and knew every thing around him. His speech, however, failed in the same manner as his power of writing, and he perceived that he spoke other words than those he intended. In less than an hour he recovered himself from this confusion, and felt nothing but a slight headache. On examining the receipt on which the aberration first betrayed itself, he found that, instead of the words "fifty dollars, being one half-year's rate," he had written "fifty dollars, through the salvation of Bra—" the last word being left unfinished, and without his having the least recollection of what it was intended to be.

GENUS V.

PARONIRIA.

SLEEP DISTURBANCE.

THE VOLUNTARY ORGANS CONNECTED WITH THE PASSING TRAIN OF IDEAS OVERPOWERED BY THE FORCE OF THE IMAGINATION DURING DREAMING, AND INVOLUNTARILY EXCITED TO THEIR NATURAL OR ACCUSTOMED ACTIONS; WHILE THE OTHER ORGANS REMAIN ASLEEP.

PARONIRIA, from *παρά* and *δρεῖρον*, signifies "depraved, disturbed, or morbid dreaming." So in Dioscorides (vol. ii., p. 127), *δυσδρεῖρος* signifies "tumultuous et malis somniis molestans."

In treating of the genus EPHALTES, or nightmare (Vol. i., Cl. I., Ord. II., Gen. V.), I endeavoured to explain its course and nature; and hereby pointed out the essential distinction which exists between that disease and the present, and the impropriety of uniting the species which be-

long to both of them under one head, as Dr. Cullen has done in his genus *oneirodynia*; since, with the exception of their occurring in the night, and during sleep, and therefore involuntarily, they have little or no connexion or resemblance, in cause, symptoms, or even mode of cure.

The three following species are so clearly and decidedly of one and the same family, as to prevent all dispute in their present position. They are here, however, associated for the first time in a genus distinct from ephialtes.

- | | |
|------------------------|------------------|
| 1. Paroniria Ambulans. | Sleep-walking |
| 2. ——— Loquens. | Sleep-talking. |
| 3. ——— Salax. | Night-pollution. |

The nature of these singular affections, and the means by which they are produced, have never yet been explained; and rarely, so far as I know, has any explanation been attempted. To understand them fully, it would be necessary for us to enter into a minute development of the physiology of sleep and dreaming, which the limits of the present work will not allow. On some future occasion, the author may perhaps follow it up into such a detail; but a few general remarks must suffice for the occasion before us.

In sleep, accompanied with dreaming, the faculties of the mind bear a pretty close parallel with those of the body, as to the effect produced upon them. Some of them, as the will, the perception, the judgment, are in a state of general torpidity, like the voluntary organs of the body; while the memory and the imagination, like the vital or involuntary organs of the body, are in as high activity as ever. Hence, the sensory is as much crowded with ideas as at any time; but, destitute of a controlling power, they rush forward with a very considerable degree of irregularity, and would do so with the most unshapeable confusion, but that the habit of association still retains some degree of influence, and produces some degree of consonance and proportion in the midst of the wildest and most extravagant vagaries. And hence that infinite variety which takes place in the character of our dreams; and the greater regularity of some, and the greater irregularity of others. Hence a combination of thoughts or ideas, sometimes only in a small degree incongruous, and at other times most frantic and heterogeneous; occasionally, indeed, so fearful and extravagant as to stimulate the external senses themselves into a sudden renewal of their functions, and consequently to break off abruptly the sleep into which they were thrown.

Now, as the stimulant force of our ideas in dreaming is often sufficient to rouse the external senses generally, and to awake us all of a sudden, it may be of such a kind, and just of such a strength, as to excite into their accustomed action the muscles of those organs or members only which are more immediately connected with the train of our dreams or incoherent thoughts, while every other organ may still remain torpid. And hence the muscles chiefly excited being those of speech, some persons

talk, or the muscles chiefly excited being those of locomotion, other persons walk in their sleep, without being conscious, on their waking, of any such occurrence.* And by the same means we may easily account for the third species of the genus, or that which consists in dormant and involuntary salacity.

SPECIES I.

PARONIRIA AMBULANS.

SOMNAMBULISM. SLEEP-WALKING.

THE MUSCLES OF LOCOMOTION EXCITED INTO THEIR ACCUSTOMED ACTION BY THE FORCE OF THE IMAGINATION DURING DREAMING.

In profound sleep, all the faculties of the mind, as well as all the voluntary organs of the body, are in a state of inactivity or torpitude, and the only organs that preserve their active tenour are the involuntary ones; so that, in this state, there is neither thought nor idea of any kind. In dreaming, some of the mental faculties only sleep or are torpid, while the others, like the involuntary organs of the body, continue wakeful or active: the somnolent faculties, we have already observed, are the will, the perception, and the judgment; the wakeful are the memory and the imagination.

It would not be difficult, if we had time, to show why the involuntary organs do not require rest, or, in other words, become torpid like the voluntary; nor why the will and the judgment sooner associate in the general sleep of the external senses than the imagination; but this would carry us too far into the subject of animal physiology. There are two physiological remarks, however, which it is necessary to make, in explanation of the morbid affection immediately before us. The first is, that sleep is a natural torpitude or inertness, induced upon the organs of the body (with the exception of the involuntary) and the faculties of the mind by fatigue and exhaustion. And the next is, that, in the production of sleep, it is not necessary that all these powers of body and mind should have been equally exposed to exhaustion: for such is the effect of association and habit, that as soon as one faculty or organ feels fatigue or becomes exhausted, the rest participate in the same condition, and the sleep or torpitude becomes common to the whole. It is hence the body is made drowsy by mental study, and the mind by corporeal labour; that muscular exercise wearies all the senses, and the exertion of the senses wearies the muscles: though there can be no doubt that the general tendency to sleep is also partly superinduced by the indirect exhaustion sustained by the organs or faculties that have been less employed, in consequence of the share of sensorial energy which, as from a common stock, they have themselves contributed towards the support of the more active and hence more debilitated powers.

* Hennings, von den Träumen und Nachtwandlern, Weimar, 1784. Horst, De Naturâ, Differentiis, et Causis eorum qui dormientes ambulant, &c., Lipsæ, 1593, 8vo.

Now it sometimes happens, either from disease or peculiarity of constitution, that all the external organs of sense do not associate in the general action that has taken place, or yield alike to the general torpor to which it gives rise; and that the auditory, the optical, or some other sense, continues awake or in vigour while all the rest are become inert; as it does also, that such particular sense, like the muscles of particular members, as observed a page or two above, is awakened or restimulated into action in the midst of the soundest sleep, by the peculiar force and bent of the dream, while the rest still sleep on and are unaffected.

If the external organ of sense thus stimulated be that of sight, the dreamer may perceive objects around him, and be able to distinguish them: and if the tenour of the dreaming ideas should as powerfully operate upon the muscles of locomotion, these also may be thrown into their accustomed state of action, and he may rise from his bed, and make his way to whatever place the drift of his dream may direct him, with perfect ease and free from danger. He will see more or less distinctly in proportion as the organ of sight is more or less awake: yet, from the increased exhaustion, and, of course, increased torpor of the other organs, in consequence of an increased demand of sensorial power from the common stock, to supply the action of the sense and muscles immediately engaged, every other sense will probably be thrown into a deeper sleep or torpor than if the whole had been quiescent. Hence, the ears may not be roused even by a sound that might otherwise awaken the sleeper. He may be insensible, not only to a slight touch, but a severe shaking of the limbs; and may even cough violently without being recalled from his dream. Having accomplished the object of his visionary pursuit he may safely return, even over the most dangerous precipices, for he sees them distinctly, to his bed; and the organ of sight being now quite exhausted, or there being no longer any occasion for its use, it may once more associate in the general inactivity, and the dream take a new turn, and consist of a new combination of images.*

* A remarkable instance of somnambulism occurred in 1833-4, at Springfield, Mass., in the person of Jane C. Rider, and was observed by Dr. L. W. Belden, of that town, from whose statement (An Account of Jane C. Rider, the Springfield Somnambulist, Springfield, 1834) we quote the following particulars:—The mother of Miss R. died suddenly of disease of the brain. The young lady, when these attacks commenced, was in her seventeenth year, and of a full habit. A small spot on the left side of her head has, from her earliest recollection, always been tender or painful on pressure, and much more so whenever she suffers from headache, with which she is occasionally affected. During the paroxysms of somnambulism, this spot is frequently the seat of intense agony. Her eyes are extremely sensible to the light.

The first paroxysm of somnambulism appeared in June, 1833; from this she was relieved by an emetic; in a month, however, she was again affected, and the paroxysms recurred at different

Somnambulism occurs in many persons without any manifest predisponent cause, though it is generally connected with a considerable irritability of habit. A morbid state of the stomach, where this habit exists, has very frequently proved an exciting cause; of which Dr. Yeates has given us an example in the case of a young gentleman of ten years of age.—(*Med. Trans.*, vol. v., art. xxviii., p. 444.) He was of a delicate frame, often troubled with sickness; sometimes ejected his food undigested, after having lain two days in his stomach: his bowels were costive, and the stools were dark, offensive, and ill formed. The sympathetic symptoms were frequent headaches, with occasional stupor, general coldness of the skin, and limpid urine. After being in bed for about two hours, he was wont to start up suddenly, as if in a fright, dart rapidly into the middle of the chamber, or of the room adjoining, and walk about with much agitation. In this state he would run over quickly, but incorrectly, the transactions of the day; and he once attempted to spell a word which in the daytime he had spelled wrong, in doing which he jumbled a number of letters together. When spoken to he would make a rational re-

intervals until February, 1834. From the 6th to the 13th of December she had from one to three paroxysms daily. "At first they occurred only in the night; and generally soon after she went to bed. As the disease advanced, they commenced earlier; she then fell asleep, or rather passed into the state of somnambulism in the evening, sitting in her chair. At a still later period, the attacks took place at any hour during the day or evening. After she began to be affected in the daytime, the fit seldom commenced when she was in bed. The duration of the fits varied from a few minutes to forty-eight hours.

"The state of somnambulism was usually preceded by a full, heavy, unpleasant feeling in the head; sometimes by headache, ringing in the ears, cold extremities, and drowsiness. To a spectator she seemed as if going to sleep; the respirations became long and deep; her attitude and the motions of her head resembled those of a person in a profound slumber. During the fit, the breathing, though sometimes natural, was often hurried, and attended with a peculiar moan. The pulse was at times accelerated, but generally it did not vary much from the natural standard. Occasionally the whole system was thrown into violent agitation, and she appeared like a person in hysterics. The eyes were generally closed, but at times they were open, and the pupil was then considerably dilated. These different states of the eye seemed to occasion no difference in the power of seeing—she saw apparently as well when they were closed as she did when they were open. All attempts to rouse her during a paroxysm were unsuccessful. She heard, felt, and saw; but the impressions she received through the senses had no tendency to waken her.

"At the termination of a paroxysm she sunk into a profound sleep. The frown disappeared from her brow; the respirations again became long and deep; she soon began to gape and rub her eyes; and in fifteen or twenty minutes from the first appearance of these symptoms she opened her eyes, and recollection was at once restored.

"Her manner differed exceedingly in different

ply; and, in one of his sleeping perambulations, he called for an epitome of the History of England, which he was in the habit of reading. The nurse brought him a book, but not the one he called for: on perceiving the difference he immediately threw it from him with great violence, and with expressions of anger and disappointment. On these occasions his eyes were wide open, though he did not seem conscious of seeing, nor of his situation at the time. It was, says Dr. Yeates, a perfect state of dream throughout, though partaking of the acts of the waking state, for he would avoid objects walking about the room. His face was quite pallid at the time.

In this case, much of the nervous hurry and agitation seems to have depended upon the debilitated and irritable state of the patient's frame. But where the affection proceeds from idiosyncrasy, or where there is no disturbance of the general health, the dreamer often proceeds far more coolly and collectedly; and the eyes, instead of being wide open, as though staring, are often not more than half unclosed, in some cases even less than this; which has given occasion to marvellous stories of somnambulists walking over dangerous places, or avoiding dan-

paroxysms; sometimes she engaged in her usual occupations, and then her motions were remarkably quick and impetuous—she moved with astonishing quickness, and accomplished whatever she attempted with unusual celerity. She attended to her domestic occupations, and was sometimes employed in sewing, reading, writing, &c. In the intervals of reading or talking, and even when thus engaged, her nods, her expression of countenance, and her apparent insensibility to surrounding objects, forced on the mind the conviction that she was asleep. Occasionally she was cheerful, but generally she was petulant and irritable. How far she was sensible to the presence of surrounding objects, it is very difficult to determine. Indeed, facts seem to prove that she was not in every paroxysm alike in this respect. In the early stage of her complaint she appeared to take little notice of persons unless they were connected with her train of thought; but at a later period she seemed more of what transpired in her presence. She recollected during a paroxysm circumstances which occurred in a former attack, though there was no remembrance of them in the interval. She occasionally imitated the manners, language, and sentiments of those around her with great fidelity; though in her natural state she had no imitative powers, and could even sing accurately and agreeably, although when in health she can do neither."

The most remarkable feature, however, of this curious case, was the extraordinary power of vision attending the earlier paroxysms. Although her eyes were carefully covered by a white handkerchief folded so as to make eight or ten thicknesses, and the spaces below the bandage filled with strips of black velvet, yet she read, played backgammon, gave answers as to the colours of different objects presented to her, &c., &c., with the utmost precision. She took a pencil, and while rocking in a chair wrote her own name, each word separately, and dotted the *i*.

In this case the disease evidently depended on a derangement of the digestive organs, and was cured by appropriate remedies.—D.

gerous objects, with their eyes completely shut all the time.*

The remedial treatment which it may be necessary to pursue we shall defer till we have briefly noticed the succeeding species, as the same treatment will apply to the whole.

SPECIES II. PARONIRIA LOQUENS. SLEEP-TALKING.

THE MUSCLES OF SPEECH EXCITED INTO THEIR
ACCUSTOMED ACTION BY THE FORCE OF THE
IMAGINATION DURING DREAMING.

It is not necessary to dwell upon this species, as we have already explained the general principles of the inordinate action in the preceding pages. As the train of ideas which form the dream, when peculiarly lively and immediately connected with the organs of locomotion, may stimulate those organs into their accustomed activity, and thus give the dreamer a power of walking without consciousness; in like manner, if a similar train of dreaming ideas be immediately connected with the organs of speech, these may also be equally influenced, and the dreamer be able to talk without being conscious of it, or having any recollection of such exertion when he awakes. And as, for reasons already specified, the organ of sight is sometimes in the same way roused from a state of sleep or torpitude to a state of wakefulness, while all the other external senses continue somnolent, or from idiosyncrasy, or some local or accidental cause, do not join in the general repose, but continue vigilant during its dominion, the organ of hearing may be roused in the same manner, or exhibit the same anomaly; and in this case the dreamer, who, under the influence of the last species of affection, is able to see as well as to walk, is able, under the present, to hear as well as to speak.† Examples, in-

* It seems to Dr. Uwins, that the phenomena characterizing that remarkable condition of the brain and nerves which leads to sleep-walking, might be adduced in favour of the principle that one series of organs may be active while another is dormant. It is well known, says he, that the perceptions are so exceedingly acute in sleep-walkers as to enable them to pass over narrow bridges, &c., the contemplation of which they have shuddered at when awake. "Is not this superior adroitness referrible to the suspended agency of other parts of the brain, rather than to a positive augmentation of power in the parts in exercise? And is not this the pivot or main-spring upon which aberration turns and depends? Wake a sleep-walker, and he is immediately alive to his danger; prove to a maniac the untenable nature of his assumptions, and he is directly conscious of, or awake to, all his insane wanderings."—Dr. Uwins on those Disorders of the Brain and Nervous System usually called mental, p. 31, 8vo., London, 1833.—Ed.

† Dreaming seems to Dr. Uwins to differ from the condition of actual madness, inasmuch as there are in it no correctives against aberration from the senses: "when these are called into exercise, all the lofty conceits and wild combinations

deed, are given, in which a by-stander, obtaining some clew into the train of thoughts of which the dream is composed, has been able not only to keep up an irregular conversation, but, by dexterous management, and the artful assumption of a character which he finds introduced into the dream, to draw from the dreamer the profoundest secrets of his bosom, the dreaming ideas generally consisting of those on which the dreamer is most employed when awake, or which lie nearest his heart. I have never met with a case of this kind in my own practice, but it is given as a fact by various physiologists from the time of the Greeks and Romans to our own day.*

SPECIES III. PARONIRIA SALAX. NIGHT POLLUTION

THE SEXUAL ORGANS EXCITED INTO VENEREAL
ACTION BY THE FORCE OF THE IMAGINATION
DURING DREAMING.

By Sauvages this affection is absurdly placed among the species of gonorrhœa, which, with great looseness of generic character, is defined "*passio, cujus præcipuum symptoma est fluidi puriformis vel seminiformis effluxus stillatitius ex urethrâ.*" This definition is, indeed, wide enough to embrace the affection before us; but the absurdity consists in intermixing a natural discharge, produced by the ordinary orgasm, with morbid discharges, in which, in most cases, there is no orgasm whatever. Dr. Cullen, however, has continued to assign the same place and the same name to the present species, and this with still greater inconsistency: since he has struck out of his definition of gonorrhœa the epithet *seminiformis*, and confined it to a "*fluxus humoris ex urethrâ præter naturam.*" So that he has been obliged to break his own bounds, to introduce this natural flux into the place he has allotted it. And hence, in laying down the treatment of gonorrhœa in his Practice of Physic, he takes no notice of his gonorrhœa *dormientium*, as though feeling that it was altogether a different subject.

We have already observed, that whatever part of the animal frame is immediately connected with the tenour of the somnolent vision, it is often roused, under particular circumstances, from the general sleep or torpitude in which it had participated, and becomes wakeful, while every other part perseveres in the common repose. During sleep, moreover, our ideas are often more lively and operative than during

of the dreamer are in a moment over; while they continue in the mad, despite of the sensual information; nay, the workings of the brain seem occasionally to change these sensual guards against aberration into actual ministers of misconception."—On Dis. of the Brain, &c., p. 31.—Ed.

* The lectures on moral philosophy of Dr. Samuel S. Smith, the late president of Princeton College, contain many valuable remarks on the causes of the morbid phenomena adverted to by Dr. Good when treating of paroniria.—See likewise the ingenious work of MacNish on sleep.—D.

wakefulness, and this on two accounts; first, because from the uninterrupted activity of the involuntary organs, there is a more ready secretion of sensorial as well as of most other fluids in a state of perfect tranquillity; and next, because the ideas that predominate at the time are not broken in upon or weakened by exterior impressions and disturbances. It is on this account, when the faculty of the judgment is stimulated into activity instead of the ear or eye, or the motory powers, a man has sometimes been able to solve difficulties in dreaming which proved too hard for him when vigilant. And to this effect Dr. Spurzheim: "Somnambulists," says he, "even do things of which they are not capable in a state of watching; and some dreaming persons reason sometimes better than they do when awake."—(*Physiognomical System*, p. 175, 8vo., Lond., 1815.) A singular and amusing instance of this occurred not many years ago to a very excellent and justly celebrated friend of the author's, the Reverend William Jones, of Nayland, Suffolk, who, among other branches of science, had deeply cultivated that of music, to which, indeed, he was passionately attached. He was a man of irritable temperament, ardent mind, and most active and brilliant imagination; and was hence prepared by nature for energetic and vivid ideas in his dreams. On one occasion during his sleep he composed a very beautiful little ode of about six stanzas, and set the same to very agreeable music; the impression of which was so firmly fixed in his memory, that, on rising in the morning, he sat down and copied from his recollection both the music and the poetry.

It is hence not difficult to conceive, that members so irritable as the sexual organs, when once the imagination leads energetically to the subject of concupiscence, should occasionally participate in the vision and prove their sympathy by the result.

In some morbid states of the body, and especially when accompanied with local irritation, produced by inflammation, fibrous entony, the debility of old age, or a habit of vicious indulgence, a seminal flux has sometimes taken place without any connexion with the dream, and sometimes without either erection or turgescence; but this does not constitute the affection immediately before us; in which the stimulant power lies in the sensory, and is propagated from that organ to those of generation.

The Roman poet, who so admirably unlocked the NATURE OF THINGS to his contemporaries by following the footsteps of nature herself into most of her deepest recesses, directed his attention to this subject, among other physiological facts, and has elegantly explained it in the above manner; adducing at the same time another instance of the influence which the ideas of dreaming sometimes exercise over the organs connected with them, derived from the evacuation of the bladder, which frequently takes place in children, whose dream is directed to this natural want, and who image to themselves the ordinary vessel employed for such purpose as at hand for their use (*De Rer. Nat.*, iv., 1020):—

"Pueri sæpe, lacum propter, seu dolia curta,
Somno devincti, credunt se extollere vestem;
Totius humorem saccatum corporis fundunt;
Quom Babylonica, magnifico splendore, rigan-
tur.

Tum, quibus ætatis freta primitus insinuantur,
Semen ubi ipsa dies membris matura creavit,
Conveniunt simulacra foris e corpore quoque,
Nuncia præclari voltus, pulchrique coloris,
Qui ciet irritans loca turgida semine multo,
Ut, quasi transactis sæpe omnibus rebus, profun-
dant,
Fluminis ingenteis fluctus, vestemque cruen-
tent."

In the medical treatment of all these species of paroniria we must never lose sight of this principle, that although in many instances their predisponent cause is a peculiar idiosyncrasy or habit, their exciting cause is in all cases general or local irritation; and that this irritation is of two very opposite kinds, which it also becomes us very particularly to attend to, namely, that of entony, or excess of power, and that of atony, or deficiency.

It is to the former that Lucretius alludes, and which is by far the most common exciting cause; and where this exists, our first indication is to reduce the superabundant vigour by venesection, purgatives, laborious exercise, and a limitation to a plain and spare diet. While, on the contrary, where the exciting cause is debility, our attention should be directed to a tonic course of medicines, and particularly to those tonics which prove sedative at the same time that they strengthen the system. Several of the mineral acids are entitled to this character, and especially the sulphuric; and a still greater number of the vegetable bitters, and particularly the extracts of hop and lettuce. Dr. Cullen, indeed, as we have already observed, supposes a sedative power to exist in all the bitters, though not equally in all. How far the prussic acid might be usefully employed for this purpose, I cannot say from personal practice.

Our next object of attention should be to prevent all undue accumulation of the sensorial principle during sleep; and this may be accomplished in two very distinct and opposite ways. The first is the use of a hard mattress, with so small a covering of clothing that the sleep may be somewhat less sound than ordinary, and consequently more easily broken off. For the force of our dreaming ideas will always be in proportion to a certain degree of soundness in our sleep; I say a certain degree; because if the fatigue, or exhaustion, or torpitude be extreme, the sleep will become profound or lethargic, all the faculties of the mind will participate in it, and, as already observed, there will be no ideas or dreaming whatever.

And hence the second mode of preventing an accumulation of sensorial and especially of irritable power will be the employment of narcotics till the morbid habit is destroyed; for these, when carried to a sufficient extent, diminish vascular action, and consequently take off sense and motion so completely as to extinguish the vital principle altogether; and hence not only to suppress all power of dreaming, but even life itself.

I had lately under my care, for the last species, a very modest and regular young man, who was a student of Christ's College, Cambridge; and was alarmed at the idea of having his constitution undermined by its continuance. He was rapidly growing, of slender make, and of a relaxed habit. Nitre, which has been so often recommended as a sedative, in this case did no service; but, under the use of a pill composed of one grain of opium and five of camphire, taken nightly, and draughts of myrrh and infusion of columbo acidulated with sulphuric acid, he lost the tendency in a fortnight, after having been subject to the discharge for many weeks. His bowels were kept at the same time constantly stimulated by the pill of aloes and myrrh, and the cold bath formed a part of his regimen. Pagini and De Cazelles (*Journ. de Médecine*, tom. lxxiv.) have recommended electricity; but the author has never tried its effects, having uniformly succeeded without it.*

Where either of these species, but particularly the two former, are connected with a morbid state of the stomach, the disease must be attacked in this quarter; as it was with great judgment and a favourable issue in the case quoted from Dr. Yeates.

GENUS VI

MORIA.

FATUITY.

DEFECT OR HEBETUDE OF THE UNDERSTANDING.

MORIA is a Greek term, from *μῶρος*, "stultus, fatuus." It is here limited to its proper signification. Vogel employs it, though with a different termination (*morosis* instead of *mória*), in the same or very nearly the same sense; but he is almost the only medical writer that does so. By Nenter and Sauvages, *mória* is used to denote *melancholia complacens* (self-complacent melancholy), while by others it is employed synonymously with *aneæ* or *idiotism*. To complete the confusion, *morosis* (*amentia morosis*) is the name given by Sauvages to mental imbecility (*mória imbecillis*), though, as already observed, he had just before used *mória* in the sense of melancholy. It is precisely in the signification now offered, that the term is employed by Erasmus in his celebrated treatise entitled "*Moria Encomium*," or "The Praise of Folly," which he dedicated to Sir Thomas More.

Mora, *moror*, *morosus*, *morositas*, are derived from this common source; and uniformly import "waywardness, tardiness, dulness, impediment;" though the lexicographers, not having hit upon the right path, have wandered in different directions without being able to satisfy themselves. In Sauvages and Sagar *morositates* are

* In the entonic state of *paroniria salax*, we are often obliged to employ the usual antiphlogistic remedies. When it depends on an opposite condition, which is more frequently the case, we rely on bark, iron, chalybeate waters, country air, and agreeable society. Blisters to the perineum are often serviceable, and so too with cold hip-baths. Opium, tobacco, and other narcotics are thought by some to possess an anti-aphrodisiac power.—D.

in fact "*corporea moria*," defects or hebetudes of the bodily faculties.

The preceding genera are founded upon a morbid perversion or misrule, a diminished or excessive excitement, of one or more of the powers of the mind, operating upon the mind itself or upon the body. The present is founded upon a natural or permanent dulness or hebetude of one or more of the same powers, producing a deficiency in the understanding, which, however, may be regarded as the general frame or constitution of the mind, in the same manner as the body is the general frame or constitution of the organs which form its separate parts. *Mória*, thus explained, will be found, as a genus, to embrace the two following species:—

1. *Mória Imbecillis*. Imbecility.
2. ——— *Demens*. Irrationality.

SPECIES I.

MORIA IMBECILLIS.

MENTAL IMBECILITY.

THE DEFECT OR HEBETUDE PARTIAL, OR CONFINED TO PARTICULAR FACULTIES OF THE UNDERSTANDING.

We have already observed that all the faculties of the mind are as subject to a diseased disturbance as the organs of the body; and hence all of them are liable to be affected by the present species. The whole of the varieties, therefore, under which mental imbecility is capable of being contemplated, might form an extensive list: but it will be sufficient to confine ourselves to the four following:—

- α *Stupiditas*. Dulness and indolence of the apprehension; torpidity and poverty of the imagination.
- β *Amnesia*. Feebleness or failure of the memory.
- γ *Credulitas*. Weakness and undue pliancy of the judgment, with a facility of being duped.
- δ *Inconstantia*. Instability and irresolution of the will.

In STUPIDITY, there is generally a dulness in several of the faculties besides the apprehension and the imagination; and sometimes, perhaps, in all of them: but then it originates in these, and the rest are for the most part only secondarily dull, as not being furnished with a sufficient number of ideas, or in sufficient rapidity for their use. Thus the judgment of a heavy or stupid man is often as sound in itself as that of a man of capacious comprehension; and more so, perhaps, for a reason we have already observed under *alusia facetosa*, or crack-brained wit, than that of a man of facetious quickness of parts: but the heavy man requires time and patience to collect his ideas, and compare them with each other; for they are neither furnished to him in a free current from his memory or his imagination, nor does he readily apprehend or lay hold of them as they are offered from external objects to his perception, which, in effect, is little more than a synonyme for the apprehension—the ap-

prehension being the perception in a state of exercise or exertion. There is hence a material difference in physiology, though perhaps little in practice, between ignorance and stupidity. The former is want of knowledge from want of its ordinary means; and by the use of such means may perhaps soon be gotten the better of: the latter is dulness in the use of such knowledge as by ordinary means has been acquired, and exists in the sensory, though in a state of stagnation or dormancy. Mr. Locke has made the same distinction, though he has justly enough observed, that for all practical purposes, the man of stupidity had almost as well be without his knowledge as with it. "He," says this admirable writer, "who, through this default in his memory, has not the ideas that are really preserved there ready at hand when need and occasion call for them, were almost as good be without them quite, since they serve him to little purpose. The dull man, who loses the opportunity while he is seeking in his mind for those ideas that should serve his turn, is not much more happy in his knowledge than one that is perfectly ignorant. It is the business of the memory to furnish those ideas which it has present occasion for; and in the having them ready at hand on all occasions, consists that which we call invention, fancy, and quickness of parts."—(*Essay concerning Hum. Underst.*, b. ii., ch. x., sec. 8.)*

Stupidity or dulness of apprehension may be idiopathic; but it may also proceed from want of education, or education irregularly conducted; for all the faculties of the mind, like the muscles of the body, become invigorated and are rendered more alert by a well-disciplined exercise. And hence stupidity is a natural result of idleness; as it is more particularly of idleness in conjunction with an undue use of wine and fermented liquors, which have a proverbial power of besotting the understanding. It is also produced temporarily or habitually by various corporeal diseases; as hemicrania, chronic inflammation or dropsy of the head, gout in the head, and sometimes repelled cutaneous eruptions or habitual discharges.

Stupidity, like wit, is propagable; and hence we frequently see it run from one generation to another; and not unfrequently it forms a distinctive mark in the mental character of districts or nations: in many cases, indeed, where they border closely on each other. The Dutch have at least as much solid sense as their neighbours, the French; but they are certainly less quick, or, in other words, they have a duller fancy and apprehension. Bœotia, in respect to chorography, was merely separated from Attica by Mount Cithæron; but in respect to genius, the two countries were as far apart as the poles. So, in the Pacific Ocean, the natives of Otaheite

learn every thing with facility; the natives of New South Wales have no aptitude, and learn nothing. The residence of a few missionaries among them for a short term of years has nearly civilized the former: the actual possession of the country for a far longer period by a British public and a British government, with a perpetual intercourse and the kindest encouragement, has made little or no impression upon the latter.

A FAILURE OF MEMORY, however, which forms the SECOND SPECIES of mental imbecility before us, is a far more severe evil than dulness of perception with poverty of imagination; for as all the sources of information to which we have been privy cannot be always immediately before us to excite the perception, we must necessarily draw upon our recollection for those which are not so, and whose ideas or impressions we stand in need of. And hence the memory is the great storehouse of intelligence; and in one sense at least the Platonic doctrine is universally true, that "all knowledge is reminiscence." There are some minds in whom this faculty has been peculiarly retentive, as that of Newton, who made it answer the purpose of intuition; and of Pascal, who is said never to have forgotten, till his health failed him, any thing he had ever done, read, or thought of.*

Retention of memory, however, is a different property from that of quickness. They may and often do co-exist, but they are also found separate; for there are many persons who can well catch hold of an entire song, an entire sermon, or a series of speeches in parliament, and can recite them almost, if not altogether, verbatim immediately afterward, but who lose all recollection of them in a day or two; while there are others who are obliged to pause over the subject submitted to them, or to have it repeated for several times before they can get it by heart, yet who, when they have once fixed it in the memory, retain it as long as they live. Mr. W. Woodfall, the celebrated reporter of the parliamentary debates, was an instance of the former of these talents in regard to his powers of apprehension; the well-known Jedediah Buxton of the latter; though it should be remarked, that Mr. Woodfall retained with as much ease as he first fixed speeches in his memory.

Failure of memory takes place in a variety of ways.† It is sometimes general, and extends to every subject; but it is frequently far more

* Actors, who are compelled by their professional pursuits to cultivate the memory, often present remarkable examples of the powers of apprehension and retention of this mental faculty. Hodgkinson, a celebrated comedian, was able, by three or four readings, to recite the contents of a newspaper without error. The distinguished Dr. S. L. Mitchill could repeat, in earlier life, an entire sermon which he had heard a few hours previously.—D.

† The curious case related by Major Elliot of West Point, N. Y., merits attention:—

"The patient was a young lady of cultivated mind, and the affection began with an attack of somnolency, which was protracted several hours beyond the usual time. When she came out of it, she was found to have lost every kind of acquired

* As stupidity sometimes depends on mechanical causes, so, too, after the operation of the same causes in stupid persons, the mind sometimes manifests more energy. The celebrated Père Mabillon was considered as stupid till a tile fell upon his head: he then began to display great abilities.—D.

manifest on some subjects than on others. Sal-muth mentions a case in which the affected person had forgotten to pronounce words, but could nevertheless write them.—(Cent. ii., obs. 41.) Mr. J. Hunter was suddenly attacked with a singular affection of this kind in December, 1789, when on a visit to the house of a friend in town. "He did not know in what part of the house he was, nor even the name of the street when told it, nor where his own house was: he had not a conception of any thing existing beyond the room he was in, and yet was perfectly conscious of the loss of memory. He was sensible of impressions of all kinds from the senses, and therefore looked out of the window, although rather dark, to see if he could be made sensible of the situation of the house. The loss of memory gradually went off, and in less than half an hour his memory was perfectly recovered."—(Sir Eeerard Home's *Life*, prefixed to his *Treatise on the Blood, Inflammation, &c.*, 4to., 1794.) This might possibly be connected with a gouty habit, to which Mr. Hunter was subject, though not at this time labouring under a paroxysm. The late bishop of Landaff, Dr. Watson, gives a singular case of partial amnesia in his father, the result of an apoplectic attack. "I have heard him ask twenty times a day," says Dr. Watson, "'What is the name of the lad that is at college?' (my elder brother); and yet he was able to repeat, without a blunder, hundreds of lines out of classic authors."—(*Anecdotes of the Life of Richard Watson*, D. D., Bishop of Landaff.) And hence there is no reason for discrediting the story of a German statesman, a Mr. Von B., related in the seventh volume of the *Psychological Magazine*, who, having called at a gentleman's house, the servants of which did not know him, was under the necessity of giving in his name; but unfortunately at that moment he had forgotten it, and excited no small degree of laughter by turning round to a friend who accompanied him, and saying, with great earnestness, "Pray tell me who I am, for I cannot recollect."*

knowledge. She immediately began to apply herself to the first elements of education, and was making considerable progress, when, after several months, she was seized with a second fit of somnolency. She was now at once restored to all the knowledge which she possessed before the first attack, and without the least recollection of any thing that had taken place during the interval. After another interval she had a third attack of somnolency, which left her in the same state as after the first. In this manner she suffered these alternate conditions for four years, with the very remarkable circumstance that during one state she retained all her original knowledge, but during the other that only which she had acquired since the first attack. During the healthy interval, for instance, she was remarkable for the beauty of her penmanship; but during the paroxysm wrote a poor, awkward hand. Persons introduced to her during the paroxysm, she recognised only in a subsequent paroxysm, and not in the interval; and persons whom she had seen for the first time during the healthy interval, she did not recognise during the attack."—D.

* The late Hon. Thomas Law of Washington

From severe suffering of the head in many fevers, a great inroad is frequently made upon the memory, and it is long before the convalescent can rightly put together all the ideas of his past life. Such was one of the effects of the plague at Athens, as we learn from Thucydides: τοὺς δὲ καὶ λήθη ἐλάβανε παραυτίκα ἀναστάντας τῶν πάντων ὁμοίως καὶ ἠγνόησαν σφᾶς τε αὐτοὺς, καὶ τοὺς ἐπιτηδείους: "and many, on recovery, still experienced such an extraordinary oblivion of all things, that they knew neither themselves nor their friends." A few years ago a man with a brain-fever was taken into St. Thomas's Hospital, who, as he grew better, spoke to his attendants, but in a language they did not understand. A Welsh milk-woman, going by accident into the ward, heard him, answered him, and conversed with him. It was then found that the patient was by birth a Welshman; but had left his native land in his youth, forgotten his native dialect, and used English for the last thirty years. Yet, in consequence of this fever, he had forgotten the English tongue, and suddenly recovered the Welsh.*

Boerhaave, however, gives a still more extraordinary instance of oblivion in the case of a Spanish tragic author, who had composed many excellent pieces, but so completely lost his memory in consequence of an acute fever, that he forgot not only the languages he had formerly learned, but even the alphabet; and was hence under the necessity of beginning to read again. His own poems and compositions were shown to him, but he could not be persuaded that they were his production. Afterward, however, he began once more to compose verses, which had so striking a resemblance to his former writings, that he at length became convinced of his being the author of them.†

city, the brother of Lord Ellenborough, was a remarkable instance of this peculiarity. He frequently was unable to give his name when calling at the postoffice for letters: yet on other occasions, as in respect to past events and on business of importance, his powers of memory were strong and acute.—D.

* In a case occurring under the notice of Dr. John Ware of Boston, where the patient had suffered excessively from sea-sickness, the memory of recent events was entirely lost. The gentleman could recollect distinctly what had occurred several years before, but retained no trace whatever of what had happened a few months previous to his illness.—See *Am. Journal of Med., Sc. &c.*, vol. v., p. 379.—D.

† *Prælect. Acad. in Instit. Med. ex edit. Haller*, tom. iv., p. 463. See also *Crichton of Ment. Derangement*, i., 370. Dr. Uwins considers the very condition of madness as implying some sort of forgetfulness, or forgetfulness of something, which, were memory to recall, the hallucination would be over. "Both in actual dreams and in the day-dreams of madness, we bring together into one point of time the most extravagant *alibis*, and join in conversation with those who have paid nature's great debt many years before. The portions of the brain implicated, if they tell us nothing but the truth, but at the same time do not tell us the whole truth, lead to all these misconceptions as to time, and place, and circumstance. *How* they do this, and *how* they leave that undone, constitutes the

The memory may also be prematurely impaired (for in age it is a natural defect)* by various other causes. Idleness or inattention will do it, as in the case of stupidity, as will also an over-exertion of the faculty, injuries of the head, rheumatic or gouty pains in it, dyspeptic maladies, various narcotic poisons, prostrating hemorrhages or want of food, and libidinous indulgence.—(*Dissert. de Memoria Læsione ex nimis Vener. Usu, Alt.*, 1695.)

Dependant upon this last cause, Sir Alexander Crichton has given a single example of what may be called perverse oblivion in an old attorney, nearly seventy years of age, who, though married to a lady much younger than himself, kept a mistress, whom he visited every night. He was suddenly seized with great prostration of strength, giddiness, and forgetfulness; but the last was of a peculiar kind, and consisted in the mistaking the name of one thing for that of another; so that, if he wanted bread, he would ask for his boots; and though enraged at the latter being brought to him, he would still call out for his boots or shoes. In like manner, if he wanted a tumbler to drink out of, it was a thousand to one but he would call for the ordinary chamber utensil; or, if this were wanted, he would call for a tumbler or a dish. This gentleman, however, was cured of the complaint by large doses of valerian and other cardiacs.

In CREDULITY, constituting the THIRD VARIETY of the imbecility before us, the faculty of the judgment is the chief seat of disorder. It is unquestionably more generally to be found among ignorant people, than those whose minds are well stored with the elements of knowledge; but as we also frequently perceive among the former a most obstinate and wilful incredulity, and among the latter extraordinary proofs of the present failing, it cannot be regarded as altogether an effect of a general want of ideas: it is in reality a hebetude or indolence of the judgment or power of ratiocination, which induces a man to take things upon trust, and allow others to think for him, not for want of ideas, but for want of comparing one idea with another, those of probability with those of improbability, and fairly striking the balance; in consequence of which, under the influence of this mental osci-

tancy, he readily yields himself, body and soul, to the opinions of others, and follows such opinions blindfold: as those who shut their eyes must be led by those who see, or else fall into the ditch.

This is voluntary credulity; yet many have been so long accustomed to it that it has all the effect of a chronic disease, and is as difficult of cure as the most obstinate. There are some men, however, whose judgment is more morbidly dull by nature than from inactivity or a neglected education; or may possibly have been rendered so by intemperance; who are deficient in natural skill to use the evidence they possess of probabilities: and being incapable of carrying on a train of consequences in their heads, and of weighing exactly the preponderance of contrary proofs and testimonies, are easily misled, and rendered the dupes of every plausible sophist, and the playthings of every impostor. "There are some men," says Mr. Locke, "of one, some but of two syllogisms, and no more; and others that can but advance one step further. These cannot always discern that side on which the strongest proofs lie; cannot constantly follow that which in itself is the more probable opinion."—(*Human Understand.*, book iv., ch. xix., § 5.)

There is another imbecility we have noticed, as strangely interfering with the integrity of the understanding: and that is FICKLENESS, or an instability and irresolution of the will. The faculty of the will requires not only to be directed aright in infant life, but to be fortified and strengthened by a course of exercise and discipline as much as any faculty whatever. This we may say as physiologists; but as moralists we may speak a bolder language, and maintain that it demands the spur and trammels of education even more than all the other faculties put together, since it is designed by nature to be the governing power, and to exercise an absolute sway over the rest, even over the desire itself, by which, however, it is moved in all ordinary cases.

A child whose inclinations have never been reined in is perpetually letting the will and the desire run together, and changing both every moment; and if this disposition be suffered to grow into a habit, it will produce the fickleness of which we are now speaking, and form a character on which there can be no reliance; whose determination of to-morrow cannot be known from that of to-day: because the will itself, void of all firmness or resolution, is the sport of every transient incident, every interposing uneasiness or pleasure; and which hence becomes its own torment still more than the torment of those around it; since, being ever instigated by the feelings of the moment, and sacrificing the future to the present, it often purchases a fleeting gratification, and of subordinate value, at an expense of permanent and substantial happiness.

Upon the REMEDIAL PROCESS for the mental infirmities which appertain to this species, little is to be said in a work of medical instruction. So far as they relate to corporeal causes, and we have pointed out various causes of this kind

great and still unsolved problem in mental philosophy."—*Uwens on Mental Disorders*, p. 44.—Ed.

* The impairment produced by age is not so much insanity as imbecility or fatuity: the memory fails, but it only fails with the other mental powers. "Musicians have told me," says Dr. Conolly, "that as they became old, they found they could not play the music learned in later years without having the music before them; but could still go through long compositions learned in early life without the book, and without the mistake of a note. The susceptibility to sensations and emotions is diminished; the attention is less excited by them; they make a weak and fading impression on the memory. Those things which yet excite more attention are better remembered, even in old age. Old men, Cicero remarks (*De Senect.*), do not commonly forget where they have deposited their money."—See *Inquiries concerning the Indications of Insanity*, p. 282.—Ed.

applicable to several of them, those causes should be minutely inquired into, and, as far as possible, removed or palliated; and whatever will tend to invigorate the entire frame, as the metallic tonics, regularity of diet, sleep, exercise, and above all, cold bathing, must supply the rest. To the arms of mental and moral instruction, however, the sickly understanding must be chiefly intrusted; and where these are properly applied, the mind may often be rendered sufficiently sound for all the ordinary purposes of life, and even for some of its elegances; though it may never be distinguished for terseness, brilliancy, or comprehension. The leading aim should be to lay hold of the strongest faculty, and to make the direct cultivation of this an indirect cultivation of the rest.

SPECIES II.

MORIA DEMENS.

WITLESSNESS. IRRATIONALITY.

DEFECT OR HEBETUDE OF ALL THE FACULTIES OF THE UNDERSTANDING.

Of this species we have three varieties that seem to require a distinct notice:—

- | | | |
|---|---|--|
| a | Stultitia.
Silliness.
Folly. | Shallow knowledge, vacant countenance, light frivolous fancy; for the most part with good-nature; sometimes with obstinacy. |
| β | Lerema.
Dotage. Su-
perannuation. | Impotence of body as well as of mind, from premature old age; childish desires and pursuits; drawling speech or garrulous babble, composed of ideas for the most part associated by previous habit. |
| γ | Anœa.
Idiotism. | General obliteration of the mental powers and affections; paucity or destitution of ideas; obtuse sensibility; vacant countenance; imperfect or broken articulation; with occasionally transient and unmeaning gusts of passion. |

The difference between the understanding of some men and that of others is extreme; yet it is not every minute variation from the standard of soundness that constitutes a disease, whether in mind or body: but as soon as in either case such variation becomes a marked or serious evil, it is entitled to this name; and, in the subject before us, falls within the range of the first of the preceding varieties.

This, which is what we ordinarily denominate *SILLINESS*, is generally a natural infirmity, and in some families appears to be hereditary. A well-directed education, however, may do much, as there is commonly some faculty that will bear cultivating better than the rest, and which points to the particular line to which the study of the individual should be especially addressed, and in which he may appear respectable. He may have imitative powers, and make a good painter

or engraver, though he may not have creative powers, and make a good orator or poet. He may be fond of arithmetic, and fitted for trade and accounts, though he may not possess a taste for scientific subtleties, or be well calculated for any one of the professions.

DOTAGE, when a mere result of old age, is hardly to be regarded as a disease, and is rarely accompanied by any effervescence of the passions. But it often appears prematurely,* and is especially accelerated by excessive indulgence in corporeal pleasures; sometimes by violent mental emotion, as anger, or by long-continued grief. Under the two former of these causes, there is often combined with it an incessant garrulity, a very high degree of passionate but unmeaning effervescence and puerile mobility. M. Pinel gives a striking example of this in a person whom he had frequently an opportunity of seeing. "His motions," says he, "his ideas, his broken sentences, his confused and momentary glimpses of mental feeling, appeared to present a perfect image of chaos. He came up to me, looked at me, and overwhelmed me with a torrent of words without order or connexion. In a moment he turned to another person, whom, in rotation, he deafened with his unmeaning babble, or threatened with an evanescent look of anger; but as incapable of determined and continued excitement of the feelings as of a just connexion of ideas, his emotions were the effect of a momentary effervescence, which was immediately succeeded by a calm. If he went into a room, he quickly displaced or overturned the furniture, without manifesting any direct intention. Scarcely could one look off before he would be at a considerable distance, exercising his versatile fondness for bustle in some other way. He was quiet only when food was presented to him. Even at night he rested but for a few moments." A strong desire of food, however, is by no means common under this species: it is perhaps most frequently met with in the dotage of old age; but in premature *lerema*, we often find the appetite entirely banished, and a resistance to food of all kinds when offered.

IDOTISM, the THIRD VARIETY, is often the result, as we have already observed, of an original misformation of the cranium, sometimes in respect to thickness, more frequently in respect to shape; by both which the internal cavity, and

* Much difference is observed in different individuals, with respect to the period of life at which the mental faculties acquire their ultimate degree of power, and at which they begin to decline. Some men attain that prudence at twenty, which others, with equal advantages of precept and example, do not acquire in less than ten years after that age. If the youthful temperament remain beyond the age of thirty-five, Dr. Conolly believes that the mind never acquires much intellectual power. In some instances, the mind, after displaying considerable powers, has seemed to become exhausted soon after forty; while in others of a more agreeable nature, minds of ordinary power have risen into greatness, or superior minds have preserved it, long after that period.—See Dr. Conolly's *Inquiry into the Indications of Insanity*, pp. 271-276.—Ed.

consequently the capacity of the brain, are unduly diminished.

The internal causes are habitual inebriety, excessive and enervating pleasures, violent agitation of the passions, whether pleasurable or painful, as overwhelming joy, startling terror, deep and protracted grief, or furious anger; tumours within the cavity of the cranium; apoplectic attacks; injury of the brain from external violence; injudicious management in ecphronia; and especially an excessive use of the lancet.

Idiotism, however, is more frequently congenital than accidental; and it is melancholy to think that it is also sometimes hereditary. Of those who are idiots from birth, many, moreover, are sooner or later afflicted with palsy or epilepsy, or both; a clear proof of the existence of some organic affection of the brain or nerves, the former being sometimes partial, and confined to the face only, or extending down one of the sides. Idiots rarely attain old age; they seldom exceed the term of thirty years; and when paralysis or epilepsy is concomitant, they usually die at a much earlier period.

In idiotism the ideas of sensation and of reflection appear to be equally inaccurate. There is a vague, unsteady, wandering eye, seldom fixed for any length of time upon one determinate object; a stupid expression of countenance, in which no sign of intelligence is portrayed; a gaping mouth, from which the saliva flows continually; a perpetual rolling and tossing of the

head; no memory, no language, no reason. The idiot has all the animal instincts, and some of the passions. Of the last, joy, fear, and anger, are those with which he is most frequently affected, but these are of a very limited kind. His joy is unmeaning mirth; his fear a transient qualm; his anger a momentary fit of violence. The toys of children, and the gratification of hunger and thirst, are his only pleasures; bodily pain, or fear of bodily pain, his only distresses. It is said that idiots have sometimes shown a strong sexual appetite; but this is not common, for they rarely seem to attend to any distinction of sex.—(*Crichton of Ment. Derangement*, i., p. 314.)

The treatment, where medical assistance can be of any use, must chiefly depend upon the nature of the case. Blistering and internal stimulants to increase the action of the nervous system, and augment the habitual torpitude of the abdominal viscera, which are usually affected in this malady, offer the fairest chance of advantage. Accidental commotion of the brain, an occasional cause, has occasionally also proved serviceable, as has likewise a fracture of the cranium. Hence, too, fevers have relieved the disease; and active paroxysms of mania have proved a complete cure; and I once knew a cure effected in a lad who fell from the first floor of a house into the street, the torpitude or obstruction, or whatever was the cause, being hereby removed.*

ORDER II.

ÆSTHETICA.

DISEASES AFFECTING THE SENSATION.

DULNESS, DEPRAVATION, OR ABOLITION OF ONE OR MORE OF THE ORGANS OF CORPOREAL SENSE.

ÆSTHETICA is derived from *αἰσθάνομαι*, "sentio, et propriè, sensû corporis." The term applies, however, to all the external senses, and, in the language of Galen, peculiarly expresses *ἡ αἰσθητικὴ δύναμις*, "the power or faculty of sensation." It must also be admitted that it is occasionally applied to mental sensation, as in Isocrates to Demonicus, *ὁρῶ τὴν ἐκείνων γνώμην αἰσθίσην*, "thus will you feel their mind or inclination."

The term has hence been used in different significations by different medical writers. It has seldom, indeed, been applied to the mind, but has strangely varied between expressing sensation generally, and the sense of touch alone. In Dr. Young's excellent volume on Medical Literature it runs for the most part parallel with its meaning in the present work, and imports diseased action of all the corporeal senses; but

with this appropriation of the term, there seems to be an incorrectness in applying it, as the same author does immediately afterward, to *defective memory*, which he names *dysæsthesia interna*, and ranks in the same list or genus with defect of the external senses. Sauvages, and after him Sagar and Cullen, have applied *dysæsthesiæ* to a morbid state of the corporeal senses generally; whence *anæsthesia* should, in their hands, have expressed atony or total inactivity of these senses generally. But while *dysæsthesiæ* extends to all the senses, *anæsthesiæ* is by the same writers limited to the single sense of touch, with no small perplexity to the young student.

In the Physiological Proem to the present class, we have taken so full a survey of the connexion which exists between the brain and the corporeal senses, by means of the nerves, that it is not necessary to say more upon the subject at present; and I shall only therefore further observe, in these preliminary remarks, that where one of the senses is deficient, and especially where naturally deficient, the rest have very frequently been found in a more than ordinary degree of vigour and acuteness; as though the sensorial power were primarily derived from a common source, and the proportion belonging to the organ whose outlet is invalid, were distributed among the other organs.†

* On this interesting subject Dr. Spurzheim's *Observations on the Deranged Manifestations of the Mind, or Insanity*, may be consulted with great profit. Dr. T. R. Beck also, in his able treatise on Medical Jurisprudence, has learnedly discussed the subject of mental affections.—D.

† Trinckhusius, *De Cæcis, sapientiâ ac eruditione, claris mirisque cæcorum quorundam ac-*

The genera, under the order before us, are taken in a regular series from the corporeal senses themselves in a state of morbid action, and are in number six; of which the first five are derived from the five external senses, and the last from a diseased state of particular branches of the nerves distributed over the frame generally, for the common and pleasurable feeling of health in the different organs through which they are dispersed.

I. Paropsis.	Morbid Sight.
II. Paracusis.	——— Hearing.
III. Parosmis.	——— Smell.
IV. Paragustus.	——— Taste.
V. Parapsis.	——— Touch.
VI. Neuralgia.	Nerve-ache.

GENUS I. PAROPSIS. MORBID SIGHT.

SENSE OF SIGHT VITIATED OR LOST.

PAROPSIS is literally "diseased or depraved vision," from *παρά*, *male*, and *ὄψις*, *visus*; as *paracusis*, "diseased or depraved hearing," from *παρά*, and *ἀκουή*.

The ophthalmic monographers, by making every variety of affection a distinct disease, have most unmercifully enlarged the list under this genus.—(*Campiani Raggionamenti sopra tutti i Mali degli Occhi descritti*, &c., Genoa, 1759.) To say nothing of Campiani, Taylor has in this manner mustered them at two hundred and forty-three (*Catalogue of two hundred and forty-three Diseases of the Eyes*, Edin., fol., 1749), while Plenck has contrived to multiply them to nearly six hundred.—(*Doctrina de Morbis Oculorum*, 8vo., Vienna, 1783, 2d edit.) Upon a comprehensive view of the subject, it will, I think, be found, that this formidable number may be reduced to the twelve species following:—

1. Paropsis Lucifuga.	Night sight.
2. ——— Noctifuga.	Day sight.
3. ——— Longinqua.	Long sight.
4. ——— Propinqua.	Short sight.
5. ——— Lateralis.	Skew sight.
6. ——— Illusoria.	False sight.
7. ——— Caligo.	Opaque Cornea.
8. ——— Glaucoſis.	Humoral Opacity.
9. ——— Cataracta.	Cataract.
10. ——— Synzesis.	Closed Pupil.
11. ——— Amaurosis.	Drop Serene.
12. ——— Strabismus.	Squinting.

tionibus, Geræ, 1672. Meckren. *Observ. Med. Chir.*, cap. xx. Whether the principle adverted to in the text be true or not, the editor will not undertake to say; but it is more certain that another principle is generally concerned, resolvable into habit or practice. Thus, a blind man, whose eyes cannot apprise him of danger, or convey to him any kind of information, is habitually all attention with his ears; just as the organ of touch, in a deaf and dumb person, is, from necessity, continually exerted, and brought by habit to acquire a nice power of feeling and discrimination, far superior to what is enjoyed by the generality of mankind.—ED.

Most of these fall rather within the province of the ophthalmic surgeon than that of the physician; but as their general nature ought to be known to every practitioner, we shall proceed to give a glance at each of them in their order. The maladies of the eye dependant on inflammation, and constituting ophthalmia, have been already treated of in Class III., Order II., *HÆMATICA PHLOGOTICA*.

SPECIES I. PAROPSIS LUCIFUGA. NIGHT SIGHT.

VISION PAINFULLY ACUTE IN A STRONG LIGHT;
BUT CLEAR AND PLEASANT IN A DEEP SHADE
OR THE DUSK OF THE EVENING.

The specific term *lucifuga* is so distinct as at once to point out the general nature of the affection, while constituting a very prominent symptom. The author, however, has found a necessity for introducing this new name, not more from its own clearness than from the confusion which has taken place among earlier writers in distinguishing the disease by two directly opposite terms, *nyctalopia* and *hemeralopia*, according as these terms have been used in a literal or a technical and implied sense. The Greeks called it by the former name, literally *night sight*, in consequence of the person labouring under it being only able to see at night or in a deep shade; while *nyctalopia* has been used by most modern writers in the opposite sense of *night-sightache*, agreeably to the technical and implied meaning of *opia* when applied pathologically; in which case it always imports diseased vision, as though a contraction of the term *paropia* or *paropsis*; whence *nyctalopia* has necessarily been made to import *day sight* instead of *night sight*, or that imperfection of vision in which the eye can only see in the day, or whenever there is a strong light. And hence *hemeralopia*, the opposite to *nyctalopia*, has been used with the same confusion and contradiction of signification; by the Greeks importing *day sight*, being taken naturally or literally; by the moderns *day-sightache*, and consequently *night sight*, being taken technically or by implication; and hence Sauvages, "*Græcis hemeralopia; neotericis nyctalopia*." It is the *luscitas* of Beer (*Lehre von der Augenkrankheiten, als Leitfaden zu seinen öffentlichen Vorlesungen entworfen*; 2wey bände, 8vo., Wien, 1817); the *day blindness* of various other writers.

The disease is dependant upon a peculiar irritability of the retina, produced by two very different causes; a sudden exposure to a stronger light than the eye has been wont to sustain, and a deficiency of the black pigment which lines the choroid tunic. If the iris be weak and torpid, it is enlarged; if strong and contractile, diminished.

From the first cause, this disease is common to those who live almost constantly in dark caverns or chambers, as mines, dungeons, or dark prisons, or who have recently had a cataract depressed or extracted, the growth of which

has still more effectually excluded the light from the retina. And in all these cases we find it accompanied with a perpetual nictitation, from the sympathy which prevails between the retina and the orbicular muscles of the palpebræ.

Ramazzini asserts that this complaint is common to the peasants of Italy who are employed in agriculture; but in whom he is able to trace no other peculiarity than a considerable enlargement of the pupil.—(*De Morbis Artificum, &c.*) It is not difficult, perhaps, to assign a reason for such an affection among these people, though Ramazzini is silent upon the subject. The sky of Italy is peculiarly bright, its atmosphere particularly clear, and its temperature relaxingly warm. The peasants of Italy, therefore, are exposed to the joint operation of almost every cause that can produce habitual debility in the iris, and irritability in the retina. And we find these causes acting with renewed power at the time when the disease chiefly makes its attack, which we are told is on the return of spring, or rather at the vernal equinox, when a double flood of day breaks on them. And such is the dimness it produces, that the peasants lose their way in the fields in the glare of noon; but on the approach of night they are again able to see distinctly. It is hence necessary for them to keep for some weeks in the shade, or in comparative darkness, till the eyes recover their proper tone; and the weakness, and consequently the disease, subsides. And hence Ramazzini tells us that in the course of the succeeding month, or in other words, after they have taken due care of themselves, the peasants recover their sight. The glare of the sun in tropical regions, and especially where reflected from bright chalk-hills, has often produced the same effect.

A deficiency of the black pigment is occasionally found in persons of a fair complexion and light hair; and as the retina is hereby deprived of the natural shade that softens the light in its descent upon this very sensible membrane, its morbid irritability is not to be wondered at. Albinos, who are without the common pigment that lies between the cuticle and cutis in other persons, are always deficient in this also: and hence are painfully sensible to light. Indeed, they are hardly able to open their eyes in a strong sunshine; they contract their brows, and keep the eyelids nearly closed during the day; but no sooner does twilight come, than they are able to see quite distinctly. In old persons the same deficiency of black pigment is sometimes traced, but without painful vision; for at this time of life the optic nerve is become more obtuse. In horses, this want of pigment constitutes what is called a *wall-eye*.

[There are many states of the organ in which vision is very imperfect, even to blindness, in the strong light of the day; and much better sight is enjoyed in twilight and the dusk; but Mr. Lawrence has never seen such a state as an amaurotic affection, or what is here called *night sight*, dependant on disease of the retina or optic nerve. In central leucoma of the cornea, in incipient opacity of the lens, in partial

central opacity of the capsule, in contractions of the pupil from prolapsus iridis, or adhesion of the pupillary margin, connected with either of the former circumstances, the patient will see best in a weak light; and find vision very imperfect in a strong glare. The enlargement of the pupil in the former, and its contraction in the latter state, sufficiently account for this difference. On the same ground, sight is much improved in some of these circumstances by the use of belladonna. In strumous ophthalmia, the intolerance of light often amounts to blindness during the day; the symptoms remitting in the evening, at which period the eyes are opened, and the patient sees well. Unnatural sensibility to light is the form which sympathetic affection of the retina sometimes assumes.—(*See a Treatise on the Diseases of the Eye, by Wm. Lawrence, p. 570, 8vo., Lond., 1833.*)

Acuteness of night vision is natural to various animals that prowl in the dark; as cats, lynxes, lions, and perhaps all the feline genus; which save their eyes from the pain produced by broad daylight, by a closer contraction of their pupils than mankind are able to effect; expanding them gradually as the night shuts in, till, by the extent of the expansion, they are able to see much better than mankind in the dark. Owls, bats, cockroaches, moths, sphinxes, and many other insects, have a similar power.

Where the disease proceeds from an accidental irritability of the retina, sedative applications, as the tincture of belladonna and internal sedatives, as hyoscyamus and conium, have often proved serviceable, and the more so when combined with the bark. In old age, or an early deficiency of the black pigment that covers the choroid tunic, medicine has very little chance of success; and all we can hope for is to afford occasional relief by palliatives, if the irritation be violent, or accompanied with inflammatory symptoms.

SPECIES II.

PAROPSIS NOCTIFUGA.

DAY SIGHT.

VISION DULL AND CONFUSED IN THE DARK; BUT CLEAR AND POWERFUL IN BROAD DAYLIGHT.

THIS species, the nyctalopia of neoteric authors, or night blindness, is said to be endemic in Poland, the West Indies, Brazils, and the intertropical regions generally.—(*Hautesierck, Recueil d'Obs. de Médecine, i., ii.*) Its cause is precisely the reverse of that of the preceding species, and proceeds from too great instead of too small an habitual exposure to light, whence the retina becomes torpid, and requires a strong stimulus to raise it. At noontide, therefore, it is sensible to the impressions of objects; but does not clearly discern them in the shade, or towards the close of day. [Hence the present complaint is rarely met with, except in climates or situations where the light is very powerful. Between the tropics, as Mr. Lawrence observes, the full glare of a vertical sun in an unclouded sky, and the strong reflection of the

solar rays from the sea, or from a sandy soil, produces an excitement of the retina to which we are wholly unaccustomed in our latitudes; although, in some parts of Europe, analogous influences exist in a sufficient degree to cause the affection. Europeans in the West Indies, and particularly soldiers and sailors, who are much exposed to the sun, often have the complaint. In all the cases which Mr. Lawrence has seen, the disease commenced in the East or West Indies, and was brought to England.

In the commencement, the person can see by moonlight, or when the room is lighted by a candle; but as the disorder proceeds, he can see nothing after sunset; and in the morning, vision returns. There is no change of appearance in the eye, and, of course, if the patient can see perfectly during the day, the organ can have undergone no important change. At first, a slight increase of irritability is remarked; but as the disorder increases, the pupil becomes rather dilated, and the case is alleged to terminate sometimes in amaurosis. The feeble light of night and twilight does not impress the retina, after it has been so strongly excited in the day, sufficiently for perfect vision.—(See *Lawrence's Treatise on the Diseases of the Eye*, p. 569.)]

Day sight is said to be endemic in some parts of France (*Mém. de la Soc. Royale de Méd.*, 1786); and particularly in the neighbourhood of Roche Guyon, on the banks of the Seine. And so general is its spread there, that in one village we are told it affects one in twenty of the inhabitants, and in another one in ten, every year. It makes its attack in the spring, and continues for three months; sometimes, though in a slighter degree, returning in the autumn; and there are individuals who have had annual returns of the complaint for twenty years in succession. It passes off, after having run its course, or rather, perhaps, after having been treated with due medical attention, without any inconvenience, excepting a weakness in a few eyes that renders them impatient of wind and strong light. The soil is here a dazzling chalk, and the keenness of the first reflected light, after the dreariness of the winter, is probably one cause of so general an evil. [According to M. de Hautesierck, the disorder at one time prevailed extensively among some French troops stationed in Belleisle, under a combination of local peculiarities calculated to act powerfully on the retina, and at a season of the year favourable to their influence.—(*Recueil d'Obs. de Méd. des Hopitaux Militaires*.)] Perhaps, however, there is no part of the world in which this disease is found more commonly, or more decidedly, than in Russia: but then it is rarely found except in the Russian summer, when the eye is exposed, almost without intermission, to the constant action of light, as the sun dips but little below the horizon, and there is scarcely any interval of darkness. The malady, again, mostly makes its appearance at this time among the peasants, who protract their hard labour in the fields from a very early to a very late hour; and at the same time exhaust and weaken them-

selves by their daily fatigue. The sight is soon restored by rest, a proper shade, and bathing the eyes with an infusion of any bitter and astringent vegetable. Dr. Guthrie, in the *Memoirs of the Medical Society of London*, from which this account has been taken, gives also an example of the disease having appeared suddenly, a few springs before, in a detachment of Russian soldiers; who, being ordered to attack a Swedish post, at the moment of its incursion, had nearly destroyed one another by mistake. These men had been harassed by long marches, and been exposed night and day to the piercing glare of an uninterrupted scene of snowy mountains; both which causes had concurred in producing this effect.

Sir Gilbert Blane has found it occasionally occur in scorbutic patients; but no such diseases appeared in the Russian soldiery. Hens are well known to labour under this defect naturally; and hence they cannot see to pick up small grains in the dusk of the evening, and so employ this time in going to roost: on which account the disease is sometimes called *hen-blindness*.

[All practitioners who have had opportunities of witnessing this disorder, concur in delivering a favourable prognosis. When it is recollected that Mr. Bampffield (see *Med. Chir. Trans.*, vol. v.), a naval surgeon, saw in the East Indies about three hundred cases, and that they were all easily cured without any permanent injury of sight, no doubt can be entertained of the generally favourable result of proper treatment, in which the avoidance of the cause of the affection is one of the most important things to be observed.]

Tonics and gentle stimulants have been much recommended. The bark may be freely employed internally, and blisters externally, with the vapour of camphire, ether, or carbonated ammonia; and a few drops of the tincture of opium, the citrine ointment, or a minute portion of prussiate of iron, also in the form of an ointment, occasionally applied to the ball of the eye. In most of the endemic cases it seems to be an intermittent, as the preceding species appears to be occasionally; and in such circumstances, a free use of the bark used to be the plan chiefly depended upon. [Of late years, however, in consequence of the great and decided success with which Mr. Bampffield cured every case by means of blisters on the temples, and aperient medicines, this practice is now generally preferred. With it, Mr. Lawrence has occasionally associated cupping from the temples or nape of the neck.]

When the sight is once stimulated by the full light of the day, it occasionally becomes peculiarly acute and vivid. Plenck asserts, that he has known some men labouring under this disease evince so high an excitement of vision as to be able to distinguish the stars at noon.

Dr. Heberden has communicated a singular case of this species, which it will be best to give in his own words.—(*Med. Transactions*, vol. i.) "A man about thirty years old had in the spring a tertian fever, for which he took too small a quantity of bark, so that the returns of

it were weakened without being entirely removed. He therefore went into the cold bath; and after bathing twice, he felt no more of his fever. Three days after this last fit, being then employed on board of a ship in the river, he observed, at sunsetting, that all objects began to look blue, which blueness gradually thickened into a cloud; and not long after he became so blind as hardly to perceive the light of a candle. The next morning, about sunrising, his sight was restored as perfectly as ever. When the next night came on, he lost his sight again in the same manner; and this continued for twelve days and nights. He then came ashore, where the disorder of his eyes gradually abated, and in three days was entirely gone. A month after he went on board another ship, and after three days' stay in it the night blindness returned as before, and lasted all the time of his remaining in the ship, which was nine nights. He then left the ship, and his blindness did not return while he was upon land. Some little time afterward he went into another ship, in which he continued for ten days, during which time the blindness returned only two nights, and never afterward."

I have observed that *nyctalopia noctifuga* is often an intermittent affection. In the present case it was distinctly of this nature, and evinced a decided quotidian type. We are not acquainted with the exciting cause of this intermittent; but we know that when once a circuit of action has been established in a weakened and irritable habit, it adheres to the system with almost invincible tenacity, and is recalled with the utmost facility upon a repetition of such a cause. And hence the uniform return of the affection on shipboard, where it commenced, till a cure was obtained.*

SPECIES III. PAROPSIS LONGINQUA. LONG SIGHT.

VISION ONLY ACCURATE WHEN THE OBJECT IS
FAR OFF.

This is the *dysopia proximorum* of Cullen, the *vue longue* of the French.

In both the preceding species the morbid affection seems chiefly to appertain to the retina; in the present species it belongs chiefly to the iris, which is habitually dilated, and not easily stimulated to a contractile action. "For it is well known," observes Dr. Wells, "to those who are conversant with the facts relating to human vision, that the eye in its relaxed state is fitted for distant objects, and that the seeing of near objects accurately is dependant upon muscular exertion."

* Dr. Davenport remarks, that "this disease is frequently, perhaps commonly, sympathetic of disordered stomach or derangement of the biliary organs." Three instances have been observed by him where *p. noctifuga* was congenital. In two of these the occurrence of *oblique* vision was noticed during the usual nocturnal paroxysm.—See the Boston Med. and Surg. Journal, vol. xi, p. 415.—D.

