loses its crystalline form. A hundred parts of this acid are soluble in seventy-five of water at 60°. Though it is less alterable than most other solutions of vegeta-ble acids, it will undergo decomposition when long kept.

It is not altered by any combustible substance : charnt is not altered by any combustible substance; charcoal alone appears to be capable of whitening it. The
most powerful acids decompose it less easily than they
do other vegetable acids; the sulphuric evidently converts it into acetic acid. The nuric acid likewise, if
employed in large quantity, and heated on it a long
time, converts the greater part of it into acetic acid,
and a small portion into oxalic.

The citrate of lime has been mentioned already, in

The citrate of time has been mentioned already, in treating of the mode of purifying the acid.

The citrate of potassa is very soluble and deli-

The citrate of soda has a dull saline taste; dissolves The citrale of soda has a dull saline taste; dissolves in less than twice its weight of water, crystallizes in six-sided prisms with flat summits; effloresces slightly, but does not fail to powder; boils up, swells, and is reduced to a coal on the fire. Lime water decomposes it, but does not render the solution turbid, notwithstanding the little solubility of citrate of lime.

Citrate of ammonia is very soluble; does not crystallize unless its solution be greatly concentrated; and forms elongated prisms.

forms elongated prisms.

Citrate of magnesia does not crystallize. When its solution had been boiled down, and it had stood some days, on being slightly shaken it fixed in one white opaque mass, which remained soft, separating from the sides of the vessel, contracting its dimensions, and rising in the middle like a kind of mushroom.

All the citrates are decomposed by the powerful acids, which do not form a precipitate with them, as with the oxalates and tartrates. The oxalic and tartrate acids decompose them, and form crystallized or insoluble precipitates in their solutions. All afford these of acetic acids acre product of the same nature. traces of acetic acid, or a product of the same nature, on being exposed to distillation: this character exists particularly in the metallic citrates. Placed on burning coals they melt, swell up, emit an empyreumatic smell of acetic acid, and leave a light coal. All of them, if dissolved in water, and left to stand for a time, undergo decomposition, deposite a flocculent mucus which grows black, and leaves their bases combined with carbonic acid, one of the products of the decomposition. Before they are completely decomposed, they appear to pass to the state of acetates.

The affinities of the citric acid are arranged by Vau quelin in the following order: barytes, lime, potassa, soda, strontian, magnesia, ammonia, alumina. for zircone, glucine, and the metallic oxides, are not ascertained.

The citric acid is found in many fruits united with the malic acid.

Citric acid being more costly than tartaric, may be occasionally adulterated with it. This fraud is dis-covered, by adding slowly to the acid dissolved in water a solution of subcarbonate of potassa, which will give a white pulverulent precipitate of tartar, if the citric be contaminated with the tartaric acid. When citric be contaminated with the tartaric acid. one part of citric acid is dissolved in 19 of water, the solution may be used as a substitute for lemon-juice. If before solution the crystals be triturated with a little sugar and a few drops of the oil of lemons, the re-semblance to the native juice will be complete. It is an antidote against sea scurvy; but the admixture of mucilage and other vegetable matter in the recent fruit of the lemon, has been supposed to render it preferable to the pure acid of the chemist."-Ure's Chem. Dict.

CITRINA'TIO. Complete digestion. CITRI'NULA. (A diminutive of citrus.) A small citron or lemon.

CITRON. See Citrus medica.
Citrul, Sicilian. See Cucurbita citrullus.
CITRU'LLUS. See Cucurbita citrullus.
CITRUS. 1. The name of a genus of plants in the Linnwan system. Class, Polyadelphia; Order,

CITRUS AURANTIUM. The systematic name of the orange tree and fruit. Aurantium; Aurantium Hispalense; Aurantium Chinense; Malus aurantia major; Malus aurantia; Aurantium vulgare; Malus aurantia vulgaris; Mala aurea; Chrysomelia; Nerantia; Martianam pomum; Poma aurantia. The China and Seville orange are both only varieties of the same species: Citrus:—petiolis alatis, foliis acumina The name of the lemon. See Citrus medica. same species: Citrus:—petiolis alatis, foliis acumina tis, of Linnæus. The latter is specified in our pharmacopæias; and the flowers, leaves, yellow rind, and juice, are made use of for different medical purposes.

CIT CLA

The flowers, flores napha, are highly oderiferous, and are used as a perfume; they are bitter to the taste; they give their taste and smell both to water and to spirit, but most perfectly to rectified spirit of wine. The water which is distilled from these flowers, is called aqua forum napha. In distillation, they yield a small quantity of essential oil, which is called oleum vel essential recoil; they are brought from Italy and leaven trees agree. The citron when sweetvel essentia neroù: they are brought from Italy and France. Orange flowers were, at one time, said to be a useful remedy in convulsive diseases; but experience has not confirmed the virtues attributed to

The seaves have a bitterish taste, and yield, by distillation, an essential oil; indeed, by rubbing them between the fingers and the thumb, they manifest con-

between the fingers and the thumb, they manifest considerable fragrance. They have been applied for the same purposes as the flowers, but without success.

The yellow rind of the fruit, freed from the white fungous part, has a grateful aromatic flavour, and a warm, bitterish taste. Infused in boiling water, it gives out nearly all its smell and taste: cold water extracts the bitter, but very little of the flavour. In distillation, a light, fragrant, essential oil rises, without the bitter. Its qualities are those of an aromatic and bitter. It has been employed to restore the tone of the bitter. It has been employed to restore the tone of the stomach, and is a very common addition to combinations of bitters, used in dyspepsia. It has likewise been given in intermittents, in doses of a drachm, twice or thrice a day. It is also much celebrated as a powerful remedy, in menorrhagia, and immoderate uterine evacuations.

The juice of Seville oranges is a grateful acid, which, by allaying heat, quenching thirst, promoting various excretions, and diminishing the action of the sanguiferous system, proves extremely useful in both ardent and putrid fevers; though the China orange juice, as impregnated with a larger proportion of sugar, becomes more agreeable, and may be taken in larger quantities.

more agreeable, and may be taken in larger quantities. The Seville orange juice is particularly serviceable as an antiscorbutic, and alone will prevent or cure scurvy in the most apparently desperate circumstances. In dyspepsia, from putrid bile in the stomach, both lemon and orange juice are highly useful.

CITRUS MEDICA. The systematic name of the lemon-tree. Limon; Limonia mala; Malus medica; Malus limonia acida; Citrea malus; Citrus. The tree which affords the lemon is the Citrus:—petiolis linearibus, of Linnaus: a native of the upper part of Asia, but cultivated in Spain, Portugal, and France. The juice, which is much more acid than that of the orange, possesses similar virtues. It is always preferred where a strong vegetable acid is required. Saturated with the fixed vegetable alkali, it forms the citrate of potassa, which is in frequent extemporanecitrate of potassa, which is in frequent extemporane-ous use in febrile diseases, and by promoting the secre-tions, especially that of the skin, proves of considera-ble service in abating the violence of fever. This medicine is also often employed to restrain vomiting. As an antiscorbutic, lemon juice has been often taken on board ships destined for long voyages; but even when well depurated of its mucilaginous parts, it is found to spoil by long keeping. To preserve it in purity for a considerable length of time, it is necessary that it should be brought to a highly concentrated state, and for this purpose it has been recommended to expose the juice to a degree of cold sufficient to conto expose the juice to a degree of cold sufficient to congeal the aqueous and mucilaginous parts. After a crust of ice is formed, the juice is poured into another vessel; and, by repeating this process several times, the remaining juice, it is said, has been concentrated to eight times its original strength, and kept without suffering any material change for several years. Whytt found the juice of lemon to allay hysterical palpitations of the heart, after various other medicines had been experienced ineffectual; and this juice, or that of oranges, taken to the quantity of four or six that of oranges, taken to the quantity of four or six ounces in a day, has sometimes been found a remedy in the jaundice. The exterior rind of the lemon is a very grateful aromatic bitter, not so hot as orange peel, and vielding in distillation a less quantity of oil very grateful aromatic bitter, not so not as orange peet, and yielding in distillation a less quantity of oil, which is extremely light, almost colourless, and generally brought from the southern parts of Europe, under the name of Essence of Lemons. The lemon-peel, though less warm, is similar in its qualities to that of the orange, and is employed with the same intentions. The pharmacopeelas direct a syrup of the juice, syrupus limonis, and the peel enters into some vinous and pus limonis, and the peel enters into some vinous and

The citron-tree is also considered as belonging to the same species, the Citrus medica of Linnaus. Its fruit is called Cedromela, which is larger and less succulent than the lemon; but in all other respects the citron and lemon trees agree. The citron juice, when sweetened with sugar, is called by the Italians Agro dicedro. The Citrus mella rosa of Lamarck, is another variety of the Citrus medica of Linnaus. It was produced at first casually, by an Italian's gradies a produced, at first, casually, by an Italian's grafting a citron on a stock of a bergamot pear-tree; whence the fruit produced by this union participated both of the citron-tree and the pest-tree. The essence prepared from this fruit is called essence of bergamote and es sentia de cedra.

CITTA. A voracious appetite.

CITTA. A voracious appetite.
CITTO SIS. See Chlorosis.
CIVET-CAT. See Zibethum.
CIVETTA. (From sebet, Arabian.) Zibethum.
Civet; an unctuous odoriferous drug used by perfumers, collected between the anus-and the organs of generation of a fierce carnivorous quadruped mer with in China and the East and West Indies, called a civet-cat, the Viverra Zibethum of Linneus, but bearing a greater resemblance to a fox or marten than a cat.
Several of these animals have been brought into

Several of these animals have been brought into Holland, and afford a considerable branch of commerce, particularly at Amsterdam. The civet is squeezed out in summer every other day, in winter twice a-week: the quantity procured at once is from two scruples to a drachm or more. The juice thus collected is much purer and finer than that which the animal sheds against shrubs or stones in its native

Good civet is of a clear yellowish or brownish co-lour, not fluid nor hard, but about the consistence of butter or honey, and uniform throughout; of a very strong smell; quite offensive when undiluted; but agreeable when only a small portion of civet is mixed with a large one of other substances.

Civet unites with oils, but not with alkohol. Its

nature is therefore not resinous. CLAP. See Gonorrhaa.

CLAP. See Gonorrhaa.
CLA'RET. (Claretum; from clareo, to be clear.)
A French wine, that may be given with great advantage, as a tonic and antiseptic, where red port wine disagrees with the patient; and in typhoid fevers of children, and delicate females, it is far preferable, as a common drink

CLARE'TUM. 1. The wine called claret. See Claret.

2. A wine impregnated with spices and sugar, called by some Vinum Hippocraticum.

3. A Claretum purgetorium, composed of a vinous infusion of glass of antimony with cinnamon water and sugar, is mentioned by Schræder.

CLARIFICATIO. The depuration of any thing, or process of freeing a fluid from heterogeneous mat-

or process of freeing a fluid from heterogeneous matter, or feculencies.

["CLARK, John. The name of John Clark has been, for a longer succession of years than any other in our country, distinguished in the ranks of medical practitioners. Of the earliest physician of that name, who probably came from England in 1631 or 1632, and after living a few years in Boston, removed to Rhode Island, where he died April 20th, 1676, filling a long course of service in administering to the religious as well as natural wants of his neighbours." He was succeeded by several individuals of the same page. weil as natural wants of his neighbodis. He was succeeded by several individuals of the same name, who were all conspicuous members of the medical profession.—Thach, Med. Biog. A.]
CLASS. (Classis; from καλεω, congrego, a class being nothing more than a multitude assembled apart.)
The man of a primary division of bedies in a reimary division of bedies in

The name of a primary division of bodies in natural

history.
CLARY. See Salvia.
CLA'SIS. (From κλαω, to break.) Clasma. Λ fracture.

CLAU'STRUM. (From claude, to shut.) Clei-thrum gutturis. Any aperture which has a power of contracting itself, or closing its orifice by any means; as the passage of the throat.

CLAUSTRUM VIRGINITATIS. The hymen. CLAUSU'RA. (From claude, to shut.) An imperferation of any canal or cavity in the body. Thus

clausura uter is a preternatural imperforation of the uterus; clausura tubarum Fallopiarum, a morbid im-perforation of the Fallopian tubes, mentioned by

Perforation of the Fallopian under, manuscript Ruysch as one cause of infecundity.

CLAVA RUGOSA. See Acorus calamus.

CLAVARIA. (From clava, a club.) The name of a genus of plants, Class, Cryptogamia; Order, Fungi. Club-shaped fungus.

CLAVARIA COROLLOIDES. The systematic name of the Fungus corolloides of old writers; called also crotelus. It was once used as a strengthener and

CLAVA'TIO. (From clava, a club.) A sort of articulation without motion, where the parts are, as it were, driven in with a hammer, like the teeth in the

sockets. See Gomphosis. CLAVATUS. Clubbed. Applied to parts of

plants, as the stigma of the Genipi.

plants, as the stigma of the Genipi.

CLAVELLATUS. (From clavus, a wedge. The name cineres clavellati originated from the little wedges or billets, into which the wood was cut to burn for potassa.) See Potassa impura.

CLA'VICLE. (Clavicula, diminutive of clavis; so called from its resemblance to an ancient key.) Collar-bone. The clavicle is placed at the root of the neck, and at the upper part of the breast. It extends across, from the tip of the shoulder to the upper part of the sternum; it is a round bone, a little flattened tothe sternum; it is a round bone, a little flattened towards the end, which joins the scapula; it is curved like an Italic S, having one curve turned out towards the breast: it is useful as an arch, supporting the shoulders, preventing them from falling forwards upon the breast, and making the hands strong antagonists to each other; which, without this steadying, they could not have been.

1. The thoracic end, that next the sternum, or what may be called the inner head of the clavicle, is round and flat, or button-like; and it is received into a suitable hollow on the upper piece of the sternum. It is not only, like other joints, surrounded by a capsule or purse; it is further provided with a small moveable cartilage, which, like a friction wheel in machinery, saves the parts and facilitates the motions, and moves continually as the clayicle moves.

2. But the outward end of the clavicle is flattened, as it approaches the scapula, and the edge of that flatness is turned to the edge of the flattened acromion, so that they touch but in one single point. This ower end of the clavicle, and the corresponding point of the acromion, are flattened and covered with a crust of cartilage; but the motion here is very slight and quite insensible; they are tied firmly by strong ligaments; and we may consider this as almost a fixed point, for there is little motion of the scapula upon the clavicle; but there is much motion of the clavicle upon the breast, for the clavicle serves as a shaft, or axis, firmly tied to the scapula, upon which the scapula moves and turns, being connected with the trank only by this single point, viz. the articulation of the clavicle with the breast-bone.

CLAVICULA. See Clavicle.
CLAVICULUS. See Clavicle.
CLAVIS. (From claudo, to shut.) The clavicle.
CLAVUS. (A nail.) 1. A corn called clavus, from its resemblance to the head of a nail; Ecphyma clavus of Good. A roundish, horny, cutaneous extu-berance, with a central nucleus, sensible at its base; found chiefly on the toes, from the pressure of tight shoes

2. A painful and often an intermitting affection of the head, and mostly a severe pulsating pain in the forehead, which may be covered by one's thumb, giving a sensation like as if a nail were driven into the When connected with hysterics, it is called Clavus hystericus

3. An artificial palate.

4. Diseased uterus.

CLAVUS HYSTERICUS. See Clavus. CLAVUS OCULORUM. A staphyloma, or tumour on

the eyelids.

CLAY. Argilla. Argillaceous earth, of which there are many kinds, and being opaque and noncrystalized bodies, of dull fracture, afford no good principle for determining their species; yet as they are extensively distributed in nature, and are used in many arts, they deserve particular attention. The argillaceous minerals are all splitcipally soft in he courtehed. ceous minerals are all sufficiently soft to be scratched

by iron; they have a dull or even earthy fracture; they exhale, when breathed on, a peculiar smell called argillaceous. The clays form with water a called argillaceops. The clays form with water a plastic paste, possessing considerable tenacity, which hardens with heat, so as to strike fire with steel. Marles and chalks also soften in water, but their paste is not tenaceous, nor does it acquire a siliceous hardness in the fire. The affinity of the clays for mois, re is manifested by their sticking to the tongue, and by the intense heat, were sary to make them. and by the intense heat necessary to make them per feetly dry. The odour ascribed to clays breathed upon, is due to the oxide of iron mixed with them. Absolutely pure clays emit no smell.

1. Porcelain earth, the kaolin of the Chinese.—This

I. Porcelain earth, the kaolin of the Chinese.—This mineral is friable, meagre to the touch, and, when pure, forms with difficulty a paste with water.

2. Potter's clay, or plastic clay.—The clays of this variety are compact, smooth, and almost unctuous to the touch, and may be polished by the finger when they are dry. They have a great affinity to water, form a tenacious paste, and adhere strongly to the tongue.

3. Loam - This is an impure potter's clay, mixed

with mica and iron ochre.

4. Variegated clay.—Is striped or spotted with white, red, or yellow colours.

5. State ctay.—Colour, gray or grayish-yellow.
6. Claystone.—Colour, gray, of various shades, sometimes red, and spotted, or striped.

7. Adhesive state.—Colour, light greenish gray.
8. Polishing state of Werner.—Colour, cream-yellow, in alternate stripes.

9. Common clay may be considered to be the same as loam.

CLAY, PURE. See Alumina.
CLAY-SLATE. Argillaceous slate. Argillite of Kirwan. A mineral which is extensively distributed, forming a part of both primitive and transition moun-

tains of state, is found in many countries.
["CLAYTON, Dr. JOBN, an eminent botanist and physician, of Virginia, was born in England in 1685, and came to Virginia in 1705, and resided near Williamsburg. He was elected a member of several of the first literary societies of Europe, and corresponded with many of the most learned naturalists of that period. riod. As a practical botanist, he was, probably, not inferior to any one of the age. He passed a long life in exploring and describing the plants of his country, and is supposed to have enlarged the botanical cataand is supposed to have chiarged the botanical cata-logue as much as any man who ever lived. He is the author of "Flora Virginica," a work published by Gronovius at Leyden, 8vo. in 1739, 1743, and 1762. He published in the philosophical transactions several communications, treating of the culture of the differ-ent species of tobacco, and an ample account of the medicinal plants which he had discovered in Virginia. He also left behind him two volumes of manuscript meaths recovered for the press and a Hortus Sierus with neatly prepared for the press, and a Hortus Siccus with marginal notes and references for the engraver who should prepare the plates for his proposed work. He died December 15th, 1773, in the 88th year of his age. During the year preceding his decease, such was the vigour of his constitution, even at this advanced pe-riod, and such was his zeal in botanical researches, that he made a botanical tour through Orange County; and it is believed that he bad visited most of the set tled parts of Virginia. His character stands very high as a man of integrity, and as a good citizen."—Thach.

Med. Biog. A.]

["CLAYTON, Dr. Joshua, was Governor of the State of Delaware, and a member of the United States Senate; he died in 1729. He was highly respectable in the medical profession, in which he practised for

many years.

In 1792, he addressed a friend as follows: "During In 1792, he addressed a friend as follows: "During the late war, the Peruvian bark was very scarce and dear. I was at that time engaged in considerable practice, and was under the necessity of seeking a substitute for the Peruvian bark. I conceived that the poplar, Liriodendron tulipifera, had more aromatic and bitter than the Peruvian, and less astringency, and bitter than the Peruvian, and less astringency. To correct and amend those qualities, I added to it nearly an equal quantity of the bark of the root of dogwood, cornus florida, and half the quantity of the inside bark of the white-oak tree. This remedy I prescribed for several years, in every case in which I conceived the Peruvian bark necessary or proper, with

species of intermittent, gangrenes, mortifications, and in short, every case of debility."—Thach. Med. Biog. A.]
CLEAVAGE. This term is applied to the mechanical division of crystals, by showing the direction in which their laminæ can separate, enables us to determine the mutual inclination of these laminæ: Werner called it durchgang, but he attended only to the number of directions in which this mechanical division of the plates, or cleavage, could be effected. In sion of the plates, or cleavage, could be effected. In the interior of many minerals, the direction of the cleavage may be frequently seen, without using any

mechanical violence.

CLEAVERS. See Galium aparine.

CLEGHORN, GEORGE, was born near Edinburgh, in 1716, and, after studying in that city, went at the age of twenty to Minorca, as a regimental surgeon. During the thirteen years that he spent there, he sedulously studied the natural productions of the island. In 1750, coming to London, he published his "Treatise on the Diseases of Minorca," which displays great observation and ability. He then went to Dublin, and gave because on anatomy with such success, that he gave lectures on anatomy with such success, that he was soon after appointed public professor; and, in 1774, an honorary member of the College of Physicians there. He died in 1789, Clet'pion. Clidion. The epithet of a pastil, de-

CLET'DION. Clidion. The epithet of a pastil, described by Galen and Paulus Agineta; and it is the name also of an epithem described by Actius.

CLEIDO MA. (From κλειδοω, to close.) A pastil, or troch. Also the clavicle.

CLEIDOMASTOIDE US. (From κλεις, the clavicle, and μασοειδης, the mastoid process.) See Sterno-

CLEISA GRA. (From κλως, the clavicle, and μγρα, a prey.) The gout in the articulation of the clavicles. CLETTHRON. (From khadow, to shut.) See Claus-

CLE MATIS. (From $\kappa\lambda\eta\mu\alpha$, a tendril; so named from its climbing up trees, or any thing it can fasten upon with its tendrils.) The name of a genus of plants in the Linnwan system. Class, Polyandria; Order, Polygynia.

Polygynia.

CLEMATIS RECTA. The systematic name of the upright virgin's-bower. Flammula Jovis. Clematis—foliis pinnatis, foliolis ovato lanceolatis integerrimis, caule erecto, floribus pentapetalis tetrapetalisque of Linneus. More praises have been bestowed upon the virtue which the leaves of this plant are said to possess, when exhibited internally, as antivenereal, by foreign physicians, than its trials in this country can justify. The powdered leaves are sometimes applied externally to ulcers as an exhautic. externally to ulcers, as an escharotic.

CLEMATIS VITALBA. The systematic name of the traveller's-joy. Vitalba; Atragene; Viorna; Clematis arthragene of Theophrastus. This plant is common in our hedges, and is the Clematis—folits pinna-tius, foliolis cordatis scandentibus, of Linnaus. Its leaves, when fresh, produce a warmth on the tongue, and if the chewing is continued, blisters arise. The same effect follows their being rubbed on the skin. The plant has been administered internally to cure lues venerea, scrofula, and rheumatism. In France, the young sprouts are eaten, when boiled, as hoptops

the young spread of the same as clematis.

CLEMATI'TIS. The same as clematis.

CLEMATI'TIS. The name of a collyrium

An astringent formula of myrrh, CLEONIS GLUTEN. frankincense, and white of egg mixed together.

Trankincense, and white of egg inixed together.

CLE 'PSYDRA. (From κλεπτω, to conceal, and νόωρ, water.) Properly, an instrument to measure time by the dropping of water through a hole, from one vessel to another; but it is used to express a chemical vessel, perforated in the same manner. It is also an instrument mentioned by Paracelsus, contrived to convey suffumigations to the uterus in hysterical cases.

CLEYER Asperw, was born at Cassal, in the he

CLEYER, Andrew, was born at Cassel, in the beginning of the 17th century. After studying medicine, he went as physician to Batavia, where he resided many years. He transmitted several interesting communications to the Imperial Academy, of which he had been chosen a member, particularly "An Account of Hydatids found in a Human Stomach," and "Of the Custom of the Indians of taking Opium;" also descriptions and drawings of the plants indigenous in Java, especially the moxa, ginseng, and tea-plant. He with the law the band of the local particularly and the composed, e. 19 and 1 have through. Chinese medicine.

CLI'BANUS. (Quasi καλιδανος; from καλυπ/ω, to conceal.) A portable furnace, or still, in which the materials to be wrought on are shut up.

CLIFTON, Francis, after studying at Oxford, came to London, and was admitted Fellow of the College of Physicians, as well as of the Royal Society, about the year 1730. Two years after, he published on "The State of Physic, ancient and modern, with a Plan for improving it;" in which a law is proposed, to compel practitioners to send to a public institution descriptions of the several cases which come under their care. He was also author of "A plain and sure Way of practising Physic;" and translated some parts of Hippocrates into English, with notes.

CLIMA'CTER. (From κλιμαζω, to proceed gradually.)

CLIMA'CTER. (From κλιμαζω, to proceed gradually.)
The progression of the life of man. It is usually divided into periods of seven years.

vided into periods of seven years.

Climacteric. See Septenary.

CLIMATE. The prevailing constitution of the atmosphere, relative to heat, wind, and moisture, peculiar to any region. This depends chiefly on the latitude of the place, its elevation above the level of the sea, and its insular or continental position. Springs which issue from a considerable depth, and caves about 50 feet under the surface, preserve a uniform temperature through all the vicissitudes of the season. This is the mean temperature of that country.

temperature through all the vicissitudes of the season. This is the mean temperature of that country.

It appears very probable, that the climates of European countries were more severe in ancient times than they are at present. Casar says, that the vine could not be cultivated in Gaul, on account of its wintercold. The rein-deer, now found only in the zone of Lapland, was then an inhabitant of the Pyrenees. The Tiber was frequently frozen over, and the ground about Rome covered with snow for several weeks together, which almost never happens in our times. The Rhine and the Danube, in the reign of Augustus, were generally frozen over for several months of winwere generally frozen over for several months of win-ter. The barbarians, who overran the Roman empire a few centuries afterward, transported their armies and wagons across the ice of these rivers. The improvement that is continually taking place in the climate of America, proves, that the power of man extends to phenomena, which, from the magnitude and variety of their causes, seemed entirely beyond his control. At Guiana, in South America, within five degrees of the line, the inhabitants living amid immense forests, a century ago, were obliged to alleviate the severity of the cold by evening fires. Even the duration of the rainy season has been shortened by the clearing of the country and the warrath is so increased that a few country, and the warmth is so increased, that a fire now would be deemed an annoyance. It thunders continually in the woods, rarely in the cultivated

Drainage of the ground, and removal of forests, however, cannot be reckoned among the sources of the increased warmth of the Italian winters. Chemical writers have omitted to notice an astronomical cause of the progressive amelioration of the climates of the northern hemisphere. In consequence of the apogee portion of the terrestrial orbit being contained apogee portion of the terrestrial orbit being contained between our vernal and autumnal equinox, our summer half of the year, or the interval which elapses between the sun's crossing the equator in spring, and in autumn, is about seven days longer than our winter half year. Hence also, one reason for the relative coldness of the southern hemisphere.

[While Dr. Priestley was engaged, during the month of July, 1801, in making experiments with a double convex lens upon some metallic substances at Northumberland, in Pennsylvania, he wrote thus to Dr. Mitchin-

berland, in Pennsylvania, he wrote thus to Dr. Mitchill:

"If I have a few days more sunshine, I shall finish
what I am about, and write the next post. Happily
we are never long without sunshine, whereas in England I have often waited months; and the days in
which I could use a burning lens have not, I am confident, exceeded one fortnight in some whole years,
and I have often watched every gleam the year
through. I think the climate of this country greatly
preferable to that of England."—Med. Repos. A.]
CLIMAX. (From khuala. to proceed.) A name berland, in Pennsylvania, he wrote thus to Dr. Mitchill:

CLΓMAX. (From κλιμαζω, to proceed.) A name of some antidotes, which, in regular proportion, increased or diminished the ingredients of which it was composed, e. g. R. Chamædryos 3111. Centaurii 311

Climbing birthwort. See Aristolochia clematitis.

Climbing stem. See Caulis.
CLI NICAL. (Clinicus; from κλινη, a bed.) Any thing concerning a bed: thus clinical lectures, notes, a clinical physician, &c.; which mean lectures given at the bedside, observations taken from patients when in bed, a physician who visits his patients in their

CLINKSTONE. A stone of an imperfectly slaty nature, which rings like metal, when struck with a

hammer

CLI'NOID. (Clinoideus; from κλινη, a bed, and αιδος, resemblance.) Resembling a bed. The four processes surrounding the sella turcica of the sphenoid CLI'NOID. bone are so called, of which two are anterior, and two

CLINOMASTOIDE'US. A corruption of cleidomastoi-cus. See Sterno-eleido-mastoideus. CLINOMETER. An instrument for measuring the

dip of mineral strata.

Chi'ssus. A chemical term denoting mineral com-pound spirits; but antimony is considered as the basis clyssi. See Clyssus.

CLITO'RIDIS MUSCULUS. See Erector clitoridis.
CLITO'RIDIS MUSCULUS. See Erector clitoridis.
CLITORIS. (From khttw, to enclose, or hide; because it is hid by the labia pudendorum.) Columella. A small glandiform body, like a penis in miniature, and, like it, covered with a prepuce, or fore-skin. It is situated above the nymphæ, and before the opening of the urinary passage of women. Anatomy has discovered, that the clitoris is composed, like the penis, of a cavernous substance, and of a glans, which has no perforation, but is like that of the penis, exquisitely sensible. The clitoris is the principal scat of pleasensible. The clitoris is the principal seat of pleasure: during coition it is distended with blood, and after the venereal orgasm it becomes flaccid and falls. Instances have occurred where the clitoris was so en-larged as to enable the female to have venereal commerce with others; and, in Paris, this fact was made a public exhibition of to the faculty. Women thus formed appear to partake, in their general form, less of the female character, and are termed hermaphrodites. The clitoris in children is larger, in proportion, than in full-grown women: it often projects beyond the external labia at birth.

CLITORI SMUS. (From KAET TOPES; the clitoris.)
An enlargement of the clitoris.

CLO'NIC. (From κλονεω, to move to and fro.) See Convulsion.

CLONO DES. (From κλονεω, to agitate.) A strong

unequal pulse.

CLONUS. (From κλονεω, to agitate.) The name of a genus of disease in the Class, Neuroses; Order, Lenetica, of Good's Nosology. Clonic spasm, comprising six species: Clonus singultus, sternulatio, pal-

pitatio, nictitatio, subsultus, and pandiculatio.
["CLOSSEY, SAMUEL, M.D. was an Irish physician, of very respectable attainments, who established himself in medical practice in New-York. He had, previously to his arrival in America, attained a high degree of eminence in the medical profession, both as a practitioner, and an author of an interesting volume on morbid anatomy; this was entitled "Observations on some of the Diseases of the Human Body, chiefly taken from the Diseases of Morbid Bodies;" it was published in London in 1763. He was for a short time chosen to the anatomical chair, and the professorship of Natural Philosophy in King's College, now Columbia College. Here the organization of the first Columbia College. Upon the organization of the first medical school in New-York, in 1768, Dr. Clossey was chosen the professor of Anatomy, and directed his la-bours with great assiduity to the establishment of that institution. Political difficulties in the American government, caused him to return to his own country, where he died a short time after his arrival."- Thach.

Clove-gilliflower. See Dianthus caryophyllus.
Clove-pink. See Dianthus caryophyllus.
Cloven-leaf. See Leaf.
CLOWES, WILLIAM, an eminent English surgeon of the 16th century, received his education under George Keble, whose skill he strongly commends. After serving for some time professionally in the navy, he settled in London, and was made surgeon to Christ's and St. Barthelemen's hospitals, and agnesure to have and St. Bartholomew's hospitals, and appears to have

had considerable practice. In 1586, he was sent to the Low Countries, to the assistance of the army under the Earl of Leicester; and on his return was appointed surgeon to the Queen. His works are in the English language, but evince much learning, as well as skill in his profession. The first which he published was on the lues venerea, in 1585; in which he notices the increasing frequency of that disease, and states that in five years he had cured above a thousand patients laborating under it at St. Parthelement's heavily. bouring under it at St. Bartholomew's hospital. But his most celebrated publication appeared three years after, on the method of treating wounds of various kinds, the result of extensive experience, sanctioned by references to the most approved writers. He appears to have possessed as enlarged understanding, and was very severe on all quacks and impostors; and he may justly be reckoned among the restorers and improvers of surgery in modern times.

CLUNE'SIA. (From clunes, the buttocks.) An inflammation of the buttocks.

CLU'PEA. The name of a genus of fishes, in the

Linnæan system.

CLUPEA ALOSA. The Linnaan name for the shad or chad, the flesh of which is by some commended as

a restorative.

[CLUPEA is the generic name for the herring tribe, to which the shad belongs, and which is the best and largest of them all. It is one of the most excellent eatable fish that frequents the waters of the United States. It is a migratory fish appearing on our coast in March and April, and disappearing by June. It comes from the Gulf of Mexico, and in its course northwardiy, ascends our fresh water rivers to deposite its spawn. It is taken in immense numbers in the Delaware, the Hudson, and the Connecticut rivers, in April and May. After depositing its spawn in the upper and small branches of these fresh streams, the shad returns to the ocean, so altered in shape and size as hardly to be known for the same fish; and hence it as hardy to be known for the same hish; and hence it is called maugre shad, not fit to eat, and not suffered to be sold in the New-York markets. A.]

Cluppa encrasicolus. The auchovy, a little fish found in great abundance about the island of Gorgona,

near Leghorn. It is prepared for sale, by salting and pickling. It is supposed the ancient Greeks and Ro-mans prepared a kind of garum for the table from this

fish. Its principal use is, as a sauce for seasoning. CLU'SIA. (So called in memory of Charles Clusius, an eminent botanist.) The name of a genus of plants in the Linnman system. Class, Polygamia;

Order, Monacia. Balsam-tree.
CLU'STER. See Rasemus.
CLU'TIA. (Named after Cluyt, and sometimes spelled cluytia.) The name of a genus of plants in the Linnaran system. Class, Diacia; Order, Gynandria. CLUTIA ELUTHERIA. The systematic name of the tree which is by some supposed to afford the cascarilla

CLUY'TIA. See Clutic. CLY'DON. Κλυδων. A fluctuation and flatulency in the stomach.

CLYPEA'LIS. (From clypeus, a shield.) Formed

like a shield. CLY'SMUS. (From κλυζω, to wash.) Clysma.

A glyster.

Cix'ssus. Clissus. A term anciently used by the chemists for medicines made by the reunion of different principles, as oil, salt, and spirit, by long digestion; but it is not now practised, and the term is almost lost. CLYSSUS ANTIMONII. Clyssus mineralis. A weak

acid of sulphur.

CLY'STER. (Clysterium. From κλυζω, to cleanse.)
A glyster. See Enema.
CNE'MIA. (From κνηρη, the tibia.) Any part connected with the tibia.

CNEMODACTYLE'US. (From κνημη, the tibia, and δακ Γυλος, a finger, or toc.) A muscle, the origin of which is in the tibia, and insertion in the toes. See Extensor longus digitorum pedis.

CNE'SIS. (From κγαω, to scratch.) Cnismos. A pointful include.

painful itching.

CNICLLE'ON. (From κγικος, cnicus, and ελαιον, oil.)

Oil made of the seeds of cnicus. Its virtues are the same with those of the ricinus, but in an inferior de-

gree. CNFCUS. (From κναω, to scratch.) The plant used by Hippocrates by this name, is supposed to be

nodding cnicus, the tender stalks of which are, when boiled and peeled, eaten by the Siberians as a food. CNICUS LANATUS. Cha malim verum. The distaff

thistic. Formerly used as a depuration, but now for-

CNICUS OLERACEUS. Round-leaved meadow thistle. The leaves of this plant are boiled in the northern parts of Europe, and eaten as we do cabbage.

CNICUS SYLVESTRIS. See Centaurea benedicta.
CNICUS SYLVESTRIS. See Centaurea benedicta.
CNICUS GRANA. See Daphne metereum.
CNICH GRANA. See Daphne metereum.

CNICH GRANA. See Daphne metereum.

CNICH GRANA. See Daphne metereum.

1. An itching sensation, such as is perceived from the nettle.

2. A dry ophthalmy. CNIFO'TES. An itching. CNI'SMOS. See Cnesis.

CNY'MA. (From κναω, to scrape, or grate.) In Hip-pocrates it signifies a rasure, puncture, or vellication: also the same as cnesis.

COADUNATE. (From coadunare, to join or gather together.) The name of an order of plants, in Linnæus's Fragments of a Natural Method.

COA'GULABLE. Possessing the property of co-

COA'GULABLE. Possessing the property of coagulation. See Albumen.

Coagulable lymph. See Albumen.

COAGULA'NT. (Coagulans; from coagulo, to increasate, or curdle.) Having the power of coagulating the blood or juices flowing if om it.

COAGULA'TION. (Coagulatio; from con, and ago, to drive together.) The separation of the coagulable particles, contained in any fluid, from the more thin and not coagulable particles: thus, when milk curdles, the coagulable particles form the curd; and when acids are thrown into any fluid containing coagulable particles, they form what is called a coagulum.

agulable particles, they form what is called a congulum.

COA'GULUM. A term applied frequently to blood and other fluids, when they assume a jelly-like consistency.

COAGULUM ALUMINIS. This is made by beating the white of eggs with a little alum, until it forms a coagulum. It is recommended as an efficacious application to relaxations of the conjunctive membrane of

COAK. Charred coal.

["The substance called coke is light, spongy, and of a shining steel-gray colour. It burns less easily than coal, but produces a great heat, and does not cake nor smoke. The preparation of coke may be conducted in the same manner as that of charcoal from wood. By this process, from 700 to 1100 fbs. of coke are obtained from one ton of coal; but the volatile products, consisting of bitumen, or coal-tar, and aumonia, are lost. For collecting these a plan has been monia, are lost. For collecting these, a plan has been contrived by Lord Dundonald, and successfully executed. The coke is prepared in ovens, or stoves, almost close; and from 120 tons of coal are collected about 3½ tons of tar, and a quantity of ammoniacal salt."—Cleav. Min.

In the modern process of making gas for burning

from bituminous coal, the profit arises principally from preserving the coak and ammoniacal liquor, while most of the tar is decomposed and converted into gas. A.]
COAL. A combustible mineral, of which there are many species.

CUALTE RNA FEBRES. (From con, and alternus, alternate.) Fevers mentioned by Bellini, which he describes as two fevers affecting the same patient, and the paroxysm of one approaching as that of the other

COARCTA'TIO. (From coarcto, to straighten.)
The contraction or diminution of any thing. Formerly applied to the pulse: it meant a lessening in

number.

COARCTATUS. Crowded. A paniele is so called, which is dense or crowded; as in Phleum paniculatum, the inflorescence of which broks, at first sight, like a cylindrical spike; but when bent to either side, separates into branched lobes, constituting a real paniele.

COARTICULA'TIO. (From 1201, and articulation.) That sort of articulation which has manifest motion.

manifest motion.

COBALT. A brittle, some what soft, but difficultly |

the carthamus; but mode in botanists exclude it from the species of this plant.

CNICUS CERNUUS. The systematic name of the Wedgewood. It is generally associated in its ores with Wedgewood. It is generally associated in its ores with nickel, arsenic, iron, and copper; and the cobalt of commerce usually contains a proportion of these metals. To separate them, calcine with four parts of nitre, and wash away, with hot water, the soluble arseniate of potassa. Dissolve the residuum in dilute nitric acid, and immerse a plate of iron in the solution, to precipitate the copper. Filter the liquid and evaporate to dryness. Digest the mass with water of ammonia, which will dissolve only the oxides of nickel and cobalt. Having expelled the excess of alkali by and cobalt. Having expelled the excess of alkali by and cobalt. Having expelled the excess of aikali by a gentle heat from the clear ammoniacal solution, add cautiously water of potassa, which will precipitate the oxide of nickel. Filter immediately, and boil the liquid, which will throw down the pure oxide of cobalt. It is reduced to the metallic state by ignition in contact with lamp-black and oil. Laugier treats the above ammoniacal solution with oxalic acid. He then redissolves the precipitated oxalates of nickel and then redissolves the precipitated oxalates of nickel and cobalt in concentrated water of ammonia, and exposes cobalt in concentrated water of ammonia, and exposes the solution to the air. As the ammonia exhales, oxalate of nickel, mixed with ammonia, is deposited. The nickel is entirely separated from the liquid by repeated crystallizations. There remains a combination of oxalate of cobalt and ammonia, which is easily reduced by charcoal to the metallic state. The small quantity of cobalt remaining in the precipitated salt of nickel, is separated by digestion in water of ammonia. Cobalt is susceptible of magnetism, but in a lower degree than steel and nickel.

Oxygen combines with cobalt in two proportions:

degree than steel and nickel.

Oxygen combines with cobalt in two proportions; forming the dark-blue protoxide, and the black deutoxide. The first dissolves in acids without effervescence. It is procured by igniting gently in a retort the oxide precipitated by potassa from the nitric solution. Pront says, the first oxide consists of 100 metal + 19.8 oxygen; and Rothoff makes the composition of the deutoxide 100 + 36.77. If we call the first 18.5, and the second 37; then the prime equivalent of cobalt will be 5.4; and the two oxides will consist of will be 5.4; and the two oxides will consist of

Protox.	Cobalt, 5.4	100	84.38
	Oxygen, 1.0	18.5	15.62
			100.00
Deutox.	Cobalt, 5.4	100	73
	Oxygen, 2.0	37	27
5 2			100

The precipitated oxide of cobalt, washed and gently heated in contact with air, passes into the state of black peroxide.

When cobalt is heated in chlorine, it takes fire, and forms the chloride. The iodide, phosphuret, and sul-phuret of this metal, have not been much examined. The salts of cobalt are interesting from the remark-

The salts of cobalt are interesting from the remarkable changes of colour which they can exhibit.

Their solution is red in the neutral state, but green with a slight excess of acid; the alkalies occasion a blue-coloured precipitate from the salts of pure cobalt, but reddish-brown when arsenic acid is present; sulphuretted hydrogen produces no precipitate, but hydrosulphurets throw down a black powder, soluble in excess of the precipitant; tincture of galls gives a yeilowish-white precipitate; oxalic acid throws down the red oxalate. Zinc does not precipitate this metal.

COBALUS. The demon of mines, which obstructed and destroyed the miners.

ed and destroyed the miners.

COBHAM. The name of a town in Surrey, in the neighbourhood of which is a weak saline purging

COBRA DE CAPELLO. (From cobra, the head, or covering, Spanish. See Crotalus horridus.

Cocao, butter of. See Butter of Cocao.

Cocao-nut. See Cocos nucifera.

Сосса смідіа. See Daphne mezereum. Сосса війм. (From коккор, а berry.)

small pill.
COCCINE'LLA. (Diminutive of coccus, a berry;
from its resemblance to a berry.) See Coccus cacti.
Cocco-Balsamum. The fruit of the Amyris gilea-

Coccogni'dia. See Daphno metercum:

2. The name given by De Candolle, in his Systema Natura, to a new genus of plants.
3. Cocculus indicus. See Menispermum cocculus.
4. Cocculus palmatus. The systematic name of the plant, which affords the calumba root of the phar-

macopæias. See Calumba. Co CCULUS INDI AROMATICUS. Jamaica pepper.

See Myrtus pimenta.

CO'CCUM. A species of capsule, but separated from it by Gartner, who defines it to be a dry seed-vessel, more or less aggregate, not solitary, the sides of which are elastic, projecting the seeds with great force; as in the Euphorbia.

COCCUM BAPRICUM. A name for chermes.

CO'CCUS. The name, in entomology, for a tribe of innects

Coccus cactt. The systematic name of the cochineal animal, or insect. Coccinella; Coccinilla; Ficus India grana; Scarabaolus hemispharicus; Cochinelifera cochinilla; Coccus Americanus; Cochinella; Coccus indicus tinctorius. Cochineal. That which is used is the female insect found on, and collected in South America from, the Opintia, or Indian fig-tree. It possesses estimulating qualities, and is ordered by the College in the tincture corderons of companying and tinc-College in the tinctura cardamomi composita, and tinctura cinchona composita; but, most probably, merely on account of the beautiful red colour which it im-

[The cochineal is not now used in this country as a

The cocumeal is not now used in this country as a medicine. It is principally employed in producing a beautiful scarlet colour, in dying calico, colouring morocco leather, &c. A.]

COCCYGE'US. (Coccygeus; from κοκκυξ: because it is inserted into the coccyx.) A muscle of the os coccygis, situated within the pelvis. Ischio-cocigien of Dugnas. It arises tendinous and fleshy, from the spinous process of the ischium, and covers the inside of nous process of the ischium, and covers the inside of the sacro-ischiatic ligament; from this narrow beginning it gradually increases to form a thin fleshy belly, interspersed with tendinous fibres. It is inserted into the extremity of the os sacrum, and nearly the whole length of the os coccygis laterally. Its use is to support and move the os coccygis forwards, and to tie it more

Tirmly to the sacrum.

CO'CCYGIS OS. (From ROKKUE, the cuckoo, the bill of which bird it is said to represent.) Cauda.

Ossis saeri acumen. Coccyx. This bone is a small appendage to the point of the sacrum, terminating this inverted column with an acute point, and found in very different conditions in the several stages of life. In the child, it is merely cartilage, and we can find no point of bone: during youth, it is ossifying into distinct bones, which continue meveable upon each other till manhood: then the separate bones gradually unite with each other, so as to form one conical bone, with bulgings and marks of the pieces of which it was originally composed; but still the last bone continues to move upon the joint of the sacrum, till, in advanced years, it is at last firmly united; later in women than in men, with whom it is often fixed at twenty or twenty-five. It is not, like the os sacrum, flat, but of a roundish form, convex without, and concave inwards; forming with the sacrum the lowest part of the pelvis behind. It has no holes like the sacrum; has no communication with the spinal canal, and transmits no nerves; but points forwards to support the lower very different conditions in the several stages of life. no nerves; but points forwards to support the lower parts of the rectum; thus it contracts the lower opening of the pelvis, so as to support effectually the rectum, bladder, and womb; and yet continues so moveable in women, as to recede in time of labour, allowing

the head of the child to pass.

CO'CCYX. (Kokkel, the cuckoo.) See Coccygis

os. Also the part in which the os coccygis is placed.

CO'CHENILIN. Carminium. The name of the colouring principle of cochineal.

Co'chia. (From κοχαω, to turn or make round.) An ancient name of some officinal pills. The pill of cochia of the shops, in the present day, is the compound colocynth pilt.

Co'CHINEAL. See Coccus cacti.

CO'CHLEA. (From κοχαζο, to turn round.) A

COCCOLITE. A mineral of a green colour, of various shades, found with granular limestone, garnet, and magnetic iron-stone, in Norway, Sweden, and Spain.

CO'CCOS. See Daphne metercum.

CO'CCULUS. (Diminutive of KOKKOS, a berry.) 1.

A little berry.

2. The name given by De Candolle, in his Systema Natura, to a new genus of plants.

See Manisnermum cocculus.

Cocculiated to hold half a fluid ounce; cochleare medium is a dessert or half a fluid ounce; cochleare medium is a dessert or pap spoon, supposed to hold two tea-spoonfuls; and cockleare minimum, a tea-spoon, which holds about one fluid drachm.

COCHLEA'RIA. (From cochlears, a spoon; so called from its resemblance.) The name of a genus of plants in the Linnman system. Class, Tctradyna-

of plants in the Linnean system. Class, Tetradynamia; Order, Siliculosa.

Cochlearla armoracia. The systematic name of the horse-radish; Raphanus rusticanus; Armoracia; Raphanus marinus; Raphanus sylvestris; Cochlearia—foliis radicalibus lanceolatis crenatis caulinis incisis, of Linnæus. The root of this plant has long the plant has long the plant has long the plant has long the plant of the plant of the plant has long the plant of been received into the materia medica, and is also well known at our tables. "It affects the organs both of taste and smell with a quick penetrating pungency; nevertheless it contains in certain vessels a sweet juice, which sometimes exudes in little drops upon the surface. Its pungent matter is of a very volatile kind, being totally dissipated in drying, and carried off in evaporation, or distillation by water; as the pungency exhales, the sweet matter of the root becomes more sensible, though this also is, in a great measure, dissi-pated or destroyed. It impregnates both water and spirit, by infusion, or by distillation, very richly with its active matters. In distillation with water, it yields

as active matters. In distillation with water, it yields a small quantity of essential oil, exceedingly penetrating and pungent."

Dr. Cullen has mentioned every thing necessary to be known-respecting the medicinal virtues of horseradish, we shall therefore transcribe all that the ingenious professor has written on this subject. "The root of this plant only is employed; and it affords one of the most aerid substances of this order (Siliculoss), and therefore roots a provestal stimulant whether and therefore proves a powerful stimulant, whether externally or internally employed. Externally, it readily inflames the skin, and proves a rubefacient that may be employed with advantage in palsy and that may be employed with advantage in passy and rheumatism; and if its application be long continued, it produces blisters. Taken internally, it may be so managed as to relieve hoarseness, by acting on the fauces. Received into the stomach, it stimulates this, and promotes digestion; and therefore is properly employed as a condiment with our animal food. If it be ployed as a condiment with our animal food. If it be infused in water, and a portion of this infusion be taken with a large draught of warm water, it readily proves emetic, and may either be employed by itself to excite vomiting, or to assist the operation of other emetics. Infused in water, and taken into the stomach, it proves stimulant to the nervous system, and is thereby useful in palsy, and, if employed in large quantity, it proves heating to the whole body; and thereby it proves often useful in chronic rheumatism, whether arising from scurvy or other causes. Bergius has given us a partiscurvy or other causes. Bergius has given us a parti-cular method of exhibiting this root, which is, by cutcular method of exhibiting this root, which is, by cutting it down, without bruising, into small pieces; and these, if swallowed without chewing, may be taken down in large quantities, to that of a table-spoonful. And the author alleges, that, in this way, taken in the morning for a month together, this root has been extremely useful in arthritic cases; which, however, I suppose to have been of the rheumatic kind. It would seem, in this manner employed, analogous to the use of unbruised mustard-seed; it gives out in the stomach its subtile volatile parts, that stimulate considerably without inflaming. The matter of horse-radish, like the same matter of the other siliquose plants carried without inflaming. The matter of horse-radish, like the same matter of the other siliquose plants carried into the blood-vessels, passes readily into the kidneys, and proves a powerful directic, and is therefore useful in dropsy; and we need not say, that, in this manner, by promoting both urine and perspiration, it has been long known as one of the most powerful antiscorbutics."

Lemon scurvy-grass, COCHLEARIA HORTENSIS. See Cochlearia officinalis.

See Cochlearia officinalis.

Cochlearia officinalis.

The systematic name of the lemon scurvy-grass.

Cochlearia hortensis;

Cochlearia—foliis radicalibus cerdato subretundis;

caulinis oblongis subsinuatis, of Linnaus. This indigenous plant is cultivated in gardens for its medicinal

COC CŒL

morpha, and the seeds of the Salsola.

Cocho'ng. (From κοχαω, to turn round.) Galen explains this to be the juncture of the ischium, near the seat or breech; whence, says he, all the adjacent parts about the seat are called by the same name. Hesychius says, that cochone is the part of the spine

Mesychius says, that cocaone is the part of the spin-which is adjacent to the os sacrum.

["COCHRAN, John, M.D. This gentleman was born in 1738, in Chester county, state of Pennsylvania. About the time he finished his medical studies, the war of 1755 commenced in America, between England and France. The army then presented to the mind of Dr. Cochran a scene of usefulness and farther improvement. As there were not any great hospitals at that time in the provinces, he readily perceived that the army would be an excellent school for his improvement, especially in surgery, as well as in the medical treatment of many diseases. He soon obtained the appointment of Surgeon's Mate in the Hospital Despirational and become continued with the northern partment; and having continued with the northern army during the whole of that war, enjoying the friendship and advice of Dr. Munro, and other eminent

surgeons and physicians, he quitted the service with the character of an able and experienced practitioner. When (twenty years after) the war became serious between Great Britain and the United States, Dr. Cochran was too zealous a whig, and too much attached to the interests of his native country, to remain an idle spectator. Towards the last of the year 1776, he offered his services as a volunteer in the hospital department General Washington afterward recommended him to Congress. He was accordingly appointed, in April, 1777, Physician and Surgeon General in the middle department. In the month of October, 1781, Congress was pleased to give him the appointment of Director General of the hospitals of the United States; an appointment that was the more honourable because it was not solicited by him. A short time after the peace, Dr. Cochran removed with his family to New-York, where he attended to the duties of his profession until the adoption of the new Constitution, when his friend President Washington, retaining, to use his own words, "a cheerful recollectached to the interests of his native country, to remain retaining, to use his own words, "a cheerful recollec-tion of his past services," nominated him to the office of Commissioner of Loans for the State of New-York. This office he held until a paralytic stroke disabled him in some measure from the discharge of its duties; upon which he gave in his resignation, and retired to Palatine, in the county of Montgomery, where he terminated a long and useful life, on the 6th of April, 1807, in the 77th year of his age."—Thach. Mcd. Biog. A.] COCK. The male of the domestic fowl. See Pha-

COCKBURN, WILLIAM, was born in the latter part COCKBURN, WILLIAM, was born in the latter part of the 17th century. After being some years physician to the navy, he settled in London; and soon distinguished himself so much, that he was admitted into the College, as well as the Royal Society, and made physician to King William. He published a "Treatise on Sea Diseases," which was often reprinted, and translated into French and German. He referred the scurvy principally to the diet of seamen, and considered fresh provisions as the chief remedy for it. He wrote also on Alvine Fluxes, on Gonorrhæa, (which he contends may exist independent of syphilis,) and on the Human (Economy; which latter publication was much noticed at the time, but is since superseded by more accurate treatises. by more accurate treatise

CO'COS. (So called from the Portuguese coco, or

coquen, the three holes at the end of the cocoa-nut shell, giving it the resemblance of a monkey's head.) The name of a genus of plants in the Linnman system.

Class, Monacia; Order, Hexandria. Cocos BUTYRACKA. The systematic name of the plant which affords the palm oil; Cocos—inermis, frondibus, pennatis; foliolis simplicibus, of Linnæus. The oleum palmæ is produced chiefly by bruising and dissolving the kernels of the fruit in water, without the aid of heat, by which the oil is separated, and rises to the surface, and on being washed two or three times, is rendered fit for use. When brought into this country, it is of the consistence of an ointment, and country, it is of the consistence of an ointment, and

qualities. Its expressed juice has been long considered as the most effectual of the scorbutic plants.

COCHLEATUS. Spiral, like the winding of a shell. Applied in botany to leaves, leguminous seeds, &c.; as legumen cochleatum, seen in Medicago polymorpha, and the seeds of the Salsala.

Cocos NUCLERA. The systematic name of the

advantage over other bland oils.