VOL. II.—P

The species offers three varieties, as follow :—

- | | |
|--|---|
| <p>α Vulgaris.
Common long sight.</p> <p>β Paretica.
Unalterable long sight.</p> <p>γ Senectutis.
Long sight of age.</p> | <p>Iris relaxed, but moveable; cornea mostly too flat.</p> <p>Iris incontractile, pupil unchangeable, from partial paralysis.</p> <p>Cornea less convex; relaxation and hebetude common to all the powers of the eye.</p> |
|--|---|

The FIRST VARIETY is common to every period of life, in which the iris is affected with an habitual relaxation. [The truth of the foregoing statement, that long sight is dependant on the state of the iris, is not very manifest. No doubt, the pupil is often large; but it may be questioned whether this may not be only an effect of the infirmity; for nothing is more certainly established than that this defect of vision, as well as the opposite one, called short sight, is principally occasioned by a peculiarity in the refractive powers of the eye. In long-sighted persons the rays of light are not collected in the proper place, the focus in which they would meet being behind the retina. Like short sight, it is, as Mr. Lawrence has observed in his Lectures, "merely consequent upon some circumstances in the transparent media of the eye, which, in all other respects, is perfectly natural. Now the eye being in a great part of its functions a mechanical instrument, must be subjected to mechanical laws; and we find that a given configuration of the transparent media, a certain relation of them to each other, and their position at a determinate distance from the retina, are necessary to the formation of a distinct picture upon that nervous expansion. There is a certain distance from the eye which is called the point of distinct vision, at which we can see objects in all their details with perfect clearness. Every eye, considered as an optical instrument, has its point of distinct vision. The latter, therefore, varies in different persons, and is generally different in the two eyes of the same individual. Objects are not so distinctly seen when moved nearer to or further from the eye than this point. In ordinary well-constructed eyes, the distance ranges from fifteen to twenty inches." Too flat a configuration of the cornea or crystalline lens, too little distance between the retina and the lens, or too weak a refraction of the rays of light, from insufficient density of the humours and transparent media, total loss of the crystalline lens by operations for cataract, may be so many causes of long sight. It has been remarked by Mr. Wardrop, that when people advance in life, the cornea gradually loses its convexity, perhaps from the humours of the eye being diminished. The change, however, is not absolutely restricted to old persons; for the same writer speaks of a girl eight years of age, the cornea of whose eyes was observed to be remarkably flat, and her vision very imperfect from her infancy. In subjects much enfeebled by considerable evacuations, by numerous bleedings, or by disease, the quantity of the

aqueous humour diminishes, the convexity of the cornea is lessened, and they can only see objects at a distance.—(See *Wardrop's Essays on the Morb. Anat. of the Human Eye*, p. 115; *Portal, Anatomie Médicale*.) The ingenious experiments of Sir Everard Home and the late Mr. Ramsden, recorded in the *Philosophical Transactions*, prove, however, that the sphericity of the cornea is altered according to the distance at which objects are viewed. Hence, an impairment of this power of accommodation in the eye may sometimes be concerned in the present infirmity, as well as in the opposite one of near sight. In the present, the faculty which the eye has of adapting itself to near objects is presumed to be defective.]*

The SECOND VARIETY constitutes the disease called IMMUTABILITY OF SIGHT by Dr. Young (*Phil. Transact.*, year 1793); and is admirably described by Dr. Wells in the *Philosophical Transactions*, in an interesting case of a young person, about thirty-five years of age, whose retina was as sensible to the stimulus of light as ever; yet who, from a paresis or permanent dilatation of the pupil, saw near objects with considerable confusion, but remote objects with perfect accuracy. The power of moving the upper eyelid was also lost. It was an extreme case of the disease before us, complicated with partial paralysis of the adjoining muscles, and may be imitated by applying the tincture of belladonna. It was easily remedied by the use of spectacles with convex glasses, by means of which the patient was able to read without difficulty in a printed book, whose letters he was scarcely able to distinguish from each other before the spectacles were applied.

The THIRD VARIETY, or that produced by old age, constitutes the presbyopia and presbyopia of medical writers, from *πρεσβυς*, *senex*, and takes place in various degrees. The rays of light unite into a focus too late; that is to say, they strike the retina before they have conjoined into a focus; and the focus which they are calculated to form would be situated behind the retina. [The eyes undergo certain changes in age, which have the effect of diminishing their refractive power. Persons after fifty, and sometimes before that age, generally find that they cannot distinguish near objects so well as they have been accustomed to do. The rays of light are more divergent the nearer the object is to the eye: and the further it may be, the more do they approach to the parallel direction; consequently, a greater refractive power is necessary in the former than the latter case. Far-sighted persons can see distant inscriptions, or distinguish the hour by a distant church clock, when they cannot read a common print held in their own hands, or see the figures and hands of a watch. The custom of old persons to hold a

book or letter a long way from their eyes, and to draw back their heads, in order to be able to read it, when they have not their spectacles at hand, is familiarly known.]

In the present, as in the other varieties of this affection of the eyes, the best remedy for supplying the deficient convexity of the cornea, as well as the deficient irritability of the iris, is convex spectacles; adapting their power to the precise demand of the eye, and increasing it as the demand grows more urgent.

They should be of that power which will enable the patient to see without straining the organ, and should only be worn for reading, writing, or the examination of near objects.

SPECIES IV.

PAROPSIS PROPINQUA.

SHORT SIGHT.

VISION ONLY ACCURATE WHEN THE OBJECT IS NEAR.

THIS (the myopia of many writers) is in most respects an opposite disease to the preceding; for it not only produces an opposite effect, but proceeds, in the main, from an opposite cause. In the former, the iris is for the most part relaxed and weakly; here it is sound, often too much contracted: in the former, the cornea is in almost all cases too much flattened; in the present, it is too convex or polarized. The best palliative, therefore, is spectacles of an opposite character to those recommended under the preceding species; and with these we must satisfy ourselves till age brings us a natural relief, by taking off the entony and depressing the cornea. Unfortunately, however, this is a relief that does not always continue for many years, since the excess of tone becomes too much lowered as the age advances, and the sight grows imperfect from this cause.

Mice are said to have this kind of vision naturally, and hence one of the technical names for it is myopia or myopiasis, literally "mouse-sight."

[The explanation of the infirmity is, that rays of light are collected too soon, and brought into a focus before they reach the retina. Although a sound eye never discerns remote objects so clearly as near ones, inasmuch as the rays of light entering the eye from a distant thing are always fewer in proportion to its distance from the organ, yet a short-sighted eye sees objects at even a very small distance very indistinctly. The degrees of short sight are various: some individuals cannot discern things which are beyond two inches from their eyes. In the worst form, the person squints in examining an object with care; for he is compelled to put it so close to the eyes that the visual axis of the two eyes cannot be made simultaneously to bring it within their scope. This defect of vision depends upon the refractive powers being too strong, the eyeball being too long, or the impairment of that faculty by which the eye accommodates itself to distant as well as to near objects. The premature formation of a focus within the eye some-

* See *Farther Observations on Vision*, by Dr. Hosack, published in the *Trans. of the Royal Society for 1794*: in this paper the author attributes to the action of the external muscles of the eye its power of accommodation to objects of different focal distances. On this principle Mr. Ramsden formed his artificial eye.—D.

times depends on the great convexity of the cornea; a state which is always promoted by the humours being very abundant in the eye. Hence the reason why a short sight is most frequent in young persons; why it sometimes decreases with age; and why any accidental causes increasing or diminishing the quantity of humours in a sound eye may render it sometimes rather short-sighted, and sometimes oppositely disposed. It is a common opinion, that persons who are short-sighted from too great a convexity of the cornea always have objects depicted upon their retinae in a larger and plainer way than is the case in the eyes of other individuals. This circumstance, which does not appear to be well founded, is ascribed to the strong refractive powers of the eye. According to Mr. Lawrence, there is no ground for the notion that a near sight is strong sight. Another thing generally promulgated by writers, and already mentioned here, does not coincide with this gentleman's observations. "The eye, in progress of age," he says (op cit., p. 580), "becomes presbyopic, and it might be supposed that this natural change in the organ would remedy the excess of refractive power in the near-sighted, and enable them to dispense with their concave glasses: but this is not the case; the near-sighted continue so in old age." As this account disagrees with that given by Richter (*Anfangsgr. der Wundarzn.*, b. iii., p. 487), and other men of great experience in disorders of the eye, it is noticed here as one meriting further investigation. Besides great convexity of the cornea, other causes of short sight are generally enumerated; as too great convexity of the lens; preternatural density of the transparent parts of the organ; too great a space between the cornea or lens, and the retina; or a loss of the power by which the eye accommodates itself to the varying distances of objects. On this subject there is an interesting passage in Mr. Lawrence's Treatise, in p. 578. "It may be a question," he says, "whether this state of the eye depends upon the habits of the individual. I am inclined to think that the habitual mode of employing the organ has some influence. In persons of a literary and studious character, who use their eyes much in reading or writing, and in others who are constantly occupied on minute objects near the eye, we observe that the sight is frequently myopic. I remember once attending a book-sale, at which I was struck by the number of persons wearing spectacles: having counted them, I found there were twenty-three gentlemen in the room, and that twelve of the number had spectacles on. Mr. Ware endeavoured to ascertain the proportional number of the near-sighted in the different ranks of society, and he consulted the surgeons of the different regiments of Guards in and about London, at that time comprehending about 10,000 men; and he was informed that near-sightedness was almost unknown among them; not six individuals had been discharged, nor six recruits rejected, on this account, in twenty years. He pursued the investigation at the Military Asylum at Chelsea, containing 1300 children,

P 2

among whom only three were near-sighted. He then made some comparative inquiries of the heads of colleges at Oxford and Cambridge, and found near-sightedness very prevalent in all those institutions. In one particular instance, where the society consisted of 127 members, thirty-two either wore spectacles or used hand-glasses.—(*Ware's Tracts on the Eye*, p. 201, &c.) From these facts, together with the well-known far-sightedness of sailors and country people, we may infer that the habitual mode of employing the eyes has a decided influence in rendering them either myopic or presbyopic. Near-sightedness is not observed early in life; you never see persons trying to use glasses until towards the age of fourteen, or from that to eighteen." Mr. Lawrence admits, however, that the defect may exist previously without being noticed, as very young persons do not attend minutely to the state of their sight, or compare accurately their own vision with that of others.

The only assistance which a near-sighted person can obtain is from concave glasses, which should be such as will enable him to see distant objects distinctly, without producing any sense of painful exertion in the eye. As there is great reason to believe, with Mr. Lawrence, that the optical powers of the eye accommodate themselves to the circumstances under which vision is habitually exercised, near-sighted persons should not wear spectacles constantly, but only at periods when such aid is particularly required.—(See *Lawrence*, op. cit., pp. 579–580.)]

SPECIES V.

PAROPSIS LATERALIS.

SKEW SIGHT. SIGHT ASKEW.

VISION ONLY ACCURATE WHEN THE OBJECT IS PLACED OBLIQUELY.

In this species the patient can only see in an oblique direction, in consequence of some partial obfuscation of the cornea (usually, perhaps, from scratches or slight scars), or of the humours through which the light is transmitted, or from a partial paralysis of the retina. This must not be confounded with strabismus, or squinting, as it sometimes has been, but which proceeds from a different cause, and is accompanied with different phenomena. In skew sight, or lateral vision, the axis of the eye affected usually coincides with that of the sound eye, though it runs somewhat obliquely, to avoid the obstruction in the tunic. In strabismus the two axes do not coincide, and the judgment is formed from the strongest eye alone. If, however, in lateral vision, the obstruction be such as to make the optical axis of the affected eye at variance with that of the sound eye, squinting must be a necessary consequence of the disease.

SPECIES VI.

PAROPSIS ILLUSORIA.

FALSE SIGHT.

IMAGINARY OBJECTS FLOATING BEFORE THE

SIGHT; OR REAL OBJECTS APPEARING WITH IMAGINARY QUALITIES.

This species, thus defined, clearly includes two varieties, as follow:—

- | | | |
|---|---------------------------------------|--|
| a | Phantasmatum.
Ocular spectres. | Appearances of objects before the sight that have no real existence. |
| β | Mutationis.
Ocular transmutations. | Real objects apparently changed in their natural qualities. |

Both these varieties offer a very numerous family of distinct illusory perceptions, which require to be noticed in their order.

Of the OCULAR SPECTRES, constituting the FIRST VARIETY, one of the most frequent forms is that of DARK SPOTS. These are the *muscæ volitantes* of many authors; and are "sometimes," says Dr. Young, "if not always, occasioned by an opacity of some of the vessels of the vitreous humour near the retina. They are seen in a full light, and cannot, therefore, as Sauvages has justly remarked, be caused by any thing in the anterior part of the eye; and they may often be observed to change their form with the motions of the eye; which they could not do if they did not depend on some floating substance. Their apparent change of position, when we attempt to follow them with the eye, is a necessary consequence of the motion of the eye itself which contains them."—(*Delius, Diss. Phantas. ante oculos volitantia*, Erlang, 1751.)

If, however, these phantasmata depended upon vascular opacity of any kind, it is difficult to account for their mobility. And hence Demours is perhaps nearer the mark, in ascribing them to small portions of Morgagni's humour that have acquired an increase of density, weight, and refractile power, without losing their transparency.—(*Traité des Maladies des Yeux*, p. 409.) And in this view of their formation Mr. Guthrie coincides.*

Another form these ocular spectres exhibit is that of NET-WORK; hence called *suffusio reticularis* by Sauvages, and *visus reticularis* by Plenck. This is sometimes permanent, sometimes transitory; and is probably, as conjectured by Sauvages, produced by a morbid affection of the arteriolæ of the retina.

A third form is that of SPARKS: and hence called by Sauvages *suffusio scintillans*. It proceeds generally from a blow, or excess of light.

* Lectures on the Operative Surgery of the Eye, p. 211, 1823, 8vo. Mr. Lawrence is of opinion, that the immediate cause of *muscæ volitantes* has not yet been satisfactorily explained. The notions of partial pressure on the nervous structure, by distention of vessels in the retina or the choroid, or by inequality in the surface of the latter membrane, he regards as purely conjectural. The explanation derived from minute particles supposed to be floating in the aqueous humour, seems to him to have no better foundation.—(See Lawrence's Treatise on the Diseases of the Eye, b. 567.) We know that *muscæ volitantes* are an early symptom in amaurosis; and probably in all cases they depend upon functional derangement of the retina, temporary or permanent. Such disorder may be combined with organic disease.—ED.

The eye is also troubled with an imaginary sense of DAZZLING, constituting the marmoryge of the Greek writers. Its usual cause is supposed to be a plethora of the minute vessels of the eye.

Sometimes, from the same cause, the ocular spectres assume an IRIDESCENT APPEARANCE; or exhibit, in splendid succession, all the colours of the rainbow. This Sauvages calls *suffusio coloris*. It is occasionally a regularly intermittent affection, or returns at stated periods, and particularly in the evenings; and occasionally the morbid appearance is confined to a single colour. Dr. Heberden has given a curious example of an affection of this kind in a lady of advanced age, who took lodgings on the eastern coast of Kent, in a house that looked immediately upon the sea, and was of course very much exposed to the glare of the morning sun. The curtains of the bed in which she slept, and of the windows, were of white linen, which added to the intensity of the light. When she had been there about ten days, she observed one evening, at the time of sunset, that first the fringes of the clouds appeared red, and soon after the same colour was diffused over all the objects around her, and especially if the objects were white, as a sheet of paper, a pack of cards, or a lady's gown. This lasted the whole night; but in the morning her sight was again perfect. The same alternation of morbid and sound sight continued the whole time the lady was on the coast, which was three weeks, and for nearly as long after she left it; at which time it ceased suddenly and entirely of its own accord. Excess of light upon a delicate and irritable habit appears to have been the cause of this singular affection. The retina was too strongly excited to throw off the impression easily; and that of the red rays of the descending sun constituting the last impression communicated, remained after the sun itself had disappeared. The circle of action may be easily accounted for by a uniform return of the same cause.

THE SECOND VARIETY OF FALSE SIGHT, or that in which real objects appear changed in their natural qualities, is by Plenck denominated, in consequence of such change, metamorphopsia.

Sometimes the change exhibits ERROR OF FORM; and the objects appear too large, too small, cut in half, or distorted.

Sometimes ERROR OF MOTION: in consequence of which they seem to be dancing, nodding, or in rapid succession.

Sometimes ERROR OF NUMBER: and then they appear double, triple, or otherwise increased or multiplied; constituting the diplopia of Sauvages and many other writers.

Sometimes ERROR OF COLOUR; in which case one hue is mistaken for another, as red for green, or green for yellow, or every hue appears alike. Examples of this imperfection are not unfrequent. Mr. Scott has given a singular instance of it (*Phil. Trans.*, vol. lxxiii., 1778, p. 611), and Dr. Priestley another.—(Id., lxxvii., 1777, p. 260.) The last is especially worthy of notice, as in some degree a family defect; and was communicated to Dr. Priestley by Mr. Huddart,

of North America. Of five brothers and two sisters, all adults, three of the former were affected with it in a greater or less degree; while the remaining two and the two sisters possessed perfect vision. One of the brothers could form no idea whatever of colours, though he judged very accurately of the form and other qualities of objects; and hence he thought stockings were sufficiently distinguished by the name of stockings, and could not conceive the necessity of calling some red and others blue. He could perceive cherries on cherry-trees, but only distinguished them, even when red-ripe, from the surrounding leaves, by their size and shape. One of the brothers appears to have had a faint sense of a few colours, but still a very imperfect notion; and upon the whole, they seem to have possessed no other distinguishing power than that of light and shade, into which they resolved all the colours presented to them; so that dove and straw-coloured were regarded as white, and green, crimson, and purple, as black or dark. On looking at a rainbow, one of them could distinguish it as consisting of stripes, but nothing more.

Dr. Nicholl, of Ludlow, has published two papers* on the imperfection of vision producing a delusive appearance of colours. His cases were hereditary, and not symptomatic of amaurosis. In one, the imperfection seems to have been confined to one or two colours alone. The patient could easily distinguish the green of the grass, or the leaves of the trees; but like those in Mr. Huddart's statement, he confounded with the green the red fruit or flowers which happened to be intermixed with it. The false sight in this case was also connected with *paropsis longinqua*; for the patient saw objects at a greater distance than other people, and more distinctly in the dark. The irides were here also gray, with a yellow tinge round the pupil.†

The causes of these varieties are not always assignable: many of them, however, are the same as have been pointed out under the variety

of ocular spectres. Diplopia, or errors of number, have often been occasioned by long exposure to severe cold; sometimes by local spasm, sometimes by hydrocephalus.—(*Justi, Baldinger, N. Mag.*, bande xi., p. 446.) Baumer gives a case produced by a wrong position of the pupil.—(*Act. Hafn.*, i., art. xxvii.) Raghellini another caused by a double pupil.—(*Lettera al S. Coechi sopra l' offesa della vista in una Donna, Veneta*, 1748, 1479.) In Letin is a singularly complicated example of objects seen triply.—(*Lib. ii.*, obs. 20.)

The chief diagnostic of many of these illusions is their mobility (*Guthrie, Lectures, &c.*, ut supra, p. 212), which distinguishes them very decidedly from the fixed spots perceived in the eye, and which depend on an opacity of the lens. They are well known frequently to precede amaurosis. Sometimes, however, when they have reached a certain point, they cease to become more troublesome, or rather, from habit, to be troublesome at all, and are little attended to: for if amaurosis do not soon follow, there is no reason for expecting it; a consolation of no small moment, as no certain remedy has hitherto been discovered.

In other cases, and especially where the misaffection is not structural, but dependant upon an entonic or an atonic condition of the optic nerve, muscular fibres, or bloodvessels, benefit has been derived in the first instance from local bleeding, blisters, and sedatives; the sedatives being employed both generally and topically;* and in the last instance from stimulant collyriums and general tonics.

Many of these varieties of false sight, and especially ocular spectres, are also found as symptoms in several species of dinus, syspasia, syncope, plethora, cephalitis, dyspepsy, and various fevers: some few of the filaments of the great sympathetic passing off, at its origin within the cavernous sinus, to the orbit, and uniting with the lenticular ganglion.—(*Cloquet, Traité d'Anat. Descriptive; Bloch, Besch. des fünfter Nervenpaares, &c.*, Leip., 1817.)

SPECIES VII. PAROPSIS CALIGO. OPAQUE CORNEA.

DIMNESS OR ABOLITION OF SIGHT, FROM OPACITY OF THE CORNEA OR SPOTS UPON ITS SURFACE.

THE Latin term *CALIGO* sufficiently explains the nature of the disease, by importing "dimness, darkness, cloudiness, obscurity." In old English, this opacity, as well as the pterygium, was denominated a "web of the eye," from its giving the idea of a film spreading across the sight; whence Shakspeare in *King Lear*, "This is the foul fiend Flibbertigibbet: he gives the

* *Transact. of the Medico-Chir. Soc.*, vols. vii. and ix. For additional facts on this subject, consult *Glasgow Med. Journ.*, vol. ii., art. 2.

† The following observations on the cause of this curious infirmity, are delivered by Mr. Lawrence:—"This peculiarity, which is an original defect, and not a pathological condition, is seated, according to the opinion of Drs. Gall and Spurzheim, in the sensorium. They conceive that the function of the eye is limited to the receiving certain impressions, but that the judging of these impressions, the power of understanding the relations which colours bear to each other, is the function of the sensorium; and they assign this faculty to a particular part of the brain. It is certain that an eye may be excellent for the general purposes of vision, and capable of distinguishing the minutest objects, and yet the individual may not be able to judge of colours. The latter power, with the accurate perception of the harmony of colours, and their various relations to each other, is a higher endowment: indeed, only a few persons possess it eminently."—(*See Treatise on Diseases of the Eye*, p. 574.) The incapacity of distinguishing colours, viewed as an original defect, and one seated in the organization of the brain, must be incurable.—Ed.

* Several forms of *paropsis illusoria*, or false vision, depend on a disturbed state of the digestive organs or on plethora. Hence, too, some one of them is more apt to occur when the tone of the system has become impaired by previous illness, by a long course of inebriation, or by excess in eating and drinking, and also by great efforts of mind.—D.

WEB and the PIN: squints the eye, and makes the hare-lip." The PIN is a variety of the synizesis, "closed or contracted pupil."

[Surgeons usually divide common opacities of the cornea into four varieties or kinds:—

- | | |
|------------------|--|
| a Nebula corneæ. | Superficial opacity. |
| β Albugo. | Deep-seated dense opacity. |
| γ Leucoma. | A white cicatrix. |
| δ Arcus senilis. | Circular loss of transparency, extending in old age from the margin of the cornea. |

The first or simple opacity, or *nebula corneæ*, as it is often termed, is a diffused cloudiness of the whole or a part of that membrane, without any distinct or circumscribed boundary. Hence it is always greatest in its centre, and gradually diminishes towards its circumference. The iris and pupil are discernible through the dimness, and the patient yet has a degree of vision. It rarely extends to the deep lamellæ of the cornea, but is generally restricted to a cloudiness or milky thickness, arising from the albuminous secretion effused under the corneal conjunctiva, or in the texture of this delicate membrane itself.

When this superficial cloudiness of the cornea is accompanied with active inflammation of the eye, the treatment must be regulated by the principles applicable to ophthalmia in general. The disease is mostly attended with groups of turgid, knotty vessels in the conjunctiva. If this be the case, another indication presents itself besides that of diminishing inflammation; namely, to reduce the enlarged vessels; and if that be impracticable, to cut off all communication between the trunks of the most prominent of them in the conjunctiva, and the branches immediately distributed to the nebulous portion of the cornea. For the first purpose, Scarpa recommends the unguent. hydrarg. nitrat. and astringent collyria; for the second, the excision of a fasciculus of the enlarged vessels.* These measures may often be proper; but in Scarpa's practice the cause of the affection is not much considered; and if the treatment were regulated with reference to it, some of the plans which he proposes would not be needed. As a nebulous state of the cornea generally arises from inflammation or irritation, and is kept up by it, whatever removes the cause will also disperse the cloudiness of that membrane. Thus, the nebula is often dependant on the irritation of hard fungous granulations on the inside of the eyelid, a sequel of purulent ophthalmia: now, if these granulations are removed, the nebula soon disappears without any other proceeding. The first indication, when inflammation is present, is to put a stop to it. If we do this, and wait a little, we shall find that the opacity will diminish of itself. Afterward, coun-

* This practice is not approved by Mr. Lawrence: he has little confidence in its efficacy, and objects to it also on the ground that the vessels of the cornea are derived from the sclerotica, and not from the conjunctiva. Scarpa means, however, the vessels visibly extending to the opaque part of the cornea to be partially removed by excision, without any reference to their origin.—ED.

ter-irritation by issue, or seton in the temple, with attention to diet, and the state of the stomach and bowels, will be proper. Then the absorption of the opaque matter may be promoted by collyria containing the nitrate of silver in the proportion of two grains of it to one ounce of distilled water at first, the strength being gradually increased. It may be dropped into the eye, or applied to the opaque part with a camel-hair pencil.—(See *Lawrence on Diseases of the Eye*, p. 371.)

Albugo and *leucoma* are deeper opacities of the cornea, arising from previous severe ophthalmia, or an ulcer or wound of the cornea. The term *leucoma* is particularly applied to the pearl-coloured opacity, produced by the cicatrix of a wound or ulcer. In these deep opacities, the texture of the cornea is often so disorganized that they cannot be removed; for they do not consist merely of an effusion of a thin milky secretion, but of a dense lymph, which insinuates itself between all the lamellæ of the cornea, and becomes inseparably connected with them. When an *albugo* is recent, however, its dispersion may be attempted by applying the ung. hydrarg. nitrat. to it, and bathing the eye with a collyrium made of rose-water, and two grains of the nitrate of silver to each ounce of it. The *leucoma* occasioned by a cicatrix is evidently incurable.

The *arcus senilis*, or that opacity formed in persons of advanced years round the whole or part of the margin of the cornea, and sometimes extending considerably towards the pupil, so as to lessen the sphere of vision, is the effect of old age, and absolutely incurable. It comes on without any pain or uneasiness, and at length renders the texture of the cornea, in the part which it occupies, entirely impervious to light. This opaque circle, Mr. Lawrence observes (op. cit., p. 369), is not situated at the very margin of the cornea, but there is generally a transparent rim which intervenes between it and the sclerotic coat. In some cases, the opacity is very narrow; and in other cases, it becomes much broader; but he has never seen it interfere with vision, a sufficiency of the centre of the cornea for this purpose being left transparent. He describes it as a natural change in the part, from causes independent of disease. It shows itself, he says, much earlier in some cases than others; being occasionally seen between the ages of thirty and forty, but generally later. He compares it to the opaque knots which take place in the internal coat of the larger arteries of old persons.]

In newly-born infants spots on the cornea are occasionally met with, which soon vanish spontaneously (*Farr, Med. Commen.*, ii., 30): probably, the rays of light acting as a salutary stimulus upon the occasion.

SPECIES VIII.

PAROPSIS GLAUCOSIS.

HUMORAL OPACITY.

DIMNESS OR ABOLITION OF SIGHT FROM OPACITY OF THE VITREOUS HUMOUR.

GLAUCOSIS is a Greek term, from γλαυκός, "blue-

ish or greenish tinted," from the common colour of the obscurity. It was also called by the Greeks *glaucoma*, and by the Romans *glauco*. Glaucoma is here preferred to *glaucoma*, because the final *oma* imports usually, and, for the sake of simplicity and consistency, ought always to import, external protuberance; as in *staphyloma*, *sarcoma*, and various others noticed in detail in the volume of Nosology.

[It is remarked by Mr. Lawrence that the term *glaucoma* was formerly given to cataract, but is no longer so applied. We use it now to denote a certain change of the vitreous humour consequent on inflammation of that part of the eye, attended with an alteration in the colour of the pupil. The first symptom of *glaucoma*, as our author prefers to call it, is a pain in the head, usually situated over the brow. In conjunction with this pain, the patient begins to complain of dimness or of weakness of the sight; and if the eye be now examined, the pupil presents a greenish, muddy-green, or yellowish-green colour, instead of its natural deep-black. In a strong light, the appearance resembles a yellowish metallic reflection from the bottom of the eye. At the same time, the pupil is generally rather dilated, and the motions of the iris sluggish. The state of vision is different in different instances: in some, an alteration of the pupil is distinctly produced, and yet the eyesight may be tolerably perfect; while in other cases vision is entirely lost, with apparently no more discoloration of the back part of the eye, or change of the pupil, than in the former instance. Glaucoma has of late years generally been regarded as an inflammation of the vitreous humour, the texture and colour of which are changed. As the retina lies close upon this humour, there is no difficulty in accounting for their both being inflamed; and whether they both suffer from the commencement or not, if the inflammation of the vitreous humour be not checked it will involve the retina, and produce such changes in its structure as to render the eye permanently amaurotic. The eyesight becomes gradually worse and worse; the discoloration behind the pupil grows more and more considerable; and the iris becomes more and more sluggish, until it is at last motionless, and vision is entirely lost. The lens also is sometimes attacked, and with it the iris propelled forward, so that, as Mr. Lawrence remarks, it is no uncommon thing for cataract to occur subsequently in an eye originally attacked by glaucoma.]

Glaucoma, the precise causes of which are not known, occurs chiefly after the middle period of life, and in persons not of the most healthy character. It appears to Mr. Lawrence to be merely a chronic form of what is sometimes termed arthritic inflammation of the deep part of the eye; but he particularly mentions that it does not occur more frequently in gouty and rheumatic persons than in others; so that the expression *arthritic* cannot be very eligible.

In glaucoma, the colour of the pupil is green, or yellowish-green; and if the eye be viewed laterally, no discoloration can be seen; but in cataract, the pupil looks gray, or of a grayish

white, and it remains so, whether it be regarded laterally or not. The loss of vision in glaucoma is not in direct proportion to the change of colour of the pupil; for, with an inconsiderable change of this kind, vision may be entirely destroyed or very seriously impaired. But in cataract there is a direct proportion between the state of the opacity or change of colour, and the injury to sight. In cataract, vision is best in a weak light; but in glaucoma, sight is most perfect in a strong light.—(Lawrence, op. cit., p. 393.)

It is not yet decided among pathologists, whether the opacity in this disease be seated in the delicate membranous septa of the tunica hyaloidea, or in the fluid contained in the cells of the vitreous humour; or whether both are altered. Beer, in dissecting a glaucomatous eye, found the vitreous humour immediately surrounding the foramen of Soemmerring much more deeply coloured than the rest of it. Were this fact corroborated by further observations, we might perhaps infer that this is generally the original seat of the disease, and that the morbid changes extend from this point.*

Beer delivers a most discouraging prognosis, asserting that nothing will prevent glaucoma from terminating in amaurosis. All practical writers seem to agree that we possess no means of removing the opacity of the vitreous humour; but Mr. Lawrence is of opinion that the disease may be checked, and any degree of sight now enjoyed preserved, by having recourse to suitable treatment. There is, he says, a decided congestion about the brain and orbit, and the removal of that congestion is attended with considerable benefit. Hence, he recommends antiphlogistic remedies; cupping; active purgatives; alterative doses of mercury; a regulated diet; and repose of the eye. By such means, he has known cases kept for two or three years stationary.]

SPECIES IX.

PAROPSIS CATARACTA. CATARACT.

DIMNESS OR ABOLITION OF SIGHT, FROM OPACITY OF THE CRYSTALLINE LENS.

The cataract, as it is now called, was by old English writers named *PEARL EYE*, or *PEARL IN THE EYE*, and is so denominated by Holland,

* G. Frick, on Diseases of the Eye, p. 220, 2d ed. by Welbank, 1826. Mr. Mackenzie observed the following changes in eyes affected with glaucoma:—1. The choroid coat, and especially the portion of it in contact with the retina, was of a light brown colour, without any appearance of pigmentum nigrum. 2. The vitreous humour was in a fluid state, perfectly pellucid, colourless, or slightly yellow. There was no trace of hyaloid membrane. 3. The lens was of a yellow or amber colour towards its centre, its consistence firm, and its transparency perfect, or nearly so. 4. In the retina, no trace of limbus luteus, nor of the foramen centrale.—See Glasgow Med. Journ., vol. iii., p. 259; and Mackenzie's Treatise on Diseases of the Eye.—Ed.

the faithful translator of Pliny. Cataracta, as a Greek term, is usually derived from *καταβάσσω*, "to disturb, destroy, or abolish." *Καταβάκτης* or *καταπάκτης*, however, was employed by the Greek writers themselves to signify a gate, door, or loophole, and the bar which fastens it, and becomes the impediment to its being opened. And it is probably from this last sense that the term cataract was first applied to the disease in question, as forming a bar to the eyes, which were called the loopholes or windows of the mind by various philosophers, as we learn from Lucetius, who thus closes his opposition to their view:—

"Dicere porro oculos nullam rem cernere posse,
Sed per eos animum ut foribus spectare reclusis
Difficile est."*

To deem the eyes, then, of themselves survey
Naught in existence, while the interior mind
Looks at all nature through them, as alone
Through windows, is to trifle—

Whence, perhaps, Shakspeare, in the speech of Richmond:—

"To thee I do commend my wakeful soul,
Ere I let fall the windows of mine eyes."

The Greeks themselves, however, called this disease indifferently *hypochyma*, *apochysis*, and *hypochysis*. The earlier Latins, *suffusio*: while cataracta seems first to have been made use of by the Arabian writers, and was probably introduced into the medical nomenclature by Avicenna. Yet the more common name among the Arabians was *gutta obscura*, as that for amaurosis was *gutta serena*; the pupil, in this last species, being serene or transparent.

The Arabians, who had adopted generally the humoral pathology of Galen, conceived both these diseases to be the result of a morbid rheum or defluxion falling on a particular part of the visual orb; in the one case producing blindness with obscurity, whence the name of an obscure rheum or *gutta*; and in the other without obscurity, whence the contrary name of a transparent or serene rheum or *gutta*. But as various other diseases, and particularly of the joints, were also supposed to flow from a like cause, and were far more common, the terms *gutta* and *rheuma* were afterward emphatically applied and at length altogether limited to these last complaints, whence the terms *gout* and *rheumatism*, which have descended to the present day, as the author has already had occasion to observe under *ARTHRITIS PODAGRA*. For *gutta* the Arabian writers sometimes employed *aqua*; and hence cataract and amaurosis are described by many of them under the names of *aqua obscura* and *aqua serena*; and the former, by way of emphasis, sometimes under the name of *aqua* or *argua* alone.

The opacity producing a cataract may exist in the lens alone, the capsule alone, or in both; thus laying a foundation for the three following varieties:—

- α Lenticularis. The opacity existing in the lens itself, and confined to it.
- Lenticular cataract.

- β Capsularis. The opacity confined to the capsule or membranous cataract.
- γ Complicata. The opacity common to the lens and its capsule.
- Complicated cataract.

We are told moreover by Richter (*Von der Ausziehung des Grauen Staars*, Gott., 1773, 8vo.), of a cataract of the humour of Morgagni, or the interstitial fluid which lies between the capsule and the lens: whence this has also been copied by Plenck, Beer, and Sir William Adams, into the list of modifications; but rather as a possible than an actual case; for none of these practitioners give a single example of such a variety ever having occurred to them with certainty, though Beer suspected it in one case.—(*Lehre von den Augenkrankheiten*, band ii., sect. 56.)

[Mr. Lawrence doubts the separate existence of this as a distinct species of cataract. How, he asks, could we determine that this fluid was opaque, and the lens transparent? Can it be supposed that it could undergo this change, and the capsule and lens remain transparent? He thinks, therefore, that in a practical consideration of the subject, this kind of cataract might be safely omitted.]

Cataract is sometimes accompanied with a sac, enclosing a small body of pus or ichor, and is probably the result of the inflammation that produced it. In this case it forms the cataracta capsulo-lenticularis cum bursa ichorem continente of Schmidt.—(*Ueber Nachstaar und Iritis*, &c., Wien, 1801.) Beer affirms that this sac is commonly seated between the lens and posterior part of the capsule, and very rarely between the former and the anterior part.—(*Lehre von den Augenkrankheiten*, band ii., p. 301, 1813.)

Professor Beer seems to have refined a little too much in his divisions and subdivisions of cataract; for he not only assigns a distinct place to the Morgagnian and this pustular cystic, but to a cystic form without pus, to a siliquose, and a trabecular; while he further partitions the capsular into two separate forms, according as it is before or behind the lens itself, thus giving us a catalogue of nine distinct forms of what he calls the *true* cataract, while he allots four other subdivisions to what he denominates the *spurious* cataract: meaning hereby some other obstacle to vision, the seat of which is without the crystalline capsule, between its anterior hemisphere and the iris.

[The most striking circumstances observable in cataract are an opaque body placed behind, or even filling up the pupil, and the impaired state of vision which is the result of that change. In both these respects it agrees in its incipient stage with glaucoma and some forms of amaurosis; but as the treatment is essentially different in these several affections, it is very necessary to discriminate them accurately. In incipient cataract we can do little or nothing; we must wait until the opacity has become complete before we perform an operation: but

* De Rer. Nat., iii., 260.

in the early state of amaurosis we must take means to arrest the affection; for if we should leave the case to itself, under the supposition of its being a cataract, loss of sight would be inevitable and irremediable. The diagnosis of cataract from other affections, Mr. Lawrence, therefore, very properly represents as an important subject; and in doubtful cases we shall be much assisted by the influence which the belladonna has in dilating the pupil, and affording as clear a view as possible of what lies behind that opening.—(Op. cit., p. 397.)

The situation of the opacity is the best ground of distinction between glaucosis and cataract: in the latter it is very near the pupil; but in glaucosis, and also amaurosis, the discoloration of the pupil is much more deeply seated; it looks as if it were at the back of the eye; and hence, when the eye is viewed laterally in glaucosis, no opacity is perceived. The discoloration cannot be seen unless the surgeon look directly into the pupil; it is also equally diffused, and sometimes the opacity has a concave appearance.

The following observations, by the same surgeon, are highly valuable to the practitioner. In cataract, the opacity begins generally in the centre of the pupil; consequently it is more dense in the centre, and less so towards the sides. Hence, some light passes through the circumference of the pupil, enabling the patient to see objects laterally, when he cannot see them directly in front of the eye. Dilatation of the pupil, by exposing the margin of the lens, which is sometimes transparent when the centre is opaque, and at all events is much thinner, and therefore less densely opaque, improves vision considerably, especially in incipient lenticular cataract. Such patients see best in the dusk or twilight, or when the pupil has been artificially dilated by the belladonna. They see best when their back is turned towards the window. These circumstances particularly distinguish cases of cataract from those of glaucoma and amaurosis; for, in the latter affections, the sensibility of the retina being impaired, the individual generally sees better in strong lights, and his sight is not improved by belladonna.

In the commencement of cataract, objects seem as if surrounded by a mist or fog; the patient fancies that there is something interposed between his eye and the object at which he is looking; while the haziness or cloudiness increases gradually in proportion to the degree of opacity. A cataract patient sees a lighted candle as if it were involved in a cloud, which becomes thicker as the opacity proceeds, and ultimately shrouds the flame so completely that its position only is discernible. To an amaurotic patient the flame of a candle would appear as if scattered into rays, like a star, or surrounded by a halo, or confused with prismatic colours. In cataract, the sight is impaired in proportion to the degree of opacity; but there is no such direct ratio in glaucosis and amaurosis; for, with only a slight greenish discoloration of the pupil, there may be a considerably impaired state of vision, such as the opacity would not

account for; indeed, sight may be entirely destroyed when there is only a trivial change in the colour of the pupil.

With respect to the iris and figure of the pupil, Mr. Lawrence observes, they are not generally affected by cataract, or at any rate, not in the early period of its formation. The iris continues to move as usual, and the pupil retains its circular shape. In some cases, indeed, where the bulk of the lens is increased, this body presses against the iris and impedes its motions; but this happens chiefly in soft cataracts, and not in the early stage of them. In cases of cataract, the margin of the pupil represents a black circle, formed by the uvea, in consequence of the white or grayish-white ground which the opaque lens constitutes behind that opening.—(Lawrence, op. cit., p. 399; also, Beer, *Lehre*, &c., b. ii., p. 281.)

Cataracts are of different colours and of different degrees of consistency, from circumstances influencing the morbid action with which we are but little acquainted; and as little with the occasional causes of such action, though old age seems to be a common predisposing cause. They are therefore black,* white, leaden-hued, ferruginous, amber; as they are also fluid or milky, soft, firm, hard, horny, and even bony. They are not unfrequently the result of an hereditary taint, adhering to generation after generation, and appearing either congenitally, or by a very general predisposition afterwards.

All ages are subject to cataracts; children are even born with them; and they may occur at any age, from infancy to the remotest period of life. Perhaps elderly persons are most subject to the complaint, especially from fifty, sixty, or upwards.† Cataracts are never hard in young persons; you will never meet with a hard lens below the age of puberty. They are not always hard in old persons; you may have soft cataracts in such, and hard ones during the middle period of life.—(Lawrence, op. cit., p. 410.)

Mr. Pott inculcated what experience has amply confirmed, that when the opaque crystalline is perfectly dissolved, so as to form a soft cataract, it is somewhat enlarged; and that when such dissolution does not take place, and a hard cataract is produced, the crystalline is in some degree lessened. The hard cataract has also

* The occurrence of black cataract is still a matter of dispute. Dupuytren, with his vast experience, has never seen a case of it.—See his *Clinical Lectures on Surgery*, translated by Doane, New-York, 1833, p. 39.

† The following table is compiled from the observations of Drs. Manno and Fabini.

Of 612 cases of cataract,

14 were between 1 and 10 years of age.

been distinguished by the name of *ripe*, as the soft by that of *unripe*. "But if we would think and speak of this matter," observes Mr. Pott, "as it really is, we should say that a dissolution or softening of the crystalline lens is by much the most common effect; and that seven times out of nine, when it becomes opaque and tends to form a cataract, it is more or less softened: the softening sometimes extending through the whole range of the lens, and sometimes through only a part of it; while, however, the part that remains undissolved is rarely, if ever, so firm as the centre of the sound crystalline." Mr. Pott proposes it as a question, whether cataracts which have been found perfectly soft have not in general grown opaque by slow degrees; and whether those which have been discovered to be firm have not become opaque hastily, and been preceded by or accompanied with severe and deep-seated pain in the head, particularly in the back part of it?—(*Chirurgical Observations relative to the Cataract*, &c., 8vo., 1775, London.)

There is no ophthalmologist, however, who has paid so much attention to this subject as Professor Beer; and though his divisions are perhaps a little too minute, yet the microscopical accuracy with which he has followed up all the modifications of the cataract, is entitled to our most serious attention. He agrees with Mr. Pott that a hard cataract is always comparatively small, though he adds, that every small cataract is not necessarily hard. He is peculiarly minute in examining all the qualities which the disease may exhibit, of position, colour, shadow, shape, range; together with the mobility and degree of prominence of the iris; and till all these characters have been accurately weighed, he hesitates to determine as to the variety of the cataract; or, in effect, whether it be a cataract at all. The shadow cast by the iris constitutes his leading clew. If the lens in an opaque state maintain the size it possessed when transparent, there is a manifest shadow thrown back upon the surface of the cataract by the iris. If the cataract be less than the natural lens, this shadow is broader than usual. If the opaque lens be swollen, no shadow is present; as the capsule is pushed forward into contact with the iris, and the posterior chamber is abolished. And by carefully comparing all the signs that lie before him, he is able to indicate with certainty, in every instance, the seat, the size, and the consistence of the cataract.

[The most frequent species of lenticular cataract is that called hard or firm. In this state of the lens the opacity has a grayish appearance, with more or less of the yellowish brown or amber tint towards the centre. In the firm and darker coloured portion it resembles wax in consistence, slightly softened by heat; the circumference is lighter coloured and softer, being about the consistence of soft jelly. The more of the amber colour is seen, and the deeper the tint, the harder is the cataract; the grayer its appearance, the softer is the consistence. The common firm cataract here described, presenting the amber tint in the middle, shaded off into a gray, is the ordinary form of the com-

plaint in elderly persons. The lens in such a case is generally smaller than natural; and the capsule being unaffected, the opaque body appears at a small distance behind the pupil. There is a marked interval between that aperture and the cataract; the iris has its full play; and the patient retains the power of distinguishing objects during the formation of the cataract, by the passage of light through the less opaque circumference of the lens.—(See *Lawrence*, op. cit., p. 400; *Richter's Anfangsgr.*, &c., b. ii.) Mr. Pott's opinion, that the colour of a cataract affords no clew to its consistence, we find, from what has been here stated, to be at variance with modern experience.

In the *soft* cataract, the lens is not soft in the circumference only, but its whole texture is changed, having various degrees of consistence, as that of cheese, jelly, or milk. Soft cataracts are larger than the hard; so that they press against the iris and render its front surface convex. Their surface is distinguished by a bluish kind of white.

The opacity extends uniformly to the circumference of the lens; it intercepts the light more completely than the hard cataract does; and the patient at last retains merely the power of distinguishing light from darkness.

Capsular cataracts are those in which the front or back of the capsule of the lens is alone affected, and those in which the whole capsule is opaque. An opacity of the capsule does not begin in the centre, but in all parts of the membrane indifferently: it is not uniform, but in spots or streaks, with less opaque or transparent intervals. These opaque portions have a glistening chalky white, or bluish white, or pearly appearance. In the anterior capsular cataract, the opacity always projects as far forward as the edge of the pupil. The capsule cannot become extensively opaque without the lens being also affected; and when the anterior portion of the membrane is opaque, the lens is in the same condition. We may have, Mr. Lawrence observes, a single streak of opacity in the capsule after iritis; but that will not constitute a cataract: the capsule may be more extensively yet partially covered by a new adventitious membrane, the rest remaining clear; but there is no such case as a capsule, generally opaque, containing a transparent lens.—(*On Diseases of the Eye*, p. 404.)

When the posterior part of the capsule becomes opaque, while its front portion and the lens continue transparent, the opacity is situated at a marked distance behind the pupil: its situation corresponds to the known position of the capsule. It presents a concave surface, with partial streaks, the intervals of which are transparent. The posterior capsular cataract has not that glistening white colour which distinguishes the anterior, because it is seen through the lens, and acquires a yellowish and rather dull appearance. This change in the capsule is followed by opacity of the lens, which, however, may not occur for a considerable time. Mr. Lawrence adverts to two patients who were attending the Ophthalmic Infirmary, in whom pos-

terior capsular cataracts could be very distinctly seen. One of them could read the large print of a Bible; and when the pupil was dilated with belladonna, the spaces between the opaque radii, through which the light gained admission to the eye, were very manifest. As the lens becomes more opaque, vision decreases.*

What our author denominates *complicated cataract*, or the case in which both the lens and capsule are opaque, is very frequent. It is the *capsulo-lenticular cataract* of the Germans. Generally speaking, the lens in these cases is soft and the cataract large, often pushing forwards the iris, and impeding its motions. The streaks of the anterior portion of the capsule on a level with the edge of the pupil, the different tint of the opaque lens seen through the less opaque parts of the capsule, and the considerable degree in which sight is interrupted, owing to the bulk of the lens, are characteristic of this example of cataract. The varieties of appearance presented in the capsulo-lenticular cataracts, have afforded the German oculists abundance of opportunity for minute distinctions. Thus they describe the *cataracta marmoracea*, where the opaque capsule exhibits a marbled appearance; *c. fenestrata*, with bars, fancied to resemble those of a window; *c. punctata*, with spots, &c. Also the *cataracta arida siliquosa*, or *dry-shelled cataract*, in which the capsule has a thickened and corrugated appearance, and contains only the nucleus of the lens. This variety is often met with in children, and frequently mistaken for a congenital affection. In young infants, Beer says, it is manifestly produced by a slow and neglected inflammation of the lens and its capsule, excited by the stimulus of too strong a light. In adults, the case is generally the result of external violence. Schmidt supposed that in infants the siliquose cataract might be caused by convulsions, attended with violent action of the muscles of the eye; but the correctness of this opinion is now beginning to be disbelieved.

In a cataract complicated with glaucoma, or glucosis, as our author chooses to name it, the vitreous humour is first affected, and the lens subsequently. If, says Mr. Lawrence, the iris is altered in colour; if the pupil is fixed in the dilated state; if the sight was lost with considerable headache, and before the cataract had formed, the eye may be inferred to be glaucomatous.

The complication of cataract with amaurosis is denoted by the inability to discern light from darkness. The insensibility of the retina may not be totally destroyed, and thus the power of discerning the difference between light and darkness may exist with a cataract attended by imperfect amaurosis. Here, as Mr. Lawrence explains, the practitioner must attend to the symptoms under which the loss of sight has occurred, as well as to the present state of the eye. Simple cataract comes on without pain; while, in

amaurosis, there is often considerable pain in the head, or neighbourhood of the eye. In cataract unattended with enlargement of the lens or adhesion, the iris has generally its natural power of motion. A motionless or sluggish iris, and a fixedly dilated pupil, are therefore strong evidence of an amaurotic affection, when they are not accounted for by the particularities of the cataract itself.]

Like *PAROPSIS glaucosis*, or opacity of the vitreous humour, a cataract has sometimes, though very rarely, ceased spontaneously, or without any manifest cause.* Helwig gives an instance in which the cessation was not only spontaneous but sudden.—(*Observ. Physico-Med.*, 23, Aug. Vind., 1680, 4to.) It has also, at times, been carried off by a fever.†

There is hence specious ground for conceiving that some medicine might be discovered, capable, by some general or specific action, of producing a like change, and proving a remedy for the disease; and the more so, as we find ganglions and other accidental deformities frequently removed from the extreme parts of the system by external or internal applications. But no such remedy has hitherto been discovered, or at least none that can be in any degree relied upon, excepting in those cases of supposed but mis-called cataracts which have consisted in a deposition of lymph from an inflammation of the iris and ciliary processes: for recourse has been had to mercurial preparations, both external and internal, as almost every other metallic salt, aconite, the pasque-flower, or pulsatilla, to protracted vomiting, electricity, and puncturing the tunics of the eyes, but without any certain advantage.—(*Beytr. zur Chir. und Augenheilkunst*; Von Franz Reisinger, &c., Göttingen, 1814.) This is the more to be lamented, because, whatever surgical operation may be determined upon as most advisable, there is no guarding, on all occasions, against the mischievous effects which may result; I do not mean from the complication or severity of the operation; for this, under every modification, is simpler and less formidable than the uninitiated can readily imagine; but from the tendency which is sometimes met with, from idiosyncrasy, habit, or other irritable principle, to run rapidly into a state of destructive inflammation; and in a single night, or even a few hours, in spite of the wisest precautions that can be adopted, to endanger a total and permanent loss of vision. I speak from personal knowledge, and have in

* Haggendorn, *Observ. Med.*, cent. i., obs. 50, Franc., 1698, 8vo. Ludolf, *Miscel. Berol.*, tom. iv., 258. Walker on the Theory and Cure of a Cataract.

† Velschius, *Episagm.* 20. The cases which occasionally disappear spontaneously, are generally such as have been induced by injuries of the eye, followed by manifest inflammation. The attempt to disperse other cataracts is now deemed a hopeless experiment. "It may be asserted without any qualification, that no external application nor internal medicines with which we are at present acquainted, can alter the condition of the opaque lens and capsule."—Lawrence, *op. cit.*, p. 411.—Ed.

* This kind of cataract seems particularly frequent in children; of fifty-four cases observed by Saunders, only twenty-three occurred in adults.—D.

one or two instances seen such an effect follow, after the operation had been performed with the utmost dexterity, and with every promise of success; and where a total blindness has taken place in both eyes, the operation having been performed on both; neither of them being quite opaque antecedently, and one of them in nothing more than an incipient state of the disease, and the patient capable of writing and reading with it.* And hence it is far better, in the author's opinion, to have a trial made on one eye only at a time, and that the worst, where both are affected and one is still useful, than to subject both to the same risk; for the sympathy between them is so considerable, that if an inflammatory process from any constitutional or accidental cause should show itself in either, the other would be sure to associate in the morbid action. [This advice is supported by that of Scarpa and Lawrence. The latter offers the following arguments for the decision. If you restore sight in one, it is sufficient for all useful purposes, and the patient will generally be satisfied. The other may be operated on afterward, or be retained as a reserve in case the restored sight should fail, or be lost by disease or accident. When both are operated on together, they are not both necessarily involved in any unfavourable subsequent occurrence; yet they are likely to suffer together from common causes, and under such circumstances the patient loses all chance of regaining sight. On the other hand, if things go on unfavourably, it is a great consolation both to the patient and surgeon to know that one eye only is risked. These arguments seem perfectly convincing.]

There are some cases, as Mr. Lawrence says, in which it is better for the patient to be content with very imperfect vision, than to submit to an operation which may end in total blindness. The restorative powers, he observes, are feeble in very old persons; in them, and in cases where the propriety of operating may be doubtful for other reasons, it is best to employ the palliative aid of belladonna, as long as it will procure any degree of useful vision. He

* The prognosis, which should be regulated by circumstances, is here too discouraging. In order to counteract this impression, the judicious remarks of Mr. Lawrence upon this part of the subject are introduced. "The prognosis," he says, "is completely favourable when the affection is confined to the lens or capsule; when the sensibility of the retina is undiminished; when the motions of the iris are unimpaired; when the constitution of the patient is sound, and the health is good at the time of operating; and when the patient is of a spare rather than a full habit. Under these circumstances, the prognosis is completely favourable; that is, supposing the operator to understand the subject well, to select the kind of operation most suited to the particular species of cataract, and to possess sufficient manual dexterity for performing it in the most advantageous way. The prognosis will be particularly favourable in congenital cataracts; in those of young persons (in whom, however, it seldom arises, except in consequence of injuries), and in the firm lenticular cataract of elderly persons. It is bad when

advises no operation, in such cases, until the patient is quite blind; until the sight is in that state in which the failure of the operation can make it no worse. In general, he thinks we should not operate till all useful vision is gone. At all events, says he, this rule is absolute in doubtful cases. He mentions one exception; namely, where the cataract is mature in one eye and immature in the other the former may be operated upon, so as to give the patient the use of that eye while the cataract is forming in the other. Much difference of opinion prevails on the question, whether the operation should be done when only one eye is affected and the other is sound; but on this topic we shall not enter, as it is generally discussed in surgical works; and shall merely mention that this is a point of practice on which a candid statement of cases is much desired.]

The usual modes of operating for the cure of a cataract are three: that of couching or depression, that of extraction, and that of what is called absorption. The first was well known to the practitioners of Greece and Rome; and is ably described by Celsus, who advises, in cases where the lens cannot be kept down, to cut it into pieces with the sharp-edged needle, by which means it will be the more readily absorbed. And from this last remark we have some reason for believing that even the third of the above methods, that of absorption, was also known at the same time; as it is probable, indeed, that the second, or the operation by extraction, was likewise; since we find Pliny recommending the process of simple removal or depression in preference to that of extraction or drawing it forth: "*squammam in oculis emovendam potius quam extrahendam*" (*Nat. Hist.*, lib. xxix., cap. i.), which Holland has thus honestly, though paraphrastically translated: "a cataract or pearl in the eye is to be couched rather, and driven down by the needle, than quite to be plucked forth."

In the east, however, both these plans appear to have been pursued through a much longer period. Both are noticed by the Arabian writers in general, and especially by Avicenna and

the cataract is complicated with glaucoma or amaurosis; with a fluid state of the vitreous humour; with a varicose condition of the bloodvessels; with dropsy of the eye; or with a very contracted or closed pupil. Indeed, some of these circumstances would form decided objections to the operation. It is also bad when the cataract has been preceded or accompanied by severe pains in the head or in the eye; by *muscae volitantes*, sparks or flashes of fire before the eye; as all these circumstances indicate affection of the nervous structure. The prognosis is doubtful when cataract is the result of internal inflammation of the eye, or of that vascular disturbance which comes under the head of congestion. Adhesions of the pupil are unfavourable, since the laceration and removal of them may excite inflammation in the iris and internal tunics; particularly in gouty individuals, in whom such adhesions are most frequent, and who are most likely to suffer from inflammation after the operation. The prognosis is doubtful in cases of cataract affecting one eye, when the other is amaurotic or glaucomatous."—Ed.

Rhazes; and both seem to have been practised from time immemorial in India, and, according to the account of the cabirajahs, with wonderful success. Dr. Scott was informed by one of the travelling operators, who, however, spoke without a register, that in the operation of depression, this success was in the proportion of a hundred who were benefited to five who obtained no advantage whatever.

[*Extraction* consists in making an incision through the cornea, dividing the crystalline capsule, and letting the lens escape through the pupil, and the opening made in the cornea.

There is a particular modification of couching, or depression, that was first suggested and practised by Willburg, and named *reclination*: in this the lens is not pushed downwards in a straight direction, but is turned on its axis, so as to be placed horizontally in the vitreous humour, behind the lower part of the iris, or, as is sometimes advised, at the bottom of the vitreous humour, between the inferior and external straight muscles.—(*Frick, on Dis. of the Eye*, 2d edit., by Welbank, p. 200.) In this operation the posterior surface of the lens is turned downwards, the anterior upwards; the superior margin is backwards, the inferior forwards.]

One form of extraction was introduced as an improvement by Sir William Adams: after detaching the cataract, he first passed it through the opening of the pupil into the anterior chamber by means of his needle, and then extracted it by an opening on the outer side of the cornea, instead of by one in its inferior part. The method is now very properly abandoned.

The simplest and least irritating of these operations, however, is that by absorption, as it is now commonly called: it was named precipitation by Maître-Jan (*Traité des Maladies de l'Œil*, edit. sec., Troyes, 1711), on his first noticing the disappearance of portions of the opaque lens; but which in effect is neither absorption nor precipitation, but solution, or dissolution, as Mr. Pott correctly described it. But it should be known to the operator, that while the solvent power of the aqueous humour is wonderfully active, that of the vitreous is weak and inconsiderable: and hence the solvent or absorbent plan practised by Scarpa, consists in dividing the cataract, after its separation, into small fragments, and passing them with the needle by which they are thus divided through the pupil into the anterior chamber, which constitutes the seat of the aqueous humour, apparently in perfect coincidence with the method first practised by Gleize, and since recommended by Richter.—(*Chirurgische Bibliothek*, band x.) The fragments thus deposited are usually dissolved in a few weeks; and where the cataract is fluid, they have often been dissolved and absorbed in a few seconds, and sometimes even before the needle has been withdrawn.

[In the proceeding by *absorption*, or *solution*, as it is sometimes termed, the needle may be introduced either through the cornea and pupil, or behind the iris, as it is in the operation of depression, the pupil having been first dilated with belladonna. These two methods are dis-

tinguished by the appellations of the anterior and posterior operations. The anterior operation, invented by Buchorn (*Buchorn de Keratonyxide*, Halæ, 1806), or rather by Conradi, has been named *keratonyxis*,* a term derived from the Greek, and signifying puncture of the cornea. This practice was introduced into this country by Mr. Saunders, who does not seem to have been aware that it had ever been done abroad. No person who understands the subject would advise either of these operations to be exclusively employed. Each method has its advantages, and is eligible under certain circumstances: our object then should be, not to select one operation, with the view of practising it in all cases; but to consider the circumstances which make one preferable to the other, and to select in each instance that which is best suited to the particular form of the complaint.—(*See Lawrence, on Dis. of the Eye*, p. 417.)

The principles which should determine the preference in individual cases, and the details of the several operations, must be sought in works on surgery.]

PECIES X.

PAROPSIS SYNIZESIS.

CLOSED PUPIL.

DIMNESS OR ABOLITION OF SIGHT FROM CONTRACTION OR OBLITERATION OF THE PUPIL.

THE term SYNIZESIS is derived from συνίζω, "consido, coëo, coalesco;" and was used among the Greek grammarians, before it obtained an introduction into the medical vocabulary, to signify the coalescence of two or more syllables into one. [The pupil may be simply contracted or closed; or these changes may be combined with opacity of the lens or capsule, with an adventitious membrane in the pupil, with adhesion of the iris either to the capsule (synechia posterior) or the cornea (synechia anterior), with protrusion of the iris, displacement of the pupil, or opacity of the cornea. All these conditions of the eye are the consequence of severe inflammation, either external or internal. As Mr. Lawrence correctly observes, it must also be recollected, that this serious inflammation may not have confined itself to the production of the foregoing evils, but extended its effects to the nervous structure of the eye, or to other parts of the organ. Hence, says he, it is necessary to ascertain correctly whether the loss of vision is produced by the changes of the pupil only, before a decision is made about an attempt to form an artificial pupil.] This species exhibits two varieties:—

- | | |
|----------------------|------------------------------|
| α Simplex. | Simple closure of the pupil. |
| Simple closed pupil. | |

* M. Dupuytren has made a number of experiments to ascertain the value of this operation. Of twenty-one individuals operated upon by him in this mode, seventeen recovered their sight. For many valuable remarks on the nature and treatment of cataract, see his *Clinical Lectures on Surgery*, trans. by Doane, New-York, 1833.

β Complicata. Closure of the pupil complicated with cataract, opaque cornea, or other changes specified above.

The pupil sometimes becomes closed or obliterated from a gradual contraction, and at length coalition, of the muscular fibres of the iris, unattended with any other change or impairment of the eye. In all these cases, it is a SIMPLE OBLITERATION OF THE PUPIL. It is COMPLICATED when the obliteration is combined with an opacity of the cornea, with a cataract, with adhesions of the iris to the cornea or capsule of the lens, &c. When the disease is an effect of inflammation, it forms the ATRESIA IRIDIS of Dr. Schmidt of Vienna, who further subdivides it into *complete*, *incomplete*, and *partial*, according as the vision is totally destroyed, impaired, or confined to a part of the pupil.—(*Ueber Nachstaar und Iritis nach Staaroperationen*, 4to., Wien, 1801.)

The natural shape of the human pupil is circular, this being the natural form of the fine fringe of the iris by which it is surrounded. But in a few instances the fringe or rays of the iris have evinced a different figure, and the pupil, in consequence, has been found oblong or heart-shaped.—(*Eph. Nat. Cur. Dec.*, iii., ann. vii., viii., obs. 21.) The first has occurred most frequently, and according to Albinus, has sometimes preceded loss of vision.—(*Anat. Acad.*, lib. vi., cap. 3.) Bloch gives an instance in which the disease was congenital and hereditary.—(*Medicinische Bemerkungen*, p. 1.)

If the iris contract irregularly, sometimes only a few of its fibres spread across the pupil, while others are retracted: and hence we have examples of double or more than double pupils, though of smaller dimensions than the natural circle. Solinus gives an instance of two pupils hereby produced (*Vide Marcel. Donat.*, lib. vi., cap. 2, p. 619), and Janin of not less than five.—(*Mémoires*. &c.)

Medicines in this disease are of little avail. In the first variety, an external application of the tincture of belladonna, or a solution of stramonium, which is said to answer the same purpose,* has occasionally effected a cure by destroying the contractile action; and so have dilute solutions of brandy, camphire, or sulphate of zinc, by their tonic or stimulant power. When the disease does not yield to this mode of treatment, or consists of the complicated variety, it belongs manifestly to the art of surgery, and its removal must be sought for in books on that subject: among the best of which may be mentioned, Mackenzie's Treatise on Diseases of the Eye, Lawrence's work on the same subject, Mr. Guthrie's Lectures on the Eye, and Beer's Essay on Staphyloma and Artificial Pupil, published in 1804,† and his Doctrine of the Diseases

of the Eye, published in 1817.—(*Lehre von den Augenkrankheiten*, &c., ut *suprà*.) According to the nature of the coalition, Beer employs three varieties of operation; incision, excision, and separation; which he distinguishes by the names of COROTOMIA, CORECTOMIA, and CORODIALYSIS. The first is the simplest, and that most usually had recourse to. In the second, an incision being made with a cataract-knife, close to the edge of the cornea, and not larger than the third part of its circumference, the iris, if it protrude, is laid hold of with the hook; or, if no protrusion take place, the hook, introduced through the incision, is made to lay hold of the pupillary edge of the iris, which drags it through the wound when a sufficient portion of it is removed with a pair of scissors. In the third method, which is that originally proposed by Dr. Reisinger, the operation is performed with a double hook or hook forceps.*

SPECIES XI.

PAROPSIS AMAUROSIS.

DROP SERENE.

DIMNESS OR ABOLITION OF SIGHT, RESULTING FROM AN AFFECTION OF THE NERVOUS STRUCTURE OF THE EYE, WHETHER SEATED IN THE RETINA, OPTIC NERVE, OR BRAIN; AND WHETHER DIRECTLY THE RESULT OF ORGANIC CHANGES IN THOSE PARTS THEMSELVES, OR INDIRECTLY THE EFFECT OF THEIR SYMPATHY WITH DISORDER OF OTHER ORGANS.

THIS is the GUTTA SERENA of the Arabic writers, whence the term "Drop Serene," of our own tongue; terms we have already explained under PAROPSIS CATARACTA. Milton is well known to allude to this affection in his beautiful address to light, as he does also to the cataract, by him called *suffusion*, as the Latins call it *suffusio*; but it is singular that, in the course of this allusion, he seems doubtful as to which of the two diseases he ought to ascribe his own blindness:—

"Thee I revisit safe,
And feel thy sovereign vital lamp; but thou
Revisit'st not these eyes, that roll in vain
To find thy piercing ray, and find no dawn.
So thick a DROP SERENE has quench'd their orbs,
Or dim SUFFUSION veil'd."*

The term AMAUROSIS is derived from the Greek *αμαυρός*, "obscurus, caliginosus, opacus." The most common cause is a paralysis of the retina, usually in conjunction with a paralysis and dilatation of the iris. Occasionally, however, this is rigidly contracted. From the different degree in which the disease presents itself, and from its assuming at times an in-

don, 1819; and Lawrence's Treatise on Diseases of the Eye, p. 452 et seq., 8vo., Lond., 1833.

* See also D. Weller's Treatise Ueber künstliche Pupillen, und eine besondere Methode, diese fertigen; published in Langenbeck's Neue Bibliothek, b. ii., st. 4. See also Dr. Schlagintweit Ueber den gegenwärtigen Zustand der künstlichen Pupillenbildung, &c., München, 1818.

† Par. Lost, iii., 21.

* Annual Report of the Liverpool Institution for Diseases of the Eye. By Alexander Hannay, M. D., 1822.

† Ansicht der Staphylomatoien Metamorphosen des Auges, und der Künstlichen Pupillenbildung. Also, particularly, G. J. Guthrie on the Operations for the Formation of an Artificial Pupil, 8vo., Lon-

termittent type, it has three principal varieties:—

- a Perfecta. Attended with total blindness. Complete amaurosis.
- β Imperfecta. With vision impaired, but not altogether destroyed. Incomplete amaurosis.
- γ Intermittens. With periodical cessations and returns. Intermittent amaurosis.

Plenck makes a distinct disease of an unalterable pupil, with or without injury of the vision, under the name of MYDRIASIS. When accompanied with injured vision, it is evidently a variety of amaurosis; and it is questionable whether an unalterable pupil is ever to be traced without defective vision.

It is probably to the cases attended with contraction of the pupil, that Shakspeare chiefly alludes by the term *pin* or *pin-eye*, the pupil being sometimes contracted to nearly the diameter of a pin's head; though the synizesis is equally entitled to the name. I have quoted one example already under P. Caligo, which he calls web-eye; another is contained in the following couplet:—

—“Wish all eyes
Blind with the PIN and WEB.”

[In the former editions of this work, the author made the state of the pupil the ground of two of his varieties of amaurosis. When the pupil was dilated, the amaurosis was termed *atonic*; when contracted, *spasmodic*. Thus the iris was more attended to than the real seat of the disease, and incidental changes were mistaken for essential ones, and considered to be absolutely dependant upon atony and spasm. These errors the editor is happy to have the opportunity of expunging; and in their place he has substituted the two varieties of *perfect* and *imperfect amaurosis*, as cases admitted by every modern writer on diseases of the eye, and the distinct consideration of which is highly useful in practice. The *intermittent* amaurosis, the third variety adopted by the author, remains; though the principal examples of it are comprised in the subjects of day blindness and night blindness. Other better founded and more practical distinctions than those formerly given by our author, are the *organic*, and the *sympathetic* or *functional*; the former depending upon a diseased state of the retina or optic nerve; the latter consisting of a suspension of the functions of the nervous structure of the organ of vision, in consequence of the influence of the disease or disorder of some other part of the body on the eye. This last case is also sometimes denominated *symptomatic* amaurosis, being the mere effect of another disease, which is the primary one. In this point of view, the loss of vision or paralysis of the retina from various organic changes affecting the whole eyeball, as hydrophthalmia, fungus hæmatodes, &c., may be considered as a symptomatic amaurosis. Besides the important division of this disease into the *perfect* and *imperfect, organic* and *functional* varieties, some others, not noticed by our author, cannot be

overlooked by the practitioner, because they make very considerable differences in the prognosis. The further distinctions here alluded to are those of *recent* and *inveterate*, and of *complicated* amaurosis.

Amaurosis is generally characterized by a very dilated state of the pupil, which is frequently not affected by any degree of light that is made to fall upon the retina. Sometimes the pupil is extraordinarily contracted. Hence, as already stated, the varieties formerly selected by the author of this work were badly chosen; because they were founded, not upon any intelligible differences in the condition of the retina, but upon incidental states of the iris. His second or *spasmodic* variety, indeed, as far as the definition went, might have signified rather synizesis, or impediment to vision from great and permanent contraction of the pupil. In amaurosis the pupil seldom retains its circular form, but becomes more or less irregular or angular. Neither does it commonly exhibit the clear appearance of a sound eye, but a grayish or dark green hue, resembling what is observable in the eye of a horse. In certain examples, a whitish or greenish-yellow spot is perceptible apparently in the fundus of the eye, and a little to one side of the visual axis, with a splendid disk, like the tapetum of sheep, or the coloured choroid of fishes. Another change in the pupil, noticed by Beer and all the most correct writers on amaurosis, is an alteration in its position: it is mostly drawn towards the internal and superior portion of the eye. The iris is in general very sluggish, or absolutely motionless; but in a few cases it preserves its usual power of motion (*Caldani ad Haller, vide Richter, Nov. Comm. Soc. Goett.*, tom. iv., p. 79; *Hey, Med. Obs. and Inq.*, vol. v.), and sometimes acts with greater rapidity than in a healthy eye. Amaurosis is ordinarily preceded by certain defects in the sight, and illusive appearances before the eye. One of the most important is what is termed by writers the *visus interruptus*. Thus, in reading, it seems to the patient as if syllables, words, or whole lines were deficient; and he is obliged to move the eye or head ere he can discern what seems wanting. If he look upon any other object he will seldom see the whole of it, unless he make a similar motion of his eye or head. On other occasions, he will see the whole of the object when it is held in a particular direction, but he loses it again as soon as this is altered.

A common precursor of amaurosis is an appearance as if motes or small bodies were incessantly moving about in front of the eye. This is the *visus muscarum*, or *muscæ volitantes* of surgical writers. When it is a dark-coloured speck that the patient fancies to interrupt his sight, it receives the technical name of *scotoma*; for appearances of this kind may be either single or very numerous, and of diversified shapes. They are most troublesome when the patient looks at very bright or light-coloured surfaces. In incipient amaurosis every object frequently appears to the patient as if it were surrounded by a zone of variegated colours; but sometimes things have a different look, seeming as if they were

enveloped in a mist, gauze, or network. In many cases, single objects appear to be double: this defect of vision is termed *visus duplicatus*, and proceeds from impairment of the faculty by which the axis of vision in each eye is made to adapt itself to the object looked at.