Cocos NUCIFERA. The systematic name of the plant, the fruit of which is the cocoa-nut. Within the nut is found a kernel, as pleasant as an almond, and also a large quantity of liquor resembling milk, which the Indians greedily drink before the fruit is ripe, it being then pleasant, but when the nut is matured, the liquor becomes sour. Some full-grown nuts will contain a pint or more of this milk, the frequent drinking of which seems to have no bad effects upon the Inof which seems to have no bad enects upon the in-dians; yet Europeans should be cautious of making too free with it at first, for when Lionel Wafer was at a small island in the South Sea, where the tree grew in plenty, some of his men were so delighted with it, that at parting they resolved to drink their fill, which they did; but their appetites had like to have cost them their lives, for though they were not drunk, yet they were so chilled and benumbed, that they could not stand, and were obliged to be carried aboard by those who had more prudence than themselves, and it was many days before they recovered. The shells of these nuts being hard, and capable of receiving a polish, they are often cut transversely, when, being mounted on stands, and having their edges silvered, or gilt, or otherwise ornamented, they serve the purpose of drinking-cups. The leaves of the tree are used for thatching, for brooms, baskets, and other utensils; and of the reticular web, growing at their base, the Indian women make cauls and aprons.

CO'CTION. (Coctio; from coque, to boil.) Concoction. 1. The digestion of the food in the stomach.

See Digestion.

2. A boiling or decoction. See Decoction.

3. It was formerly used in a medical sense, signifying that alteration, whatever it be, or however occasioned, which is made in the crude matter of a discharge or temper, whereby it is either fitted for a discharge, or rendered harmless to the body. This is often brought about by nature; that is, by the vis vite, or the disposition or natural tendency of the matter itself, or else by proper remedies, which may so alter its bulk, figure cohesion, or give it a particular determination, so as to prevent any farther ill effects, or drive it quite out of the body. And that time of a disease wherein this action is performing, is called its state of coction. It is now failen into disuse.

Cocu'sxx. The name for courbaril temper, whereby it is either fitted for a discharge, or

Cocu'stu. The name for courbaril.

CODA GA PALA. See Nerium antidysentericum.
CODEGELLA. A name given by the Italians to the carbuncle. See Anthrax.
CODOCE LE. (From κωδια, a bulb, and κηλη, a tu-

mour.) A bubo.

CCCA'LIS. (From cacum, the blind gut, through which it runs.) A vein, being a branch from the con-

Cœ'LA. (From κοιλος, hollow.) Applied to depression, or hollow parts on the surface of the body, as the

sion, or hollow parts on the surface of the body, as the hollow pits above, and sometimes below the eyes: the hollow parts at the bottom of the feet.

CŒLIA. (From κοιλος, hollow.) A cavity in any part of the body; as the belly, the womb, &c.

CŒLIAC. (Caliacus, belonging to the belly; from κοιλια, the belly.) Appertaining to the belly.

CŒLIAC ARTERY. Arteria caliaca. The first branch given off from the aorta in the cavity of the abdomen. It sends branches to the diaphragm, stomach, liver, pylorus, duodenum, omentum, and spleen.

CŒLIAC PASSION. (From κοιλια, the belly.) Calica chylosa; Calica lactea. There are very great differences among physicians concerning the nature of this disease. Sauvages says it is a chronic flux, in which ences among physicians concerning the nature of this disease. Sauvages says it is a chronic flux, in which the aliment is discharged half digested. Dr. Cullen considers it as a species of diarrhæa, and mentions it in his third and fourth species, under the terms mucosa, chylosa, lactea; making the purulenta only symptomatic. See Diarrhæa. It is attended with great pains in the stomach, resembling the pricking of pins; rumbling and flatus in the intestines; white stools, because deprived of bile; while the patient becomes weak and lean.

CCELIACA. (Caligars: from release elements.)

CŒLIACA. (Caliacus; from κολαια, alvus ven-ter.) Dr. Good selects this name for the first class of diseases in his Nosology; diseases of the digestive

function. Splanchnica.

CŒLO MA. (From κοιλος, hollow.) An uncer in the tunica cornea of the eye.

CŒLOSTO'MIA. See Coilostomia.

CŒNOLO'GIA. (From κοινος, common, and λιγος, discourse.) A consultation, or common consideration of a disease, by two or more physicians.

- CŒNO'TES. (From κοινος, common.) The physicians of the methodic sect asserted that all diseases are section relaxation, stricture, or a mixture of both. arose from relaxation, stricture, or a mixture of both-These were called canotes, viz. what diseases have in common.

CERU'LEUS LAPIS. The sulphate of copper. See

CCETE. (From Keihai, to lie down.) A bed, or

couch, for a sick person.

COFFEA. (From kofuah, a mixing together, Hebrew; so called from the pleasant potation which is made from its berry: others assert that the true name is Caffe, from Caffa a province in South America, where the tree grows spontaneously in great abundance.) The name of a genus of plants in the Linnwan system. Class, Pentandria; Order, Monogynia: The coffee-tree.

COFFEA ANABICA. The plant which affords coffee. Jasminum Arabicam; Choava. Coffee is the seed of the Coffea—floribus quinquefidis, dispermis, of Lin-

The coffee-tree is cultivated in Arabia, Persia, the East Indies, the Isle of Bourbon, and several parts of America. Good Turkey coffee is by far the most salu-tary of all liquors drunk at meal-time. It possesses nervine and adstringent qualities, and may be drunk with advantage at all times, except when there is bile in the stomach. It is said to be a good antidote against an over dose of opium, and to relieve obstinate spasmodic asthmas. For the latter purpose, the coffee ought to be of the best Mocco, newly burnt, and made very strong, immediately after grinding it. Sir John Pringle commonly ordered one ounce for a dose; which is to be repeated fresh, after the interval of a quarter or half an hour; and which he directed to be taken without milk or sugar.

Besides the peculiar bitter principle, which is de-scribed under the name Caffein, coffee contains several other vegetable products. According to Cadet, 64 parts of raw coffee consists of 8 gum, 1 resin, 1 extractive and bitter principle, 3.5 gallic acid, 0.14 albumeu, 43.5 fibrous insoluble matter, and 6.86 loss. Herman found in 1920 grains of

The nature of the volatile fragment principle devetoped in coffee by roasting, has not been ascertained.

The Dutch in Surinam improve the flavour of their coffee by suspending bags of it, for two years, in a dry atmosphere. They never use new coffee.

If coffee be drunk warm within an hour after din-

ner, it is of singular use to those who have headache, from weakness in the stomach, contracted by sedentary habits, close attention, or accidental drukenness. tary habits, close attention, or accidental drukenness. It is of service when the digestion is weak; and persons afflicted with the sick headache are much benefited by its use, in some instances, though this effect is by no means uniform. Coffee is often imitated by roasting rye with a few almonds.

["COFFIN, NATHANIEL, M.D., son of Dr. N. Coffin, one of the most eminent physicians in the state of Maine. The first ancestor of his family who came to this country was Tristram Coffin, who emigrated from

this country was Tristram Coffin, who emigrated from

England in 1642.

Dr. Nathaniel Coffin was born in Portland, on the Dr. Nathamet Coffin was born in Portland, on the 3d of May, 1744, in which place he always lived, and where he closed his long and useful life. The country at the time of his birth, for may miles round Casco bay, including the site of Portland, was called Falmouth; afterward, the part most thickly settled, lying on the harbour, was incorporated into a separate town by the name of Portland.

He completed his preparatory medical education

It contains two orders, Enterica and a.

(From κοιλος, hollow.) An ulcer in the improvement then existing in this thinly peopled section of the eye.

(MIA. See Coilostomia.

(From κοινος, common, and λιγος, A consultation, or common consideration e, by two or more physicians.

(From κοινος, common.) The physicians age of twenty-one. age of twenty-one.

Possessing a constitution naturally healthy and vigorous, and a mind resolute and intelligent, there was no peril which he was not prepared to encounter, and no adversity which he could not endure; and he has well deserved the distinction awarded him by the public, for his constant and unremitted exertions during a period of more than sixty years.

public, for his constant and unremitted exertions during a period of more than sixty years.

Dr. Coffin was surrounded, in the early part of his career, by suffering friends and patients; but his life was closed amid the blessings of freedom and independence. In the peaceful evening of his days, all the enjoyments of prosperity and affection clustered around his dwelling; but it should not be forgotten that the respectability and happiness he had experienced, were the well earned reward of the virtues, the talents, and the faithfulness of former years. the talents, and the faithfulness of former years.

In his manners, he was a polished specimen of the state of American society existing before the Revolution; he was one of the most graceful gentlemen of the old school, and his deportment was marked by a uniform and captivating urbanity. He died on the 18th of October, 1826, aged 82 years."—Thacher's Med.

Biog. A.]
COGAN, WILLIAM, was born in Somersetshire, about the middle of the 16th century. He studied, and took the degree of bachelor in medicine, at Oxford; soon after which he was appointed master of the school at Manchester, where he also practised in his profession till his death in 1607. He published a curious book, abounding in classical quotations, entitled "The Haven of Health," in which he strongly recommends temperance and exercise. There is added an account of the sweating sickness; and of a remarkable disorder, which prevailed at Oxford in July and August, 1575, before he left it, by which he states, that in thirty-exercise all. that in thirty-seven days " there died 510 persons, all men, and no women."

COHE'SION. (Cohæsio; from con, and hæreo, to stick together.) Vis cohæsionis; Vis adhæsionis; Vis attractionis. That power by which the particles of bodies are held together. See Attraction. Cohoba'Tion. (A term invented by Paracelsus.) Cohobatio; Cohobium; Cohoph. The ancient chemists use this term to signify the distillation of a fluid convented force when a superior of the same kind as

poured afresh upon a substance of the same kind as that upon which it was before distilled, and repeating this operation several times to make it more efficacious

Co'HOL. (Cohol, Hebrew.) Castellus says this word is used in Avicenna, to express dry collyria for the eyes, in fine powder.

the eyes, in fine powder.

Col'Lima. (From κοιλια, the bowels.) A sudden swelling of the belly from wind.

COILOSTO'MIA. (From κοιλος, hollow, and ςομα, the mouth.) Calostomia. A defect of speaking, from the palate, or through the nose, the voice being so obscured as to sound as if it proceeded from a cavern.

COINDICA'NTIA. (From con, and indico, to indicate.) Signs, or symptoms, are called coindicant, when, besides the usual incidental appearances, there occur others, as age, habit, season, &c.

occur others, as age, habit, season, &c.

Cor'ra. A name for catechu.

COITER, VOLCHER, was born at Groningen in 1534.

After studying at the different universities in Italy, he attended as physician to the French army during one attended as physician to the French army during one campaign, that he might have more opportunity for investigating human anatomy. He then settled at Nuremberg, where he continued till his death in 1576. He made considerable improvements in anatomy and surgery. He found that the brain had a motion communicated to it by the arteries; and that in some animals the organ might be removed without destroying life. He first described the corpora lutea in the ovaria; and noticed the order in which the parts of the chick are evolved. He described the frontal sinuses, and the organ of hearing, more accurately than any preceding author. He pointed out two muscles which depress the eyebrows, and two which perform the the name of Portland.

He completed his preparatory medical education depress the eyebrows, and two which perform the

COL COL

[Coke. See Coak. A.]
CO'LA. (From κωλον, a joint.) The joints.
Colato'ria Lactea. Astruc says they were formerly called glands, and are situated in the third and internal tunic of the uterus, and that they are vesiculo-vascular bodies.

COLATO RIUM. (From colo, to strain.) A strainer

of any kind. (From colo, to strain.) A filtered

or strained liquor.

COLBATCH, John, was born in the latter part of the 17th century. He practised in London, first as a surgeon and apothecary, afterward as a physician, and had considerable repute. He published several works: the first was "A New Light of Chirurgery," condemning the use of tents, and the injection of acrid substances into wounds; then a treatise, in which most diseases are ascribed to alkalescency, and acids strongly recommended; this, in a subsequent publication, he applied particularly to the gout; lastly, he highly extolied the misletoe, as a remedy for epilepsy and other nervous diseases.

highly extolled the misletoe, as a remedy for epilepsy and other nervous diseases.

COLCHESTER. The name of a scaport on the coast of Essex, near which is a mineral water, aqua Colcestrensis, which is of the bitter purging kind, similar to that of Epsom, but not so strong.

CO'LCHICUM. (From Colchis, a city of Armenia, where this plant is supposed to have been common.)

1. The name of a genus of plants in the Linnæan system. Class, Hexandria; Order, Trigynia. Meadow-saffron.

2. The pharmacopæial name of the meadow-saffron. See Colchicum autumnale.

COLCHICUM AUTUMNALE. The systematic name of the common meadow-saffron. Colchicum—foliis planis lanceolatis crectis, of Linnæus. A native of England. The sensible qualities of the fresh root are England. The sensible qualities of the fresh root are very various, according to the place of growth and season of the year. In autumn it is almost inert; but in the beginning of summer, highly acrid: hence some have found it to be a corrosive poison, while others have eaten it in considerable quantity, without experiencing any effect. When it is possessed of acrimony, this is of the same nature with that of garlic, and some other plants, and is entirely destroyed by drying. The German physicians have celebrated its virtues as a diuretic, in hydrothorax and other dropsies; and, in France, it continues to be a favourite remedy; but it

The German physicians have celebrated its virtues as a diuretic, in hydrothorax and other dropsics; and, in France, it continues to be a favourite remedy; but it is, nevertheless, in this country, unsuccessful, or at best a very uncertain remedy. The expressed juice is used, in Alsace, to destroy vermin in the heads of children. The officinal preparations of colchicum are, syrupus colchici autumnalis, Edin. Pharm. The oxymel colchici of the former London pharmacopæia is now omitted, and the acetum colchici ordered in its room; as the honey may easily be added extemporaneously, if it be thought requisite. The active ingredient of this plant has lately been ascertained to be an alkali, possessing peculiar properties. See Veratria.

["Colchicum is in large doses a deleterious, acrid narcotic; in small ones, a cathartic and diuretic; possessing, likewise, peculiar properties of a sedative kind. It appears to have been known to the ancients as a poison, and during the last century it has been occasionally employed as a medicine in dropsy, asthma, and some other chronic diseases. Recently it has excited much notice, especially in Great Britain, as a remedy in gout, and a sedative in various painful and inflammatory affections. The interest excited by a secret French specific, the Eau Medicinale, which was found to relieve the paroxysms of gout, led to various imitations and substitutes for that preparation. Among these, a various tincture of colchicum was found very nearly to resemble the foreign compound, both in its sensible qualities and medicinal effects. Accordingly, the Wine of Colchicum became a prevailing medicine for gout, and was used with various success in that

same office to the lips. He observed, that injuries to the brain are more dangerous when the dura mater remains entire; and therefore he boldly divided that membrane. He was also accustomed to pare down fungi arising from the brain. He published good plates of the cartilages, of the feetal skeleton, and of those of various animals, &c.

COITUS. (From coco, to go together.) The conjunction of the male and female in the act of procreation. medicine, when possessed of its full activity, may be so managed, as to diminish morbid force and frequency of the pulse, to allay pain and other phenomena of inflammation, and in certain cases to fulfil the object of depletion by the lancet. The Messrs. Haden inform us, that in pure inflammations, if it be given every four hours until it produce an abundant purgative effect, the pulse will become nearly natural, from being either quick and hard, or slow and full; that in many cases, its use may be substituted for blood-letting, at least when inflammation does not exist to an alarming degree in a vital part; and that the patient is left in a state favourable to more rapid recovery, when fever and inflammation have been removed by colchicum, than when the same end has been effected by other means. In chronic rheumatism, it is said rarely to fail, if persevered in for a time sufficiently long; in habitual discharges of blood from plethora, it has been substituted for frequent venescctions; and after accidents, it is said to have the power of averting the severe consequences which usually follow such cases. In Boston, considerable attention has been bestowed upon the effects of colchicum in different diseases. The article employed has been the bulb, imported in a live

upon the effects of colchicum in different diseases. The article employed has been the bulb, imported in a live state, packed in sand, and dried immediately after its arrival. The sprouting of the flower-bud, during transportation, did not appear to lessen its activity. Administered in powder, this medicine has been found, in a variety of instances, to relieve the symptoms of pulmonary and of peritoneal inflammation, in a manner not easily to be accounted for, except by the reduction of the inflammation. Its most frequent operation, I believe, when fairly tried, has been to allay pain, reduce the pulse, and diminish symptomatic fever; to move the bowels, generally within twenty-four hours, and to excite nausea and great disgust, if the dose be large. It has, nevertheless, sometimes failed to produce these effects. In rheumatic complaints, its success has been equivocal, but, on the whole, rather favourable to its reputation than otherwise.

Colchicum has, of late, been most frequently administered in powder. Five grains may be given, three times a day, to an adult, where the stomach is not particularly delicate. This quantity I have found to remain on the stomach, and to move the bowels, commonly on the second day. In important cases, the dose may be increased to eight or nine grains, if nausea does not prevent. In chronic cases, the dose of five or six grains may be given, according to Mr. Hayden, once a-day, in the morning, and continued for weeks together. This writer combined with it small quantities of sulphate and carbonate of potass, and gave it in a state of effervescence, with an acid. article employed has been the bulb, imported in a live

ties of sulphate and carbonate of potass, and gave it in

together. This writer combined with it small quantities of sulphate and carbonate of potass, and gave it in a state of effervescence, with an acid.

It is prudent to begin the use of a new parcel, or specimen, with smaller doses than those above specified, and gradually to increase them, since the root is at some times more active than at others. The variable activity of the medicine is, indeed, a great impediment to its usefulness, and nothing can be more discordant than the statements of writers on this subject. Professor Murray has cited various instances in which this root has produced distressing, and even fatal effects; while, on the other hand, an author by the name of Kratochville asserts, that himself and others have eaten drachms of the root, both in spring and fall, with impunity; and Orfila tells us, that he had repeatedly given several bulbs to dogs, in the month of June, without causing them any inconvenience."—

Big. Mat. Med. A.]

[Colchici semina. The seeds of Colchicum.—These have been proposed, by Dr. Williams, as a substitute for the bulb, possessing all the medicinal advantages of the plant, attended with greater mildness and uniformity of operation. Several practitioners have agreed in their accounts of the efficacy of these seeds, particularly in chronic rheumatism. Dr. Williams uses a wine, made by infusing two ounces of the seeds in a pint of sherry. From one to three drachms are given, once or twice a-day, in aromatic water. He also employs a tincture, made with the same propor-

tions. In this country, colchicum seeds have been used with some benefit in rheumatic complaints. They apparently possess the advantage of being less liable than the root to alter by age. I have found two or three grains of the powder to produce vomiting and purging in a mild degree, and ten grains to bring on powerful vomiting and purging, with vertigo and impaired vision during twenty-four hours."—Big. Mat. Med. A.i

COLONICUM ILLYRICUM. The plant supposed to afford the root called hermodactyl. See Hermodac-

COLCOTHAR. Chalcitis; Colcothar vitrioli. The brown-red oxide of iron, which remains after the distillation of the acid from sulphate of iron.

COLCOTHAR VITRIOLI. See Colcothar.

COLD. 1. A privation of heat. It is nothing positive, but somewhat of the negative kind. The human body contains within itself, as long as it is living, a principle of warmth: if any other body, being in contact with it, abstracts the heat with unusual rapidity, it is said to be cold; but if it carries off the heat more slowly than usual, or even communicates heat to our body, it is said to be hot. 2. A cold is a popular name also for a catarrh. See

Catarrhus.

Cold Affusion. See Affusion.

["COLDEN, CADWALLADER, Esq. This truly worthy and eminent character, who united in himself the several qualities we are accustomed to admire in the several qualities and philosopher, was the son the physician, naturalist, and philosopher, was the son of the Rev. Alexander Colden, of Dunse, in Scotland, and was born on the 17th day of February, 1688. After he had laid the foundation of a liberal education, under the immediate inspection of his father, he went to the University of Edinburgh, where, in 1705, he completed his course of collegiate studies. He now completed his course of collegiate studies. He now devoted his attention to medicine and mathematical science, until the year 1708, when, being allured by the fame of William Penn's colony, he came over to this country about two years after. He practised physic, with no small share of reputation, till 1715, when he returned to England. While in London, he was introduced to that eminent philosopher, Dr. Edmund Halley, who formed so favourable an opinion of a paper on Animal Secretion, written by Dr. Colden in early life, that he read it before the Royal Society, the notice of which learned body it greatly attracted. At this time he formed an acquaintance with some of the this time he formed an acquaintance with some of the most distinguished literary and scientific characters, with whom he ever after maintained a regular corres pondence. From London he went to Scotland, and married a young lady of a respectable Scotch family, by the name of Chrystie, with whom he returned to America in 1716.

In 1718, he settled in the city of New-York; but soon after relinquished the practice of physic, and be-came a public character; he held, in succession, the office of Surveyor General of the Province, Master in Chancery, Member of the Council, and Lieutenant Governor. Previous to his acceptance of this last station, he obtained a patent for a tract of land, designated by the name of Coldenham, near Newburgh, to which place he retired with his family, about the year 1755, and spent a great part of his life. Here he appears to have been occupied, without interruption, in the pursuit of knowledge, particularly in botanical and ma-thematical studies, at the same time that he continued his correspondence with learned men in Europe and

In 1761, he was appointed Lieutenant Governor of New-York, which commission he held until the time of his decease, the administration of the government repeatedly falling on him, by the death or absence of several governors in chief. His political character was rendered very conspicuous by the firmness of his conduct, during the violent commotions which preconduct, during the violent commotions which pre-ceded the Revolution. His administration is also me-morable for several charters of incorporation, for use-ful and benevolent purposes. After the return of Go-vernor Tryon, in 1775, he was relieved from the cares of government. He then retired to a seat on Long Island, where a recollection of his former studies, and a few select friends, ever welcomed by a social and hospitable disposition, cheered him in his last days. He died in the 89th year of his age, on the memorable

28th of September, 1776, a few hours before the city of New-York was in flames, retaining his senses to the

last, and expiring without a groan.

last, and expiring without a groan.

Dr. Colden began, at an early period of his life, to pay great attention to the vegetable productions of America, in which delightful study his daughter afterward became distinguished. In honour of Dr. Colden, Linnæus named a plant, of the tetandrous class, Coldenia. This plant, Miss Colden had first described. He was attentive to the physical constitution of the country, and left a long course of digrnal obof the country, and left a long course of diurnal ob-servations on the thermometer, barometer, and winds. He also wrote a history of the prevalent diseases of the climate, and, if he was not the first to recommend the cooling regimen in the cure of fevers, he was cer-tainly one of its earliest and warmest advocates; and

tainly one of its earliest and warmest advocates; and opposed, with great earnestness, the prevailing mode of treatment in the small-pox.

In the years 1741 and '42, a fever, which occasioned great mortality, prevailed in the city of New-York, and created much alarm. He communicated his thoughts to the public, on the most probable method of curing the calamity, in a small treatise, in which he enlarged on the pernicious effects of marshy exhalations, moist air, damn cellars, filthy stores and directions. enlarged on the pernicious effects of marshy exhalations, moist air, damp cellars, filthy stores, and dirty streets; showed how much these nuisances prevailed, in many parts of the city, and pointed out the remedies. The corporation of the city presented him their thanks, and established a plan for draining and clearing out the city, which was attended with the most salutary effects. He published a treatise "On the Cure of Cancer." Another essay of his, "On the Virtues of the Great Water Dock," introduced him to an acquaintance with Linneus. In 1753, he published some observations on an epidemical sore throat, which appeared in Massachusetts, in 1735, and had spread over a great part of North America. These observations are to be found in Cary's American Museum.

When he became acquainted with Linneus's system of botany, he applied himself with new delight to that study. His descriptions, of between three and four hundred American plants, were printed in the Acta

that study. His descriptions, of between three and four hundred American plants, were printed in the Acta Upsaliensia. He published the "History of the Five Indian Nations," in 2 vols. 12mo. But the subject which drew Dr. Colden, at one period of his life, from every other pursuit, was what he first published, under the title of "The Cause of Gravitation," which being much enlarged, was republished by Dodsley, in 1751, in 1 vol. 4to., entitled, "The Principles of Action in

Matter, &c.

Though his principal attention, after the year 1760, was necessarily directed from philosophical to political was necessarily directed from philosophical to pointed a matters, he maintaind, with great punctuality, his literary correspondence, particularly with Linnaeus of Upsal, Gronovius of Leyden, Drs. Porterfield, and Whytte of Edinburgh, Dr. Fothergill, and Mr. Collinson, F.R.S. of London. There were also several communications on mathematical and astronomical subjects, between him and the Earl of Macclesfield. With most of the eminent men of our own country he with most of the eminent men of our own country he held an almost uninterrupted epistolary correspondence. Among them we may mention the names of Dr. Garden, Mr. J. Bartram, Dr. Douglass, Dr. John Bard, Dr. Samuel Bard, James Alexander, Esq., and Dr. Franklin. With Dr. Franklin, in particular, he was a constant and intimate correspondent, and they regularly communicated to each other their philosophysical discoveries especially on electrical discoveries especially on electric phical and physical discoveries, especially on electri-city. In their letters are to be observed the first dawnings of many of those discoveries which Dr.

dawnings of many of those discoveries which Dr. Franklin has communicated to the world, and which so much astonished and benefitted mankind. In a letter to one of his friends, Dr. Franklin gives an account of the organization of the American Philosophical Society, in which he mentions that Dr. Colden first suggested the idea and plan of that institution.

The numerous manuscript papers left by Dr. Colden at the time of his death, which for many years were supposed to have been lost, have been lately found, and are now in possession of his grandson, Cadwallader D. Colden, Esq. They are chiefly on historical and philosophical subjects, and many of them are of the greatest value. Among these are Observations on Smith's History of New-York, in a series of letters to his son, Alexander Colden: An Introduction to the Study of Philosophy: a correct copy of his Account of the Fever which prevailed in New-York in the

years 1741-2. This production may be found in Hosack and Francis's Register, vol. i. An Inquiry into the Principles of Vital Motion: A Translation of the Letters of Cicero, with an introduction by C. Colden: Plantæ Coldenhamiæ in provincia Noveboracensi spontanca crescentes, quas ad methodum Linnæi Sexualem, anno 1742, observanit Cadwallader Colden: A corrected and approprieted copy of his Principles of Accorded corrected and augmented copy of his Principles of Ac-tion in Matter: A Treatise on Electricity, &c. Besides these, there is a great mass of correspondence on medical, philosophical, and literary subjects, with many eminent physicians and philosophers in Europe and America. These letters carry his correspondence back to the year 1710, and bring it down, almost uninterruptedly, till the time of his death. There are, too, a great variety of papers on public affairs, which must be considered as documents of primary importance, as they necessarily contain numerous facts which throw light on the history of this State. Dr. Colden was unlight on the history of this State. Dr. Colden was un-questionably a man of various and extensive learning, of superior talents, of the most indefatigable industry, of superior talents, of the most indefatigable industry, and, indeed, in many respects, his character will not suffer by a comparison with that of our illustrious countryman, Benjamin Franklin.—Thacker's Med. Biography. A.]

COLE, WILLIAM, studied at Oxford, and took his degree there in 1666. After practising some time in Bristol, he came to London, and distinguished himself by several publications on physiology and medicine.

by several publications on physiology and medicine, which, however, are too theoretical. The principal are on animal secretion, on apoplexy, on the cause of fever, on insensible perspiration, &c. He published also a case of epilepsy, cured, in his opinion, by the

misletoe

(From καυλος, a stalk.) Colis. The Co'LES.

COLEWORT. See Brassica.
CO'LICA. (From κωλον, colon, the name of one of the intestines.) The colic. The appellation of colic is commonly given to all pains in the abdomen, almost indiscriminately; but, from the different causes and circumstances of this disorder, it is differently denominated. When the pain is accompanied with a vomiting of bile, or with obstinate costiveness, it is called a bilious colic; if flatus causes the pain, that is, if attended with temporary distention, relieved by the discharge of wind, it takes the name of flatulent or windy colic; when accompanied with heat and inflammation, it takes the name of inflammatory colic, or enteritis. When this disease arises to a violent height, and is attended with obstinate costiveness, and or enteritis. When this disease arises to a violent height, and is attended with obstinate costiveness, and an evacuation of faces by the mouth, it is called passio iliaca, or iliac passion.

Dr. Cullen places this genus of disease in the class neuroses, and order spasmi; and defines it pain of the abdomen, particularly around the umbilicus, attended with vomiting and costiveness. He enumerates seven

species.

1. Colica spasmodica, with retraction of the navel, and spasm of the muscles of the belly.

2. Colica pictonum. This is called from the place where it is endemial, the Poictou, the Surinam, the Devonshire colic; from its victims, the plumbers' and the painters' colic; from its symptoms, the dry bellyache, the nervous and spasmodic colic. It has been attributed to the poison of lead, and this is undoubtedly the cause, when it occurs to glaziers, painters, and those employed in lead works; but, though this is one it is by no means the only cause. In Devonshire. and those employed in lead works; but, though this is one, it is by no means the only cause. In Devonshire, it certainly more often arises from the early cider, made of harsh, unripe fruit, and in the West Indies from new rum. The characteristics of this disease are, obstinate costiveness, with a vomiting of an acrid or porraceous bile, pains about the region of the navel, shooting from thence to each side with excessive violence, strong convulsive spasms in the intestines, and a tendency to a paralysis of the extremities. It is occasioned by a long-continued costiveness; by an accumulation of acrid bile; by cold, applied either to the extremities or to the belly itself; by a free use of unripe fruits, and by great irregularity in the mode of living. From its occurring frequently in Devonshire, and other cider countries, it has been supposed to arise from an impregnation of lead received into the stomach; but this seems to be a mistake, as it is a very mach; but this seems to be a mistake, as it is a very prevalent disease in the West Indies likewise, where no cider is made, and where there is only a very small intestines by the pain being wringing, and not of a

quantity of lead in the mills employed to extract the juice from the sugar-canes. One or other of the causes just enumerated, may justly be said always to give rise

to this species of colic

The disease comes on gradually, with a pain at the pit of the stomach, extending downwards to the intestines, accompanied with cructations, slight sickness at the stomach, thirst, anxiety, obstinate costiveness, and a quick contracted pulse. After a short time, the pains increase considerably in violence; the whole region of the belly is highly painful to the touch; the muscles of the abdomen are contracted into hard irregular knots or largest the paints. or lumps; the intestines themselves exhibit symptoms of violent spasm, insomuch that a glyster can hardly be injected, from the powerful contraction of the sphincter ani; and there is constant restlessness, with a frequent vomiting of an acrid or porraceous matter, but more particularly after taking either food or medi-

Upon a farther increase of the symptoms, or their not being quickly alleviated, the spasms become more frequent, as well as violent; the costiveness proves in-vincible, and an inflammation of the intestines ensues, which soon destroys the patient by gangrene. L: an advanced stage of the disease, it is no uncommon occurrence for dysuria to take place, in a very high de-

The dry bellyache is always attended with some degree of danger; but which is ever in proportion to the violence of the symptoms, and the duration of the disease. Even when it does not prove fatal, it is too apt to terminate in palsy, and to leave behind it contractions of the hands and feet, with an inability in their muscles to perform their office; and in this miserable state of existence, the patient lingers out many wretched years.

wretched years.

Dissections of this disease usually show the same morbid appearances as in common colic, only in a much higher degree; namely, irregular contractions and distentions of the intestines, often with marks of

inflammation.

[Miners, and manufacturers of white-lead, red-lead, plumbers, pewterers, shot-casters, are all subject to the same forms of disease which attack painters. In same forms of disease which attack painters. In making white-lead, in the old way, the most dangerous time is when the pots are uncovered, and during that operation, few or none of those engaged in the corroding house escape without a severe turn of the painters' cholic. In making red-lead, the persons who attend the furnace and stir the metal, never escape the operation with impunity, being attacked with weakness, loss of appetite, nervous trembling, or cholic. White and red-lead are the most extensively used, and produce the most mischief, but the other preparations produce the most mischief, but the other preparations of lead exert a similar injurious effect upon the human constitution.

Dr. James Mann, hospital-surgeon in the U.S. army Dr. James Mann, hospital-surgeon in the U. S. army during the late war, has related the ill effects arising from the use of the acetate of lead as an astringent. When the dysentery prevailed in the northern army on the frontiers of New-York and Canada, it was found that a few grains of acetate of lead was effectual in restraining the evacuations. In some cases, where it was necessary to continue the remedy, the disease was allayed; but the patients afterward died with torpor or paralysis of the intestines, or other fatal operation of the lead as a poison. A.]

3. Colica stercorea, which happens from obstinate and long continued costiveness.

4. Colica accidentalis, called also cholera sicca, from

4. Colica accidentalis, called also cholera sicca, from acrid undigested matters.

5. Colica meconialis, in infants, from a retention of

meconium.

meconium.
6. Colica callosa, with a sensation of a stricture in some part of the colon, and frequently of previous flatulence, gradually passing off; the habit costive, or faces liquid, and in small quantity.
7. Colica calculosa, from calculi formed in the intestines, attended with a fixed hardness in some part of the abdomen. It is distinguished by the previous discharge of calculi.

discharge of calculi.

8. Colica flatulentia may be added to these species. It is distinguished by a sudden fulness, with pain and constipation, relieved by a discharge of wind from the mouth, or anus.

The colic is distinguished from inflammation of the

marning kind; by the spasmodic contraction of the abdominal muscles; by the absence or trifling degree of fever; by the state of the pulse, and by the diminution of pain upon pressure, which increases it in enteritis.

The flatulent and inflammatory colic are thus dis-tinguished from each other:—In the flatulent colic, the pain comes on by fits, flies from one part of the bowels to another, and is much abated by a discharge of wind, either upwards or downwards; but in the inflammatory colic the pain remains equable, and fixed and set-tled in one spot; the vomitings are severe, and fre-quently bilious; the belly is obstinately bound, and the pulse quick and feverish.

The colic should be distinguished from a fit of the The colic should be distinguished from a fit of the gravel; stones passing through the ureters; rheumatic pains in the muscles of the belly; a beginning dysentery; the blind piles; and from a stone passing through the gall-duct. Gravet in the kidneys produces often colic pains, not easily distinguishable; but when stones pass through the ureters, the testicle on that side is often retracted, the leg is benumbed, a pain shoots down the inside of the thigh; symptoms occasioned by the stone passing through the ureter over the spermatic chord, or the sacro-sciatic nerve. Rheumatic pains in the muscles of the belly rarely-affect so accurately the umbilical region, but dart in various directions. rately the umbilical region, but dart in various direc-tions, to the chest, or to the pelvis, and are attended with soreness, not confined to the abdomen. A be-ginning dysentery differs little from colic. The pain from the blind piles is confined to the rectum: and that from a stone in the gall-duct, is felt in the pit of the stomach, occasionally shooting through the body to the back.

The treatment of this disease must vary according to its form: but the leading indications are, 1. To obviate inflammation. 2. To relax the spasm, and relieve the pain attending. 3. To remove local irritation, especially by evacuating the alvine contents. 4. By various prophylactic measures to guard against a

1. The chief danger arising from inflammation supervening, it may be prudent to anticipate this, where the habit and strength will allow, by taking away an adequate quantity of blood from the arm, or more generally by leeches to the abdomen, but especially where any sign of inflammation appears, this plan becomes necessary, followed by a hot bath, or fomentations, a blister to the abdomen, &c. as detailed under

enteritis.

2. The means already noticed may serve to relax spasm also, though not requisite in slight cases, besides the various antispasmodic remedies, as ather, assafetida, &c., likewise aromatics, or spirituous liquors, will often by their stimulus on the stomach afford relief in a state of the colie. flatulent colic, though their use is sometimes hurtful; but by far the most powerful remedy is opium in ade-quate quantity, which is best regulated in severe at-tacks, by giving divided doses at short intervals till ease is obtained.

3. Local irritation may sometimes be relieved by chemical remedies, as antacids, particularly magnesia, &c.; but for the most part the evacuation of the intestines should be attempted, when the pain is relieved. To prepare for this, caloniel may be given in conjunction. tion with the opium, and when the patient has been some time at ease, this may be followed up by castor oil, sulphate of magnesia, or other mild laxative, re-peated till the desired effect be produced; or where these do not presently operate, some more active catharties, as the compound extract of colocynth, jalap, &c. should be tried. If the stomach be irritable, the effervescing saline draught may enable it to retain them; and clysters will often assist the articles taken by the mouth, particularly where there are indurated faces. In very obstinate cases, an injection of tobacco smoke has often succeeded in procuring evacuations: also putting the feet for some time in cold water, or pouring this on the abdomen and lower extremities. Sometimes it has been necessary to remove fœcai ac-

Sometimes it has been necessary to remove focal accumulations mechanically per anum.

4. The great liability of this complaint to return renders it necessary for some time after carefully to regulate the diet, to attend to the state of the bowels, as well as of the liver, to avoid the several causes, especially cold, maintaining the functions of the skin by suitable clothing, exercise, &c. In the colica picto-

num, stimulant aperients, as the peruvian balsam, mustard, &c. steadily persisted in, will mostly effect a complete cure; and mercury has been by some highly extolled; by others, astringents, especially alum, though certainly somewhat objectionable, as liable to confine the bowels.

COLICA ACCIDENTALIS. Colic from crudities in the

COLICA ARTERIA SINISTRA. The lower mesenteric

COLICA ARTERIA SUPERIOR. The upper mesenteric artery.

COLICA BILLIOSA. Colic from excess of bile.

COLICA CALCULOSA. Colic from stony matters in the intestines.

COLICA CALLOSA. Colic from hardened and obstinate strictures.

COLICA DAMNONIORUM. Colic peculiar to Devonshire. See Colica.

COLICA FEBRICOSA. Colic with fever.
COLICA FLATULENTA. Colic from wind.
COLICA GRAVIDARUM. Colic in pregnant women.
COLICA HYSTERICA. Hysteric colic.

COLICA LAPSONICA. Colic peculiar to nurses.
Colica Lapsonica. Colic peculiar to Laplanders
Colica meconialis. Colic from meconium in infants.

COLICA MESENTERICA. Colic from diseased me-

COLICA NERVOSA. The nervous colic.

COLICA PHLOGISTICA. Colic with inflammation.
COLICA PICTONUM. See Colica.
COLICA PITUITOSA. The spasmodic colic.
COLICA PLETHORICA. The inflammatory colic.
COLICA PLUMBARIORUM. The colic of lead-workers.
COLICA PULSATLIS. The inflammatory colic.
COLICA SATURNINA. The Devonshire colic. See

Colica.

COLICA SCIRRHOSA. The colic from scirrhous tumours.

COLICA SPASMODICA. The spasmodic colic. COLICA STERCOREA. Colic from retained fæces. COLICA VENA. A branch of the upper mesenteric

COLICA VENA RECTA. The vein of the colon.
COLICA VERMINOSA. The colic from worms.
CO'LICE. The colic.
COLIFO'RMIS. (From cola, a strainer, and forma, a likeness; so called from its having many perforations, like a strainer.) Califorme os. A name for merly given to the ethmoid bone.

Coll'Philm. (From κωλον, a limb, and ιφι, strongly.) A kind of bread given to wrestlers. It was made of flour and bran together, and was thought to

make men athletic.

Colla See Coles.

Colla See Coles.

Colla PSUS. (From collabor, to shrink down.)

A wasting or shrinking of the body, or strength.

Collate'nna. A specific vulnerary.

Collatera Les. So Spigelius calls the erectores penis, from their collateral order of fibres.

Colle Tica. (From κολλα, glue.) Conglutinating modicines.

medicines.

COLLICIE. (From colligo, to collect.) of the ducts, which convey the humours of the eyes from the puncta lachrymalia to the cavity of the nose. COLLI CULUM. (Diminutive of collis, a hill.)

A small eminence.

2. The nympha, or prominency, without the vagina

COLLIGA'MEN. (From colligo, to tie together.)

A ligament.

COLLINS, SAMUEL, was born in the early part of the 17th century. After studying at Cambridge and Oxford, he went to the Russian court as physician, and continued there nine years. On his return, he was made Fellow of the College of Physicians in London. He afterward published a History of the Court of Russia, and, in 1685, a system of anatomy, treating of the body of man, animals, and plants, with numerous plates. The comparative anatomy, to which Dr. Tyson greatly contributed, was much admired, though now superseded by other publications.

COLLIQUAME NTUM. (From colliquee, to melt.) A term first made use of by Dr. Harvey, in his appli-

cation of it to the first rudiments of an embryo, in ge-

COLLI'QUATIVE. (Colliquativus, from colliqueo, to melt.) Any excessive evacuation is so called which melts down, as it were, the strength of the body: hence colliquative perspiration, colliquative

COLLÍ SIO. (From collido, to beat together.) A

contusion.

Co'LLIX. (From κολον, food.) A troch, or lozenge. Co'LLIX. (From κολλαω, to glue together.) Colobroma. 1. The growing together of the eyelids. 2. The want of any member of the body. Collo'DES. (From κολλα, glue.) Glutinous. Co'LLUM. (From κωλον, a member, as being one of the chief; or diminutive of columna, as being the pillar and support of the head.) The Neck. See Neck.

Neck.
COLLUTION. Collatio. The washing of the mouth, or any other part.
COLLUTO'RIUM. (From colluo, to wash.) A gargarism, or wash for the mouth.
COLLUTIES. (From colluo, to cleanse.) Fifth; Excrement. The discharge from an old tilcer.
CO'LLYRIS. (Κολλυρις. A little round cake; so called from its likeness to a cake.) A bump, or knob, which rises after a blow.

which rises after a blow.

COLLY RIUM. (From κωλυω, to check, and ρους, a defluxion; because it stops the defluxion.) A medicine was formerly so called which was applied to check any discharge. The term is now only given to

fluid applications for the eyes, or eye-waters.
[Collyriam. "The Collyria of the Pharmacopaia are metallic lotions, prepared of such strength as to be applicable to the eyes in many cases of disease; also occasionally to mucous membranes of other parts, and to inflamed or excoriated surfaces.

COLLYRIUM PLUMBI ACETATIS. Collyrium of acetate of lead. This is of use as a sedative and astringent lotion in some forms of chronic ophthalmia. It is also useful as a discutient in crysipelatous and other superficial inflammations. It is sometimes employed as an injection in gonorrhem; but when this practice is adopted, a weaker solution is preferable.

Collyrium plumbi acetatis et ofit. Collyrium of opium and acetate of lead. This resembles the pre-

ceding, but agrees better with irritable cases of chronic opthalmia.

COLLYRUM ZINCI ACETATIS. Collyrium of acetate of zinc. A double decomposition takes place during the preparation of this article; sulphate of lead is deposited, and acetate of zinc remains dissolved. It is a valuable astringent collyrium.

Collyrium zinci sulphatis. Collyrium of sulphate of zinc. This is one of the best astringent lotions for cases of ophthalmia, which requires remedies of that class. I have observed it to agree particularly well with the weak eyes of nursing women.—Big. Mat.

Med. A.] COLOBOMA. See Colloboma.

COLOBO MATA. In Celsus this word is expressed by curta. Both the words signify a deficiency in some part of the body, particularly the ears, lips, or alæ of the nostrils.

the nostrils.

Coloca'sia. (From κολον, food, and καζω, to adorn; so called from its use as a food, and the custom of wearing its flowers in wreaths.) The faba Ægyptia. See Nymphaa nelumbo.

COLOCY'NTHIS. (From κολον, the colon, and κινω, to move; because of its great purging powers.) Coloquinteda. See Cucumis colocynthis.

COLO'MBO. See Calumba.

CO'LON. (Colon, i. neut.; Κωλον, quasi κοιλον; from κοιλος, hollow: so called from its capacity, or from its generally being found empty, and full of wind in dissection.) The greater portion of the large intestine is so called. It proceeds towards the liver, by the name of the ascending portion of the colon; and having reached the liver, forms a transverse arch across to the other side. The colon then descends, forming what is termed its sigmoid flexure, into the pelvis, where the gut is called rectum. See Intestine.

COLOPHO'NIA. (Κολοφωνια, the city from whence it was first brought.) Colophony. 1. The black resin which remains in the retort, after distilling the common resin with a strong fire.

mon resin with a strong fire.

2. Paracelsus seems to mean by it what is now pre-

2. Paracelsus seems to mean by it what is now prescribed by the name of terebinthina cotta.

3. The ancients, and particularly Galen, seemed to
understand by it a soft kind of mastich, from Chio,
probably the same as our Chio turpentine.

COLOPHONITE. Resinous garnet of Hady and
Jameson. A mineral of a blackish or yellowish brown,
or orange-red colour, and a resino-adamantine lustre,
found in magnetic ironstone, in Norway and in
Covlon.

Ceylon.

COLOQUINTIDA. See Cucumis colocynthis.

COLORATUS. Coloured: applied to leaves, calyces, seeds, &c. to express any colour besides green, as in Arum bicolor; or to any part thereof when of another colour than green, as in Amaranthus tricolor; and to a perianthium, when not of a green colour, as that of the Gomphrena globosa: and the seeds of Charachallum gurcum.

COLO'STRUM. (From κολον, food, or κολλωμαι, to agglutinate; so called, either because it is the first food of the young, or from its being at that time peculiarly glutinous.)

1. The first milk in the breasts after delivery.

2. An emulsion made by the solution of turpentine

with the yelk of an egg.

COLOT, Germain, a French surgeon of the 15th
century, appears to have been the first of the profession who practised lithotomy, that operation having
been previously in the hands of itinerant practitioners. He acquired great celebrity by his skill, and was much in favour with Lewis IX., who granted him a pension. Several of his descendants, in succession, enjoyed great reputation as lithotomists.

great reputation as lithotomists.

COLOT, Francis, the last of them, left a treatise, published in 1727, describing the method of operating with the greater apparatus, the invention whereof he ascribes to John de Romanis, an Italian physician, about two centuries before. But this has long been superseded by the less apparatus, which Mr. Sharp attributes to another French surgeon, Mons. Foubert.

Colotol'des. (From κωλωτης, a lizard, and ειδος, likeness.) Variegated like the skin of a lizard. Hippocrates applied it to the excrements.

pocrates applied it to the excrements.

Coloured leaf. See Leaf. COLPOCE'LE. (From κολπος, the vagina, and κηλη, a tumour.) A hernia forced into the vagina.

κηλη, a tumour.) A herma forced into the vagina. See Hernia vaginalis.

COLPOPTO'SIS. (From κολπος, the vagina, and πεπτω, to fall down.) A bearing down of the vagina. See Hernia vaginalis.

COLT'S-FOOT. See Tussilago.

CO'LUBER. (Quod colit umbram, because it delighteth in the shade.) A genus of animals in the linean arrangement, of which there are many species.

COLUBER BERUS. The systematic name of the viper, which possesses the power of forming a poisonous fluid in little bags near its teeth. The flesh is perfectly innocent, and often taken by the common people against the king's evil, and a variety of disorders of the skin. Experience evinces it to be an inefficacious substance.

COLUBRI'NA VIRGINIANA. See Aristolochia ser-

COLUBRINUM LIGNUM. (Colubrinus; from coluber: so called from the snake-like contortions of its roots.) This species of snake-wood is brought from America. It is solid, ponderous, acrid, extremely bitter, and in-odorous; its bark is of a ferruginous colour, covered

odorous; its bark is of a ferruginous colour, covered with cineritious spots.

COLU'MBA. See Calumba.

COLUMBIC ACID. Acidum Calumbicum. "The experiments of Hatchett have proved, that a peculiar mineral from Massachusetts, deposited in the British Museum, consisted of one part of oxide of iron, and somewhat more than three parts of a white-coloured substance, possessing the properties of an acid. Its basis was metallic. Hence he named this Columbium, and the acid the Columbic. Dr. Wollaston, by very exact analytical comparisons, proved, that the acid of Hatchett was the oxide of the metal lately discovered in Sweden by Ekeberg, in the mineral yttrocovered in Sweden by Ekeberg, in the mineral yttro-tantalite, and thence called tantalum. Dr. Wollastantante, and thence caned tantatum. Dr. Wollas-ton's method of separating the acid from the mineral is peculiarly elegant. One part of tantalite, five parts of carbonate of potassa, and two parts of borax, are fused together in a platina crucible. The mass, after

being softened in water, is acted on by muriatic acid.

being softened in water, is acted on by muriatic acid. The iron and manganese dissolve, while the columbic acid remains at the bottom. It is in the form of a white powder, which is insoluble in nitric and sulphuric acids, but partially in muriatic. It forms with barytes an insoluble salt, of which the proportions, according to Berzelius, are 24.4 acid, and 9.75 barytes. By oxidizing a portion of the revived tantalum or columbium, Berzelius conclides the composition of the acid to be 100 metal, and 5.485 oxygen."

COLUMBINE. See Aquilegia.

COLUMBIUM. Hatchett describes the ore, from which this metal is obtained, as being of a dark brownish gray externally, and more inclining to an iron-gray internally; the longitudinal fracture he found lamellated, and the cross fracture had a fine grain. Its lustre was vitreous, slightly inclining, in some parts, to metallic; moderately hard, and very brittle. The colour of the streak, or powder, was dark chocolatebrown. "If the oxide of columbium, described under Columbic acid, be mixed with charcoal, and exposed to a violent heat in a charcoal crucible, the metal columbium will be obtained. It has a dark gray colour; and when newly abraded, the lustre nearly of iron, and when newly abraded, the lustre nearly of iron. to a violent heat in a charcoal crucible, the metal co-lumbium will be obtained. It has a dark gray colour; and when newly abraded, the lustre nearly of iron. Its sp. gr., when in agglutinated particles, was found by Dr. Wollaston to be 5.61. These metallic grains scratch glass, and are easily pulverized. Neither ni-tric, muriatic, nor nitro-muriatic acid, produces any change in this metal, though digested on it for several days. It has been alloyed with iron and tungsten."

[This metal, which was said to have been found in Massachusetts it ap-

covered in a specimen found in Massachusetts, it appears (Med. Repos. vol. viii. p. 437,) was taken from a spring of water in the town of New-London, in Connecticut, and near the house in which Governor Winthrop used to live, about three miles distant from the margin of the salt water at the head of the harbour.

"Within a short time after the discovery of columnian the Markett in 1801, a matallic substructure."

bium by Mr. Hackett in 1801, a metallic substance was also discovered in Sweden, by Mr. Ekeberg, differing from every metal then known to him; and according from every metal then known to him; and accordingly he described the properties by which it might be distinguished from those which it most nearly resembled. But although the Swedish metal has retained the name of Tantalum, given to it by Mr. Ekeberg, a reasonable degree of doubt has been entertained by chemists, whether these two authors had not, in fact, described the same substances; and it has been regretted that the discoverers themselves, who would have been most able to remove the uncertainty had not been most able to remove the uncertainty, had not had opportunities of comparing their respective minerals, or the products of their analyses."—Min. Jour.

The doubt, however, has been removed, as Dr. Wollaston had obtained portions of both metals, and upon examination and analysis has determined, that Co-lumbium and Tantalum are one and the same me-

tal.

tal. A.]
COLUMBO'BE. See Calumba.
COLUME'LLA. (Diminutive of columna, a column.)
1. A column or little pillar.
2. The central column, or filament, which unites the partitions of the capsule of plants. The seeds are usually attached to it. See also Uvula and Clitoris.
COLUMELLA'RIS. (From columella, a little column.)
A name of the dens caninus.

COLUMELLA'RIS. (From columella, a little column.)
A name of the dens caninus.
COLU'MNA. A column, or pillar. Many parts of the body, which in their shape or office resemble columns, are so named; as columna carneæ, &c.
COLUMNA CARNEA. See Heart.
COLUMNA NASI. The lowest and fleshy part of the nose, which forms a part of the septum.
COLUMNA ORIS. The uvula.
COLUMNIFERÆ. The name of an order of plants in Linguist's Fragments of a Natural Method.

plants in Linnæus's Fragments of a Natural Method, consisting of plants, the stamina and pistil of which have the appearance of a pillar in the centre of the

rower.

COLUMNULA. A little column. The name given by botanists to the filament which passes through the middle of the capsule of frondose mosses, to which the seeds are connected; also called Sphrongidium.

Colu Rium. (Παρα το κολλαν τον φουν: because it prevents a defluxion.) A tent to thrust into a sore, to prevent a defluxion of humours.

CO'MA. (From κω, οr κεω, to lie down.)

In pathology, a propensity to sleep. This word anciently meant any total suppression of the powers

of sense; but now it means a lethargic drowst-

In botany, 1. A fasciculus of leaves on the top of a stem or stipe. It is said to be, a. Foliose, when formed of leaves; as in Bromelia

ananas.

b. Frondose, when proceeding from the frond at the apex of the stipe; as in Palms.

c. Bracteal, formed of floral leaves; as in Laven-

dula stæchas.

2. Gærtner applies this term to the feathery crown

of seeds furnished with a capsule.

Coma somnolentum. Is when the patient continues in a profound sleep; and, when awakened, immediately relapses, without being able to keep open his eyes.

A disease where the patients are con-COMA VIGIL.

tinually inclined to sleep, but cannot.

CO MATA. (Comata, the plural of coma.) An order of the class Neuroses of Cullen's Nosology, embracing diseases that are characterized by a diminution of the powers of voluntary motion, with sleep or

the senses impaired.

COMATOSE. Having a strong propensity to sleep.

COMBINATION. The intimate union of the particles of different substances by chemical attraction, so as to form a compound possessed of new and pecu-

liar properties.

COMBUSTIBLE. Having the property of burning.

See Combustion

COMBU'STIO. (From comburo, to burn.) A burn,

or scald. See Burn.

COMBUSTION. (Combustio; from comburo, to burn.) Burning. Among the various operations of chemistry, none acts a more conspicuous part than combustion; and in proportion to its utility in the science, the necessity of thoroughly investigating its nature and mode of action, becomes more obvious to the philosophical chemist.

Lavoisier's Theory of Combustion.

Lavoisier's theory of combustion is founded upon

the absorption of oxygen by a combustible body.

Taking this for granted, it follows that combustion is only the play of affinity between oxygen, the matter

of heat, and a combustible body.

When an incombustible body (a brick for instance) is heated, it undergoes no change, except an augmentation of bulk and temperature; and when left to itself, it soon regains its former state. But when a combustible body is heated to a certain degree, in the open air, it becomes on a sudden intensely hot, and at last emits a copious stream of caloric and light to the surrounding bodies. During this emission, the burning body gradually wastes away. It either disappears entirely, or its physical properties become totally altered. The principal change it suffers, is that of being no longer capable of combustion. If either of these phenomena, namely, the emission of heat and light, and the waste of substance, be wanting, we do not say that a body is undergoing combustion, or that it is burning. It follows, therefore, that every theory of combustion ought to explain the following facts:

1. Why a burning body is consumed, and its indivi-

dualily destroyed.

2. Why, during the progress of this alteration, heat and light are emitted.

1. Layoisier's

For the elucidation of these objects, Lavoisier's

theory has laid down the following laws:

1. Combustion cannot take place without the presence of oxygen, and is more rapid in proportion to the quantity of this agent, in contact with the inflamed

2. In every act of combustion, the oxygen present is

consumed.