Amaurosis may present itself as an uncombined local affection of the optic nerve or retina, or as conjoined with some other disease of the organ or general system. Among the local complications are to be noticed cataract, fungus hæmatodes of the eye, glaucosis, cirsophthalmia, hydrophthalmia, exophthalmus, atrophy, paralysis of one or more muscles of the eyeball or lids, ophthalmitis, &c. The general complications especially meriting enumeration are, diseases of the nervous system, the debility from typhoid and other fevers, hydrocephalus, organic and functional diseases of the abdominal viscera, worms, pregnancy, and diseases of the brain and cranium.

Amaurosis is not restricted to any particular age or sex. Perhaps, on the whole, persons of middle age are most liable to it. Children are less liable to the disease than adults, but congenital cases are upon record. In Germany, an opinion prevails, that dark-coloured eyes are more frequently attacked by amaurosis than those of light colour. A tendency to the disorder is produced by pregnancy, by every kind of immoderate exertion of the eyes on small or shining objects, a full habit, and whatever has the effect of keeping up a great determination of blood to the head and eyes. Mr. Lawrence considers organic amaurosis as not essentially different from a very slow insidious inflammation of the retina, and not a disease of debility, as represented by numerous writers. His opinion on the pathology of amaurosis, of course, has great influence on the practice which he particularly inculcates; and which, in the early stage, is generally antiphlogistic; in the second, mercurial.—(See *Treatise on the Diseases of the Eye*, 8vo., 1833.)

The doctrine most usually adopted, however, refers a certain class of cases to debilitating causes; as typhoid fevers, profuse discharges or evacuations, excessive venery, the suckling of infants, &c.

That particular articles of food or medicine will produce amaurosis sympathetically, is amply proved. It is true, that in some of the examples of this fact we are obliged to suppose the existence of an idiosyncrasy; as when a person is affected with blindness whenever he takes chocolate or bitters, which have not the slightest effect upon the sight of other persons. The sympathy of the eyes with the stomach and intestines is often illustrated in cases of worms, which, according to the admission of every writer, are not an unfrequent occasion of amaurosis. A child has been known to become amaurotic from accidentally swallowing a bead, and to regain sight on the foreign body being voided by means of an emetic. In Germany and Italy, indeed, the opinion that amaurosis is very frequently prevalent on gastric disorder has been entertained to a great and perhaps an unwarrant-

able extent; we say unwarrantable, because in this country, experience does not furnish evidence of the efficacy of the treatment which the doctrine naturally points out, and which, in the hands of Schmücker, Richter, and Scarpa, has proved remarkably successful. Beer himself had little faith in the opinion, except in relation to the amaurosis from worms; and in this metropolis, repeated trials of the emetic practice have not created an impression in its favour.

The great influence of hereditary disposition in producing amaurosis has been remarked by all the most correct observers. Beer in particular adverts to the frequent examples of this fact, and mentions a certain family, in which all the females who had not had children became amaurotic about the period of the cessation of the menses; and what is very remarkable, it is stated that this had been the case through three generations.

One form of imperfect amaurosis, named amblyopia senilis, is ascribed by Beer to deficiency of the pigmentum nigrum. This case is commonly attended with a tremulous or vibratory motion of the globe: the admission of light produces great uneasiness, and vision is seriously weakened. It is usually met with only in old persons; but sometimes occurs in others after fevers, and in the last stage of consumption.—(*Vetch on Diseases of the Eye*, p. 144.) Although it is declared to be incurable, the power of vision may be very usefully assisted with cylindrical shades, goggles, and other contrivances calculated to absorb light.

An amaurosis rarely cured, is that arising from blows on the eyebrow, or injury of the frontal nerve. All cases, likewise, depending upon organic changes in the eye itself, optic nerve, brain, or orbit, do not admit of relief. The prognosis in every instance of complete amaurosis is unfavourable. The functional and sympathetic forms of the complaint are generally more easy of cure than the organic; but whether they can be relieved or not, will depend upon the circumstance whether the original complaint in another part of the body, with which they are connected, can itself be removed or not. The length of time that the loss of sight has prevailed, will also materially influence the prognosis. Generally speaking, amaurosis that has been formed recently and suddenly, but without violence or immoderate previous inflammation of the eye, is more easily cured than that which has come on with great slowness. The disease is absolutely incurable, when accompanied by any change in the shape and dimensions of the eyeball. When amaurosis affects only one eye, unless it be from sympathy with a neighbouring part,* as a carious tooth, the other eye is in great danger of being also attacked. The occasional mobility of the iris in this disease, and a moderate dilatation of the pupil, are no proof that the amaurosis will be more easily cured; for the iris often regains its mobility without the least im-

* See Wardrop's *Essays on the Morbid Anatomy of the Eye*; and Frick on *Diseases of the Eye* by Welbank, p. 150, 2d edit.

provement in vision, and sometimes the eyesight may improve, though the iris continue sluggish or even motionless.

The treatment of amaurosis must of course be regulated by the view taken of the cause of the disease. Thus, notwithstanding the fact that emetics have not proved as successful in this country as they have abroad, they should be prescribed when bilious disorder of the gastric organs is evidently present, and unaccompanied with much determination of blood to the head. Richter has recorded the case of a priest who became suddenly blind in a fit of passion, but recovered his sight immediately after taking an emetic. Schmucker cured many cases by a combination of the emetic and antiphlogistic practice, and the evidence of Scarpa is strongly in favour of the same method. In general, it is to be taken into the account, that emetics and bleeding have been assisted with the simultaneous exhibition of purgatives, so that it would be assuming too much in numerous examples to refer the success of the practice altogether to the emetics. Purgatives are, on the whole, in far greater repute for their good effects on amaurotic disorders, than the free employment of tartarized antimony. They are particularly indicated when there is much disorder of the primæ viæ, when the disease is attended with habitual costiveness, and any manifestly increased determination of blood to the brain and eyes. This state may be presumed to exist whenever amaurosis is connected with the suppression of any accustomed discharge, as of the menses, bleeding from piles, secretion of matter from an old ulcer, &c. The origin of the greater number of cases of amaurosis, that is to say, of those which directly affect the retina or optic nerve, is ascribed by Mr. Lawrence to vascular excitement, to congestion, or even a slow inflammation of the nervous structure constituting the seat of vision. His practice, therefore, in such instances, is at first decidedly antiphlogistic, comprehending local and general bleeding, purgatives, low diet, &c., afterward followed up by the free use of mercury, aided with blisters or a seton.

This mode of treatment, however, he recommends to be graduated according to the violence of the attack, the constitution, age, and strength of the individual, and other circumstances. It must not be supposed, he observes, that all amaurotic patients require to be bled and salivated. When we meet with the affection in the form of active inflammation of the retina, more especially in young and vigorous individuals of full habit, where there are obvious marks of local vascular congestion and constitutional excitement, the antiphlogistic treatment cannot be too active or too quickly followed up. Amaurosis often comes on in a slow and very insidious manner in persons of enfeebled constitution: the organ suffers from habitual excessive exertion, at the same time that the constitution is depressed by residence in confined dwellings, bad air, by sedentary occupations, unwholesome diet, costiveness, and other hurtful influences. In the treatment of a thin, pallid, feeble woman, who had destroyed her health by close confine-

ment to needlework, less active measures would be required. Emptying the alimentary canal, perhaps, taking away a little blood by cupping, or by leeches to the temples, and then using mercury in the alterative manner, with mild aperients, would here be the best plan. Mr. Lawrence recommends a few grains of Plummer's pill to be given every night or every second night, and the bowels to be kept open with occasional doses of electuary, castor-oil, or rhubarb and magnesia. The blue-pill, he says, may be taken in combination with aloes or the compound extract of colocynth. It may be necessary to persevere with the mercury, slowly increasing the dose until the mouth is slightly affected. A nutritious diet without stimuli, good air and exercise, and repose of the organ, Mr. Lawrence deems important auxiliaries. With these means may be joined a succession of moderate sized blisters. After mild antiphlogistic means, and the alimentary canal has been cleared, it may be expedient to combine tonics with aperients, as rhubarb with bark, columba, or cascarilla, and allow a generous diet, with a little porter and wine. Dr. Frick has seen much benefit from mercury or calomel in those cases of incipient amaurosis which come on with deep-seated pain in the head and orbit, more particularly when such pain is found to intermit.—(*On Diseases of the Eye*, 2d edit. by Welbank, p. 153.)

Although modern practitioners place little reliance on the real utility of various local stimulating applications in the treatment of amaurosis, and not much more on electricity, galvanism, and several internal medicines, once supposed to have a specific effect in removing blindness, the editor has considered it right not to suppress the following remarks delivered by the author, as they bring before us many plans which have occasionally been strongly recommended.]

Sternutatories demand attention: they are best formed of turbeth mineral, with about ten times its proportion of mild snuff, or any other light powder. The vapour of ammonia, ether, or camphire, mixed with hot water, has sometimes also afforded benefit; as has probably the use of moxa frequently repeated, so warmly recommended by Baron Larrey. "By this remedy," says he, "not only has the progress of amaurosis been arrested, but in some cases removed, even where the blindness was complete."—(*Rec. des Mém. de Chirurgie*, &c., Paris, 8vo., 1821.)

Professor Beer is minute in describing the modifications that proceed from plethora, and a morbid state of the digestive organs; but gives a still more copious detail of that which depends upon local rheumatism, and which he hence calls the rheumatic amaurosis. In this he remarks, that the pupil is perfectly clear, and the iris unalterable, slightly dilated, and thrust a little nearer the nose and the eyebrow than naturally, so as to be in a small degree displaced inwards and upwards. The tears flow on slight occasions, and the light is often troublesome, accompanied with an aching pain in the eyeball. The movement of the eye is impeded, and more in one direction than in others.

This modification rarely proceeds to perfect blindness.

The rheumatic form is frequently treated with success, and principally by diaphoretics. Beer employs guaiacum and camphire combined during the day, and Dover's powder at night; and with these he has recourse also to blisters, placed in succession behind the ear, on the temple, and over the eyebrow, so as to maintain a catenation of counter-irritative actions. Both this and the plethoric modification, in which local bleeding is of the utmost benefit, are frequently hurried on to a complete development of disease and a total insensibility of the retina by stimulants, and particularly by galvanism and electricity.

Where it has followed repelled eruptions, it has also been occasionally found to yield to setons and blisters, or a restoration of the suppressed efflorescence; and as in other diseases, what has sometimes proved the source of its production, has been found its best remedy; so that the cause has become the cure. Thus, it has at times yielded to the violence of a fever, to that of a sudden blow on the head, to a strong light, to a paroxysm of convulsions. Electricity, and especially voltaism, has probably been serviceable in some instances; at least, the assertions to this effect are very numerous, though in various cases both these have sometimes been altogether unsuccessful, and, as just observed, sometimes highly mischievous. Nor is the magnet without its recommendations, having been applied to the upper part of the spine, while minute bags filled with iron filings were placed on the eyes.—(*Wirkung des Kunstlichen Magnets*, &c., pp. 24, 25; *Heil. v. Nootnagel*, 1, c., § 22; *Eph. Nat. Cur. Dec.*, ii., ann. v., obs. 247.) The chief dependances, besides these, have been on camphire, cajeput, musk, mercury, iron, bark, arnica, and externally the *pulsatilla nigra*. Collier employed the flowers of arnica in decoction (*Dr. Layard, Phil. Trans.*, 1757-8, vol. 1, p. 747) in the proportion of about half an ounce to a pint of the strained liquid, which may be taken in a day or a day and a half. Richter, Schmücker, and other German writers, declare it to be of no avail. The *pulsatilla* is certainly better entitled to attention. "I would recommend it," says Dr. Cullen, with his usual liberality, "to the attention of my countrymen, and particularly to a repetition of trials on that disease, so frequently otherwise incurable, the amaurosis. The negative experiments of Bergius and others are not sufficient to discourage all trials, considering that the disease may depend upon different causes, some of which may yield to remedies, though others do not."—(*Mat. Med.*, vol. ii., part ii., chap. v., p. 216.) When distilled with water, it gives forth a terebinthinate substance resembling camphire, which necessarily possesses a stimulant, and hence a medicinal power. Whence the *euphrasia officinalis*, or eye-bright, obtained the character it once possessed as a specific in this disease, it is difficult to say. By Hildanus and Lieutaud, however, it was chiefly confined, even in its zenith of

popularity, to the amaurosis of old age. Its chief sensible quality is that of being a mild astringent. Rue, which rivalled it at one time, and by Milton is put upon a level with it, has far better pretensions when used externally in the form of a potent infusion; for it unites the properties of volatile pungency and bitterness: both which, as concentrated in strong chamomile tea, I have occasionally found highly serviceable in an incipient state of this disease, produced by weakness; though, as already remarked, none of these should be employed in several forms of the disease.

With respect to narcotics, the aconite has been chiefly popular in Germany: it has been strongly recommended by many writers of reputation, and has sometimes been given by gradual augmentation to the amount of a drachm daily.* Chevillard combined the use of antimonials with blisters; but cold applied externally, and cold bathing, as recommended by Warner, is much entitled to our attention.

Dr. Powell relates a case of sudden loss of vision, preceded by an acute cephalæa, in which an emetic was found, during the act of vomiting, abruptly to restore sight to the right eye (for both were affected), with a sensation as if a flash of lightning had taken place, but the vision was soon again lost. More than a twelvemonth afterward, the patient returned to emetics; when, after the use of the second, the pupils of the eyes recovered the power of dilating and contracting on exposure to light, and preserved it till death; but the power of vision was not restored. During the whole of this case of blindness, the sense of hearing was peculiarly acute.—(*Trans. Med.*, vol. v., p. 226.) The discovery of Dr. Bock, that a few nervous filaments, appertaining to the great sympathetic nerve, are thrown off while this nerve is within the cavernous sinus, and entering the orbit unite with the lenticular ganglion, may account for these remote influences; the ear, as is frequently the case, sympathizing with the morbid state of the eye, either directly or reversely.*—(*Beschreibung des fünften Nervenpaares und seiner Verbindungen mit anderen Nerven*, &c., von D. A. Carl Bock, Leipsic, 1817.)

SPECIES XII.

PAROPSIS STRABISMUS.

SQUINTING.

OPTIC AXES OF THE EYE NOT COINCIDING ON AN OBJECT.

This disease, in colloquial language now called *squinting*, was formerly denominated *goggle-eye*, whence the word *goggles* is still applied to the glasses which are used by persons affected with the complaint. The French called

* Beobachtungen und Untersuchungen, &c., band ii., Nuremb., 1767. All faith in the virtue of these medicines against amaurosis, is at the present day totally abandoned.—Ed.

† Dr. Hays has published an extremely judicious article on amaurosis, in the American Cyclopædia of Practical Medicine, vol. i. See likewise Copland's Dictionary of Practical Medicine, p. 50.—D.

these glasses *masques à louchette*, literally *squinting-guards*. The technical term STRABISMUS, is derived from the Greek *στραβός*, "tortus oculis," or "sight-twisted."

The optic axis is an imaginary line passing from the centre of the vitreous humour, lens, and globe of the eye, to the object of vision. In perfect vision, the optic axis of the one eye is in unison with that of the other; and consequently, they converge or coincide at the same point; and the object which would otherwise appear double, as being seen by each eye, is contemplated as single. In order to this coincidence the muscles of each eye must constantly assume the same direction, their position and configuration be precisely alike, and the sight be of an equal power and focus: a deviation from each of which postulates must necessarily produce squinting, or an inaccordant action of one eye with the other. From common and early habit we acquire an equal command over the muscles of both, and are able to give them any direction, or power of direction, and to fix them upon any object we please. And such is the force of habit, that they at length involuntarily associate in the same action, and it is difficult for us to give to the one eye a different direction from that of the other; or in other words, to make their optic axes diverge instead of converge. In persons born blind no benefit can be derived from this unity of action, and hence it is never attempted; and the muscles being never subjected to discipline, the eyeballs roll at random, and wander in every direction. In consequence of which, one of the most difficult tasks to be acquired by such persons, after obtaining sight, is that of keeping their eyes fixed, and giving the same bearing or convergent line to each. And hence, again, they see things double at first, and in a state of great confusion.

When one eye is naturally stronger, or of a more favourable focus, or more frequently employed, than the other, as among watchmakers and jewellers, the latter, from comparative neglect, relapses into an undisciplined state, and less readily obeys the control of the will. Its muscles do not assume the same direction as those of the eye employed; and if they do, in the two former cases, the object still appears double; and hence the neglected or weaker eye wanders and stares at one or at various objects, while the eye relied upon is fixed upon some other. And it is this divergence of the optic axes, this inaccordance of direction, or looking at different objects at the same time, that constitutes the present disease.*

* When the axis of the eyes of persons who do not squint, and sometimes also of amaurotic individuals, are directed in different lines, objects are seen double: squinting persons, however, do not see objects double. Yet the principal reason assigned for the singular phenomenon, that the images impressed upon the two eyes excite only one image in the mind, is, that the two images fall upon corresponding points of the retina. The probability therefore is, that in a squinting person, both eyes do not see the object looked at. In many cases, as Sir Everard Home has remarked, "this is pretty evident to a by-stander, who is able

It is obvious, therefore, that strabismus may have three varieties:—

- | | |
|---------------|--|
| α Habitualis. | From a vitiated habit; or the custom of using one eye, and neglecting the other. |
| β Atonicus. | From debility of the affected eye, whence the sound eye possesses a different focus and power of vision, and is alone trusted to: in consequence of which the weak or neglected eye insensibly wanders as already stated.* |
| γ Organicus. | From the eye being differently constructed in form or position.* |

The FIRST of these VARIETIES constitutes the NYSTAGMUS of Dr. Plenck, and its cause is sufficiently obvious. In the SECOND, the sound eye is alone trusted to, because it is the only eye on which any dependance can be placed; and hence the weak eye, neglected by the will, wanders insensibly, as in the preceding order we have seen that any one of the mental faculties will wander in like manner under the same want of discipline. [It has been ascertained by experiment, that in individuals who have a confirmed squint of this kind, one of the eyes is too imperfect to see distinctly. Of this, however, the patient is not always conscious, as was evinced in a young lady whose case is re-

to determine that the direction of one of the eyes differs so much from that of the other, that it is impossible for the rays of light from any object to fall on the retina of both, and therefore that one eye does not see the object. The same thing may be proved in another way. For since a small deviation in the direction of either eye from the axis of vision produces double vision, any greater deviation must have the same effect, only increasing the distance between the two images, till it becomes so great that one eye only is directed to the object. In squinting, there is evidently a greater deviation from the axes of vision than in double vision, and the object does not appear double; it is therefore not seen by both eyes."—Phil. Trans., vol. lxxxvii., 1797.—Ed.

* Besides the hypothesis here adopted in explanation of the manner in which strabismus is produced, others have been suggested. M. de la Hire conceived that the defect might arise from the more sensible part of the retina not being placed in the axis of the eye, but at some distance from it, on one side or the other; and that, consequently, not the axis, but this more sensible part of the retina, is turned towards the object on which the axis of the other eye is fixed, so that both axes are not directed to the same point. A case of this description would of course be absolutely incurable. Dr. Darwin's observations rather tend to show the possibility of such a form of strabismus; but both this hypothesis, and that of obliquity of the crystalline lens, are mostly considered to have been refuted by Dr. Jurin. Buffon refers the cause of squinting to an inequality in the goodness or in the limits of distinct vision in the two eyes; a doctrine, the truth of which is at present generally admitted. The exclusive adoption of any one hypothesis will obviously not explain all the varieties of strabismus.—Ed.

lated by Sir Everard Home. Neither she herself nor her friends believed that any defect of the eye existed; and upon being asked if she saw objects distinctly with her eyes, she said, certainly, but that one was stronger than the other. To ascertain the truth of this, he covered the strong eye, and gave her a book to read; when, to her astonishment, she found she could not distinguish a letter, or any other near object. More distant objects she could see, but not distinctly: when she looked at a bunch of keys in the door of a bookcase about twelve feet from her, she could see the bunch of keys, but could not tell how many there were. The obscurity of vision in one eye, then, is the cause of this common species of squinting, and may occasion this irregularity in the following way. The obscure image being so imperfectly formed in the weak eye as to excite little attention in the mind, the use of the eye, and its uniform direction to the same object with the other, may have been neglected from the beginning; for as distinct vision was obtained at once by the perfect eye, the end was answered, and therefore there was no necessity for any exertion of the other; or, in the effort to get rid of the confused image, the muscles may have acquired an irregular and unnatural action. Under either of these circumstances the eye is directed towards the nose, because, as Sir Everard Home remarks, this direction is determined by the superior force of the adductor muscle.] In the THIRD VARIETY, the difference of form or position respects the situation or figure of the one eye compared with the other, or of the particular parts of the one eye compared with those of the other: in consequence of which the one is favoured, and the other thrown into disuse. [Dr. Porterfield has pointed out two cases referrible to this variety, or rather, constituting two distinct varieties themselves. One depends upon an oblique position of the crystalline lens within the eye, by which the image of an external object is refracted out of the line of the axis of the eye; and the other from an oblique position and greater protuberance of the cornea, producing a similar effect.*]

In this last variety a complete cure is hardly to be expected. In the second it is attended with considerable difficulty; and in the first is rather to be accomplished by what, in mania, we have called *moral* treatment, than by medicine. A constant and resolute exertion on the part of the patient to obtain a command over the weak or irregular eye is of absolute necessity, while the neglected eye itself, if weak,

should be strengthened by tonics and gentle stimulants. Goggles, though often recommended, are seldom serviceable, and especially to children; for although the sight must hereby be restrained in each eye to a common line, the child will still use the sound eye alone, and leave the irregular eye unemployed. It is a better plan to affix some object near the orbit of the affected eye at such a distance, that it may constantly catch and draw off the pupil from the inner angle to the outer. [If squinting has not been confirmed by long habit, and one eye be not much worse than the other, Dr. Darwin recommends a piece of gauze, stretched on a circle of whalebone, to cover the best eye some hours every day, so as to reduce distinctness of vision in this eye to a similar degree of imperfection to what exists in the other eye.] But the method that I have myself found by far the most effectual, is to blindfold the sound eye with a blink for a considerable part of every day, and thus force the affected eye into use and a subservience to the will. I recommend this simple plan most strongly, and especially in the case of children; and may venture to predict that it will be sure to succeed in the first variety of the disease, that of habit, and frequently in both the others. [The same plan, which was first suggested by Dr. Jurin (see *Smith's Optics, Rem.*, p. 30), is recommended by Mr. Lawrence, who mentions, however, that the squinting eye has sometimes been cured by it, but the opposite one has then become affected. As strabismus, says he, occurs from so many causes, of course the treatment cannot be uniform. A close investigation, with the view to discover the particular cause, is a necessary preliminary to any remedial measures. When this has been accomplished, the course of treatment will be obvious; or we shall see, perhaps, that the defect cannot be remedied. In the forms of strabismus arising from accidental irritation affecting the sensorium or alimentary canal, the treatment will of course turn upon the removal of the cause. When strabismus and double vision occur in the commencement of amaurotic affection, they will disappear if we succeed in removing that disorder. The squinting which is produced from change in the pupil and cornea, will hardly admit of relief.—(Op. cit., p. 575.)]

Dr. Darwin mentions a singular case of squinting, in which the patient was equally expert in the use of either eye, but viewed every object presented to him with only one eye at a time, and always with the eye on the side opposite the object. Thus, if the object was present-

* Edin. Essays, vol. iii., art. xii. "The eye may be turned inwards or outwards, towards the nose or towards the temple, the one case being termed *strabismus convergens*, the other *strabismus divergens*. The deviation is not always confined to one eye; in some cases both are affected, the patient appearing sometimes to squint with the right eye, and at other times with the left. If the sound eye be covered, and the patient be directed to look at any object, the squinting eye resumes its proper position, and can be moved in any direction in obedience to the will; but there are instances in which this cannot be done."—See

Lawrence on the Diseases of the Eye, p. 574. In the junior school of the London University, there is at the present time (May, 1834) a boy, who squints with one eye when he looks at near objects, and with the other when he looks at distant ones. Here it is manifest that the power of accommodation to distances is different in the two eyes; and consequently, that when this boy is looking at near objects, the eye adapted only to distant objects cannot preserve any harmonious movement and position with respect to the other eye, which alone is now employed.—Ed.

ed on his right side, he viewed it with his left eye; and when it was presented on his left side, he viewed it with his right eye. At the same time, Dr. Darwin found that he turned the pupil of that eye which was on the same side with the object in such a direction, that the image of the object might fall on that part of the bottom of the eye where the optic nerve enters it, and where it would of course excite no impression; and this insensible portion of the retina Dr. Darwin ascertained, by some ingenious experiments, to be four times greater in this patient than in ordinary persons. When an object was held directly before the patient, he turned his head a little to one side, and observed it with but one eye; viz., with that most distant from the object, turning away the other in the manner just mentioned; and when he became tired of examining it with that eye, he turned his head the contrary way, and observed it with the other eye alone with equal facility; but never turned the axis of both eyes on it at the same time.

For remedying this curious example, in which there was no defect in either eye, but merely a depraved habit of using both eyes separately, Dr. Darwin says, "a gnomon of thin brass was made to stand over his nose, with a half circle of the same metal to go round his temples; these were covered with black silk; and by means of a buckle behind his head, and a cross-piece over the crown of his head, this gnomon was managed so as to be worn without any inconvenience, and projected before his nose about two inches and a half. By the use of this gnomon, he soon found it less inconvenient to view all objects with the eye next to them, instead of the eye opposite to them.

"After this habit was weakened by a week's use of the gnomon, two bits of wood, about the size of a goose-quill, were blackened, all but a quarter of an inch at their summits. These were presented for him to look at, one being held on one side of the extremity of this black gnomon, and the other on the other side of it. As he viewed these, they were gradually brought forwards beyond the gnomon, and then one was concealed behind the other. By these means, in another week, he could bend both his eyes on the same object for half a minute together.

"By the practice of this exercise before a glass almost every hour in the day, he became in another week able to read for a minute together with his eyes both directed on the same objects: and I have no doubt, if he has patience enough to persevere in these efforts, he will in the course of some months overcome this unsightly habit.—(*Phil. Trans.*, vol. lxxiii., pp. 86–89.)

GENUS II. PARACUSIS. MORBID HEARING.

SENSE OF HEARING VITIATED OR LOST.

PARACUSIS is a term of Hippocrates, derived from *παράκουω*, "perperam, depravatè, vitiosè audio." The mechanism of the ear is as com-

plicated as that of the eye, and is admirably adapted, in all its parts, to the perfection of the sense which constitutes its function. Its lobes, its entrances, its openings, its various drums, its minute and multiplied foramina, its delicate bones, all contribute to one common effect. Even the surrounding bones, and, still more than this, the teeth, are in no small degree auxiliary to the same object, as the experiments of M. Perolle, given in the fifth volume of the *Turin Transactions*, have abundantly established; as they have also, that bone in general is a far better conductor of sound than air, alcohol, or water.

We may hence learn one very important use of the four minute bones deposited in the posterior chamber of the tympanum, the loss of any one of which impairs the hearing, and in some instances, has produced total deafness; of which we have a striking proof in the case of a lad who had parted with the incus on one side, and both the incus and malleus on the other, by means of an ulcerated sore throat that opened a passage from the fauces into each ear, and through which the bones were discharged. The tympanum, on the boy's recovery, seems not to have lost its vibratory power; for he was sensible of violent or sudden sounds, but altogether insensible to conversation, and apparently as deaf in the ear that had only parted with the incus, as in that which had parted with both bones.*

From the complicated organism of the ear, it follows necessarily that, like the eye, it must be subject to a great variety of diseases; while many of the diseases of the one sense must bear a striking analogy to those of the other. Thus, painful and obtuse hearing and deafness may be well compared with painful and obtuse vision and blindness. As the eye is sometimes affected with illusory objects, so is the ear with illusory sounds; and as, when the optic axes do not harmonize, as in strabismus, the same object may be seen double, so may the same sound be heard double when the action of the one ear is inaccordant with that of the other.

And hence it is not at all to be wondered at that a peculiar degree of sympathy should exist between these senses, and the state of the one be frequently affected by that of the other. Bartholine gives a case in which deafness and blindness alternated with each other (*Epist.*, cent. iv., No. xl.); and we shall presently have to observe, that a temporary affection of the eyes may sometimes be produced by particular noises.

As the organ of the ear, however, is less ex-

* *Phil. Trans.*, vol. ii., No. 1, 1761. The editor has seen one case in which a boy who was reported to have lost all the ossicula of one ear, was not completely deaf from it; though certainly his hearing on that side was dull. Sir Astley Cooper is acquainted with another example of the same kind. According to Mr. Mayo, the stapes is so strictly applied to the membrana fenestræ ovalis, that the loss of this bone necessarily produces incurable deafness by injuring the labyrinth.—*Outlines of Human Physiology*, 2d edit., p. 415, 8vo., Lond. 1828.

posed than that of the eye, we are far less acquainted with the immediate seat of its diseases, and even with the exact bearing which every particular part sustains in the general phenomenon of hearing. It was at one time supposed that the nicest power of discriminating sounds, or in other words, that accuracy of distinguishing which constitutes what is called a musical ear, is seated in the cochlea; birds, however, whose perception is exquisite, have no cochlea. It has since been conceived by Sir Everard Home, that it is the membrana tympani in which this fine feeling is peculiarly lodged (*Phil. Trans.*, year 1800), and that it depends upon the muscularity of this membrane; yet the same feeling has remained, and in a high degree, in persons whose membrana tympani has been ruptured. —(See *Bell's Anatomy*, vol. iii., p. 180, Lond., 1820; and *Buchanan's Physiological Illustrations of the Organ of Hearing*, p. 14, London, 1828.) [Sir Charles Bell does not conceive that the cochlea, or any part of the organ, particularly conduces to the bestowing of a musical ear, although it is by hearing that we are capable of the perceptions of melody and harmony, and of all the charms of music. It would seem, says he, that this depends upon the mind, and is not an operation confined to the organ. It is enjoyed in a very different degree by those whose simple faculty of hearing is equally perfect.]

Paracusis as a genus includes the following species:—

- | | |
|---------------------|----------------------|
| 1. Paracusis Acris. | Acrid Hearing. |
| 2. ——— Obtusa. | Hardness of Hearing. |
| 3. ——— Perversa. | Perverse Hearing. |
| 4. ——— Duplicata. | Double Hearing. |
| 5. ——— Illusoria. | Imaginary Sounds. |
| 6. ——— Surditas. | Deafness. |

SPECIES I.

PARACUSIS ACRIS.

ACRID HEARING.

HEARING PAINFULLY ACUTE, AND INTOLERANT OF THE LOWEST SOUNDS.

THIS occurs occasionally as an idiopathic affection in nervous and highly irritable idiosyncrasies, and bears a striking analogy to that acritude of sight which we have noticed under *paropsis lucifuga*. It is the *hyperacusis*, or, as it should rather be, the *hyperacusis*, of M. Itard, who also regards it as an idiopathic affection in various cases.—(*Traité des Maladies de l'Oreille et de l'Audition*, 2 tomes, 8vo., Paris, 1821.)

It depends upon a morbid excitement, sometimes of the whole of the auditory organs, but more generally of some particular part, as the tympanum or the labyrinth, and especially the cochlea, or some of the internal canals. In many instances it seems confined to the branches of the nerve; and Bonet gives an instance of it from the very singular cause of a triple auditory nerve formed on either side (*Sepulchr.*, lib. i., sect. xix., add. obs. 7), in which case there is sufficient ground for its idiopathic origin. It is found more frequently, however, as a

symptom of earache, headache, epilepsy, otitis, cephalitis, and fevers of various kinds.

The sensation is sometimes so keen as to render intolerable the whisperings of a mere current of air in a room, or the respirations of persons present, while noises before unperceived become highly distressing.

I have at this moment before me a most impressive description of this effect in a letter from a young lady of about twenty-eight years of age, of an irritable habit, great genius, and a highly cultivated mind, who about a twelvemonth ago was attacked with a cephalitis which proved severe and alarming. The mental powers are rendered more acute, and the external senses, especially those of hearing and seeing, strangely sympathize with each other. "You think me," says she in this letter, "unfit for study; but study I must, whether I am fit for it or not, otherwise my mind preys upon itself, and no power can prevent my thinking, which is almost as bad as reading. Last night I was kept awake for some hours by so powerful an excitement of the brain, that I really thought it would have taken away my senses. The pain is very acute, but I do not mind that so much as the distraction which accompanies it. It usually comes on with a most painfully quick hearing. I feel as if the tympanum was stretched so tight as to make the least sound appear almost as loud as thunder; and a loud noise is just as if I received a blow quite to the centre of the brain. This really is not imagination, but actual sensation. Moreover, a noise affects my eyes so much, that I am obliged to darken my room when at any time I am under the necessity of hearing any thing like a noise: a loud sound affects my eyes, and a strong light my ears. They seem to act reciprocally. My head is certainly not so bad, nor any thing like it, as it was at Clifton, but still the sudden attacks I have from over-exertion of the mental powers, or upon any other excitement, make me always fearful I shall lose my senses."

Injections of warm water, or a few drops of almond-oil dropped into the ear, will occasionally afford relief. But cold water, and cold applications about the ear, and even pounded ice where there is no tendency to a periodic rheumatism, by directly inducing torpidity, will at times have a better effect; laudanum may also be introduced into the ear, and a blister be applied to its immediate vicinity.

SPECIES II.

PARACUSIS OBTUS.

HARDNESS OF HEARING.

HEARING DULL AND CONFUSED, AND DEMANDING A CLEAR AND MODULATED ARTICULATION.

THIS may proceed from organic defect; from local debility, in which case it is called *NERVOUS DEAFNESS*; or from some accidental obstruction in the external tube or passage, as that of mucus, wax, sordes, or any other extrinsic body; or, in the internal or Eustachian tube, from mucus, inflammation, or ulceration and its conse-

quences.* It is also found occasionally as a symptom or sequel in various fevers, in hemiplegia, apoplexy, otitis, lues, and polypous cancrules or concretions in the passage of the ear; and has followed on drinking cold water during great heat and perspiration of the body, of which several examples are given in the *Ephemerides of Natural Curiosities*. Among the cases of organic defect, one of the least common is atresia, or imperforation; yet Albucasis (vide *Marcell. Donat.*, lib. vi., cap. ii., p. 619) gives us an instance of this, as does Bartholin† and Hencel.—(*N. Anmerk.*, ii.) And among the more singular obstructions of an accidental kind may be mentioned insects and the grub of insects or worms. Bartholine mentions a leech which was once found to have burrowed in the ear; and Walker a small stone which had unaccountably become lodged there, and was discharged by a fit of sneezing.†

The cure must depend upon the nature of the cause. All foreign bodies must be carefully removed or destroyed, and the cavity of the ear be washed by means of a syringe. Accumulations of wax may be softened by oil of almonds and alcohol, which will dissolve whatever resi-

* That hardness of hearing sometimes depends on deficiency of the ceruminous secretion within the meatus auditorius, is a fact of which most surgeons are perfectly aware. It is a cause, however, that does not appear to have received the author's notice. The ceruminous lining of the meatus auditorius is regarded by Mr. Buchanan as very essential to perfect hearing; and he has termed it the "*ceruminous tubular circle*." "Without this provision," says he, "the undulations would affect or strike upon various parts of the membrana tympani irregularly, and produce confused vibratory action. And hence we find, in patients divested of this secretion, almost total inability to partake of the pleasure of a conversational party, where the news, politics, or other matters are discussed by the generality of the company; more especially if an argument ensue, in which a part of the discussion is taken by each individual." Mr. Buchanan compares the effect of the "*ceruminous tubular circle*," in absorbing what he calls the *resilient* pulsations of sound, to that of the pigmentum nigrum in the eye, which absorbs the superabundant rays of light, and prevents them from being reflected so as to injure the retina, or render vision indistinct.—See Buchanan's *Physiological Illustrations of the Organ of Hearing*, p. 21, 8vo., Lond., 1828.

† Hist. Anat., cent. vi., n. 36. The editor of this work has seen a child which was born entirely destitute of both auricles, and with the places of the meatus auditorii covered by the common integuments. In this case the hearing was dull, but not annihilated.

† *Observ. Medico-Chirurg.*, xx., 8vo., 1718. I once removed two pebbles from the ears of a child after they had remained there a twelvemonth, having been introduced by another child in play. The little patient was, at the time of my seeing him, in considerable pain; inflammation had attacked each meatus auditorius, and there was complete deafness. I succeeded in bringing out the pebbles by throwing warm water into the meatus with some considerable force by means of a syringe. I recommend surgeons to prefer this simple expedient to more painful, and dangerous, and less efficacious measures.—Ed.

nous part it possesses; and a like inunction will be found the best means of destroying insects. Atonic or nervous deafness will often bid defiance to our utmost exertions, but it will sometimes yield to local stimulants and tonics: of the former are alcohol, ether, camphorated spirits, essential oil of turpentine combined with olive-oil, and the tinctures of the gum-resins, as myrrh, amber, kino, balsam of Tolu, and blisters about the ear; of the latter, cold water, and solutions of alum, sulphate of zinc, or other metallic salts.

[When hardness of hearing depends upon a deficiency of cerumen, Mr. Buchanan recommends warmth and stimulant applications. Two drops of the subjoined formula* he advises to be applied to the interior parts of the tube every night at bedtime, and a table-spoonful of the mixture, the composition of which is given below,† to be taken at the same time. If the patient be costive, the pilulæ rhei comp. are also to be prescribed. When the wax is deficient in quality, or deficient both in quantity and quality, Mr. Buchanan, with the view of improving the state of the digestive organs, gives two table-spoonfuls of an infusion of quassia, with rhubarb and magnesia. The patient should reside in a dry airy place; take regular exercise; use the warm bath at bedtime once or twice a week; and immediately after getting into bed take pulv. ipecac. comp. ℥j. and hydrarg. submur. gr. ij. Mr. Buchanan directs the underwritten injection‡ to be used every second or third day. He speaks also favourably of bathing the feet in warm water, and a light nourishing diet, with a glass of port wine after dinner. Sometimes he applies blisters behind the auricle, or uses them and an antimonial embrocation§ alternately.—(See *Th. Buchanan's Illustrations of Acoustic Surgery*, p. 60 et seq., 8vo., Lond., 1825.)

Where hardness of hearing is habitual, and cannot be radically cured, we can only endeavour to diminish the evil by advising the use of a hearing-trumpet, which is, in fact, an instrument formed upon the principle of imitating the cavities of the labyrinth of the ear itself, and the object of which is to collect a large body of sonorous tremours, and send them to the tympanum in a concentrated state by means of a convergent tube, or in other words, to increase as much as possible the vibratory power of the sound. Now sound is well known to be propagated in straight lines, and hence persons partially deaf will always hear most distinctly when directly opposite the speaker. For the same reason the trumpet itself should be formed as nearly as possible in a straight line; though we are sometimes, for the sake of convenience, obliged to deviate from this direction, and to bend the tube into the segment of a circle, by which

some degree of power is always lost. The metal of which the tube is made should be that which is found most sonorous, or, in other words, which most completely reflects instead of absorbing the sound; and while the funnel or large aperture is as wide as possible, the extreme end of the pipe cannot be too small. M. Itard has found that a parabolical figure has no advantage over a conical or pyramidal tube; but that the tube is assisted in producing distinctness of sounds by an insertion into it of slips of gold-beater's leaf, at proper distances, in the manner of partitions.—(*Traité de Maladies de l'Oreille et de l'Audition*, 2 tomes, Paris, 1821.)

SPECIES III.

PARACUSIS PERVERSA.

PERVERSE HEARING.

THE EAR ONLY SENSIBLE TO ARTICULATE SOUNDS WHEN EXCITED BY OTHER AND LOUDER SOUNDS INTERMIXED WITH THEM.

This is a very extraordinary hebetude of the organ, though it has occasionally been met with in most countries. Where it exists, the ear, as in other cases of imperfect hearing, requires to be roused in order to discriminate the articulate sounds addressed to it, but finds the best excitement to consist in a great and vehement noise of almost any kind.—(*Feilix in Richter Chir. Bibl.*, band ix., p. 555.) It consists, according to Sauvages, who seems to judge rightly concerning it, in a torpitude or paresis of some parts of the external organ, which, in consequence of this additional stimulus, convey the proper sounds addressed to them beyond the membrane of the tympanum, in the same manner as the drowsy, or those who are sluggish in waking, do not open their eyes, or admit the light to the retina, unless a strong glare first stimulates the exterior tunics. It seems, however, sometimes to depend upon an obstruction of the Eustachian tubes.

Under the influence of this species, it occasionally happens that particular sounds or noises prove a better stimulus than others, though equally loud, or even louder; as the music of a pipe, of a drum, or of several bells ringing at the same time. Holder relates the case of a man who never heard but when he was beating a drum (*Phil. Trans.*, 1668, No. xxvi.); and Sauvages a similar case of a woman, who on this account always kept a drum in the house, which was constantly played upon while she was conversing with her husband. The latter gives another case of a person who was always deaf except when travelling in a carriage, during which time, from the rauling of the wheels, he was perfectly capable of hearing and engaging in conversation. And Stahl gives an instance of like benefit derived from the shrill tones of a pipe.—(*Colleg. Casual.*, N., lxxvi.)

In ordinary cases of practice, if we can once hit upon a stimulus that succeeds in giving temporary tone to a debilitated organ, we can often avail ourselves of it to produce a permanent benefit, and sometimes a complete restoration, by raising or lowering its power, continuing its

power for a longer or shorter term of time, or modifying it in some other way, so as to adapt it to the particular exigency. And it is hence probable, that if any of these sonorous stimuli were to be employed medicinally, and with a due respect to length of time and acuteness of tone, they might in some instances be made the medium of obtaining perfect success. Dr. Birch, indeed, gives an instance of such success in a person who only heard during the ringing of bells; and who, by a permanent use of this stimulus, recovered his hearing altogether.—(*Hist.*, vol. iv.) Voltaism may here also be employed in many cases with a considerable promise of advantage; and especially in connexion with the ordinary routine of general and local tonics and stimulants, as cold, and cold bathing, pungent masticatories and injections, bark, valerian, alone or with ammonia, and a free use of the siliquose and coniferous plants as a part of the common diet.

SPECIES IV.

PARACUSIS DUPLICATA.

DOUBLE HEARING.

THE ACTION OF THE ONE EAR INACCORDANT WITH THAT OF THE OTHER; SOUNDS HEARD DOUBLY, AND IN DIFFERENT TONES OR KEYS.

This pravity of hearing depends upon an inaccordance of the auditory nerve on the one side with that on the other; so that the same sound produces on each side a very different effect, and is consequently heard, not homotonously, or in like tones, but heterotonously, or in separate and unlike. And hence this species of morbid hearing, as I have already observed, has a considerable parallelism with that of strabismus or squinting, in which the optic axis of the one eye is not accordant with that of the other, whence the same object is seen double, and often in a different position. Sauvages has given two or three very curious examples of this affection. A musician, while blowing his flute, heard two distinct sounds at every note. The sounds were in different keys, and consequently not in harmony; and as they were heard simultaneously, the one could not be an echo of the other. On another occasion he was consulted by a person who for several months had been troubled with a hearing of two distinct voices whenever he was spoken to; the one at least an octave higher than the other, but not in unison with it, and hence producing a harsh and insupportable discordance.

This affection is mostly temporary, and, as proceeding altogether from a morbid condition of the auditory nerve, has been cured by blisters and other local stimulants. From not being attended to, however, in due time, it has sometimes assumed a chronic character, when it is removed with great difficulty; and in a few instances it has been connected with a constitutional irritability of the nervous system, in which case a plan of general tonics must co-operate with local applications.

[Mr. Buchanan does not coincide with the author respecting the cause of *paracusis dupli-*

cata, but ascribes its symptoms to an imperfect secretion of cerumen in only one ear.—(See *Buchanan's Physiological Illustrations of the Organ of Hearing*, p. 24, Lond., 1828.) In this view of the case, nothing more need be said on the treatment than what has already been stated under the head of *paracusis obtusa*. If some observations published by Sir Everard Home be correct, double hearing may sometimes arise from another cause, not adverted to by Dr. Good. "An eminent music-master (says he), after catching cold, found a confusion of sounds in his ears. On strict attention, he discovered that the pitch of one ear was half a note lower than that of the other; and that the perception of a single sound did not reach both ears at the same instant, but seemed as two distinct sounds following each other in quick succession, the last being the lower and weaker. This complaint distressed him for a long time, but he recovered from it without any medical aid. In this case (Sir Everard Home observes), the whole defect appears to have been in the action of the radiated muscle (of the tympanum), exerted neither with the same quickness nor force in one ear as in the other, so that the sound was half a note too low, as well as later in being impressed on the organ."—(*Phil. Trans.*, 1800.) This case seems to be very similar to those above cited from Sauvages. Mr. Buchanan expresses his doubts about the reality of the alleged cause, which he suspects might be a defective state of the ceruminous secretion.]

SPECIES V.

PARACUSIS ILLUSORIA.

IMAGINARY SOUNDS.

INTERNAL SENSE OF SOUNDS WITHOUT EXTERNAL CAUSES.

THIS is in most instances strictly a nervous affection, and bears a striking analogy to *paropsis illusoria*, or that illusory or false sight in which unreal objects, of various forms, colours, and other sensible qualities, appear before the eyes. The morbid state is often confined to the auditory nerves, or some of the branches alone; yet it is not unfrequently the result of a peculiar irritability that extends through the whole of the nervous system. And occasionally it proceeds from an obstruction of one or both the Eustachian tubes. M. Itard ascribes it to two other causes: a peculiar state of the blood-vessels, local or general, and an impeded motion of the air in the tympanal cavity (*Traité des Mal. de l'Oreille et de l'Audition*, 2 tomes, 8vo., Paris, 1821); [Mr. Buchanan, to the imperfect secretion of cerumen.—(*Physiological Illustrations of the Organ of Hearing*, p. 23.)] The sounds hereby produced differ greatly in different persons, and sometimes in the very same person at different periods; but it is sufficient to contemplate them under the three following varieties, all which the French express by the term *bourdonnements*:—

α Syrigmus.	A sharp, shrill, successive
Ringing or tinkling.	sound.
β Susurrus.	An acute, continuous, hissing sound.
Whizzing.	
γ Bombus.	A dull, heavy, intermitting sound.
Beating.	

Heister recommends, in cases arising from a debility of the local nerves, to fumigate the ears with the vapour of a hot vinous infusion of rosemary and lavender; and where a spasmodic affection of the inner membrane may be supposed to follow such debility, he advises a simultaneous use of diaphoretics internally. If it proceed from an obstruction of the Eustachian tubes, in consequence of spasm or inflammation, the fumes of tobacco drawn into the mouth, and forcibly pressed against these tubes by closing the lips and nostrils, and then urgently sniffing the vapours upwards to the palate, have often proved serviceable, by taking off the irritability on which the spasmodic or inflammatory action is dependant. Stimulating the external ear by blisters or aromatic injections has sometimes availed, though not often. Chronic cases are extremely difficult of cure; though I had lately an elderly lady for a patient, who after having at different times suffered from each of these modifications of illusory sounds for several years, and tried every remedy that could be suggested in vain, at length lost the distressing sensation by degrees, and without the assistance of any medicine.*

SPECIES VI.

PARACUSIS SURDITAS.

DEAFNESS.

TOTAL INABILITY OF HEARING OR DISTINGUISHING SOUNDS.

IN the preceding species, the sense of hearing is in various ways depraved or impaired; in the present, it is altogether abolished, and may proceed from causes which offer three distinct varieties of affection:

α Organica.	From organic defect or impediment.
Organic deafness.	
β Atonica.	From local debility or relaxation.
Atonic deafness.	
γ Paretica.	From nervous insensibility.
Paretic deafness.	

THE ORGANIC DEFECT or impediment may exist in the outer or inner entrance, or in the cavity of the ear. The outer entrance has in a few instances been imperforate (*Cels de Medicin.* lib. vii., c. 8; *Büchner, Miscell. Phys. Med.*, p. 318, 1727), but far more generally blocked up with indurated wax, excrescences, concretions, or some other substance. The inner entrance or Eustachian tube has been sometimes also found imperforate on both sides, but more frequently obliterated by ulceration (*Haller, Elem. Phys.*, tom. v., p. 286), or

* The treatment suggested by Mr. Buchanan has already been briefly noticed under the head of *Paracusis Obtusa*.

closed by the mucous secretion of a catarrh, or the pressure of the tonsils, in whatever way morbidly enlarged. If the defect or impediment exist in the cavity of the ear, its precise nature can seldom be known during the life of the patient, and if known would rarely admit of a remedy. It often consists of a malformation of the helix; and, as we have already seen under PAROTITIS, in a loss of the articulation or substance of one or more of the tympanal bones.

ATONIC DEAFNESS, or that dependant on local debility or relaxation, may be superinduced by a chronic cold, abruptly plunging the head into cold water in a heated state, a long exposure to loud and deafening noises, or the sudden and unexpected burst of some vehement sound upon the ears (*Schulze, Diss. de Auditûs Difficultate*, sect. 23), as that of a cannon or a thunderclap (*Borelli, Observ.*, cent. iv., Paris, 1656), where the constitution is in a state of great nervous irritability: in which state, moreover, it has in a few instances been produced by a violent fright.—(*Eph. Nat. Cur.*, cent. ix., obs. 6.) It has also proceeded from an atony of the excretories of the outer ear, in consequence of which there has been neither wax nor moisture of any kind. And it has followed as a sequel upon various fevers and inflammations, especially cephalitis and otitis, rheumatic hemicrania, and other nervous headaches, repelled gout, and repelled cutaneous eruptions.

PARETIC DEAFNESS may be regarded in many cases as nothing more than an extreme of atonic deafness; and almost all the causes producing the one, when operating with greater violence or upon a feebler frame, may also produce the other. It has not only been induced suddenly by loud sounds and violent frights, but by a vehement fit of sneezing, and from sympathy, by the use of powerful sternutatories (*Eph. Nat. Cur.*, dec. ii., ann. ix., obs. 26); the olfactory nerve hereby becoming insentient through all its branches.

Deafness has often been transmitted hereditarily; of which numerous instances are to be found in Hoffmann (*Consult. et Respons.*, cent. i., cas. 40), Morgagni (*De Sed. et Caus. Morb.*, epist. xlviii., art. 48), and other writers of established reputation.

The most usual causes of total deafness are beyond the power of the medical art to relieve; and hence the disease runs very generally through the whole period of life. Where the cause is an imperforation of either of the passages, an opening has been often effected with success. Many other impediments, as of indurated wax, or infarction from inflammation, are in general removable still more easily; and some obstructions have been suddenly carried off by a fall, or other violent concussion of the head. The great difficulty, however, is in getting at such impediments when they are formed in the tympanal cavity. The perforation of the mastoid process, recommended by Riolanus, has been practised occasionally with success, and especially by the Swedish anatomists, Jasser and Hagström. But the difficulties are so con-

siderable, that the plan has usually been superseded by a puncture of the membrane, or by injecting the Eustachian tube, as first proposed by an unprofessional artist, Guyot of Versailles, and since followed up successively by Cleland, Petit, Douglas, and Wathen. Of late, however, even this has been dropped; though now once more revived in France by M. Itard, and in Great Britain by Mr. Buchanan.—(*Engraved Representation of the Anatomy of the Human Ear*, &c., Hull, 1823.)

In deafness from atonic relaxation, almost all the stimulant and tonic methods pointed out under the preceding species have been tried in turn, occasionally with palliative success, sometimes altogether in vain. The fumes of tobacco sniffed up the Eustachian tubes from the mouth, in the manner described under the last species, were recommended by Morgagni (*Epist. Anat.*, vii., art. 14; *Eph. Nat. Cur.*, dec. i., ann. vi., obs. 110) and many other writers of earlier times, and have occasionally been found beneficial in our own day; the spasm or other obstruction of the fine tubes ceasing of a sudden, and with the sensation of a smart snap, that almost startles the patient. And as sight has sometimes been restored in amaurosis by a violent fever or a flash of lightning, so has deafness from atony, approaching to paralysis, been recovered by a like fever or a thunderclap (*Bresl. Samml.*, 1718, p. 1541); ordinary causes being thus transferred into extraordinary modes of cure.

Among the stimulants most useful, where the deafness is dependant upon debility of the membrane of the tympanum, or the nerve of hearing, have been the aura of voltaic electricity, applied two or three times a day for half an hour or longer each time, and persevered in for many weeks, a series of blisters continued for a long period, and a diluted solution of nitrate of silver. Yet a chronic ulcer forming in the ear, and discharging plentifully, has often proved still more effectual.

Mr. Gordon relates a case of total deafness, produced suddenly in a soldier in good health, by plunging overhead into the sea; which, after a long routine of medicines had been tried in vain for three months, yielded to the use of mercury as soon as the mouth began to be affected. A gentle salivation supervened, his hearing was gradually restored, and in six weeks from its commencement, he returned to his duty perfectly cured.—(*Edin. Med. Comm.*, vol. iii., p. 80.) The excitement of the salivary glands seems in this case to have extended by sympathy to the Eustachian tubes, or whatever other parts of the organ of hearing were diseased.

When the Eustachian tubes are imperforate or irrecoverably closed, which may commonly be determined by an absence of that sense of swelling in the ears which otherwise takes place on blowing the nose violently, Riolanus, and afterward Cheselden, proposed a substitute for the canal by making a small perforation through the membrane of the tympanum; and Sir Astley Cooper has boldly put their recommenda-

tion to the test. The artificial opening does not destroy the elasticity of the membrane, and it has hence been occasionally attended with success; and perhaps would be always, if it were to be limited, as M. Itard (*Traité des Maladies de l'Oreille et de l'Audition*, &c., 2 tomes, Paris, 1821) has shown it ought to be, to a permanent obstruction of the Eustachian tube, unaccompanied with inflammation or any other cause of deafness. And it is from a wanton application of this remedy to other cases that it has so often been tried in vain since Sir Astley Cooper's successful sanction.

GENUS III.

PAROSMIS.

MORBID SMELL.

SENSE OF SMELL VITIATED OR LOST.

This is the parosmia and anosmia of many writers; from *παρὰ*, "malè," and *ὀσφρ*, "olfacio," analogous with PARACUSIS and PAROPSIS: anosmia, however, will not include one of its species, and the present termination is preferred on account of its analogy with that of the parallel terms.

Under this genus may be arranged the three following species:—

- | | |
|--------------------|----------------|
| 1. Parosmis Acris. | Acrid Smell. |
| 2. ——— Obtusa. | Obtuse Smell. |
| 3. ——— Experts. | Want of Smell. |

SPECIES I.

PAROSMIS ACRIS.

ACRID SMELL.

SMELL PAINFULLY ACUTE OR SENSIBLE TO ODOURS NOT GENERALLY PERCEIVED.

GENERALLY speaking, the sense of smell in all animals is in proportion to the extent of the Schneiderian or olfactory membrane with which the nostrils are lined, and over which the branches of the olfactory nerves divaricate and ramify. And hence this membrane is much more extensive in quadrupeds and birds, which chiefly trust to the sense of smell in selecting their food, than in man; for it ascends considerably higher, and is for the most part possessed of numerous folds or duplicatures. It is hereby the hound distinguishes the peculiar scent thrown

forth from the body of the hare, and the domestic dog recognises and identifies his master from all other individuals.

Yet the nerves of smell are not only spread in great abundance over the olfactory membrane of all animals possessing such an organ, but they are distributed so near the surface as to be almost naked;* and hence in every class they are easily and hourly excited into action, being covered with little more than a layer of bland, insipid mucus, thin at its first separation, but gradually hardening by the access of air into viscid crusts, and which is expressly secreted for the purpose of defending them. From this nearly naked state it is, that they are stimulated by aromatics, however finely and impalpably divided; whence the violent sneezings that take place in many persons in an atmosphere in which only a few particles of sternutatories or other acrid olficients are floating: and hence also the rapidity with which a sympathetic action is excited in the neighbouring parts, or in the system at large, and the refreshment which is felt on scenting the pungent vapour of carbonate of ammonia, or vinegar, or the grateful perfume of violets or lavender, in nervous headaches or fainting-fits. The fetid odours are well known to affect the nostrils quite as poignantly as the pleasant, and to produce quite as extensive a sympathy; and hence the nausea, and even intestinal looseness, which often follow on inhaling putrid and other offensive effluvia.

Under peculiar circumstances, however, the ordinary apparatus for smell possesses an activity, and sometimes even an intolerable keenness, which by no means belongs to it in its natural state. M. Virey, who has written a very learned treatise upon the subject of odours, asserts that the olfactory sense exists among savages in a far higher degree of activity than among civilized nations, whose faculty of smell is blunted by an habitual exposure to strong odours, or an intricate combination of odours, and by the use of high-flavoured foods. And he might have added, that this sense, like every other, is capable of cultivation, and of acquiring delicacy of discrimination by use; that savages, many of whom make an approach to the life of quadrupeds, employ it, and trust to it in a similar manner; and that this is perhaps the chief cause of the difference he has pointed

* Over the whole of the Schneiderian membrane, branches of the fifth nerve are distributed. In the human subject, the first or olfactory nerve does not spread so extensively, but goes principally to the septum narium and upper turbinated bone. M. Magendie has ascertained the effect of the separate division of the first and fifth nerves in animals; and has thus more correctly demonstrated how much of the impression received by the nostrils belongs to smell, properly so called, and how much to touch. "It appears that upon the division of the first nerve, the animal remains as sensible as before to the disagreeable impression of odours which act pungently. A young dog thus mutilated, appeared conscious of an unpleasant impression when ammonia, acetic acid, oil of lavender, or Dippel's oil, was held to its nose. On the other hand, after the division of the

fifth, the first nerve remaining entire, an animal is not affected by the presence of the substances above mentioned." But a dog that survived the division of the fifth nerve for a considerable period, would at times, when food was offered to it rolled up in paper, unroll the paper, and expose and eat the food although at other times he appeared to want the power of distinguishing by smelling the presence of objects placed near it. "Pungent odours seem to offend the nose upon the same principle that they irritate the conjunctiva of the eye; their acrid impression, without their scent, being perceived when the influence of the first nerve is artificially destroyed." The first nerves, therefore, constitute the organ of smell.—See Mayo's *Outlines of Physiology*, p. 412, 2d edit.; and Magendie's *Journ. de Physiol. Exp.*, tom. iv., p. 173.—Ed.

out. It is in like manner relied upon by persons who are deprived of one or two of the other external senses, as those of sight or hearing, or both: not merely in consequence of more frequent employment, but from the operation of the law we have already pointed out, that where one of the external senses is destroyed or constitutionally wanting, the rest, in most cases, are endowed with an extraordinary degree of energy; as though the share of sensorial power naturally belonging to the defective organs were distributed among the rest, and modified to their respective uses. One of the most interesting examples that I am acquainted with of this transfer of sensorial power, is to be found in the history, first given to the public by Mr. Dugald Stewart, of James Mitchell, a boy born both blind and deaf; and who, having no other senses by which to discover and keep up a connexion with an external world than those of smell, touch, and taste, chiefly depended for information on the first, employing it on all occasions, like a domestic dog, in distinguishing persons and things. By this sense he identified his friends and relatives; and conceived a sudden attachment or dislike to strangers, according to the nature of the effluvium that escaped from their skin. "He appeared," says Mr. Wardrop, who has also published an account of him, "to know his relations and intimate friends by smelling them very slightly, and he at once detected strangers. It was difficult, however, to ascertain at what distance he could distinguish people by this sense; but from what I could observe, he appeared to be able to do so at a considerable distance from the object. This was particularly striking when a person entered the room, as he seemed to be aware of such entrance before he could derive information from any other sense than that of smell. When a stranger approached him, he eagerly began to touch some part of the body, commonly taking hold of his arm, which he held near his nose; and after two or three strong inspirations through the nostrils, he appeared to form a decided opinion concerning him. If it were favourable, he showed a disposition to become more intimate, examined more minutely his dress, and expressed, by his countenance, more or less satisfaction; but if it happened to be unfavourable, he suddenly went off to a distance, with expressions of carelessness or disgust."^{*}

The *Journal des Sçavans* for 1667 gives a curious history of a monk who pretended to be able to ascertain, by the difference of odour alone, the sex and age of a person, whether he were married or single, and the manner of life to which he was accustomed. This, as far as the fact extended, may possibly have been the result of observations grafted upon a stronger natural sense than belongs to mankind in general, and is scarcely to be ranked in the list of diseased actions. But among persons of a

highly nervous or irritable idiosyncrasy, I have met with numerous instances of an acuteness of smell almost intolerable and distracting to those who laboured under it; which has fairly constituted an idiopathic affection, and sometimes nearly realized the description of the poet, in making its possessors ready at every moment to

"Die of a rose in aromatic pain."

Mr. Pope seems to have written this line as a play of fancy at the time, but the writings of various collectors of medical curiosities abundantly show that he has here described nothing more than an occasional and sober fact. Thus M. Orfila gives us an account of a celebrated painter of Paris, of the name of Vincent, who cannot remain in any room where there are roses without being in a short time attacked with a violent cephalæa, succeeded by fainting (*Sur les Poisons*, tom. ii., Cl. v., sect. 972); and M. Marrigues informs us that he once knew a surgeon who could not smell at a rose without a sense of suffocation, which subsided as soon as the rose was removed from him; as he also knew a lady who lost her voice whenever an odoriferous nosegay was applied to her nostrils.—(*Journ. de Physique*, year 1780.)

We have observed that a keen stimulation of the olfactory nerves is often productive of a very powerful sympathetic action in other organs. There are few persons who, on inhaling the fine particles of black hellebore and colocynth while in the act of being pounded, would not feel their effect on the intestines by a copious diarrhœa; but where the acuteness of smell exists which constitutes the present disease, whether limited to particular odours, or extending to all odours equally, the sympathetic action is sometimes of a very singular description. M. Valtain gives the history of an officer who was thrown into convulsions and lost his senses by having in his room a basket of pinks, of which, nevertheless, he was very fond. The flowers were removed, and the windows opened, and in the course of half an hour the convulsions ceased, and the patient recovered his speech. Yet, for twelve years afterward, he was never able to inhale the smell of pinks without fainting.—(*Hygiène Chirurgicale*, p. 26.) And M. Orfila relates the case of a lady, forty-six years of age, of a hale constitution, who could never be present where a decoction of linseed was preparing, without being troubled, in the course of a few minutes afterward, with a general swelling of the face, followed by fainting and a loss of the intellectual faculties; which symptoms continued for four-and-twenty hours.—(*Sur les Poisons*, loc. citat.)

The predisponent cause of the species before us is a nervous or irritable habit. The occasional causes are, local irritation from a slight cold, in which the contact of the air alone, as inhaled, often produces sneezing; or excoriation of the mucous membrane of the nostrils, from the use of sternutatories in those not accustomed to them. It is often the result of idiosyncrasy; and perhaps at times, as in *paracosis acris*, of a superfluous distribution of olfactory

* History of James Mitchell, a boy born blind and deaf, &c.; by James Wardrop, F. R. S., 4to. edit., 1813.

nerves. As a symptom, it is often found in ophthalmia and rheumatic hemicrania.

Where the disease is connected with the habit, the nervous excitement should be diminished by refrigerants and tonics, as the shower-bath, bark, acids, neutral and several of the metallic salts. And where it is chiefly local, we may often produce a transfer of action by blisters in the vicinity of the organ; or relax the Schneiderian membrane, and moisten its surface by the vapour of warm water. The sniffing up cold water will also prove serviceable in many instances, by inducing torpitude at first, and additional tone afterward. Dr. Darwin advises errhines for the first of these purposes, that of exhausting the excitability and blunting the sense.

SPECIES II. PAROSMIS OBTUSA. OBTUSE SMELL.

SMELL DULL AND IMPERFECTLY DISCRIMINATIVE.

THIS is often a natural defect, but more frequently a consequence of an habitual use of sternutatories, which exhaust, weaken, and torpify the nerves of smell, just as exposure to a strong light weakens and impairs the vision, and sometimes destroys it altogether. To those unaccustomed to sternutatories, the mildest snuffs will produce such an excitement as is marked by a long succession of sneezing, which is nothing more than an effort of the remedial power of nature to throw off the offending material; while those who have habituated themselves to snuff for years, can hardly be excited to sneeze by the most violent ptarmics.

The evil is here so small, that a remedy is seldom sought for in idiopathic cases; and in sympathetic affections, as when it proceeds from catarrhs or fevers, it usually, though not always, ceases with the cessation of the primary disease. It is found also as a symptom in hysteria, syncope, and several species of cephalæa, during which the nostrils are capable of inhaling very pungent, aromatic, and volatile errhines, with no other effect than that of a pleasing and refreshing excitement.

Where the sense of smell is naturally weak, or continues so after catarrhs or other acute diseases, many of our cephalic snuffs may be reasonably prescribed, and will often succeed in removing the hebetude. The best are those formed of the natural order verticillatæ, as rosemary, lavender, and marjoram: if a little more stimulus be wanted, these may be intermixed with a proportion of the *teucrium Marum*; to which, if necessary, a small quantity of asarum may also be added; but pungent errhines will be sure to increase instead of diminishing the defect.

SPECIES III. PAROSMIS EXPERS. WANT OF SMELL.

TOTAL INABILITY OF SMELLING OR DISTINGUISHING ODOURS.

THIS species is in many instances a sequel of

the preceding; for whatever causes operate in producing the former, when carried to an extreme, or continued for a long period, may also lay a foundation for the latter. But as it often occurs by itself, and without any such introduction, it is entitled to be treated of separately. It offers us the two following varieties:—

- | | |
|---|---|
| <p>α Organica.
Organic want of smell.</p> <p>β Paralytica.
Paralytic want of smell.</p> | <p>From natural defect, or accidental lesion, injurious to the structure of the organ.</p> <p>From local palsy.</p> |
|---|---|

THE FIRST VARIETY occurs from a connate destitution of olfactory nerves, or other structural defect; or from external injuries of various kinds; and is often found as a sequel in ozænas, fistula lachrymalis, syphilis, smallpox, and porphyra. The SECOND is produced by neglected and long-continued coryzas, and a persevering indulgence in highly acrid sternutatories.

The author once knew a very beautiful and elegant young lady, who had from birth so total a want of smell as not only to be incapable of perceiving any difference in the odours of different perfumes or flowers, but of sweet and corrupt meats, and who could inhale very powerful errhines without sneezing. Though this affection seemed to have been connate, and dependant upon a natural imperfection of the nerves of smell, the Schneiderian membrane had something of the thickening which is ordinarily produced by catarrhs, and the lady always spoke as though under the influence of a slight cold.

When this affection is a sequel of local irritation, as from a coryza or catarrh, warm stimulating vapours, as of vinegar or frankincense, are often useful. If produced by syphilis, the fumes of cinnabar may be inhaled by the nostrils, or a sternutatory may be used, composed of turbeth mineral and ten times the quantity of any mild and light powder, as orris-root.

GENUS IV. PARAGEUSIS. MORBID TASTE.

SENSE OF TASTE VITIATED OR LOST.

PARAGEUSIS is derived from *παρά*, "malè," and *γεῦω*, "gustum præbeo," whence *παπαγεῖω*, and consequently *παπαγεῖσις*. The author has preferred, with Vogel, the present termination to parageusia, as analogous to the names of the preceding genera of the order before us.

In the senses of taste and smell there is a considerable association. The young lady I have just noticed, who was destitute, or nearly so, of the sense of smell, was equally destitute of that of taste, and could not distinguish by this criterion between beef, veal, and pork; and consequently, in respect to all these, had no preference.

The chief organ of taste is the tongue; but this is not the only organ, nor is it absolutely necessary for an existence of the sense. The Philosophical Transactions give us examples of persons who possessed a perfect taste after the

tongue had been wholly destroyed; and Professor Blumenbach, in his Comparative Anatomy, affords us a similar example in an adult whom he visited, and who was born without a tongue. Consonant with which, many insects appear to have a faculty of taste, though they have no organ of a tongue; and among these the gustatory function is supposed by Professor Knoch to be performed by the posterior pair of palpi or feelers; while, on the other hand, there are many animals possessing a tongue who do not use it as an organ of taste. All birds possess a tongue, for even the pelican, which has been said to be tongueless, has a rudiment of this member; yet there are but few birds, comparatively, that taste or are able to taste with this organ. Parrots, predaceous and swimming birds, are an exception to this remark; for they possess a soft thick tongue, covered with papillæ, and moistened with a salivary fluid, and select that food which is the most agreeable. Yet, in by far the greater proportion of birds, we do not find the tongue appropriated to this purpose. In many of them, indeed, it is stiff, horny, and destitute of nerves. The tongue of the toucan, though sometimes several inches in length, is scarcely two lines broad at its root: it has throughout the appearance of whalebone, and its margins are fibrous. The tongues of the woodpecker and cock of the woods are equally hard and horny: in themselves they are short, and in a quiescent state lie backward in the mouth, and are covered with a sort of sheath issuing from the os hyoides or the œsophagus: but they possess a mechanism which renders them extremely extensile, and capable of being thrust forward to a considerable distance. That of the woodpecker is sharp-pointed, with barbed sides, and is darted with great rapidity out of the mouth to an extent of some inches; by which means it follows up such insects as the animal is in pursuit of through all their crannies in the bark of trees, sticks them through with its apex, and in this state drags them out for food. The chameleon has a tongue of a somewhat similar kind, which in like manner answers the purpose, not of taste, but of preying for food. It is contained in a sheath at the lower part of the mouth, and has its extremity covered with a glutinous secretion. It admits of being projected to the length of six inches; and is used in this manner by the animal in catching its spoil, and especially in catching flies. It is darted from the mouth with wonderful celerity and precision; and the viscous secretion on its extremity entangles minute animalcules, which constitute another portion of its food.

The tongue, when it forms an organ of taste, as in man, is studded, and especially on its upper surface and lateral edges, with innumerable nervous papillæ, issuing from a peculiar membrane that lies beneath, and has a near resemblance to the skin in other parts, but is softer and more spongy. Its external tunic or cuticle is an exquisitely fine epithelium, which is moistened, not by an oily fluid like that of the surface of the body, but a peculiar mucus.

We have here, therefore, a more exquisite sense of touch than on the general skin, whose papillæ are not only smaller but dry.