The weight of the products of every body after combustion, corresponds with the weight of the body before combustion, plus that of the oxygen con-

4. The oxygen absorbed by the combustible body may be recovered from the compound formed, and the weight regained will be equal to the weight which disappeared during the combustion.

5. In every instance of combustion, light and heat, or fire, are liberated.

6. In a limited quantity of air, only a certain quantity of the combustible body can be burnt.
7. The air, wherein a body has been burnt, is ren

dered unfit for continuing combustion, or supporting

Though every case of combustion requires that light and heat should be evolved, yet this process proceeds very differently in different circumstances; hence the terms ignition; or glowing heat; inflammation, or ac-cension; and detonation, or explosion.

Ignition takes place when the combustible body is not in an aeriform state.

Charcoal, pyrophorous, &c. furnish instances of this kind.

It seems as if the phenomenon of glowing was peculiar to those bodies which require a considerable quantity of caloric, to become converted into the

The disengagement of caloric and light is rendered

more evident to the senses in the act of

Inflammation, or accension. Here the combustible substances are more easily converted into an elastic or substances are more easily converted into an elastic or aeriform state. Flame, therefore, consists of the inflammable matter in the act of combustion in the gaseous state. When all circumstances are favourable to the complete combustion of the products, the flame is perfect; if this is not the case, part of the combustible body, capable of being converted into the gaseous state, passes through the luminous flame unburnt, and exhibits the appearance of smoke. Soot, therefore, always indicates an imperfect combustion. Hence a common tamp smokes, an Argand's lamp Hence a common lamp smokes, an Argand's lamp yields no smoke.

This degree of combustion is very accurately ex-

emplified in the

Flame of candles.—When a candle is first lighted, which must be done by the application of actual flame, a degree of heat is given to the wick, sufficient to destroy the affinity of its constituent parts; part of the tallow is instantly melted, volatilized, and burnt. As this is destroyed by combastion, another portion melts, rises, and supplies its place, and undergoes a like change. In this way combustion is maintained. The tallow is liquefied as it comes into the vicinity of the flame, and is, by the capillary attraction of the wick,

drawn up to supply the place of what is burnt; the unmelted tallow, by this means, forms a kind of cup.

The congeries of capilary tubes which form the wick is black, because the charcoal of the cotton becomes predominant, the circumambient air is defended by the flame from oxidising it; it therefore remained to the control of the cotton becomes predominant, the circumambient air is defended by the flame from oxidising it; it therefore remained to the control of the cotton becomes predominant, and the circumambient air is the cotton becomes predominant. mains, for a considerable time, in its natural state; but when the wick, by the continual consumption of tallow, becomes too long to support itself in a perpendicular position, its upper extremity projects nearly out of the cone of the flame, and there forms a support for an accumulation of soot, which is produced by the imperfect combustion. A candle, in this situation, affords scarcely one-tenth of the light it can otherwise give, and tallow candles, on this account, require continual snuffing.

But if the candle be made of wax, the wick does not long occupy its place in the middle of the flame; its thinness makes it bend on one side, when its length is too great for its vertical position; its extremity comes then into contact with the air, and is completely burnt, or decomposed, except so much of it as is de-fended by the continual afflux of the melted wax. This small wick, therefore, performs the office of snuffing itself. The difficult fusibility of wax enables us to use a thinner wick for it than can be used for tallow, which is more fusible. But wax being a substance which contains much more oxygen than tallow or oil, the light it affords is not so luminous.

Detonation is an instantaneous combustion, accompanied with a loud report; it takes place in general when the compounds resulting from the union of two when the compounds resulting from the union of two or more bodies, occupy much more or less space than the substances did before their union; a great impulse is therefore given to the surrounding air, or else a vacuum is formed, and the air rushing in from all sides to fill it up is the cause of the report.

A mixture of oxygen and hydrogen gases detonates very loud. Gunpowder, fulminating gold, silver, and mercury; oxygenated muriate of potassa; and various other explosive compounds, are capable of producing very loud detonations.

wery loud detonations.

With respect to the disengagement of light and

By the older chemists, it was universally supposed

that the light and heat emitted during combustion, proceeded from the inflammable body; and this opi-nion would indeed appear unquestionable, while the composition of the atmosphere was imperfectly known. The burning body appeared luminous and felt hot, and no other agent was supposed to be concerned; the conclusion that the light and heat were evolved from the burning substance, was, therefore, unavoid-able. But when the nature of the astmosphere was ascertained, and when it became evident that part of ascertained, and when it became evident that part of the air was absorbed during combustion, the former conclusion fell to the ground; for when twobodies exert a mutual action on each other, it becomes a priori equally probable that the products may be derived from either of them; consequently, the light and heat evolved might proceed either from the one or the other. Whether they proceed from the atmosphere, or from the combustible body, they must be separated at the part where the combination takes place; that is, mon the surface of the burning body itself; and conupon the surface of the burning body itself; and consequently it appeared luminous and heated, while the air being invisible escaped observation.

When the laws of heat became known, at least when it was ascertained that bodies contain at the

when it was ascertained that bodies contain at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, the conclusion became probable, that the caloric evolved in combustion proceeded rather from the oxygen gas of the atmosphere, than from the combustible body; since the former contains a much larger quantity than the latter. The caloric evolved was therefore supposed to be derived from the condensation of the oxygen gas in the new combination into which it entered.

Though approaching to the truth, this explanation is not strictly true. It is not merely from the oxygen gas being condensed that the caloric is evolved, because, in many cases of combustion, the product still exists in the gaseous state, and in others, the quantity of caloric evolved bears no proportion to the degree of condensation. Philosophers ascribed this to a change of capacity; for, in different bodies, the difference in the proportion of the capacities before and after combustion, is by no means uniform; and hence the dif-ference in the quantities of caloric extricated in various cases of combustion.

This being premised, it remains to explain the origin of the light emitted during combustion; for although we take it for granted that the caloric is evolved from the oxygen gas, we cannot infer that the light has the

same origin.

It is very probable that light is a constituent part of inflammable bodies; for it is frequently evolved in combinations when the oxygen is merely transferred from one inflammable substance to another. In those cases it must proceed from the inflammable body. The accension of oils by the affusion of acids, the combustion of metals in the same way, furnish in stances of the kind.

It seems, therefore, probable, that the light is derived from the inflammable substance; and that the oxygen, combining with the bases of these substances,

disengages the light.

It may be concluded then, that light enters into the composition of all combustible bodies; but as we are unable to separate the light, so as to obtain these bodies pure, we treat of them as simple bodies.

According to this theory, the combustion of phosphorous in oxygen gas, is, therefore, the effect of a double affinity. The basis of the oxygen gas unites with the phosphorus, to form phosphoric acid; and the light disengaged from the phosphorus, together with the heat of the oxygen gas, produces the vivid

The quantity of light emitted by different bodies is The quantity of light emitted by different bodies is supposed to depend on the quantity contained in them, and on the proportion in which it is united to caloric. Such is the theory of combustion of Lavoisier, modified by Gren, Leonardi, and Richter.

Thomson's Theory of Combustion.

Though the preceding theory of combustion is simple and beautiful, it appears, from what we are now going to state, to be by no means completely satisfactory.

It has misled chemists, by confining the term combustion to the act of oxygenation, and considering that all bodies, during their combustion, combine with oxygen, without at the same time recollecting that this latter effect may take place without any of the phenomena usually attendant on combustion; and that, though certainly all combustion presupposes the comthough certainly all combustion presupposes the com-bination of oxygen with a base, yet this combination may be, and repeatedly is, effected where no combus-tion can possibly take place. Nothing can be more evident than the difference which, in numberless in-stances, prevails between the act of oxygenation in bodies and that of combustion, inasmuch as neither the phenomena attending on, nor the results arising from them, are the same. That a distinction there-fore should be made between these processes is obvious; and it is on this account that Dr. Thomson has offered a theory, which considers this subject in a new point of view, and which bids fair to enable us to estimate the phenomena of combustion much better than has hitherto been done.

According to Dr. Thomson's theory, all the bodies concerned in combustion are either, 1. Combustibles.
 -2. Supporters of combustion.—3. Incombustibles.

I. COMBUSTIBLE BODIES are those substances which are said, in common language, to burn. During the combustion, they appear to emit light and heat, and, at the same time, gradually waste away. When this change has reached its maximum, the process of combustion is at an end.

The class of combustibles is very numerous; but all the bodies belonging to it may be subdivided into three sets, namely:

1. Simple combustibles. 2. Compound combustibles. 3. Combustible oxides, &c.

Simple Combustibles.

4. Hydrogen gas. 1. Sulphur.

2. Phosphorus.
3. Diamond, or Carbon.
6. Boron.
Compound Combustibles.
The compound combustibles consist of compounds, formed by the simple combustibles uniting together, and are of course much more appropriate than the simple control of the simple combustibles uniting together, and are of course much more appropriate than the simple control of the s and are of course much more numerous than the sim-ple combustibles. They may be arranged under the five following heads:

 Sulphurets.
 Phosphurets. 3. Carburets. 2. Phosphurets. 4. Alloys.
5. Sulphuretted, phosphuretted, and carburetted

hydrogen.

The combustible oxides are either simple, having a single base, or compound, having more than one base. All the simple combustible oxides are by combustion converted into acids.

The compound combustible oxides are by far the

most numerous.

II. The supporters of combustion are bodies which are not of themselves, strictly speaking, capa-ble of undergoing combustion, but which are abso-hitely necessary for the process; for no combustible body can burn unless some one or other of them be present. Whenever they are excluded, combustion ceases. All the supporters of combustion known at present are oxygen, chlorine, iodine, and the com-

There are indeed certain substances besides these, which possess nearly the same properties; these shall be afterward enumerated under the title of partial

III. The incombustible bodies are neither capable of undergoing combustion themselves, nor of support-ing the combustion of those bodies that are; they are therefore not immediately connected with combustion; though most of them appear to be the results of that process. Azot, the alkalies, earths, &c. come under this division.

Some of the alkalies and earths possess certain properties in common with combustibles, and are capable of exhibiting phenomena somewhat analogous to com-bustion; which will be described afterward under

the title of semi-combustion.

In every case of combustion, there must therefore be present a combustible body, and a supporter of combustion. During combustion, the combustible always unites with the supporter. It is this combina tion which occasions the apparent waste and alteration of the combustible. The new compound thus formed is a product of combustion. Every product of combustion is either, 1. an acid, or, 2. an oxide, &c. It is true, indeed, that other bodies sometimes make their appearance during combustion, but these will be found,

upon examination, not to be products, nor to have undergone combustion.

Thus one of the two characteristic marks which distinguish combustion, namely, the apparent waste and alteration of the combustible body, has been fully explained. For the explanation of it we are indebted to Lavoisier, as stated before.

But though the combination of the combustible with oxygen, or other supporter, be a constant part of combustion, yet the facility with which combustibles burn is not proportional to their apparent affinity for

oxygen.
Phosphorus, for instance, burns more readily than charcoal; yet charcoal is capable of abstracting oxygen from phosphorus, and of course has a greater affinity for it. Some of the combustible oxides take fire more readily than some of the simple combustibles; alkohol, æther, and oils, are exceedingly combustible, whereas all the metals require very high temperature when the supporter is air.

This greater combustibility of combustible oxides is probably owing to the weaker affinity by which their particles are united. Hence they are more easily separated than homogeneous particles, and of course combine more readily with oxygen; those simple combustibles which melt easily, or which are in the state of lastic fluids, are also very combustible, because the cohesion between their particles is easily overcome.

It is owing to the same inferiority in the cohesion of heterogeneous particles, that some of the compound supporters occasion combustion in circumstances when the combustibles would not be acted on by

simple supporters.

Thus phosphorus burns in air at the common temperature; but it does not burn in oxygen gas, unless its temperature be raised. Thus also oils burn rapidly when mixed with nitric acid. Nitrous gas and nitrous oxide constitute exceptions to this rule.

None of the products of combustion are combustible, according to the definition of combustion here given. This want of combustibility is not owing to their being saturated with oxygen; for several of them This want of combustibility is not owing to are capable of combining with an additional dose of it. But, during this combination, no caloric or light is ever emitted; and the compound formed differs essentially from a product of combustion; for by this addi-tional dose of oxygen, the product is converted into a supporter. Hence we see that combustion ought not to be confounded with the combination of a body with ozygen, as was done formerly.

Combustion, indeed, cannot take place without the combination of oxygen or other supporter; but oxygen may combine with bodies in different proportions without the phenomena of combustion; and the product obtained by combustion is capable of becoming converted into a supporter of combustion; for instance, if lead be melted, and kept so for some time, it be comes covered with a gray pellicle, or ozide of lead, a product consisting of oxygen and lead; but if this oxide is suffered to be heated longer, it absorbs an additional quantity of oxygen, and becomes converted into a yellow powder, called *yellow oxide of lead*. If this yellow oxide be again exposed to heat, it absorbs still more oxygen, and becomes converted into red oxide of lead. When the supporters thus formed by the combination of oxygen with products, are made to support combustion, they do not lose all their oxygen, but only the additional dose which constituted them supporters. Of course they are again reduced to their original state of products of combustion. Hence it follows, that they owe their properties as supporters, not to the whole of the oxygen which they contain, but to the additional dose which constituted them supporters. porters. We may therefore call them partial sup-porters; indicating by the term, that part only of their oxygen is capable of supporting combustion, and not

the whole.

All the partial supporters with which we are acquainted, contain a metallic basis; for metallic oxides are the only products at present known, capable of combining with an additional dose of oxygen. It is a circumstance highly deserving attention, that when metals are capable of combining with several doses of oxygen, the product, or oxide formed by combustion, is seldom or never that which contains a maximum of oxygen.

oxygen.
Thus it is evident that several of the products of

COM COM

The incombustibility of products, therefore, is not owing to their want of affinity for oxygen, but to some other cause.

No product of combustion is capable of supporting combustion. This is not occasioned by any want of affinity to combustible bodies; for several of them are combustion. This is not occasioned by any want of affinity to combustible bodies; for several of them are capable of combining with an additional dose of their basis. But by this combination, they lose their properties as products, and are converted into combustibles. The process, therefore, differs essentially from combustion. Thus phosphoric acid, a product of combustion, is capable of combining with an additional dose of phosphorus, and forming phosphorus acid, a combustible body. When this last acid is heated in contact with a supporter, it undergoes combustion; but it is only the additional dose of the combustible which burns, and the whole is converted into phosphoric acid. Hence we see that it is not the whole basis of these compounds which is combustible, but merely the additional dose. The compounds, therefore, formed by the union of a product and combustible, may be termed partial combustibles; indicating by the name, that a part only of the base is capable of undergoing combustion. Since the products of combustion are capable of combining with oxygen, but never exhibit the phenomena of combustion, except when they are in the state of partial combustibles, combustible bodies must contain a substance which they lose in burning, and to which they owe their combustibility; for, after they have lost it, they unite to oxygen without exhibiting the phenomena of combustion.

Though the products of combustion are not capamena of combustion.

they unite to oxygen without exhibiting the phenomena of combustion.

Though the products of combustion are not capable of supporting combustion, they not unfrequently part with their oxygen just as supporters do, give it out to combustibles, and convert them into products; but during this process, no heat or light is ever evolved. Water, for instance, gives out its oxygen to iron, and converts it into the black oxide, a product. Thus we see that the oxygen of products is capable of converting combustibles into products, just as the oxygen of supporters; but during the combination of the last only, are heat and light emitted. The oxygen of supporters then contain something which the oxygen of products wants.

Whenever the whole of the oxygen is abstracted from products, the combustibility of their base is restored as completely as before combustion; but no substance is capable of abstracting the whole of the oxygen, except a combustible, or a partial combustible. Water, for instance, is a product of combustion, whose base is hydrogen. To restore the combustibility of the nydrogen, we have only to mix water with iron or zinc filings, and an acid; the metal is oxidized, and the hydrogen gas is evolved as combustible as ever. But no substance, except a combustible, is capable of separating hydrogen gas from water, by combining the hydrogen gas is evolved as combustible as ever. But no substance, except a combustible, is capable of separating hydrogen gas from water, by combining with its oxygen. Thus we see that combustibles are capable of restoring the combustibility of the bases of products; but they themselves lose their combustibility by the process, and are converted into products. Combustibility, therefore, may be thrown at pleasure from one body to another.

From these facts it is obvious that the products of

one body to another.

From these facts it is obvious, that the products of combustion may be formed without combustion; but in these cases a new combustible is always evolved. The process is merely an interchange of combustibility; for the combustible is converted into a product only by means of a product. Both the oxygen and the base of the product having undergone combustible have lest competiting which is essential to combustions have lest competition because of the product of the product having undergone combustions have lest competition because of the product of the product having undergone combustions have lest competition because the product of the product of the product of the product having undergone combustions are lest competition to the product of t the base of the product having undergone combus-tion, have lost something which is essential to combus-tion. The process is merely a double decomposition. The product yields its oxygen to the combustible, while at the same time the combustible gives out something to the base of the product; the combustibility of that base then is restored by the loss of its oxygen, and by the restoration of something which it receives from the other combustible thus converted into a product.

There is indeed another method of forming the products of combustion without actual combustion in certain cases; but the phenomena are much more complicated. This method is to expose them to the action of some of the supporters dissolved in water; especially nitric acid. Thus most of the metallic oxides may be formed without combustion by the action of the resident the metalls. But in that case a new of that acid on the metals. But, in that case, a new

combustion are capable of combining with oxygen. supporter is always evolved, namely, nitrous gas; amThe incombustibility of products, therefore, is not out of monia, a new combustible, is also usually formed; and, not unfrequently, the product is converted into a

partial supporter.

partial supporter.

No supporter can be produced by combustion, or by any equivalent process. As several of the supporters consist of oxygen combined with a base, it follows as a consequence, that oxygen may combine with a base without losing that ingredient, which occasions combustion. The act of combination of oxygen with a base, therefore, is by no means the same with combustion. If we take a view of the different supporters, we shall find that all of them which can be obtained artificially, are procured either from other supporters, or by the agency of electricity.

I. Oxygen gas may be procured from nitric acid,

supporters, or by the agency of electricity.

I. Oxygen gas may be procured from nitric acid, and from several of the partial supporters, as the black oxide of manganese, the red oxides of lead and of mercury. The action of heat is always necessary; but the process is very different from combustion.

II. Air, as far as is known at present, cannot be formed artificially. The gas, indeed, which comes over during part of the usual distillation of nitrate of potassa and sulphuric acid, to obtain nitric acid, resembles air very closely. But it is obtained from a supporter.

supporter.

III. NITROUS OXIDE has hitherto been only procured from nitrous gas and nitric acid, (in nitrate of ammonia,) both of which are supporters.

ammonia,) both of which are supporters.

IV. Nitrous gas can only be procured by the decomposition of nitric acid, a supporter.

V. Oxymuriatic acid, a supporter.

V. Oxymuriatic acid, or Chlorine, can be formed by the action of muriatic acid on the black oxide of manganese, the red oxides of lead, iron, or mercury; all of which are partial supporters.

VI. Nitric acid is formed spontaneously upon the surface of the earth, by processes with which we are but imperfectly acquainted; but which certainly have no resemblance to combustion. Its oxygen is probably furnished by the air, which is a supporter; at least, it has been observed, that nitrogen and oxygen, at high temperatures, are capable of forming nitric acid.

This formation of nitric acid by means of electricity, has been considered as a combustion, but for what reason it is not easy to say: the substance acted upon is not a combustible with a supporter, but a supporter alone. Electricity is so far from being equivalent to combustion, that it sometimes acts in a manner

lent to combustion, that it sometimes acts in a manner diametrically opposite; unburning, if we may use the expression, a substance which has already undergone combustion, and converting a product into a combustible and a supporter. Thus it decomposes water, and converts it into oxygen and hydrogen gas; therefore it must be capable of supplying the substances which the oxygen and combustible lose when they combine by combustion, and form a product. combine by combustion, and form a product.

combine by combustion, and form a product.

Several of the supporters and partial supporters are capable of combining with combustibles, without undergoing decomposition, or exhibiting the phenomena of combustion. In this manner, the yellow oxide of gold combines with ammonia; the red oxide of mercury with oxalic acid; and oxymuriatic acid with ammonia. Thus also nitrate of potassa may be combined, or at least intimately mixed, with several combustible bodies, as in gunpowder, fulminating powder, &c. In all these compounds, the oxygen of the supporter and the combustible retain the ingredients which render them susceptible of combustion; hence the compound is still combustible. And in consequence of the intimate combination of the component parts, the least alteration is apt to destroy the equiliparts, the least alteration is apt to destroy the equili-brium which subsists between them; the consequence is, combustion and the formation of a new compound. Hence these compounds burn with amazing facility, not only when heated, but when triturated, or struck smartly with a hammer. They have therefore received the name of detonating or fulminating bodies. Thus we have fulminating gold, fulminating mercury, fulminating powder. fulminating powder, &cc.

Such are the properties of the combustibles, the supporters, and the products; and such the phenomena which they exhibit when made to act upon each

other.

If we compare together the supporters and the products, we shall find that they resemble each other in many respects. Both of them contain oxygen, or other supporter, as an essential constituent part; both are capable of converting combustibles into products; and several of both combine with combustibles and with additional doses of oxygen. But they differ from each other in their effects on combustibles. The former only produce combustion; whereas the products convert combustibles into products without combustion. Now, as the ultimate change produced upon combustibles by both these sets of bodies is the same, and as the substance which combines with the combustibles is in both cases the same, oxygen, for instance, we is in both cases the same, oxygen, for instance, we must conclude that this oxygen in the supporters contains something which the oxygen of the products wants, something which separates during the passage of the oxygen from the product to the combustible, and occasions the combustion, or emission of fire, which accompanies this passage. The oxygen of supporters then contains some ingredient which the oxygen of products wants. Many circumstances concur to render it probable that this ingredient is caloric. The combustibles and the products also resemble each other. Both of them contain the same or a similar base, both frequently combine with company

each other. Both of them contain the same or a similar base; both frequently combine with combustibles, and likewise with oxygen; but they differ essentially in the phenomena which accompany their combination with oxygen. In the one case, fire is emitted; in the other, not. If we recollect that no substance but a combustible is capable of restoring combustibility to the base of a reduct and that the combustibility to the base of a product, and that at its combustibility to the base of a product, and that at its doing so it always loses its own combustibility; and if we recollect farther, that the base of a product does not exhibit the phenomena of combustion even when it combines with oxygen, we cannot avoid concluding, that all combustibles contain an ingredient which they lose when converted into products, and that this loss contributes to the fire which makes its appearance during the conversion. Many circumstances contriduring the conversion. Many circumstances contri-bute to render it probable that this ingredient is light.

bute to render it probable that this ingredient is light.

If we suppose that the oxygen of supporters contains caloric as an essential ingredient, and that light is a component part of all combustibles, the phenomena of combustion above enumerated, numerous and intricate as they are, admit of an easy and obvious explanation. The component parts of the oxygen of supporters are two; namely, I. a base, 2. caloric. The component parts of combustibles are likewise two; namely, I. a base, 2. light. During combustion, the base of the oxygen combines with the base of the combustible, and forms the product; while, at the same time, the caloric of the oxygen combines with the light of the combustible, and the compound flies off in the form of fire. Thus combustion is a double decomposition: the oxygen and combustible divide themselves sition: the oxygen and combustible divide themselves each into two portions, which combine in pairs; the one compound is the product, and the other the fire, which escapes.

Hence the reason that the oxygen of products is Hence the reason that the oxygen of products is unfit for combustion. It wants its caloric. Hence the reason that combustion does not take place when oxygen combines with products, or with the base of supporters. These bodies contain no light. The caloric of the oxygen of course is not separated, and no fire appears. And this oxygen still retaining its caloric, is capable of producing combustion whenever a body is presented which contains light, and whose base has an affinity for oxygen. Hence also the reason why a combustible alone can restore combustibility to the base of a product. In all such cases, a double decomposition takes place. The oxygen of the product combines with the base of the combustible, while the light of the combustible combines with the base of the product.

But the application of this theory to all the different phenomena described above, is so obvious, that it is needless to give any more examples. Let us rather inquire, with the author, into the evidences which can be brought forward in its support.

As caloric and light are always emitted during com-

As caloric and light are always emitted during combustion, it follows that they must have previously existed in the combustible, the supporter, or in both.

That the oxygen of the supporters contains either one or both of these substances, follows incontrovertibly from a fact already mentioned, namely, that the oxygen of products will not support combustion, while that of supporters will. Hence the oxygen of supporters must contain something which the oxygen of the products wants, and this something must be caloric, or light, or both.

That the oxygen of some of the supporters at least That the oxygen of some of the supporters at least contains caloric, as an ingredient, has been proved, in a atisfactory manner, by the experiments of Crawford, Lavoisier, and La Place. Thus the temperature of hot-blooded animals is maintained by the decomposition of air. Now, if the oxygen of one supporter contains caloric, the same ingredient must exist in the oxygen of every supporter, because all of them are obviously in the same state. Hence we conclude that the oxygen of every supporter contains caloric as an the oxygen of every supporter contains caloric as an essential ingredient.

The light emitted during combustion must either proceed from the combustible or the supporter. That it proceeds from the combustible, must appear pretty obvious, if we recollect that the colour of the light emitted during combustion varies, and that this varia-tion usually depends, not upon the supporter, but upon the combustible. Thus charcoal burns with a red flame, sulphur with a blue or violet, zinc with a green-

ish white, &c.

The formation of combustibles in plants, obviously requires the presence and agency of light. The leaves of plants emit oxygen gas, when exposed to the sun's rays, but never in the shade, or in the dark.

Besides vegetation, we are acquainted with two other methods of unburning products, or of converting them into products and combustibles, by exposing them, in certain circumstances, to the agency of fire, or of electricity. The oxides of gold, mercury, &c. when heated to redness, are decomposed, oxygen gas is emitted, and the pure metal remains behind. In this case, the necessary caloric and light must be furnished by the fire; a circumstance which explains why such reductions always require a red heat. When carbonic acid is made to pass repeatedly over red-hot charcoal, at combines with a portion of charcoal, and is converted into gaseous oxide of carbon. If this gas be a combustible oxide, the base of the carbonic acid and its oxygen must have been supplied with light and caloric from the fire; but if it be a partial combustible, it is merely a compound of carbonic acid and charcoal; which of the two it is, remains still to be ascertained. ascertained.

Electricity decomposes water, and converts it into oxygen gas and hydrogen gas; it must, therefore, sup-ply the heat and the light which these bodies lost when

converted into a product.

These facts, together with the exact correspondence of the theory given above with the phenomena of combustion, render it so probable, that Dr. Thompson has ventured to propose it as an additional step towards a full explanation of the theory of combustion. Every additional experiment has served to confirm it more and more. It even throws light upon the curious experiments of the accension of metals with sulphur, which succeed in vacuo, under mercury, in nitrogen

gas, &c.