There can be no question, also, that the sentient fluid with which they are supplied is differently modified from that of the skin; and hence the provinces of the two senses, though they occasionally approach each other, are still kept distinct; and the tongue becomes a discernor of certain qualities which the skin cannot discriminate, as sour, sweet, rough, bitter, salt, and aromatic.*

Thus much we know; but we do not know the cause of that different effect, or in other words, of that variety of tastes which different substances produce upon the papillæ of the tongue, and which constitute their respective flavours. It was supposed by the Epicureans, and the doctrine has descended to the present day, that all this depends upon the geometrical figure of the sapid corpuscles; and particularly so with respect to saline bodies, which are cubic in sea-salt, prismatic in nitre, and equally diversified in vitriol, sugar, and other crystals. It is sufficient, however, to annul this explanation, to observe, that many crystals of very different forms are alike insipid; while others of the same, or nearly the same shape, possess very different flavours; as also that the flavour in any of them continues the same, even where we are able to change the figure; as, for example, by rendering common nitre cubical. The cause of flavours, therefore, appears to reside in the ele-

* Instead of this hypothesis of a modification of the nervous fluid, modern discoveries teach us rather to seek in the different nerves with which the tongue is supplied for an explanation of the cause of the peculiar and diversified faculties which it enjoys; as, for instance, the power of motion, the power of common sensation or touch, and the power of taste. "In man," as Mr. Mayo has observed, "the apparent sense of taste is the tongue and palate; the same surfaces have an exquisite sense of touch; and an attentive examination shows that the latter occupies a larger surface than the former, and is, indeed, the only sense with which the palate is endowed."

"Upon the surface of the tongue, again, the sense of taste is very partially distributed, being restricted to the papillæ fungiformes. The largest of these are found upon the dorsum of the tongue, while the smaller and more numerous are situated along the sides and towards the tip of the tongue. They are vascular and erectile, and shoot up when the tongue is touched by a sapid substance."—(See Outlines of Human Physiology, p. 406, 2d edit.) It is clear, however, that if some facts to which the author of the Study of Medicine has adverted be correct, either the sense of taste must be more extensive than here represented, or else that, under particular circumstances, other parts than those specified must acquire a gustatory power. The ninth pair of nerves, which are distributed to the muscles of the tongue, are merely the nerves of motion; while those of taste and sensation appear to be, first, the gustatory branch of the ganglionic portion of the third division of the fifth, which is distributed not merely to the muscles of the tongue, but to its mucous surface and to two of the salivary glands; and secondly, the glosso-pharyngeal nerve, which sends branches to the surface of the root of the tongue.—Ed.

mentary principles of substances that lie beyond the reach of our senses.

But the variable condition of the peculiar covering of the papillæ of the tongue, together with the condition of the adjoining organs which concur in the purpose of the tongue, as also the changeable nature of the saliva and of the substances lodged in the stomach, all concur in influencing the taste, and giving a character to the flavour. And hence the same flavours do not affect persons of all ages, nor of all temperaments; nor even the same person at all times. In general, whatever contains less salt than the saliva, seems insipid. The spirituous parts of plants are received, in all probability, either into the papillæ themselves, or into the absorbing villi of the tongue; and hence the rapid refreshment and renovation of strength, not easy to be accounted for otherwise, which these stimulating materials produce, even when they are not taken into the stomach.

It is from the diversity of flavours by which nature has distinguished different substances, that animals are taught instinctively what is proper for their food: for, speaking generally, no aliment is unhealthy that is of an agreeable taste; nor is any thing ill-tasted that is fit for the food of man. We here take no notice of excess, by which the most healthy foods may be rendered prejudicial, nor of mineral preparations, which are not furnished by nature, but prepared by art. And hence the wisdom of Providence incites man to select the nutriment that is best fitted for his subsistence, equally by the pain of hunger and the pleasure of tasting. Man, however, is often guided by instruction and example, as well as by his own instinct: but animals, which are destitute of such collateral aids, and have to depend upon their instinct alone, distinguish flavours, as we have already observed they do smells, with a far nicer accuracy than mankind; and, admonished by this correct and curious test, abstain more cautiously than man himself from eating what would be injurious. And hence herbivorous animals, whose vegetable food grows often intermixed with a great diversity of noxious plants, are furnished with much longer papillæ and a more delicate structure of the tongue than mankind, as they are endowed also with a more accurate sense of smell; both which, indeed, they jointly rely upon for the same purpose.

The sense of taste, therefore, which possesses so close an analogy to that of smell, is subject to a similar train of specific diseases, and consequently the genus *parageusis* must contain the three following species:—

- | | |
|-----------------------------|---------------|
| 1. <i>Parageusis Acuta.</i> | Acute Taste. |
| 2. ———— <i>Obtusa.</i> | Obtuse Taste. |
| 3. ———— <i>Expers.</i> | Want of Taste |

SPECIES I. PARAGEUSIS ACUTA. ACUTE TASTE.

TASTE PAINFULLY ACUTE, OR SENSIBLE TO SAVOURS NOT GENERALLY PERCEIVED.

The sense of taste, like that of sight, smell,

or hearing, is capable of acquiring a higher degree of accuracy by use: and hence those who are in the habit of tasting wines by this organ perceive a variety of flavours, or modifications of flavour, which another person, not versed in such trials, is insensible of. We also perceive that the nerves of taste, like those of every other sense, become exhausted, and consequently torpid, by much labour and fatigue. And hence the nicest discriminator, after having tried a variety of wines, spirits, or other pungent savours in quick succession, is far less capable of judging concerning them, and has at last little more than a confused perception of gustatory excitement.

Morbid acuteness of taste, however, varies essentially from accuracy of taste: for, under particular states of irritation, pungent savours, of whatever kind, give equal pain to the tongue, which at the same time is altogether incapable of distinguishing between them.

This painful acuteness may proceed from two causes: a morbid or excessive sensibility in the nerves of taste, or a deficient secretion of the peculiar mucus that lubricates the lingual papillæ; in consequence of which the latter are exposed in a naked state to whatever stimuli are introduced into the mouth. The former is sometimes found, though for the most part only temporarily, in highly nervous and irritable constitutions, and especially during a state of pregnancy; the latter in certain morbid conditions of the stomach, accompanied with great thirst and a parched tongue. Both these causes, however, very frequently coexist; as in ulcerated sore throats, or other excoriations of the mouth, in which the papillæ are in a state of the keenest excitement, while the tongue is sore, either from a defective secretion of mucus, or from its being carried off by a morbid and augmented action of the absorbents as fast as it is formed.

In this state of diseased action, moreover, it not unfrequently happens that the mucus itself is secreted in a morbid condition; and the palate, instead of being soft and smooth, becomes harsh and rugous or furrowed, exquisitely irritable, and intolerant of the slightest touch or the mildest savours. I have sometimes met with this distressing affection, apparently as an idiopathic ailment, or at least unconnected with any manifest disease of the stomach or any other organ; and seemingly induced by a rheumatic pain from carious teeth. It is, however, far more frequently a symptom of dyspepsy, porphyra, and chronic syphilis.

In treating this affection, we should in the first instance direct our attention to the state of the stomach, and clear it of whatever sordes may probably be lodged there. This may sometimes be done by aperients, but it will be the surest way to commence with an emetic.

The local symptoms may, in the meanwhile, be relieved in two ways. First, by changing the nature of the morbid action, or exhausting the accumulated sentient power by acid or astringent gargles, or a free use of the coldest water alone; for which purpose also sage leaves and acrid bitters have often been employed with

advantage. And next, the naked and irritable tongue may be sheathed with mucilages of various kinds, and thus a substitute be obtained for its natural defence. And in many cases, both these classes of medicines may be conveniently united.

When the affection is a symptom of some other disease, as in the case of syphilis and scurvy, it can only be cured by curing the primary malady. Carious teeth, if such exist, should be extracted; and if the palate be rugous or spongy, scarification should be employed.

SPECIES II. PARAGEUSIS OBTUSA. OBTUSE TASTE.

TASTE DULL AND IMPERFECTLY DISCRIMINATIVE.

This species rarely calls for medical attention. It occurs sometimes idiopathically, and seems to be dependant on a defective supply of nerves, or nervous influence, subservient to the organ of taste. I have seen it under this form in various instances; and as already observed, have found it connected in a few cases with obtuseness of smell. The patient has not been altogether without taste or smell, but both have been extremely weak and incapable of discrimination. In the case alluded to at the commencement of this genus, the individual could distinguish the smell of a rose from that of garlic, and the flavour of port wine from that of mountain or madeira; but she could not discriminate between the odour of a rose and that of a lily, nor between the taste of beef, veal, or pork, and consequently gave no preference to either of these dishes.

As a symptom, this affection occurs in almost all the diseases that are accompanied with hebetude of smell, as catarrh, hysteria, and several species of cephalæa.

SPECIES III. PARAGEUSIS EXPERS. WANT OF TASTE.

TOTAL INABILITY OF TASTING OR DISTINGUISHING SAVOURS.

As an utter want of smell is sometimes a natural or congenital effect, so in a few instances is an utter want of taste; and unquestionably from the same cause, an absolute destitution of nerves or nervous power subservient to the gustatory organ. This default is altogether immedicable: as is also for the most part the same when a result of palsy, general or local; though here stimulant gargles or masticatories, as mustard-seeds, horseradish, pyrethrum, and camphire, have sometimes succeeded in restoring action to the torpid nerves. When, however, it occurs, as it sometimes does, from a long use of tobacco, whether by smoking or chewing, or of other acrid narcotics, these stimulants will be of no use.

In fevers, various exanthems, and inflammations, this species exists temporarily, partly perhaps from a diminished or morbid production of sensorial power, but chiefly from a conversion of the mucus of the tongue into a dry, hard, or

tough and viscid sheath. And where there is much increased heat and action, the epithelium or cuticle of the tongue itself becomes often peculiarly thickened and coriaceous or leathery. Acids, in the form of gargles, are the pleasantest means of removing this morbid substance, but they will often succeed best if rendered viscid and converted into a soap by mixing with them a little almond-oil, which may at the same time be sweetened with honey.

GENUS V. PARAPSIS. MORBID TOUCH.

SENSE OF TOUCH OR GENERAL FEELING VITIATED OR LOST.

PARAPSIS is derived from the Greek terms, *παρά* and *ἄστρομαι*, "*perperam tango*." The common technical name for the genus is *dysæsthesia*, but not quite correctly; since this word, as we have already had occasion to observe, is also employed to express morbid external sensation of any kind, whether of touch, taste, smell, sight, or hearing: while by Dr. Young it is equally applied to one at least of the faculties of the mind, as in *dysæsthesia interna*, which he characterizes as "a want of memory, or confusion of intellect."

This genus embraces three species as follow:—

- | | |
|--------------------|---|
| 1. Parapsis Acuta. | Acute Sense of Touch or General Feeling. |
| 2. ——— Expers. | Insensibility of Touch or General Feeling. |
| 3. ——— Illusoria. | Illusory Sense of Touch or General Feeling. |

[The skin is the principal seat of touch; though modifications of this sense are said to reside in various mucous surfaces, and in the voluntary muscles. The power of distinguishing with the finest discrimination the tangible properties of bodies is certainly in the hand, and especially in the extremities of the fingers. "The nerves," says Mr. Mayo (*Physiology*, p. 402, 2d edit.), "which minister to the sense of touch, are the posterior roots of the spinal nerves, the large division of the fifth, the nervi vagi, and the glosso-pharyngeal nerves. The body, the neck and occiput, and the limbs, are supplied by the spinal nerves; the face, temples, and fauces, by the fifth; the pharynx and œsophagus by the nervi vagi and glosso-pharyngeal nerves. It is remarkable, that the nerves of touch have ganglions near their origin."]

SPECIES I. PARAPSIS ACUTA.

ACUTE SENSE OF TOUCH.

THE SENSE OF TOUCH PAINFULLY ACUTE, OR SENSIBLE TO IMPRESSIONS NOT GENERALLY PERCEIVED.

This species of morbid sensibility shows itself under almost innumerable modifications; but the four following are the chief:—

α Teneritudo.	Soreness.
β Pruritus.	Itching.
γ Ardor.	Heat.
δ Algor.	Coldness.

In the first variety, or that of SORENESS, there is a feeling of painful uneasiness or tenderness, local or general, on being touched with a degree of pressure that is usually unaccompanied with any troublesome sensation. This is often an idiopathic affection; but more generally a symptom or sequel of fevers in their accession or first stage, inflammations, or external or internal violence, as strains, bruises, and spasms.

It is not always easy to account for this feeling, and perhaps the cause is in every instance more complicated than we might at first be induced to suppose. It occurs where there is distention of the vessels, where there is contraction of them, and where there is neither. Wherever it exists, however, it is a concomitant of debility, and may in many instances be regarded as the simple pain of debility, the uneasiness of an organ thrown off from its balance of health. The general health of the body depends in a very considerable degree upon the harmonious co-operation of its respective organs; insomuch, indeed, that this harmony of action, as we had occasion to observe in the Physiological Proem prefixed to the present class, was supposed, by a distinguished school of ancient philosophers, and is still supposed by many physiologists of the present day, to constitute the principle of life itself. Regarded as a universal principle, the hypothesis is unfounded, though in many respects beautiful and plausible. Yet, notwithstanding that the life of the animal frame does not altogether depend upon an harmonious co-operation of the whole of the organs that enter into its make, much of the comfort of life has such a dependance; and we trace the same principle in the minutest and comparatively most trivial parts of the animal functions, as manifestly as in the largest and most complicated organs. Where every portion of a member, however subordinate in itself, as a toe or a finger, works well or healthily, there is a feeling of ease and comfort; but wherever it works ill or with difficulty, there is a sense of disquiet, and, under peculiar circumstances, of tenderness or soreness. A change in the diameter of a vessel, whether by dilatation or contraction, provided it be moderate and gradual, is accompanied with no uneasy sensation whatever; but if it either be violent or sudden, a feeling of soreness is a certain result.

Warmth, gentle friction, and stimulants, as spirits, balsams, and essential oils, are of general advantage, wherever the kind of tenderness we are now describing occurs, and is unconnected with inflammation.

The sense of *ITCHING*, which may be defined a painful titillation, local or general, relieved by rubbing, is commonly a result of some mechanical or morbid irritant applied externally or internally to the part affected; though sometimes, unquestionably, dependant upon a morbid sensibility of the nerves of feeling themselves. If the summit of the nerves or their extreme points

be alone touched, the effect is *TICKLING* or *TITILLATION*, as in the vellication of the skin by a feather; if it descend a little below the summit, it is accompanied with a vibratory feel which we call *TINGLING*, as when the beard of barley-corns creeps unobserved by us up the arms; and if it reach still deeper, it is combined with a sense of piercing which we call *PRICKING*, as when the keen hairs of several species of dolichos or cowhage are handled or blown upon the skin by a light breeze.

In many cases all these modifications of itching are the effect of some acrimonious secretion on the surface of the body, or of an acrimonious change in the common matter of perspiration, in consequence of its lodging in the cutaneous follicles longer than it should do. The *PAPULOUS EFFLORESCENCES* we shall have to treat of under the third order of the sixth class, will afford abundant examples of both these causes of itching, apparently produced by, or closely connected with, a morbid sensibility of the cutaneous nerves themselves. For the present we can do nothing more than refer generally to various species of exormia, as lichen and prurigo; and of eczema, as impetigo and scabies. It is, moreover, highly probable, that the disorder called *FIDGETS* is sometimes chiefly dependant on a morbid sensibility of the summits or extreme ends of the cutaneous nerves.

This affection is also found as a very troublesome symptom in *pernio* and other cutaneous inflammations, as likewise in *urticaria* and other rashes.

The sensations of *HEAT* and *COLD* may be explained at the same time. An easy and pleasurable warmth depends, in a state of health, upon a moderate temperature of the atmosphere, which cannot be very accurately laid down, because, from habit or constitution, or some other circumstance, different persons enjoy very different temperatures. Now it is the well-known property of heat and cold to disturb the temperature, whatever it may be, that affords ease and comfort to the nerves of feeling; and to produce disquiet as they either raise or depress it. And this both of them do in two distinct ways. *HEAT* is a strong irritant, and even if it made no change in the bulk of a living organ, or the juxtaposition of its particles, like all other irritants, it would still excite a troublesome feeling, amounting at length to acute pain, if raised to a considerable range beyond the ordinary scale. But it does, in every instance, excite a change in the bulk of living organs and the juxtaposition of their particles; for it enlarges the former in every direction, and only does this by separating the particles from each other; in which forcible and sudden divellication we have a second source of the troublesome and acute sensation which so constantly accompanies a temperature when carried very considerably above the point of health.*

* The effects of heat upon the human body are partly influenced by the state of the innervation at the period of its application. This is illustrated by a fact mentioned in Mr. Earle's Essay on

Heat, as an idiopathic affection, occurs chiefly in plethoric and irritable habits. In the former it is relieved by bloodletting, and evacuates of neutral salts; in the latter by mild diaphoretics, and afterward cold bathing and other tonics.

As a symptom it is found also in the second stage of fever, in inflammation, and entonic emphysema.

Cold is also a strong irritation, though it acts by the opposite means of heat. When the atmospheric temperature is too high, it is a pleasant and reviving agent, inasmuch as it both reduces the heated medium, and restores the particles of the affected organ from a state of disquieting tenseness to their usual scale of approximation. If the cold be pushed farther, it may go a little beyond this, and still be pleasant and healthful; for the organ or the general system may be in a state of morbid relaxation, and consequently, in their actual scale of approach, the living particles may be too remote for the purposes of high elasticity and vigour. And it is in such a condition as this that cold chiefly shows its stimulant power, and is so generally resorted to as a tonic. But if the agency of cold be carried farther than this, it produces uneasiness to the nerves of feeling by a process precisely the reverse of that we have just shown to be pursued by heat, and consequently in a twofold manner. First by sinking the warmth of the organ, or of the system, below its scale of ease and comfort; and next, by forcing the living particles into too close and crowded a state, and not allowing them sufficient room for play.

Cold, as an idiopathic affection, is chiefly local, and most common to the head and feet. It is temporarily relieved by warmth and stimulants, and particularly by the friction of a warm hand; and, where it can be used, the exercise of walking. It is permanently relieved by the warmer tonics, as sea-bathing and aromatic bitters.

Considerable mischief has often been produced by a sudden exposure of the feet to severe cold, and especially in delicate and irritable habits, unused to such applications: as colic, cephalæa, catarrh, fevers of various kinds, and, in a podagral diathesis, gout. But the application of severe and sudden cold to the head or stomach by drinking ice or cold water, and especially when the individual is heated and perspiring, has been followed with more alarming effects, and even with death itself. Mauriceau relates an instance of death produced during baptism, by applying to the head the water of the baptismal font.—(Tom. ii., 348.) But this must be a rare occurrence; while the fatal effects of drinking ice or iced water in a state of heat are innumerable.

It is observed by Dr. Fordyce (*On Simple Fever*, p. 168), and the observation is quoted

Burns:—A lady met with a comminuted fracture of the clavicle, and severe injury of the shoulder, producing paralysis of the arm; and it was noticed, after the accident, that she could not put her hand into moderately warm water without redness, vesication, and the other usual consequences of the application of high degrees of heat, being immediately excited.—Ed.

and called curious by Dr. Darwin, "that those people who have been confined some time in a very warm atmosphere, as of 120 or 130 degrees of heat, do not feel cold, nor are subject to paleness of their skins, on coming into a temperature of 30 or 40 degrees; which would produce great paleness and painful sensation of coldness in those who had been for some time confined in an atmosphere of only 86 or 90 degrees." The cause is not difficult of explanation. The sensorial power is exhausted, and the nerves of feeling rendered torpid, by a long exposure to the heat of 120 or 130 degrees, and the turgid capillaries, whose dilatation produces the general blush, lose their power of constriction or collapse; while in a heat of 86 or 90 degrees neither of such effects takes place.

Cold, as a symptom, is found in the first stage of fever, in syncope, hysteric dyspnoea, nausea, and atonic emphysema; in all which the affection is general.

SPECIES II.

PARAPHSIS EXPERS.

INSENSIBILITY OF TOUCH OR GENERAL FEELING.

THE ORGAN OF TOUCH TOTALLY IMPERCIPIENT OF OBJECTS APPLIED TO IT.

UNDER this species, by some writers denominated amblyopia, we may mention the two following varieties:—

- | | |
|----------------------------|---|
| α Simplex. | Confined locally or generally |
| Numbness. | to the organ of touch: sometimes accompanied with uneasiness. |
| β Complicata. | Complicated with insensibility |
| Complicated insensibility. | in several of, or all the other senses. |

Occasional and local NUMBNESS is common to most persons. A tight bandage, or accidental pressure of one limb upon another, by obstructing the communication or activity of the nervous influence, will often produce this, when the limb is commonly and emphatically asserted to be asleep. A very slight motion, however, takes it off, when the irregular transmission of the sensorial power, on its first return, produces a sense of pricking, as though a ball of needles were in the limb, and pushing in every direction. Where such numbnesses, however, occur without pressure or any manifest cause, they well deserve watching and resisting by tonics or stimulants, local or general; for they clearly show a tendency to paresis, if not to paralysis.

But there are some persons who possess by nature a numbness, or privation of the sense of feeling, in particular organs or parts of the surface, which appears to depend on a natural destitution of the nerves of touch wherever such insensibility is to be found. And hence they are able, in such parts of the body, to prick or cut themselves, or to run pins to any depth below the skin, without pain. I have seen several striking examples of this peculiar affection. Sometimes the numbness has been limited to a single limb, but common to the whole of it, as the hand, for example, which at the same time has pos-

sessed a full power of motion. Sometimes the insensibility has been universal, or extended over the whole surface. Lamarck relates a case in which this want of feeling was confined to the arm; but at the same time was so complete, that the man who laboured under it had no pain during the progress of a phlegmon; and who, on another occasion in which he broke his arm, felt nothing more than a crash, and merely thought he had broken the spade, he was at work with. Dr. Yelloly has described another interesting case in the third volume of the *Medico-Chirurgical Transactions*. The patient, aged 58, had been first affected in Jamaica about three years before, and the affection had become permanent. "The hands," says Dr. Yelloly, "up to the wrist, and the feet half way up the legs, are perfectly insensible to any species of injury, as cutting, pinching, scratching, or burning. The insensibility, however, does not suddenly terminate; but exists to a certain degree nearly up to the elbow, and for some distance above the knee. He accidentally put one of his feet, some time ago, into boiling water, but was no otherwise aware of the high temperature, than by finding the whole surface a complete blister on removing it. The extremities are insensible to electrical sparks taken in every variety of mode."*

As an example of the SECOND MODIFICATION, or insensibility in the organ of touch, complicated with insensibility in several other senses, we may mention the following, which Sauvages has copied from the *Academy Collections*:—"The patient, a delicate young man, was suddenly in the morning deprived equally of speech and of the sense of touch, without any assignable cause or premonition. Punctured and pricked in different parts of his body, in his head, neck, back, shoulders, breast, arms, abdomen, he felt nothing whatever, and even laughed at the singularity of the phenomenon; as, with the exception of numbness and cutaneous insensibility, he laboured under no kind of disease. The complaint continued two days, and seemed to have yielded to venesection."

Insensibility of touch, either simple or complicated, is also felt as a symptom in apoplexy, palsy, catalepsy, epilepsy, dyspasia, and syncope.

Where the numbness is complete and constitutional, it lies beyond the reach of medicine; where it is recent and less extreme, it will often yield to friction alone, or with camphorated oil or spirits; to heat, especially that of the warm bath; ether, ammonia, and water, and the voltaic stream, or small shocks of electricity.

SPECIES III.

PARAPHSIS ILLUSORIA.

ILLUSORY SENSE OF TOUCH.

IMAGINARY SENSE OF TOUCH, OR GENERAL FEELING, IN ORGANS THAT HAVE NO EXISTENCE.

THIS is the pseudæsthesia of Ploucquet; and

* In the case mentioned in the note to page 258 of the present volume, a paralytic state of the arm rendered it extraordinarily susceptible of the influence of heat.—Ed.

is frequently found among persons that have suffered amputation; who, for a long time after the loss of the separated limb, have still a sense of its forming a part of the body, and suffer in idea the same kind of pain, or other inconvenience, they endured before its removal.

It proceeds from the close sympathy which peculiarly prevails between the extremities of the living fibre in all organs whatever, and which, as we have already had occasion to show, extends also between the terminating links of various chains of action that run into organs at a considerable distance from each other. Of the first we have an example in the constrictive pain produced in the glans penis, when the neck of the bladder is irritated by the lodgment of a calculus upon it. So, if the fauces or upper end of the œsophagus be tickled by a feather, the stomach at the lower end will be excited to nausea and sickness; and if the stomach itself feel suddenly faint and enfeebled, the rectum will at the same time give way, and involuntarily discharge its contents. Of the second kind of sympathy, or that which shows itself between remote organs engaged in a common chain of action, we have a striking instance in the swelling of the mammae on the irritation of the uterus in pregnancy; and we had occasion to point out another equally striking, when treating under the last class of several species of marasmus, in which the chylific and assimilating organs, constituting the two extremities of the great chain of the nutritive function, maintain, on various occasions, a wonderful harmony both of energy and weakness.*

And hence, in a diseased limb, the pain which originates in the part affected is often extended, or even transferred, by sympathy, to its tendinous extremities, where the morbid impression remains in many instances long after the diseased portion of it has been removed. Nor is this protraction of the impression to be wondered at; for we are perpetually witnessing cases in which, when a morbid impression has once been established, it continues to manifest itself in the same manner. Thus, when dust has been blown into the eye, a sensation of pricking is just as much felt in the conjunctiva for some hours after the dust has been washed out, as when it was actually goading the tender tunic: and in like manner, when an ague has been once generated in the animal frame by an exposure to marsh miasm, the patient will be still subject for many weeks, or perhaps months, to the same return of febrile paroxysm, how widely soever he may remove from the tainted region, and thus free himself from the cause of the disease.

In the case before us, the illusory feeling becomes fainter by degrees, and as the affected fibres return to a healthy condition. And if in the meantime it be very troublesome, it may generally be relieved by a moderate use of narcotics.

A like imaginary sensation is occasionally felt

* Vol. ii., Cl. III., Ord. IV., Gen. III., Spe. 1, *Marasmus Atrophia*; and Spe. 3, *M. Climactericus*.

John R. D. Duncan
L. R. Westman

as a symptom in hypochondrias, and various other mental affections; in which ideas of pain and distress are mistaken for realities, and produce as severe a suffering.*

GENUS VI.
NEURALGIA.
NERVE-ACHE.

ACUTE SENSIBILITY AND LANCINATING PAIN IN THE COURSE OF ONE OR MORE BRANCHES OF NERVES IN AN ORGAN; MOSTLY WITH AN IRREGULAR MOTION OF THE ADJOINING MUSCLES; RECURRENT IN SHORT PAROXYSMS, WITH INDETERMINATE INTERVALS OR REMISSIONS.

THE term NEURALGIA, from *νεῦρον*, "nervus," and *ἄλγος*, "dolor," has been for many years

* The history of Caspar Hauser, the individual who, as is well known, was kept in a dungeon, separated from all communication with the world, from early childhood till about the age of seventeen, and who was found at Nuremberg in 1828, presents a most wonderful instance of morbid exaltation of the senses of seeing, hearing, tasting, and feeling. His biographer, the eminent Feuerbach, remarks as follows:—

"As to his sight, there existed in respect to him no twilight, no night, no darkness. This was first noticed by remarking that at night he stepped everywhere with the greatest confidence; and that in dark places he always refused a light when it was offered to him. He often looked with astonishment or laughed at persons, who in dark places, for instance, when entering a house or walking on a staircase by night, sought safety in groping their way or in laying hold on adjacent objects. In twilight, he even saw much better than in broad daylight. Thus, after sunset, he once read the number of a house at the distance of 180 paces, which in daylight he would not have been able to distinguish so far off. Towards the close of twilight, he once pointed out to his instructor a gnat that was hanging in a very distant spider's web. At a distance of certainly not less than sixty paces, he could distinguish the single berries in a cluster of elderberries from each other, and these berries from black currants. It has been proved by experiments carefully made, that in a perfectly dark night he could distinguish different dark colours, such as blue and green, from each other.

"When at the commencement of twilight a common eye could not yet distinguish more than three or four stars in the sky, he could already discern the different groups of stars, and he could distinguish the different single stars of which they were composed from each other, according to their magnitudes and the peculiarities of their coloured light. From the enclosure of the castle at Nuremberg, he could count a row of windows in the castle of Marloffstein; and from the castle, a row of the windows of a house lying below the fortress of Rothenberg. His sight was as sharp in distinguishing objects near by, as it was penetrating in discerning them at a distance. In anatomizing plants, he noticed subtle distinctions and delicate particles which had entirely escaped the observation of others.

"Scarcely less sharp and penetrating than his sight was his hearing. When taking a walk in the fields, he once heard, at a distance comparatively very great, the footsteps of several persons,

employed with great accuracy to express a division of diseases which will probably hereafter be found to be peculiarly numerous, and in some modification or other, to appertain to most of the organs of the animal frame.

The term neuralgia has of late been employed by various nosologists to express this group of diseases, especially by Professor Chaussier of Paris, and Dr. Meglin of Strasburg. Yet, till of late, only the neuralgia of the face seems to have been known to any pathologist: M. Chaussier, however, has added the second of the present species, under the name of *neuralgia plantaris*.

Since the publication of the volume on Nosology, I have been consulted on a very striking disease of the same kind, occurring, with a few local peculiarities of feature, in the female breast; and we are hence put into possession of another

and he could distinguish these persons from each other by their walk. He had once an opportunity of comparing the acuteness of his hearing with the still greater acuteness of hearing evinced by a blind man, who could distinguish even the most gentle step of a man walking barefooted. On this occasion he observed that his hearing had formerly been much more acute; but that its acuteness had been considerably diminished since he had begun to eat meat; so that he could no longer distinguish sounds with so great a nicety as that blind man.

"Of all his senses, that which was the most troublesome to him, which occasioned him the most painful sensations, and which made his life in the world more disagreeable to him than any other, was the sense of smelling. What to us was entirely scentless, was not so to him.—The most delicate and delightful odours of flowers, for instance the rose, were perceived by him as insupportable stench, which painfully affected his nerves.

"What announces itself by its smell to others only when very near, was scented by him at a very considerable distance. Excepting the smell of bread, of fennel, of anise, and of caraway, to which he says he had already been accustomed in his prison,—for his bread was seasoned with these condiments—all kinds of smells were more or less disagreeable to him. When he was once asked, which of all other smells was most agreeable to him? he answered, none at all. His walks and rides were often rendered very unpleasant by leading him near to flower-gardens, tobacco-fields, nut-trees, and other plants which affected his olfactory nerves; and he paid dearly for his recreations in the free air by suffering afterward from headaches, cold sweats, and attacks of fever. He smelt tobacco when in blossom in the fields at the distance of fifty paces, and at more than one hundred paces when it was hung up in bundles to dry, as is commonly the case about the houses in the villages near Nuremberg. He could distinguish apple, pear, and plum-trees from each other at a considerable distance, by the smell of their leaves. The different colouring materials used in the painting of walls and furniture, and in the dying of cloths, &c., the pigments with which he coloured his pictures, the ink or pencil with which he wrote, all things about him, wafted odours to his nostrils which were unpleasant or painful to him. If a chimney-sweeper walked the streets, though at the distance of several paces from him, he turned his face shuddering from his smell. The smell of an old cheese made him feel

species, making the entire number three that have now exhibited themselves under precise and determinate characters. These species, therefore, are as follow :—

1. Neuralgia Faciei. Nerve-ache of the Face.
2. ——— Pedis. Nerve-ache of the Foot.
3. ——— Mammæ. Nerve-ache of the Breast.

unwell, and affected him with vomiting. The smell of strong vinegar, though fully a yard distant from him, operated so powerfully upon the nerves of his sight and smell as to bring the water into his eyes. When a glass of wine was filled at table at a considerable distance from him, he complained of its disagreeable smell, and of a sensation of heat in his head. The opening of a bottle of champaign was sure to drive him from the table or to make him sick. What we call unpleasant smells were perceived by him with much less aversion than many of our perfumes. The smell of fresh meat was to him the most horrible of all smells. When Professor Daumer, in the autumn of 1828, walked with Caspar near to St. John's churchyard, in the vicinity of Nuremberg, the smell of the dead bodies, of which the professor had not the slightest perception, affected him so powerfully that he was immediately seized with an ague, and began to shudder. The ague was soon succeeded by a feverish heat, which at length broke out into a violent perspiration, by which his linen was thoroughly wet. He afterward said that he had never before experienced so great a heat. When on his return he came near to the city gate, he said that he felt better; yet he complained that his sight had been obscured thereby. Similar effects were once experienced by him (on the 28th of September, 1828), when he had been for a considerable time walking by the side of a tobacco-field.

"Professor Daumer first noticed the peculiar properties of Caspar's sense of feeling, and his susceptibility of metallic excitements, while he was yet at the tower. Here a stranger once made him a present of a little wooden horse and a small magnet, with which, as the forepart of the horse was furnished with iron, it could be made to swim about in different directions. When Caspar was going to use this toy according to the instructions he had received, he felt himself very disagreeably affected; and he immediately locked it up in the box belonging to it, without ever taking it out again, as he was accustomed to do with his other playthings, in order to show to his visitors. When he was afterward asked why he did so, he said that that horse had occasioned him a pain which he had felt in his whole body and in all its members. After he had removed to Professor Daumer's house, he kept the box with the magnet in a trunk; from which, in clearing out his things, it was accidentally taken and brought into notice. The idea was suggested thereby to Professor Daumer, who recollected the occurrence that had formerly taken place, to make an experiment on Caspar with the magnet belonging to the little horse. Caspar very soon experienced the most surprising effects. When Professor Daumer held the north pole towards him, Caspar put his hand to the pit of his stomach, and drawing his waistcoat in an outward direction, said that it drew him thus; and that a current of air seemed to proceed from him. The south pole affected him less powerfully; and he said that it blew upon him. Professor Daumer and Professor Herrmann made afterward several other experiments similar to these, and calculated to deceive him; but his feelings always told him very correctly, and even

There can be little doubt that other organs besides these are subject to the same misaffection; and it is not improbable that accident or a minuter investigation of the subject may show that almost every part of the body may become a seat of neuralgia.* M. Recamier has of late met with a painful and intractable disease of the

though the magnet was held at a considerable distance from him, whether the north pole or the south pole was held towards him. Such experiments could not be continued long, because the perspiration soon appeared on his forehead, and he began to feel unwell.

"In respect to his sensibility of the presence of other metals, and his ability to distinguish them from each other by his feelings alone, Professor Daumer has selected a great number of facts, from which I shall select only a few. In autumn, 1828, he once accidentally entered a store filled with hardware, and particularly with brass wares. He had scarcely entered before he hurried out again, being affected with violent shuddering, and saying that he felt a drawing in his whole body in all directions.—A stranger who visited him, once slipped a piece of gold of the size of a kreutzer into his hand, without Caspar's being able to see it: he said immediately that he felt gold in his hand.—At a time when Caspar was absent, Professor Daumer placed a gold ring, a steel and brass compass, and a silver drawing-pen, under some paper, so that it was impossible for him to see what was concealed under it. Daumer directed him to move his finger over the paper without touching it; he did so; and by the difference of the sensation and strength of the attraction which these different metals caused him to feel at the points of his fingers, he accurately distinguished them all from each other, according to their respective matter and form.—Once, when the physician, Dr. Osterhausen, and the royal crownfiscal, Brunner, from Munchen, happened to be present, Mr. Daumer led Caspar, in order to try him, to a table covered with an oil cloth, upon which a sheet of paper lay, and desired him to say whether any metal was under it; he moved his finger over it and then said, there it draws! 'But this time,' replied Daumer, 'you are nevertheless mistaken; for,' withdrawing the paper, 'nothing lies under it.' Caspar seemed at first to be somewhat embarrassed; but he put his finger again to the place where he thought he had felt the drawing, and assured them repeatedly that he there felt a drawing. The oil cloth was then removed, a stricter search was made, and a needle was actually found there.—He described the feeling which minerals occasioned him, a kind of drawing sensation which passed over him, accompanied at the same time with a chill, which ascended accordingly as the objects were different, more or less up the arm; and which was also attended with other distinctive sensations. At the same time, the veins of the hand which had been exposed to the metallic excitative, were visibly swollen. Towards the end of December, 1828, when the morbid excitability of his nerves had been almost removed, his sensibility of the influence of metallic excitatives began gradually to disappear, and was at length totally lost."—D.

* The editor has seen several examples of neuralgia of the arm, which arose from injuries of the thumb or fingers. M. Ribes has recorded a case of neuralgia of the external sciatic popliteal nerve, which disorder gradually extended its paroxysms of violent pain, with convulsions of the muscles, over the greatest part of the body. It

uterus, which he has regarded as of this kind, and has denominated *uterine neuralgia*, though he does not speak of it with much decision.*

The corporeal senses which have hitherto passed within the range of our observations as the seats of different genera of diseases, are external, and serve to convey impressions peculiar to themselves. It is, however, sufficiently known to every one, that there is not an organ in the body but is possessed of nerves productive of a very different kind of sensibility from any of these; less distinct perhaps and elaborate, but the index of its weal or wear, its comfort or disquiet; and which may be sufficiently expressed by the name of *general feeling*. It is possible, indeed, that this general feeling may in some degree be differently modified in every organ; but as the distinctions, whatever they may be, are not nice enough for us to trace out and arrange, as they are in the local senses, it is sufficient for all the purposes of pathology to regard this feeling as common to all the sentient organs, and consequently as one and the same. We have already taken some notice of it in the proem to the present class, and have observed that it has been described by some pathologists under the name of *cænesthesis*, and by the Germans is denominated *Gemeingefühl*, or general feeling. Dr. Hubner published an inaugural dissertation on this subject in 1794, in which he enumerates its properties at some length.—(*Commentatio de Cænesthesi Dissert. Inaug. Medica; Auctore C. F. Hubner*, 1794.) I have never seen this treatise, but Sir Alexander Crichton, who has, describes it as a very ingenious production.

It is these nerves of general sensibility that seem to constitute the seat of disease in the three species we are now about to enter upon, and consequently indicate that the present is their proper place in a system of physiological nosology.†

SPECIES I.

NEURALGIA FACIEI.

NERVE-ACHE OF THE FACE.

LANCINATING PAINS SHOOTING FROM THE REGION OF THE MOUTH TO THE ORBIT, OFTEN TO THE EAR, AND OVER THE CHEEK, PALATE, TEETH, AND FAUCES; WITH CONVULSIVE TWITCHINGS OF THE ADJOINING MUSCLES.

THIS is the *trismus maxillaris* or *t. dolorificus* of M. de Sauvages, for it is not necessary

arose from a gunshot wound of the upper third of the leg, and resisted various medicines, the moxa, &c.; but was very materially relieved, though not completely, by the division and excision of a portion of the above nerve.—See Magendie's Journ. Expér. de Physiol., tom. ii., p. 343. See also cases of neuralgia in various situations, by Dr. Evans, in Edin. Med. Journ., No. lxxix., p. 278.

* *Tableau des Maladies observées à l'Hôtel-Dieu, dans les Salles de Cliniques, &c.* Par L. Martinet, *Révue Médicale*, &c., 1824.

† Dr. Good's prophecy, "that accident or a minuter investigation of the subject may show that almost every part of the body may become a seat of neuralgia," is fully verified. In addition to those species of neuralgia mentioned by Dr. Good and the London editor, Itard has observed

to make a distinction between them, as Sauvages himself has done; by Dr. Fothergill it is denominated *dolor crucians faciei*. As the French give the name of *tic* to trismus or locked-jaw, they distinguish this first species of neuralgia, affecting the nerves about the jaw, by the name of *tic douloureux*, by which term the disease is, perhaps, chiefly known even in our own country in the present day. I shall have occasion to observe more at large, under the genus *TRISMUS*, that the word *tic* is commonly supposed to be an onomatopoeia, or a sound expressive of the action it imports; derived, according to some, from the pungent stroke with which the pain makes its assault, resembling the bite of an insect; but according to Sauvages and Soleysel, from the sound made by horses, that are perpetually biting the manger when labouring under this peculiar affection. We do not, however, appear to be acquainted with the real origin of the term.

From the symptoms by which this complaint is distinguished, it is not difficult to decide concerning both its seat and nature. The character of the pain is very peculiar, and its course corresponds exactly with that of the nerves. The second branch of the fifth pair is perhaps more frequently affected than either the first or the third. But the *portia dura* of the seventh pair, which is distributed more extensively upon the face, under the name of *pes anserina*, is more frequently the seat of affection than any of the branches of the fifth pair seem to be; which is a matter of no small regret, as it is difficult for any operation to reach this quarter effectually, although it is a difficulty which we shall presently find has, in one instance at least, been encountered and surmounted. When, however, the disease is seated in the seventh pair of nerves, we can be at no loss to decide concerning it, in consequence of the course and divarications of the pain, which commences with great acuteness in the forepart of the cheek, towards the mouth and ala of the nose, sometimes spreading as high as the forehead, and ramifying in the direction of the ears. At other times, the forehead, temple, and inner angle of the eye on the side affected, and even the ball of the eye itself, form the chief lines of pungent agony, while, from irritation of the lachrymal gland, the eye weeps involuntarily. In this case we may reasonably suspect the disease to be seated in some part of the superior maxillary nerve, constituting the second branch of the fifth pair. And it is hence obvious, that the radiation of the pain must vary according to the nerves or nervous twigs that are affected.*

neuralgia of the ear; Siebold that of the *intercostal nerves*; Chaussier and Jadelot in the first lumbar nerve; Francis and Barras in the spermatic nerve; and Cotugno and Chaussier in the anterior crural nerve. Boisseau has described a still greater number of neuralgic affections.—See his *Nosographie Organique*, vol. iv., p. 714.—D.

* Some practitioners, remembering that the *portio dura* is only a nerve of motion, consider it doubtful whether this nerve is ever truly the seat of neuralgia. One of Dr. Elliotson's patients,

The disease has been occasionally mistaken for rheumatism, hemicrania, and toothache: but the brevity of the paroxysm, the lancinating pungency of the pang, the absence of all intumescence or inflammation, the comparative shallowness, instead of depth, of its seat, and its invariable divarication in the course of the facial nerves or their offsets, will always be sufficient to distinguish it from every other kind of pain.

Of its exciting causes we know but little. It seems sometimes to have been produced by cold, and sometimes by mental agitation, in persons of an irritable temperament. But it has been found in the robust as well as in the delicate, in the middle-aged as well as in the old. In a few cases the irritation has been local, of which Mr. Jeffreys has given a very striking instance in a young woman, who, when only six years old, fell down with a teacup in her hand, which was hereby broken, one of the cheeks lacerated, and a fragment of the teacup imbedded under the skin. The wound healed, though slowly and with difficulty; the buried fragment of the teacup was not noticed, and consequently was not extracted. From an early period, a violent nervous pain returned nightly, and one side of the face was paralytic. These dreadful symptoms were endured for fourteen years: at the end of which time an incision was made through the cicatrix down upon what was then found to be the edge of a hard substance, and which appeared, when extracted, to be the piece of the teacup above noticed. From this time the neuralgia and paralysis ceased; the affected cheek recovered its proper plumpness, and the muscles their due power.*

It is possible, as suggested by M. Martinet, that as a symptom, it may sometimes occur in what he calls, and perhaps correctly, an inflammation of the nerves, or a thickening of the neurilemma in some particular organ, of which he has given various examples, accompanied with a reddish or even violet tinge, and studded with minute ecchymoses.† But that this is not

however, complained of the disorder not only in the cheek, but in the course of the portia dura from the stylo-mastoid foramen. Two, or even all the three branches of the fifth pair may be affected, and the pain may extend also to the other side of the face. Dr. Elliotson has known it extend down the neck to the shoulder, and along the inside of the arm to the ends of all the fingers and the thumb. Various nerves of the legs, arms, fingers, or toes, are occasionally the seat of the disease; and an intercostal, a lumbar, and even the spermatic nerve, have been attacked. The pain does not always shoot in the course of the nerve, but frequently in the opposite direction.—See Cyclop. of Pract. Med., art. NEURALGIA.—Ed.

* Lond. Med. and Phys. Journ., March, 1823, p. 199. Sir Henry Hallford mentions the case of a lady who suffered violent *tic douloureux* till an apparently sound tooth was extracted, on account of the attacks being frequently preceded by uneasiness in it: an exostosis was found at its root. Another case was relieved by an exfoliation of a portion of the antrum.—Ed.

† Mémoire sur l'Inflammation des Nerfs, &c.

the only, or even the ordinary proximate cause, is clear, since, in the cases alluded to, pressure upon the part is intolerable, while in idiopathic neuralgia it is commonly consolatory, and considerably diminishes the agony.

André appears to have been the earliest writer who remarked this painful affection with accuracy; and he succeeded in removing it permanently by applying a caustic to the infra-orbital or maxillary branch of nerves in one case in which a previous division of the nerve by the scalpel, as practised by Marechal, had produced only a temporary cure. André, who resided at Versailles, published his account in 1756, whimsically enough inserting it in a treatise on diseases of the urethra. A few unsatisfactory experiments and operations were given to the public in the course of the next fifteen years, chiefly by French practitioners, from which little of real value is deducible. In 1776, Dr. Fothergill, in the fifth volume of Medical Observations and Inquiries, communicated a very full and elaborate description and history of the disease: since which time M. Thouret and Pujol have each published a valuable paper on the same subject, in the Memoirs of the Society of Medicine of Paris, containing various cases collected and described with great minuteness; and we have already adverted to the more recent publications of Dr. Meglin and Professor Chaussier.

It has of late been suspected, that in some cases, at least, of this disease, the seat of irritation might be at the origin instead of at the extremity of the nerve; an idea that has arisen from the powerful sympathetic action manifested by the eye and the stomach* forming the boundaries of the chain, upon which subject we shall have to speak at large when treating the genus ENTASIA in the ensuing order. "The nerves," remarks Dr. Parr, "that supply the eye externally, and the slight connexion of the intercostal with the brain, are nearly from the same spot in the cerebrum, and it did not seem improbable in the case alluded to, that the disease may have really been at the origin of the nerves, although felt as usual at its extremity." Dr. Parr was in consequence induced to try arsenic, and in one instance, he tells us, with a decidedly good effect. It is also said to have

1824. Also, cases by Evans in Edin. Med. Journ., No. lxxix., p. 282.

* Dr. Elliotson assures us that he has never seen one case of neuralgia referrible to disorder of the digestive organs.—(See Cyclop. of Pract. Med., art. NEURALGIA.) Where inflammation is obvious, whether rheumatic or not, he approves of local bleeding, mercury, colchicum, and antiphlogistic treatment in general. Should these means fail, he recommends anodynes to be added to them. When the complaint is rheumatic, but inflammatory; he approves of stimulants, internal and external, especially ammoniated tincture of guaiacum, a generous diet, tonics, mercury, and all modes of counter-irritation. In some cases, warm temperature and warm clothing seem essential; in some, the warm water or steam bath; and in others, the cold bath, followed by friction, answer best.—Ed.

been since found serviceable in a few other cases. In Mr. Thomas's hands, however, we shall presently perceive that it completely failed. Mercury is also reported to have occasionally proved successful, and especially when carried to the extent of salivation; though in numerous instances it has been tried even to this last effect without any benefit whatever. [Some cases of facial neuralgia have been cured by applying a drop or two of the oil of croton to the tongue.—(*Med. Chir. Review*, Sept., 1821.) The effect on the nerve was almost instantaneous. Bark, and the sulphate of quinine,* have also been tried with various results.]

When, about thirty years ago, animal magnetism was a fashionable study in France, it was had recourse to for this disease among others, and had its day of favour as a popular remedy.—(*Edin. Med. and Surg. Journ.*, July, 1823.) Of late, however, neuralgia has been attempted to be cured in France by an external use of acetic ether; while in Germany Dr. Meglin has employed pills composed of the extract of henbane,† and sublimed oxyde of zinc, and according to his own statement, with great success. But, beyond controversy, one of the most valuable medicines that have hitherto been tried is the subcarbonate of iron, for the first use of which, so far as I know, we are indebted to the late Mr. Hutchison,‡ of Southwell, who commonly employed it in doses of a drachm three times a day.

[Dr. Borthwick, however, has found the last

* Obs. de Neuralgie sus-orbitaire droite, guérie par le Sulfate de Quinine, par M. Piedagnel. *Magendie, Journ. de Physiologie Expér.*, tom. ii., p. 124.

† The best anodyne narcotics for trial in cases of neuralgia, are the acetate, muriate, or sulphate of morphine, and the extracts of stramonium and belladonna. The editor has known great relief produced by the application of a plaster to the integuments covering the painful nerves, which was composed of one or two drachms of the extract of belladonna and an ounce of soap cerate.—Ed.

‡ Cases of Neuralgia Spasmodica, &c., by B. Hutchison, &c., 8vo., Lond., 1825. Numerous examples of the utility of subcarbonate of iron are now on record, and Dr. Elliotson adduces his testimony in favour of its efficacy in chronic neuralgia. When there is debility, and especially paleness, iron in full quantities operates much more effectually, he says, than quinine. Should no structural nor mechanical cause, and no inflammation, be present, and should the disease be of the exquisite character, he deems iron the remedy most worthy of trial. Although the doses specified in the text sometimes succeed, it is found that children will often take an ounce or six drachms every four hours. If given in twice its weight of treacle, Dr. Elliotson finds that it rarely constipates; but the bowels must always be kept open during its employment, for otherwise it is apt to accumulate in the intestinal canal in large masses.—(*See Cyclop. of Pract. Med.*, art. NEURALGIA.) Ice applied to the parts has sometimes been of service.—*See Med. Chir. Trans.*, vol. xiii., p. 252; and *Cyclop. of Pract. Med.* Also, Crawford, in *Med. Chir. Review*; Dr. Belcher's case of neuralgic amaurosis, successfully treated by the carbonate of iron.—*Edin. Med. Journ.*, No. lxxxvi., p. 37.—Ed.

plan so successful, and his confidence in it is such, that he regards the point now almost settled in practice, "that iron will relieve, if not cure, tic douloureux (neuralgic affections, generally speaking), as certainly and as speedily as quicksilver, in particular forms, will relieve and cure the lues venerea." The dose which he gives in severe cases, is one drachm and a half four times a day.—(*See Edin. Med. Journ.*, No. lxxxiii., p. 297.)]

The instances of success appear to be very numerous, though this also, like all other medicines, has often failed. But there is another energetic medicine, which has also a fair claim to attention from a very different property—that of subduing the sensibility; and this is *prussic acid*. Mr. Taylor, of Cricklade, Wilts, has made repeated trials of this powerful sedative in various cases, and apparently with more rapid relief than is afforded by the carbonate of iron. He commenced his career with a drop of Scheele's preparation, in twenty-four hours, in divided doses; but as he grew better acquainted with the effects of the medicine, he gave a drop for a dose at first, and then increased the dose to two drops, repeating it three times a day. In one or two instances he has carried the quantity, by a gradual augmentation, to twenty-four drops a day, in the course of a month's use; and very often to five and six drops a day, by adding a drop to every day's account.—(*Edin. Med. and Surg. Journ.*, July, 1823.) Time alone must determine whether the cures thus obtained will prove as permanent as those effected by the tonic power of the subcarbonate of iron. To induce ease, however, under any circumstances, and for any period of time, in the midst of so much torment, is an invaluable blessing.

In effect, neither narcotics nor tonics, nor any other class of medicines hitherto employed, can be in every case depended upon for a radical cure, though some of them, and particularly the subcarbonate of iron, are worthy of high commendation. "My father," says Dr. Perceval of Dublin, in his manuscript comment on the present author's *Nosology*, "was subject to neuralgia faciei for several years, and used a variety of medicines without relief. He was worse in close damp weather, and much worse when his mind was occupied. At length he had an issue inserted in the nucha, kept his bowels free with James's analeptic pills, and exchanged a town residence for the country. In this situation he soon threw off the disease, from which he was free for a considerable time before his death." Change of scene, a transfer of morbid action, and a recruited cheerfulness of spirits, are valuable auxiliaries in the present as in every other nervous affection; but I much question whether these alone have ever operated a cure. A spontaneous cure is the work of time alone; and time, though often a long and tedious period is requisite, will generally accomplish it, and probably did so in the case before us. The fact is, that the nervous system in every part, and every ramification, becomes gradually torpedified by excess of action; and as

the eyes grow blind and the nostrils inolfacient by strong stimulants applied to them, so the nervous twigs of every kind, after a long series of irritation from the present disease, become exhausted of power and obtuse in feeling: and it is probably by hastening this state, that the most active stimulants and the warmer tonics produce whatever benefit is to be ascribed to them.

[In the treatment of various cases of neuralgia, Baron Larrey was very successful with the moxa, which he repeated the application of according to circumstances. Delpech used the actual cautery, and after the separation of the eschar, kept up a discharge for a long time.]

How far acupuncture or needle-pricking, the zin-king of the Chinese, which we have already described under chronic rheumatism, might be useful, has not yet been determined. It has at least a fair claim for experiment, before having recourse to a curative attempt by the knife.

This radical cure consists in a division of the affected branches, provided they can be followed home. Dr. Haighton completely succeeded, some years ago, in a case in which he divided the sub-orbital branch of the fifth pair; and Mr. Cruickshank and Mr. Thomas more recently in a case of considerable complication, and where the affection was evidently not confined to the different branches of any single nerve. This last case is given by Dr. Darwin, whom the patient had intermediately consulted, in the second part of his *Zoonomia*, and is one of the most interesting sections of the work. The patient, a Mr. Bosworth by name, was between thirty and forty years of age. When he first applied to Dr. Darwin, he complained of much pain about the left cheek-bone. Dr. Darwin suspected the antrum maxillare might be diseased; and as the second of the grinding teeth had been lately extracted, directed a perforation into the antrum, which was done, and the wound kept open for two or three days without advantage. Afterward, by friction about the head and neck with mercurial unguent, he was for a few days copiously salivated, and had another tooth extracted by his own desire, as also an incision made in such direction as to divide the artery near the centre of the ear next the cheek, which gave also a chance of dividing a branch of the affected nerve; but without success. When the pain was exceedingly violent, opiates were administered in large quantity; bark being used freely in the intervals, but without effect.

The pain spread in various directions from a point in the left cheek a little before the ear, sometimes to the nose, and forepart of the lower jaw, and sometimes to the orbit of the eye on the same side; the under part of the tongue being at times also affected. It returned on some days many times in an hour, and continued several minutes; during which period (it is well worth observing, as showing the connexion between an irregular sensitive and an irregular motive power in the same muscles) the patient, says Dr. Darwin, seemed to stretch and exert his arms, and appeared to have a tendency to epileptic actions, so that his life was rendered miserable. The complaint gradually

grew worse, and Mr. Bosworth removed to London, for the purpose of again putting himself under Mr. Cruickshank's care, and of submitting to any operation he should recommend. The pain was now intolerably acute and almost unremitting; and opiates afforded him little or no relief, though taken to the quantity of six teaspoonfuls of laudanum at a time. The operation of dividing the diseased nerve was therefore determined upon.

"As the pain," says Mr. Thomas, in his letter to Dr. Darwin after its completion, "was felt more acute in the left ala of the nose and the upper lip of the same side, we were induced to divide the second branch of the fifth pair of nerves as it passes out at the infra-orbital foramen. He was instantly relieved in the nose and lip; but towards night the pain from the eye to the crown of the head became more acute than ever. Two days after, we were obliged to cut through the first branch passing out at the supra-orbital foramen: this afforded him like relief with the first. On the same day the pain attacked, with great violence, the lower lip on the left side, and the chin: this circumstance induced the necessity of dividing the third branch, passing out at the foramen mentale. During the whole period, from the first division of the nerves, he had frequent attacks of pain on the side of the tongue; these, however, disappeared on division of the last nerve.

"The patient was evidently bettered by each operation: still the pain was very severe, passing from the ear under the zygoma towards the nose and mouth, and upwards round the orbit. This route proved pretty clearly that the portio dura of the auditory nerve was also affected, at least the uppermost branch of the pes anserina. Before I proceeded," continues Mr. Thomas, "to divide this—Mr. Cruickshank had operated hitherto—I was willing to try the effect of arsenic internally; and he took it in sufficient quantity to excite nausea and vertigo, but without perceiving any good effect. I could now trust only to the knife to alleviate his misery, as the pain round the orbit was become most violent; and therefore intercepted the nerve by an incision across the side of the nose, and also made some smaller incisions about the ala nasi. To divide the great branch lying below the zygomatic process, I found it necessary to pass the scalpel through the masseter muscle till it came in contact with the jaw-bone, and then to cut upwards: this relieved him as usual. Then the lower branch was affected, and also divided: then the middle branch running under the parotid gland. In cutting this, the gland was consequently divided into two equal parts, and healed tolerably well after a copious discharge of saliva for several days.

"I hoped and expected that this last operation would have terminated his sufferings and my difficulties; but the pain still affected the lower lip and side of the nose, and upon coughing or swallowing his misery was dreadful. This pain could only arise from branches from the second of the fifth pair passing into the cheek, and lying between the pterygoideus in-

ternus muscle and the upper part of the lower jaw. The situation of this nerve rendered the operation hazardous, but, after some attempts, it was accomplished.* This finished the series of operations, and restored the afflicted patient to perfect health.

I have dwelt the longer on this interesting case, because it seems to show, first, that there is occasionally no certain cure but in the use of the knife;* secondly, that a delay in performing the operation only affords time for the disease to spread from one branch of the affected nerve to another, and even to different branches of nerves in a state of contiguity; and thirdly, that the disease betrays the spasmodic character of the diathesis when minutely watched, even in cases in which this character is most obscure. Dr. Darwin objects, properly enough, to arranging this disease as a trismus, "since no fixed spasm," says he, "like the locked-jaw, exists in this malady." He adds, indeed, that in the few cases he has witnessed, there has not been any convulsion of the muscles of the face; but in Mr. Bosworth's case he has expressly noticed the morbid stretching of the arms, and the tendency to epileptic actions. Its proper place, however, seems to be where it is now arranged.

SPECIES II.

NEURALGIA PEDIS.

NERVE-ACHE OF THE FOOT.

RACKING AND LANCINATING PAINS RANGING ABOUT THE HEEL, AND TREMULOUSLY SHOOTING IN IRREGULAR DIRECTIONS TOWARDS THE ANKLE AND BONES OF THE TARSUS.

THIS is the *neuralgia plantaris* of Professor Chaussier; who mentions a very decided case of it, to which Dr. Marino, a physician of Piedmont, had been long subject. It commenced, he tells us, in early life; was relieved by the mineral waters of Vivadio, and still more by the pressure of a tight bandage. With advancing years it became less severe, the cause of which we have already explained in the preceding species, but never ceased altogether. It alternated with other nervous affections, and was at length complicated with convulsive asthma.

In calling the attention of the medical profession to this species, by introducing it into the volume of *Nosology*, so long ago as the beginning of 1817, I had my eye directed to a very marked case, which had then lately occurred to me in a clergyman of this metropolis, about forty-five years of age, but otherwise in firm health and cheerful spirits. He had for many years been a victim to it. The paroxysms were short, and of uncertain recurrence, but so acute as nearly to make him faint, and at length compelled him to relinquish the duties of the pulpit, for which, from his zeal and eloquence, he was admirably qualified, but where he had frequently been obliged to break off with great abruptness from the unexpected incursion of a

* As this expression may induce young practitioners to promise too much from the operation, the editor deems it right to mention that the knife has frequently failed.

fresh paroxysm. The pain usually extended up the calf of the leg towards the knee, and ramified towards the toes in an opposite direction; and was usually compared by himself to that of scalding verjuice poured over a naked wound. The tibial branches of the popliteal nerve, and particularly the plantar twigs, seem in this species to have been the part chiefly affected, though it is probable that some of the offsets from the peroneal branch associated in some instances in the morbid action.

Every therapeutic process that the art of medicine in the hands of the most experienced physicians of this metropolis could devise, was in this case tried, in a long and tedious succession, in vain. Sometimes external and sometimes internal preparations, or a tight ligature, appeared to afford a temporary alleviation, and to protract the intervals: but never any thing more. It was in consequence proposed by a surgeon of great eminence to amputate the leg, which was at one time on the point of being submitted to, though protested against by the present author on two accounts. First, the uncertainty whether the morbid condition of the nerve might not be seated chiefly in its origin instead of in its extremity, in which case amputation could be of no avail; and secondly, the chance, that in process of time the keen sensibility of the affected branches would be worn out and obtunded by the violence of the action. Such was the undecided and miserable condition of this patient at the time of noticing his case on the publication of the author's volume of *Nosology*. Since this period, the prediction that the disease would gradually wear itself out has been completed: the paroxysms are now slight and tolerable, and the intervals much longer: and the patient has for nearly a twelvemonth been able to resume the duties of his profession without any interruption.

SPECIES III.

NEURALGIA MAMMÆ.

NERVE-ACHE OF THE BREAST.

SHARP, LANCINATING PAINS, DIVARICATING FROM A FIXED POINT IN THE BREAST, AND SHOOTING EQUALLY DOWN THE COURSE OF THE RIBS AND OF THE ARM TO THE ELBOW; THE BREAST RETAINING ITS NATURAL SIZE, COMPLEXION, AND SOFTNESS.

ABOUT the year 1820, I was requested by Mr. Blair to examine a young woman, then eighteen years of age, who for more than two years had been subject to a painful disorder of the breast, that seemed equally to defy all parallel and all modes of treatment. On examining into the nature of the symptoms, I found them as described in the preceding definition. The organ was full-formed, soft, and globular, without the slightest degree of inflammation or hardness. When the paroxysm of pain was not present, it would bear pressure without inconvenience; but during the pain, the whole breast was acutely sensible. The paroxysms returned at first five or six times in the course of the day, and were short and transient: but as the disease

became more fixed, it became also more severe and extensive; for the agonizing fits at length recurred as often as once an hour, and sometimes more frequently; and, from being comparatively concentrated, the lancinating shoots darted both downward in the course of the circumjacent ribs, and upwards to the axilla, whence they afterward descended to the elbow, below which I do not know that they proceeded at any time. These fits were at length so frequent and vehement as to imbecillate her whole life, and incapacitate her from pursuing any employment; for it frequently happened, that if she attempted needlework, her fingers abruptly dropped the needle a few minutes after taking hold of it, from a mixture of pungent pain and tremulous twitching. The twitching or snatches in the shoulder, for it at length reached to this height, were at one time so considerable as to give the patient an idea, to use her own words, that something was alive there; while, though the lancinating pain did not descend below the elbow, a considerable degree of trepidation reached occasionally to her fingers' ends. Her general health was in the meantime unaffected, and she was regular in menstruation.*

I had no hesitation in regarding this as a non-descript species of neuralgia; and as little in communicating my fears that no plan of medicine we could lay down would be more than palliative, even if it should prove thus far beneficial, and that we must trust to time alone for a cure, and that obtuseness of sensibility, which I have already noticed as a common consequence of high nervous irritation, continued till the organ becomes exhausted and torpedified.

Every remedial process was nevertheless tried in series for the purpose of obtaining relief, if not full success. Bleeding, local and general, frequently and profusely repeated; purgatives of all kinds; tonics and antispasmodics of every sort; the hot and cold bath; electricity and galvanism in every form; rubefacients, blisters, setons, issues, and whatever else could be suggested, were enlisted into service in succession. But every thing was equally without avail; nor do I know that even a temporary relief was obtained by any of these. Narcotics of all kinds proved impotent: drowsiness, indeed, and a comatose stupor, were hereby in various instances obtained, but the interval of wakeful-

ness was as much as ever tormented with the same racking paroxysms. From the powerful influence of *nux vomica* in many cases of nervous affection, to some of which we shall have occasion to advert hereafter, I had some hope of producing a slight impression on the nerves affected; but the hope proved illusory: the patient took it in infusion as far as to about eight grains at a dose three or four times a day, till her head was intolerably confused, and every other part became numb; but the paroxysms were intractable.

The poor sufferer, whose relations were incapable of affording the resources of private practice, tried one dispensary after another, and at length one of the largest hospitals of this metropolis, without the smallest benefit, and from each was discharged as incurable. About six months since, however, being nearly four years from the commencement of the disease at home, and having utterly relinquished all medical means, with the exception of a seton under the breast, which was not dried up, she began to think herself rather better, and has continued to improve ever since, till a week ago, when her mother came to inform me she was worse again. This intelligence greatly surprised me, till I learned that the seton was now quite healed. It has since been opened, and there is a hope of her again improving.*

* Since the time of Fothergill, neuralgia has been noticed by many physicians and surgeons in this country. Prof. James Jackson, of Boston, seems to have been the first who wrote at any length on the subject, and according to him, little attention was paid to it prior to his publication in 1813: the remarkable case of the late Dr. Jones of New-York, who died from neuralgia, had however already appeared in the Phil. Med. Museum of 1809, and Dr. Hosack remarks, that he had repeatedly encountered this disease many years before.—*Am. Med. and Phil. Reg.*, vol. iv. At the present day it is unfortunately not uncommon, and seems to be more frequent in females than in males.

In regard to treatment, although the division of the nerve may at times prove successful, yet surgery must surrender her claims to the physician in removing this calamity. From carefully examining the recorded cases of neuralgia, if we except those from mechanical injury we are led to conclude that in many instances it is constitutional, and hence that the treatment must be conducted with reference to the whole system. Among particular remedies, the *datura stramonium* is in more repute among American physicians than *conium* or *belladonna*, and the arsenical solution is sometimes employed with success. Dr. Hosack has on several occasions prescribed the volatile tincture of *guaiacum* with good effect. Dr. James Jackson, pursuing the suggestions of Fothergill, has administered three hundred grains of *conium* in six hours: the patient was cured. The carbonate and phosphate of iron, so warmly recommended by Hutchison, are frequently given with it. Dr. Francis has found that sulphate of quinine relieved, in many cases, where the narcotics had failed: his practice is recommended by Roche and Sanson.—See their *Nouveaux Pathol. Med. Chirurg.*, vol. ii. *Veratrum* has been employed by Dr. Turnbull in many instances.—(See Turnbull on *Veratrum*.) And recently some curious cases have been published in the London Lancet, show-

* Many good practical observations on this subject will be found in Sir Astley Cooper's *Illustrations of the Diseases of the Breast*, chap. ix., part i., 4to., Lond., 1829. "The breast," says he, "is liable to become irritable without any distinct or perceptible swelling, as well as to form an irritable tumour composed of a structure unlike that of the gland itself, and which, therefore, appears to be a specific growth. Both states of disease, in the greatest number of examples, occur in young persons from the age of 16 to 30 years. I have never witnessed it prior to the commencement of puberty."—(P. 76.) The suffering increases very much just as menstruation is about to take place; it is somewhat relieved on the evacuation occurring, and decreases on its cessation. An operation, when there is no distinct tumour, must be entirely out of contemplation.—ED.

Thus far was written in the first edition of this work. The patient, under the kindness of Sir William Blizard, obtained an entrance into the Margate Sea-bathing Infirmary, and, after five or six weeks' use of the marine bath, returned home—not indeed entirely free from pain, but in comfortable ease, and able to resume the use of her needle. About six months afterward, however, the complaint returned with as much violence as ever, and again the most powerful tonics and antispasmodics were tried in vain. The subcarbonate of iron, in the

fullest doses employed by Mr. Hutchison, was had recourse to, and steadily persevered in, but to as little purpose as every other medicine. She has now again returned to the Margate Infirmary, where I hear she has again found benefit. In various cases, however, even in this species, I have reason to believe that the iron has proved as successful as in *neuralgia faciei*. And Dr. Alderson has given another example in a very striking instance of mammary neuralgia, but in an older and less irritable period of life.*

ORDER III. CINETICA.

DISEASES AFFECTING THE MUSCLES.

IRREGULAR ACTION OF THE MUSCLES OR MUSCULAR FIBRES: COMMONLY DENOMINATED SPASMS.

HAVING, in the Physiological Proem to the present class, glanced, as far as our space would allow, at the disputed question concerning the nature of muscular irritability, or *contractility*, to adopt the language of Dr. Bostock, and its affinity with sensorial or nervous influence, it is only necessary at present to take a very brief view of the general character and mode of action of muscles, as they appear to the naked eye in a massive form, or in other words, as composed of an almost infinite variety of minute fibres.

A muscle, thrown into action, increases in absolute weight, in density, and in power of resistance. It is also said to increase in absolute bulk, but the experiments on this subject are contradictory; the middle or belly of the muscle, indeed, is at this time evidently enlarged, but then its length appears to be proportionally diminished. [The ventricular portion of the heart, removed from a large dog immediately after the animal had been hanged, was immersed in warm water, contained in a glass vessel which was closed below with a ground glass stopper, and terminated above in an open vertical tube one third of an inch in diameter. The ventricles continued alternately to contract and dilate for a considerable length of time, during which the water stood at the same level in the tube, totally unaffected by the varying condition of the muscular fibres.—(*Mayo's Anat. and Physiolog. Commentaries*, vol. i., p. 12.)] Muscles constitute the cords, as bones do the levers of the living frame; and in most cases the muscles

grow tendinous, as the bones do cartilaginous, towards their extremities, by which means the fleshy and the osseous parts of the organs of motion become assimilated, and fitted for that insertion of the one structure into the other upon which their mutual action depends: the extent and nature of the motion being determined by the nature of the articulation, which is varied with the nicest skill to answer the purpose intended. Whether, however, the substance of tendons consists of the same fibres as the belly of a muscle, but only in a state of closer approximation, and possessed of finer vessels, which do not admit the introduction of red blood, or whether they form a distinct system of fibres, merely attached to those of the muscles, is at present undecided. It is certain that tendons possess nothing of the peculiar structure of muscles, and seem to be more nearly allied to the simple solid.—(*Bostock's Physiology*, p. 67, 8vo., 1824.)

It appears singular, at first sight, that the tendinous fibres, which thus seem to be compacted into a firmer and more substantial cord than those of the muscles, should be sometimes broken by muscular exertion, while the muscular fibres remain uninjured; yet this unquestionably depends upon their greater rigidity, and, consequently, inability of yielding to the force by which they are opposed. And hence the bones themselves are sometimes broken in the same manner as by a violent jerk, or a sudden spasmodic contraction, of which we shall presently meet with examples, especially in the patella, the ribs, and the arms. The muscles themselves, however, are occasionally ruptured by a like irregular violence and excess of power, as the recti abdominis in tetanus, and the gastrocnemii in cramps.

Muscular action, then, consists in a mutual attraction and concentration of the constituent fibres and muscles, in a manner peculiar to liv-

ing that magnetism sometimes has a powerful effect.—D.

* Cases of Neuralgia Spasmodica, &c., by B. Hutchison, &c., 8vo., London, 1822. Sir Astley Cooper considers equal parts of soap cerate and extract of belladonna, or a poultice with solution of belladonna and bread, the best applications. Covering the breast with oil-silk, or hareskin, he has also found tranquillize the part, by exciting perspiration from it. "As constitutional remedies, the submuriate of mercury, with opium and conium, should be given for a time, with an occasional aperient; and then, the medicine which I

have prescribed with most advantage in lessening the irritability of the part, is as follows:—R. Extracti conii, extracti papaveris ā gr. ij.; extracti stramonii e seminibus gr. ss. M.; ft. pil."

The above pill may be given twice or three times during the day; but if the gr. ss of the extract of stramonium be found too powerful, half that quantity may be tried. When the menses are obstructed, Sir Astley Cooper prescribes the carbonas ferri, the ferrum ammoniatum, or the mist. ferri comp. combined with aloes. He also recommends a hip-bath of seawater.—See Illustrations of the Diseases of the Breast, pp. 79, 80.—ED.

ing matter; for we cannot imitate it by any combination or action of mechanical fibres. It is not, however, a contraction in every dimension, since in this case the muscular volume would be diminished; but in length only, attended with a proportional increase of bulk, so as to preserve the absolute volume unchanged, or nearly so.

It is easy to conceive, from these few remarks, that the force exerted by muscular contraction may be enormous; but by the mechanical physicians it was calculated in the most extravagant manner, from premises in many instances wholly chimerical. Thus Borelli estimated the force with which the heart contracts, in order to carry forward the circulation of the blood, to be equal to not less than 180,000 lbs. at each contraction; while Pitcairn, applying the same speculation to the function of digestion, conceived that this process is accomplished by a muscular exertion, divided equally between the stomach and the auxiliary muscles that surround it, amounting in the stomach alone to the force of 117,088 lbs., for which, "had he assigned five ounces," says Professor Monro, "he would have been nearer the truth."—(*Monro, Comp. Anat., Pref., p. 8.*) Yet we do not want these visionary calculations to prove the wonderful power possessed by muscular fibres; the facts we have already adverted to, and others we shall have to notice in the course of the present order, are sufficient to establish their astonishing energy, without having recourse to unfounded hypotheses or exaggerated statements.

In general, says Dr. Parr, in a very excellent article upon this subject (*Med. Dict. in verb., Musculus*), it appears that the force with which a muscle contracts is in proportion to the number of its fleshy fibres, and the extent of the surface to which these fibres are attached; but its degree of contraction, or the extent of its motion, is in proportion to their length. The limits of contraction differ in the long and in the circular muscles: for the former do not contract more than one third of their length, but the circular fibres of the stomach, which in their utmost dilatation may be expanded to a foot in circumference, may, after much fasting, be reduced to the circle of an inch. It must, however, be added, that in circular muscles no fibres pass completely round; bundles of fibres are collected and end at different points, while some begin where others end. Each may therefore admit of only a limited contraction, while the dilatation just mentioned may be the sum of the whole.

The action of muscles never intermits, and is only diminished in the sleeping state; though, where the sleep is profound and lethargic, the diminution amounts to almost a cessation, except in the involuntary organs. When the muscles are not exercised (to use the words of Haller), "the vis insita is very slightly exerted;" but we can still trace its influence by the position which the limbs assume, and discover the relative strength of the antagonizing muscles. Thus we find the flexors stronger than the extensors; for, during sleep, the head falls forward, and the body, legs, arms, and fin-

gers, are slightly bent. The cause of this additional strength is easily explained: for the flexors have stronger and more numerous fibres, their insertion is farther from the centre of their motions, and under a larger angle, which must increase when flexion has begun. This superiority of the flexors bends the fœtus in the womb into a round ball. The same superiority of power continues, though in a less degree, after birth, and hence frequent pandiculations are required to give activity and energy to the extensors, which they again lose in advanced age. On awakening from a sound sleep, the same yawnings and stretchings occur from the same cause; and Bethel fancifully refers the crowing of the cock, and the fluttering of his wings, to a similar purpose. It is always useful in diseases to examine the position of the limbs during sleep, particularly the sleep of children. If they deviate from the ordinary degree of flexure to a more straight position, there is generally some irregularity in the state of tone, and of course in the vital influx.

The irritability or contractility of a muscle is a very different power from that of elasticity. The latter always depends upon simple reaction, and is never a source of actual energy: it merely restores, in a contrary direction, the force which had been impressed, and the effect which it produces can never be greater than the amount of the cause. But in muscular contraction, the mechanical effect produced is infinitely greater than the mechanical cause producing it, as, when the organ of the heart, recently detached from the body just dead, is slightly scratched in its inside by a needle, it will contract so strongly as to force the point of the needle into its substance.—(*Fordyce, Phil. Trans., 1788, p. 80.*) But the chief proof of the difference between the two is, that the irritable power of a muscle is often excited without any mechanical cause at all, and from the mere influence of the will, which has no effect upon the simple elasticity of organs. Hence, while contractility belongs to the muscular structure alone, elasticity appertains to many other substances as well, whether animal, vegetable, or even metallic. Muscles also have their elasticity, but the principle is altogether of a different kind, though often confounded with the preceding by modern pathologists; and particularly in their use of the term *tonicity* (*Bostock, Physiology, p. 168, 8vo., 1824*), which is often employed with little precision, and frequently means nothing more than this common principle of elasticity, to which indeed it seems directly to be applied by Dr. Cullen.

The muscles of the body may be divided into two grand classes; voluntary or animal, and involuntary or automatic. In the former we meet with some that are peculiarly remarkable for strength and continuity of contraction, as the greater part of the round muscles; and others as remarkable for mobility and vacillation, among which we may place most of the long muscles. These properties are strikingly exemplified in a state of disease, and call for particular attention; the muscles characterized

by mobility presenting examples of atonic or agitated spasm while those that are conspicuous for continuity of action, are chiefly subject to rigid or entastic spasm.

Continuity of exertion, however, is generally less evident in the voluntary than in the involuntary muscles, of which last some organs, as the heart, continue their efforts through life without intermission; though all of them relax, or remit, occasionally or periodically. For this greater permanency and regularity of action they are indebted to the peculiar provision which has been made for their supply of nervous power; for while the voluntary muscles are furnished in a direct line from the sensorium, whence indeed the close connexion they hold with it, the control the will exercises over them, and their catenation with the prevailing emotion of the moment, the involuntary muscles are dependant chiefly on the intermediate or ganglionic system described in the proem to the present class, and are more remotely connected with the sensorium: they are in consequence far less influenced by the variable impulses of the mental faculties, and are placed beyond the jurisdiction of the will. And hence the tenour of their action is more equable, more permanent, more uninterrupted, and less subject to fatigue or weariness.

But as these organs are by no means free from the power of injury or diseased action, they are also subject at times, in common with the voluntary organs, to those abnormal motions which are ordinarily denominated spasms: and it is not a little curious to observe the uniform tendency which different spasmodic affections manifest towards some organs or functions, rather than towards others. Thus the vital function, in which the heart and lungs are such prominent agents, is chiefly disturbed by palpitation and syncope; the natural, or that in which the abdominal organs so generally co-operate, by hysterics; and the animal, extending through the range of the voluntary organs, by tetanus and epilepsy. In the prosecution of the present order, indeed, we shall see that this does not hold universally; that epilepsy, for instance, is often a disease rather of the stomach or intestines than of any other organ, and that the heart is sometimes affected with rigid instead of with clonic spasm: but the rule holds generally, and is not essentially shaken by these casual exceptions.

Dr. Cullen has contended, that in all spasmodic affections the brain is the actual seat of disease, and that they consist in some morbid modifications of its energy. "The scope and purpose of all that he has said," he tells us, "is to establish the general proposition, that spasmodic affections, whether they arise primarily in the brain or in particular parts, do consist chiefly, and always in part, in an affection and particular state of the energy of the brain: and that the operation of antispasmodic medicines must consist in their correcting this morbid or preternatural state in the energy of the brain, by their correcting either the state of preternatural excitement or collapse, or by ob-

viating the too sudden alteration of these states."

This proposition seems rather to follow from Dr. Cullen's singular doctrine concerning the mutable condition of the energy of the brain, and the immutable nature of the nervous power, which is propagated from it by vibrations, than from the clear face of facts before us. Spasms, in many instances, are altogether local; they are confined to particular muscles, or particular sets of associate muscles, and have no effect on the brain whatever, so as to disturb its energy; of which we have examples in hiccup, priapism,* chorea, and often in palpitation. They depend upon some irritation existing not at the origin but at the extremity of the nerves: and where such is their source, even though the chain of morbid action should at length reach the brain and affect its energy, as in convulsions from teething, epilepsy from worms, or some palpitations from ossific or polypos concretions, all the antispasmodics in the world will afford no relief, so long as the local cause of irritation continues to operate; while, the moment this is removed, where it is capable of removal, as by the use of a gum-lancet or active anthelmintics, all the powers of the brain become instantly tranquillized; its faculties are rendered clear, its energy is re-invigorated, and its motive power or sensorial energy is distributed in an uninterrupted tenour. The greater number of spasmodic affections, therefore, do not so much depend upon the state of the brain as of the living fibres that issue from it, and maintain a correspondence with it; for the stream may be vitiated while the fountain is untouched. We have seen, indeed, in the proem to the present class, from the concurrent results of various physiological experimenters, that although, while the organ of a brain exists, it exerts a certain influence over the principle of muscular motion, this principle is far less dependant upon the encephalon than that of general feeling or of the local senses; that it is found abundantly in animals totally destitute of a brain; and that, hence, those possessing a brain may be excited not only into abnormal and spasmodic, but even into a continuation or reproduction of regular and natural motions of various muscular organs after the brain has been separated from the spinal chain, by stimuli applied to this chain, or even by the artificial breath of a pair of bellows.

We have seen, also, that the nervous filaments of the muscles are of two kinds, sensific and motific; the former proceeding from the cerebellum, or the posterior trunk of the spinal cord, to which it gives rise, and the latter from the cerebrum, or anterior trunk of the same double cord; and as these two sets of filaments do not necessarily concur in the same affection, it is obvious that the muscles of a limb, or of the whole body, may be thrown into the most violent agitation, or the firmest rigidity, without

* This cannot be explained by the action of any muscle, and consequently is not a spasmodic affection.—ED.

much, or perhaps any degree of painful emotion or increased sensibility. And we can hence readily account for the little complaint that is made by patients upon this subject, on their being freed from a severe paroxysm of tetanus, convulsion-fit, or hysterics.

The following are the genera of diseases which will be found to appertain to the present order :

- | | |
|-----------------|---------------------|
| I. Entasia. | Constrictive Spasm. |
| II. Clonus. | Clonic Spasm. |
| III. Synclonus. | Synclonic Spasm. |

GENUS I. ENTASIA. CONSTRICTIVE SPASM.

IRREGULAR MUSCULAR ACTION, PRODUCING CONTRACTION, RIGIDITY, OR BOTH.

ENTASIA is derived from the Greek *ἐντασις*, "intento," "vehementia," "rigor," from *ἐντελλω*, "intendo." By many nosologists the genus is called tonos, or tonus, which is here dropped in favour of the present term, because tonus or tone is employed by physiologists and pathologists, in direct opposition to irregular vehemence or rigidity, to import a healthy and perfect vigour, or energy of the muscles; and by therapeutists to signify medicines capable of producing such or similar effects.

The genus ENTASIA includes the following species:—

- | | |
|------------------------|-----------------------------------|
| 1. Entasia Priapismus. | Priapism. |
| 2. ——— Loxia. | Wry neck. |
| 3. ——— Rhachybia. | Muscular Distortion of the Spine. |
| 4. ——— Articularis. | Muscular Stiff-joint. |
| 5. ——— Systremma. | Cramp. |
| 6. ——— Trismus. | Locked-jaw. |
| 7. ——— Tetanus. | Tetanus. |
| 8. ——— Lyssa. | Rabies. Canine Madness. |
| 9. ——— Acrotismus. | Suppressed Pulse. |

SPECIES I. ENTASIA PRIAPISMUS. PRIAPISM.

PERMANENT RIGIDITY AND ERECTION OF THE PENIS WITHOUT CONCUPISCENCE.

THE specific term is derived from the name of Priapus, the son of Venus and Bacchus, who is usually thus represented in paintings and sculptures, but with a concupiscent feeling. Galen applies the term also to females, as importing a rigid elongation of the clitoris without concupiscence.

Spasm is, in all instances, a disease not of vigour, but of debility, with a high degree of irritability; and there is no case in which this is more striking than in the present species. It has been found occasionally in infancy; but it is far more frequently an attendant upon advanced years. It has sometimes also followed cold, and especially local cold, clap, dysury, and the use of cantharides. It has at times been a result of free living, and particularly hard drinking. The spasms consist in a stiff and perma-

nent contraction of the erectores penis,* unconnected with any stimulus arising from a fulness of the vesiculæ seminales.

Dr. Darwin says he had met with two cases where the erection, producing a horny hardness, continued two or three weeks, without any venereal desire, but not without pain. The easiest attitude was lying upon the back with the knees bent upward. The corpus cavernosum urethræ at length became soft, and in a day or two the whole rigidity subsided. One of these patients had been a free drinker, had a gutta rosacea on his face, and died suddenly a few months after his recovery from the present complaint. It is singular that this spasm should sometimes continue after death; at least we have accounts of such cases in Marcellus Donatus and other writers.†

As the disease is a case of both local and general debility, its cure is in most instances difficult. Antispasmodics and tonics are the only medicine that promise relief, as camphire, opium, bark, warm aromatics, warm bathing, cold bathing: but the whole are often tried without effect.

[In the case which surgeons most frequently meet with, namely, that excited by the irritation of ulcers and excoriations about the glans, or by gonorrhœa attended with chordee, the most effectual treatment is the antiphlogistic, combined with antispasmodics. This is quite inconsistent with the notion of the complaint being connected with debility, a notion that has no foundation, except the author's hypothesis of the cause of spasm.]

SPECIES II. ENTASIA LOXIA. WRY NECK.

PERMANENT CONTRACTION OF THE FLEXOR MUSCLES ON THE RIGHT OR LEFT SIDE OF THE

* That the author has fallen into an error in representing *priapismus* to be a species of constrictive spasm, cannot be doubted; because erection of the penis is not really produced by the action of the erectores muscles, as they are termed, but by the injection and distention of the glans, corpus spongiosum urethræ, and corpora cavernosa, with blood. "Each of the crura penis gives attachment at its origin to a tolerably strong muscle, named the erector penis, probably because, when a power capable of producing the effect indicated by that name was sought by anatomists, this muscle seemed to be their only resource. At present the name appears very ill adapted, since the muscles in question obviously draw the penis downward and backward, instead of upward and against the pubes. Those who explain the erection of the penis by the compression of its vein, should find out a power capable of elevating the organ against the bone, and of carrying it forward."—(See Rees's Cyclopædia, art. GENERATION.) In fact, mechanical pressure of the vein will not produce erection.—ED.

† Dr. Francis remarks, "that in cases of severe parturition, when the head has been greatly compressed, the child is often born with a strong erection of the penis." In instances of sudden death, where opium has been taken freely, the penis is sometimes found erect.—D.

NECK, DRAWING THE HEAD OBLIQUELY IN THE SAME DIRECTION.

THE term *LOXIA* is derived from the Greek, *λοξος*, "obliquus, tortus;" whence *loxarthrus* in surgery, an obliquity of a joint of any kind, without spasm or luxation. By the Greeks, however, the term was specially applied to the joints or muscles of the neck.

This disease, in its genuine form, proceeds from an excess of muscular action, particularly of the mastoid muscle on the contracted side. But we frequently meet with a similar effect from two other causes: one in which there is a disparity in the length of the muscles opposed to each other, and consequently a permanent contraction on the side on which they are shortest; and the other in which, from cold or a strain, there is great debility or atony on the side affected, and consequently an incurvation of the neck on the opposite side, not from a morbid excess, but an overbalance of action.

This species, therefore, offers us the three following varieties:—

- | | |
|-------------------|--|
| α Dispars. | From disparity in the length |
| Natural wry neck. | of the muscles opposed to each other. |
| β Irritata. | From excess of muscular action on the contracted side. |
| Spastic wry neck. | |
| γ Atonica. | From direct atony of the |
| Atonic wry neck. | muscles on the yielding side. |

THE FIRST VARIETY is mostly congenital, though sometimes produced by severe burns or other injuries. And a like effect occasionally issues from a cause that may be noticed in the present place, though not connected with a morbid state of the muscles,—a displacement of the muscles, from an incurvation in the vertebræ of the neck;* by which, though the antagonist muscles be of equal length and power, those on the receding side of the neck are kept on a perpetual stretch, while those on the protruding side are in a state of constant relaxation. The other TWO VARIETIES are commonly the result of cold, or inflammation, or a strain; often by carrying too heavy loads on the head. M. Boyer gives instances of the disease produced by moral causes: and Wepfer relates the case of a man who had a wry neck, occasioned by a convulsive action of the muscles on one side of the neck, which appeared whenever he was tormented by chagrin, but ceased as soon as he was restored to a state of mental tranquillity.—(*Traité de Maladies Chirurgicales*, &c., tom. vii., 8vo., Paris, 1821.)

The cure must depend upon the nature of the cause: In colds and strains, warmth, the friction of flannel, and the stimulus of the ammonia or camphire liniment combined with opium, will be found most serviceable, as tending to diminish pain, and restore action to the weakened

* In almost every instance, the change in the bones is the consequence of the long-continued action of the preponderating muscle. This doctrine, which is maintained by Jörg, is now generally admitted.—Ed.

organ. In direct spasms the same process will also frequently be found useful; but the application of cold water will often answer better. [About four years ago the editor was consulted by a gentleman at Clapham, whose right sternocleido mastoideus muscle was not only affected with permanent and rigid spasm, but had attained a vast increase of bulk and force. Under the direction of Dr. Babington, Mr. Brodie, and Sir Charles Bell, the patient had tried various narcotics, ammoniated copper, and different local applications, without benefit. A seton in the nape of the neck, and friction over the muscle with camphorated mercurial ointment, was now suggested, with a course of the compound calomel pill, combined with hyosciamus and conium, and occasional purgatives; but the patient had not courage to begin the plan. In this case, the wry neck was evidently associated with considerable disorder of the nervous system; and the patient could only lift a glass to his mouth by using both hands for the purpose.] Where the antagonist muscles are of unequal length, the case lies beyond the reach of medical practice; and if relieved at all, can only be so by a surgical operation. If the cervical vertebræ be incurvated, but the bones sound, the disease may not unfrequently be made to yield to a skilful application of machinery by the hands of an ingenious surgeon. It sometimes happens, however, that the bones in this case are soft and occasionally carious, and the slightest motion of the head is attended with intolerable pain. Setons have here been found serviceable, with an artificial support of the head; but this kind of affection is often connected with a constitutional softness of the bones, of which we shall have to treat in the first order of the sixth class, under the head *PAROSTIA flexilis*.

SPECIES III.

ENTASIA RHACHYBIA.

MUSCULAR DISTORTION OF THE SPINE.

PERMANENT AND LATERAL CURVATURE OF THE SPINE, WITHOUT PARALYSIS OF THE LOWER LIMBS: MUSCLES OF THE BACK EMACIATED; MOSTLY WITHOUT SORENESS UPON PRESSURE.

DISTORTION of the spine is produced in various ways; and it is chiefly owing to a want of due attention to this fact, that so much confusion has of late prevailed respecting the real nature of the particular case to be treated, and the particular treatment that ought to be adopted.

The disease, under this general name, was first introduced before the public with any considerable degree of notoriety by Mr. Pott, as connected with a palsy of the lower extremities, and as dependant upon a scrofulous diathesis; which at length fixed itself upon some part of the vertebral column, softened or rendered carious the bones that became affected, and hereby necessarily produced crookedness, and a morbid pressure upon the right line of the spinal marrow.

This is a case that often happens, and a like effect occasionally occurs in a very early period of life from a rachitic instead of a scrofulous

diathesis; though from the greater facility with which the principle of life is able to adapt itself to deviations from the ordinary laws of health at this latter period than afterward, a paralysis of the lower extremities is less common,* and even the mischiefs incidental to a misformation of the chest less fatal. So that, while the disease of a humpback can rarely take place in puberty or later life without a serious injury to almost every function, we often find it occur in infancy without making much encroachment on the general health.

In all cases of this kind, the malady is primarily and idiopathically an affection of the vertebral bones; and there is always to the touch a mollescence in their structure, or a manifest soreness and ulceration. And from the peculiar contour of the vertebral column, the distortion is always from within outwards, forming what has been called an *angular*, in contradistinction to a *lateral* curvature. So that the characters of the osseous gibbosity are sufficiently clear and specific.

But the muscles of the vertebral column and their appendages, the ligaments and cartilages into which the latter are inserted, are of as much importance to its healthy contour as its bones. And hence any morbid affection of these several structures may as essentially interfere with the natural curve of the spine, and the wellbeing of the constitution, as a disease of the vertebral bones.

It is possible that these are all affected in particular instances, sometimes separately, sometimes jointly (*Copeland on the Spine*, p. 15); but there can be no doubt that the muscular fibres of the neck, back, and loins, those on which all the complicated movements of the vertebral column depend, and which compose more than three hundred distinct muscles in the

whole, are most frequently thus enfeebled, either in part or in their entire range; though an enfeebled state of any of these organs must produce an inability of preserving the spine in its natural sweep and equilibrium. And where distortion proceeds from this cause, the indications are in most cases as clear as where it is the result of a diseased condition of the bony structure; for first the morbid curvature, instead of being *from within outwards*, takes place *laterally*, the crookedness being manifestly on the right or the left side, according as the muscles on the one side or the other overpower the action of their antagonists; there is little or no soreness upon pressure, unless indeed the bones or their cartilages should ultimately become affected from the protracted state of the disease; and the distortion being less abrupt or angular than in the ossific gibbosity, the lower limbs are not affected with paralysis.

The distinction, therefore, between the osseous and the muscular distortion of the spine, is clear and definite; and so far as regards the peculiar character of the curvature, was minutely noticed by the Greek writers, who identified the first by the name of LORDOSIS or CYRTOSIS, according as this curvature was anterior or posterior, and the second or the lateral curvature by the term HYBOSIS, from ὕβος (*hybos*), incurvus. It is from this term that the author has derived the name which he has ventured to assign to the present species—RHACHYBIA—as an allowable contraction of *rhachyhybia*, literally SPINAL INFLECTION. Swediaur has denominated it, from the same source, *hyboma Scoliosis*.—(Tom. ii., p. 740.)

The distinction is very accurately pointed out by Mr. Pott, who, while he affirms that “the ligaments and cartilages of the spine may become the seat of the disorder (scrofula) without

* Scrofulous caries of the corpora vertebrarum, whether in adults or children, most frequently after a time causes paralysis of the lower extremities, though exceptions are met with. In rickets, where the spine may be said to be deformed rather from imperfect development of the bones than from disease of them, palsy of the legs is not produced, however great the lateral curvature of the back. Cruveilhier, in his *Anatomie Pathologique*, livr. iv., gives us the particulars of a case in which no paraplegia existed, though not less than five of the dorsal vertebræ had been totally annihilated by disease, and the alteration in the shape of the vertebral column was such, that the upper half formed over the lower an extremely acute angle, which, from what is demonstrated in the engraving, would have been still more acute if it had not been prevented by the eleventh and fifth dorsal vertebræ touching each other. The intervertebral foramina were all preserved, though more or less deformed, contracted, or displaced backwards. In those which were most diminished the corresponding intercostal nerves must have been compressed, and consequently, the action of the intercostal muscles impaired, and an asthmatic affection been the result. The engraving shows how nature in this instance contrived to maintain the integrity of the vertebral canal, and the spinal cord uncompressed, in the midst of such a deviation of the spine from its normal shape. Although five of the vertebræ were de-

molished, ankylosis took place, and the medulla suffered no pressure adequate to the production of paralysis of the lower parts of the body. A beautiful preparation, illustrative of an equally extensive destruction of the bodies of the vertebræ, and of as sudden a bend of the spine, may be seen in the anatomical museum of the London University. Cruveilhier also gives the particulars of the body of a child ten years old that was brought to his dissecting-room, in which only a few vestiges of the third, fourth, fifth, sixth, seventh, eighth, ninth, tenth, and eleventh dorsal vertebræ were left. According to this pathologist, diseases of the vertebral column, like those of every other part of the osseous system, are seated, not in the osseous tissue itself, but in the adipose cellular or medullary tissue occupying its interstices. When this cellular tissue inflames, sometimes it pours out pus in abundance, constituting an abscess; sometimes in scanty quantity, which admits of being entirely absorbed. The cells of the osseous tissue being distended by the development of the cellular tissue, and deprived of the materials of nutrition, may be completely absorbed; and thus Cruveilhier accounts for the total disappearance of the texture of bone, without a vestige of it being left. The reader is probably aware, that Cruveilhier's doctrine is, that all disease is seated in the cellular tissue of organs, the other tissues being only liable to atrophy and hypertrophy.—ED.

any affection of the vertebræ," in which case "it sometimes happens that the whole spine, from the lowest vertebra of the neck downwards, gives way laterally, forming sometimes one great curve to one side, and sometimes a more irregular figure, producing general crookedness and deformity of the whole trunk of the body, attended with many marks of ill health;"—yet admits that paralysis of the lower limbs never accompanies cases of this sort, so far as his experience had extended, nor even that untempered and misshapen structure of the spine which occurs at birth or during infancy from a rachitic softness of the bony material. "I have never," says he, "seen paralytic effect on the legs from a malformation of the spine, however crooked such a malformation might have rendered it, whether such crookedness had been from the time of birth, or had come on at any time afterward during infancy.—None of those strange twists and deviations which the majority of European women get in their shapes from the very absurd custom of dressing them in stays during their infancy, and which put them in all directions but the right, ever caused any thing of this kind, however great the deformity might be. The curvature of the spine which is accompanied by *this affection of the limbs* (i. e. that which takes place from a diseased condition of the bones themselves subsequently to childhood, and from a supposed scrofulous diathesis), whatever may be its degree or extent, is at first almost always the same; that is, it is always from within outwards, and seldom or never to either side."

Now it has unfortunately happened, that as Mr. Pott's remarks were written chiefly to explain this last form of spinal distortion, and addressed to the single cause of scrofula, the hints he has given respecting distortions from every other cause have been too often forgotten; and the moment a young female is found to have a tendency to a vertebral distortion of any kind, it has too generally been taken for granted that the bones were in a diseased state, or on the point of becoming so; that the patient was labouring under the influence of a strumous diathesis, which was manifesting itself in this quarter; and all the severe measures of caustics or setons, with an undeviating permanent confinement to a hard mattress, or inclined plane, for many weeks or months, which a strumous affection of this kind calls for and fully justifies, has been improvidently had recourse to, with a great addition to the sufferings of the patient, and, in many instances, no small addition to the actual disease which has been so unhappily misunderstood.

Mr. Baynton seems justly chargeable with having adopted this general view of the subject, and extending it indiscriminately to every case. Mr. Wilson, who, though he conceived the disease to originate in a rachitic rather than a strumous diathesis, and had recourse, as we shall observe presently, to a different mode of treatment, seems to have stretched his parallel hypothesis over the same extent of ground. And Mr. Lloyd, who has lately favoured the profes-

sion with a valuable work on the same subject, in like manner contemplates every case of spinal distortion as issuing from a common, and that a strumous cause; to which cause also it has since as uniformly been assigned by Dr. Jarrold. —(*Inquiry into the Curvature of the Spine, &c.*, 8vo., 1824.) Mr. Lloyd, correctly indeed, distinguishes between the angular and the lateral curvature; and with equal correctness observes, that "in the former there is always some destruction of some portion of the vertebral column, and often, for a considerable time, progressive destruction of bone, cartilage, and ligament; and the vertebræ undergo precisely the same changes as the extremities of other bones in scrofulous diseases of the joints:" while he adds that "in the latter there is no destruction of parts, but merely an alteration of structure;" that "a wasting of the muscles always attends it in a greater or less degree;" and that "it has been supposed by some authors that the cause of the curvature is entirely in the action of the muscles. But although," he continues, "this may be and most probably is the *immediate* cause, I am much more inclined to believe that the *primary* cause is in the vertebræ; that scrofulous action is set up in them, which increases their vascularity, and softens their texture."

Here, then, is a distinct recognition of the two forms of morbid distortion of the spine to which I am anxious to direct the attention of the reader: and each of them is allotted its peculiar seat and diacritical signs; the bones with manifest injury of the bones, and the muscles with manifest injury of the muscles. The rest is matter of mere hypothesis, and needs not urge us into a discussion.

So obvious and so much more common indeed is muscular than osseous distortion of the spine, that other pathologists, from this fact chiefly, have contended that this is the only form of the disease in its commencement. Such was the opinion of the late Mr. Grant, of Bath, and such is the opinion of Dr. Dods, of the same city, in an interesting tract he has lately published on this subject (*Path. Obs. on the Rotated or Contorted Spine*, 8vo., Lond., 1824); while Dr. Harrison refers its origin to "the connecting ligaments of the vertebræ." "These," he observes, "get relaxed, and suffer a single vertebra to become slightly displaced;" in consequence of which, he adds, "the column loses its natural firmness, other bones begin to press unduly upon the surrounding ligaments; they in turn get relaxed and elongated, by which the dislocation is increased, and the distortion permanently established. The direction becomes *lateral, anterior, or posterior*, according to circumstances; but the malady has in every instance the same origin, and requires the same mode of cure."—(*Lond. Med. and Phys. Journ.*, No. cclxiv.)

There is much ingenuity in this explanation, and I have no doubt that it is a correct expression of various cases of vertebral distortion. It chiefly fails, like the osseous hypothesis, in too wide a spirit of simplification, and in allowing no

other origin in any instance, than that which forms the keystone of its own pretensions. Admitting the disease to commence in the connecting ligaments, the associating muscles must soon be involved in the mischief; while, if it commence in the latter, the ligaments which unite them to the bones cannot long continue unaffected. So that the question is merely one of primogeniture, and imposes little or no difference in the mode of treatment. Nay, even the bones themselves, by being irregularly pressed upon, may at length suffer in such parts from increased absorption, become thinner and more spongy, or even ulcerate and grow carious; so as in process of time to give a direct proof of osseous or angular contortion, though induced instead of taking the lead.

One of the chief difficulties, in cases where we have no reason to apprehend a morbid state of the bones, consists in accounting for the change that seems to take place in the relative position of several of the vertebræ or their processes; and especially in the greater elevation or prominence of their transverse processes on one side, while those on the other are scarcely perceptible. And it is in truth chiefly to solve this question, that most of the hypotheses of the present day are started in opposition to each other. The idea of an actual dislocation of the vertebral bones, which enters into that of Dr. Harrison, would sufficiently account for the fact, if such a dislocation could be unequivocally shown. But while the change of position does not seem in any instance to amount to a complete extrusion of a vertebra from its seat of articulation, the ease and quietude with which, under judicious management, it often seems to recover its proper position, and to evince its proper shapes, are inconsistent with the phenomena that accompany a reduction of luxated bones in every other part of the body.

The explanation, therefore, has not been felt satisfactory to a numerous body of pathologists; and Dr. Dodds has hence offered us another solution, which is also highly ingenious, and may perhaps in the end be found correct in those cases in which the miscurvature is very considerable, and especially where it becomes double or assumes a sigmoid figure. He supposes, in the first place, that the whole disease in its origin is seated in the extensor muscles of the back, or that part of them to which it is confined: more especially in the quadratus lumborum, sacro-lumbalis, and longissimus dorsi. He supposes next that the right hand being habitually more exerted than the left, the effect of such surplus of force, in consequence of our throwing the body towards the left to preserve its centre of gravity, and hence strongly contracting the muscles of this side of the spine, must fall in a greater degree upon those muscles, and more dispose them "to suffer disorganization and become contracted;" and he hence accounts for the greater frequency of contortion on the right side than on its opposite. He then proceeds to account for the single or double curvature which the contortion effects, by remarking that the morbidly contracted muscles of the left side, in

overcoming the action of the muscles of the right, do not drag the vertebræ forward towards themselves in a direct line, but rotate the vertebræ to which they are attached, because of the angles formed relatively between the vertebræ and the pelvis (the points of origin and insertion of these muscles), and the force of their contraction acting upon moveable, horizontal, or transverse levers, namely, the transverse processes of the vertebræ.—(Op. cit., p. 93.)

Morbid curvature of the spine, therefore, in the opinion of Dr. Dodds, does not consist in an evulsion of separate vertebræ from their natural course and position, but in a twist of a great part of the entire column, by which means the morbid lateral flexure is nothing more than the natural sigmoid sweep of the vertebral chain, wrested more or less round to one side, as by the turning of a corkscrew.

Whatever displacement is met with in the ribs, or the other bones of the chest, is necessarily a result of the first deviation from the line of health. "All the ribs," he observes, "have a double attachment to the vertebræ: one, by their heads to the bodies of them; and the other, by their tubercles to the transverse processes. When the vertebræ, then, are made to rotate upon each other in the manner described, by the permanent contraction, and this, for example, to the right side, which is the more frequent direction they take, from the causes noticed, they by this movement push out or backward the heads of the ribs of the left side, and force their sternal extremities considerably forward, because of the quick circular turn which the ribs make between their angles and their points of attachment to the vertebræ, and the very small motion, from such a formation of them, requisite here to produce them. Together with this movement of the ribs, which produces the projection of the left side of the chest in front, they are also made, from their double attachment to the vertebræ, to fall down and approximate, or, as it were, overlap each other, at their angles. This causes that hollowness or sinking in of the left side of the chest behind. The falling down of the ribs here described appears to me to be in part owing, also, to the permanent contraction of the sacro-lumbalis muscle, which is inserted into all their angles. While these movements take place with the ribs on the left side of the body, the very opposite, of necessity, happens to those on the right. By the rotatory movement of the vertebræ, the ribs on the right side have their heads, contrary to those on the left, drawn inward, and their sternal extremities made to recede backward, while their double connexion with the vertebræ causes them, contrary also to those of the left side, to be raised up and separated from each other at their angles. This rising up and separation of the ribs at their angles is what produces the projection of the right side of the chest behind."

From this general change of position, and particularly the twist of the ribs, Dr. Dodds accounts for the unnatural situation of the scapulæ, and in many instances, of the clavicles and the sternum, with the falling down of the right shoul-

der. He observes, moreover, that though the contortion of the spine most frequently takes place to the right side, yet that it occasionally takes place to the left; that the whole column is not always moved round, but only a part of it; and that hence, instead of a profile of three morbid flexures brought into view, which invariably follows in the former case, we have often a profile of only two: and that where the muscles of both sides of the column become contracted from position, which sometimes takes place, the greater number of the vertebral joints acquire an ankylosis, and the body is arched backwards.

There is much ingenuity through the whole of this explanation, which plausibly accounts for that ridgy line of projection so frequently felt on the left side of the loins when the morbid curvation is on the right, ascending nearly to a level with the spinous processes, while there is not only no such ridge on the opposite side, but even no appearances of the transverse processes. Upon the hypothesis before us, these processes are conceived to be equally elevated on the one side and depressed on the other, which gives us the two phenomena of an unnatural and ridgy prominence in the former line, and of an unnatural disappearance in the latter. The hypothesis nevertheless (for at present it cannot be entitled to a higher appellation) requires further elucidation and support; and after all, can never altogether reach the precise object at which it aims,—that of establishing itself at the expense of every other view, and especially of subverting the doctrines of a diseased action of the other moving powers or their appendages, the ligaments of the spinal muscles, or the cartilages into which they are inserted; a morbid condition of which is often capable of proof from the very limited area of pain and tenderness to which, on pressure, the disease seems to be confined: to say nothing of the affection of the vertebral bones themselves, in which, as already observed, spinous distortion sometimes commences, though from a very different source, and in which, even when derived from the source now contemplated, it sometimes terminates.

There can be no doubt, however, that the spinal distortion of the present day is a disease far more frequently of the muscles and their appendages than of the bones, and is the result of a want of equilibrium between the antagonist forces on the one side and on the other of the vertebral column, as well those of the trunk as of the back; in consequence of which this column is deranged in its natural sweep, and either twisted or deflected in particular parts, or in its whole length: all the other changes in the general figure, and deviations from the general health, being dependant upon this primary aberration.

It is hence a disease of muscular debility, or irregular, and hence-clonic, action in the fibres of the yielding muscles, and an inability to resist the encroachment that is made on them by their more powerful antagonists.

The complaint almost invariably shows itself from the age of puberty to that of mature life, though sometimes later; and is nearly limited

to females, and, among females, to those of delicate habits, and who are especially disciplined in the false and foolish rules for obtaining a fine figure. It is hence a perpetual inmate in our public female schools, and is by no means an unfrequent attendant upon domestic education.

The progress of the disease may be so easily collected from the physiological survey we have already taken, that only a few words in addition will be necessary.

The complaint first shows itself by a general listlessness and aversion to muscular exertion of any kind, and an unwonted desire to lounge and loll about. No signs of constitutional disease, however, are as yet manifest; the nights are not disturbed, the appetite does not fail, the evacuations are regular, and the pulse unaffected. There is soon after a sense of weariness, and even at times uneasiness, about the back, and especially the loins; and if the muscles of these parts be minutely examined, several of them will give proof of flaccidity and emaciation. If no steps be taken at this time to arrest the disease in its march, or if the steps taken be injudicious or inadequate, the vertebral column will soon be involved in the morbid action; and especially, as Mr. Ward observes, "on the occurrence of any particular disturbance to the constitution" (*Pract. Obs. on Distortions of the Spine, Chest, and Limbs*, p. 36, 8vo., 1822): its numerous joints will lose their nicely-adjusted poise; they will in various parts be left too loose on the one side, and dragged too rigidly on the other; and the elegant contour of the spinal chain will progressively be broken in upon. All the other changes, whether upon the general form or the general health, which progressively take place in the advance of the disease, are entirely consecutive upon the symptoms before us, and may be anticipated by any one. From the morbid contest which is thus continually going on between the antagonist muscles, their internal organization must necessarily become greatly affected, and the growing debility, which is manifest in the contractile and extensile power of their aggregate fibre, will enter into every part of every separate fibril, and affect their vis insita. The debility and irregular action of one muscle will spread by sympathy or association to various others; and from the derangement of the bones of the spine and the chest, the functions of respiration and digestion, and consequently, in a greater or less degree, all the other functions of the body, must be interfered with in their respective powers, so that there is scarcely any other disease but may follow; and the frame will become generally emaciated.

As the proximate cause is debility of the extensor muscles of the back or loins on either side, the occasional cause will consist in whatever has a tendency to produce such debility. Too rapid growth is a frequent source of this complaint; a casual strain of the muscles on either side is a source not less common; chlorosis, or any other constitutional weakness, may lead to the same effect; and assuredly the use of stiff and girding stays, or any other part of

that fashionable compression which is designed, in the school-discipline of the present day, to mould the form into a somewhat different and more graceful shape than perhaps the niggard hand of nature has intended—such as backboards, braces, steel bodices or steel crutches, spiked collars, neck-swings, and even education-chairs. The tendency of all these to produce deformity where it does not exist, and to aggravate it where it does, is forcibly pointed out by Dr. Dods; who nevertheless seems to censure, with rather more acrimony than needful, the whole system of school-drilling education, as practised in many of our most fashionable establishments. A course of discipline for giving grace and elegance to the growing form, if conducted with judgment, devoid of rigorous compression to the expanding organs, and allowing a sufficient alternation of relaxation and ease, so far from being injurious to the health and strength of the general frame, has a natural tendency to invigorate it. But the greater frequency of the lateral distortion of the spine in our own day compared with its apparent range in former times, together with the increased coercion and complication of the plan laid down in many of our fashionable schools for young ladies, seems clearly to indicate that some part at least of its increased inroad is chargeable to this source: and the following remarks of Mr. Pott upon the various instruments applied to a growing girl in order to prevent a crooked shape, have a wider claim to attention in the present day than when they were first given to the world. "These," says he, "are used with design to prevent growing children from becoming crooked or misshapen; and this they are supposed to do by supporting the backbone, and by forcing the shoulders unnaturally backward. The former they cannot do; and in all cases *where the spine is weak, and therefore inclined to deviate from a right figure*, the latter action of these instruments must contribute to, rather than prevent, such deviations, as will appear to whoever will with attention examine the matter. If, instead of adding to the embarrassment of children's dress by such iron restraints, parents would throw off all of every kind, and thereby give nature an opportunity of exerting her own powers; and if, in all cases of manifest debility, recourse were had to friction, bark, and cold bathing, with due attention to air, diet, exercise, and rest; the children of the opulent would perhaps stand a chance of being as stout, as straight, and as well-shapen, as those of the laborious poor."

The simple fact is, that the system of discipline is carried too far, and rendered much too complicated; and ART, which should never be more than a handmaid of NATURE, is elevated into her tyrant. In rustic life we have health and vigour, and a pretty free use of the limbs and the muscles, because all are left to the impulse of the moment to be exercised without restraint. The country girl rests when she is weary, and in whatever position she chooses or finds easiest; and walks, hops, or runs, as her fancy may direct, when she has recovered her-

self; she bends her body and erects it as she lists, and the flexor and extensor muscles are called into an equal and harmonious play. There may be some degree of awkwardness, and there generally will be, in her attitudes and movements; and the great scope of female discipline should consist in correcting this. With this it should begin, and with this it should terminate, whether our object be directed to giving grace to the uncultivated human figure or the uncultivated brute. We may modify the action of muscles in common use, or even call more into play than are ordinarily exercised, as in various kinds of dancing; but the moment we employ one set of muscles at the expense of another, keep the extensors on a full stretch from day to day, by forbidding the head to stoop, or the back to be bent, and throw the flexors of these organs into disuse and neglect, we destroy the harmony of the frame instead of adding to its elegance, weaken the muscles that have the disproportionate load cast upon them, render the dejected muscles torpid and unpliant, sap the foundation of the general health, and introduce a crookedness of the spine instead of guarding against it. The child of the opulent, while too young to be fettered with a fashionable dress, or drilled into the discipline of our female schools, has usually as much health and as little tendency to distortion as the child of the peasant: but let these two, for the ensuing eight or ten years, change places with each other; let the young heiress of opulence be left at liberty, and let the peasant-girl be restrained from her freedom of muscular exertion in play and exercise of every kind; and instead of this, let her be compelled to sit bolt upright in a high narrow chair with a straight back, that hardly allows of any flexion to the sitting muscles, or of any recurvation to the spine; and let the whole of her exercise, instead of irregular play and frolic gayety, be limited to the staid and measured march of Melancholy in the Penseroso of Milton—

"With even step and musing gait;"

to be regularly performed for an hour or two every day, and to constitute the whole of her corporeal relaxation from month to month, girded moreover, all the while, with the paraphernalia of braces, bodiced stays, and a spiked collar; and there can be little doubt that, while the child of opulence shall be acquiring all the health and vigour her parents could wish for, though it may be with a colour somewhat too shaded and brown, and an air somewhat less elegant than might be desired, the transplanted child of the cottage will exhibit a shape as fine, a demeanour as elegant, as fashion can communicate; but at the heavy expense of a languor and relaxation of fibre that no stays or props can compensate, and no improvement of figure can atone for.

Surely it is not necessary, in order to acquire all the air and gracefulness of fashionable life, to banish from the hours of recreation the old rational amusements of battledoor and shuttlecock, of tennis, trap-ball, or any other game that calls into action the bending as well as the ex-

tending muscles, gives firmness to every organ, and the glow of health to the entire surface.

Such, and a thousand similar recreations, varied according to the fancy, should enter into the school-drilling of the day, and alternate with the grave procession and the measured dance, for there is no occasion to banish either; although many of the more intricate and venturous opera dances, as the Bolero, should be but occasionally and moderately indulged in; since, as has been sufficiently shown by Mr. Shaw, "we have daily opportunities of observing, not only the good effects of well-regulated exercise, but also the actual deformity which arises from the disproportionate development that is produced by the undue exertion of particular classes of muscles.—(*On the Nature and Treatment of Distortions, &c.*, p. 15, Lond., 8vo., 1823.) It may be observed," continues the same excellent writer, "that the ligaments of the ankles of some of the most admired dancers are so unnaturally stretched, that in certain postures, as in the Bolero dance, the tibia nearly touches the floor. So bad, indeed, is the effect occasionally produced by a frequent stretching of the ligaments, that the feet of many of them are deformed; for the ligaments which bind the tarsal and metatarsal bones together become so much lengthened by dancing and standing on the tips of the toes, that the natural arch of the foot is at length destroyed."—(*Inquiry into the Causes of the Curvature of the Spine, &c.*, ut *suprà*, p. 119.)

Such, then, are the best preventive means against muscular or ligamentous distortion of the young female frame, and especially of the vertebral column, in conjunction with pure air, plain diet, and well-regulated hours of rest.

If, notwithstanding such means, a tendency to crookedness on either side should manifest itself, evidenced by the symptoms already pointed out, no time should be lost in making an accurate examination of the spinal chain: and if such tendency should be accompanied with pains about the pelvis and lower extremities, our attention should be particularly directed to the state of the vertebræ seated in the centre of the different flexures of the column, but especially of the lumbar, for it is probable, in this case, that one or more of them may be in a state of inflammation.

Where this is the case, the usual means of taking off inflammatory action, and especially depletion by cupping-glasses, should be instantly had recourse to. But where the cause is debility alone, and a want of equilibrium between antagonist sets of muscles, rest, reclination, general tonics, especially myrrh, steel, and in many cases the sulphate of quinine, sea-bathing, and, in effect, whatever may tend to introduce a greater firmness of fibre and general vigour of constitution, constitute the best plan of treatment.

To these should be added a series of friction, and especially of shampooing or manipulation, applied down the whole course of the spine, and particularly that part of it where the distortion is most evident; and it may be of advantage, as propo-

sed by Dr. Dods, to direct the course of the manipulation in a particular manner to such transverse processes of the vertebræ as appear peculiarly elevated, so as artfully, and by insinuation, to assist in restoring them to their proper position. It will also be found expedient in most cases to smear the hand with oil, or some other unctuous substance, in order to prevent the friction from irritating or excoriating the skin.

Those who ascribe the disease to a strumous diathesis in every instance, have of course a medical treatment of their own adapted to this view of the case. Such is the practice of Dr. Jarrold, who has lately written a treatise upon this subject containing many valuable hints, but who limits the seat of the malady to the intervertebral cartilages, as he does its cause to a strumous taint. His *Materia Medica*, therefore, for the present purpose, is nearly restricted to burnt sponge and carbonate of soda. "Conceiving," says he, that "there might be some relation between it and bronchocele, I have made use of similar remedies."—(*Inquiry into the Causes of the Curvature of the Spine, &c.*, ut *suprà*, p. 119.) To which he occasionally adds, when the debility is considerable, twenty drops of nitric acid daily. And with this simple process he tells us that he has been so successful in a restoration of health, strength, plumpness, and uprightness, that "medical treatment is seldom further required, unless the appetite and digestion be impaired."

Not acceding to this causation, I have not tried the plan; which seems here to have been far more successful than in bronchocele itself; even when the more powerful aid of iodine is called into co-operation, which it is singular that Dr. Jarrold does not appear to have had recourse to. To all the confederate means, however, of recumbency, friction, shampooing, pure air, and occasional exercise, he is peculiarly friendly: and as these have of themselves effected a cure in the hands of various other practitioners, it is not improbable that Dr. Jarrold is far more indebted to such confederates than he is aware of, and that his auxiliaries have been of more service to him than his main force.

It has been made a question of some importance, which is the best position for a patient to rest in who is labouring under the complaint before us, or has a striking tendency to it; as also what is the best formed couch for him to recline upon?

All seem to agree that the couch should be incompressible, or nearly so, in order that the weight of the body may be equally instead of unequally sustained, and not one part elevated and another depressed; and hence a mattress is judged preferable to a bed, and a plain board is by many esteemed preferable to a mattress. It is also very generally agreed, that the board or mattress should form an inclining plane, so that the body, placed directly on the back, may be kept perpetually on the stretch: while Dr. Dods maintains, in opposition to this general opinion, that the line should be horizontal, or even curved; that a position on the back is by no means necessary; and that a posture of extension can-

not fail of being injurious, and adding to the strength or extent of the disease.

Either of these opinions may be right or wrong, according to the nature of the case; and hence neither of them can be correct as a universal proposition. Ease and refreshment are the great points to be obtained; and whatever couch or whatever position will give the largest proportion of these, is the couch or the position to be recommended, whether that of supine extension or relaxed flexure.*

Dr. Dods, who refers all kinds of lateral distortion to debility of the fibres of the extensor muscles, prescribes an extended position in every instance; and as already observed, recommends a curved relaxing couch in its stead, so that the patient may sink into it at his ease, instead of being put upon the stretch. The advice is good so far as the opinion is correct, and the disease is dependant upon debility of the extensor muscles alone; for here nothing can afford so much ease to the patient as such an indulgence. But it is not to be conceded that the fibrous structure of these muscles forms the seat of the disease in every case, and consequently the recommendation will not always apply; for the flexor muscles may be affected, or the debility be seated in the extensor ligaments, or the vertebral cartilages with which they are connected. I have at this moment under my care a lady just of age, who for four years past has been labouring under a slight affection of lateral distortion, feeling much more of it whenever she suffers fatigue, or is affected in her spirits. A position strictly supine, and somewhat extended, upon a hard mattress or a level floor, is the only posture that affords her ease, and takes off the sense of weight on the spine and oppression on the chest. She has often tried other positions, but in vain. To this, therefore, she has uniformly recourse after dinner, and occasionally, at other times in the day as well. Pure country air has also been of great service; but above all things, sea bathing. She has just returned from an excursion around the Devonshire coast. The first day's journey, though in a reclined position in an open landaulet, with every attention that could afford ease and accommodation, proved so fatiguing, and produced so much pain in the spine, that it was doubtful whether she would be able to proceed. A better night, however, than was expected, capacitated her for another trial, and the fatigue was considerably less: on the third or fourth day she had an opportunity of beginning to bathe; and by a daily perseverance in the same, was enabled, soon after reaching Teignmouth, to engage in long walks, climb its loftiest hills, and enjoy the entire scenery: her appetite became almost unbounded, and her flagging spirits were restored to vivacity.

It is hence perfectly clear, that while that position and that mode of dress are most to be

* The figures of several machines, invented by Dr. Wm. Grigg, and which have proved extremely useful in treating distortions of the spine, may be seen in the Boston Med. and Surg. Journal, vol. xi., p. 228.—D.

recommended which afford the highest degree of ease and comfort, gestation, pure air, sea-bathing, and every other kind of tonic, whether external or internal, are also of the utmost importance; and that perfect and continued rest, in whatever position it be tried, is far less efficacious than when interrupted by such motion as can be borne, though with some degree of fatigue, and the other tonic auxiliaries just adverted to. In extreme cases, indeed, such exercise as is here adverted to should be postponed till the debilitated and, most probably, irritable organs, have lost some part of their disease; yet the motion of friction or manipulation by a skilful and dexterous hand may still be adverted to, and should supply its place: and although the use of tight and girding stays cannot be too much reprobated as applied to growing girls in the full bloom and health of nature, and may well be accused as an occasional cause of the deformity before us; yet there is much soundness of judgment in Mr. Shaw's recommendation of a dress of this kind, capable of giving support without cramping the form by too close a lacing, in cases where the complaint has in any considerable degree established itself, and the mischief is not now to be warded off, but to be prevented from becoming worse. In this case stays may not only be allowed, but "they should be made sufficiently stiff and strong to sustain the weight, which the muscles that have been deteriorated by want of action are unable to support."—(*Further Illustrations on the Lateral or Serpentine Curvature of the Spine, &c.*, 8vo., 1825.) This, indeed, is the only mechanical aid that should be allowed; and if applied with caution, and without an uneasy restraint, they will often be found an auxiliary of great value.

SPECIES IV.

ENTASIA ARTICULARIS.

MUSCULAR STIFF-JOINT.

PERMANENT AND RIGID CONTRACTION OF ONE OR MORE ARTICULAR MUSCLES OR THEIR TENDONS.

THE joints of the limbs are as subject to muscular contractions as the neck, and in many instances from like causes: the following are the varieties of affection hereby produced:—

- | | |
|----------------------|--------------------------|
| α Irritata. | From excess of action in |
| Spastic stiff-joint. | the muscles contracted. |
| β Atonica. | From direct atony in the |
| Atonic stiff-joint. | yielding muscles. |
| γ Inusitata. | From long confinement |
| Chronic stiff-joint. | or neglect of use. |

Besides the ordinary causes of cold, inflammation, and strains, by which the first and second variety are produced, the former has sometimes followed a sudden fright.—(*Starke, Klin. Instit.*, p. 32.) Freind, also, mentions a case in which it has been cured by a fright (*Vit. Gabriel*); and Baldinger, one in which it disappeared on the revival of a suppressed eruption which had given rise to it.—(*N. Magazin*, and

xi., 78.) Rheumatism has often produced it, and particularly the second variety, in the joint of the knee and thigh-bone.

In a case of the latter kind, it was successfully attacked by Richter (*Chir. Bibl.*, band x., 219) with a cautery of a cylinder of cotton. In this and the third variety, much benefit is often derived from repeated and long-continued friction with a warm hand, or with some stimulant balsam or liniment. In an obstinate contraction of the fingers succeeding to a fractured arm, Dr. Eason relates an instance, in which the rigidity suddenly gave way to a pretty smart stroke of electricity after every other means had failed; and the patient had the use of his fingers from this time.—(*Edin. Med. Comment.*, v., p. 84.) Such exercise, moreover, or exertion of the limb, should be recommended, as it may bear without fatigue. The cold bath, as an antispasmodic, has sometimes been serviceable in the FIRST VARIETY,* and more frequently, as a tonic, in the SECOND.

Most men exhibit proofs of the THIRD VARIETY, or chronic stiff-joint, from a neglect of using many of their muscular powers: for nearly a fourth part of the voluntary muscles, from being seldom called into full and active exertion, acquire a stiffness which does not naturally belong to them; while many that by exercise might have been rendered perfectly pliant and obedient to the will, have lost all mobility, and are of no avail. Tumblers and buffoons are well aware of this fact, and it is principally by a cultivation of these neglected muscles that they are able to assume those outrageous postures and grimaces, and exhibit those feats of agility, which so often amuse and surprise us. It is a like cultivation that gives that measured grace and firmness, as well as erect position in walking, by which the soldier is distinguished from the clown; and that enables the musician to run with rapid execution, and the most delicate touch, over keys or finger-holes that call thousands of muscular fibres into play or into quick combinations of action, which in the untutored are stiff and immoveable, and cannot be forced into an imitation without the utmost awkwardness and fatigue.

SPECIES V.

ENTASIA SYSTREMA.

CRAMP.

SUDDEN AND RIGID CONTRACTION AND CONVOLUTION OF ONE OR MORE MUSCLES OF THE BODY, MOSTLY OF THE STOMACH AND EXTREMITIES: VEHEMENTLY PAINFUL, BUT OF SHORT DURATION.

SYSTREMA, literally "contortio, convolutio," "globus," is derived from *συστρέφω*, "contorqueo," "convolve in fascem." Strema, the

* In an example of this kind, brought on by a wound of one of the fingers, the editor applied a succession of blisters to the back of the hand and wrist; and the patient, a woman residing at Weybridge, was very soon enabled to extend her fingers again.

primary noun, is an established technical term for "strain, twist, wrench;" and the author has hence been induced to add the present term to the medical vocabulary in the sense now offered, for the purpose of superseding and getting rid of *crampus*, which has hitherto been commonly employed, though at the same time commonly reprobated, as a term intolerably barbarous, derived from the German *krampf*. The proper Latin term is, perhaps, "raptus nervorum;" whence *opisthotonia* or *opisthotonos* is denominated by the Latin writers "raptus supinus." But *raptus* is upon the whole of too general a meaning to be employed on the present occasion, unless with the inconvenience of another term combined with it.

The parts chiefly attacked with cramp are the calves of the legs, the neck, and the stomach. The common causes are sudden exposure to cold, drinking cold liquids during great heat and perspiration, eating cold cucurbitaceous fruits when the stomach is infirm and incapable of digesting them, the excitement of transferred gout, and overstretching the muscles of the limbs; in which last case it is an excess of reaction produced by the stimulus of too great an extension. Hence many persons are subject to it, and especially those of irritable habits, during the warmth and relaxation of a bed, and particularly towards the morning, when the relaxation is greatest, the accumulation of muscular or irritable power most considerable, and the extensor muscles of the legs are strained to their utmost length, to balance the action which the flexor muscles have gained over them during sleep. Cold night-air is also a common cause of cramp, and it is a still more frequent attendant upon swimming, in which we have the two causes united of cold and great muscular extension. An uneasy position of the muscles is also in many cases a sufficient cause of irritation; and hence we often meet with very painful cases of cramp in pregnant women, down the legs, or about the sides, or the hypogastrium.

When the hollow or membranous muscles are affected, they feel as though they were puckered and drawn to a point; the pain is agonizing, and generally produces a violent perspiration; and if the stomach be the affected organ, the diaphragm associates in the constriction, and the breathing is short and distressing. If the cramp be seated in the more fleshy muscles, they seem to be writhed and twisted into a hard knot; and a knotty induration is perceivable to the touch, accompanied with great soreness, which continues for a long time after the balance of power has been restored.

In common cases where the calves of the legs are affected, an excitement of the distressed muscles into their usual train of exertion is found sufficient; and hence most people cure themselves by suddenly rising into an erect position. I have often produced the same effect, and overcome the reaction without rising, by forcibly stretching out the affected leg by means of other muscles, whose united power overmatches that of the muscle that is contracted. Warm friction with the naked hand, or with

camphorated oil or alcohol, will also generally be found to succeed. A forcible exertion of some remote muscles, which thus collects and concentrates the irritable power in another quarter, will also frequently effect a cure; and it is to this principle alone, I suppose, we are to refer the benefit which is said to arise from squeezing strenuously a roll of brimstone, which suddenly snaps beneath the hold. The brimstone snaps from the warmth of the hand applied to it; but its only remedial power consists in affording a something for the hand to grasp vehemently, and thus excite a sudden change of action.

Where the stomach is affected, brandy, usquebaugh, ether, or laudanum, affords the speediest means of cure; and it is often necessary to combine the laudanum with one or other of the preceding stimulants. Here also the external application of warmth, and diffusible irritants, as hot flannels moistened with the compound camphire liniment, are found in most cases peculiarly beneficial. Exciting a transfer of action to the extremities, as by bathing the feet in hot water, or applying mustard sinapisms to them, is frequently of great advantage; as is the use of hot, emollient, and anodyne injections, whose palliative power reaches the seat of spasm by sympathetic diffusion, and often affords considerable quiet. Here, also, the patient should be particularly attentive to his diet and regimen, confining himself to such viands as are most easy of digestion, and least disposed to rouse the stomach to a return of these morbid and anomalous actions; for a habit of recurrence is soon established, which it is difficult to break off.

In pregnancy, where the crampy spasms are often migratory and fugitive, the position should frequently be changed, so as to remove the stimulus of uneasiness by throwing the pressure upon some other set of muscles; and if the stomach be affected with gout, opium, rhubarb, chalk, or aromatics, should be taken on going to rest.

The best preventives when the cause is constitutional, are warm tonics, and habituating the affected muscles to as much exercise as their strength will bear: and hence the same forcible extension used in swimming which produces cramp the first or second time of trial, will rarely do so afterward.

Cramp is also found as a symptom, and as one of the severest symptoms of the disease, in various species of colic and cholera; in which cases it must be treated according to the methods already pointed out under those respective heads.

SPECIES VI.

ENTASIA TRISMUS.

LOCKED-JAW.

PERMANENT AND RIGID FIXATION OF THE MUSCLES OF THE LOWER JAW.

THIS disease is by the French writers called *tic*. The technical term is derived from the Greek *τερίζω*, "to gnash or grind the teeth;" which, like the French synonyme, is supposed by

the lexicographers to be an onomatopoeia, or a word formed from the sound that takes place in the act of gnashing.

In truth, it was to a disease in which morbid gnashing formed a symptom, that both the Greek and French term were originally applied; for the trismus of the old writers consisted, not of a rigid, but convulsive or agitative spasm of the lower jaw; an affection comparatively trifling, and rarely to be met with, and when it does occur, appertaining to the *CLONUS* of the present system of nosology, the clonic spasm of authors in general. And the use of trismus or tic to import a state of muscle directly opposed to that which it first indicated, is another striking proof of the incongruous change which is perpetually occurring in the nomenclature of medicine, for the want of established rules and principles to give fixation and a definite sense to its respective terms.

Dr. Akerman is the only writer of reputation I am acquainted with in recent times who has used trismus in its original intention, or rather, who has united its original with its modern meaning. For he employs the term generically; and arranges under it the two species of *trismus tonicus*, being that now under consideration, and *trismus clonicus*, or the disease it originally denoted. But this arrangement is uncalled for and inconvenient, and has not been received into general use; the term trismus being, with every writer of the present day, limited to the first of these two species alone, notwithstanding the origin of the word. And hence, as it is so generally and completely understood, there would be an affectation in changing it for any other. The Germans call it *kinnbakkenzwange*, which is precisely parallel with the *LOCKED-JAW* of our own tongue.

Dr. Cullen, in the first edition of his *Nosology*, made trismus and tetanus, our next species, distinct genera; but he altered his opinion before the publication of his *First Lines*, and regarded them as nothing more than degrees or varieties even of the same species. "From the history of the disease," says he, "it will be evident, that there is no room for distinguishing the tetanus, opisthotonos, and trismus or locked-jaw, as different *species* of this disease, since they all arise from the same causes, and are almost constantly conjoined in the same person."—(*Pract. of Phys.*, book iii., sect. i., chap. i., § 1267.) In consequence of which, in the later editions of Dr. Cullen's *Synopsis*, in which the supposed error is attempted to be corrected, the disease is introduced with a very singular departure from nosological method: for first, tetanus is employed as the term for a distinct genus, defined "a spastic rigidity of many muscles;" and next, under this generic division are given no species whatever, but two varieties of degree alone; to the first of which is again applied the name of *TETANUS*, defined "the half or whole of the body affected with spasms," and to the second that of *TRISMUS*, defined "spastic rigidity, chiefly of the lower jaw."

Passing by this irregularity of method, the proper view of the subject seems to lie in a

middle course; in contemplating trismus and tetanus, not as distinct genera, or mere varieties of a single disease, but as distinct species of a common genus; and under this view it is contemplated in the present arrangement. Trismus bears the same relation to tetanus as synochus does to typhus: the two former, like the two latter, may proceed from a common cause and require a similar treatment; and the first may terminate in the last. But trismus, like synochus, may run its course alone, and continue limited to its specific symptoms. And as Dr. Cullen has thought proper to make synochus and typhus distinct genera, he ought at least to have ranked trismus and tetanus as distinct species.

Trismus is found in all ages, sexes, temperaments, and climates. In warm climates, however, it occurs far more frequently than in cold; and chiefly in the hottest of warm climates. Dr. Cullen observes, that the middle-aged are most susceptible of the disease, men more so than women, and the robust and vigorous than the weakly. Other animals are subject to this complaint as well as man, particularly parrots; and from many of the causes (*Bajon. Abhandlungen von Krankheit. auf der Insel Cayenne, &c.*) that affect the human race.

These causes, for the most part, are chilliness and damp operating upon the body when heated, and hence sudden vicissitudes of heat and cold; wounds, punctures, lacerations, or other irritations of nerves in any part of the body; whence it has not unfrequently followed venesection when unskillfully performed (*Delaroché, Journ. de Med.*, tom. xv., p. 213; *Forestus*, lib. x., obs. iii.; *Schenck*, obs. l., i., N. 250), and still more frequently amputation, worms, or irritation in the stomach and bowels, especially in those of infants. We have thus the three following varieties offered to us, which, however, chiefly differ in symptoms peculiar to the period of life in which the disease is most disposed to show itself, or in the interval between the casual excitement and the spastic action:—

- | | | |
|---|---------------------------------------|--|
| α | Nascentium.
Locked-jaw of infancy. | Attacking infants during the first fortnight after birth. |
| β | Algidus.
Catarrhal locked-jaw. | Occurring at all ages, after exposure to cold and damp, especially the dew of the evening, the symptoms usually appearing within two or three days. |
| γ | Traumaticus.
Traumatic locked-jaw. | Occurring as the consequence of a wound, puncture, or ulcer, with particular frequency in hot climates; and rarely appearing till ten days or a fortnight after local affection. |

The pathology is highly difficult, if not mysterious, and has hence been purposely avoided by most preceding writers. Dr. Cullen expressly avows that he “cannot in any measure attempt it.”—(*Pract. of Phys.*, book iii., sect. i., chap. i., § 1269.) There is one principle, however, to which I have frequently had occasion

to direct the reader's attention, which will help us in a considerable degree to develop something of its obscurity, and to account more especially for so remote a separation between the seat of primary irritation and that of spasmodic excitement, which constitutes, perhaps, its most embarrassing feature. The principle I allude to is the sympathy that prevails throughout the whole of any chain of organs, whether continuous or distinct, engaged in a common function, and which is particularly manifest at its extremities; so that let a morbid action commence in whatever part of the chain it may, the extremities in many instances become the chief seat of distress, and even of danger. We had occasion to notice this law of the animal economy when treating of *PARAPHSIS ILLUSORIA*, or that imaginary sense of feeling and of acute pain in a limb that has been amputated and is no longer a part of the body, which we referred to the principle before us; and farther noticed, by way of illustration, the pain often suffered at the glans penis from the mechanical irritation of the neck of the bladder by a calculus. So, irritating the fauces with a feather excites the stomach, and even the diaphragm, to a spasmodic action, and the contents of the organ are rejected. Irritating the ileum, as in ileac passion, produces the same effect upon the stomach and œsophagus; at the same time that the other extremity of the canal is attacked with rigid spasm, and consequently with obstinate costiveness: while in cholera both extremities are affected in a like way, and we have hence both purging and vomiting. It is to the same principle we are to ascribe it, that when the surface of the body is suddenly chilled, as on plunging into a cold bath, the bladder becomes irritated, and evacuates the contained urine: and in treating of *MARASMUS* we had occasion to show, that while in one of its species the disease seems to commence in the digestive, and in another in the assimilating organs, constituting the extreme ends of a very long and complicated chain of action, it very generally happens, that at which end soever the decay commences, the opposite end is very soon affected equally.

In a continued chain of nervous fibres, however, this principle of sympathy, which induces remote parts, and particularly remote extremities, to associate in the same morbid action, is peculiarly conspicuous. Hence, if a long muscle be lacerated in any part of its belly, the tendinous terminations are often the chief seat of suffering. As the ulnar nerve sends off twigs from the elbow to supply the forearm and fingers, a blow on the internal condyle of the humerus gives a tremulous sensation through the forearm and hand: and as the ulnar nerve itself is only an offset from a plexus or commissure of the cervical nerves, which also give a large branch to the scapula, a paralysis of the ring or little finger has sometimes been removed by stimulating the scapular extremity by a caustic applied at the internal angle of the scapula. In inflammation of the liver, a severe pain is often felt at the top of the shoulder; and in palpitation of the heart, at the left orifice of the stomach.

Both these are to be accounted for by recollecting that the radiations of the phrenic nerve extend in an upper line to the shoulder, and in a lower to the diaphragm, which constitutes its extreme points; and that one of its branches passes over the apex of the heart. Now as the under surface of the diaphragm participates, from its contiguity, in an inflammation of the liver, the top of the shoulder suffers, as forming the extreme point of the phrenic chain by which these organs are connected; and as the upper surface of the diaphragm is in direct contact with the left and very sensible orifice of the stomach, an uneasiness at the apex of the heart becomes the cause of irritation to this orifice in consequence of its connexion with the diaphragm, and hence, of necessity, with the lower branch of the phrenic nerve at its extreme distribution.

These remarks apply with particular force to the disease before us, and many others of the same class with which it has a close analogy, as tetanus, lyssa, and hemicrania. And although, from the intricacy of the intersections and decussations with which various nerves pursue their radiating courses, it is impossible for us, in many instances, to determine why one line of connexion suffers while another remains unaffected; yet in most instances we may be able, by an accurate survey, to trace the catenation, and hence to obtain some insight into the physiology of these exquisitely curious and complicated disorders.

In mapping the nervous ramifications which give rise to trismus or locked-jaw, we must regard the ganglionic system, consisting of the various branches of the intercostal trunk, and the numerous branches which unite with it from the whole line of the spinal marrow, as constituting the centre; and as from this centre we perceive ramifications radiating in every direction to the face, the entire length of the back, the upper and lower limbs, and the thoracic and abdominal viscera, we see a foundation laid, even by a continuous chain, for an association of remote parts and even extreme points in morbid changes, though we may not be able, satisfactorily perhaps, in any instance, to trace out the individual line by which the diseased action is carried forward, and to separate it from other lines with which it is inextricably interwoven. Thus, in the case of *trismus nascentium*, forming the first variety under the present species, the irritation of the nerves of the stomach, which is very clearly the primary seat of disease in most cases, is propagated directly to the central branches of the ganglionic system by the tributary offsets which the stomach receives from it. But we have already observed, that the chief contribution to this grand junction canal is derived from the intercostal nerve itself. In the first instance, an arm from the trigeminus or fifth pair of nerves, two branches of which radiate upwards, constitute the maxillaris superior and maxillaris inferior, and are lost in the muscles of the jaws: so that the upper extremity of the nervous line distributed over the stomach is the nerves of the jaws

themselves; while various branches of the fifth occasionally unite with the portio dura, or respiratory trunk of the seventh pair, which divaricates not only to the diaphragm, but over all the muscles that have the remotest connexion with the respiratory system. And hence, agreeably to the law of the animal economy we have just pointed out, the muscles of the jaws, forming this extremity in the chain of morbid action, are the organs in which we may expect an irritation of the nerves of the stomach in various instances to manifest itself most strikingly.