Dr. Thompson has noticed, that the same emission of caloric and light, or of fire, takes place when melted sulphur is made to combine with potassa, or with lime, in a crucible or glass tube, and likewise when melted phosphorus is made to combine with lime heated to redness. He supposes that, in all probability, barytes and strontia exhibit the same phenomenon when combined with melted sulphur or phosphorus; and perhaps some of the metals when combined with phos-

The phenomena Dr. Thompson explains thus:—The sulphur and phosphorus are in the melted state, and Incretore contain caloric as an ingredient; the alka-lies, earths, and metals which produce the phenomenon in question, contain light as an essential ingredient. The sulphur, or phosphorus, combines with the base of the metal, earth, or alkali; while at the same time, the caloric, to which the sulphur or phosphorus owed its fluidity, combines with the light of the metal, earth, or alkali; and the compound flies off under the form therefore contain caloric as an ingredient; the alka-

or alkali; and the compound these same with combusof fire.
Thus the process is exactly the same with combustion, excepting as far as regards the product. The
melted sulphur, or phosphorus, acts the part of the
supporter, while the metal, earth, or alkali, occupies
the place of the combustible. The first furnishes caloric, the second light, while the base of each combines
together. Hence we see that the base of sulphurets
and phosphurets resembles the base of products in
being destitute of light; the formation of these bodies

exhibiting the separation of fire like combustion, but exhibiting the separation of fire like combustion, but the product differing from a product of combustion in-being destitute of oxygen, Dr. Thompson distinguishes the process by the title of semi-combustion; indicating by the term, that it possesses one half of the charac-teristic marks of combustion, but is destitute of the other half.

The only part of this theory which requires proof is, that light is a component part of the earths and alkalies. But as potassa and lime are the only bodies of that nature, which we are certain to be capable of exhibiting the phenomena of semi-combustion, the proofs must of necessity be confined to them. That lime contains light as a component part, has been long brown. Mover and Pelleting observed long ago, that known. Meyer and Pelletier observed long ago, that when water is poured upon lime, not only heat but light is emitted. Light is emitted also abundantly, when sulphuric acid is poured upon magnesia, or upon lime, potassa, or soda, freed from the water of crystallization. In all these cases, a sent-combustion takes place. The water and the acid being solidified, give out caloric, while the time or potassa gives out light.

That lime, during its burning, combines with light,

and that light is a component part of lime, is demonstrated by the following experiment, for which we are

indebted to Scheele.

indebted to Scheele.

Fluor spar (fluate of lime) has the property of phosphorescing strongly when heated, but the experiment does not succeed twice with the same specimen. After it has been once heated sufficiently, no subsequent heat will cause it to phosphoresce. Now phosphorescence is merely the emission of light; light of course is a component part of fluor spar, and heat has the property of separating it. But the phosphorescing quality of the spar may be again recovered to it, or, which is the same thing, the light which the spar had lost may be restored by the following process:

Decompose the fluate of lime by sulphuric acid, and

Decompose the fluate of lime by sulphuric acid, and preserve the fluoric acid separate. Boil the sulphate of lime thus formed, with a sufficient quantity of carbonate of soda; a double decomposition takes place; sulphate of soda remains in solution, and carbonate of lime precipitates. Ignite this precipitate in a crucible, till it is reduced to lime, and combine it with the fluoric acid to which it was formerly united. The fluor spar thus regenerated, phosphoresces as at first. Hence the lime, during its ignition, must have combined with

That potassa contains light, may be proved in the same manner as the existence of that body in lime. Now, as potassa is deprived of its carbonic acid by lime, the Doctor supposes that the process must be a double decomposition; namely, that the base of the lime combines with carbonic acid, while its light combines with the potassa.

These remarks on semi-combustion might easily be

much enlarged upon: for it is obvious, that whenever a liquid combines with a solid containing light, and

the product is a solid body, something analogous to semi-combustion-must take place.

COMEDO. (From comedo, a glutton.) The comedones of old writers are a sort of worm which eats into the skin and devours the flesh.

COMFREY. See Symphytum.
COMFREY. See Symphytum.
COMFSDL. The gum-arabic.
COMFSTE. The epilepsy. This name arose from the frequency of persons being seized with this disorder, while in the assemblies called Comitia.

COMITI'SSA. A countess. Some preparations are distinguished by this name; as Pulvis Comitissa de Cantia, the Countess of Kent's powder. Also the Cinchona was called Pulvis Comitissa.

COMMAGE NUM. (From Commagene, a place in Syria, whence it was brought.) Syrian ointment, mentioned

COMMANDUCA TIO. (From commanduco, to eat.)

The act of mastication, or chewing.

Comma'nsum. (From commando, to eat.) ticatory. A medicine put into the mouth and chewed,

to promote a discharge of phlegm, or saliva.

Commendato'Rius. (From commendo, to recommend.) An epithet of the traumatic balsam, tinetura Benzoes composita, from its singular virtues and use-

Co'MMI. Gum. When alone it signifies gumarabic. The κομμι λευκον, mentioned by Hippocrates in his De Morb. Mulieb., is gum-arabic.

COMMISSURA. (From committe, to join together.) A suture, juncture, or joint. A term applied in anatomy to the corners of the lips, where they meet together; and also to certain parts of the brain which go across and join one hemisphere to the other.

COMMISSURA ANTERIOR CEREBRI. The white nerve-like whether we which crosses the anterior part of the

like substance which crosses the anterior part of the third ventricle of the brain, immediately above the infundibulum, and between the anterior crura of the formx; uniting one hemisphere of the brain with the

COMMISSURA MAGNA CEREBRI. The corpus callo-sum of the brain is so termed by some writers.

COMMISSURA POSTERIOR CEREBRI. A white nerve-like substance, which passes from one hemisphere of the brain across to the other, immediately over the opening of the aqueduct of Sylvius, in the posterior part of the third ventricle of the brain, and above the corpora quadrigemina.

COMMU'NICANT. (From communico, to make partake.) A term applied by Bellini, to fevers of two kinds afflicting the same person, wherein as one goes off the other immediately succeeds.

Compa'Ges. (From compingo, to put together.) A suture, or joint. A commissure.

COMPA'RATIVE. That which illustrates by comparing with the human badge, applied to anatomy and

paring with the human body: applied to anatomy and

paring with the human body, appared to analomy and physiology. See Anatomy.

COMPERA. See Piper Cubeba.

Complete Flower. See Flos.

Complete Flower. See Flos.

Complete Flower in various acceptations; but latterly it signifies only the same as Plethora.

COMPLETING. From complete to comprise a

COMPLE'XUS. (From complector, to comprise.)
Complexus seu-biventer cervicis of Albinus. Dorso
trackelon occipital of Dumas. A muscle situated on
the back part of the neck, that draws the head backwards, and to one side: and when both act, they draw the head directly backward. It arises from the transverse processes of the seven superior vertebræ of the back, and four inferior of the neck, by as many distinct tendinous origins; in its ascent, it receives a fleshy slip from the spinous process of the first vertebra of the back; from these different origins it runs upwards, and is every where intermixed with tendinous fibres. It is inserted, tendinous and fleshy, into the inferior edge of the protuberance in the middle of the os occipitis, and into a part of the curved line that runs forwards from that protuberance. It draws the head backwards.

Complexus minor. See Trachelo-mastoideus.
COMPOSITUS. Compound. The result or effect
of a composition of different things; or that which
arises from them. It stands opposed to simple. In
botany, applied to leaves and flowers. See Flos, and

COMPOUND. See Compositus.

Compound affinity. See Compositus.

Compound affinity. See Attraction.

COMPRE'SSION. (Compressio; from comprimo, to press together.) A diseased state of the body, or of a part, the effect of something pressing upon it. The term is generally applied to the brain. Compression of the brain should be distinguished from concussion and inflammation. When the brain is compressed either by bone, extravasated blood, or any other fluid, there is a general insensibility, the eyes are half oven either by bone, extravasated blood, or any other fluid, there is a general insensibility, the eyes are half open, the pupils dilated and motionless, even when a candle is brought near the eye; the retina is insensible; the limbs relaxed; the breathing stertorous; the pulse slow, and, according to Abernethy, less subject to intermission than in cases of concussion. Nor is the patient ever sick, when the pressure on the brain, and the general insensibility, are considerable; for the very action of vomiting betrays an irritability in the stomach and opsophagus.

very action of vomiting betrays an irritability in the stomach and esophagus.

COMPRE'SSOR. (Compressor; from comprimo, to press together.) A name applied to those muscles which press together the parts on which they act.

Compressor naris. Ringus vel nasalis of Douglas. Transversalis vel myrtiformis of Winslow. Dilatores alarum nasi of Cowper; and Maxillo narinal of Dumas. A muscle of the nose, that compresses the aim towards the septum nasi, particularly when we want to smell acutely. It also corrugates the nose, and want to smell acutely. It also corrugates the nose, and assists in expressing certain passions. It arises, by a narrow beginning, from the root of the ala nasi exter-nally, and spreads into a number of thin, separate

fibres, which run up along the cartilage in an oblique manner towards the back of the nose, where it joins with its fellow, and is inserted into the narrow extremity of the os nasi, and nasal process of the superior maxillary bone.

Compressed; flattened laterally;

applied to leaves. See Leaf.

COMPTONITE. A new mineral first brought into this country by Lord Compton, and found in drusy cavities, in ejected masses, on Mount Vesuvius.

COMPU'NCTIO. (From compungo, to prick.) A punc-

CONA'RIUM. (From κωνος: so named from its conical shape.) A cone. See Pineal gland. Concau'sa. (From con, with, and causa, a cause.)

A cause which co-operates with another in the pro-

A cause which co-operates with another in the production of a disease.

CONCAVUS. Hollow; depressed in the middle. Applied to leaves, petals, &c. depressed in their centre, owing, as it were, to a tightness in some part of the circumference; as in Cyamus nelumbo, and the petals of the Galanthus nivalus.

CONCENTRATION

CONCENTRATION. (Concentratio; from con, and centrum, a centre.) The volatilizing of part of and centrum, a centre.) the water of fluids, in order to improve their strength. The matter to be concentrated, therefore, must be of superior fixity to water. This operation is performed on some acids, particularly the sulphuric and phosphoric. It is also employed in solutions of alkalics and neutral salts.

CONCENTRIO. Bulbus concentricus. tric bulb, is one of the laminated kind, well illustrated

in the common onion, Allium cepa.

CONCEPTACULUM. A former name for what is now called in botany receptaculum.

CONCE PTION. (Conceptio; from concipio, to conceive.) The impregnation of the ovulum in the female ovarium, by the subtile prolific aura of the semen virile. In order to have a fruitful coition, it is necessary that the semen be propelled into the uterus, or vagina, so that its fecundating vapour shall be conveyed through the Fallopian tube to the ovarium: it is also necessary that there be a certain state of the ovaalso necessary that there be a certain state of the ovarium of the female in order to impregnate it; which is, that the ovum shall be mature, and embraced by the fimbrize of the Fallopian tube, to convey that vivifying principle to the ovum. See Generation.

CONCHA. (Concha, κογχη, a liquid measure among the Athenians.) A term applied by anatomists to several parts of the body; as the hollow of the ear, the spongy bones of the nose, &c.

CONCHA AURICULE. See Auricula.

CONCHA AURICULE. The hollow part of the cartilage of the outer ear.

the outer ear ...

CONCHA MARGARITIFERA. The shell from which

pearls are obtained. See Margarita.

Conche narium. The turbinated portion of the ethmoid bone, and the inferior spongy bones of the nose, which are covered by the Schneiderian mem-

brane, are so termed. CO'NCHUS. (From κογχη, a shell; so named from their likeness to a shell.). The cranium, and the cavity

[CONCHOLITE. See Organic relics.]
CONCIDENS. (From concide, to decay.) 1. A decrease of bulk in the whole or any part of the body.

A diminution of a tumour.

Concoagula'Tio. (From con, and coagulo, to coagulate together.) The coagulation or crystallization of different salts, first dissolved together in the same

CONCO'CTIO. (From concoquo, to digest.) 1. Concoction; digestion. This term was formerly very generally used to express that operation of nature upon morbid matter which renders it fit to be separated from the healthy fluid.

2. The alteration which the food undergoes in the

primæ viæ.

CONCREMA'TIO. (From con, and creme, to burn to-

gether.) Calcination. CONCRETION. (Concretio; from concresco, to

grow together.)

1. The condensation of any fluid substance into a more solid consistence.

2. The growing together of parts which, in a natu-

ral state, are separate.

CONCU'RSUS. (From concurro, to meet together.)
The congeries or collection of symptoms which constitute and distinguish the particular disease.
CONCU'SSION. (From concutto, to shake together.) Concussion of the brain. Various alarming symptoms, followed sometimes by the most fatal consequences, are found to attend great violence offered to the head; and upon the strictest examination, both of the living and the dead, neither fissure, fracture, of the living and the dead, neither fissure, fracture, nor extravasation of any kind can be discovered. The same symptoms and the same events are met with, when the head has received no injury at all ab externo, when the head has received no injury at all ab externo, but has only been violently shaken; nay, when only the body, or general frame, has seemed to have sustained the violence. The symptoms attending a concussion, are generally in proportion to the degree of violence which the brain itself has sustained, and which, indeed, is cognizable only by the symptoms. If the concussion be very great, all sense and power of motion are immediately abolished, and death follows soon; but between this degree and that dish teaching. soon; but between this degree and that slight confusion (or stunning, as it is called,) which attends most violences done to the head, there are many shades. The following is Abernethy's description of the symptoms of concussion, which he is of opinion, may be divided

into three stages

The first is that state of insensibility and derangement of the bodily powers which immediately suc-ceeds the accident. While it lasts, the patient scarcely feels any injury that may be inflicted on him. His breathing is difficult, but in general without stertor; breathing is difficult, but in general without sterior; his pulse intermitting, and his extremities cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which is considered as the second stage of concussion. In this, the pulse and respiration become better, and, though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The feeling of the patient is now so far restored, that he is sensible of his skip being pinched; but he lies stupid sensible of his skin being pinched; but he lies stupid and inattentive to slight external impressions. As the and mattentive to sight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to his chief suffering at the time, as pain in the head, &c.; otherwise he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate, but as the former abates, the latter colors. moderate; but as the former abates, the latter seldom fails to increase; and this constitutes the third stage, which is the most important of the series of effects proceeding from a concussion.

These several stages vary considerably in their de-gree and duration; but more or less of each will be found to take place in every instance where the brain has been violently shaken. Whether they bear any certain proportion to each other or not, is not known; indeed, this will depend upon such a variety of circumstances in the constitution, the injury, and the after treatment, that it must be difficult to determine.

To distinguish between an extravasation and a con-To distinguish between an extravasation and a concussion by the symptoms only, Mr. Potts says, is frequently a very difficult matter; sometimes an impossible one. The similarity of the effects, in some cases, and the very small space of time which may intervene between the going off of the one and accession of the other, render this a very nice exercise of the judgment. The first stunning or deprivation of sense, whether total or partial, may be from either, and no man can tell from which; but when these first symptoms have tell from which; but when these first symptoms have been removed, or have spontaneously disappeared, if such patient is again oppressed with drowsiness, or stupidity, or total or partial loss of sense, it then be-comes probable that the first complaints were from concussion, and that the latter are from extravasation; and the greater the distance of time between the two, the greater is the probability not only that an extravasation is the cause, but that the extravasation is of the limpid kind, made gradatim, and within the

Whoever seriously reflects on the nature of these two causes of evil within the cranium, and considers them as liable to frequent combination in the same them as hable to frequent combinator in the same subject, and at the same time considers that, in many instances, no degree of information can be obtained from the only person capable of giving it, (the patient) will immediately be sensible how very difficult a part

CON CON

a practitioner has to act in many of these cases, and how very unjust it must be to call that ignorance which is only a just diffidence arising from the obscurity of the subject, and the impossibility of attaining materials to form a clear judgment.

Abernethy observes, that in cases of simple concussion, the insensibility is not so great, as where compression exists, the pupils are more contracted, the muscles less relaxed, little or no stertor attends, but the pulse is very intermitting, and in slight cases there is often considerable sickness.

Very different modes of treating these accidents.

Very different modes of treating these accidents.

the pulse is very intermitting, and in slight cases there is often considerable sickness.

Very different modes of treating these accidents have been practised, and no doubt the same means should not be pursued indiscriminately. Much must depend on the state of the patient, when he received the injury, the degree of this, the time which has elapsed since, and other circumstances. Abernethy considers, that in the first stage little should be done; that the stimulants often employed may be even injurious; but more especially so in the second stage, increasing the tendency to inflammation; and where this has come on, that the antiphlogistic plan must be actively pursued. However, a moderate abstraction of blood, general or topical, will be commonly proper at first, where the habit will allow it, as congestion may be suspected, and to obviate inflammation, especially where the person was intoxicated at the time of the accident; and the effect of this measure may influence the subsequent treatment. If the pulse rose after it, and the patient became more sensible, we should be led to pursue the evacuating plan, taking perhaps ence the subsequent tréatment. If the pulse rose after it, and the patient became more sensible, we should be led to pursue the evacuating plan, taking perhaps more blood, exhibiting active catharfies, as the bowels will be found very torpid, applying cold lotions to the head, &c. These means, however, will be especially called for, when marks of inflammation appear. Sometimes brisk emeties have been very beneficial, as sulphate of zinc, &c.: they are particularly recommended, where the person was under the influence of anger; or the stomach full, when the accident happened; but they are liable to objection, where there are marks of congestion, or increased action in the vessels of the head. If bleeding should lower the pulse, and render the patient worse, evacuations must not be pursued; it may be better generally to wait the gradual return of sensibility, unless the torpor be alarming, like a state of syncope: in which case, or if it continue very long, stimulants appear justified, as ammonia, or others of transient operation, with a blister to the head, to restore some degree of sensibility. If, in the sequel, marks of irritation appear, as spasms or convulsions, opium joined with antimony, or in the form of Dover's powder, will probably be useful, the necessary evacuations being premised, and the warm bath. In all cases the head should be kept quiet; as the patient is convalescent, tonics, and the shower-bath may be employed with advantage; and it will bath. In all cases the head should be kept quiet; as the patient is convalescent, tonics, and the shower-bath may be employed with advantage; and it will be particularly necessary to avoid great bodily exertion, stimulating liquors, &c. Should paralytic symptoms remain, stimulants, general or local, may be required. Where alarming symptoms follow an injury to the head, extravasation may be suspected: and the operation of trepanning, skilfully performed, will do no harm to the patient, but may materially relieve, even by the loss of blood attending.

CONDENSA'TION. (Condensatio; from condenso, to make thick.) A thickening of any fluid.

CONDIME'NTUM. (From condio, to preserve, or sweetmeat.

CONDUCTIO. (From conduco, to draw along.) In Colius Aurelianus, it is a spasm, or convulsion, draw-

Cœlius Aurelianus, it is a spasm, or convulsion, drawing the muscles out of their proper positions.

CONDU'CTOR. (From conduce, to lead, or guide.)

A surgical instrument, the use of which is to direct the

knife in certain operations. It is more commonly called a director.

called a director.

CONDUPLICATUS. Folded. Applied to leaves, when the margins are clapped flatly together; as in Roscoza purpurea, and the bases of sword-shaped leaves. See Leaf.

CO'NDYLE. (Condylus; from κονόν, an ancient cup, shaped like a joint.) A round eminence of a bone in any of the joints.

CONDYLO'MA. (Condyloma, atis. n.; from κονόνλος, a tubercle, or knot.) A soft, wart-like excrescence, that appears about the anus and pudendum of both sexes. There are several species of condylomata, which have received names from their appearances.

CONE. See Scrottas.

CONETON. (From Kweap, to turn round.) In Hippocrates it imports hemlock. It is said to be thus named, because it produces a vertigo in those who take it inwardly. See Conium.

CONE'SSI CORTEX. See Nerium antidysenteri-

ficio, to make up.) means any thing made up with sugar. The term, in the new London Pharmacopæia, includes those articles which were formerly called electuaries and con-serves, between which there do not appear to be suffi-

cient grounds to make a distinction.

["Confections are soft solids, in the composition of which sugar forms a principal article. The term includes what have been called conserves, made from recent vegetable substances, beaten with sugar as a preservative; and electuaries, which were formed of dry powders, &c. brought to a proper consistence

dry powdets, &c. brought to a proper consistence with syrup, either to facilitate their deglutition, or to conceal their taste."—Big. Mat. Med.

The Pharmacopeaia of the United States has the following:—Confectio aromatica, Confectio aurantii corticis, Confectio cassia, Confectio rosa, Confectio scammonia, Confectio scama. A.]

Confectio anygodalarum. Confection of almonds. Take of sweet almonds an ounce: Accels gum now

Take of sweet almonds, an ounce; Acacia gum powdered, a drachm; refined sugar, half an ounce. The almonds having been previously macerated in water and their external coat removed, beat the whole to gether, until they are thoroughly incorporated. It has been objected to the almond mixture, which is an article of very general use, that it requires considerable time for its extemporaneous preparation, and that it spoils, and cannot be kept when it is made. This will be obviated by the present form, which does keep for a sufficient length of time, and rubs down into the mixture immediately.

Confectio aromatica. This preparation was formerly called Confectio cardiaca. Confectio Rabeighana. Take of cinnamon bark, nutmegs, of each two ounces; cloves, an ounce; cardamom seeds, half an ounces; cloves, an ounce; cardamom seeds, half an ounce; saffron dried, two ounces; prepared shells, sixteen ounces; refined sugar powdered, two pounds; water, a pint. Reduce the dry substances, mixed together, to very fine powder; then add the water gradually, and mix the whole, until it is incorporated. This preparation is now much simplified by the London college. It is an excellent medicine, possessing stimulant, antispassmodic, and adstringent virtues and stimulant, antispasmodic, and adstringent virtues and is exhibited with these views to children and adults, in a vast variety of diseases, mixed with other medi-cines. It may be given in doses of 10 gr. to a drachm.

drachm.

Conserva corticis exterioris aurantii hispaleasis. Conserva flavedinus corticum aurantiorum. Take of fresh external rind of oranges, separated by rasping, a pound; refined sugar, three pounds. Bruise the rind with a wooden pestle, in a stone mortar; then, after adding the sugar, bruise it again, until the whole is thoroughly incorporated. This is well calculated to form the basis of a tonic and stomachic confection, and may be given alone in doses of from two to five drachms, twice or three times a day. times a day.

CONFECTIO CARDIACA. See Confectio aromatica. Confectio cassiz. Electuarium cassia. Electuarium e cassia. Confection of cassia. Take of fresh

arium e cassia. Confection of cassia. Take of fresh cassia pulp, half a pound; manna, two ounces; tamarind pulp, an ounce; syrup of roses, half a pint. Bruise the manna; melt it in the syrup by a waterbath; then mix in the pulps, and evaporate down to a proper consistence. This is a very elegant, pleasant, and mild aperient for the feeble, and for children. Dose from two drachms to an ounce.

Convectio oru. Confectio opiata. Philonium Londinense. Philonium Romanum. Confection of opium. Take of hard opium powdered, six drachms; long pepper, an ounce; ginger root, two ounces; caraway-seeds, three ounces; syrup, a pint. Rub together the opium and the syrup previously heated; then add the remaining articles reduced to powder, and mix. To the credit of modern pharmacy, this is the only one that remains of all those complicated and confused

preparations called mithridate, theriaca, &c.; it more nearly approximates, in its composition, the philonium than any other, and may be considered as an effectual substitute for them in practice. This very warm and stimulating confection is admirably calculated to relieve diarrhæa, or spasms of the stomach and bowels, and is frequently ordered in doses of from 10 grs. to half a drachm. About 36 grains contain one of opium.

CONFECTIO FIFERIS NIGRI. Confection of black pepper. Take of black pepper; elecampane, of each a pound; fennel seeds, three pounds; honey; refined sugar, of each two pounds. Rub the dry ingredients together, so as to reduce them to a very fine powder; then, having added the honey, rub them again so that then, having added the honey, rub them again, so that the whole may incorporate. This confection is given the whole may incorporate. internally against a relaxed condition of the extremity of the rectum, producing partial prolapse, and against that piley state which results from weakness. A similar compound has been long celebrated and sold under the name of Ward's paste.

Conserva fructus cynosbati. Conserva cynosbati.

Conserva fructus cynosbati. Conserve of hips. Confection of dog-rose. Take of dog-rose pulp, a pound; refined sugar powdered, twenty ounces. Expose the pulp in a water bath to a gentle heat; then add the sugar gradually, and rub them together until they are thoroughly incorporated. This representation is continuous. thoroughly incorporated. This preparation is cooling and adstringent; it is seldom given alone, but mostly joined to some other medicine, in the form of linctus,

CONFECTIO ROSE GALLICE. Conserva rose. Conserva roseum rubrarum. Conserva roseum rubrarum. Conserva for rose. Take of the petals of the red rose, before it is expanded, and without the claws, a pound; refined sugar, three pounds. Bruise the petals in a stone mortar; then, having added the sugar, beat them again together, until they are thoroughly incorporated. This is an excellent sub-astringent composition. Rubbed down with water, it forms an excellent drink, with some lemon juice, in hamorrhagic complaints: it may also be in hæmorrhagic complaints; it may also be given with vitriolated zinc, in the form of an electuary.

CONFECTIO RUT & Electuarium e baccis lauri. Confection of rue. Take of rue leaves dried, caraway seeds, bay-berries, of each an ounce and a half; sagapenum, half an ounce; black pepper, two drachms; clarified honey, sixteen ounces. Rub the dry articles together, into a very fine powder; then add the honey, and mix the whole. Its use is confined to clysters.

Confectio scammonex. Electuarium scammonii. Electuarium e scammonio. Electuarium caryocostinum. Confection of scammony. Take of scammony gum resin powdered, an ounce and a half; cloves gum resin powdered, an ounce and a half; cloves bruised, ginger root powdered, of each, six drachms; oil of caraway, half a drachm; syrup of roses, as much as is sufficient. Rub the dry articles together, into very fine powder; next rub them again while the syrup is gradually added; then add the oil of caraway, and mix the whole well together. This is a strong stimulating cathartic, and calculated to remove worms from the primæ viæ, with which view it is mostly exhibited. Dose from 3 ss. to 3 j.

Confectio sennæ. Electuarium sennæ. Electu-

CONFECTIO SENNE. Electuarium sennæ. Electuarium lenitivum. Confection of senna. Take of senna leaves, eight ounces; figs, a pound; tamarind pulp, pulp of prunes, cassia pulp, of each half a pound; coriander seeds, four ounces; liquorice root, three ounces; refined sugar, two pounds and a half. Powder the senna leaves with the coriander seeds, and separate, by sifting ten ounces of the mixed powder. Boil the remainder with the figs and the liquorice-root, in four pints of water, until it be reduced to half; then press out and strain the liquor. Evaporate the liquor, press out and strain the fiquor. Evaporate the liquor, until a pint and a half only remains of the whole; then add the sugar, to make syrup. Lastly, mix the pulps gradually with the syrup, and, having added the sifted powder, mix the whole together. This is a mild and elegant aperient, well adapted for pregnant women, and those whose bowels are easily moved.

CONFERTUS. Clustered, or crowded together:

CONFERTUS. Clustered, of crowded together.
applied to leaves. See Leaf.
CONFERVA. (From conferveo, to knit together.)
1. The name of a genus of plants in the Linnwan system. Class, Cryptogamia; Order, Alga.
2. A kind of moss: named from its use formerly in healing broken bases.

healing broken bones.

CONFERVA HELMINTHOCORTOS. See Corallina cor

CONFERVA RIVALIS. This plant, Conferva; filamentis simplicissimus aqualibus longissimus, of Linnaus, has been recommended in cases of spasmodic asthma, phthisis, &c. on account of the great quantity of vital air it contains.

CONFIRMA'NTIA. CONFIRMA'NTIA. (From con, and firmo, to strengthen.) 1. Restoratives.