In like manner we may account for the second and third varieties of trismus, or that produced by a chilly dampness or irritative violence applied to the upper or lower extremities: for as these are all supplied by nerves from the vertebral source, which, we have already remarked, gives off branches from every aperture in the spine to the ganglionic system, and as this system, at its upper end, terminates in the maxillary branches of the fifth pair of nerves, the muscles into which these nerves are distributed constitute one extreme point of a long chain of nervous action, while those of the upper and lower limbs constitute the other. And hence the same law which produces a spastic fixation of these muscles in certain irritations of the stomach, may reasonably be expected to operate with like effect in certain irritations of the upper and lower limbs. And as the intercostal nerve, at its first rise from the common source of itself and the maxillary branches, receives also, in its progress, offsets from the sixth, seventh, eighth, and ninth pairs of cerebral nerves, as well as from all the vertebral, and as all these, in consequence of such an interunion and decussation, are sending forth branches over the muscles of the back, the chest, and the thorax, there is no difficulty in conceiving, when a rigid spasm has once commenced in the lower jaw, why it should be propagated through any of the muscles appertaining to these parts of the system, or even originate in them from any of the causes that excite locked-jaw, and hence lay a foundation for tetanus as well as trismus, both as a primary and a secondary disease. And I have touched upon this subject now, that we may not have to repeat the present explanation when treating of tetanus in its proper place.*

* See Cloquet, *Traité d'Anatomie Descriptive*. Bock Beschreibung des fünften Nervenpaares und seiner Verbindungen mit anderen Nerven, vorzüglich mit dem Ganglien Systeme, Leips., 1817. The whole of the above hypothesis is only an attempt to explain the origin and extension of tetanic disorders, by the intricate communications of the nerves of different parts of the body. The view of the pathology of tetanic affections entertained by Dr. Elliotson is, that they depend upon a peculiar state of that part of the brain, or spinal marrow, which is immediately connected with the nerves of the voluntary muscles. The mind is unaffected, and so is sensibility. The disorder appears to be an affection of the voluntary muscles through the medium of the voluntary nerves, and those parts of the brain and spinal marrow with which they are connected.—See Dr. Elliot.

In the simplest state of trismus, indeed, there is some degree of stiffness found at the back of the neck, and even in the sternum. The disease, in some cases, shows itself with sudden violence, but more usually advances gradually; till at length the muscles that pull up the jaw become so rigid, and set the teeth so closely together, that they do not admit of the smallest opening.

In tropical climates, for Dr. Cullen's remark that it is most common to the middle-aged, only applies to the temperate regions of Europe, children are particularly subject to this complaint, and with a few peculiarities, which, though producing no specific difference, are sufficient to establish a variety. The disease in this case is vulgarly known by the absurd name of FALLING OF THE JAW. It occurs chiefly between the ninth and fourteenth day from birth; seldom after the latter period. Without any febrile accession, and often without any perceptible cause whatever, the infant sinks into an unnatural weariness and drowsiness, attended with frequent yawnings, and with a difficulty, at first slight, of moving the lower jaw, which last symptom takes place in some instances sooner, in others later. Even while the infant is yet able to open its mouth, there is, occasionally, an inability to suck or swallow. By degrees, the lower jaw becomes rigid, and totally resists the introduction of food. There is no painful sensation; but the skin assumes a yellow hue, the eyes appear dull, the spasms often extend over the body, and in two or three days the disease proves mortal.

The ordinary cause is irritation in the intestinal canal. Hence viscid and acrimonious meconium frequently produces it; as worms are said also to do some months after birth. It seems, moreover, in some instances, to have followed from irritation in tying the navel-string,* its not being properly attended to afterward, in which case, though the stomach may be affected by contiguous sympathy, the disease makes a near approach to the third or traumatic variety. Yet the appearance of the spastic action is as early as where the stomach is primarily affected.

In cold and even mountainous countries, this variety is also sometimes found. "I am informed," says Dr. Cullen, "of its frequently occurring in the Highlands of Scotland; but I never met with any instance of it in the low country."—(Loc. citat., § 1281.) Whether, according to the conjecture of this celebrated writer, it is more common to some districts than to others, has not been sufficiently determined. "It seems," says he, "to be more frequent in Switzerland than in France." Hot climates, however, constitute its principal domain; and hence it is not very surprising, that

son's Lectures on Medicine, as delivered at the Univ. of London, and reported in Med. Gaz. for 1832-3, p. 470.—Ed.

* Two cases of trismus, arising from this cause, have occurred in the practice of Dr. Francis; in one of these there was considerable hemorrhage from the cord.—D.

Bajon should place one of its chief residences at Cayenne (*Bajon, Abhandlung von Krankheit. auf der Insel Cayenne, &c.*, Erp. 1781), or that Akerman should assert it to be endemic in Guinea.

In the SECOND VARIETY of the disease, or that proceeding from cold or night dew, the symptoms often appear within a day or two after exposure to the exciting cause. It is not common that the spasm extends to the muscles of the chest or back, so as to produce tetanus, though there is often an uneasy sensation at the root of the tongue, with some difficulty in swallowing liquids after their introduction into the mouth; the disease thus making an approach towards lyssa, or canine madness, in its symptoms, as we have just endeavoured to show that it does in its physiology. According to the observations of Baron Larrey, indeed, this approach is in many instances very considerable; for he informs us, that on post-obituary examinations he has often found the pharynx and œsophagus much contracted, and their internal membranes red, inflamed, and covered with a viscid reddish mucus. Dr. Hennen, however, does not place much dependance upon any such appearances: he admits, nevertheless, that they are to be traced occasionally, though he ascribes them more to an increased flow of blood, consequent on increased action, than to any other cause.—(*Principles of Military Surgery*, 246.)

In this variety, from the slighter nature of its attack, the patient not unfrequently recovers by skilful medical treatment, and there are unquestionably instances of spontaneous recovery (*Briot, Hist. de la Chirurgie Militaire en France, &c.*, 8vo., Besançon, 1817), though cases of this kind are very rare. The intellect remains unaffected, there is little quickness of the pulse, sometimes none whatever, and little or no disorder of any kind, though the bowels are usually very costive. If the patient pass the fourth or fifth day, we may begin to have hopes of him; for the spasmodic constriction will then frequently remit or intermit; but as, even in the last case, it is apt to return at uncertain intervals, there is still a considerable danger for many days longer.

When, as in the THIRD VARIETY, the disease proceeds from a nerve irritated by a wound* or

* Trismus traumaticus sometimes follows surgical operations, and very frequently lacerated wounds of the fingers, toes, and other tendinous parts. The editor has seen several cases of it brought on by gunshot injuries, amputation, castration; and he knew of one instance in which it was induced by the amputation of a cancerous breast. In warm climates it occurs from very slight causes, and hence is much more frequent in them than in temperate and cold countries. A wound will sometimes not produce the disease till the person is suddenly exposed to cold, and then he will have it immediately. Last autumn, the editor saw an example of this in a farmer, who had met with a lacerated wound of the scalp, by being thrown from his horse: from this accident he was recovering in the most favourable way; but on going out into the cold air, at the end of a

sore, the spasmodic symptoms are much later in showing themselves; and sometimes do not make their appearance till eight or nine days afterward, occasionally, indeed, not at all till the wound is healed. The disease is more dangerous in proportion to the delay; the adjoining muscles of the face become more affected, and, as is already observed, the spasms often shoot downward into the back or chest, and trismus is complicated with tetanus. The breathing is nasal and abrupt, the accents are interrupted and slow, and uttered by the same avenue; the muscles of the nose, lips, mouth, and the whole of the face, are violently dragged and distorted, and the patient sinks from nervous exhaustion and want of nutriment, the jawbone being set so fast that it will often break rather than give way to mechanical force.

The disease, from this cause, is generally fatal; and we are indebted to the ingeniousness of Sir James M'Grigor and Dr. Hennen for a confession that, whatever remedies were employed in the British army, whether in India or in Spain, the mortality was nearly the same. But as the treatment of the present variety and the ensuing species should be founded on a like principle, we shall reserve this subject till we have entered upon a distinct history of the latter.

SPECIES VII.

ENTASIA TETANUS.

TETANUS.

PERMANENT AND RIGID FIXATION OF MANY OR ALL THE VOLUNTARY MUSCLES; WITH INCURVATION OF THE BODY, AND DYSPNŒA.

TETANUS is derived from *τετανω*, which itself is a derivative from *τελω*, "tendo, extendo." Like trismus, it is a term common to the early Greek writers, among whom it was used synonymously with opisthotonos and emprosthotonos, though the two latter were afterward employed to express two distinct modifications of the disease.

From peculiarities in the seat or mode of its attack, this species offers us the four following varieties:—

fortnight, when the wound was nearly healed, he was attacked with trismus, which soon assumed the form of universal tetanus, and he died in about six or seven days from the commencement of the disorder. Tetanus occurs in all conditions of wounds; in some of a healthy, and others of an unhealing appearance: sometimes also when they are almost, or even entirely, healed up. It occurs, too, whether the wound be large or small. Dr. Elliotson had a case of tetanus, as severe as any he ever saw, where there had been merely a contusion of the thumb. There was no pain, no irritation; the nail was separated and loose, but under it all was dry, and no secretion was going on. A case is mentioned in the Trans. of the Lond. Med. Society, in which the disease occurred after a burn, at the time when there was merely a dry scab on the leg, and no inflammation around it; nay, as Dr. Elliotson observes, the disease has sometimes declined and ceased, while the wound every day grew worse and worse. In Egypt, the wounded of the French army were

<i>α</i> Anticus.	Tetanus of the flexor muscles. The body rigidly bent forwards.
Tetanic procurvation.	
<i>β</i> Dorsalis.	Tetanus of the extensor muscles. The body rigidly bent backward.
Tetanic recurvation.	
<i>γ</i> Lateralis.	Tetanus of the lateral muscles. The body rigidly bent laterally.
Tetanic transcurvation.	
<i>δ</i> Erectus.	Tetanus of both the posterior and anterior muscles. The body rigidly erect.
Tetanic inflexibility of the body.	

The FIRST of these VARIETIES is the emprosthotonos of early writers; the SECOND the opisthotonos; the THIRD the pleurosthotonos of authors of a later date; the FOURTH the proper tetanus of Dr. Lionel Clarke and a few others. To these varieties it has been usual to add the singular disease called catochus; which by Sauvages, Cullen, and various other authorities, is regarded as closely connected with this species. It has a near affinity to it unquestionably, and hence, out of deference to concurrent opinions, it was suffered to stand as a variety of tetanus in the first edition of the author's Nosology; but with a note intimating that it seems rather to belong to the genus CARUS of the fourth order of the present class, and to be a modification of the species ECSTASIS, under that genus: and as this appears to be its proper place, it will now be found arranged there accordingly.

The general physiology, so far as it seems capable of elucidation, has been already given under the preceding species; the proximate cause being that of a peculiar irritation of a certain chain or association of nerves, chiefly operating with the greatest violence at the two extremities of the morbid line. This irritation seems, in many instances, to consist in inflammation; and hence is made a common cause by many of the most valuable writers of the present day. Professor Frank seems first to have started the idea, and he has been followed in succession by Dr. Saunders of Edinburgh, Dr. Chisholm, Dr. James Thomson, and Dr. Abercrombie, who have been upheld in Italy by MM. Brera, Rachetti, and Bergamaschi, and in France by M. Esquirol. Bergamaschi* advances, indeed, so far as to maintain, that where

found by Larrey to be safe from traumatic tetanus, if they were not attacked by it before the sixteenth day. Sir Gilbert Blane has known the disease commence at all periods of a wound between the second day and the end of the fourth week. In Spain and Portugal, Sir James M'Grigor found the twenty-second day the limit. Dr. Murray relates an instance in which a midshipman trod on a rusty nail one evening at nine o'clock; and, after exposing himself to the cold night air in keeping watch, had tetanic symptoms on the following morning at eight o'clock.—(See Lond. Med. Gaz. for 1832-3, p. 623.) In hot countries the disease has been known to follow a local injury directly after its occurrence.—ED.

* Osservazioni Medico-pratiche sul Tetano. Giornale di Medicina pratica del Sig. Cons. e Prof. Cav. V. L. Brera.

wounds themselves, of whatever form, are the remote cause, a neurostenia,* as he calls it, or inflammatory affection of the nerves, is still the proximate cause; extending itself from the wounded part, by the nervous extremities, to the spinal marrow and the brain, or, *vice versâ*, from the brain to the spinal marrow and principal nerves, and thence to the parts that are subservient to locomotion. Dissection, however, is very far from giving proofs of such inflammatory change in every instance; while in many cases the disease is of too fugitive a character, and makes its seizure or its disappearance too rapidly, for the more measured progress of inflammation.*

The exciting causes are also for the most part those of TRISMUS; though it appears in infancy far less frequently, unless as a concomitant of that disease. Damp and cold, therefore, and simple nervous irritation from wound† or sores in hot climates and crowded hospitals, are the chief sources of its production; and where these accessories exist, terror seems to be a powerful auxiliary, and has alone, in some instances, been sufficient for its production. "Passion or terror," says Dr. Hennen, "after wounds and operations, has been known to produce the disease in some; and sympathy, though a rare cause, in others." It is said also to have been produced by insolation or exposure to the direct rays of the sun (*Pathol.*, lib. v., p. 372); and has unquestionably followed, as M. Magendie and numerous other French authors (*Desportes, Raf-fenean, Fonquier, Dupuy*) have abundantly shown, from various irritant narcotics, as strychnine, or the active principle of *nux vomica*, as

* Dissections reveal no appearance of any regular or constant description in the bodies of persons who die of tetanus. In most cases nothing remarkable is met with; and hence the best modern pathologists all agree, that when morbid changes are noticed, they are not essential, but incidental. Sometimes there are traces of inflammation of the spinal marrow; though if the weather be hot and the body not examined promptly, the coverings of the spinal marrow will look red, though no inflammation may have existed in it.—Ed.

† Dr. Armstrong mentions that one of his friends, who had had extensive experience in hot climates, never knew a case of tetanus occur without local injury; and he was led to believe that such was the fact by a careful examination of the whole surface of the body.—(See *Lectures on the Morbid Anatomy, Nature, and Treatment of Acute and Chronic Diseases*, p. 742, 8vo., Lond. 1834.) There can be no doubt, however, that many cases of tetanus are idiopathic, and not traumatic, because we know that the latter are infinitely more difficult to control, and more frequently fatal. Dr. Armstrong states that the local injuries which most frequently produce tetanus are those which are accompanied with friction. Lacerated or punctured wounds of tendinous parts, injuries of the fingers, thumb, or toes; dislocations, especially compound ones; burns, scalds, and ulcers, may be exciting causes of traumatic tetanus; and what is remarkable, the disorder may come on, as already noticed, when the wound or sore is healing, or nearly healed. It may be produced by the irritation of a seton, an issue, the partial division of a nerve or the inclusion of it in a ligature.—Ed.

also from galvanism, when raised to a sufficient power for the purpose.

LATERAL TETANUS is very rarely to be met with, and seems to be rather a chronic than an acute malady. Fernelius, who first described it (*Med. Obs. and Inq.*, vol. vi.), gives a case in which it occurred annually, but only in the winter, during which season the patient had two or three paroxysms daily: the head was first attacked with a peculiar vibratory feeling, which gradually descended to the neck, with a sensation of cold; and by the time it reached the scapula was immediately succeeded by symptoms of opisthotonos, and afterward of lateral contraction; during which the mind and external senses were unaffected, but the flexor muscles were so firmly fixed, that no antagonist force of the bystanders was able to overpower the contortion.

Nor are the other varieties nearly so frequent as trismus, except where they form a subsequent part of the general chain of morbid action. My observant friend, Dr. Hennen, confesses that, during the whole period of his superintending the British hospitals in Spain, he never met with but one case of emprosthotonos, and even this he describes as an incurvation that rather approached it than constituted the disease itself. "It was observed," says he, "at the same time and in the same hospital, with the various degrees of trismus: rigid spasms of almost every muscle of the body, and violent periodical convulsions, all from similar injuries to that in which it was produced."—(*Military Surgery*, p. 247, 8vo., Edin., 1820.)

From the complicated manner, indeed, in which tetanus shows itself, and its anomalous attack upon different sets of muscles at the same time, it seems in many instances to put all the subordinate divisions of classification at defiance. It is, in truth, for the most part, a mixed disease, affecting various and opposite sets of muscles; and this in many cases so equally, that the spastic action of the flexors just balancing that of the extensors, "the patient," to adopt the language of Dr. Lionel Clarke, "seems often to be braced between opposite contractions." It is to this form, indeed, that this last very intelligent writer has limited the name of tetanus, as that to which it applies most emphatically. Like Dr. Hennen, he asserts that he had never seen a single case of genuine emprosthotonos; and that of the other two varieties of which he treats, the opisthotonos and proper tetanus, the former occurs most frequently.*

In opisthotonos, or TETANIC RECURVATION, the symptoms sometimes show themselves suddenly, but more commonly advance slowly and

* According to Baron Larrey, who had extensive opportunities of seeing tetanus while he was serving with the French army in Egypt, it appears that in that country, when the wound was in the back, tetanus commonly assumed the form of opisthotonos; but if the wound happened to be in the anterior part of the trunk, and tetanus followed, the latter was generally in the shape of emprosthotonos. Sir Gilbert Blane published two cases, where the side of the body on which the local injury was situated became the seat of tetanic disorder.—Ed.

imperceptibly, the patient mistaking the uneasy stiffness which he feels about the shoulders and cervical region for a crick in the neck, produced by cold and rheumatism. The stiffness, however, increasing, he finds it impossible to turn his head on either side without turning his body: he cannot open his jaws without pain, and he has some difficulty in swallowing. A spastic and aching traction now suddenly darts at times towards the ensiform cartilage, and thence strikes through to the back, augmenting all the previous symptoms to such a degree, that the patient is no longer able to support himself, and is compelled to take to his bed. The pathognomonic symptom in this variety is the spasm under the sternum, which is perpetually increasing in vehemence; and instead of returning, as at first, once in two or three hours, returns now every ten or fifteen minutes. Immediately after which all the host of concomitant contractions renew their violence, and with additional severity: the head is forcibly retracted, and the jaws snap with a fixation that rarely allows them to be afterward opened wide enough to admit the little finger. This vehemence of paroxysm may not, perhaps, last longer than for a few minutes or even seconds; but the spastic action prevails so considerably, even through the intervals, that it is difficult for an attendant to bend the contorted limbs into any thing like an easy or reclined position.* The breathing is quick and laborious; and the pulse, though calm and less hurried, small and irregular. The face is sometimes pale, but oftener flushed; the tongue stiff and torpid, but not much furred; the whole countenance evinces the most marked signs of deep distress; and swallowing is pertinaciously abstained from, as accompanied with great difficulty, and often producing a sudden renewal of the paroxysms. The last stage of the disease is truly pitiable. The spasms return every minute, and scarcely allow a moment's remission. The anterior muscles join in the spastic action, but the power of the posterior is still dominant; and hence, while every organ is literally on the rack from the severity of the antagonism, the spine is more strongly recurvated than ever, and forms an arch over the bed, so that the patient rests only on the back part of the head and on the heels. During the exacer-

bation of the spasms, the lower extremities, even while they continue rigid, are so violently jerked that the utmost attention is necessary to prevent the patient from being projected from his bed: and Desportes gives a case, in which both the thigh bones were broken from the violent contraction of the flexor muscles during a momentary remission of the extensors (*Hist. des Maladies de St. Domingue*, ii., p. 171); similar results to which we shall have occasion to notice hereafter.

The tongue is in like manner darted spasmodically out of the mouth, and the teeth snapped suddenly and with great force; so that unless a spoon covered with soft rags, or some other intervening substance, is introduced between the teeth at such periods, the tongue must be miserably bitten and lacerated.* The exertion is so laborious, that the patient sweats as in a hot bath; and the heat has in some instances been raised to 110° Fahrenheit. The pulse is at this time small and irregular; the heart throbs so violently that its palpitations may be seen; the eyes are sometimes watery and languid, but more commonly rigid and immoveable in their sockets; the nostrils are drawn upward, and the cheeks backward towards the ears, so that the whole countenance assumes the air of a cynic spasm or sardonic grin, while a limpid or bloody froth bubbles from the lips. There is sometimes delirium, but this is not common: the patient is worn out under this laborious agony in a few hours; though more usually a general convulsion comes to his relief, and he sinks suddenly under its assault.

In the ERECT TETANUS, in which there is a balance of spastic action between the anterior and posterior sets of muscles, the progress of the disease is not essentially different. The march of the spastic action, however, varies in some degree, as we have already observed, in almost every instance, from trismus to tetanus, and from one modification of tetanus to another: yet the course we have now described is that which chiefly takes place where the disease advances in something of a regular and uninterrupted progress. Its danger and duration are commonly to be estimated from the degree of violence of the incursion. Where this is very severe, the patient rarely survives the third day, and is sometimes cut off on the second, or even in six-and-thirty or four-and-twenty hours. But where the attack is less acute, the patient may continue to suffer for a week before he reaches his tragic termination. If he have strength enough to survive the ninth day, he commonly recovers; for the paroxysms diminish in violence, the intervals of remission are longer, and the muscles being generally more relaxed, he is able to take a little nourishment. Through the whole period there is an obstinate costiveness; partly from want of food in the stomach, but chiefly from an association of the mouths of the

* One symptom, very characteristic of the disease, is the pain at the scrobiculus cordis. As Dr. Elliotson observes in his invaluable Lectures on the Practice of Medicine, it is a pain not increased by pressure, but a sudden, violent, sharp, stabbing pain; it may be more or less constant, but at periods it is exceedingly severe. Then the spasmodic rigidity of the muscles is constant, not convulsive; not a spasm alternating with relaxation. The peculiar posture into which the body is drawn in opisthotonos, emprosthotonos, and pleurosthotonos, and the closed or nearly closed state of the jaw in trismus, without any inflammation, or any organic disease near the part to account for such closure, are all so many circumstances throwing light on the diagnosis. There is no terror in this disease, no excitement of mind, no morbid corporeal sensibility, no fear of noise, light, a current of air, &c., as in hydrophobia.—ED.

* The muscles of the fingers are observed to remain unaffected, even in the latest stage of the disorder. Sometimes, but not invariably, the sphincter ani is so violently contracted that it is difficult to administer a clyster.—ED.

intestinal excrements in the spasmodic constriction.*

The general principle of cure is far more easily expressed than carried into execution. It is that of taking off the local irritation, wherever such exists, and of tranquillizing the nervous erethism of the entire system. The first of these two objects is of great importance in the locked-jaw or trismus of infants; for by removing the viscid and acrimonious meconium, or whatever other irritant is lodged in the stomach or bowels, we can sometimes effect a speedy cure without any other medicine. Castor-oil is by far the best aperient on this occasion, and it may be given both by the mouth and in injections. But if this do not succeed, we should have recourse to powerful anodynes; and of these the best by far is opium, which should be administered from three to five drops in a dose, according to the age of the patient. Musk and the host of antispasmodics have been tried so often with so little success, that it is not worth while to put the smallest dependence upon them; nor has the warm or cold bath produced effects sufficiently general or decisive to allow us to lose any time in trusting to their operation. They may be employed, however, as auxiliaries; but our sheet-anchor must be opium; which, if the spastic action have made much advance when we first see the patient, should instantly be employed in conjunction with the prescribed aperient. By taking off the constriction from the intestinal canal, and thus restoring and quickening the peristaltic motion, it may even expedite the dejections.

In trismus or tetanus from wounds or sores, the local irritation is not so easily subdued; nor is its removal of so much importance, though in no case of small moment. But generally speaking, the spastic action is in these instances as much dependant upon constitutional as upon topical irritability; and when it has been once excited it will run through its career, whether the local cause continue or not. It is owing chiefly to this fact, that the best and most active plan of cure so often fails of success; and the most cautious practitioners hesitate in their prognostications, whatever be the march of symptoms, for the first four or five days. "From the state of the pulse," says Dr. Hennen, "I have derived no clew to either the proper treatment or the probable event: it has, in the cases I have met with, been astonishingly unaffected. From the state of the skin, I have been left equally in the dark. Sweating, which some have imagined critical, I have seen during the whole course of the disease, and attended with the most pungent and peculiar smell; while in others it has never appeared

at all: and suppuration, which is generally interrupted, I have seen continue unaffected by the spasms. Even the process of healing, which, it would be reasonable to conclude, should be altogether put a stop to, has gone on apparently uninfluenced by the disease: and in the most severe case I ever saw, which occurred after a shoulder-joint amputation, sent into Elvas from before the lines of Badajos, the life of the patient and the perfect healing of the wound were terminated on the same day." So powerfully does the constitutional irritability operate in many cases after the disease has once displayed its hideous features, and render the local treatment of subordinate importance.

In numerous instances, however, a change in the condition of the wound has produced a beneficial result; and hence various means have been resorted to for the purpose of effecting such a change, as local bleeding, anodyne applications to allay the morbid sensibility, resinous, terebinthinate, or mercurial stimulants to excite a new action, and amputation of the diseased limb. The first of these three plans is the ordinary mode of practice, and in full plethoric habits it has sometimes proved favourable; the second plan seems to have been very generally employed by Baron Larrey, who occasionally used stimulants of a far higher power, as pencilling the wound with lunar caustic, or an application of the actual cautery. It is upon this principle of counter-irritation that advantage has sometimes been derived from needle-puncturing, of which the periodical journals have lately furnished us with various examples (*London Med. Repos.*, vol. xx., p. 403, case furnished by Mr. Finch); and, by the French pathologists, from an employment of strychnine or the active alkaline part of nux vomica, where the disease has not been primarily induced by this irritant.—(*M. Coze, Remarques sur la Nux Vomique, &c.*) Amputation seems to have answered in a few cases, if we may give full credit to those who have chiefly tried and recommended it;* but it is at best a clumsy and desperate kind of remedy; and for reasons already assigned, must be often altogether inefficient if it do not add to the constitutional erethism.

The general treatment has consisted in a free use of opium, salivation, the hot or cold bath, and wine or ardent spirits, in some instances so far as to produce intoxication. Dr. Cross gives a case in which, after other medicines had been used in vain, and every hope seemed to fail, the patient was inebriated with spirits, and kept in this state for ten days, with

* If tetanus arise from a wound, the result is generally fatal. It is an observation made by Dr. Parry, that in tetanus, if the pulse be not above 100 or 110 on the fourth or fifth day of the attack, the patient mostly recovers; but that when the pulse is quicker than this in the early stages, the issue is commonly unfortunate. The danger generally lessens in proportion to the protracted duration of the disorder.—Ed.

* Silvester, *Med. Obs. and Inq.*, i., art. i. White, *Med. Obs. and Inq.*, ii., art. xxxiv. Mr. Liston amputated in a case of tetanus from laceration of a branch of the median nerve distributed to the thumb; but though partial relief followed, the patient died. After the operation, it was wished to let the stump bleed for a time; but not more than eight ounces of blood could be thus obtained, and only one vessel was tied. "Could this arise," says Mr. Liston, "from the coats of the vessels partaking in some measure of the general rigidity and contraction?"—See *Edin. Med. Journ.*, No. lxxix., p. 292.—Ed.

the result of a perfect recovery.—(*Thomson's Annals of Philosophy*.) A generous use of wine appears to be almost indispensable,* and considering the ordinary constitution in which the disease occurs, the difficulty of supporting the system by common means, and the great sensorial exhaustion which is perpetually taking place, it is far from difficult to explain in what manner it operates beneficially; but intoxication is a frantic experiment, and where it succeeds once, we have reason to apprehend it would kill in a hundred instances.

The warm and the cold bath have each of them a much better claim to attention; and their votaries are so equally divided, that it is no easy matter to say which is most strongly recommended. The latter demands more general strength in the system than the former; but neither of them is to be depended upon except as an auxiliary. The cold bath has the authority of Dr. Lind in its favour (*Essay on Diseases in Hot Climates*, p. 257), and has in some instances been tried with success in America.—(*Tallman, Amer. Phil. Trans.*, i., xxi.; *Cochran, Edin. Med. Comm.*, vol. iii., p. 183.)

Mercury, in various forms, has been had recourse to from a very early period; and on the authority of Dr. Stoll, has occasionally been used for the purpose of exciting salivation. On what ground it has been carried to this extent I do not know, except it be that a pretty free flow of saliva from the mouth spontaneously has, by many persons, been regarded as a favourable sign. The disease, however, does not seem to be accompanied with any symptom that can be called critical; and it is hence probable, that this spontaneous flow of saliva is nothing more than a result of the violent action and alternating relaxation of all the parts about the fauces. Nevertheless, salivation, where it has been accomplished, is said by many writers to have been serviceable, though I know of no practitioner who has relied on it alone. And, in reality, such is the rapidity with which both trismus and tetanus usually march forward, where they have once taken a hold on the system, that we have seldom time to avail ourselves of this mode of cure, were its pretensions still more decisive than they seem to be. It is most successfully employed after copious venesection, and in conjunction with opium.

Opium, indeed, in every stage and every variety of both tetanus and locked-jaw, is the remedy on which we are to place our chief, if not our only dependence; but to give it a full chance of success it should be administered in very free doses, and it is not easy for us to be too free in its use. In the *Edinburgh Medical Commentaries* (vol. i., p. 88) we have a case, in which five hundred grains were taken within seventeen days, which is about thirty grains a day; and in the *Edinburgh Journal* (*Edin. Med. and Surg. Journ.*, No. lxxi.; Mr. Barr's case) an-

other case, in which, after smaller doses along with calomel, the practitioner at last gave a drachm of solid opium at one time. This, however, proved too high a dose; for the induced stupor was accompanied with very laborious respiration, and nearly an extinction of the pulse; and the patient was obliged to be roused by stimulants. He recovered ultimately. Yet, in the West Indies, opium is often carried, with the most beneficial effects, to as great an extent as this, though not at once. Thus Dr. Gloster of St. John's, Antigua, gave to a negro, labouring under tetanus from an exposure to the night air, not less than twenty grains every three hours, in conjunction with musk, cinabar, and other medicines; and continued it with but little abatement for a term of seventeen days, in the course of which the patient took five hundred grains of this narcotic. For the first six days, little benefit seemed to be effected; but after this period the symptoms gradually declined under the same perseverance in the medicine, and in thirteen days more, they were so much diminished that no further assistance was thought necessary.*

If there be any thing which adds to the sedative power of opium in this disease, it is sudorifics, and particularly ipecacuanha. And upon this subject Dr. Latham has given a valuable paper in the *Medical Transactions*, in which he offers examples of failure in the use of James's powder, when used either alone or in alternation with opium; but of full success by uniting the two powers of the narcotic and the sudorific, though he afterward preferred ipecacuanha to James's powder, and prescribed it in the form of the compound powder of this name. He gives cases in which he employed this compound in very severe attacks, and sometimes in what seemed to be its last stage of the disease, with an immediate arrest of its symptoms, and progressively a perfect restoration to health. His doses consisted of ten grains, repeated every three or four hours. In no instance was there any unusual inclination to sleep, how long soever this treatment was continued, which, in one case, was for a fortnight; nor was there any degree of sickness, nor any other inconvenience, except that of a perspiration, troublesome from its excess.—(*Med. Trans.*, vol. iv., art. iv.)

It is only necessary to observe further, that, during the treatment either of trismus or tetanus, a very particular attention should be paid to ventilate the chamber with pure air; and especially to purify the air of close and crowded hospitals, without which no plan of treatment in the world can be of any avail. We should also remove, if possible, the costiveness, to

* In Hosack's *Essays*, vol. ii., reference is made to a number of instances of tetanus cured by the use of wine. Dr. H. gives also the details of a case treated by himself, and with success, in which the quantity of wine used was three gallons.—D.

* In the West Indies one hundred drops of laudanum are sometimes given as the first dose, and repeated every two hours, with an addition of one third to every succeeding dose. This plan is combined with the free use of mercury, an allowance of wine and ardent spirits, the employment of the warm bath, and attention to remove constipation. Dr. Morrison has given a favourable report of the effect of this practice, even in traumatic tetanus.—ED.

which the bowels are so peculiarly subject, by some gentle aperient: for it sometimes happens, not only in infantile trismus or tetanus, but in that from obstructed perspiration, or cold and dampness, that the primary cause of irritation is seated in the bowels; while, whatever accumulation takes place in this quarter during the course of the disease, may add to and exacerbate the general erethism. At the same time, nothing can be more mischievous than the drastic purges which practitioners are apt to give at the commencement of this disease, consisting of jalap, scammony, and aloes. We have already seen, that the general excitement

is so extreme, that the slightest occasional irritation, even that of changing the position of the head, is sometimes sufficient to produce a return of the spasms; and hence there can be nothing more likely to do it than the griping effects of such medicines. And it will be far safer to pass by the constipation altogether, than to attempt to remove it by such dangerous means. The best medicine is castor-oil, which may be given either by the mouth or in the form of injections; and if this do not succeed, we may employ calomel. But the action of the bowels must only be solicited, and by no means violently excited.*

* The editor freely confesses that he does not participate in the author's aversion to the employment of strong purgatives in tetanus. While Dr. Good condemns them, we find some other physicians prescribing them in extraordinary doses, and with decided success. Thus, in an example under Mr. Manifold, of Liverpool, on which Dr. Briggs has offered some reflections, half a drachm of calomel, as much scammony, and fifteen grains of gamboge, were given in one dose, followed by a clyster of half an ounce of turpentine and two drachms of aloes. As these powerful means had produced no effect, two drops of the oil of croton in a little treacle were given in the evening, and at the same time a clyster of four ounces of the sulphate of magnesia in a pint of infusion of senna. In less than an hour afterward a black stool was voided, and relief immediately experienced from the evacuation. By continuing the same active remedies, a cure was effected.—(See *Edin. Med. Journ.*, No. lxxxv., p. 277.) Indeed, the oil of croton, owing to its great efficiency in procuring stools, promises to be a most valuable medicine in tetanus. Dr. Briggs even maintains, in direct opposition to Dr. Good, that the principle on which the utility of purgatives rests in this disorder, is that of *counter-irritation* on the bowels; a theory which we need not investigate too deeply, provided the practice be found to answer.

Dr. Good describes opium as the sheet-anchor in the treatment; yet, in almost every case in which the editor has seen this medicine used as the chief or only one, the disease proved fatal.

Our author has not delivered any opinion with regard to venesection as a means of relieving tetanus. Sir Astley Cooper has found it hurtful; and the editor of this work has seen some cases in which he thought that the patient's chances of recovery were rendered worse by it. Dr. Elliotson states that the bleeding is not at all useful unless the wound is inflamed, or there is some decided internal inflammation present, or the patient is in a state of plethora.

In consequence of many practitioners suspecting tetanus to be dependant upon inflammation of the spinal marrow or its coverings, they have had recourse to blistering the skin in the track of the vertebral column. The efficiency of the plan is far from being well proved.

One remedy for tetanus, in favour of which we have now many facts recorded, is tobacco.† Two examples of its efficiency are detailed by Dr. Anderson, of Port Spain, Trinidad. He fomented the jaws, throat, and chest frequently with a strong

decoction of this plant, and applied cataplasms of the boiled leaves to the lower jaw and throat. The patient was also put into a warm bath, impregnated with tobacco, every three hours, and had a clyster of the decoction administered to him twice in twenty-four hours. Purgatives, consisting of gamboge, calomel, and of ricini, were likewise employed.—(See *Ed. Med. Chir. Trans.*, vol. i., p. 187.) An earlier paper, particularly in recommendation of tobacco and the purgative practice, is that of Mr. O'Beirne, who adverts to various opinions and facts communicated on this subject by other previous writers.—(See *Dublin Hospital Reports*, vol. iii., p. 343, &c.) From the share which the state of the medulla spinalis is sometimes conceived to have in the production of the disease, the practice of applying a blister the whole length of the spine has been derived. Dr. Reid is an advocate for this practice and powerful cathartics.—(See *Trans. of Physicians of King's and Queen's College*, vol. i., p. 122.) Oil of turpentine is another valuable medicine in tetanus. It is given by the mouth, and in clysters. The facts in its favour are numerous. It operates with excellent effect on the bowels. Prussic acid and belladonna have been tried in tetanus, and found to do no good.

In consequence of the benefit which Dr. Elliotson had seen the carbonate of iron produce in some examples of St. Vitus's dance, another spasmodic disease, he determined to try it in tetanus; and the account which he has published of the results of some cases which fell under his own observation, and of others which occurred in the West Indies, certainly encourages the hope that this medicine will be a valuable one in the present disorder. The editor has tried it only in one case of traumatic tetanus, but in that it did not succeed; indeed, the trial was not a fair one, because commenced in too advanced a stage of the disease.

Whether veratria would prove serviceable, as a means of relieving tetanus, is a point which may deserve further investigation. Its external use seems to have great power in mitigating and curing neuralgia, and other nervous affections. From \mathfrak{zj} . to \mathfrak{zj} . of it may be blended with ointment, and rubbed on the painful or disordered parts. Dr. Turnbull, some months ago, mentioned to the editor several very extraordinary proofs of the power of veratria, employed in this way, in curing neuralgic diseases.

In traumatic tetanus, amputation has sometimes been practised, with the view of stopping the disorder; but the most experienced surgeons disapprove of the proceeding as useless. The plan of dividing the nerve distributed to the wounded part, has also been done with various results. One of the strongest facts in support of this practice was published a little while ago by Dr. Murray, assistant surgeon in the Honourable East In-

† Dr. Skinner, of N. Carolina, has communicated a case of tetanus treated successfully by tobacco injections.—See the *Phil. Journ. of Med. and Phys. Sc.*, May, 1827. Arsenic, also, has been found efficacious by Dr. Holcombe of Virginia.—D.

SPECIES VIII.
ENTASIA LYSSA.
RABIES.

SPASMODIC CONSTRICTION OF THE MUSCLES OF THE CHEST; SUPERVENING TO THE BITE OF A RABID ANIMAL; USUALLY PRECEDED BY A RETURN OF PAIN AND INFLAMMATION IN THE BITTEN PART: GREAT RESTLESSNESS, HORROR, AND HURRY OF MIND.

THE Greek term for rabies was LYSSA: and the antiquity of the disease is sufficiently established from its being referred to several times under this name by Homer in his *Iliad*, who is perpetually making his Grecian heroes compare Hector to a mad dog, *κύνα λυσσώδη*, which is the term used by Teucer; while Ulysses, speaking of him to Achilles, says,

— κρατερὴ δὲ ἰ ΛΥΣΣΑ δόρυκεν.*
“So with a furious LYSSA was he stung.”

The author has ventured to restore the Greek term, not only as being more classical, but as being far more correct than the technical term of the present day, which is *hydrophobia*, or *water-dread*; since this is by no means a pathognomonic symptom; being sometimes found in other diseases; occasionally ceasing in the present towards the close of the career; and though almost always observable among mankind, in numerous instances wanting, even from the commencement, in rabid dogs, wolves, and other animals. “Constat repetitâ,” says Sauvages, “apud Gallo-provinciales experientiâ, canes luposque rabidos bibisse, manducasse, flumen transisse, ut olim Marologii, et bis Forolivi observatum, adeoque nec cibum nec potum aversari.” The same fact is affirmed of rabid wolves, in a case given by Treacourt in his *Chirurgical Memoirs and Observations*. Dr. James in like manner relates the case of a mad dog, that both drank milk and swam through a piece of water (*On Canine Madness*, p. 10); and one or two similar cases are said to have occurred among mankind;† though even here a

spasmodic constriction of the muscles of the chest, and sometimes of the throat, seems to have been present. Dr. Vaughan, indeed, gives the case of a patient who called for drink through the whole course of the disease, and only ceased to ask for it a short time before his death.

I have occasionally met, on the contrary, with a few obstinate cases of hydrophobia, or water-dread, without any connexion with rabies: one especially in a young lady of nineteen years of age, of a highly nervous temperament, which was preceded by a very severe toothache and catarrh. The muscles of the throat had no constriction, except on the approach of liquids, and the patient, through the whole of the disease, which lasted a week, was able to swallow solids without difficulty; but the moment any kind of liquid was brought to her, a strong spastic action took place, and all the muscles about the throat were violently convulsed if she attempted to swallow.

Similar examples are to be found in Battini, Dumas, Alibert, and several of the medical records, and particularly one of great obstinacy in the *Edinburgh Medical Essays*, which was chiefly relieved by repeated venesections (*Inflammation of the Stomach, with Hydrophobia, &c.*, by Dr. J. Innes; *Ed. Med. Ess.*, i., p. 227), as the preceding case was by large doses of opium. Hydrophobia is therefore too general and indefinite a term to characterize the genus before us, unless we mean to include under it diseases to which it is by no means commonly applied, and which, in truth, have little connexion with rabies. Hunauld has, indeed, employed it in this extensive signification, and has hence made it embrace no less than seven distinct species, of which two only are irremediable (*Discours sur la Rage, et ses Remèdes, Chateau-Gontier, 1714, 12mo.*); and Swediaur has followed his example.—(*Nov. Nosol. Meth. Syst.*, vol. i., p. 511.)

There is, even in the present day, so little satisfactorily known, and so few opportunities of acquiring any practical knowledge concerning the general nature and pathology of rabies, that it might, perhaps, be most prudent to imitate the example of modesty which Dr. Collen has set us upon this subject, and to let it pass without a single remark. Yet the following hints, derived from the only three cases in which the author has ever been consulted, compared with the larger range of observation and practice of a few other physicians, and especially the valuable work of Professor Trollet of Lyons, together with the reflections to which they have given rise in his own mind, may afford a little glimmering light into the principle of the dis-

be attended with a decided remission. Dr. Elliotson had a patient with this disorder, who, to please him, would wash his hands, stir the water about, and play with it. In the *Medical and Surgical Journal*, vol. v., p. 497, is a case related by Dr. Macrorie of Liverpool, in which so marked an amendment took place, that the patient became almost free from the dread of swallowing liquids, and took coffee without difficulty.—Ed.

dia Company's service.—(See *Med. Gaz.*, 1832-3, p. 623.) A midshipman in the ship “James Pattison,” aged fifteen, trod upon a rusty nail, which penetrated the left foot, between the metatarsal bones of the great toe and the adjoining one. After the accident the patient kept his watch, and was exposed to cold. At eight o'clock on the following morning, the symptoms of locked-jaw had commenced. Under the administration of opium the disorder gained ground; Dr. Murray therefore cut down to and divided the posterior tibial nerve, about an inch behind the malleolus internus. Although the patient had not been able to speak before the operation, he immediately opened his mouth with an exclamation, and expressed that he felt himself already greatly relieved. The original wound was then dilated, and covered with a poultice containing laudanum, and the case had a favourable termination.—Ed.

* *Iliad*, ix., 239.

† Fehr. *Nachricht von einer tödlichen Krankheit nach dem tollen Hundsbisse*, Gött., 1790, 8vo. In a case published by Dr. Satterley, the patient had fits of biting, and between these he was perfectly well—even took warm fluids, and had a sound sleep. It seems, then, as if the disease may

ease, and give an opportunity to succeeding pathologists of describing it more perspicuously.

The symptoms enumerated in the definition, and especially the constrictive spasm that oppresses the muscles of deglutition and of the chest generally, sufficiently show that the present species of disease bears a very close analogy to the two preceding, in the mischief which it excites; and as by far the most frequent cause of the two preceding species is the irritation of a wound or puncture on the surface of the body, it bears quite as close an analogy to them in the nature of its cause as in that of its effects.

We have seen it to be a law, operating throughout the animal system, that if a morbid action commence in any part whatever of a continuous chain of functions or of fibres, it often produces a peculiar impression upon its extremities; so that the extremities themselves form, in many instances, the chief seat of distress, and even of danger; and this more especially when the one extremity of the chain becomes affected in consequence of the primary affection of the other. And we have also endeavoured to show, from the general course and intermediate connexion of the nerves which supply the surface of the body, and particularly the extremities, that they constitute a direct fibrous chain, of which those that are, in all common cases, primarily irritated by wounds or punctures in the spastic diseases before us, form the one extremity, and those which enter into the muscles of the upper regions of the chest and the cheeks the other. It is not necessary, therefore, to travel over the same ground again; the reader may turn to it at his leisure: and he will find that we have hence endeavoured to trace out something of the means by which trismus and tetanus are produced by simple wounds or punctures in the limbs, and especially in an irritable habit.

Now, if the reasoning be sound, as applied to trismus and tetanus, it must be equally good as applied to lyssa; and will induce us to expect a more complicated disease, and a still more severe and desperate result: as we have, in the present instance, not merely an ordinary and mechanical, but a specific and chymical source of irritation to encephalon, and so indecomposable in its nature, that it is capable of lurking in the system, and apparently in the part where it may chance to be deposited, for weeks or even months, without losing its activity; of continuing dormant, if there be no sufficient irritability of constitution or nervous fibre for it to operate upon, and of operating as soon as such a condition may arrive: for that some exciting cause is usually necessary to rouse it into action, will sufficiently appear in the sequel of this inquiry. Sir Lucas Pepys, however, Dr. Bardsley, and various other writers, have made it a question, whether the virus of rabies is ever originated or produced spontaneously, or in any other way maintained, than by a direct communication from one animal to another; while M. Girard of Lyons has denied that there is any such thing at all, and contended that ra-

bies consists in nothing more than an acute degree of local irritation, and its effects on a highly mobile and excitable constitution. We have long, however, had various examples on record, and have recently been furnished with another by Mr. Gillman, in which a dog, chained up in a yard, and cut off from all medium of contamination with other animals, has occasionally been attacked with genuine lyssa, and exhibited its most decisive characters. Professor Trollet, whose extensive experience I shall soon have occasion to advert to more minutely, while he has no doubt of its occasional spontaneous origin, limits its appearance in this form to the dog, the wolf, the fox, and the cat, believing that all other animals only receive it from the one or the other of these by inoculation.*

Nevertheless, while we are thus establishing that the symptoms of rabies are dependant upon a specific virus, it may not be foreign to remark, that most animals, when roused to a high degree of rage, inflict a wound of a much more irritable kind than when in a state of tranquillity: and we have numerous examples in which such wound has been very difficult of cure, and not a few in which it has proved fatal; as though at all times, under such a state of excitement, some peculiar acrimony were secreted with the saliva. In the *Ephemera of Natural Curiosities* is an example of symptoms of hydrophobia or water-dread, produced by the bite of a man worked up into fury (*Ann. ix., x., App., p. 249*); and in the *Leipsic Acta Eruditorum* is another instance of the same kind (*Ann. 1702, p. 147*), though neither of them seems to have been fatal. Meekren (*Observ., cap. lxvii.*), however, Wolff (*Observ. Med. Chir., lib. ii., N. 5.*), and Zacutus Lusitanus (*Prax. Admir., lib. iii., obs. 84, 88*), have each an instance of such a bite terminating in death, yet without hydrophobia. Le Cat gives a case of death produced by the bite of an enraged duck (*Recueil Périodique, ii., p. 90*); and, in a German miscellany of deserved repute, we have another of the same kind.—(*Samml. Med. Wahrnehm., b. ii., p. 98.*) The instances, indeed, are innumerable; but it may be sufficient to observe further, that Thiermayer gives us two cases; one in which the bite of a hen, and another in which that of a goose, proved fatal on or about the third day (*In Gockelii Consil. et Obs., N. 19*), without hydrophobia; and that Camerarius has an instance of epilepsy produced by the bite of a horse.†

* Nouveau Traité de la Rage; Observations Cliniques, Recherches d'Anatomie Pathologique, et Doctrine de cette Maladie, 8vo., Lyon, 1820.

† Diss. de Epileps. freq., p. 15. No doubt many of the cases here adverted to were of the nature of traumatic tetanus. At the present day, medical practitioners are less likely to confound other nervous diseases with hydrophobia. If the case be a spurious one, the difficulty in swallowing generally comes on too early after the bite. In true hydrophobia, a certain period, usually some weeks, elapses between the bite and the commencement of the disease. One great feature of the complaint is a sudden and deep inspiration

Marvellous as these facts may appear, it is more consistent with reason to accredit them, than to impugn the host of authorities to whose testimony they appeal. And unless tetanus were mistaken for hydrophobia, an error that no doubt has frequently happened, it follows, that the passion of rage, whose influence is always considerable on the salivary glands, has often a power of stimulating them, among most animals, to the secretion of a malignant virus with which the saliva becomes tainted.

Rabies, however, has sufficiently shown itself to be dependant upon a peculiar virus, and capable of producing specific effects; to be sometimes originated, and sometimes received by communication. Now the only animals which have hitherto been ascertained to have a power of originating it are, as just observed, several species of the genus *canis*, as the dog, fox, and wolf, and one species of the genus *felis*, which is the domestic cat. It is probable, however, that there are others belonging to different classes endowed with a like power; and some writers have attempted to bring instances from the horse, mule, ass, ox, and hog, yet they are not instances to be depended upon. In like manner, Plater, Doppert, and even Sauvages himself, have asserted the same of mankind, and have brought forward a few casual cases in support of such assertion. These, however, are in every instance modifications of *empathema*, and especially of rage or fright, grafted on a highly irritable temperament, and hence associated with hysterical or some other spasmodic motions.

Of the remote or predisposing causes of this disease, we know nothing. The excitement of vehement rage, putrid food, long-continued thirst from a want of water to quench it, severe and pinching hunger, a hot and sultry state, or some other intemperament of the atmosphere, have been in turn appealed to as probable predisponents; but the appeal in no instance rests upon any authority. That the stimulus of vehement rage will often produce a peculiar influence affecting the saliva, and rendering it capable by a bite of exciting the most alarming symptoms of nervous irritation, may not be impossible; but these symptoms are not those of *lyssa*; and the virus, whatever it consists in, appears to be of a different kind. Putridity is, perhaps, the ordinary state in which dogs and cats obtain the offal, on which for the most part they feed: they show no disgust to it, and it offers a cause far too general for the purpose. In long voyages, again, when a crew has been without water, and reduced to short provisions, dogs have been in innumerable instances known to die

with which the patient is frequently affected, the diaphragm all at once descending, as it does when a person first enters a cold bath. The patient also generally sighs a good deal, and is severely agitated by the impression of cold air, the glare of a mirror, the noise of a pump, the sound of water, and other circumstances which do not commonly disturb, in any remarkable degree, persons who are labouring under some tetanic or nervous difficulty of swallowing.—Ed.

both of thirst and hunger, without betraying any signs of genuine rabies. That a peculiar intemperament of the atmosphere may at times be a cause, it is impossible to deny; but the disease, even when of spontaneous origin, has appeared under perhaps every variety of meteorological change, and seems to be far less common in hot and tropical regions, than in those of a more moderate temperature; for it is not known except by report in South America, though it is said to have occasionally appeared in the West Indies, as I have been repeatedly informed by intelligent residents in those quarters; while M. Volney tells us that it is equally uncommon in Egypt and Syria, and Mr. Barrow, at the Cape of Good Hope and in the interior of the country, where the Caffrés feed their dogs on nothing but putrid meat, and this often in the highest degree of offensiveness.

It is not improbable, that several of these may occasionally become exciting causes; but it is obvious, that they are not competent of themselves to produce the disease. Some of them, indeed, have been put to a direct test, and have explicitly proved their incompetency. Thus, in the wards of the Veterinary School at Alfort, three dogs were shut up and made the subjects of express experiments. One was fed with salted meats, and totally restrained from drinking; the second was allowed nothing but water; and the third allowed neither food nor drink of any kind. The first died on the forty-first day of the experiment, the second on the thirty-third day, and the third on the twenty-fifth: not one of them evincing the slightest symptom of rabies.

That the specific virus of rabies is less volatile and active than many other kinds of morbid poisons, is clear, from the fact that it is never found diffused in the atmosphere, so as to produce an epidemic; that it never operates on those who are most susceptible of its influence, except when accompanied with a wound or inserted into the cutis; and that, even in this case, it usually requires in mankind, and probably also in other animals, some auxiliary excitement to enable it to carry forward the process of assimilation: for it rarely happens, that all the men or quadrupeds that are bitten by a rabid dog suffer from the inoculation. Mr. Hunter, indeed, gives an instance, in which out of twenty persons who were bitten by the same dog, only one received the disease. This want of activity is a happy circumstance, as it affords an important interval for medical treatment, if we should ever be so fortunate as to hit upon any curative process that may be depended upon. At the same time I cannot avoid again to observe, that as this virus is less volatile than most others, it is perhaps less indecomposable than any of them; and hence is capable of remaining in a dormant and unaffected state in any part of the system into which it has been received by insertion, for a far longer period than any other known contagion whatever.* It is generally calculated, but

* According to Sir David Barry, "The notion that the hydrophobic poison is absorbed, after the

I do not know upon what data, that of those who are exposed to the venom, about one in four matures the complaint, and the rest escape.

When the disease has once fixed itself among a large establishment of hounds, it has been said that the poison becomes more concentrated and active, operates through an unbroken skin, and even taints the atmosphere. There is, however, no solid foundation for such an opinion; and, though the disease runs rapidly from one dog to another, and it may be difficult in many cases to trace the marks of a bite, yet, considering that the smallest and most imperceptible scratch of a tooth may be a sufficient medium of infection, and that every inoculated dog adds to the sources from which it may be derived, there is no difficulty in accounting for such rapidity of spread, without ascribing anomalies to the laws by which it is regulated. Heister, indeed, has given a case of lyssa in one of the foreign collections, produced in a man by his having merely put into his mouth the cord by which the mad dog had been confined: but, as in this instance there was probably some ulceration in the mouth at the time, there is nothing marvellous in its production. Palmaris, in like manner, relates the case of a peasant

manner of other substances similarly circumstanced, but that it does not produce its peculiar effects until it has wandered through the *penetralia* of the animal for forty days or longer, is in direct opposition to all analogy. The experiments which we have witnessed with the vegetable, mineral, and reptile poisons, applied to animals externally, prove that the commencement of the symptoms is synchronous with the consummation of absorption, and that their repetition is dependant upon its renewal."—(Experimental Researches on the Influence of Atmospheric Pressure upon the Blood in the Veins, &c., p. 151.) However, although the hypothesis rejected by Sir David Barry is said by him to be contrary to all analogy, a somewhat similar one was adopted by John Hunter, and even now generally prevails in relation to syphilis, the constitutional effects of which follow absorption of the virus at very indeterminate periods, and in a great diversity of forms. Now this absorption is not a conjecture, but often actually proved by the occurrence of a bubo. The editor, however, merely adverts to those circumstances, in order to remind the reader that analogy is not entirely against the hypothesis of the hydrophobic poison being absorbed some time previously to the commencement of the symptoms, and not with the view of denying the correctness of Sir David Barry's conclusion. In hydrophobia it is not improbable, as this gentleman's arguments maintain, that the poison which is afterward to affect the constitution, is generated in the wounded part from the germ first deposited there by the tooth of the rabid animal, just as we see happen in variola, vaccinia, and lues itself. But, if the commonly received opinions of syphilis be well founded, its virus is generally absorbed, without giving rise to any immediate constitutional effects, and even is sometimes expelled again without such effects ever taking place at all. The assertion of Dr. Marochetti, that the hydrophobic poison is translated to the place on each side of the frænum of the tongue, where the submaxillary salivary ducts terminate, and where it produces vesicles or pustules, will be presently noticed.—Ed.

who, in the last stage of the disease, communicated it to his children in kissing them and taking leave of them.—(*De Morb. Contagios.*, p. 266, Paris, 4to., 1518.) Yet, unless we could be certain that there were no cracks or other sores on the lips, and no eruption on the cheeks of these children, the example affords no proof.

I can distinctly state, that I have seen the same intercommunication successively repeated between a rabid young man and a young woman to whom he was betrothed, and who could not be restrained from such a token of affection, without any evil consequences; notwithstanding that the patient was labouring at that time under hydrophobia and all the severest marks of the disease, which destroyed him in a few hours afterward, and had also a perpetual desire to spit his saliva about the room. M. Trollet asserts, not only that the virus will not permeate a sound skin, but that it is only contained in the frothy matter communicated from the lips; and that neither the blood nor the secretions of any kind are tainted with it, or give rise to the disease, whatever scratch or other injury may be received during dissection.

It has still farther been doubted whether the virus itself is capable of propagation from the human subject to any animal, even by inoculation: but a bold experiment of M. Magendie and M. Breschet has completely settled this question; for on June 19, 1813, having collected upon a piece of linen a portion of the saliva of a rabid man in the last stage of the disease, they inserted it under the skin of two dogs that were in waiting, both of them in good health; of which one became rabid on the 27th of July, and bit two others, one of which also fell a victim to the disease just a month afterward.*

* The experiments made on rabid animals at the veterinary school at Berlin, by Dr. Hertwich, are curious and valuable. The results he has obtained are as follows: of 59 dogs inoculated, 14 became affected with lyssa canina. In those cases where the inoculation failed, no assignable cause for failure could be discovered. There exists, accordingly, a peculiar disposition for the virus of rabies, as for that of other contagious diseases—(a mastiff, 4 years old, went through several regular series of experiments, but without effect, while several other dogs who were inoculated with him and in the same manner became rabid. Several dogs were inoculated several times before any contagion took place: in others the effect was observed after the first experiment). It appears accordingly, that in cases of doubtful rabies, one or two accidental inoculations are not sufficient to serve as negative proofs of the existence of rabies. No communication of rabies ever took place by the perspiration; the contagious matter of rabies cannot therefore be of a volatile nature. Its vehicle is saliva, the mucus of the mouth, the blood, and the substance of the salivary glands. It does not appear to exist in the nervous pulp. The power of infecting exists at every period of the confirmed disease, and even for about twenty-four hours after the death of the animal. The virus of rabies appears to be inactive if administered internally: of 22 dogs which were made to swallow it, none took the disease. The application of saliva to fresh wounds appears to be as often followed by rabies as the bites of rabid animals. Hence the dis-

The general aggregate to the symptoms point forcibly to the nervous system as the immediate quarter of disturbance. Such was the opinion of Morgagni, Cullen, Percival, and Marcet; and such indeed is the common opinion of the present day. By many writers, however, the effects have been rather referred to the sanguiferous system, and regarded as a fever; Mangor describes it as a continued fever (*Act. Hafn.*, ii.), and Rush and many others as an inflammatory affection; Bader as a fever *sui generis*.—(*Versuch einer neuen Theorie*, &c.) Nor is the difficulty in the least degree removed by dissection, for nothing can be more at variance than the appearances in different cases. Generally speaking, the fauces and parts adjoining exhibit redness and inflammatory characters. But while in some instances these are so considerable as to be on the point of gangrene, in others there is no inflammatory appearance whatever. Morgagni has examined and described bodies in both these states. Rolinc gives one or two decided cases of the latter sort (*Dissert. Anat.*, lib. i., cap. xii.); while Ferriar notices examples, in which the inflammation of the fauces had spread over the whole œsophagus, and even the stomach (*Medic. Facts and Observations*, vol. i.); and another writer has recorded an instance, in which it had descended to the ileum, which was in a state of gangrene.—(*N. Act. Nat. Cur.*, vol. iv., obs. 20.) In some cases, the encephalon, and even the spinal marrow, have appeared to be as much diseased as the fauces: the vessels turgid; the plexus choroides blackish; the ventricles loaded with water: though, in the cases examined by M. Magendie, which were confined to dogs, there was no appearance of inflammation either in the brain or spine. Sometimes the lungs have been inflamed; sometimes the liver; sometimes the vagina; while the blood, according to Sauvages, has been also found in a dissolved state, and, according to Morgagni, in a state highly tenacious and coagulable. From all which we can only conclude, that owing to the violence of the disease, every organ is greatly disturbed, and those the most so that in particular cases are most severely

ease is produced neither by the lesion, as Gerard thinks, nor by the fear of the patient. The opinion of Bader and Capello, that in dogs who had become rabid from the bite of an animal primarily affected with the disease, the saliva did not contain the contagion, and thinks it existed only in primary rabies, has been proved by several experiments to be erroneous. During the period of the inactivity of the virus, there is no morbid alteration observable either locally or in the general health of the dog thus infected, nor does the lower surface of the tongue ever exhibit vesicles. The disease generally breaks out within fifty days after the inoculation or the infliction of the wound: inoculation or infection from animals afflicted with fierce rabies, very often produces the other modification of the disease, and vice versa; they are consequently only different forms of one and the same disease. Healthy dogs are unable to distinguish those affected with rabies by the smell; nor do they abhor food mixed with the secreta or excreta of rabid dogs.—See *Am. Journ. of Med. Sc.*, vol. v., p. 485.—D.

affected. Riedel asserts, that among dogs, a highly offensive fetor of a peculiar character is thrown forth from every part of the body (*Act. Acad. Mogunt.*, Erf., 1757): but I have not found this remark confirmed by the veterinary practitioners of our own country; and it certainly does not apply to mankind, with an exception or two that seem to depend upon some accidental circumstances; for Wolf informs us, that in one of his patients, and a patient that ultimately recovered, the blood stunk intolerably as it was drawn from a vein; and a patient of Dr. Vaughan's complained of a most offensive smell that issued from the original wound, but of which no one was sensible except himself. In like manner, the patient described by Dr. Marcet, towards the close of the disease, complained loudly of an intolerable stench that issued from his body generally, but without being perceived by any other person.—(*Medico-Chir. Trans.*, i., 132.) Dissection in this case produced nothing striking.

Desault, in his treatise on rabies, tells us that he has often met with numerous minute worms in the heads of those who have died of this disease; and he hence regards such animalcules as its cause. But this writer was a slave to the Linnéan hypothesis of invermation, and applied the same cause to syphilis, which he also supposed to be maintained by a transfer of vermicules from one individual to another: and hence proposed to treat syphilis, lyssa, and itch, as diseases of a like origin, with the common antidote of mercury; and gives instances of a success which no one has met with out of his own practice. The cases, however, which he describes, had not advanced to the stage of water-dread; and, in all of them, he thought it prudent to combine with his mercurial inunction, cold bathing and Palmarius's antilyssic powder.

Vander Brock, and after him Rahn, maintain that the return of pain and inflammation to the bitten part, on the onset of the disease, does not occur from any virus which has hitherto been lying dormant there, but from the universal excitement alone. It may be observed, however, in opposition to such an opinion, that this local affection is in most instances a prelude to the general disease, and forms the punctum saliens from which it issues; as though the contagious ferment had remained dormant there, and was at length called into action by some exciting cause.

There seems, nevertheless, to be a slight departure from the general character of the disease in a few cases, and particularly in those that are produced by the bite of a rabid cat, whether the latter have originated it, or received it from a rabid dog, as though by a passage through the domestic cat the virus undergoes a similar change to that which takes place in the virus of smallpox, when passing through the system of an individual who has previously submitted to the influence of cowpox: for, upon the whole, the disease appears to evince somewhat less malignity, to be more disposed to intermit, and its spastic symptoms, and especially

that of water-dread, to be both less frequent and less violent: so that in respect to symptoms we may perhaps mark out the two following varieties:—

- α Felina.
Feline rabies. The spastic symptoms less acute and frequently intermitting; produced by the bite of a rabid cat.
- β Canina.
Canine rabies. The spastic constriction, for the most part, extending to the muscles of deglutition, which are violently convulsed at the appearance or idea of liquids: produced by the bite of a rabid dog, wolf, or fox.

There is a case of FELINE RABIES, if it be rabies, in Morgagni, and which is copied from him into Sauvages' Nosology, in which the above distinction is so strongly marked, that the author, in the first edition of his own Nosology, was induced to follow M. de Sauvages' mode of classifying it, and made it, after him, a distinct species, though he deviated from the name under which it occurs in this justly celebrated writer, which is that of *Anxietas à Morsu*.—(Classis vii., Ord. i., v., 6.) The history of the enraged cat is not given, nor is it certain that the rage was that of rabies. The master of the animal was attacked and wounded both by its teeth and claws. The symptoms took place four days after the bite, and were confined to spasms of the chest without hydrophobia; nor do these seem to have been of great violence, for they are described as "*magna præcordiorum anxietas*." Local and general bleedings were useless: a frequent repetition of the warm bath afforded relief; but it only yielded to an ephamera with copious sweat. The intervals were lunar: for it returned with the full moon for two years; the bitten part, as usual, first becoming highly irritable, and the spasms or vehement anxiety of the præcordia supervening, which were now relieved by bleeding. After this period, it returned with every fourth full moon for two years more, and then appears to have ceased.

A few instances of intermission, with a return of periodical paroxysms, produced by the bite of a rabid dog, are also to be found in the medical collections: of which Dr. Peters' case (*Phil. Trans.*, 1745, No. cccclxxv.) affords a striking example, the paroxysm returning for many months afterward, severely, once a fortnight, or at every new and full moon, and slightly at the quarters, or in the intervening weeks. Selle, indeed, asserts that he has met with an instance of the same kind of intermission among dogs; and hence, where the individual recovers, both varieties seem occasionally to subside in this manner.—(*Neue Beiträge zur Natur und Arznei-wissenschaft*, b. iii., 118.)

Dr. Fothergill has given two cases of unquestionable affection from feline rabies, produced by the same animal. The cat first bit

the maid-servant, and afterward the master of the house, about the middle of February. The wound inflicted on the maid-servant remained open and irritable from the first, and continued to resist every application for many months; it healed, however, at length, and no constitutional symptoms supervened. The wound inflicted on the master healed easily and in a short time, but in the middle of the ensuing June, being four months afterward, the usual symptoms of lyssa appeared, yet with comparatively slight and occasional water-dread; insomuch that the patient, far from resisting the use of the warm bath, sometimes called for it, expressed a high sense of the comfort it afforded him, and was able at times to dash the water over his head with his own hands. It terminated, however, fatally, and with the usual symptoms of distress.*

In the Transactions of the Medical Society of London we have a highly interesting case of the same kind, which proved equally fatal, in seventy-four days from the time of receiving the injury, and fifty-eight hours from the commencement of the disease; all the symptoms, moreover, exhibiting less violence than usually occurs in canine madness, with little or no water-dread, and consequently an ability to drink fluids to the close of the disease, though the muscles of deglutition, as well as those of the chest, evinced always some degree of constriction, with occasional exacerbations.—(Vol. i., art. iv., p. 78, 8vo., 1810.) The patient was a young lady of eighteen years of age; the attack was made in the month of January, with both claws and teeth, by a domestic cat that was lurking under the bed, and which, though not known to be ill, had for some time before been observed to be wild, and had been roving in the woods. The fate of the animal is not mentioned. The lacerated parts were incised and purposely inflamed by the application of spirit of turpentine. The wounds healed, and the general health of the patient continued perfect till the beginning of the ensuing April, when she was suddenly frightened by looking out of a window, and seeing a mad dog pursued by a crowding populace. This proved an exciting cause. She instantly expressed alarm, anxiety, and dejection of mind. In the afternoon she complained of an unusual stiffness in moving her left arm, and its sense of feeling was impaired; she discovered an aversion to company; the irritations of noise, heat, and light were offensive to her; she avoided the fire, and forbade a candle to be brought near her. The rigidity and insensibility of the affected arm seemed to shoot in a line from the middle finger which had been lacerated, and was accompanied with an acute pain which termi-

* Med. Observ. and Inquir., vol. v. On the other hand, Dr. A. Thomson has recorded, in the Medico-Chir. Trans., an instance, proving, that when the disease arises from the bite of a rabid cat, the dread of swallowing fluids may be as strongly marked as in examples proceeding from the bites of rabid dogs. What was noticed by Dr. Fothergill is not a constant feature in the disorder as it appears after the bite of a rabid cat.—ED.

nated in the glands of the axilla, where she complained of a considerable swelling. Yet neither of the hands (for both had been injured) was affected with discoloration, tension, tumefaction, or any other mark of local injury, though a degree of lividity had been observed upon the lacerated part of the finger a short time before the disease made its appearance. She had a painful constrictive sensation in her chest, and the respiration was interrupted by frequent sighings. The spasmodic symptoms increased, and at length the whole system, but especially the lungs, was affected with violent convulsions: the breathing was exquisitely laborious, but the paroxysm subsided in about two minutes. Frequent sickness and vomiting followed: the convulsive spasms about the throat obliged her to gulp what she swallowed, and she showed a slight reluctance, but nothing more, to handling a glass goblet. The pulse was 132 strokes in a minute; the skin was cool, the tongue moist, the bowels open, the thirst urgent, without any tendency to delirium. She was worn out, however, by sensorial exhaustion and distress, and at last expired calmly, at the distance of time from the attack already stated.

In the general progress of CANINE RABIES, all the above indications are greatly aggravated, and the mind often participates in the disease, and becomes incoherent. Whatever be the exciting cause, the wounded part almost always, though not universally so, takes the lead in the train of symptoms, and becomes uneasy; the cicatrix looking red or livid, often opening afresh, and oozing forth a little coloured serum, while the limb feels stiff and numb. The patient is next oppressed with anxiety and depression, and sometimes sinks into a melancholy from which nothing can rouse him. The pulse and general temperature of the skin do not at this time vary much from their natural state. A stiffness and painful constriction are, however, felt about the chest and throat; the breathing becomes difficult, and is interrupted by sobs and deep sighs, as the sleep is, if any be obtained, by starts and frightful dreams. Bright colours, a strong light, acute sounds, particularly the sound of water poured from basin to basin, even a simple agitation of the air by a movement of the bed-curtains, are sources of great disturbance, and will often bring on a paroxysm of general convulsions, or aggravate the tetanic constriction. The patient is tormented with thirst, but dares not drink; the sight, or even idea of liquids, making him shudder: his eye is haggard, glassy, fixed, and turgid with blood from the violence of the struggle; his mouth filled with a tenacious saliva, in which, we have already shown, lurks the secreted and poisonous miasm, and he is perpetually endeavouring to hawk it up, and spit it away from him in every direction; often desiring those around him to stand aside, as conscious that he might hereby injure them. The sound which is thus made, from the great oppression he labours under, and from his vehement effort to excrete the tough and adhesive phlegm, is often of a very singular kind; and

being sometimes more acute than at others, as well as quick and sudden, and also frequently repeated, like every other motion of the body, has occasionally, to a warm and prepossessed imagination, seemed to be a kind of barking or yelping. And hence, probably, the vulgar idea that a barking, like that of a dog, is a common symptom of the disease. The restlessness is extreme, and if the patient attempt to lie down and compose himself, he instantly starts up again, and looks wildly round him in unutterable anguish. "On going into the room," says Dr. Munckley, describing the case of a patient to whom he had been called, and the author can bear witness to the accuracy of his very forcible delineation, "we found him sitting up in his bed, with an attendant on each side of him: he was in violent agitation of body: moving himself about with great vehemence as he sat in the bed, and tossing his arms from side to side. On seeing us, he bared one of his arms, and striking it with all his force, he cried out to us with the greatest eagerness, to order him to be let blood. His eyes were redder than the day before; and there was added to the whole look an appearance of horror and despair, greatly beyond what I had ever seen, either in madness or in any other kind of delirium." The patient was, nevertheless, "perfectly in his senses at this time, and there was not the least appearance of danger of his biting any person near him; nor, among the variety of motions which he made, was there any which looked like attempting to snap or bite at any thing within his reach: and they who were about him had no apprehension of his doing this."—(*Med. Trans.*, vol. ii., art. v., p. 53.) The patient had at this time reached the third day of the disease, and expired about two hours after Dr. Munckley had left him.

There is, however, a considerable difference in many of the symptoms which characterize the progress of this malady, derived from difference of age, idiosyncrasy, or some other casualty, so that it is possible no two cases are in every respect precisely parallel. The volume of the Medical Transactions, from which I have just quoted, contains three instances of lyssa, communicated by different practitioners. In the first, which is Dr. Munckley's, no notice whatever is taken of the original bite, which was both in the hand and cheek, from a favourite lapdog, and the patient does not seem to have had any return of pain or irritation in these organs. In the second case, which is that of a lad of fifteen years of age, the bite, which was in the leg, was so small that it was scarcely perceptible at the time, and from first to last never gave the least uneasiness.—(*Op. cit.*, vol. ii., art. xii., p. 192.) In the third case, which is that of an adult woman, the disease was preceded by the ordinary prelude of torpor, stiffness, and tingling in the bitten part, shooting upwards to the trunk.—(*Id.*, art. xv., p. 222.) In the first case, the patient's mind never wandered, to the last moment of life, which is a common character of the disease; in the second and third, both were furiously mad, bit themselves, the bedclothes, and whatever else fell

in their way. In all of them, however, there was a severe hydrophobia, and in all of them the pulse did not essentially vary from its common standard. The first died on the third day; the two last recovered; the one under a treatment which consisted principally of opium, and the other under that of salivation; leaving it therefore doubtful how far the recovery may be ascribed to the natural powers of the constitution, and how far to remedies so widely different in their nature. Dr. Marcet's patient did not expire till the sixth day after the appearance of water-dread, and without any affection in the bitten part (*Medico-Chir. Trans.*, i., p. 152); and, towards the close of the disease, he sometimes suddenly gulped half a pint of water, or splashed it over his body.

There is, also, in these three cases, an equal and most singular discrepancy in the interval between the infliction of the wound and the incursion of the disease, or, in the language of Professor Trollet, its period of incubation. The first interval was about six weeks, which may be regarded as the ordinary term: the second was only five days: the third is not set down with any degree of precision; the patient is only stated to have been seized "about the time that the second horse died" that had been bitten by the same rabid dog; and hence this interval consisted probably of about a fortnight.

A like variation in the course of morbid symptoms, distinguished the series of cases published by Professor Brera, and which took place in the month of November, 1804, on the incursion of a wolf sufficiently proved to be rabid. Generally the patients showed no desire to bite or otherwise injure persons about them; but, in one instance, such a desire was strikingly prominent. In another case, also, though there was a fatal water-dread, there was no flow of saliva. In some, the horror extended to liquids of every kind; in others, water alone produced it, while wine was drunk with ease.*

This discrepancy seems to depend entirely upon the nature or presence of the predisponent or exciting cause that gives energy to the virus, and without which it may lie, as we have already observed, for an almost indeterminable period dormant, but undecomposed, and therefore as malignant as when first generated.† In the

three cases just quoted from the Medical Transactions, the lad who was soonest affected seems to have had a strong predisposition to the disease from the first moment, and which alone became an exciting cause; in the woman, who suffered about a fortnight afterward, there was probably some degree of predisposition, but the immediate exciting cause appears to have been over-exertion in walking, for we are told that "she was seized as she was going on an errand on foot, and had walked about two miles."

There is a like uncertainty among quadrupeds. We have just taken the interval of ten or twelve days as the common term; but, in the instance just referred to, it may have been considerably longer. According to Meynall, the disease among dogs appears from ten days to eight months after the bite. In Earl Fitzwilliam's hounds, which were bitten June 8, 1791, the interval varied from six weeks to more than six months; and not much less in Mr. Floyer's hounds, as described by Mr. James. It is not therefore to be wondered at, that there should be a great uncertainty among mankind. And hence we find it has occurred a week or a fortnight after the bite, three weeks, a month, and sometimes six weeks, and even three months: after which last period, however, notwithstanding occasional instances to the contrary, the patient is generally considered safe. There are two cases published by Dr. Thacher (*Hosack and Francis' Amer. Med. and Phil. Reg.*, vol. i., p. 457), in which the injury inflicted by the same dog, August 16, 1810, did not produce hydrophobia in either instance till nearly three months afterward, namely, November 3, and November 14, ensuing: and it is the more remarkable, that the first case was that of a child under four years of age, the second that of an old man of seventy-three. Both terminated fatally; the former case in six days, the latter in seven, from the onset of the disease. Upon the whole, we may calculate the interval as varying from five or six days to as many months, the usual period being about the same number of weeks.*

The academical journals and monographic writers, nevertheless, have numerous instances of the malady appearing after a bite of many years standing; sometimes twelve, eighteen, twenty, and even thirty years; but the evidence is mostly imperfect. I shall presently, however, have occasion to notice one, in which it occurred

* *Commentario Clinico per la cura dell' Idrofobia, &c. Mem. Soc. Ital. Scienz.*, tom. xvii., Modena.

† If this doctrine were positively proved, the information would be of high importance in practice, as justifying the excision of the parts at a very late period after they had been healed up, when this measure, so indisputably prudent in an early stage, has been neglected. However, whether the virus first inserted lie dormant in the part or not, if the bite be known with certainty to have been inflicted by a rabid animal, the extirpation of the bitten parts is advisable also on the other hypothesis, that the virus, though not now actually present itself, may have communicated to the parts a disposition to assume at a subsequent period a specific action, by which the hydrophobic poison will be regenerated, and subjected to absorption, with all its horrible consequences.—Ed.

* Dr. Ramsay mentions a case in which fifteen months elapsed before the disease appeared. The late Duke of Richmond, Governor of Lower Canada, presents a similar instance. Having cut himself while shaving, the duke lifted a small dog to lick off the blood, and received a bite on his chin. Five months afterward he was suddenly attacked with hydrophobia; venesection gave temporary relief, but he died three days after the accident.—(Thacher on Hydrophobia.) In the fifth volume of the New York Medical Repository, Dr. Mease has communicated a case "where this destructive virus lay dormant four years and three months before it began to operate." In the same volume may be seen some valuable remarks by Physick, Mease, Cox, and others.—D.

and proved fatal more than nine months afterward: and there is another, communicated by Dr. Bardsley to the Manchester Society, strongly entitled to credit, however difficult it may be to account for the fact, in which the attack did not commence till twelve years after the bite of a dog supposed to be mad. The patient died in the Manchester Infirmary, with decided symptoms of the disease. He had been for some time antecedently labouring under great nervous agitation and considerable depression of spirits; and Dr. Bardsley inclined to ascribe it to this cause rather than to any specific poison lurking in the system. But this is to suppose that lyssa is capable, under particular circumstances, of being generated spontaneously* in the human frame, while Dr. Bardsley, as we have already observed, contends that it cannot exist, even among dogs, except by contact.†

There are few physicians, whose experience seems to have been so extensive upon this melancholy subject, and so actively followed up by judicious and even original views, and post-obit examinations, as that of Professor Trollet, to whom I have already adverted. Independently of a variety of single and unconnected cases that had fallen under his care, he gives an account of a ravage committed on not less than twenty-three persons, besides cattle and dogs, in the department of the Isère in 1807, twelve of whom, for the most part, terribly bitten in the face, were conveyed to the Hôtel Dieu at Lyons, in which he was clinical professor, and as such, were placed under his immediate care.‡

The general train of symptoms, as the patients became successively affected and died, after an active and judicious treatment of preventive as well as curative means, did not essentially vary from those just related. The local indications mostly, but not always, preceded. The interval between the bite inflicted by the rabid wolf and the access of disease, varied from a fortnight to five weeks, and the patients uniformly sank on

the second or third day after a clear development of the symptoms. In the preceding year, however, M. Trollet had a case, produced by the bite of a mad dog, in which the disease did not show itself till *five months and a half* after the infliction of the wound. The patient was a strong, robust man, of thirty years of age, and the dog had died mad in the veterinary school at Lyons soon after the injury. The first symptoms in this case were the usual ones of pain in the bitten part, which gradually extended to the arm and neck. Two days afterward, the patient was sensible of a vapour or aura, which ascended from the abdomen to the head, accompanied with a general uneasiness. The symptom of hydrophobia was manifested on the day ensuing; the depleting plan was, in this instance, followed up with a daring urgency, and the man expired on the evening of the same day.

M. Trollet's post-obit examinations are numerous, and they uniformly give proof, like the dissections already noticed, of extensive mischief in various organs remotely situated from each other; the chief of which, however, were the mucous membrane of the trachea and bronchiæ, and the membranes of the brain, especially the pia mater; all which, in direct repugnance to M. Magendie's observations, were infiltrated with red blood, and gave evident proofs of inflammatory action; while the mucous membrane of the bronchiæ and trachea were covered over with a frothy material of a peculiar kind, which M. Trollet supposes to be the seat or vehicle of the specific virus, and which, in his opinion, is driven forward into the fauces, and intermixed with the saliva by each spastic expiration from the chest. The other organs he found affected as follows: the capillary vessels of the lungs were penetrated with a larger quantity of blood than ordinarily; their substance was emphysematous, or contained an accumulation of air, as did also the heart and large bloodvessels in some instances. The blood itself was black, uncoagulating, and of an oily appearance. That taken from the veins during the disease, coagulated into an entire cake, without any separation of serum. The mucous membranes of the mouth and pharynx were of a pale gray, and lubricated by a gentle moisture; they contained no saliva, nor any frothy material. The most singular fact of the whole is, that "the salivary glands, and the cellular substance which envelops them, afforded not the least vestige of inflammation, nor the slightest alteration in their volume, their colour, or their texture."

It is this last circumstance that seems chiefly to have induced M. Trollet to venture upon a new hypothesis, and to suppose, that the actual seat of the specific virus is the mucous membrane of the bronchiæ or lower part of the trachea, rather than the fauces or the salivary glands; and had these last in every instance been discovered as clear of any manifest morbid appearance as in the dissections of this ingenious pathologist, there would be strong ground for his conjecture: but as we have already seen, that in some cases, there have been found only

* The doctrine that lyssa may be generated spontaneously is adopted by some approved physicians, among others by Dr. Francis, who remarks (Facts relating to Med. Jurisprudence), "that the causes by which spontaneous rabies may be induced are the violent emotions of the mind, sorrow, fear, rage, fright, the want of food, extreme fatigue, and the like." Dr. F. describes a case of spontaneous rabies which he attended in company with Dr. Hosack.—(See N. York Med. and Phys. Journal, vol. ii., p. 29.) Dr. Thacher has recorded a case of inflammation of the stomach, attended with spontaneous hydrophobia (see N. Y. Med. and Phys. Journal, vol. ii.), and Dr. Rush appears to have thought that many causes, independent of the bite of a rabid animal, are capable of producing it, and refers to the researches of Audry, "Sur la Rage."—D.

† The author overlooks the possibility of mistaking a tetanic affection for lyssa; yet the close approximation, which one disease frequently makes to the other, is acknowledged by all men of experience and observation.—Ed.

‡ Nouveau Traité de la Rage, Observations cliniques, Recherches d'Anatomie pathologique, et Doctrine de cette Maladie, &c., 8vo., Lyon, 1820.

slight marks of inflammatory action in the bronchæ, while the fauces and œsophagus, and occasionally the stomach and even the ileum, have been so inflamed as to approach a state of gangrene, much further investigation is necessary before the old doctrine should fall a sacrifice to the new.* The only fact we are at present able to collect from dissections, is a very extensive and violent disturbance throughout the entire frame; sometimes fastening chiefly on one set of organs, and sometimes on another.

The mode of TREATMENT is a field still perfectly open for trial; for, at this moment, we have no specific remedy, nor any plan that can be depended upon, after the disease shows itself.

Antecedently, indeed, to this period, our course is obvious, and particularly if we should be so fortunate as to be consulted at the time of the bite: it should consist in endeavouring, by the promptest and most efficacious means, to prevent the spread of the disease, by washing the part well and thoroughly at the nearest spring or river at hand, and by extirpating the virus before absorption has taken place. This has been done in various ways; for the lacerated part has been sometimes amputated or dissected out, and at other times totally destroyed by the actual or potential cautery. The actual cautery, by the means of irons heated to whiteness, was first adopted and recommended by Dioscorides (Lib. vi.), and afterward by Van Helmont, Morgagni (*De Sed. et Caus. Morb.*, ep. viii., art. 26), and Stahl: the potential cautery seems to have been proposed as a less terrific mode of operation, and has usually been accomplished by the means of lapis infernalis or decarbonated soda. It is recommended by Schenck, Pouteau, and Dr. Moseley. A notion, however, has obtained, from a very early period, that the irritation produced by a cautery, whether actual or potential, only increases the tendency to absorption; and Trampel has endeavoured to prove this (*Beobach. und Erfahr.*, &c., band ii., passim): on which account Hildanus and Morgagni have advised excision in combination with the cautery: the former proposing to cut out the eschar as soon as it is formed, without letting it remain for a spontaneous separation; and the latter, far more effectually, recommending that incision should follow the application of the knife, instead of preceding it.

Of these three modes of operating, the potential cautery is least to be depended upon; for it is not sufficiently rapid in its action. Of the other two it is, perhaps, of little consequence which is selected, and either of them will generally prove sufficiently efficacious alone, if employed early enough to anticipate absorption, and

extensively enough to make sure of extirpating or destroying every portion of the bitten part. There is reason to believe that, in many instances, this has not been done; so that Camerarius places as little confidence in the actual cautery as in the potential, and Dr. Hamilton almost as little in excision. And hence another reason for employing both means in the manner recommended by Morgagni; and in which case we shall find it unnecessary to superadd any of those irritant, exulcerant, or suppurative applications which have been employed by many practitioners with a view of introducing a fresh local action, and maintaining a fresh local discharge, and which have chiefly consisted of cantharides, camphire, alliaceous cataplasms, resins, turpentine, or, as Celsus recommends, culinary salt.—(*De Medicinâ*, lib. v., cap. xxvii., § 1.) It may likewise be advisable, as proposed by Sir Kenelm Digby, and since his time by Dr. Haygarth, to wash the wound again thoroughly with tepid water, or tepid wine and water, before the excision is commenced. M. Portal, however, thinks the application of the cautery, whether actual or potential, may be serviceable long after the wound has been inflicted, and even after it has healed, though he advises its use as early as possible.—(*Mém. sur la Nature et le Traitement de plusieurs Maladies*, tom. iv., 8vo., Paris, 1819.)

There is also another, and a very easy, and perhaps a very salutary operation, which I would strenuously recommend from the first, even before the process of ablation. I mean that of applying a tight ligature to the affected part, wherever it will admit of such an application, at a short distance above the laceration. I have never had an opportunity of trying the benefit of such a measure in my own practice; but analogy is altogether in its favour, for it is well known to be one of the most important steps we can take in confining the poisonous effects of the rattlesnake and other venomous animals, and of mitigating its violence by the torpor which follows; and it has the sanction of many authorities of deserved credit, as Hacquet, Percival, Vater, Wedel, and Trollet.*

* Trollet's belief that the hydrophobic poison is formed with and contained in the mucous secretion of the respiratory organs, never gained many partisans; for the traces of inflammation noticed by Trollet in those organs, and adopted as the ground of his doctrine, are well known not to be constant. M. Magendie dissected several rabid sheep, in which no marks of inflammation in any part of the lungs or air-passages could be perceived.—Ed.

* As the editor has already noticed, it is proved, by the ingenious experiments of Sir David Barry, that the commencement of the symptoms produced by vegetable, mineral, and reptile poisons, is synchronous with the consummation of absorption, and that their repetition is dependant upon its renewal. The same gentleman has also satisfactorily proved that absorption does not proceed under a vacuum. In the treatment of the recent bite of a rabid animal, therefore, he recommends, 1. The application of a powerful cupping-glass over the wound. This measure, he says, supersedes at once the ligature, ablation, excision, &c. during the period of its application, and for a certain time after its removal.—(See Exp. 5 and 7.) 2. After the cupping-glass has been applied for an hour at least, the whole of the parts wounded or abraded should be freely dissected out. 3. The cupping-glass should then be immediately re-applied. 4. Sir David Barry recommends the hermetical sealing of the vessels (as his expression is) with the actual cautery. 5. The part should be as little exposed to the contact of the air after the slough

If, however, the local plan should prove ineffectual, our curative practice, as already observed, is still unfortunately all afloat, and we have neither helm to steer by, nor compass to direct our course. There is indeed no disease for which so many remedies have been devised, and none in which the mortifying character of vanity of vanities has been so strikingly written on all of them. In the loose and heterogeneous manner in which they have descended to us, they seem indeed to have followed one another with-

comes away, and as soon healed up as possible.—(See *Exper. Researches*, &c., p. 149, et seq.) If the bite of a decidedly rabid animal were to be in one of the fingers, to which a cupping-glass could not be effectually applied, immediate amputation of the part would be prudent. The performance of this operation, previously to the commencement of the symptoms, is a very different practice from that of amputating parts after the symptoms have begun. A few years ago a limb was amputated in Guy's Hospital under the latter circumstances, without the least check being put to the disorder. Unless, however, a limb were bitten in many places, or very deeply in parts not admitting of excision, as through the tarsus or carpus, the editor conceives that amputation would not be warrantable, either before or after the accession of the symptoms; 1st, because the severity of the mutilation is too great to be encountered for the prevention of a disorder that is not certain of coming on at all; 2d, because the above mentioned proceedings would supersede the necessity for so severe a measure. According to Dr. Marochetti (*Magendie, Journ. de Physiol.*, tom. v., p. 279), there is only one means of preventing the development of hydrophobia, viz. that of discharging the hydrophobic poison as soon as it is formed; and he asserts that the situation where this takes place is on each side of the frænum of the tongue, where one or two little vesicles or tubercles present themselves. The period when they become manifest, he says, cannot be stated with precision; but, when they occur, it is commonly between the third and ninth day from the bite. When they are examined with a probe, he remarks, that a fluctuating liquid may be perceived in them which is, in fact, the hydrophobic poison, and which, if not discharged in twenty-four hours, is generally absorbed, and no vestiges of it remain. When a person has been bit by a rabid animal, Dr. Marochetti examines the frænum once or twice every day for forty-two days, and if the vesicles or tubercles do not appear in that time, he considers it certain that the patient has not been infected. When, however, they are seen, he opens them freely, directs the patient to wash the mouth with a gargle, and applies caustic to the cuts or incisions. Afterward, he prescribes genista in the form of decoction or powder. With respect to the vesicles or tubercles on each side of the frænum, M. Magendie apprehends that Dr. Marochetti may have mistaken the natural appearances of the orifices of Warton's ducts for the vesicles supposed to contain the hydrophobic virus. Here we see also, that Marochetti starts an hypothesis which interferes very much with prevailing opinions, already noticed, concerning the long dormant state of the poison in the bitten part, or the production of a similar poison by the vessels in this part at a late period after the bite, in consequence of the influence of a germ of the virus supposed still to continue there. Dr. Marochetti's assertions, however, require confirmation.—Ed.

out rational aim or intention of any kind. Yet, if we nicely criticise and arrange them, we shall find that this is not the case.

There are four principles by which physicians appear to have been guided in their respective attentions to this disease. That of stimulating and supporting the vital power, so as to enable it to obtain a triumph in the severe conflict to which it is exposed; that of suddenly exhausting the system by severe bleedings and purgatives, as believing the disease to be of a highly inflammatory character; that opposing the poison by the usual antidotes and specifics to which other animal poisons were supposed to yield; and that of regarding the disease as a nervous or spasmodic, instead of an inflammatory affection, and, consequently, as most successfully to be attacked by an antispasmodic course of medicines and regimen.

The very popular use of ammonia and camphire may, by some, be ascribed to the first of these views, as being powerful stimulants; yet, in fact, they were rather employed from different motives, and fall within one or two of the principles of action which yet remain to be considered. But to this class of medicines, designed expressly to support the vital power, and enable nature herself to triumph in so severe a struggle, belong expressly the warm and cordial confections and theriacs that were at one time in almost universal estimation; as also various kinds of pepper given in great abundance, oil of cajeput, different preparations of tin, copper, and iron, and, in later periods, bark.

In direct opposition to this stimulating and tonic plan, was that of suddenly debilitating and exhausting the system, upon the hypothesis that the symptoms of canine rabies were those of violent and rapid inflammation. The practice of applying ice or the coldest water to the head, and of submersion in cold water, belongs mostly to this view of the subject, as used a century ago, though in the time of Celsus it was employed in a much slighter degree to take off the spasm of hydrophobia, and to quench the thirst that accompanied it. "*Miserrimum genus morbi; in quo simul æger, et siti et aquæ metû cruciatur: quo oppressis in angusto spes est.*"—(*De Medicinâ*, lib. v., cap. xxvii., sect. 2.) In this almost hopeless state, the only remedy (*unicum remedium*), Celsus continues, is to throw the patient instantly, and without warning, into a fishpond; alternately, if he have no knowledge of swimming, plunging him under the water that he may drink, then raising his head; or forcing him under it if he can swim, and keeping him below till he is filled with the water; so that the thirst and water-dread may be extinguished at the same time. But there is here, continues our author, another danger, lest the body of the patient, exhausted and worn out by the submersion as well as by the disease, be thrown into convulsions: to prevent which, as soon as he is taken out of the pond, he is to be put into warm oil.—(*Cels.*, loco citato.)

The bolder practitioners of subsequent times, in pursuing the refrigerating plan, were regardless of convulsions, and persevered at all haz-

ards in reducing the living power to its last ebb; believing that the nearer they suffocated the patient without actually killing him, the greater their chance of success. Hence Van Helmont kept the wretched sufferer under water till the psalm "*Miserere*" was sung throughout, which, under some choristers, occupied a much longer time than under others; and, in the experiments of the Members of the Académie Royale, we meet with instances of a still more dangerous pertinacity, though success is said to have accompanied one or two of them. Thus, M. Morin relates the case of a young woman, twenty years old, who, labouring under symptoms of hydrophobia, was plunged into a tub of water with a bushel of salt dissolved in it, and was harassed with repeated dippings till she became insensible and was at the point of death, when she was still left in the tub, sitting against its sides. In this state we are told, she was at length fortunate enough to recover her senses; when, much to her own astonishment, as well as to that of the by-standers, she found herself capable of looking at the water, and even of drinking it without choking.—(*Hist. de l'Académie Royale*, Ann. 1709.)

With respect to the warm oil-bath, which Celsus recommends in succession to that of cold water, the present author can say, that, in a single instance to which he was a witness when a young man, it produced no benefit whatever. It was prescribed by a physician in consequence of the recommendation of Celsus, but who certainly had not read him attentively, nor was acquainted with the scope of his reasoning. For, in this case, cold bathing had not been tried antecedently, and consequently there was no danger of those convulsions for which alone the Roman physician enjoins the use of the oil. The experiment, however, was so far perfect, that the tub was full of oil, and deep enough to reach the patient's chin.

In connexion with the cold bath thus persevered in to suffocation, the reducent or antiphlogistic plan was still farther forwarded, at one time, by the use of strong drastic purgatives, of which colocynth was, for a long period, the favourite (*Hellot, An de Morsis à Rabido Colocynthis?* Paris, 1676); and at other times by a very bold and perilous use of the lancet.

Bleeding has lately been revived, and carried to the extent of delirium by large and rapid depletions, and the operation has been repeated almost as long as the powers of life would allow. Dr. Nugent employed it at Bath, in 1753, in one case, and the patient was restored, but musk and other antispasmodics were largely employed at the same time: and Dr. Schoolbred of Bengal has since had two patients who recovered under this process; but he employed mercury at the same time, and it is by no means certain, either from the history of the patients, or of the dog by which they were bitten, that the disease was a genuine lyssa.

Yet, whatever benefit this practice may possess, it has no pretensions to novelty; for there is not a single course of treatment ever invented for this intractable disease, that has been

for upwards of a century more extensively tried and re-tried, both moderately and profusely, or excited a warmer controversy upon its merits. Poupert, in 1699, espoused the practice, and gives the case of a woman, who perfectly recovered by bleeding her to delirium, and afterward confining her for a year to bread and water.—(*Hist. de l'Acad. des Sc.*, An. 1709.)

Berger, in the same year, recommended bleeding, but advised that the blood should be taken from the forehead. In the Breslaw Collections for 1719, is the case of a cow supposed to be rabid, and said to be cured by profuse bleeding. And the Philosophical Transactions abound with similar histories, some of them purporting to have been attended with similar success, derived from human subjects; but most of them too loosely given, or too undecided in their symptoms, to be in any measure entitled to reliance. That of Dr. Hartley and Mr. Sandys was, at one time, appealed to as demonstrative. It is the case of a groom who was bitten by a dog, supposed to be mad, towards the end of November, and who sickened about the middle of January ensuing; he had an aversion to drink, and was conjectured to be labouring under rabies. Venesection was here trusted to almost entirely, and every repetition of the lancet seemed serviceable: in consequence of which he lost a hundred and twenty ounces of blood in the course of a week, by different depletions, which consisted of sixteen or twenty ounces at each time. The man recovered: but few readers will believe him to have been really rabid, when they learn that, although he had an aversion to drink, he swallowed liquids; that his chief symptoms were sickness, trepidation, a faltering speech and memory; and that, through the whole course of the disease, he attended, though with some difficulty, to his duty in the stable.—(*Phil. Trans.*, year 1737-8.)

The Edinburgh Medical Commentaries are equally replete with cases in which the same plan of evacuation had been tried; but they are also equally unsatisfactory. Thus, Dr. Tilton informs us, that having heard of the recovery of a patient from the disease before us, who had bled profusely and almost to death, by an accidental fall from a high place, and a division of the temporal artery, he employed venesection freely in a case of his own, drawing off from twenty to thirty ounces at a time, and occasionally bleeding to delirium.—(Vol. vi., p. 432.) But the symptoms are here also so doubtful, that the result is of no importance.

The practice, therefore, has been not uncommon for at least a century and a half; and had it proved as specific as some late reports would induce us to believe, it must have descended to us with a wider and more confirmed reputation, and formed the only course to be relied on. But the misfortune is, that however salutary at times, it has often completely failed in the hands of unprejudiced and judicious practitioners; and where it has succeeded, it has generally been combined with other means that have been resorted to at the same time. There is a case of failure related by Dr. Plummer in the Edinburgh

Medical Essays (vol. v., part ii.); but it is not much to be relied on, as not more than twenty ounces of blood was lost at a second and accidental bleeding, and only ten a day or two before by a prescribed venesection. Mr. Peters however, who employed profuse and repeated bleedings, sometimes even to deliquium, had in his day so little dependance on them alone, that he uniformly combined this remedy with opium and mithridate, or other cordials; and in the case which he has introduced into the Philosophical Transactions, he ascribes the success which accompanied his plan to this combined mode of treatment.—(*Phil. Trans.*, 1745, No. 475.) In like manner, Mauchart, as quoted by Bühlmeier, while he advises bleeding, and to an extent proportioned to the length of the interval between the infliction of the wound and the attack of the paroxysm (and where the patient is of a melancholy temperament, even to deliquium), advises at the same time, that the bitten part be scarified; and when this also has bled till nothing but serum escapes, that the wound be dressed with mithridate, theriaca, or rue, and a defensive plaster put over it, and that the patient take pills, compounded of mithridate and other materials, to the number of nine every day, for nine months, keeping himself in a free perspiration, and cautiously changing his linen.

In the case of dogs, venesection, how liberally soever made use of, does not seem to be of much benefit. It has lately been the subject of a series of experiments at Paris, under the superintendence of MM. Magendie, Dupuytren, and Breschet, who have carried it to deliquium, but without any success whatever. And hence, though it has unquestionably been serviceable, in many cases, the practice cannot be regarded as a specific.

To close the whole, Professor Trollet has employed venesection so extensively, and in such variable proportions, from single or double bleedings of sixteen ounces each to not less than *seven pounds*, by different bleedings in the course of a few hours, and in every instance so entirely without effect, as reasonably to put the question at rest for ever. And the more so as, in his hands, the bolder the practice, the sooner the patient fell a sacrifice to it. We have a striking example of this in the case of the patient just referred to, whose interval between the infliction of the wound and the signs of the disease extended to upwards of five months. Early on the morning in which the hydrophobia first appeared, bloodletting to syncope was prescribed, and five pounds were drawn off before this effect was produced. The water-dread returned with the return of recollection; and, at eleven o'clock on the same morning, he was again bled to the amount of eighteen ounces, when he again fainted. The spasms of the chest and throat became more permanent. At three o'clock, fourteen ounces more were taken away, when deliquium followed, succeeded by a considerable augmentation of the spasms, in extent as well as in violence. At seven in the evening, the respiration became frothy as well as difficult, the difficulty increased, and the patient expired in a

few minutes, about twelve hours only after the commencement of the hydrophobia.

The poison of rabies has, by a numerous body of pathologists, been contemplated as of a nature akin to the poison of other venomous animals, and particularly serpents, and consequently best to be opposed by the usual remedies and specifics, to which these are found most effectually to yield. And hence in the first place, the use of the *radix Mungo* of Kämpfer (*ophiorrhiza Mungos*, Linn.), still supposed to be a specific for the bite of the cobra di capello and the rattlesnake. In India and Ceylon, it is used to the present day as an antidote against the bite of the mad dog: Kämpfer highly extols it, and Gremmius, who practised with great reputation at Columbo, employed it very largely.

Acids and alkalis belong to the same class of antilyssics. Of the former, Agricola, who was hostile to the depleting system, preferred the muriatic acid, and regarded this as a specific (*Chirurg.*, p. 391) even when restrained to a topical application. Poppius preferred the sulphuric; but, by far the greater number of practitioners, the acetous was held in most esteem. Many combined this last with butter, and used it both internally and externally: Wedel, with other materials; "as a cure," says he, "for the bite of a mad dog, let the patient drink vinegar, theriaca, and rue."—(*Exerc. Semiot. Pathol.*, cap. 8.)

The general suffrage, however, was far more considerable in favour of the alkalis, and especially of ammonia. There is some reason for this preference. It is well known that ammonia is a valuable medicine, whether applied externally or internally, against a variety of animal poisons. I have successfully used it more or less diluted, in various instances, as a lotion against the sting of wasps and bees, and the bites of gnats and vipers; and I have seen it of great service in checking the poison of the rattlesnake, and restraining the extent of the inflammation. On the continent, and especially in France, the usual form in which ammonia was formerly employed in cases of lyssa, was that of the *eau de luce*, a caustic spirit of ammonia, prepared with quicklime combined with rectified oil of amber, rendered more easily miscible by being rubbed into half its weight of soap. This was in general employed both externally and internally,* though we have several reports of a successful use of it when confined to an internal trial alone; especially one related by M. Hervet (*Journ. de Médecine*, tom. lxii.), and another by M. Rubiere.—(*Id.*, tom. lxiv.)

Mercury, from its proving a specific in syphilis, and more especially from its specific action on the salivary glands, the immediate outlet of the poison of rabies, has had a strong claim to general attention; and has been very extensively tried in various forms. It was first recommended by Desault of Bordeaux, in 1736, and afterward very confidently by Dr. James, in our own

* Sage, Erfahrungen, &c., p. 49; Guettard, Mémoires sur différentes Parties des Sciences et des Arts, p. 122, Paris, 1763.

country, as a certain cure for man and other animals. He used it both as a prophylactic at the time of the bite, and an antidote at the commencement of the disease. He employed it as well externally as internally; but his favourite form was that of the turbeth mineral, in the shape of pills. He has published a full account of his success with this medicine on Mr. Floyer's hounds, after they had made a trial of every other favourite and fashionable remedy in vain. These dogs, as we have already observed, were affected with a severe hydrophobia, which has been denied by some writers to be a symptom of the disease as appertaining to quadrupeds. All the hounds, we are told, that were salivated with the mercury, in whatever stage of the malady, recovered, and the rest died.—(*Phil. Trans.*, vol. xxxix., year 1735-6.) His experiments on mankind are less complete: for they amount to not more than three, and in each of these the medicine was employed as a preventive, shortly after the affliction of the bite; and hence, as the patients never became rabid, we cannot be sure that they had received the contagion, or would have had the disease had the mercury never been employed. The muriate of the metal was another favourite form, which, by Loisy, was used together with inunction.

The grand object was to excite a speedy salivation, and maintain it so long as there was supposed to be any danger; and especially where the administration had been delayed till the paroxysm had shown itself. Frank, Girtanner, De Moneta, Raymond, and a host of writers upon the subject, deny not only that mercury is a specific, but that it has ever produced a cure, in whatever way it may have been employed. Kaltschmid, on the contrary, with an unjustifiable confidence, calls it *remedium indubium*,* and De Choiseul a *méthode sure et facile*.† In the fortieth volume of the *Journal de Médecine*, there is a relation in which mercurial inunction seems to have been successful in a genuine case, and I have heard of one or two other instances that have occurred in our own country.

As diuretics were supposed to possess a strong alexipharmic power, or that of expurgating the system from animal poisons in general, these have also had their votaries, and been in high reputation as a remedy for lyssa. Cantharides were at one time the favourite medicine under this head, or some other stimulant insect of the coleopterous order, as the meloe, lytta, or one or two species of scarabæus; which, like mercury and ammonia, were sometimes taken internally alone, and sometimes applied topically also, to keep up a perpetual irritation. Bohadsch tells us gravely, that the disease will always yield to ten cantharides powdered and introduced into the stomach.—(*Posit. Zoolog. in Klinkosch. Diss. Select.*) Monconys, that the

powder should be continued from the bite to the time in which we may reasonably expect the symptom of hydrophobia; and adds, that this medicine, which was regarded as an arcanum in his day, was a remedy of publicity over all Greece.—(*Voyages*, i., p. 406.) He might have extended his theatre; for Egypt was as well acquainted with the general principle of this practice as Greece or Hungary; and it is a positive exhortation of Avicenna, that whatever diuretic may be employed should be carried to its utmost acrimony, even to the discharge of bloody urine.—(*Lib. iv.*, *Fen. vi.*, *Tr. iv.*) M. Axter of Vienna has of late revived the use of cantharides, and tells us, that he has for thirty years employed this medicine with far more success than any other, after having previously made experiments with and been disappointed in the use of all other remedies, as musk, camphire, belladonna, opium, or oil, used internally and externally, and water bathing. But it does not seem that he can speak further than to its supposed prophylactic powers, as he does not appear to have tried it in the acute stage of the disease.—(*Nouv. Biblioth. Germ. Medico-Chir.*, Paris, 1821.)

The ash-coloured liverwort (*lichen terrestris cinereus Raii*) was another diuretic of great popularity, and which seems at length to have triumphed over the stimulant insects, and to have superseded their use; on which account Linnæus changed its trivial name from *cinereus* to *caninus*. In our own country, this medicine was at one time peculiarly in vogue. It was given in powder, with an equal quantity of black pepper, a drachm and a half of the two forming the dose for an adult, which was taken for four mornings, fasting, in half a pint of warm cow's milk; the patient, however, was first to lose nine or ten ounces of blood, and afterward to be dipped in cold water for a month together, early in the morning. And such was the general confidence in this plan, or rather in the antilyssic power of which the lichen was supposed to be the most active principle, that its virtues formed one of the most common subjects of eulogy in the *Philosophical Transactions* at the time when Mr. Dampier introduced it to public notice at an early period of the history of the Royal Society (*Mechanical Account of Poisons*, art. 3); while, at the earnest solicitation of Dr. Mead, the powder was admitted in the year 1721 into the London Pharmacopœia, under the title of pulvis antilyssus; who declares that, "when united with the previous venesection and subsequent cold bathing, he had never known it fail of a cure (*Chirurg. parv. Nuriib.*, &c., 8vo., 1643), though he had used it a thousand times in the course of thirty years practice."

How far emetics may be serviceable, general trial has not perhaps been sufficient to determine. They have often been found capable of relieving spasms of the throat, and enabling the patient to swallow liquids, when every other plan has failed. They were hence recommended by Agricola, but only perhaps on account of their violence upon a weakened frame, as a sort of forlorn hope, for he does not advise them till

* *Dissertatio de Salivatione Mercuriali, seu indubio præservationis et curationis remedio adversus rabiem caninam*, Jan., 1760.

† *Nouvelle Méthode, sure et facile, pour le Traitement des Personnes attaquées de la Rage*, Paris, 1756.

after the third day. Dr. Satterley, however, has given a case in the Medical Transactions which he regards as rabies, in which vomiting was employed from an early period of the disease, and with very decided advantage.—(Vol. iv., p. 343.) But there seems to be a doubt whether the patient here referred to laboured under genuine lyssa. He had been bitten three months before by a dog, but the fate of the dog was not known; the cicatrix betrayed no uneasiness or irritation precursive to the disease, or during its course; the hydrophobia was remittent or intermittent, so that the patient drank liquids at times with tolerable ease; the spastic action ran to a greater extent over the muscular system than usual, so as at one time to produce emprosthotonos; and the patient did not expire till at least a week after the attack: all which are very unusual symptoms in lyssa, and have seldom if ever been combined in the same individual.

In lyssa, however, the nervous system appears to be that which is by far the most severely tried, and to which the disease may be most distinctly referred. And hence it is not to be wondered at that antispasmodics and sedatives should also have been had recourse to very extensively, and obtained a very general suffrage. In effect, whatever benefit in this disease has at any time been derived from ammonia, camphire, or cold bathing, it is more easy to resolve their palliative or remedial power into the principle of their being active antispasmodics, than to any other mode of action. The more direct antispasmodics and sedatives, however, employed in this malady, were musk, opium, belladonna, nux vomica, tobacco, and stramonium. The last has been chiefly tried in India, where three drachms and a half of the leaves, infused in a very large portion of water or other common drink, and swallowed daily for three days in succession after the bite, was at one time a very approved and popular remedy.

Musk, opium, and belladonna, however, are the antispasmodics which have been chiefly depended upon in Europe. They have sometimes been given in very large doses alone, but more generally in union with other medicines. Cullen seems doubtful of the powers of either, apparently from not having had sufficient opportunities of witnessing the disease and their effects upon it, and hence refers us, in both instances, without venturing upon any decisive opinion of his own, "to the labours of the learned industrious Société Royale of Paris, who have taken much pains and employed the most proper means for ascertaining the practice in this disease."—(*Materia Medica*, vol. ii., pp. 252, 380.) With respect to musk, he admits, however, that Dr. Johnston has given us two facts that are very much in favour of its power: and "I have," says he, "been informed of an instance in this country of some large doses of musk having proved a cure after symptoms of hydrophobia had come on."—(Ibid.) Hilary says, "in these cases it acts as a sudorific;" and Gmelin regarded it as a specific antidote.—(*Diss. de specifico antidoto novo adversus effectus morsu canis rabidi*, Tub., 1750.)

Vol. II.—U

Opium, in like manner, when employed alone, was given in large doses, and we have numerous cases on record in which this, like the preceding medicines, is said to have operated a cure.—(*Dantzic, Gazette de Santé*, 1777, p. 51.) But, unfortunately, neither musk nor opium, in whatever quantity employed, has been found successful in general practice. Tode more especially has pointed out the inefficiency of the latter, in the largest doses referred to (*Annalen*, ix., p. 33), and Raymond has confirmed his remarks.—(*Med. Observ. and Inquiries*, vol. v.) But a late experiment of Professor Dupuytren, of the Hôtel Dieu, has given a still more striking and incontrovertible proof of its utter inefficacy, if not in all cases of the disease, in certain states and circumstances. Surlo, a man aged twenty-four, had been bitten by a dog sufficiently proved to be mad, had been cauterized immediately afterward, and been discharged as supposed to be cured. In about a month from the time of the bite, he was attacked with rabies in its severest symptoms, and conveyed to the hospital. Opium was the medicine determined upon, and as the constriction of the throat prevented it from being given by the mouth, a gummy solution was injected into the veins, for which the saphæna and cephalic were alternately made use of. Two grains of the extract were in this manner thrown in, and the patient was in some degree tranquilized for an hour or two: the dose was doubled towards the evening of the same day. It was repeated at intervals, and at length increased to eight grains at a time. The relief it afforded, however, was never more than temporary, and he expired on the fifth day from the incursion.* M. Trollet used it freely in the form of pills, in combination with belladonna; but in no instance had he reason to boast of his success, though he gave in some cases twenty-seven grains of opium, and nine of the extract of belladonna, in the course of twenty-four hours. Professor Brera employed the belladonna, but united it with mercury instead of with opium: his doses were carried gradually to a great extent, inasmuch that the patients at length took the powdered root of the belladonna to the amount of three drachms a day; and in about forty-four or forty-six days swallowed seven ounces and a half of this drug, and ten grains of corrosive sublimate, besides rubbing in some ounces of mercurial ointment.—(*Mem. Soc. Ital. Scienz.*, tom. xvii., Modena.) The object was to keep the system as much as possible under the influence of mercury, evidenced by ptyalism, and of the narcotic effects of belladonna, so long as the combination was continued. As a preventive, it seems to have been successful; though several of the patients appear to have advanced to the first symptoms of acute affection, having had some degree of water-dread, and recurring irritation in the bitten parts, the disease did not proceed beyond these initiary steps. But we have no proof of success from this plan after the

* Orfila, *Traité des Poisons*, &c. The extract of belladonna in solution and other narcotics, have likewise been injected into the veins without success.—Ed.

pathognomonic signs had shown themselves. The warm bath was also combined with the above practice. In like manner, musk, opium, and belladonna have been all united; and sometimes combined with camphire, oil of amber, inunction with olive oil,* or bleeding. Musk was also at one time very generally combined with cinnabar, and in this form supposed to be peculiarly efficacious. The famous powder employed by the natives of Tonquin, and introduced into this country by Mr. Cobb, on which account it was called *pulvis Cobbii*, or *Tunguensis*, consisted of sixteen grains of musk with forty-eight grains of cinnabar, mixed in a gill of arrack. This, taken at a dose, is said to have thrown the patient into a sound sleep and perspiration in the course of two or three hours: and where it did not, the dose was repeated till such effect was produced. And this medicine also was regarded as a specific during the short career of its triumph, and a cure was commonly supposed to follow the administration of the medicine.

The sedative power of several of the preparations of arsenic, however, had perhaps a fairer pretension than any of these, and especially as, like mercury, it has for ages been employed with decided benefit in Asia in the case of syphilis. Agricola mentions its use in his day (*Comment. in Popp.*, p. 54), but the forms in which it was then employed were rude and incommensurable, and they do not appear to have been followed with much success. It is to be regretted, however, that even in the elegant and manageable form of Dr. Fowler's solution, it has not been found to be more efficacious. It has of late years been tried internally in various cases, and particularly, with great skill and in full doses, by Dr. Marcet; but in every trial it has disappointed our hopes. Applied externally, as a preventive to the bitten part, Dr. Linke of Jena thinks it has succeeded; but as his trials were made on dogs inoculated from the froth of rabid animals after death, no dependance can be placed on them.

Under this head I may also observe, that the Prussic acid has occasionally been had recourse to, but without any apparent benefit. In the form of the distilled water of the *prunus Lauro-cerasus*, it was not long since made a subject of experiment at Paris by Baron Dupuytren, who injected this fluid into the veins of various dogs, and appears to have done so in one instance into those of a man: but in every case without effecting a cure.

There are two or three other remedies, which it is difficult to arrange, but which have also acquired a considerable celebrity in the cure of lyssa; and hence it is necessary to notice them.

The first is the Ormskirk medicine, so called from its preparer, Mr. Hill of Ormskirk, supposed, for the inventor could not be prevailed upon to publish his secret, to consist of the following materials: powder of chalk, half an ounce; ar-

menian bole, three drachms; alum, ten grains; powder of elecampane root, one drachm; oil of anise, six drops. The single dose, thus compounded, is to be taken every morning for six times in a glass of water, with a small proportion of fresh milk. If this be the real formula, and the analysis of Dr. Black concurred with that of Dr. Heysham in determining it to be so, the inventor seems to have contemplated the specific virus to be an acid, for the basis of this preparation is unquestionably an alkaline earth. And with regard to its occasional efficacy, the latter writer, following the general current of opinion of the day, informs us, that this has been so thoroughly established by experience, that there can be no room to doubt it. Dr. Heysham himself, however, admits of various cases in which it failed, while in many instances his successful ones do not afford proofs of an existence of the genuine disease.—(*Diss. Med. Rabie Caninâ*, 8vo.)

The second of the anomalous remedies I have just referred to, might possibly have been introduced under the head of the common antidotes for the bites of venomous animals; but as it has reputed powers in some degree peculiar to itself, it is best to notice it separately. This is the alyssum, or *alysma Plantago* (madwort plantain), of established reputation in America as a specific for the bite of the rattlesnake, where it seems to rival the imprescriptible claims of the *opiorrhiza Mungos*, though its juice is generally given in combination with that of the common horehound—an addition that certainly does not promise much accession to its strength.

This species of alyssum has for some ages been a popular remedy for canine madness, especially in the north of Europe: and in a late communication to Sir Walter Farquhar in the Russian tongue, translated and published in Mr. Brande's *Journal of Sciences and the Arts*, No. ix., p. 142, we are told that it still retains its popular sway and reputation over a great part of the Russian empire; and that in the government of Isola it has never failed of effecting a cure in a single instance for the last five-and-twenty years. The preparation is simple: the root is reduced to a powder, and the powder is to be eaten by being spread over bread and butter. Two or three doses are said to be sufficient in the worst cases, and will be found to cure mad dogs themselves.

The butcher's broom (*genista tinctoria*), and side-leaved scull-cap (*scutellaria laterifolia*), have however rivalled the reputation of the plantago; and, in our own day, the first is powerfully recommended by M. Marochetti of Moscow, in the St. Petersburg Miscellanies of Medical Science, as employed with great success in the Ukraine; and the second by Dr. S. Spalding of New-York, who tells us that it has been successful in America in upwards of a thousand cases, not only in men, but in dogs, swine, and oxen.*

* Vater, Pr. de Olei Olivarum efficaciam contra morsum canis rabiosi, experimento Dresdæ facto, adstructâ, Viteb., 1750.

* Chymical analyses have shown this plant to be nearly inert.—See N. York Med. Repository, vol. xiv.—D.

The next remedy I have to notice is also of extensive use in the present day, and comes before us with no mean authority. While the medical practitioners of the east are pursuing their plan of abstracting rabid blood from the system, as the surest means of curing canine madness, the physicians of Finland have undertaken to accomplish the same effect, by introducing rabid blood into the morbid frame. In the second number of the *Hamburgh Medical Repository*, Dr. W. Rithmeister, of Powlowsk in Finland, has given an article, in which he has collected a multiplicity of striking cases, and various authorities in proof that the blood of a rabid animal, when drunk, is a specific against the canine hydrophobia, even where the symptoms are most strongly marked. The rabid wolf-dog, or other quadruped, is for this purpose killed, and its blood drawn off and collected as an antilyssic ptisan. Dr. Rithmeister's communication contains a letter to himself from Dr. Stockmann of White Russia, confirming this account, and stating the practice to be equally common and successful in his own country.

I will only add, that a discussion has lately taken place between two Italian physicians of distinguished reputation, Professor Brognatelli of Pavia, and Professor Valetta of Milan, upon the virtues of chlorine as an antidote for the disease in question. The former has strongly recommended it (*Giornale di Fisica, &c.*, Pavia, Dec., 1816), and the latter has denied that it is of any use (*Biblioteca Italiana*, Gennaj., 1817): in answer, however, to which denial, Professor Brognatelli has adduced various authenticated facts, by which what he calls the *specific* powers of the chlorine have been established and verified.—(*Giornale di Fisica, &c.*, Pavia, Febraj., 1817.*)

I have thus endeavoured, upon a subject of so much interest and importance, to put the reader into possession of the general history of the practice that has hitherto prevailed; and he

* M. Magendie (*Journ. de Physiol. Expér.*, tom. i., p. 44, &c.) conceived, that the sudden production of an artificial plethora might have the effect of arresting this ungovernable disease, and with this view he injected about a pint of warm water into the veins of a hydrophobia patient; but though the operation relieved for a time the violence of the symptoms, death took place nine days after the experiment. The patient having lived, however, much beyond the usual period after the dread of water had commenced, hopes were entertained that this plan might prove more successful in subsequent cases; but experience has now fully shown, that the injection of water into the venous system, is of as little use as every thing else that has hitherto been suggested for the purpose of curing the disorder, after it has been decidedly formed. The guaco, a vegetable matter employed in South America as an antidote for the bites of serpents, has been strongly recommended as a remedy for hydrophobia. It has been tried in this country by Dr. Roots, Dr. Elliotson, and others; and though in one or two instances a temporary amendment followed its exhibition, the patients all died about the usual period, namely, on the third or fourth day from the commencement of decided hydrophobia.—ED.

will at least allow, that if the result be highly unsatisfactory—as most unsatisfactory it is—such conclusion does not result from idleness on the part of the medical profession.*

But how are we to reconcile the clashing and contradictory statements which the present analysis unfolds to us? This is a question of no easy solution. Yet there are many circumstances which ought to be borne in memory, and will, in a certain degree, account for such opposite views and decisions, without rudely impeaching the veracity of any of the experimenters.

In the first place, it is possible, that the morbid poison itself, like that of plague or intermitting fever may vary in its degree of virulence, in certain idiosyncrasies, certain countries, or certain seasons of the year; and hence that a medicine which has proved useless in general practice, may succeed in particular persons, particular places, or at particular periods; or if inactive in itself, may be employed in so much milder a degree of the disease, that the constitution may be able, in most or many instances, to triumph over it by its own powers alone.

It is a just remark of Celsus, that *omnis ferè morsus habet quoddam virus* (*De Medicinâ*, lib. v., x.); and we have already given proof, that this is particularly the case when the animal that bites is labouring under the influence of violent rage or other sensorial excitement; the symptoms incident upon which produce a severe effect upon the nervous system, and often stimulate those of the genuine lyssa. And hence there can be little doubt, that these symptoms have often been mistaken for lyssa, and have given celebrity to the medicines employed for their cure, to which they were never entitled. In various cases, as we have already seen, the disease commences almost coetaneously with the external injury, or inoculation; in others, not till months or even years afterward. In some instances, the first symptoms of the disease show themselves in the bitten part, and even this in a very different manner; for there may be a troublesome sense of numbness, or of irritation; and this irritation may be confined to the cicatrix, or travel up the limb, and produce acute pain or spastic action: while, in other instances, there is no local affection whatever through the entire progress of the malady. Ordinarily speaking, hydrophobia or water-dread is one of the most common as well as one

* According to Roche and Sanson, no less than 300 medicines have been proposed as specifics for hydrophobia. The American editor, however, would add but few remedial agents to those already mentioned. Dr. Ramsay of South Carolina recommended the treatment by alkalis, as alluded to in a previous page. The *sapo* or *contreculibri*, another American remedy, has been sometimes employed; the seeds of this plant are preferred, but if these cannot be obtained, the leaves may be used. Dr. Becariè of New-Spain, speaks warmly of its efficacy.—See *Med. Repository*, vol. xvii. The vapour bath has been introduced into practice lately by M. Brisson. He has succeeded in curing upwards of 80 patients with it. It is employed at a temperature of 108° F.—D.

of the severest symptoms of the disease; yet there are instances, even where the rabies has terminated fatally, in which water-dread has not been once complained of. Most commonly again, on an early examination after death, the fauces and parts adjoining are found red and inflamed; but we have already observed, that Morgagni dissected patients in whom there was no such appearance whatever: and in two bodies, examined after death by Dr. Vaughan, the fauces, œsophagus, stomach, diaphragm, and intestines, were all in a natural state.

There can be little or no doubt, moreover, where many persons are bitten in quick succession by the same rabid animal, that the poison is not equally introduced into all of them. In some cases it may be expended entirely upon the earlier victims, and hence the rest, though bitten, may be free from the virus; while in others, where the teeth have to pass through various foldings of clothes, it is possible that the virus which still remains may be wiped off in its passage, and the laceration be nothing more than a clean wound from the first. And in all such cases a sanguine experimenter, without allowing for these circumstances, will be apt to persuade himself, whatever medicine he makes use of, that the absence of the disease is owing to the efficacy of the plan or the medicine he has prescribed, and which he is hence tempted to hold up to the world as an antidote or specific.

Some of these remarks will best explain the very different results of the same mode of treatment, in the eleven patients intrusted in 1775 to the care of M. Blaise of Cluny, after having been dreadfully bitten and torn by a mad wolf. The principal remedy was mercurial inunction, though combined with antispasmodics. The mercury was carried on in all of them to salivation, and the treatment continued for above a month, in those that lived long enough for this purpose. One died with great horror and water-dread about the twelfth day from the injury, and after the mercury had begun to act. A second perished under hydrophobia, furious, and at length comatose, just at the close of a month, his mouth and gums being slightly affected by the mercury. A third died nearly six weeks after the commencement of the mercurial plan, having been taken away by his friends on the eighteenth day, apparently in a state of doing well. The remaining eight, after having exhibited greater or less symptoms of spasmodic affection, but never amounting to hydrophobia, are said to have recovered, and were discharged accordingly (*Méthode éprouvée pour le Traitement de la Rage*); but, in a subsequent work, M. Blaise informs us, that even one of these died in a paroxysm of hydrophobia six weeks after his discharge and supposed restoration to health.*

* Hist. de la Société de Médecine, tom. ii. Dr. Elliotson saw two little girls, sisters, who were bitten at the same moment by a dog, and in the same part, namely, the face. One of them died, and the sister had the symptoms which commonly usher in hydrophobia; but, after lasting four or five days, they ceased, and she recovered. Facts

In all these cases, the success is ascribed to the action of the mercury, and the want of success to some irregularity or other, committed by the patient while under medical care. The enormities, however, are in general rather far fetched, and not very convincing. Thus, in the last of the above cases, it is ingeniously observed, that the man who had been so long discharged as well, four days only before the symptoms of hydrophobia appeared on him, had thrust his arm down the throat of an ox which was said to be mad; though no proof is offered that the ox was really mad, nor is it pretended that even this reputed mad ox inflicted any bite upon the arm whatever. Who does not see, that in all these cases, the mercury may have been guiltless of exercising any control? that those who died may have died in consequence of an effective lodgment of the virus in the wound inflicted, and that those who survived may have survived because it obtained no admission to the bitten part?

It is moreover highly probable, that a spontaneous cure is occasionally effected by the strength of the constitution, or the remedial power of nature alone. The fact appears to be, that the disease requires about six or seven days to run through its course, at the expiration of which period the system seems to be exonerated, by the outlet of the salivary glands, of the poison with which it is infested. And hence, if by any means it be able to sustain and carry itself through this period, without being totally exhausted of nervous power in the course of so protracted and prostrating a conflict, it will obtain a triumph over the disease; and any prescribed medicine made use of on the occasion, will seem to have effected the cure, and will run away with the credit of having done so, till subsequent instances dissolve the charm, and prove beyond contradiction the utter futility of its pretensions. I have already had to observe, that the contagion of lyssa, though highly malignant, is neither remarkably volatile nor very active, and in every instance perhaps, requires some exciting or predisponent cause to enable it to take effect: but, as it seems to be more indecomposable than any other contagion we are acquainted with, it is capable of lying latent and undissolved for months, if not years, till it meets with a cause of this kind. And hence the very long and uncertain interval, which sometimes occurs between the attack of the rabid animal and the appearance of rabid symptoms, has often proved another source of deception; of which we have a singular example in Mr. Nourse's case, related in an early volume of the Philosophical Transactions (No. 445), which states, that a lad, who had been bitten in the thumb by a mad dog, took morning and evening for forty days a drachm of the pulvis antilyssus already described, and bathed in the sea for ten days in succession. He was in due time reported to be

of this kind prove, at all events, that the constitutional disturbance, preceding the occurrence of actual hydrophobia, is not absolutely irremediable, and that in this stage, the patient may be saved.—ED.

well, and the cure was altogether ascribed to the specific virtues of the antilyssic powder. He was shortly afterward cut for the stone, from which also he recovered: NINETEEN MONTHS after which operation, however, he was attacked with hydrophobia and the other symptoms of canine madness, and fell a victim to their violence. Had this patient died under the operation of lithotomy, or from any other circumstance in the interval, the virtues of the antilyssic powder would have obtained a complete, and indeed a rational triumph in this instance: and even now, there may be a question whether the appearance of the disease was not retarded by the plan pursued, though its specific power can no longer be maintained for a moment. The occasional exciting cause which, in this instance, at length gave activity to the dormant virus, is not pointed out to us. But it is difficult, if not impossible, to account without such a cause for the quickening of the lurking seminum of the poison at this time rather than at any other.* And the following valuable remarks of Dr. Percival, occurring in his manuscript comment on the author's volume of Nosology, in relation to this subject, are in full illustration of the same opinion.

"A wine porter was attended, in Dispensary practice, for a low fever: after a time appeared symptoms of lyssa; and much inquiry elicited the recollection of his having been slightly bitten by a dog six weeks before. In the interval he was convicted of some fraudulent practice in the cellar of his master, to whom he owed great obligation, and was dismissed with disgrace. Anxiety on this event seemed to produce the fever, which terminated in lyssa.

"Lately, an officer in our barracks was bitten by a dog, whose madness being recognised, the bitten part was excised immediately. After an undisturbed interval of two months, he was advised to go to England to dissipate the recollection of the accident: there he exercised himself violently in hewing wood; felt pain in the hand which had been bitten; embarked for Ireland; had symptoms of hydrophobia on board the packet, and died soon after his arrival.

"I have lately seen a case of hydrophobia treated ineffectually by most profuse bleeding and large doses of opium. Here too, the bitten part was extirpated by caustic within an hour. The patient was a man of steady mind, nor could any occasional cause be assigned for bringing the poison into action, except that a bilious diarrhoea was suddenly checked.

"From the varying period of attack we might infer, that the influence of occasional causes is very considerable. In the last patient hydrophobia supervened exactly five weeks from the time of the bite; he lost a hundred and eight ounces of blood in twelve hours, which sunk

him much; violent perspiration, and at length delirium, attended the water-dread: during the last twenty-four hours he swallowed, and recovered his senses; and died slightly convulsed while cutting an egg. These cases seem to point out agitation of mind and feverish excitation as powerful occasional causes."

In a disease so intricate as lyssa, a very complex treatment is by no means unpardonable; but it may fairly, I think, be questioned, whether the complexity and the energy of the means employed to produce a cure may not rather, in some instances, have had an opposite effect, and have hastened and confirmed a fatal issue. A patient bitten by a mad dog, having in vain tried and persevered in the use of the Ormskirk medicine, was next put under the joint care of Dr. Watson and Dr. Fothergill. Having been bled standing, as long as he could stand, he was next immersed in a warm bath, where he was ordered to remain till he again became faint; a clyster of milk and water, with a drachm of Dover's powder dissolved in it, was injected as soon as he was removed from the bath; half an ounce of mercurial ointment was at the same time rubbed into the legs and thighs, and three grains of thebaic extract given in the form of pills, two grains being ordered to be continued every hour till he became sleepy.

To stand the brunt of a treatment thus vigorous, would demand no ordinary constitution, even without the co-operation of any disease. But that the wretched sufferer should sink (as he did, in a few hours) under the assault of such a malady and such a mode of cure, cannot be matter of surprise.

The whole subject is afflictive, as well in respect to its treatment as its progress. But how, after all, is a young practitioner to proceed when he meets with a case of rabies? This is a most important question; and the following remarks, submitted with great deference as the result of some little personal experience and no small degree of reflection, are meant to meet it, and to point out the path which, in the present unsettled state of the subject, it may perhaps be most expedient to adopt.

From the whole of the preceding survey it is sufficiently clear that we have no direct specific for the cure of the disease; and hence, whatever plan we employ, must be palliative only. It appears also, that the disease consists in a poison of a peculiar kind, capable of assimilating some of the animal secretions to its own nature, and that the new matter, or contagion, hereby produced, continues to be eliminated for five or six days, principally, if not entirely, from the excretories of the salivary glands, as the inflammation of gout unloads itself on the extremities, and the specific matter of exanthems on the surface generally; and that at the expiration of this period, or as soon as such depuration has been effected, the disease abates, and the patient is restored. It appears also, that the disease is one of the most dangerous in the whole catalogue of nosology, and that few patients recover from it under any plan of medicine that has ever been devised; but that nevertheless,

* It deserves to be recollected, however, that modern practitioners do not puzzle themselves about the exciting cause, in cases where the syphilitic poison first produces constitutional symptoms several weeks or months after the application of the virus, and the formation of a chancre.—Ed.

some patients have recovered under almost every mode of treatment, however incongruous and contradictory to other modes; and hence, that many cases of restoration must be rather referred to a natural or spontaneous cure than to the virtue of medicines.

In this state of things, it seems reasonable that our first intention should consist, as in various other kinds of animal poisons communicated in the same manner, in supporting the system generally, and the nervous part of it more particularly, so that it may not sink under the violent excitement and augmented secretion which the organ of the nerves has to encounter during so perilous a struggle. And it is to this principle we have to resolve all the benefit which has at any time been found to result from the use of the stimulant theriacs and other cordials of the old practitioners. On this account, ether, ammonia, and camphire have a strong claim on our attention, and especially the two last, as they may be given in a solid form. All the pungent spices belong to the same class, as cardamom-seeds and capsicum, and may be adverted to as auxiliaries; nor should wine or even ardent spirits be refrained from, if the patient can be induced to swallow them; moderately through the entire course of the disease, but liberally and profusely as his strength declines. Our grand object must be to keep him alive, and prevent a fatal torpidity in the sensorium for a certain number of days, at any expense of stimulants, or of subsequent debility. Wine is profusely given with great success in the bite of the most venomous serpents of the East, and analogy justifies us in proposing it in the present instance.

Our next intention should be to diminish, as much as possible, the spastic action of the chest and fauces, and to prevent a return of the exacerbations. And to this end as much quiet and composure as we can possibly procure, under so restless a state of body, seems imperatively called for, and is far more likely to be serviceable than the fatigue of taking the patient repeatedly out of bed for the purpose of plunging him either into a hot or cold bath. And though opium has never of itself, perhaps, produced a cure, it seems advisable to try it in liberal doses; and the more so, as several of the cases already adverted to afford a direct proof, that it is capable occasionally of producing some degree of tranquillity for a short period. In employing it, however, it seems most reasonable, from analogy, to combine it with some diaphoretic, and particularly with ipecacuanha in the form of Dover's powder, since at all times the animal frame is most disposed to be quiet and free from irregular actions when there is a general moisture upon the surface. In many cases of rabies, such a state of body has been found unquestionably favourable; and in one of the instances already quoted from the Medical Transactions, the benefit was so striking, that the practitioner could not avoid regarding it as critical. It is possible, also, though no great stress can be laid upon this remark, that a part of the virus itself may be hereby eliminated, as in various other cases of animal poisons.

To obtain and encourage such elimination should indeed be our first object, if we had any means of accomplishing it upon which we could fully depend. This, however, we have not; but as the quarter to which the virus is directed is the salivary glands, of which, indeed, we have full proof in consequence of the saliva being the fomes of the poison apparently as soon as it becomes elaborated, and as we have a medicine which possesses a specific influence on this organ, and is capable of augmenting its secretion to almost any extent, it seems of the utmost importance that, while we endeavour to support the system, and to allay the nervous irritation, we should endeavour at the same time to quicken the elimination of the morbid matter, by exciting the salivary excretories, and thus probably also carrying it off in a diluter and less irritant form. It is difficult to withhold one's assent to all the numerous instances of cure which are so confidently asserted to have followed the use of mercury carried to the point of free salivation. And hence, without allowing this medicine to be a specific more than any other, we may indulge a reasonable hope of its forming a good auxiliary, and should employ it freely, either externally, internally, or in both modes simultaneously, but with as little disturbance to the patient as possible, till a copious ptyalism is the result.

Fever, or inflammatory action, does not necessarily belong to lyssa in any stage; and the present mode of treatment is altogether grounded upon this principle. Either, however, may become incidentally connected with it, from the peculiar state of the habit or some other cause. Hence, as a preventive, the bowels should be kept moderately open; and when there is any just apprehension of plethora, or a turgid state of the vessels, and particularly of the brain, blood should be drawn freely from the arm, and, if necessary, be repeated. We have already seen that such a state of congestion is sometimes produced even at the onset of the disease, and is so forcibly felt by the patient himself, that he earnestly entreats the medical attendant to bleed him. Such entreaty should, perhaps, never be urged in vain; but the bleedings to deliquium, which have of late years been so strongly recommended, are a rash and dangerous practice.*

Such, in the doubt and darkness that at present beset us concerning the real physiology of lyssa, seems to be the safest and most promising path we can pursue. Our best time for action, however, and almost the only time we can improve, is immediately on the infliction of the wound: a tight ligature above which, with the

* Instead of persevering in these and other plans, which, when allowance is made for the ambiguous nature of many imperfectly reported recoveries, and the influence of the remedial powers of nature, cannot be said positively to have done effectual good in a single example, practitioners ought undoubtedly to make new experiments on the subject. If we always continue in the same path, we shall never discover the long desired object, namely, a method of treatment which can be depended upon.—Ep.

treble precaution of the cupping-glass, excision and cauterization, may in general be regarded as an effectual preventive. I do not know, indeed, that the profession is acquainted with any other.* It has, however, been proposed in France, to fight off the poison of lyssa by preoccupying the ground with the poison of a viper, upon the principle of combating various with vaccine matter: and for this purpose it has been suggested, that the part bitten by a mad dog should be again bitten, a little below the wound, as soon as may be, by a venomous serpent, whose virus, from its greater activity, will, in most cases, be certain of taking the lead, and may, it is presumed, guard the constitution against any subsequent effects from the wound of the mad dog. I have not, however, heard that this proposal has ever been carried into effect, and the claim of ingenuity is, most probably, the whole it will ever have to receive.†

I ought not, however, to conclude without noticing one very extraordinary fact in the economy of morbid poisons, and especially of that before us, which I have had confirmed by the testimony of several veterinary practitioners entitled to credit. It is, that no dog which has ever had the *distemper*, as it is called, which is the canine catarrh or influenza, has been known to become rabid spontaneously, though he is capable of receiving the disease by the bite of another dog. If this be true, for which however I cannot fully vouch, we have certainly another instance of morbid poisons mortally conflicting with each other; and it might be worth trying how far inoculation with the matter of canine catarrh might succeed in protecting a human subject after the infliction of a rabid bite; though in the dog, perhaps from a stronger predisposition to rabies, it seems to be impotent. In South America, rabies, as already observed, is altogether unknown, and I have hence been anxious to learn, whether the distemper be unknown there also; and in answer to this inquiry, it has been told me, by several intelligent residents in that quarter, that this last disorder is so common and so fatal, that two thirds of the dogs littered there perish of it while pups; a remark which still further confirms the home-report concerning its influence on rabies, and may partly explain the non-existence of the latter on the shores of the Plata.

SPECIES IX.

ENTASIA ACROTISMUS.

PULSELESSNESS.

FAILURE OR CESSATION OF THE PULSE, OFTEN ACCOMPANIED WITH PAIN IN THE EPIGASTRIUM; THE PERCEPTION AND THE VOLUNTARY MUSCLES REMAINING UNDISTURBED.

ACROTISMUS is literally "defect of pulse," from *κρότος*, "pulsus," with a privative *α* pre-

fixed; whence the technical term *crotophus* or *crotophium*, importing "painful pulsation or throbbing in the temple." Asphyxia is the term employed for this disease by Ploucquet, and would have been used in the present arrangement, but that it has been long appropriated to import suspended animation or apparent death; a total cessation, not of the pulse only, but of sense and voluntary motion.

This failure or cessation of pulsation sometimes extends over the whole system, and is sometimes confined to particular parts. In every case, it imports an irregularity in the action of the heart, or of the vessels that issue from it, and, in most cases, an irregularity proceeding from local or general weakness, and dependant upon a spasmodic disposition hereby produced in the muscular tunic of the vessels. Of this last cause, we have a clear proof in the universal chill and paleness that spread over the entire surface in the act of fainting or of death, to which fainting bears so striking a resemblance. Except, however, in the agony of dying, the spasmodic constriction for the most part soon subsides, and the arteries recover their proper freedom and diameter. Yet this is by no means the case always, for in violent hemorrhages, and especially hemorrhages of the womb, the rigidity has sometimes continued for several days, during the whole of which time the heart has seemed merely to palpitate, and there has been no pulse whatever. Morgagni relates, from Ramazzini, a case of this kind which extended to four days. The patient was a young man of great strength and activity, even during this suppression. The arteries were as pulseless as the heart; and through the whole period he was quite cold to the touch, and without micturition. On the fourth day he died suddenly.—(*De Sed. et Causis Morb.*, ep. xlviii., Lugd. Bat., 4to., 1767.) Examples, indeed, are by no means uncommon, in which the spasm has existed for three (*Pathology*, p. 25), four, or even five days (*Pelargus, Med. Jahngange.*, band v., p. 23) before death.