2. Medicines which fasten the teeth in their sockets.

CONFLUENT. Running together. Applied to eruptions. See Variola.

CONFLU'XION. Much used by Hippocrates, and his interpreter Galen, from a notion that parts at a distance have mutual consent with one another, and that they are all perspirable by many subtle streams. Paracelsus, according to his way, expressed the former

by confederation.

CONFORMA'TIO. (From conformo, to shape or fashion.) Conformation. The natural shape and form of any part.

CONFORTA'NTIA. (From conforto, to strengthen. Cordial and strengthening medicines.

Confortati'va. The same.

Confusion, or disorder in the eyes, proceeding from a rupture of the membranes, which include the human by which means they are all confounded to mours, by which means they are all confounded to-

CONGELA'T1. (From congelo, to freeze.) Congela-tici. Persons afflicted with a catalepsy are so called,

by which all sensation seems to be taken away.

CONGELA'TION. (Congelatio; from congelo, to
freeze.) That change of liquid bodies which takes
place when they pass to a solid state, by losing the
caloric which kept them in a state of fluidity.

CONGELATI'VA. (From congelo, to congeal.) Medicines that inspissate humours, and stop fluxions and

CONGENER. (From con, and genus, kind.) Of the same kind; concurring in the same action. It is

usually said of the muscles.

CONGE'STION. (From congero, to amass.) A collection of blood or other fluid; thus we say a congestion of blood in the vessels, when they are over dis-

gestion of blood in the vessers, when they are over distended, and the motion is slow.

CONGLOBATE. Conglobatus; from conglobo, to gather into a ball.) 1. A term applied to a gland, Glandula conglobata, which is formed of a contortion of lymphatic vessels, connected together by cellular structure, having neither a cavity nor any excretory destricts and the measurements. duct: such are the mesenteric, inguinal, axillary glands, &c. See Gland.

glands, &c. See Gland.

2. A conglobate flower, is a compound one growing in the form of a sphere or globe.

CONGLOMERATE. (Conglomeratus; from conglomero, to heap upon one.) 1. Applied to a gland, Glandala conglomerata, which consists of a number of smaller glomerate glands, the excretory ducts of which all unite into one common duct: such are the salival, parotid glands, &c.

2. Conglomerate flowers, are such as are heaped to-

gether on a footstalk, to which they are irregularly, but closely connected. See Panicula.

CONGLOMERITE. A compound mineral mass, in which angular fragments of rocks are imbedded. The Italian term breechia, has the same meaning. In pudding stone, the imbedded fragments are round, bearing the marks of having been polished by attrition.

CONGLUTINA'NTIA. (From conglutino, to glue

together.) Healing medicines; and such as unite parts

disjoined by accident. CONICUS. Conical. Applied to leaves, nectaries, receptacles, &c.—Nectarium conicum, in the Utrica-

laria foliosa, and the receptacle of the daisy, Anthemis arcensis, cotula, and Matricaria chamomilla.

CONIFERÆ. Cone-bearing plants. The name of an order in Linnæus's Fragments of a Natural Me-

CO'NIS. Koyış. Dust; fine powder; ashes; a nit in the hair; scurf from the head; and sometimes it

signifies lime.

CONITE. 1. An ash or greenish-gray coloured mineral, which becomes brown on exposure to air. It is

found in Saxony and Iceland.
2. Dr. Maccullock has given this name to a pulverulent mineral, as fusible as glass into a transparent bead,

which he found in the trap hills of Kilpatrick, and the

[3. The petrifaction of a conus. See Organic re-

CONTUM. (From κονια, dust, according to Linnaus; or from κωναω, circumago, on account of its inebriating and poisonous quality.) Hemlock.

The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Digyaia.
 The pharmacopeial name of the officinal hem-

lock. See Conium maculatum.

CONIUM MACULATUM. The systematic name for the cicuta of the pharmacopæias. It is called by some camaran; by others abiotos; and, according to Erotian, cambeion is an old Sicilian word for cicuta. Cicuta major fatida. Conium—seminibus striatis, of

Hemlock is found in every part of England, and is distinguished from those plants which bear some resemblance to it, by the spotted stem. It is generally believed to be a very active poison. In a very moderate dose it is apt to occasion sickness and vertigo; in a rate dose it is apt to occasion sickness and vertigo; in a larger quantity it produces anxiety, cardialgia, vomiting, convulsions, coma, and death. Baron Stoerk was the first who brought hemlock into repute as a medicine of extraordinary efficacy: and although we have not in this country any direct facts, like those mentioned by Stoerk, proving that inveterate scirrhuses, cancers, ulcers, and many other diseases hitherto deemed irremediable, are to be completely cured by the cicuta; we have however the testimonies of several eminent physicians, showing that some complaints which had resisted other powerful remedies, yielded to hemlock; and that even some disorders, which if not really cancerous, were at least suspected to be of that really cancerous, were at least suspected to be of that tendency, were greatly benefited by this remedy. In chronic rheumatisms, some glandular swellings, and in various fixed and periodical pains, the cicuta is now very generally employed; and from daily experience, it appears in such cases to be a very efficacious remedy. It has also been of singular use in the hooping-cough. Nor is it less efficacious when applied externally; a poultice made of oatmeal and the expressed juice, (or a decoction of the extract, when the other cannot be obtained,) allays the most excruciating torturing pains

obtained,) allays the most excruciating torturing pains of a cancer, and thus gives rest to the distracted patient. The proper method of administering conium internally, is to begin with a few grains of the powder or inspissated juice, and gradually to increase the dose until a giddiness affects the head, a motion is felt in the eyes as if pressed outwards, with a slight sickness and trembling agitation of the body. One or more of these symptoms are the evidence of a full dose, which should be continued until they have ceased, and then after a few days the dose may be increased; for little advantage can be expected but by a continuance of the greatest quantity the patient can bear. In some contage can be expected but by a continuance of the greatest quantity the patient can bear. In some constitutions even small doses greatly offend, occasioning spasms, heat and thirst; in such instances it will be of no service. As the powder of the dried leaves has been thought to act, and may be depended upon with more certainty than the extract, the following direction about the observed in the preparation. Cather the should be observed in the preparation:—Gather the plant about the end of June, when it is in flower; pick off the little leaves, and throw away the leaf-stalks: dry the small selected leaves in a hot sun, or in a tin or pewter dish before the fire. Preserve them in bags made of strong brown paper, or powder them and keep the powder in glass phials where the light is excluded; for light dissipates the beautiful green colour very soon, and thus the medicine loses its appear lour very soon, and thus the medicine loses its appearance, if not its efficacy: this mode is recommended by Dr. Withering. The extract should also be made of the plant gathered at this period. From 2 to 20 grains of the powder may be taken twice or thrice a day.

CONJUGATUS. Conjugate or yoked: applied to leaves, which are said to be conjugate or binate. They consist of one pair of leaflets; as in the Mimosa.

CONJUNCTIVA. Membrana conjunctiva. The conjunctive membrane of the eye; a thin, transparent, delicate membrane, that lines the internal superficies of one eyelid, and is reflected from thence over the anterior part of the bulb, then reflected again to

the anterior part of the bulb, then reflected again to the edge of the other eyelid. That portion which covers the transparent cornea cannot, without much difficulty, be separated from it. Inflammation of this membrane is called ophthalmia. CONJUNCTUS. Conjoined. A botanical term applied to a tuber which is said to be conjoined when in immediate contact with another, as in many of the

CONNA'TUS. (From con, and nascor, to grow together.) 1. Born with a person; the same with con-

genitus.

2. In botany it is applied to leaves, which are said to be connate when united at their base; as in Chlora

to be connate when perfoliata.

CONNEXION. See Articulation.

CONNIVENS. (From conniveo, to make as if he did not see.) In botany applied to petals of flowers, as in those of the Rumer, and to the receptacle of the fig, which the fruit really is, being a fleshy connivent receptacle, enclosing and hiding the florets.

CONNUTRI'TUS. (From con, and nutrior, to be nourished with.) It is what becomes habitual to a his particular nourishment, or what

person from his particular nourishment, or what breaks out into a disease in process of time, which gradually had its foundation in the first aliments, as

from sucking a distempered nurse, or the like.

Conquassa'Tio. Conquassation. In pharmacy it is a species of comminution, or an operation by which moist concrete substances, as recent vegetables, fruits, the softer parts of animals, &c. are agitated and bruised, till, partly by their proper succulence, or by the affusion of some liquor, they are reduced to a soft

the affusion of some liquor, they are reduced to a soft pulp.

CONRI'NGIUS, Herman, was born at Norden, in East Friesland, 1606, and graduated in medicine at Helmstat, where he soon after became professor in that science, and subsequently in physics, law, and politics. He was also made physician and aulic counsellor to the Queen of Sweden, the King of Denmark, and several of the German princes. He wrote numerous works in philosophy, medicine, and history, displaying great learning, and long highly esteemed. In one treatise he refers the degeneracy of the modern Germans to their altered mode of living, the use of stoves, tobacco, &c. He published also an "Introduction to the whole Art of Medicine, and its several Parts," containing a History of Bibliotheca Medica, with numerous Dissertations on particular Diseases. He died in 1681. He died in 1681.

CONSENT. Consent of parts. See Sympathy.

CONSERVA. (From conservo, to keep.) A conserve. A composition of some recent vegetable and sugar, beat together into a uniform mass of the consistence of honey; as conserve of hips, orange peel, &c. Conserves are called confections in the last edited. tion of the London Pharmacopæia. See Confectio.

Conserva absinthi Maritimi. See Artemisia

maritima.

Conserva art. This is occasionally exhibited as a stimulant and diuretic. See Arum maculatum

CONSERVA AURANTII HISPALENSIS. See Confectio aurantiorum.

Conserva Cynosbati. See Confectio rosa canina.
Conserva Lujula. A preparation of woodsorrel,
possessing acid, cooling, and antiseptic qualities. See
Ozalis acetosella.

Conserva Menthe. This preparation of mint is given occasionally as a stomachic, in sickness and weakness of the stomach. See Mentha viridis.

Conserva Pruni sylvestris. Astringent virtues are ascribed to this medicine, which is now seldom used but in private formulæ.

Conserva Ros z. This conserve, rubbed down with water, to which is added some lemon-juice, forms an excellent drink in hamorrhagic complaints. See Confectio rosæ gallicæ.

Conserva scille. A preparation of squills, which affords an excellent basis for an electuary, possessing expectorant and diuretic qualities.

[Conservatives. See Organic relics. A.]

Consiste 'Atla. (From consisto, to abide.) The state or acme of a disease. The appearance or state

of the humours and excrements.

CONSO'LIDA. (So called, quia consolidandi et conglutinandi vi pollet; from its power in agglutinating and joining together things broken.) See Sym-

PAYTUM.

CONSOLIDA AUREA. See Solidago virga aurea.

CONSOLIDA MAJOR. See Symphytum.

CONSOLIDA MEDIA. See Ajuga pyramidalie

CONSOLIDA MINOR. See Prunclla.

CONSOLIDA REGALIS. See Delphinium consolida.

CONSOLIDA SARACENICA. See Solidago virga aurea.
CONSOUND. See Symphytum.
Consound middle. See Jjuga pyramidalis.
CONSTANTINUS, Africanus, was born at Carthage, towards the middle of the 11th century. He lived near forty years at Babylon, and was celebrated for his knowledge of the Eastern languages. Among the sciences, medicine appears to have principally occupied his attention; and two of his works were thought deserving of being printed at Bâle, about 4 1-2 centuries after his death, which occurred in 1087. They are thought however to have been chiefly translated from Arabian writers. CONSTIPATION.

CONSTIPATION. (Constipatio: from constipo, to crowd together.) Obstipatio. Costiveness. A person is said to be costive when the alvine excrements are not expelled daily, and when the faces are so hardened as not to receive their form from the im-

pression of the rectum upon them.

CONSTITUTION. Constitutio. The general condition of the body, as evinced by the peculiarities in the performance of its functions: such are, the pecu-liar predisposition to certain diseases, or liability of particular organs to disease; the varieties in digestion, in muscular power and motion, in sleep, in the appetite, &c. Some marked peculiarities of constitution are observed to be accompanied with certain external characters, such as a particular colour and texture of the skin, and of the hair, and also with a peculiarity of form and disposition of mind; all of which have been observed from the earliest time, and divided into classes: and which received names during the prevalence of the humeral pathology which they still retain. See Temperament.

CONSTRICTI'VA. (From constringo, to bind toge-

CONSTRICTOR. (From constrings, to bind toge-ther.) A name given to those muscles which contract any opening of the body.

Constructor ale nasi. See Depressor labit su-

perioris alæque nasi.

CONSTRICTOR ANI. See Sphincter ani.

CONSTRICTOR ISTHMI FAUCIUM. Glosso-staphilinus. of Winslow, Douglas, and Cowper; and Glosso sta-philin of Dumas. A muscle situated at the side of the entry of the fauces, that draws the velum pendu-lum palati towards the root of the tongue, which it raises at the same time, and with its fellow contracts the passage between the two arches, by which it shuts the opening of the fauces.

CONSTRICTOR LABIORUM. See Orbicularis oris.

CONSTRICTOR ORIS. See Orbicularis ori

CONSTRICTOR PALPEBRARUM. See Orbicularis pal-

CONSTRICTORES PHARYNG.EI. The muscles of the

œsophagus.

Constrictor pharyngis inferior. Crico pharyngeus; Thyro-pharyngeus of Douglas and Winslow. Cricothyropharyngien of Dumas. A muscle situated on the posterior part of the pharynx. It arises from the side of the thyroid cartilage, near the attachment of the sterno-hyoideus and thyro-hyoideus muscles; and from the cricoid cartilage, near the crico-thyroideus; it is inserted into the white line, where it joins with its fellow, the superior fibres running obliquely upwards, covering nearly one-half of the middle constrictor, and terminating in a point; the inferior fibres run more transversely, and cover the beginning of the œsophagus. Its use is to compress that part of the pharynx which it covers, and to raise it with the larynx a little upwards.

it with the larynx a little upwards.

Constrictor Pharyngis Medius. Hyopharyngeus and cephalo-pharyngeus of Douglas and Winslow. Chondro-pharyngeus of Douglas. Syndesmo-pharyngeus of Winslow. Cephalo-pharyngeus of Winslow and Douglas. Hyo-glosso basi pharyngien of Dumas. A muscle situated on the posterior part of the pharynx. It arises from the appendix of the os hyoides, from the cornu of that bone, and from the ligament which connects it to the thyroid cartilage; the fibres of the superior part running obliquely upwards, ligament which connects it to the thyroid cartilage; the fibres of the superior part running obliquely upwards, and covering a considerable part of the superior constrictor, terminate in a point; and it is inserted into the middle of the cuneiform process of the os occipitis, before the foramen magnum, and joined to its fellow at a white line in the middle part of the pharyax R 2

This muscle compresses that part of the pharynx which it covers, and draws it and the os hyoides up-

CONSTRICTOR PHARYNGIS SUPERIOR. CONSTRICTOR PHARYNGIS SUPERIOR. Glosso-pharyngeus; Mylo-pharyngeus; Pterygo-pharyngeus of Douglas and Winslow, and Pterigo syndesmo staphilit pharyngien of Dumas. A muscle situated on the posterior part of the pharynx. It arises above, from the cuneiform process of the os occipitis, before the foramen magnum, from the pterygoid process of the sphenoid bone, from the upper and under jaw, near the roots of the last dentes molares, and between the jaws. It is inserted in the middle of the pharynx. Its use is to compress the upper part of the pharynx, and use is to compress the upper part of the pharynx, and to draw it forwards and upwards.

CONSTRICTOR VESICE URINARIE. See Detrusor

CONSTRICTO'RIUS. A disease attended with

constriction, or spasm.

Constringen Tia. (From constringe, to bind together.) Astringent medicines. See Astringent.
CONSUMPTION. (From consumo, to waste away.)

See Phthisis.

See Pathisis.

Contabesce'ntia. (From contabesco, to pine or waste away.) An atrophy, or nervous consumption.

CONTAGION. (Contagio; from contango, to meet or touch each other.) This word properly imports the application of any poisonous matter to the body through the medium of touch. It is applied to those very subtile particles arising from putrid substances, or from persons labouring under certain disstances, or from persons labouring under certain diseases, which communicate the disease to others; as the contagion of putrid fever, the effluvia of dead animal or vegetable substances, the miasm of bogs and fens, the virus of smallpox, lues venerea, &c. &c.

The principal diseases excited by poisonous mias-

The principal diseases excited by poisonous miasmata are, intermittent, remittent, and yellow fevers, dysentery, and typhus. That of the last is generated in the human body itself, and is sometimes called the typhoid fomes. The other miasmata are produced from moist vegetable matter, in some unknown state of the produced from the contraction of the plane. decomposition. The contagious virus of the plague, smallpox, measles, chincough, cynanche maligna, and scarlet fever, as well as of typhus and the jail fever, operates to a much more limited distance through the intermedium of the atmosphere, than the marsh miasmata. Contact of a diseased person is said to be necessary for the communication of plague; and approach within 2 or 3 yards of him, for that of typhus. The Walcheren miasmata extended their pestilential influence to vessels riding at anchor, fully a quarter of a mile from the shore,

a mile from the shore.

The chemical nature of all these poisonous effluvia is little understood. They undoubtedly consist, however, of hydrogen, united with sulphur, phosphorus, carbon, and azot, in unknown proportions, and unknown states of combination. The proper neutralizers or destroyers of these gasiform poisons, are nitric acid vapour, muriatic acid gas, and chlorine. The last two are the most efficacious; but require to be used in situations from which the patients can be removed at the time of the application. Nitric acid vapour may however, be diffused in the apartments of the may, however, be diffused in the apartments of the sick, without much inconvenience. Bed-clothes, par-ticularly blankets, can retain the contagious fomes, in an active state, for almost any length of time. Hence, they ought to be fumigated with peculiar care. The vapour of burning sulphur or sulphurous acid is used in the East, against the plague. It is much infector in power to the other antiloimic reagents.

There does not appear to be any distinction com-

monly made between contagious and infectious dis-

[The very evident distinction has long since been made and employed in this country. Contagion is applied to those diseases which are propagated from one to another by contact or close approach, and which produces a like disease; as the venereal disease, itch, smallpox, measles, &c. Diseases produced by infection, are those contracted from a vitiated atmosphere, as intermittent, remittent, billous, and yellow fevers. In 1819 and 1822, we had the yellow-fever in New-York, and the board of health shut up that part of the city where the disease prevailed, by running fences across the streets leading to it. This was called the infected district, from the local causes contaminating the atmosphere and producing the infection. (The very evident distinction has long since been made

Beyond this district the city was not unhealthy, and those who were taken sick in the infected district, when removed to other parts not infected, recovered, and did not communicate the disease to others. A.]

and did not communicate the disease to others. A.]

CONTE'NSIO. (From contince, to restrain.) It is sometimes used to express a tension or stricture.

Co'ntinens febris. A continent fever, which proceeds regularly in the same tenor, without either exacerbation or remission. This rarely, if ever, happens.

CONTI'NUA FEBRIS. (From continue, to persevere.)

A continued fever. See Febris continua.

CONTINUED. Continuus; from continuo, to persevere.) A term applied in pathology to diseases which go on with a regular tenor of symptoms, but mostly to fevers, the symptoms of which continue, without intermission, until the disease terminates: hence continual fevers in distinction to intermittent

CONTINUUS. See Continued.

CONTO RSIO. (From contorqueo, to twist about.)
A contortion, or twisting. In medicine this word has various significations, and is applied to the iliac pas-

various significations, and is applied to the iliac passion, to luxation of the vertebre, head, &c.

CONTORTÆ. Twisted plants. The name of an order in Linnæus's Fragments of a Natural Method, consisting of plants which have a single petal that is twisted or bent toward the side, as Nerium Vinca, &c.

CONTORTUS. (From con, and torqueo, to twist.) Twisted. Applied to the seed-vessel of plants; as the legumen contortum of the Medicago sating

CONTRA-APERTURA. (From contra, against, and aperio, to open.) A counter-opening. An opening made opposite to the one that already exists.

CONTRACTILITY. Contractilitas. A property in bodies, the effect of the cohesive power, by which their particles resume their former propinquity when

their particles resume their former propinquity when the force ceases which was applied to separate them. It also denotes the power which muscular fibres pos-

scss of shortening themselves.

CONTRACTION. (From contraho, to draw together.) Contractura; Beriberia. A rigid contraction of the joints. It is a genus of disease in the class Locales, and order Dyscinesia of Cullen. The species

1. Contractura primaria, from a rigid contraction of the muscles, called also obstipitas; a word that, with any other annexed, distinguishes the variety of the contraction. Of this species he forms four varicties. 1. Contractura ab inflammatione, when it arises from inflammation. 2. Contractura à spasmo, called also tonic spasm and cramp, when it depends upon spasm. 3. Contractura ob antagonistas paraliticos, from the antagonist muscles losing their action. 4. Contractura ab acrimonia irritante, which is induced by some irritating cause.

2. Contractura articularis, originating from a dis-

2. Contractura articularis, originating from a disease of the joint.

CONTRAFISSU'RA. (From contra, against, and findo, to cleave.) Contre-coup of French writers. A fracture in a part opposite to that in which the blow is received; as when the frontal bone is broken by a fall on the occiput, where the bone remains sound.

CONTRAHE'NTIA. (From contraho, to contract.) Medicines which shorten and strengthen the fibres. Astringents are the only medicines of this nature.

CONTRA-INDICATION. (Contra-indicatio; from contra, against, and indico, to show.) A symptom attending a disease, which forbids the exhibition of a remedy which would otherwise be employed; for instance, bark and acids are usually given in putrid stance, bark and acids are usually given in putrid fevers; but if there be difficulty of breathing, or in-flammation of any viscus, they are contra-indications to their use.

CONTRA-LUNA'RIS. (From contra, and luna, the moon.) An epithet given by Dietericus to a woman

who conceives during the menstrual discharge.

Contra-semen. See Artemisia Santonica.

CONTRAYE'RVA. (From contra, against, and yerva, poison, Span.; i. e. an herb good against poison.)

See Dorstenia.

Contraverva alba. Cantraverva Germanorum.
A name for a species of asclepias.
Contraverva nova. Mexican contraverva. See
Psoralea pentaphylla.
Contraverva virginiana. See Aristolothia serpentaria.

Contre-coup. See Contrafissura.

CONTRI'TIO. The act of grinding, or reducing to

CONTUSION. (Contusio; from contundo, to knock together.) A bruise, or contused wound.

CONUS. A cone. See Strobilus.

convalescentia; from convalescentia; from convalescentia; from convalescentia in the cure of a disease. The period of convalescence is that space from the departure of a disease, to the re-covery of the strength lost by it. CONVALESCENT. Recovering or returning to a

convalescent. Recovering or returning to a state of health after the cure of a disease.

Convalla'ria. (From convallis, a valley; named from its abounding in valleys and marshes.) The name of a genus of plants in the Linnæan system. Class, Hezandria; Order, Monogynia.

Convallaria majalis. The systematic name of the lily of the valley. Lillium convallium; Convallaria; Maianthemum. May-lily. The flowers of this plant. Convallaria—scapo nudo of Linnæus, have a penetrating bitter taste, and are given in nervous and catarrhal disorders. When dried and powdered, they prove strongly purgative. Watery or spirituous extracts made from them, given in doses of a scruple, or drachm, act as gentie stimulating aperients and laxatives; and seem to partake of the purgative virtue, as well as the seem to partake of the purgative virtue, as well as the bitterness of aloes. The roots, in the form of tincture, or infusion, act as a sternutatory when snuffed up the nose, and as a laxative or purgative when taken inter-

nally.

ONVALLARIA POLYGONATUM. The systematic name of Solomon's seal. Sigillum Salomonis; Convallaria—foliis alternis amplexicantibus, caule ancipiti, pedunculis axillaribus subunifloris, of Linnaus. The roots are applied externally as adstringents, and are administered internally as corroborants.

CONVEXUS. Convex. A term in very general

convoluta ossa. See Spongiosa ossa.
Convoluta ossa. See Spongiosa ossa.
Convoluta ossa. Rolled up or folded. Applied to bones, membranes, leaves, &c.
Convoluvulus. (From convolvo, to roll toge-

ther, or entwine.)

A name for the iliac passion.

2. The name of a genus of plants in the Linnæan system, so called from their twisting round others, (Class, Pentandria; Order, Monogynia,) which affords the Jalapa, mechoacanna, turbith, and scammony. The whole genus consists of plants containing a milky juice strongly cathartic and caustic.

Convolvelus americanus. The jalap root. See

Convolvulus jalapa.

Convolvulus BATATAS. Batatas. A native of the West Indies. Its root is firm and of a pale brown on the outside, and white within. When boiled it is sweet, like chesnuts, and is esteemed by some as an

[This is the sweet potato, extensively cultivated and eaten in all the southern parts of the United States,

eaten in all the southern parts of the United States, even as far north as New-Jersey. It is commonly called the Carolina potato. See Batatas. A.]

Convolvulus cantabrica. A name for the cantabrica. Convolvulus minimus spicæ foliis; Convolvulus linariæ folio; Convolvulus Cantabrica of Linnæus. Lavender-leaved bind-weed. Pliny says it was discovered in the time of Augustus, in the country of the Cantabri in Spain; whence its name. It is anthelminitic and actively cathartic.

Convolvulus colubranus. The pariera brava. See Cissammelos pareira.

Convolvelus to the same of the jalap plant. Jalapium mechoacanna nigra. Convolvulus; caule volubli; foliis ovatis, subcordatis, obtusis, obsolete repandis, subtus villosis; pedunculis unifloris of Linnæus. It is a native of South American In the shore the root is found both cut into slices. unifloris of Linnæus. It is a native of South America. In the shops, the root is found both cut into slices and whole, of an oval shape, solid, ponderous, blackish on the outside, but gray within, and marked with several dark veins, by the number of which, and by its hardness, heaviness, and dark colour, the goodness of the root is to be estimated. It has scarcely any smell, and very little taste, but to the tongue, and to the throat, manifests a slight degree of pungency. The medicinal activity of jalap resides principally, if not wholly, in the resin, which, though given in small doses, occasions violent tormina. The root powdered is a very common, efficacious, and safe purgative, as is a very common, efficacious, and safe purgative, as

daily experience evinces; but, according as it contains more or less resin, its effects must of course vary. In large doses, or when joined with calomel, it is recommended as an anthelmintic and hydragogue. pharmacopæias, this root is ordered in the form of tincture and extract; and the Edinburgh College directs it also in powder, with twice its weight of crys-

CONVOLVULUS MAJOR ALBUS. See Convolvulus

sepium.

Convolvulus maritimus. The brassica mari-

tima, or sea colewort.

CONVOLVULUS MECHOACAN. Mechoacanna; Jalapa alba; or Bryonia alba Peruviana; Rhabarbarum album. Mechoacan. The root of this species of convolvulus is brought from Mexico. It possesses aperient properties, and was long used as the common purge of this country, but is now wholly superseded by

("Convolvulus panduratus. Wild potato. The affinity of this plant to jalap, in its botanical character, has caused a medicinal quality to be ascribed to it which it does not possess. It is one of the weakest of our indigenous cathartics, and requires too large a dose to be of much use in that character. It is said to mitigate strangury and gravel, and to operate as a diuretic."

gate strangury and gravel, and to operate as a diuretic."

—Big. Mat. Med. A.]