Other irritations besides that of weakness, have occasionally led to a like spastic state of the arteries. The stimulus of aneurism of the aorta has produced it in the brachial arteries, so that there has been no pulse in the wrists;* and gout or some irritation in the stomach has operated in like manner on the arterial system to a much greater extent; as has likewise general

* The hypothesis of such a degree of spasm as is here referred to, and supposed to be capable of rendering the large arteries impervious, is one that would not be generally adopted by modern practitioners. Many physiologists, perhaps all the most eminent ones, consider the small arteries as possessing the power of becoming completely constricted by a kind of action that may be sometimes spastic, but a contraction of the arterial trunks in this degree is a position that could not be so well established. In aneurisms of the arch of the aorta, the occasional interruption of the pulse can be explained on a better principle, and one confirmed by dissection; namely, the manner in which the disease obstructs or breaks the impetus of the blood destined for the upper extremities.—Ep.

* Dr. Marochetti's prophylactic treatment has already been mentioned.—Ep.

† By referring to the article "hydrophobia" in the Dictionary of Practical Surgery, the reader will perceive that this expedient has really been tried.—Ep.

pressure on the larger thoracic or abdominal organs, from water in the chest or cavity of the peritoneum. The cause however, is not always to be traced, and hence Marcellus Donatus has given an instance, which he tells us was unaccompanied with any disease whatever (Lib. vi., cap. ii., p. 620), the irritation probably having subsided. Berryatt, in the History of the Academy of Sciences, has furnished us with a very singular example of this disease, which was general as well as chronic, and continued through the whole term of life. In all which cases, however, though the heart itself should seem to participate in the pulselessness, we are not to suppose that it is entirely without any alternation of systole and diastole, but only that its action is indistinct from weakness or irregularity. In treating of the nature of the pulse in the Physiological Proem to the third class, we observed, that it is in some persons unusually slow, and has been found, as measured by the finger, not more than ten strokes in a minute: and that, in many of these cases, the cause of retardation seems to be a spasticity or want of pliancy in the muscular fibres of the heart or arteries, or both, rather than an actual torpor, which is also an occasional cause. I have never met with any case in which the ordinary standard of the pulse was not more than ten strokes in a minute; but I have at this time a patient, of about thirty-six years of age, whose pulse has not exceeded twenty-four or twenty-six strokes, and has often been below these numbers. He is a captain in the Royal Navy, of a sallow complexion and bilious temperament; till of late he enjoyed good health, but about three years since was attacked with a fit of atonic apoplexy, from which he recovered with difficulty. At an interval of a few weeks from each other, he had several other fits; on recovering from the last of which he instantly married a young lady to whom he had for some time been engaged. He has now been married about fifteen months, has a healthy infant just born, and has had no fit whatever. His spirits are good, and he is residing by the seaside, which situation he finds agree with him best.

Dr. Latham gives a similar example in a merchant whose pulse, though never intermissive, seldom, for ten or twelve years that he had known him, exceeded thirty-two beats in a minute; occasionally was as slow as twenty-two, and at one time only seventeen. "I once," says Dr. Latham, "attended him through a regular fever, when his pulse was not more than sixty, notwithstanding the disease ran on for at least a fortnight with a hot and dry skin, white and furred and parched tongue, and occasional delirium."—(*Med. Trans.*, vol. iv., art. xx.)

In many of these anomalies there is not only no perceptible pulse, or a very retarded one, but often intermissions more or less regular, and occasionally a want of harmony between the stroke in some of the arteries compared with that in others. Reil gives a case in which the heart, the carotids, and the radial arteries all pulsed differently (*Memorabilia Clinica*, vol. ii., fasc. i., 6, Hall., 1792); and Beggi an-

other, in which the acrotism, or want of pulsation, extended over the entire frame, with the exception of the heart, which pulsed violently.—(*Opp. Pacchioni*, Rom., 4to., 1741.)

This species is strikingly exemplified in the biographical sketch of Mr. J. Hunter, drawn up and prefixed to his volume on Blood and Inflammation by Sir Everard Home. Mr. Hunter, for the four preceding years, had annually suffered from a fit of the gout in the spring. In the year 1773, this did not return, and having on a particular occasion been greatly affected in his mind, "he was attacked," says Sir Everard Home, "at ten o'clock in the forenoon, with a pain in the stomach, about the pylorus: it was the sensation peculiar to those parts, and became so violent that he tried change of position to procure ease; he sat down, then walked, laid himself down on the carpet, then upon chairs, but could find no relief: he took a spoonful of tincture of rhubarb, with thirty drops of laudanum, but without the smallest benefit. While he was walking about the room, he cast his eyes on the looking-glass, and observed his countenance to be pale, and his lips white, giving the appearance of a dead man. This alarmed him, and led him to feel for his pulse, but he found none in either arm. He now thought his complaint serious. Several physicians of his acquaintance, Dr. William Hunter, Sir George Baker, Dr. Huck Saunders, and Sir William Fordyce, all came, but could find no pulse: the pain still continued, and he found himself, at times, not breathing. Being afraid of death soon taking place if he did not breathe, he produced the voluntary act of breathing, his working his lungs by the power of the will, the sensitive principle with all its effect on the machine not being in the least affected by the complaint. In this state he continued for three quarters of an hour, in which time frequent attempts were made to feel the pulse, but in vain. However, at last the pain lessened, and the pulse returned, although at first but faintly, and the involuntary breathing began to take place. While in this state, he took Madeira, brandy, ginger, &c., but did not believe them of any service, as the return of health was very gradual. In two hours he was perfectly recovered."—(*Sir E. Home's Life of Mr. Hunter, prefixed to the Treatise on Blood, &c.*, p. 46.)

This is one of the most extraordinary cases on record, considering the extensive group of important functions that were jointly affected, and the total freedom of the rest; and nothing can more strikingly prove how close is the sympathy that in many instances prevails between discontinuous organs, the chief disease having prevailed in the heart, and the chief pain in the stomach on its upper side.

The nature of the pain and the collateral symptoms seem sufficiently to show that this disease was of a spasmodic kind; for the deficiency of pulse was subsequent to the pain, and ceased upon its removal, while the deadly paleness of the face gave proof of a constriction of the capillaries.

So far as my own experience has extended,

such failures of the pulse, whether consisting in a total suspension or a preternatural retardation, and attended with acute or with very little pain, are dependant upon the diseased state of the larger arteries, or the larger viscera of the thorax or abdomen, and generally lead to sudden death. The case of the captain of the navy which I have just related, and which was drawn up while the first edition of this work was in the press, I may now apply to in illustration of this remark; for I have since been informed by his sister, that while at Swansea, apparently in as good health as he had ordinarily enjoyed for several years, he was attacked with a fit of apoplexy, which carried him off in less than an hour. Such, too, was the fate of Dr. Latham's patient, for we are told, that "one day, when in complete health, as he then considered himself, he dropped down in the street and expired." And so sudden was the decease of Mr. J. Hunter, that feeling himself unwell while in the course of his professional attendance at St. George's Hospital, he went into an adjoining room, gave a deep groan, and dropped down dead.

In all cases of this kind, therefore, the mode of treatment must depend upon the nature of the exciting or predisponent cause, as far as we are able to ascertain it. Where the cause is constitutional, a sober, quiet, and regular habit of life, with a due attention to the ingesta and egesta, and particularly to a tranquilized state of mind, will often enable the valetudinarian to reach his threescore and tenth year with cheerfulness and comfort; but he must content himself with

"—the cool sequestered vale of life,"

and not form a party in its contentions and its glitter, its bustle and "busy hum."

Where the affection appears to be dependant upon a particular state of any one of the larger thoracic or abdominal organs, as the heart itself, the lungs, the stomach, or the liver, our attention must be specially directed to the nature of the primary disease. And, in these cases, it is often essentially relieved by some vicarious irritation, as a seton or issue, a regular fit of the gout, a cutaneous eruption, or a painful attack of piles. During the paroxysm itself, the most powerful and diffusive stimulants should be had recourse to, as brandy, the aromatic spirit of ammonia, or of ether, which is still better, and opium in any of its forms.

Some persons are said to possess a natural power of thus keeping the heart upon a full stretch, and hereby producing a universal deficiency of pulsation, and of simulating death. Of this Dr. Cleghorn and Dr. Cheyne both give an instance. It should be observed, however, that the individuals died suddenly; and one of them, Col. Townshend, within a few hours, after having maintained this rigidity of the heart for half an hour, at the expiration of which time he consented to resuscitate himself, and awoke from the apparent sleep of death. It should hence seem, that the natural energy of the heart sinks gradually, or abruptly, beneath the mischievous exertion, wherever such a power is found to exist.

GENUS II. CLONUS. CLONIC SPASM.

FORCIBLE AGITATION OF ONE OR MORE MUSCLES
IN SUDDEN AND IRREGULAR SNATCHES.

THE Greek terms κλονος and κλονησις import "agitation, commotion, concussion." The clonic or agitative spasms form two distinct orders in Sauvages, and a single genus in Parr. The first is unnecessarily diffuse; the second is too restricted. The two orders of Sauvages are in the present arrangement reduced to two genera, and constitute that immediately before us, and *SYNCLONUS*, or that which immediately follows. Dr. Cullen seems at one time to have had a desire of distinguishing the diseases of both these genera by the name of convulsions; and of limiting the name of spasms to the permanent contractions, or rigidities of the muscular fibres, produced by spastic action, constituting the different species of the preceding genus. "I think it convenient," says he, in his First Lines, "to distinguish the terms of spasm and convulsion by applying the former strictly to what has been called the tonic, and the latter to what has been called the clonic spasm." Yet the whole are treated of in his nosological arrangement under the common name of *SPASMI*, and even in his First Lines, notwithstanding this distinction, under that of "*spasmodic affections without fever.*" These spasmodic affections are, indeed, subsequently divided into a new arrangement of "*spasmodic affections of the animal functions; of the vital; and of the natural:*" throughout which an attempt is still made to separate the term *convulsion* from that of *spasm*, and apply it to all clonic or agitative motion of the muscles, while *CONVULSIO* is nevertheless retained in the Synopsis, as the technical name of that single species of disease, which is colloquially called convulsion-fit, and not extended to any others. There is doubtless a difficulty in drawing the line between entastic and clonic spasm in many cases, from the mixed nature of the symptoms; but if it be felt of importance to take terms out of their general meaning, and tie them down to a stricter interpretation, such interpretation should be rigidly adhered to, or some degree of confusion must necessarily ensue.

To understand the real nature of the spasms we are now entering upon, it may be expedient to recollect, that the nervous power appears to be naturally communicated to parts by minute jets, as it were, or in an undulatory course, like the vibrations of a musical cord. But the movement is so uniform, and the supply so regular in a state of health and where there is no fatigue, that we are not conscious of any discontinuity of tenour, and can grasp as rigidly and as permanently with a muscle as if there were no relaxation in its supply of power. To prove the nature of the influx, however, nothing more is necessary than to reduce the muscle from a state of healthy tone to a state of languor, or to wear it down by fatigue; for, in this condition, all the muscles tremble, and the stoutest man is incapable of extending his arm with a small weight

in his hand, or even of raising a glass of wine slowly to the mouth, without a manifest and even a painful oscillation.

The flow of the nervous power, in a state of health, is augmented by the application of various stimulants, both mental and corporeal. The ordinary mental stimulus is the will, but any other mental faculty, when violently excited, will answer the same purpose, though the action which takes place in consequence hereof will in some degree be irregular, as proceeding from an irregular source, and will in consequence make an approach to the character of spasms; of which a violent excitement of almost any of the passions affords examples sufficiently evident, and especially the passions of fear and anger, under the influence of which it is sometimes found impossible to keep a single limb still.

The ordinary corporeal stimulants are the fluids, which are naturally applied to the motory organs themselves. Thus the air which we breathe becomes a sufficient excitement to the action of the lungs; the flow of the blood from the veins a sufficient excitement to that of the heart; while the descent of the feces maintains the peristaltic motion of the intestinal canal.

Where these stimulants are regularly administered, and the organs to which they are applied are in a state of health, the alternations of jets and pauses in the flow of the nervous energy, as we have already remarked, are uniform. But in a state of diseased action, this uniformity is destroyed, and in two very different ways; for, first, the nervous energy may rush forward with a force that prohibits all pause or relaxation whatever, and this too in spite of all the power of the will; and we have then a production of rigid or entastic spasms, or those abnormal contractions in different parts of the body of which the preceding genus furnishes us with abundant examples: and, next, the pauses or relaxations may be too protracted; and, in this case, every movement will be performed with a manifest tremour. Where this last is the case, moreover, the succeeding jet from the accumulation of nervous power that necessarily follows upon such a retardation, must at length take place with an inordinate force and hurry; and the movement in the voluntary muscles, when attempted to be controlled by the will, must be irregular, and often strongly marked with agitation, giving us examples of convulsive or clonic spasm. And as, moreover, in such a state of the nervous system or of any part of it, there will often be found a contest between the retarding and the impelling powers, the spasm will not unfrequently partake of the nature of the two; the nervous energy, after having been irregularly restrained in its course, will rush forward too impetuously, and for a few moments without any pause: and we shall have either a succession of constrictive and clonic spasms in the same muscle or sets of muscles, or a constrictive spasm in some parts, while we have a clonic spasm in others: and hence those violent and ramifying convulsions which we shall have more particularly to notice under the ensuing genus.

A sudden and incidental application of any ir-

ritant power whatever to any of the muscular fibres, will throw them into an irregular action, not only in a morbid state when they are most prone to such irregularities, but even in a state of health. Hence the involuntary jerk that takes place in all the limbs when a boat in which we are sailing at full speed gets aground without our expecting it, or we are assailed unawares with a smart stroke of electricity.

Now, whenever a forcible and anomalous movement of this kind has once been excited in any chain of muscular fibres whatever, there is a strong tendency in them to repeat the same movement even from the first; and when from accident, or a continuance of the exciting cause, it has actually been repeated, it forms a habit of recurrence that is often broken off with great difficulty. Hence the convulsive spasm of the whooping-cough always outlasts the disease itself for some weeks, and is best removed by the introduction of some counter-habit obtained by a change of residence, atmosphere, and even hours. A palpitation of the heart, first occasioned by fright in an irritable frame, has in some cases continued for many days afterward, and in a few instances become chronic.

A habit of sneezing has sometimes been produced in the same manner, and followed an obstinate catarrh; after which the slightest stimulants, even the sneezing of another person, have been sufficient to call up fresh paroxysms, and, in some cases which I have seen, of very long and troublesome continuance.

Hiccough affords us another example of the same tendency to a recurrence of muscular abnormalities. This is usually produced by some irritation in the stomach, not unfrequently that of fulness alone: the irritation is by sympathy communicated to the diaphragm, which is thrown into a clonic spasm, and the spasm being a few times repeated, the habit becomes so established as in many instances to be broken through with considerable difficulty.

It is to these physiological laws that most of the affections we are now about to enter upon are referrible; and the concentrated view we have thus taken of their operation, will render it less necessary for us to dwell at much length upon any of them.

The genus *CLONUS* comprises the six following species:—

- | | |
|-----------------------------|---------------------------|
| 1. <i>Clonus Singultus.</i> | Hiccough. |
| 2. ——— <i>Sternutatio.</i> | Sneezing. |
| 3. ——— <i>Palpitatio.</i> | Palpitation. |
| 4. ——— <i>Nictitatio.</i> | Twinkling of the Eyelids. |
| 5. ——— <i>Subsultus.</i> | Twitching of the Tendons. |
| 6. ——— <i>Pandiculatio.</i> | Stretching. |

SPECIES I.

CLONUS SINGULTUS.

HICCOUGH.

CONVULSIVE CATCH OF THE RESPIRATORY MUSCLES, WITH SONOROUS INSPIRATION; ITERATED AT SHORT INTERVALS.

THOUGH the spasmodic action in this affec-

tion exists chiefly in the diaphragm, the principal seat of the disease is the stomach, when strictly idiopathic; an observation which was long ago made by Hippocrates, and has in recent times been more copiously dwelt upon by Hoffmann, but which Sir Charles Bell has been the first to establish by experiments on the nervous system. "Vomiting," says he, "and hiccough, are actions of the respiratory muscles, excited by irritation of the stomach.—(*Experiments on the Structure and Functions of the Nerves*; Phil. Trans., 1821, p. 406.)

Debility is perhaps the ordinary remote cause, and irritability, or some accidental stimulus, the exciting. Thus excess of food, and especially in a weak stomach, is often a sufficient stimulus: and hence the frequency of this complaint among infants.*

For the same reason, it is occasionally produced by worms, acidity, or bile in the stomach. External pressure on the stomach is another exciting cause: and hence it has sometimes followed an incurvation of one or more of the ribs (*Schenck*, lib. iii., obs. 49, *ex Fernelio*), or of the ensiform cartilage (*Bonnet. Sepulchr.*, lib. iii., sect. v., obs. 8., Appex.) of the sternum, produced by violence, and pressing on the coats of this organ. The stomach, however, is not at all times the only organ in which the morbid cause is seated, that excites the diaphragm to the spasmodic action. The liver is frequently to be suspected. "I have often," says Dr. Percival, in his manuscript notes on the volume of Nosology, "found hiccough symptomatic of an enlargement or inflammation of the liver on the upper convex side." It also frequently follows strangulated hernia; and, according to Mr. John Hunter, in numerous instances accompanies local irritation after operations of various kinds. It has sometimes attended the passage of a stone in one of the ureters.—(*Darwin, Zoonom.*, iv., i., i., 7.)

The affection is often very troublesome, but it cures itself in ordinary cases, and where the exciting cause is lodged in the stomach; for the spasmodic action very generally removes the accidental irritant; and if not, the disorder usually yields to very simple antispasmodics, as a draught of cold water, or a dose of camphire or volatile spirits. Where these have failed, a nervous action of a different kind, and which seems to operate by revulsion, has often been found to succeed, such as holding the breath, and thus producing a voluntary spasm of a rigid and opposite kind in the diaphragm; or a violent fit of sneezing. An emetic (*Rigaud, Ergo solvunt Singultum Vomitus et Sternutatio*? Paris, 1601) will sometimes answer the purpose; and, still more effectually, a sudden fright, or other emotion of the mind.—(*Riedlin, Lin. Med.*, 1696, p. 276.) If these do not prove sufficient, we must call in the aid of opium; and, in the intervals, have recourse to tonics internal and external, the warm bitters, bark, pure air, exercise, and cold bathing.

* It is very frequent in drunkards when the stomach is overloaded with spirituous drink.—D.

We have already pointed out the tendency which these irregular actions have to form a habit, and the more so in proportion to the general weakness and irritability of the frame; and hence, indeed, their arising so readily in the later stages of typhus and other low fevers, and their continuing to the last ebb of the living power.

Even where the constitution is possessed of a tolerable share of vigour, hiccough is too apt to become a chronic and periodical affection; and as the frequency of the spasm is also usually increased with the frequency of the series, it has sometimes become almost incessant, and defied every kind of medical treatment that could be devised. As a chronic affection, it has been known to return at irregular periods from four (*Bartholin, Hist. Nat.*, cent. ii., hist. 4) to four-and-twenty years (*Alberti, Diss. Casus Singultus chronici viginti quatuor annorum*, Hal., 1743); and as a permanent attack, to continue without ceasing for eight (*Riedlin*, cent. i., obs. 15), nine (*Act. Nat. Cur.*, vol. v., obs. 108), twelve days (*Tulpius*, lib. iv., cap. 25), and even three months.—(*Schenck*, lib. iii., obs. 49, *ex Fernelio*.) Dr. Parr tell us, that he once knew it continue for a month with scarcely any intermission even at night. "The sleep," says he, "was at last so profound, that the convulsion scarcely awoke the patient." In a few instances it has proved fatal. Poterius mentions one (Cent. ii., obs. xxvii.); and another, produced by cold beverage, occurs in the Ephemerides of Natural Curiosities.—(*Eph. Nat. Cur.*, dec. iii., an. i., obs. 48.)

In the Gazette de Santé for 1817 is the case of a young girl, who had been tormented for six months with an almost incessant hiccough. It ceased during deglutition, but re-appeared immediately afterward. The sleep was frequently disturbed. Baron Dupuytren, on being consulted, after antispasmodics and the warm bath had failed, applied an actual cautery to the region of the diaphragm, and the hiccough immediately ceased; but perhaps terror operated in no slight degree in this mode of cure.

SPECIES II.

CLONUS STERNUTATIO.

SNEEZING.

IRRITATION OF THE NOSTRILS, PRODUCING SUDDEN, VIOLENT, AND SONOROUS EXPIRATION THROUGH THEIR CHANNEL.

SNEEZING is a convulsive motion of the respiratory muscles, commonly excited into action by some irritant applied to the inner membrane of the nose, and not unfrequently, when so applied, to an extremity of almost any one of the respiratory nerves; in the course of which the air from the lungs is sonorously forced forward in this direction as the lower jaw is closed at the time. "In sneezing," says Dr. Young, "the soft palate seems to be the valve, which, like the glottis in coughing, is suddenly opened, and allows the air to rush on with a greater

velocity than it could have acquired without such an obstruction."—(*Med. Literat.*, p. 107.)

It is a common and rarely a severe affection in its ordinary course. But, from the habit which irregular actions of the irritable fibres are perpetually apt to assume, as we have already explained, and particularly in a relaxed and mobile state of them, sneezing has occasionally become a serious complaint. Forestus, Horstius, Lancini, and many of the German medical miscellaneous collections, give instances of its having been sometimes both permanent and violent, sometimes periodical, and a few cases wherein it proved fatal; which last termination is confirmed by Morgagni. The *Ephemerides Naturæ Curiosorum* contain one instance, in which the sneezings continued for three hundred times in a single paroxysm.

The ordinary irritants, operating immediately on the membrane which lines the interior of the nostrils, are sternutatories, a sharp pungent atmosphere, indurated mucus, the acrimonious fluid secreted in a catarrh or measles, or a morbid sensibility of the Schneiderian membrane itself. But the severest cases have usually been produced by sympathy with some remote organ, as an irritable state of the lungs, stomach, or bowels. For the same reason, sneezing often accompanies pregnancy and injuries on the head, and sometimes the last stages of low fevers. The benediction, formerly bestowed with so much courtesy on the act of sneezing, is said to have been congratulatory, on account of its frequent violence; but we do not seem to be acquainted with the real origin of this custom.

As sneezing is a symptom of catarrh, if it be repeated for some time with quick succession in an irritable habit that has been frequently affected with catarrh, it will sometimes, in the most singular manner, call sympathetically into action the whole circle of symptoms with which it has formerly been associated, and the patient will seem at once to be labouring under a very severe cold. An instance of this singular sympathy has occurred to me while writing. The patient is a lady of about fifty years of age, in good health, but of a highly nervous temperament. She began to sneeze from some trifling and transient cause, and having continued to sneeze for five or six times in rapid succession, her eyelids became swollen, her eyes bloodshot and full of tears, her nostrils discharged a large quantity of acrid serum, her fauces were swollen and irritable, and a tickling and irrepressible cough completed the chain of morbid action. The sneezing at length ceased, and, within a quarter of an hour afterward, the whole tribe of sympathetic symptoms ceased also.

Sneezing, in its ordinary production, though a convulsive, is a natural and healthy action, intended to throw off instinctively from the delicate membrane of the nostrils whatever irritable or offensive material may chance to be lodged there. But when it proceeds from a morbid cause, or becomes troublesome from habit, we should use our endeavours to remove it. That there is nothing of proper convulsion in sneezing is shown, as Sir Charles Bell has justly observed,

by the admirable adjustment of the muscles to the object. A body irritating the glottis will call into simultaneous action the muscles of respiration, so as to throw out the air with a force capable of removing the offending body; but if the irritation be on the membrane of the nose, the stream of air is directed differently, and by the action of sneezing, the irritating particles are removed from these surfaces. By the consideration of how many muscles require the adjustment to produce this change in the direction of the stream of air, we may know that the action is instinctive, ordered with the utmost accuracy, and very different from convulsion.—(*Of the Nerves which associate the muscles of the Chest in the Actions of Breathing, &c.*; *Phil. Trans.*, 1822, p. 305.)

When the complaint is idiopathic and acute, or, in other words, when the Schneiderian membrane is morbidly sensible, or stung with some irritant material, it may be relieved by copiously sniffing warm water up the nostrils, or throwing it up gently with a syringe, or forcing up pellets of lint moistened with opium dissolved in warm water, the pressure of which is sometimes of as much service as the sedative power of the fluid itself. If this do not succeed, leeches or cold epithems should be applied to the nose externally. But a free and spontaneous epistaxis, or hemorrhage from the nostrils, effects the best and speediest cure, of which Riedlin has given an instructive instance.—(*Lin. Med.*, 1695, p. 148.) Its return has been prevented by blisters to the temples and behind the ears, and frequently sniffing up cold water. It has also been attempted to be cured by pungent sternutatories, so that the olfactory nerves may be rendered torpid and even paralyzed by over-exertion; but this has rarely answered; for when once a morbid habit is established, it does not require the primary cause or stimulus for its continuance.

When the complaint proceeds from sympathy, the most effectual mean of removing it is by ascertaining the state of the remote organ with which it associates, and removing the stimulus that gives rise to it. This, however, cannot always be done; and, in such cases, camphire in free doses will often prove a good palliative, and if this do not succeed, we must have recourse to opium.

SPECIES III.

CLONUS PALPITATIO.

PALPITATION.

SUBSULTORY VIBRATION OF THE HEART OR ARTERIES.

PALMUS or PALPITATIO is used in very different senses by different writers. By Cullen and Parr it is limited to a vehement and irregular motion of the heart alone. By Sauvages and Sagar it is applied to an irregular motion "in the region of the heart." By Linnæus it is denominated "a subsultory motion of the heart or a bowel—*cordis viscerisve*;" and by Vogel is defined "a temporary agitation of the heart, a bowel, a muscle, a tendon, or an artery."

The first of these views is too contracted, for

palpitations, or quick abnormal beats, are felt almost as frequently in many other organs, and particularly those of the epigastric region. Yet, as in these, it seems in every instance, however complicated with other symptoms, to depend upon a morbid state of the heart itself, or of the arteries which supply them, or are in their vicinity; the definitions that extend palpitations to other organs than the heart and arteries, as separate from these, appear to be as much too loose and out of bounds as the first definition is too limited.

The view now offered takes a middle course: it contemplates palpitation as dependant on a diseased action of the heart alone, or of the larger arteries alone, or of the one or the other associating with some organ more or less remote; and hence lays a foundation for the three following varieties:—

- α Cordis. Palpitation of the heart.
- β Arteriosa. Palpitation of the arteries.
- γ Complicata. Complicated or visceral palpitation.

The vibratory and irregular action, which we denominate PALPITATION OF THE HEART, is sometimes sharp and strong, in which case it is called a THROBBING OF THE HEART, and sometimes soft and feeble, when it is called a FLUTTERING of this organ. Both may possibly proceed from two distinct causes; the one a morbid irritability of its muscular fibres, or some sudden stimulus applied to it, either external or internal, by which its systole becomes harsh and unpliant, and evinces a tendency to a spastic fixation; and the other an irregular motion of the entire organ of the heart in the pericardium, by which it literally strikes against the chest: the cause of which we do not always know, though we see it very frequently occasioned by a sudden and violent emotion of the mind, and have reason to believe, that it is often a result of the spastic systole or contraction of the heart which we have just noticed. When, however, the substance of the heart is thus irregularly acted upon, and jerked backward and forward from a cause extrinsic to itself, the palpitation is confined to the pericardium, and the pulse does not partake of the abnormality.

The last is, perhaps, the most common proximate cause of the palpitation of this organ, and we are indebted to Dr. William Hunter for having first pointed it out to us. The heart, in its natural state, lies loose and pendulous in the pericardium; and when the blood which it receives is, from an irritation of any kind, thrown with a peculiar jerk into the aorta, the moment it reaches the curvature of this trunk, it encounters so strong a resistance as to produce a very powerful rebound in consequence of the aorta being the first point against the spine: the influence of the heart's own action is now, therefore, thrown back upon itself, and this organ, as a result of its being loose and pendulous, is tilted forward against the inside of the chest, between the fifth and sixth ribs on the left.—(See *J. Hunter on Blood*, p. 146, note.)

The rebound of so strong a muscle as the heart against the inside of the chest, must de-

pend for its violence, upon the violence of the jerk with which the blood is spasmodically thrown into the aorta: and this has often been so powerful as to be distinctly heard by bystanders.* Castellus has given an example of this sonorous effect: and Mr. Dundas has observed it in various cases. "The action of the heart," says the latter, "is sometimes so very strong as to be distinctly heard, and to agitate the bed the patient is in so violently, that his pulse has been counted by looking at the motions of the curtain of the bed."—(*Trans. Medico-Chirurg. Soc.*, i., 27.) The heart has sometimes palpitated with a force so violent as to dislocate (*Horstii*, ii., 137-139) or break the ribs (*Schenck*, obs. 215, *ex Fernelio*), for both are stated to have occurred on respectable authorities,† and, in one instance, to rupture its own ventricles.‡—(*Portal, Mémoires de Paris*, 1784.) Upon the wonderful power of the soft parts, or rather of the muscles over the bones, when thrown into vehement spasmodic action, we had occasion to observe in the Physiological Proem to the present order: and hence we have sometimes had examples of the humerus, and other long bones, being broken by a convulsion-fit. A contraction of the left aurico-ventricular opening is sometimes found to produce the phenomenon of a double pulse.—(*Hodgson on the Diseases of Arteries and Veins*.)

I have said, that we are not always acquainted with the remote or exciting causes of the palpitation of the heart. Violent emotion of the mind, as already observed, is a frequent excitement, and one or two others have been already indicated. The first of these, is perhaps the most frequent cause; and hence we can readily admit with M. Corvisart, that palpitation, together with many other diseases of the heart, have been far more frequent in France since the commencement of its late horrible revolution. M. Portal has, indeed, proved this fact by various interesting examples, from which the following may be selected, as it is short:—A young lady, who had suddenly learned that her husband had been cruelly murdered by a band of the popular ruffians, was instantly seized with a violent palpitation that terminated in a syncope so extreme, that she was supposed to be dead. This apprehension, however, was erroneous. She recovered; but the palpitation continued for many years; and she at length died of water in her chest.—(*Mem. sur la Nature et le Traitement de plusieurs Maladies*, tome iv., 8vo., Paris, 1819.)

The remote causes are rarely to be discovered till after death, and for the most part seem to consist in a morbid structure of the heart itself, or the pericardium, by which last the muscular

* Castellus, P. Vascus. Exercit. ad affectus Thoracis, tr. ix., Toloso, 1614, 4to. Lettsom, Med. Soc. Lond., vol. i. A Vega, De Art. Med., lib. iii., cap. 8.

† The editor has no doubt of the incorrectness of such reports.

‡ Another case of spontaneous rupture of the heart is recorded by Dr. Valentine Mott, in the New-York Medical Magazine.—D.

walls of the heart have either been obstructed in their play, or have had too much liberty of action. The heart has sometimes been found ossified in its general substance, as in the case of Pope Urban the Eighth; and more frequently in its valves or in its connexion with the aorta. It has sometimes been thickened, and has grown to an enormous size, which change of structure has lately been distinguished by the name of hypertrophy, and has been found in one instance of a weight of not less than fourteen pounds.—(*Eph. Nat. Cur.*, dec. iii., ann. iii., obs. 166.) A case occurred to the present author not long ago in a young lady of fourteen, in whom it reached half this weight, and was the cause of a most distressing palpitation, as well as of a general dropsy. By close confinement and quiet, and the use of elaterium and scarification to carry off the water, she recovered an apparently good share of health; but the exercise of dancing, a few months afterward, produced a recurrence of all the symptoms in a more violent and obstinate degree, and she gradually fell a sacrifice to them.

In other cases, the heart has been peculiarly small and contracted, chiefly, perhaps, in the disease of tabes or marasmus; and consequently there has not been a sufficient capacity for the regular influx of venous blood.

The space of the pericardium has often been morbidly diminished by inflammation, or an undue growth of fat; and hence, again, the heart has been impeded in its proper action; while occasionally it seems to have been filled, or nearly so, with a dropsical fluid.

Organic injury from external violence, is also a frequent cause of palpitation. Yet it is singular to observe the severity of lesion which the heart and its appendages will sometimes undergo, when the constitution is sound, without affecting the life. M. Latour, who during the French war was first physician to the Grand Duke of Berg, attended a soldier who laboured under a tremendous hemorrhage from the breast, produced by a wound from a musket that had penetrated this organ. The hemorrhage, however, ceased on the third day, the patient's strength gradually recruited, and suppuration proceeded kindly. It was nevertheless necessary to cut several pieces of fractured rib away; yet the wound cicatrized at the end of three

months, and the only inconvenience that remained was a very troublesome palpitation of the breast, that annoyed him for three years. Six years after the accident, he died of a complaint totally unconnected with the wound. His body was opened by M. Mansion, chief surgeon of the hospital at Orleans; and the ball, which had entered his breast, was found lodging in the right ventricle of the heart, covered over in a great measure by the pericardium, and resting on the septum medium.*

To these causes may be added a scirrhus or other morbid structure of the lungs, and perhaps of the spleen, liver, stomach, or intestinal canal; for it is a frequent accompaniment upon most species of parabysma: and, in these cases, appears as a symptomatic affection alone. For reasons already assigned, it is also an occasional symptom in hydrothorax; during which it shows itself in a very violent degree upon mental agitation, especially that produced by fright or vehement rage.

We should not, however, be hasty in deciding upon any structural affection of the heart, or of any of the larger organs that closely associate with it, nor, in reality, upon any incurable cause whatever. For it has not unfrequently happened, that a palpitation of long standing, and which has been regarded as of a dangerous kind, has gradually gone away of its own accord, and left us altogether in the dark. Dr. Cullen gives a confirmation of this remark in the following very instructive case:—"A gentleman, pretty well advanced in life, was frequently attacked with palpitations of his heart, which, by degrees, increased both in frequency and violence, and thus continued for two or three years. As the patient was a man of the profession, he was visited by many physicians, who were very unanimously of opinion, that the disease depended upon an organic affection of the heart, and considered it as absolutely incurable. The disease, however, after some years, gradually abated both in its frequency and violence, and at length ceased altogether; and since that time, for the space of seven or eight years, the gentleman has remained in perfect health, without the slightest symptom of his former complaint."—*Mat. Med.*, part ii., chap. viii., p. 357.) A case precisely similar, and in a professional gentleman somewhat beyond the middle of life also,

* *Dict. des Sciences Médicales*, Art. Cas. Rares. The following causes of palpitation are specified by Dr. Hope as inherent in the heart itself:—1. Hypertrophy, and hypertrophy with dilatation. In these affections, palpitation consists in an increase both of the force and of the frequency of the heart's action. 2. Dilatation with attenuation. Palpitation in this case consists in an increase of the frequency, but often not of the strength of the beats, though the patient may experience the sensation of an increased impulse. 3. Disease of the valves. Palpitation from this cause varies in its characters, according to its nature, situation, and extent of the valvular affection, and according to the presence or absence of hypertrophy, dilatation, or both. 4. Pericarditis, carditis, and inflammation of the internal membrane. 5. Adhesion of the pericardium. Palpitation from this cause is

violent, and of an abrupt kind. As physical causes of palpitation, exterior to the heart, Dr. Hope specifies, 1. Acceleration of the circulation by muscular efforts. 2. Plethora. 3. Anæmia. 4. Convulsive, epileptic, and hysteric fits. 5. Obesity. 6. Obstructions in the lungs from hydrothorax, empyema, pneumothorax, hepatization, bronchitis, &c. 7. Asthmatic bronchial constriction. 8. Acute Laryngitis. 9. Abdominal infarction from enlarged liver or spleen, ovarian dropsy, uterogestation, &c. Afterward Dr. Hope adverts to palpitation from causes operating entirely through the nervous system.—(See *Cyclop. of Pract. Med.*, art. PALPITATION.) Nervous palpitations, as this writer correctly observes, are *intermittent*, their causes being only occasional, whereas those from organic diseases are *continued*, their causes being incessant.—Ed.

has occurred to the present author, with a spontaneous termination equally as favourable. M. Laennec's ingenious method of *MEDIATE AUSCULTATION* by the stethoscope, as we have already explained, will often be found of great importance in the different forms of this species of disease.*

The same alternating spasmodic motion, into which the muscular substance of the heart is occasionally thrown by one or other of the causes thus glanced at, seems, at times, to take place in some of the *LARGER ARTERIES*, and extends to a greater or less length in proportion to the nature of the cause, or the extent of the morbid irritability by which they are affected, producing the *SECOND VARIETY* before us. That a morbid irritability may exist in a part of an artery while the rest is free from any such condi-

* See Cl. III., Ord. IV., Gen. III., Spe. 5. In nervous palpitations, it was remarked by Laennec, that "the first impression which the application of the stethoscope to the region of the heart produces on the ear, shows at once that this organ has not great dimensions. The sound, although clear, is not loud over a great extent; and the shock, even when it at first appears strong, has little real impulsive force, for it does not sensibly elevate the head of the observer. This last sign," says Laennec, "appears to me the most important and the most certain of all, when we add to it the frequency of the pulsations—most commonly from 84 to 96 in a minute."

It is stated by Dr. Hope (*Cyclop. of Pract. Med.*, art. *PALPITATION*), that in dilatation of the heart, dulness on percussion indicates enlargement of the organ, further evidence of which is derived from the impulse being situated lower down than natural. The first sound is short, smart, and clear, resembling, and in dilatation with attenuation, becoming identical with the second.

In hypertrophy with dilatation, the dulness on percussion is increased over a still greater extent, and the dulness and impulse are also lower down than natural. Both sounds are very loud, and the impulse is much more forcible than in nervous palpitation, very frequently raising the head of the auscultator.

In simple hypertrophy the impulse is a slow, gradual, and powerful heaving, very sensibly elevating the head. Both sounds are diminished, and in extreme cases almost suppressed. In disease of the valves there is a permanent bellows sawing, or rasping murmur; whereas the murmur in nervous palpitation is only occasional, and of a soft character. If the valvular contraction be great, the action of the heart is irregular. It is further observed by Dr. Hope, that irregularity also occurs in nervous palpitation, but it is not accompanied by those symptoms of an embarrassed circulation, which invariably attend valvular disease. Should hypertrophy, dilatation, or both, coexist with valvular disease, their signs will likewise be present. In nervous palpitation, Dr. Hope finds the pulse to be jerking, but with little fullness, strength, and incompressibility. In dilatation it is full and soft; in hypertrophy with dilatation, it is full, strong, and sustained; and in simple hypertrophy, though less full, it is strong, sustained, and even hard. These and other observations on the diagnosis of palpitation from various causes, as delivered by Dr. Hope, are replete with practical instruction, whose *Treatise on the Diseases of the Heart* is a valuable contribution to medical literature.—Ed

tion, is easily conceived, since a like partial irritability is often found to exist in organs in which we are capable of tracing it in the most manifest manner. Yet, even in arteries themselves, we can sometimes ascertain the same to the conviction of our senses; as, for example, in the case of phlegmonous inflammation; in which also we find it accompanied with the throb, or alternating spasm and relaxation which constitute what is meant by palpitation. In a healthy and ordinary flow of the blood through the arteries, it is very well known, that there is no sensible series of contractions and dilatations whatever; and we have already observed in the *Physiological Proem* to the third class, that there is no actual change of bulk of any kind, and that it is the pressure of the finger or of some other substance against the side of an artery that alone produces a feeling of pulsation. In a phlegmonous inflammation, however, every one is sensible of a considerable change in this respect; for there is often a very smart and vibratory pulsation while the affected part is in perfect freedom, and no finger is applied to it: and that this is a pulsation, unconnected with the regular pulsation of the heart, is perfectly clear, because it is frequently less uniform, rarely if ever synchronous with it, and, in most instances, twice as rapid. We have here, therefore, a full proof of a local excess of irritability in an arterial tube, and of a palpitation, or alternating spasm and relaxation, as its effect.*

Yet inflammation is but one cause of this subsidiary action, or of the irritability which gives rise to it. With other causes we are not much acquainted; but we have reason to believe them very numerous, and wherever they exist, the artery operated upon will evince the same kind of vibratory throb, though, in general, the stroke will not be found quite so smart as that which takes place in the pulse of a phlegmon. It may appear singular, that this abnormal action, whether of the heart or arteries, should evince so much punctuality in its vibrations; but there is often a wonderful tendency to punctuality in all intermissive affections whatever. We see it in hemorrhoidal discharges, in gout, and above all, in intermitting fevers: and, till the cause of such punctuality is explained in this last instance, it will be in vain to expect an explanation in the case before us.

In very irritable habits, or perhaps where there is a morbid sensibility through the whole of the sanguiferous system, the palpitation will not unfrequently shoot from one artery to another; and one or two cases are given in the *Ephemerides of Natural Curiosities* (*Eph. Nat. Cur.*, dec. i., ann. vi., vii.), in which it appears

* The tenour of some of these observations disagrees with the results of certain microscopical observations made on parts in a state of inflammation. Thus Dr. Thomson of Edinburgh, in his experiments, was unable to discern any alternate expansion and contraction of the arteries. The statement about the pulse in an inflamed part not usually coinciding in number and time to the pulse of the left ventricle, is also at variance with other observations.—Ed.

to have been universal. It was so, indeed, in the very irritable organization of that singularly constituted character, J. J. Rousseau, if we may credit the account he gives of himself in relation to this subject: for he tells us, that after a peculiar paroxysm of high corporeal excitement, he became, all of a sudden, sensible of a pulsation in every part of his body, which from this time accompanied him without intermission: and he adds, that the throbbing was so distinct and strong, that he was often capable of hearing as well as feeling it.

The temporal arteries are peculiarly apt to concur in this migratory throbbing, and occasionally the carotid: and the throbbing of both is sometimes synchronous with that of the heart, and sometimes successive to it. Mr. Dundas has observed, that this affection of the carotids is most common to persons in the prime of life; and that, on dissection, the heart is often found enlarged in its size, but without any increase of muscular power; an assertion collaterally supported by the case of a young lady described under the preceding variety. We here also sometimes meet with polyposous concretions, and very generally adhesions to the pericardium.

And it is highly curious and interesting to notice the ramifying chain of morbid action, of which the heart sometimes forms the first link. I had lately a lady under my care, of delicate constitution and highly nervous habit, in the third month of pregnancy, who had for several weeks been uniformly attacked in the evening with a violent palpitation of the heart, that continued for nearly an hour or upwards; it was then transferred to the temples, which throbbed with as much violence and for as long a period of time; vertigo followed, with a tendency to delirium, immediately after which there was a general reaction in the system; the skin became heated, and at first very dry; but the dryness at length yielded to a gentle diaphoresis, which concluded the morbid series; for the patient at that time becoming tranquil, dropped into a sound and refreshing sleep, and woke free from all these symptoms in the morning.

In this case, also, there was a considerable tendency to that universal subsultus or alternating spasm of the arterial system to which we have just adverted: for all the arteries of the extremities pulsed or palpitated whenever accidentally pressed upon by any substance, though it required this additional stimulus to excite spasmodic action.

Arterial palpitation, however, is to be found, though not more frequently, still far more alarmingly, in the epigastric region, than in the head; and appears to proceed from some particular excitement of the aorta, the superior mesenteric, or some branch of the celiac artery. Its beat has here some resemblance to that of an aneurism of these vessels, and has often been pronounced to be such without the slightest foundation, to the great terror of the patient, and consequently to a considerable exacerbation of the disease. It may, for the most part, be easily distinguished from an aneurism by being destitute of any circumscribed pulsatory tumour

that can be ascertained by a pressure of the finger; by a smarter vibration in the arterial stroke; and by that degree of irregularity in the return of the stroke by which palpitation is distinguished from pulsation. In some cases, indeed, the line of the affected artery can be distinctly felt and followed up to a considerable length; and the vibration has occasionally been so strong as to be visible to the eye, even at some distance, when the surface of the epigastric region has been exposed to view. "From a good deal of experience upon this subject," says Dr. Baillie, "I am enabled to say, that the increased pulsation of the aorta in the epigastric region very rarely depends upon any disease of the aorta itself, or of its large branches in that place; and that this occurrence is almost constantly of very little importance."—(*Med. Trans.*, iv., xix.) This distinguished physiologist tells us further, that he has had an opportunity of examining the state of the arteries in the epigastric region after death, in two persons who had this pulsation very strongly marked, and who died from other diseases. In both cases all the arteries were perfectly free from every appearance of diseased structure. He was also some years ago consulted by an old man upon a paralytic affection; who afterward spoke to him incidentally concerning a palpitation of the kind before us, to which he had been subject for upwards of twenty-five years. The throb, on examination, was distinctly to be felt; and on the patient's first perceiving it, and applying to Sir Cesar Hawkins, Mr. Bromfield, and Dr. Hunter, the two former had declared it to be an aneurism, while the latter, more modestly, confessed that he did not know what it was.

Dr. Baillie, in the article now alluded to, has imitated the modesty of Dr. Hunter. "It is perhaps difficult," says he, "to ascertain, in many instances, the causes of the increased pulsation of the aorta in the epigastric region: but, in most cases, it will be found to be connected with an imperfect digestion and an irritable constitution.* And hence, whatever may improve the digestion and render the constitution less irritable, will be of use in mitigating the complaint: and, above all, will be found highly serviceable to remove the patient's anxiety on the subject, whenever it can fairly be done.† It is here that M. Laennec's stethoscope may be employed as a valuable diagnostic, and will often enable us, better than any other means, to ascertain the real nature of the malady; for an account of which the reader may turn to the remarks on Phthisis.—(Cl. III., Ord. IV., Gen. III., Spe. 5.)

* Dr. Valentine Mott has written an interesting paper on pulsation in epigastrio, which may be found in the *Transact. of the New-York Physico-Med. Society*, vol. i.—D.

† With respect to pulsation in the epigastrium, useful information will be found in A. Burn's work on *Diseases of the Heart*, Edin., 1809; and in a publication by the late Dr. Albers, of Bremen, entitled *Ueber Pulsationem im Unterleibe*, 8vo., Bremen, 1803. The subject is also introduced into the editor's *Dictionary of Practical Surgery*, under the Head of *Abdominal Pulsations*.—Ed.

But the throbbing or pulsatory motion is often communicated to other organs than the sanguiferous vessels, and forms that variety of affection, to which we have given the name of COMPLICATED PALPITATION. This is clearly dependant, in many cases, upon the vicinity or close connexion of such organs with the heart or arteries that form the seat of disease; and it may also in other cases be produced, as ingeniously conjectured by Dr. Young, by an accumulation of fluid in the pericardium or thorax, which transmits a pulsatory motion from the heart itself to whatever other organ or surface of a cavity such fluid may reach; in the same manner as the fluctuation, produced by a slight blow given to one side of the abdomen when distended with water, is distinctly propagated to the opposite side. In the case of a middle-aged woman, of a rheumatic habit, labouring under symptoms of general dropsy (*Med. Trans.*, vol. v., art. xvii.), "a palpitation," he tells us, "was observed in the right hypochondriac region, and on the right side of the neck, which exhibited a vibratory motion more rapid and less regular than that of the pulse felt at the wrist; and a similar vibration was observable in the heart itself: the pulsation of the neck was not confined to the jugular veins; it was more forcible and extensive than it could have been if it had originated from those vessels; and it had more the appearance of a violent throbbing of the carotid artery; although, in the axillary artery, the pulse was comparatively regular and natural." Dr. Young found, nevertheless, upon making a strong pressure on the right side of the neck with a single finger, that the motion of the carotid artery was very perceptible, and totally independent of that of the superficial parts, being precisely synchronous with the pulse at the wrist, although it required considerable attention to distinguish it from the more irregular palpitation. The symptoms, however, of a dropsy of the chest or pericardium in this patient appear to have been obscure; and at the time when the general hydropic enlargement, which had been much reduced in the course of the autumn, began to increase towards the end of October, the palpitation was considerably less, as well as the pulsations in the abdomen and neck, though the motion of the heart was still fluttering, the pulse at eighty, intermitting and very irregular. On the death of the patient, which occurred soon afterward, a considerable quantity of fluid was found in the pericardium, in the right cavity of the thorax, and in the ventricles of the brain, but little or none on the left side of the chest: the heart was inconsiderably enlarged, and some of its valves, as also those of the pulmonary artery, which were much ossified, so that a free passage of the blood was impeded.

I have said, that palpitation is sometimes dependant upon a morbid irritability of the sanguiferous system in general. In some instances, however, we find it rather dependant upon a morbid irritation and debility of the entire frame, and consequently connected with a very irregular performance of many, or all the func-

tions of the body. Of this highly complicated state of the disease we have a striking example in Dr. Bateman's history of himself (*Med. Chir. Trans.*, vol. ix., p. 227), which he ascribes to a poisonous action of mercury, employed on his own person copiously, in the form of an unguent, to relieve an amaurosis of the right eye, and which seems to have produced something of the mercurial erethism described by Mr. John Pearson (*Obs. on the Effects of various Articles of the Materia Medica in Lues Venerea*, ch. xii.) as taking place in some singular idiosyncrasies, already noticed by us under the head of Syphilis.—(Cl. III., Ord. IV., Gen. VII., Spe. 1.) In this case, the heart and arteries were equally subject to subsultory and violent motions, sometimes separately, and sometimes synchronously, but inaccordantly as to the number of the throbs in a given time, and almost perpetually accompanied with a most distressing sense of languor and sinking. There was also a very irksome cough, an occasional sense of constriction across the region of the diaphragm, and such a difficulty of respiration as to render an erect position at night imperatively necessary. Life was, in this case, unquestionably a forced state of being, and all the stimuli of the external senses and of the will seemed necessary to excite the sensorial organ to produce a sufficiency of nervous energy for the mere preservation of life. And hence, during sleep, or as soon as these stimuli were cut off, there was such an increase of languor, irregular action of the heart, and sinking as though in the act of dying, that it was at times necessary, notwithstanding the extreme drowsiness of the patient from a previous and long-continued watchfulness, to interrupt the sleep every two minutes; since by this time or even sooner, the failure of the pulse and the appearance of the countenance indicated a supervening deliquium. The powers of the stomach, from the repeated paroxysms of the disease, seem to have declined rapidly. Frequent supplies of food and cordials, as spiced wine, appeared at first serviceable in warding off the languor; but, at length, nothing but fluids could be taken and retained, without increasing the disturbed action of the heart. Yet so extreme was the sense of sinking and immediate dissolution, that, on one occasion, after a quarter of an hour's sleep, air was importunately demanded, and three glasses of undiluted brandy were drank in five minutes, without much relief: and afterward ammonia and ether repeated every ten minutes for two hours; when the paroxysm rapidly declined after a copious discharge of limpid urine. The disease continued a twelvemonth before the patient felt, in any essential degree, amended: and little benefit was derived from medicines of any kind. It is well known, however, that this acute pathologist and excellent man has since fallen a sacrifice to a return of the complaint.

In a disease produced by so great a diversity of causes, often obscure, and very generally complicated with other affections, it is impossible to lay down any one plan of treatment

that will apply to every case. Our first endeavour should be to ascertain, as far as we may be able, whether the palpitation be idiopathic or symptomatic; and if the last, while we endeavour to palliate the present distress, our attention should chiefly be directed to the primary malady. If any other morbid state of the stomach or bowels be suspected, this, as far as possible, should be removed; and if we have reason to suppose hydrothorax, or any other kind of dropsy to be present, the means hereafter to be recommended for this tribe of complaints should be resorted to from the first. In pregnancy, the disease will most probably cease upon a cessation of this state of body, and usually, indeed, ceases during the latter months, or after the period of quickening. And, if it seem to be chiefly dependant upon a general irritability of the sanguiferous system, or of the whole constitution, the sedative antispasmodics, tonics, and especially the metallic, quiet of mind as well as of body, regular hours, light meals, pure air, and such exercise as agrees best with the individual, will often prove of essential service, and sometimes effect a radical cure.

Much of this plan will also be requisite where we have reason to apprehend some structural affection of the heart or larger bloodvessels: and when, from any incidental excitement, the irritation is here more than ordinarily troublesome, recourse must be had to narcotics. Opium is by far the best where it agrees with the system: but its secondary effects are often very distressing, and we cannot employ it. In such cases, we must find out, by trial, what is its best succedaneum: the hop, henbane, hemlock, and prussic acid, have all been essayed in their turn, and sometimes one has succeeded where the rest have all failed. But, upon the whole, the henbane has answered far better and more generally under the author's own hands: and, in one or two instances of great obstinacy, he has known it effect a perfect cure, when all the rest had been tried in succession and had totally failed.

In Dr. Bateman's case, however, which was peculiarly severe and complicated, the henbane, though it seemed serviceable at first, taken in doses of from three to five grains of the extract every night, gradually lost its effect even when repeated three times a night in doses of five grains at a time. The tincture of hop, in doses of thirty drops every six hours, was next tried, but produced no other effect than a slight drowsiness. Musk seemed most successful in draughts of ten grains each; yet even this was of transient duration, and was abandoned as of no use. Where the palpitation is accompanied with a distressing tendency to deliquium, I have occasionally relieved it by camphire pills, with the ammoniated tincture of valerian or the aromatic spirit of ether.

The disease has occasionally been carried off by a sudden attack of some other complaint, as gout, herpes, diuresis, or the formation of an abscess: and hence, setons and issues have been recommended, and have occasionally proved serviceable. Zacutus Lusitanus found the lat-

ter produced a radical cure in palpitation of the heart, which he ascribed to the rapid healing of some chronic ulcers.—(*Prax. Hist.*, lib. viii., obs. 30.) Schenck advises the wearing a bag of aromatics at the pit of the stomach (Lib. ii., obs. 216); and hence, perhaps, the origin of camphire-bags as a specific for irregularities of the heart of another kind.*

SPECIES IV.

CLONUS NICTITATIO.

TWINKLING OF THE EYELIDS.

RAPID AND VIBRATORY MOTION OF THE EYELIDS.

To a certain extent, twinkling or winking of the eyes is performed every minute without our thinking of it. It is a natural and instinctive action for the purpose of cleansing and moistening the eyeball, and rendering it better fitted for vision. Dr. Darwin has some ingenious remarks upon this subject. "When the cornea," says he, "becomes too dry, it becomes at the same time less transparent, which is owing to the pores of it being then too large; so that the particles of light are refracted by the edges

* Our author speaks of *idiopathic* palpitation; but, according to the editor's view, such a disease has no real existence, palpitation being only a symptom of some other primary affection, either organic or nervous. Thus, it may depend upon organic disease of the heart, aneurism of the aorta, hysteria, chlorosis, indigestion, plethora, uterogestation, anæmia, or nervous disorder, which primary affections, while they continue, prohibit all effectual relief of the palpitations dependant on them. Hence, inasmuch as several of the primary complaints are incurable, the palpitations themselves must also be incurable. On the mode of treating palpitations arising from plethora we need not here dwell. With regard to those occurring in early pregnancy, if they are connected with plethora, the treatment should consist in bleeding the patient, giving her gentle aperient medicines, and making her observe a diet without stimulants. In palpitations from anæmia, Dr. Hope (*Cyclop. of Pract. Med.*) recommends the exhibition of the preparations of iron with aloes, and especially the pills employed by Dr. Abercrombie, consisting of two grains of the sulphate of iron, two of aloes, and five of the compound cinnamon powder, in two pills, taken at dinner, and, if necessary, at bedtime also. Dr. Hope speaks favourably likewise of the carbonate of iron, in doses of from one to three drachms thrice a day, and of small doses of the pil. aloes c' myrrha, and pil. galban. comp. at bedtime. A nutritious animal diet, pure air, gentle exercise, the flesh-brush, salt water sponging, and the shower bath, are likewise commended.

For nervous palpitation, Dr. Hope recommends, at first, the lightest bitters, then bark and mineral acids, and afterward, metallic tonics, one of the best of which is the sulphate of zinc in the dose of one grain, with extract of gentian, in the form of a pill, twice or thrice a day. At the same time it is admitted that, in the first instance, a bracing air by the seaside, seabathing, a nutritious unstimulating diet, and a good regimen in general, are of more importance than medicine; and that after the continuance of such means for a few weeks, chalybeates will often become extremely serviceable.—ED.

of each pore instead of passing through it; in the same manner as light is refracted by passing near the edge of a knife. When these pores are filled with water, the cornea becomes again transparent."—(*Zoonom.*, cl. i., i., 4, 2.) Moisture is indeed a frequent cause of transparency in various bodies; and hence, in dying people, whose eyelids are become torpid and do not nictitate, the cornea is sometimes so dry that its want of transparency is visible to by-standers. So when white paper is soaked in oil, and its pores filled with this fluid, from an opaque body it becomes transparent, and radiates the light that is thrown upon it; air itself is most transparent when as much moisture is dissolved in it as it will hold; when void of moisture, indeed, it forms a dry mist, which is occasionally met with in the morning, and through which distant objects are seen indistinctly; while, on the contrary, when distant objects are seen with perfect clearness, it is a sign of rain. In a mist, distant objects are also seen indistinctly; yet here the moisture is not dissolved in the atmosphere, but merely suspended, and formed by the attraction of cohesion into collected spherules. We may hence account for the want of transparency in the air, which is seen in tremulous motions over cornfields on hot summer days, and over brick-kilns, after the flame is extinguished, while the furnace still remains light. It is this dryness and want of transparency in the atmosphere over the summits of hot and arid hills, in a bright unclouded sky, as in Italy, which constitute what is called by the painters the blue shade of light, and which is copied in most pictures of Italian scenery.

The ordinary use of nictitation is therefore obvious: but there are many persons who wink or twinkle their eyes far more frequently than is necessary for the purpose of moistening the cornea, and in whom it forms an unsightly habit. This has usually been produced at first by some local irritation, as inflammation or dust in the eyes, which quickens the natural action, and, where the stimulus is considerable, renders it irregular and convulsive. If indeed the stimulus be very vehement, the nature of the spasm is changed, and the eyelids, instead of irregularly opening and shutting with great rapidity, become rigidly closed.

We have seen, in many of the preceding species of diseases, with what ease morbid actions are continued when once introduced into an organ: and hence, when any permanent irritation of the eye has excited and maintained for some days or weeks a quick repetition of twinkling, this iterative action will often be found to become habitual, and remain after the irritation has subsided.

This morbid habit has been sometimes cured by a powerful exertion of the will; but more generally by using one eye only at a time, and closing the other; the open eye being employed in examining an object for a considerable period with great attention and steadiness. A minute examination of the stars at night through a telescope has a like corrective tendency, and may be employed for the same purpose.

X 2

SPECIES V. CLONUS SUBSULTUS. TWITCHINGS.

SUDDEN AND IRREGULAR SNATCHES OF THE TENDONS.

THIS affection is to the tendinous extremities of the muscles in which the principle of irritation is often apt to accumulate, what palpitation is to the irritative fibres of the heart and arteries: and hence, as we have already seen, it is included under the general term of palpitation by Vogel.

We witness these starts or twitchings most frequently in extreme stages of debility produced by atonic fevers, and especially just before the act of dying. They are in such cases weak convulsions interruptedly undulating from one limb or part of a limb to another, too feeble to raise the limb itself, although sufficiently powerful to give slight but transient swellings to the belly of a muscle, and consequently a slight involuntary flickering to its tendons. In the ordinary close of life, they are the precursors of the fatal scene, the harbingers of the dying struggle, and generally indicate that the will has lost its hold, and the power of sensation is rapidly ceasing: thus affording another proof, if other proofs were wanting, to those adverted to in the Proem to the present class, that the irritative fibres are capable of maintaining their function, under particular circumstances, for a much later period than the organs of perception and sensation, occasionally, indeed, for some hours after the death of every other part of the body. And as debility and irritability often exhibit a joint march, the subsultory motions are apt to become stronger as the regular motion of the pulse becomes weaker, and at length work up those agonizing convulsions under which the little and loitering flame of life is sometimes extinguished instantaneously. Such twitchings of the tendons, however, do not always prove fatal, for they often show themselves where the case is not so extreme; and hence they may occasionally be allayed by cordials, antispasmodics, and warmer sedatives, and are altogether lost in a favourable turn of the disease.

It occasionally happens, that the debility producing these weak convulsive actions is local and habitual: and in such cases they may be seen to agitate and play over a limb, without any influence on the system generally, and without much injury to the limb itself. Such a state of nervous constitution may be produced by accident, but it is for the most part strictly idiopathic; and there are few practitioners perhaps who have not met with examples of it. Dr. Darwin gives us an instance in the following words: "A young lady, about eleven years old, had for five days had a contraction of one muscle in her forearm, and another in her arm, which occurred four or five times every minute; the muscles were seen to leap, but without bending the arm. To counteract this new morbid habit, an issue was placed over the convulsed muscle of her arm, and an adhesive plaster wrapped tight like a bandage over the whole forearm, by

Samuel B. Wilson
St. Blouiss

which the new motions were immediately destroyed, but the means were continued for some weeks to prevent a return."—(*Zoonomia, Cate-nation*, sect. xvii., i., 8.) The author has sometimes seen it about one of the shoulders, but the extremities are its most usual seat; and he was lately consulted by a lady of a strikingly irritable habit, who was suddenly attacked with it both in her hands and feet, so as to throw her into a considerable degree of alarm. Upon inquiring into the patient's age and state of health, he was informed, that she was between forty and fifty, that menstruation was on the point of leaving her, and had of late appeared very irregularly, and that she had a considerable oppression in her head. The cause was therefore obvious, and the cure was not difficult: for it yielded to a moderate venesection, and an habitual attention to the state of the bowels.*

SPECIES VI. CLONUS PANDICULATIO. PANDICULATION.

TRANSIENT ELONGATION OF THE EXTENSOR MUSCLES, USUALLY WITH DEEP INSPIRATION AND A SENSE OF LASSITUDE.

This is perhaps the slightest modification of spasmodic actions; but as it often occurs, as in nausea on the first stage of a febrile paroxysm, whether the will consents or not, and is frequently and irregularly repeated, it cannot but be regarded as belonging to the present family on many occasions. The muscles chiefly concerned are the extensors of the lower jaw and of the limbs: the particular kind of pandiculation to which the first of these movements gives rise being called *OSCITANCY*, *YAWNING*, or *GAPING*; and that produced by the second, *STRETCHING*. The muscles are excited to this peculiar action by a general feeling of restlessness or disquiet: and the spread of the action from one muscle or set of muscles to another, is from that striking sympathy or tendency to catenate in like movements which we so often behold in different parts of the body, without being able to explain. It is possible, however, that the synchronous motion of the muscles of the lower jaw and of the limbs, for it is rarely that yawning and stretching do not accompany each other, may be dependant upon the same line of intercourse, by which trismus so often accompanies a wound in one of the extremities, and which we have already attempted to illustrate; the irritant power, in the one case, leading to a fixed or entastic, and in the other to a transient and clonic spasm.

Pandiculation, considered physiologically, is an instinctive exertion to recover a balance of power between the extensor and flexor muscles, in cases in which the former have been encroached upon and held in subjection by the latter.

A very slight survey of the animal frame will

* There is some reason to think that clonus subsultus occurs more frequently from affections of the knee-joint than from any other local disturbance.—D.

show us that the flexor muscles have in every part some preponderance over the extensors; and that this preponderance is perpetually counteracted by the stimulus of the instinct or of the will. We see it from the first stage of life to the last, and most distinctly in those states in which there is most feebleness, and consequently in which the controlling powers are least capable of exercising and maintaining a balance. In the fetus, therefore, in which the weakness is most pressing, the power of instinct is merely rising into existence, and no habit of counterpoise established in the nascent fabric, every limb, and part of every limb capable of bending, undergoes some degree of flexure, and the entire figure is rolled into a ball, as the hedgehog habitually rolls himself even after birth. As the fetus, however, increases in size and age, and the powers of instinct, sensation, and volition become more perfect, this general confluxure produces occasionally a sense of uneasiness; and hence every parturient mother is sensible of frequent internal movements and stretchings of the little limbs of the fetus to take off the uneasiness by restoring some degree of balance to the antagonist powers. After birth, and during wakefulness, the stimulus of the will, directed rather to the extensor than the flexor muscles, renders the counterpoise complete for all the purposes for which it may be necessary. But the moment we repose ourselves in sleep, and the will becomes inactive and withdraws its control, the flexor muscles exercise their preponderance afresh, though in a less degree than in fetal life, since the extensors, from habitual use, have acquired a more than proportionate increase of power. The preponderance, however, when long exerted, still produces some degree of disquiet, and hence occasionally during sleep, and still more vigorously the moment we begin to awake, we instinctively rouse the extensor muscles into action; or in other words, yawn, stretch the limbs, and breathe deeply, to restore the equipoise that has been lost during unconsciousness.

In all these cases, pandiculation is a natural action; it is an effect produced by the will when it is called to the particular state of these two sets of muscles, or by the instinctive or remedial power of nature, which supplies its place when it is dormant or inattentive, to restore ease to a disquieted organ. But, in an infirm or debilitated condition of the system, it evinces a morbid and convulsive character, and takes place without our being able to prevent it, even when the will uses its utmost effort to resist instead of to encourage it.

How far its repetition may be of use in the shivering fit of an ague, or in a nauseating deliquium of the stomach, it is difficult to say. Yet we are at no loss to account for its frequency of recurrence; for as the whole system is, in such circumstances, thrown into a sudden prostration of strength, the extensor muscles, in consequence of being naturally weaker than their antagonists, must become soonest exhausted, and give way with a more than ordinary submission to their power. And hence we behold a painful

retraction over the whole system, and the preponderance assumes a rigid and spastic character; and we may fairly conclude, that much of the yawning and stretching which ensue, is for the purpose of getting rid of the constrictive spasm, though these counteractions themselves often run in the attempt into a spasm of another kind, and become convulsive.

Yawning and stretching, then, are among the signs of debility and lassitude. And hence, every one who resigns himself ingloriously to a life of lassitude and indolence, will be sure to catch these motions as a part of that general idleness which he covets. And, in this manner, a natural and useful action is converted into a morbid habit; and there are loungers to be found in the world, who, though in the prime of life, spend their days as well as their nights in a perpetual routine of these convulsive movements over which they have no power; who cannot rise from the sofa without stretching their limbs, nor open their mouths to answer a plain question without gaping in one's face. The disease is here idiopathic and chronic: it may perhaps be cured by a permanent exertion of the will, and ridicule and hard labour will generally be found the best remedies for calling the will into action.

GENUS III.

SYNCLONUS.

SYNCLONIC SPASM.

TREMULOUS, SIMULTANEOUS, AND CHRONIC AGITATION OF VARIOUS MUSCLES, ESPECIALLY WHEN EXCITED BY THE WILL.

WE have already observed, that *CLONUS* imports "agitative," or "tremulous motion of the muscles;" and hence, *SYNCLONUS* means necessarily their "multiplied, conjunctive, or compound agitation, or tremulous motion." The term is therefore intended to denote a group of diseases more complicated in form, of more extensive range, or more connected with the general state of the constitution than those of the preceding genus; and it runs parallel with the *clonici universales* of Sauvages, as far as they can be said correctly to belong to this family. The species included under this genus will be found to be the following:

1. *Synclonus Tremor.* Trembling.
2. ——— *Chorea.* St. Vitus's Dance.
3. ——— *Balismus.* Shaking Palsy.
4. ——— *Raphania.* Raphania.
5. ——— *Beriberia.* Barbers.

SPECIES I.

SYNCLONUS TREMOR.

TREMBLING.

SIMPLE TREMULOUS AGITATION OF THE HEAD, LIMBS, OR BOTH; MOSTLY ON SOME VOLUNTARY EXERTION.

THE proximate cause of this disease is an irregular transmission of irritable power to the motory fibres of the muscles that constitute its seat. It is strictly a disease of nervous debility, either general or local: debility produced by sudden exhaustion, as in the case of

great muscular fatigue from violent exercise, severe cold, or a vehement exertion of the passions, and particularly of the passions of fear and rage; or debility produced slowly and insensibly by causes of tardy operation, as an injudicious use of mercury, lead, opium, or other mineral and narcotic poisons; an habitual excess in hard drinking or sexual commerce; and, in some idiosyncrasies, an immoderate indulgence in tea.* And, as this disease is a result of debility, it necessarily occurs as a symptom on the general spasm and prostration of strength that so peculiarly distinguish the accession of an ague-fit, and the interruption of sensorial power that takes place in paralysis.

There are some persons, however, in whom the same convulsive action exists habitually, without any morbid state of other organs, or any other inroad upon the general health. I once knew a lady considerably beyond the middle of life, who was strikingly affected with this complaint, insomuch that the slightest voluntary exertion of any of the muscles threw the head and arms into as great a tremour as if they had been hung upon wires, but who enjoyed at the time, and had for a long term of years continued to enjoy, as perfect health as possible in every other respect; was lively, cheerful, animated, possessed of brilliant powers of conversation, and able to use a more than ordinary portion of exercise without fatigue.

The earlier part of her life had been passed in India, but her constitution did not appear to have suffered from this circumstance; and so gradual was the attack of the affection, that though she had laboured under it for many years, she could not date its commencement from any given point of time. She at length died at the age of seventy-two or seventy-three, her corporeal powers progressively declining, and laying a foundation for a general dropsy, while her mind continued firm to the last.

In all cases of this kind, the supply of nervous energy to the motory fibres of the affected muscles takes place interruptedly, and where the organ or the constitution is in a state of debility, it is also less abundant as well as less uniform. We have already observed, that the nervous energy (or fluid, as the author preferred calling it), in its natural course is transmitted only by waves or vibrations, and consequently with an interposing pause or relaxation after every efflux; but that the pause is instantaneous, and the supply so regular as to answer the purpose of a permanent and continuous tenour. In clonic tremour, the pauses are, however, prolonged, and for the most part irregular, or untrue to themselves; and the greater the retardation and irregularity, the more marked and alarming the spasmodic shake.

In the case just adverted to, there was no other diseased action whatever; the nervous power was unquestionably supplied in sufficient

* It arises also from long indulgence in tobacco, particularly in the form of snuff; it will occasionally be caused by the loss of sleep, and is sometimes seen in persons of a sanguineous temperament after severe seasickness.—D.

abundance, and the pauses, though prolonged, were uniform; and it was singular to observe the influence the will possessed over the affected muscles under these circumstances, and how completely they were still under its control: for, in consequence of the uniformity of the morbid interruptions, and from the force of habit, I have seen this patient, in the midst of a shaking that threatened every moment to overturn whatever she took hold of, raise a cup brimful of tea, or a glass brimful of wine to her lips by way of experiment, without spilling a single drop.