Convolvulus scammonia. The systematic name of the scammony plant. See Scammonium; Convolvulus syriacus; Scammonium syriacum; Diagrydium. This plant, Convolvulus—foliis sagittatis postice truncatis, pedunculis teretibus subtifioris of Linnæus, affords the concrete gummi-resinous juice termed scammony. It grows plentifully about Maraash, Antioch, Eallib, and towards Tripoli, in Syria. No part of the dried plant possesses any medicinal quality, but the root, which Dr. Russel administered in decoction, and found it to be a pleasant and mild cathartic. It is of the dried plant possesses any medicinal quality, but the root, which Dr. Russel administered in decoction, and found it to be a pleasant and mild cathartic. It is from the milky juice of the root that we obtain the officinal scammony, which is procured in the following manner by the peasants, who collect it in the beginning of June. Having cleared away the earth from about the root, they cut off the top in an oblique direction, about two inches below where the stalks spring from it. Under the most depending part of the slope, they fix a shell, or some other convenient receptacle, into which the milky juice gradually flows. It is left there about twelve hours, which time is sufficient for draining off the whole juice; this, however, is in small quantity, each root affording but a very few drachms. This juice from the several roots is put together, often into the leg of an old boot, for want of some more proper vessel, where, in a little time, it grows hard, and is the genuine scammony. The smell of scammony is rather unpleasant, and the taste bitterish and slightly acrid. The different proportions of gum and resin, of which it consists, have been variously stated; but, as proof spirit is the best menstruum for it, these substances are supposed to be nearly in equal parts. It is brought from Aleppo and Smyrna in masses, generally of a light shining gray colour, and friable texture; of rather an unpleasant smell, and in masses, generally of a light shining gray colour, and friable texture; of rather an unpleasant smell, and bitterish and slightly acrid taste. The scammony of Aleppo is by far the purest. That of Smyrna is ponderous, black, and mixed with extraneous matters. Scammony appears to have been well known to the Greek and Arabian physicians, and was exhibited internally as a purgative, and externally for the itch, tinea, fixed pains, &c. It is seldom given alone, but enters several compounds, which are administered as purgatives.

CONVOLVULUS SEPIUM. Convolvulus major albus. The juice of this plant, Convolvulus—foliis sagittatis postice truncatis pedunculis tetragonis, uniforis, of Linnæus, is violently purgative, and given in dropsical affections. A poultice of the herb, made with oil, is recommended in white swellings of the knee

joint.

Convolvulus soldanella. The systematic name CONVOLVELUS SOLDANELLA. The systematic name of the sea convolvulus. Κραμβη δαλασσια. Brassica marina; Convolvulus maritimus; Soldanella. Soldanella. This plant, Convolvulus—foliis reniformibus, pedunculis uniforis, of Linnæus, is a native of our coasts. The leaves are said to be a drastic purge. It is only used by the common people, the pharmacopenas having now substituted more safe and valuable remedies in its place.

Convolvulus syriacus. The scammony plant. See Convolvulus scammonia.

See Convolvelus scammonia.

Convolvelus turpethum. The systematic name of the turbith plant. Turpethum. The cortical part of the root of a species of convolvelus, brought from the East Indies, in oblong pieces: it is of a brown or ash colour on the outside, and whitish within. The best is ponderous, not wrinkled, easy to break, and discovers to the eye a large quantity of resinous matter. When chewed, it at first imparts a sweetish taste, which is followed by a nauseous acrimony. It is consiwhich is followed by a nauseous acrimony. It is consi-

which is followed by a nauseous acrimony. It is considered as a purgative hable to much irregularity of action—CONVULSION. (Convulsio; from conveile, to pull together.) Hieranosos; Distentio nervorum; Syspacia convulsio of Good. Clonic spasm. A diseased action of muscular fibres, known by alternate relaxations, with violent and involuntary contractions of the muscular parts, without sleep. Cullen arranges convulsion in the class Neuroses, and order Spasmi. convulsion in the class Neuroses, and order Spasmi. Convulsions are universal or partial, and have obtained different names, according to the parts affected, or the symptoms; as the risus sardonicus, when the muscles of the face are affected; St. Vitus's dance, when the muscles of the arm are thrown into involuntary motions, with lameness and rotations. hysterical epitepsy, or other epitepsies, arising from different causes, are convulsive diseases of the universal kind: the muscles of the globe of the eye throwing the eye into involuntary distortions in defithrowing the eye into involuntary distortions in defi-ance of the direction of the will, are instances of par-tial convulsion. The muscles principally affected in all species of convulsions, are those immediately under the direction of the will; as those of the eyelids, eye, face, jaws, neck, superior and inferior extremities. The muscles of respiration, acting both voluntarily and involuntarily, are not unfrequently convulsed; as the diaphragm, intercostals, &c. The more immediate causes of convulsions are, 1. Either mental affection, or any irritating cause exciting a greater action in the arterial system of the brain and nerves. 2. An in-crease of nervous energy, which seems to hold pace or arterial system of the brain and nerves. 2. An increase of nervous energy, which seems to hold pace or be equipotent with the increased arterial energy excited in the brain. 3. This increased energy, conveying its augmented effects, without the direction of the will, to any muscles destined to voluntary motion, over-irritates them. 4. The muscles, irritated by the increased nervous energy and arterial influx, contract more forcibly and involuntarily by their excited vis insita, conjointly with other causes, as long as the increased nervous energy continues. 5. This increased energy in the nervous system may be excited either by the mind, or by any acrimony in the blood, or other the mind, or by any acrimony in the blood, or other stimuli sufficiently irritating to increase the arterial action, nervous influence, and the vires insite of muscles. 6. After muscles have been once accustomed to act involuntarily, and with increased action, the same causes can readily produce the same effects on those organs. 7. All parts that have muscular fibres may be convulsed. 8. The sensations in the mind most capable of producing convulsions, are timidity, horror, anger, great sensibility of the soul, &c.

CONVULSIO CANINA. A WIY mouth.

CONVULSIO CEREALIS. Cereal convulsion is a singular disorder of the spasmodic convulsive kind, not guiar disorder of the spasmodic convuisive kind, not common to this country, but mentioned by Cartheuser under this title, from the peculiar tingling and formication perceived in the arms and legs. Motus spasmodicus of Hoffman. It is endemial in some places in Germany; but more a rural than urbanical disorder, said to arise from the use of spoiled corn.

Convulsto Habitualis. Saint Vitus's dance. See

Convulsio habitualis. Saint Vitus's dance. See Chorea Sancti Viti.
CONY'ZA. (From κονις, dust; because its powder is sprinkled to kill fleas in places where they are troublesome.) The name of a genus of plants in the Linnean system. Class Syngenesia; Order, Polygamia superflua. There is some difficulty in ascertaining the plants called conyzas by the older practitioners: they are either of the genus conyza, inula, gnaphalium, eriercen or chrysocoma. geron, or chrysocoma.

CONYZA ÆTHIOPICA. The plant so called is most probably the Chrysocoma comaurea of Willdenow, a shrub which grows wild about the Cape of Good Hope, and is cultivated in our green-houses, because it

flowers the greater part of the year.

CONYZA CŒRULEA. The Erigeron acre of Linneus answers to the description of this plant.

Convex major. Supposed to be the Inula viscosa of Linnæus.

CONYZA MAJOR VULGARIS. See Inula dysenterica.

Conyza media. See Inula dysenterica.
Conyza minor. The Inula pulicaris of Linnæus answers to the description given of this plant in most books. Its chief use is to destroy fleas and

COOPERTO'RIA. (I (From co-operio, to cover over.)

COO STRUM. The centre of the diaphragm. COPA'IBA. (Copaiba, &. fæm.; from copal, the American name for any odoriferous gum, and iba, or iva, a tree.) The name given by the College of Physicians of London to the balsam of copaiva. See Co-

paifera officinalis.
COPAI FERA. (From Copaiva, the Indian name, and fero, to bear.) The name of a genus of plants in the Linnwan system. Class, Decandria; Order, Mo-

nogynia.

Copaipera officinalis. The systematic name of the plant from which the Copaiba balsam, Balsamum Braziliense; Balsamum copaiba; Balsamum de copaibu; Balsamum capivi; Copaiba; Capevi; is obtained.

Copaiba is a yellow resinous juice, of a moderately agreeable smell, and a bitterish biting taste, very permanent on the tongue. The tree which affords it grows in Brazil, New-Spain. It is obtained by making deep incisions near its trunk, when the balsam immediately issues, and, at the proper season, flows in such abundance, that sometimes, in three hours, twelve pounds have been procured. The older trees afford the best balsam, and yield it two or three times in the same year. The balsam supplied by the young and vigorous trees, which abound with the most juice, is crude and watery, and is, therefore, accounted less valuable. While flowing from the tree, this balsam is a colourless fluid; in time, however, it acquires a yellowish tinge, and the consistence of oil; but, though by age it has been found thick, like honey, yet it never becomes solid, like other resinous fluids. By distillation in water, the oil is separated from the resin; and, Copaiba is a yellow resinous juice, of a moderately tion in water, the oil is separated from the resin; and, in the former, the taste and smell of the balsam are concentrated. If the operation is carefully performed, about one-half of the balsam rises into the receiver, in the form of oil. The balsam unites with fixed and volatile oils, and with spirit of wine. It is given in all volatile oils, and with spirit of wine. It is given in all diseases of the urinary organs, when no inflammation is present. In gleets, and in gonorrhæa, it was once a favourite remedy, but is now disused. In diseases of the kidneys it is still employed, though less frequently than usual; and in hæmorrhoids it is occasionally trusted. The dose is from 20 to 30 drops, twice or

egg, or any muchage. The bassam of copalva is occasionally adulterated with turpentine, but its virtues are not greatly injured by the fraud.

COPAL. (The American name of all clear odoriferous gums.) Gum copal. This resinous substance is imported from Guinea, where it is found in the sand on the shore. It is a hard, shining, transparent, citroncoloured, odoriferous, concrete juice of an American tree, but which has neither the solubility in water common to gums, nor the solubility in alkohol common to resins, at least in any considerable degree. By these properties it resembles amber. It may be dissolved by digestion in linseed oil, rendered drying by quicklime, with a heat very little less than sufficient to boil or decompose the oil. This solution, diluted with oil of turpentine, forms a beautiful transparent varnish, which, when properly applied, and slowly dried, is very hard, and very durable. This varnish is applied to snuff-boxes, tea-boards, and other utensils. It preserves and gives lustre to paintings, and greatly restores the decayed colours of old pictures, by filling up the cracks, and rendering the surfaces capable of reflecting light more uniformly.

Cope Lla. See Cupel.

Cope Lla. See Cupel.

three times a day, mixed with water, by means of an egg, or any mucilage. The balsam of copaiva is occa-sionally adulterated with turpentine, but its virtues

COPE'LLA. See Cupel.

CO'PHER. A name for camplior.

CO'PHOS. (Κωφος, dumb.) Deaf or dumb. Also a dulness in any of the senses.

COPHO'SIS. (From κωφος, deaf.) A difficulty of hearing. It is often symptomatic of some disease.

COPPER. (Cuprum, i. neut. quasi as Cyprium;

so named from the island of Cyprus, whence it wgs formerly brought.) "A metal of a peculiar reddishbrown colour: hard, sonorous, very malleable and ductile; of considerable tenacity, and of a specific gravity from 8.6 to 8 9. At a degree of heat far below ignition, the surface of a piece of polished copper becomes covered with various ranges of prismatic colours, the red of each order being nearest the end which has been most heated; an effect which must doubtless be attributed to oxidation, the stratum of oxide being thickest where the heat is greatest, and oxide being thickest where the heat is greatest, and growing gradually thinner and thinner towards the colder part. A greater degree of heat oxidizes it more rapidly, so that it contracts thin powdery scales on its surface, which may easily be rubbed off; the on its surface, which may easily be rubbed off; the flame of the fuel becoming at the same time of a beautift' bluish-green colour. In a heat, nearly the same as L necessary to meit gold or silver, it melts, and exhibits a bluish-green flame; by a violent heat it boils, and is voiatilized partly in the metallic state.

Copper rusts in the air; but the corroded part is

very thin, and preserves the metal beneath from far-

ther corrosion.

There are two oxides of copper:

1st, The black, procurable by heat, or by drying the hydratic oxide precipitated by potassa from the nitrate. It consists of 8 copper+2 oxygen. It is a deu-

2dly, The protoxide is obtained by digesting a solu-fion of muriate of copper with copper turnings, in a close phial. The colour passes from green to dark brown, and gray crystalline grains are deposited. The solution of these yields, by potassa, a precipitate of an orange colour, which is the protoxide. It consists of 8 copper +1 oxygen. Protoxyde of copper has been lately found by Mushet, in a mass of copper, which had been exposed to heat for a considerable time, in one of the melting furnaces of the mint under his superintendence. his superintendence.

Copper, in filings, or thin laminæ, introduced into chlorine, unites with flame into the chloride, of which there are two varieties; the protochloride, a fixed yellow substance, and the deutochloride, a yellowish-

brown pulverulent sublimate.

1. The crystalline grains deposited from the above muriatic solution, are protochloride. The protochloride is conveniently made by heating together two parts of corrosive sublimate, and one of copper filings. An amber-coloured translucent substance, first discovered by Boyle, who called it resin of copper, is obtained. It is fusible at a heat just below redness; and in a close vessel or a vessel with a parrow orifice is in a close vessel, or a vessel with a narrow orifice, is not decomposed or sublimed by a strong red heat. But if air be admitted, it is dissipated in dense white fumes. It is insoluble in water. It effervesces in nitric acid. It dissolves silently in muriatic acid, from which it may be precipitated by water. By slow cooling of the fused mass, Dr. John, Davy obtained it crystallized, apparently in small plates, semi-transparent, and of a light yellow colour. It consists, by the same Ingenious chemist, of

Chlorine, 36 or 1 prime = 4.45 35.8

Copper, 64 or 1 prime 8.00 64.2

100 12.45 100.0

2. Deutochloride is best made by slowly evaporating to dryness, at a temperature not much above 4000 Fahr, the deliquescent muriate of copper. It is a yellow powder. By absorption of moisture from the air, it passes from yellow to white, and then green, reproducing common muriate. Heat converts it into protochloride with the disengagement of chloride. chloride, with the disengagement of chlorine. Dr. Davy ascertained the chemical constitution of both these compounds, by separating the copper with iron, and the chlorine by nitrate of silver. The deutochloride consists of

Chlorine, 53 2 primes 8.9 52.7 Copper, 47 1 do. 8.0 47.3 Copper, do. 8.0 47.3 100 16.9 100.0

The iodide of copper is formed by dropping aqueous hydriodate of potassa into a solution of any cupreous salt. It is an insoluble dark brown powder.

Phosphuret of copper is made by projecting phos-

phorus into red-hot copper.

Sulphuret of copper is formed by mixing together eight parts of copper filings, and two of sulphur, and exposing the mixture to a gentle heat.

The sulphuric acid, when concentrated and boiling, Sulphate of potassa and copper is formed by discovered by d

dissolves copper.

Nitric acid dissolves copper with great rapidity, and disengages a large quantity of nitrous gas. Part of the metal falls down in the form of an oxide; and the filtrated or decanted solution, which is of a much deeper blue colour than the sulphuric solution; affords crystals by slow evaporation. This satt is deliquescent, very soluble in water, but most plentifully when the fluid is heated.

The saline combinations of copper were formerly called sales veneres, because Venus was the mytho-logical name of copper. They have the following general characters

1. They are mostly soluble in water, and their solu-tions have a green or blue colour, or acquire one of

these colours on exposure to air.

2. Ammonia added to the solutions, produces a

deep blue colour.

3. Ferroprussiate of potassa gives a reddish-brown

precipitate, with cupreous salts.

4. Gallic acid gives a brown precipitate.

5. Hydrosulphuret of potassa gives a black precipi-

6. A plate of iron immersed in these solutions throws flown metallic copper, and very rapidly if there be a slight excess of acid. The protoxide of copper can be combined with the acids only by very particular management. All the ordinary salts of copper have the peroxide for a base.

The joint agency of air and acetic acid, is neces sary to the production of the cupreous acetates. By exposing copper plates to the vapours of vinegar, the bluish-green verdigris is formed, which, by solution in

vinegar, constitutes acetate of copper.

Arseniate of copper presents us with many subspecies which are found native. The arseniate may be formed artificially by digesting arsenic acid on copper, or by adding arseniate of potassa to a cupreous saline solution.

Carbonate of copper. Of this compound there are three native varieties, the green, the blue, and the anhydrous.

Chlorate of copper is a deflagrating deliquescent

green salt.

Fluate of copper is in small blue-coloured crystals.

Hydriodate of copper is a grayish-white powder.

Protomuriate of copper has already been described

in treating of the chlorides.

Deutomuriate of copper, formed by dissolving the deutoxide in muriatic acid, or by heating muriatic acid on copper filings, yields by evaporation crystals

of a grass-green colour.

The ammonio-nitrate evaporated, yields a fulminating copper. Crystals of nitrate, mixed with phos-

phorus, and struck with a hammer, detonate.

Subnitrate of copper is the blue precipitate, occasioned by adding a little potassa to the neutral nitric

Nitrate of copper is formed by mixing nitrate of lead with sulphate of copper.

The sulphate, or blue vitriol of commerce, is a bisul-

A mixed solution of this sulphate and salammoniac, forms an ink, whose traces are invisible in the cold, but become yellow when heated; and vanish again

as the paper cools. Protosulphite of copper is formed by passing a current of sulphurous acid gas through the deutoxide of copper diffused in water. It is deprived of a part of its oxygen, and combines with the acid. The sulphate, simultaneously produced, dissolves in the wa-ter; while the sulphite forms small red crystals, from which merely long ebullition in water expels the acid.

Sulphite of potassa and copper is made by adding the sulphite of potassa to nitrate of copper. A yellow flocculent precipitate, consisting of minute crystals,

Ammonia-sulphate of copper is the salt formed by adding water of ammonia to solution of the bisulphate. It consists, according to Berzelius, of 1 prime of the cupreous, and 1 of the ammoniacal sulphate, combined together; or 20.0+7.13+14.625 of water.

Subsulphate of ammonia and coppor is formed by

Sulphate of potassa and copper is formed by di-gesting bisulphate of potassa on the deutoxide or car-

bonate of copper.

The following acids, antimonic, antimonious, boracic, chromic, molybdic, phosphoric, tungstic, form insoluble salts with deutoxide of copper. The first two are green, the third is brown, the fourth and fifth green, and the sixth white. The benzoate is in green crystals, sparingly soluble. The exalate is also green. The bipovalates of notassa, and soda, with oxide of The binoxalates of potassa and soda, with oxide of copper, give triple salts, in green needle-form crystals. There are also ammonia oxalates in different varieties.

Tartrate of copper forms dark bluish-green crystals.

Cream-tartrate of copper is a bluish-green powder, commonly called Brunswick green.

To obtain pure copper for experiments, we precipitate it in the metallic state, by immersing a plate of iron in a solution of the deutomuriate. The pulverulent copper must be washed with dilute muriatic

acid.

This metal combines very readily with gold, silver, and mercury. It unites imperfectly with iron in the Tin combines with copper, at a temway of fusion. perature much lower than is necessary to fuse the perature much lower than is necessary to fuse the copper alone. On this is grounded the method of tinning copper vessels. For this purpose, they are first scraped or scoured; after which they are rubbed with sal-ammoniac. They are then heated, and sprinkled with powdered resin, which defends the clean surface of the copper from acquiring the slight film of oxide that would prevent the adhesion of the tin to its surface. The melted tin is then poured in, and spread about. An extremely small quantity adheres to the copper, which may perhaps be supposed heres to the copper, which may perhaps be supposed insufficient to prevent the noxious effects of the copper as perfectly as might be wished.

When tin is melted with copper, it composes the

compound called bronze.

Copper unites with bismuth, and forms a reddish-white alloy. With arsenic it forms a white brittle compound, called tombac. With zinc it forms the compound called brass, and distinguished by various other names, according to the proportions of the two ingredients.

Copper unites readily with antimony, and affords a compound of a beautiful violet colour. It does not readily unite with manganese. With tungsten it forms a dark brown spongy alloy, which is somewhat

Verdigris, and other preparations of copper, act as virulent poisons, when introduced in very small quantities into the stomachs of animals. A few grains are sufficient for this effect. Death is commonly preceded by very decided nervous disorders, such as convulsive movements, tetanus, general insensibility, or a palsy of the lower extremities. This event happens fre-quently so soon, that it could not be occasioned by inflammation or erosion of the primæ viæ; and indeed, where these parts are apparently sound. It is probable that the poison is absorbed, and, through the circulation, acts on the brain and nerves. The cupreous preparations are no doubt very acrid, and if death do not follow their immediate impression on the sentient system, they will certainly inflame the intestinal canal. The symptoms produced by a dangerous dose of copper are exactly similar to those which are enumerated under arsenic, only the taste of copper is strongly felt. The only chemical antidote to cupreous solutions, whose operation is well understood, is water strongly impregnated with sulphuretted hydrogen. The alkaline hydrosulphurets are acrid, and ought not to be prescribed.

But we possess, in sugar, an antidote to this poison, of undoubted efficacy, though its mode of action be obscure. Duval introduced into the stomach of a dog, by means of a caoutchouc tube, a solution in acetic acid, of four French drachms of oxide of copper. Some minutes afterward he injected into it four ounces of strong syrup. He repeated this injection every half-hour, and employed altogether 12 ounces of syrup. The animal experienced some tremblings and convulsive movements. But the last injection was followed by a perfect calm. The animal fell asleep, and awakened free from any ailment.

Orfila relates several cases of individuals who had by accident or intention swallowed poisonous doses of by accident of incention swandwed positions access of accetate of copper, and who recovered by getting large doses of sugar. He uniformly found, that a dose of verdigris which would kill a dog in the course of an hour or two, might be swallowed with impunity, provided it was mixed with a considerable quantity

As alkohol has the power of completely neutralizing, in the eithers, the strongest muriatic and hydriodic acids, so it would appear that sugar can neutralize the oxides of copper and lead. The neutral saccharite of lead, indeed, was employed by Berzelius in his experiments, to determine the prime equivalent of sugar. If we boil for half an hour, in a flask, an ounce of white sugar, an ounce of water, and 10 grains of verdigris, we obtain a green liquid, which is not affected by the nicest tests of copper, such as ferroprussiate of potassa, ammonia, and the hydrosulphurets. An insoluble green carbonate of copper remains at the bottom of ing, in the æthers, the strongest muriatic and hydriodic green carbonate of copper remains at the bottom of the flask."—Ure's Chem. Dict.

Copper, ammoniated solution of. See Cupri ammo-

miati liquor.
CO'PPERAS. A name given to blue, green, and

white vitriol.

Coprago Ga. (From κοπρος, dung, and ayω, to bring away.) Purgatives. Coprago gum is the name of a gently-purging electuary, mentioned by Rulandus. Coprie Mesis. (From κοπρος, excrement, and εμεω, to vomit.) A vomiting of fæces.

Coprocri'tica. (From κοπρος, excrement, and κομρω, to separate.)

Coprocritica. (From κοπρος, excrement, and κοινω, to separate.) Mild cathartic medicines.
Copropho'ria. (From κοπρος, excrement, and φορεω, to bring away.) A purging.
Copros. Κοπρος. The faces, or excrements from the heart.

COPROSTA'SIA. (From κοπρος, fæces, and ιςημι, remain.) Costiveness, or a constriction of the to remain.)

COPTA'RIOM. (Κοπ7η, a small cake.) Coptarium.

A lozenge.

COPTE. $(Ko\pi/\eta, a \text{ small cake.})$ 1. The form of a medicine used by the ancients.

2. A cataplasm generally made of vegetable substances, and applied externally to the stomach, and on many occasions given internally.

["COPTIS TRIFOLIA. Gold thread. The coptis tri-folia, which was arranged among the Hellebores by Linnæus, is a beautiful native, evergreen plant, of the Innæus, is a beautiful native, evergreen plant, of the northern States. Its roots are creeping, thread-shaped, and of a bright yellow colour. They have an intensely bitter taste, without warmth or astringency. Alkohol is the best solvent of this article, forming a bright yellow tincture. Water also extracts the bitterness, but less perfectly. Gold thread is a pleasant tonic, and promotes appetite and digestion. It is a popular remedy in apthous mouths and ulcers of the throat, though it does not appear to be very powerful in these comdy in apthous mouths and ulcers of the throat, though it does not appear to be very powerful in these complaints. As a tonic it may be given in the dose of ten or twenty grains of the powder. It is, however, somewhat difficult to pulverize, owing to the tenacity of the fibres. A tincture, formed by an ounce of the root in a pint of diluted alkohol, may be given in doses of a drachm."—Big. Mat. Med. A.]

CO'PULA. (Quasi compula; from compello, to restrain.) A name for a ligament.

COQUE'NTIA. (From coquo, to digest.) Medicines which promote concoction.

which promote concoction.

COR. (Cor, dis. neut.)

1. The heart. See Heart.

3. An intense fire.

CORACI'NE. (From κοραξ, a crow; so named from its black colour.) A name for a lozenge, quoted by Galen from Asclepiades.

CORACO. The first part of the name of some muscles which are attached to the coracoid process of the blade bone.

the blade-bone.

the blade-bone.

Coraco-brachiæus. Coraco-humeral of Dumas.

Coraco-brachiæus. A muscle, so called from its origin and insertion. It is situated on the humerus, before the scapula. It arises, tendinous and fleshy, from the forepart of the coracoid process of the scapula, adhering, in its descent, to the short head of the biceps; inserted, tendinous and fleshy, about the middle of the internal part of the os humeri, near the origin of the third head of the triceps, called brachialis externus. third head of the triceps, called brachialis externus, where it sends down a thin tendinous expansion to the internal condyle of the os humeri. Its use is to raise the arm upwards and forwards.

CORACO HYOIDEUS. See Omo hyoideus.
CO'RACOID. (Coracoideus; from κοραξ, a crow, and ειδος, resemblance: shaped like the beak of a crow.) Some processes of the bones are so named which were supposed to resemble the beak of a crow. CORACOID PROCESS. Processus coracoides. See

Scapula. CO'RAL.

CORALLINA. (Diminutive of corallium.) Muscus maritimus; Corallina officinalis; Corallina alba.
Sea coralline; Sea moss; White wormseed. A machine in the core for the coralline and a small plant. rine production, or fucus, resembling a small plant without leaves, consisting of numerous brittle cretaceous substances, friable betwixt the fingers, and crackling between the teeth. Powdered, it is administered to children as an anthelminthic, in the dose of half a drachm to a drachm once or twice a day.

of half a drachm to a drachm once or twice a day.

CORALLINA CORSICANA. Helmintho-corton; Conferva helmintho-cortos: Corallina rubra; Corallina melito-corton; Lemitho-corton; Mouse de Corse. Corsican wormweed. Fucus helmintho-corton of De la Tourrette. This plant has gained great repute in destroying all species of intestinal worms. Its virtues are extolled by many; but impartial experimentalists have frequently been disappointed of its efficacy. The Geneva Pharmacopæia directs a syrup to be made of it.

CORALLINA MELITO-CORTON. See Corallina corsi-

CORALLINA RUBRA. See Corallina corsicana.

CORALLINE. See Corallina.

Coralline, Corsican. See Corallina corsicana.

[CoralLinite. See Organic relics.]

CORALLIUM. (Corallium, i. n.; from κορη, a daughter, and αλς, the sea, because it is the production of the sea.) Coral.

CORALLIUM ALBUM. A hard, white, calcareous brittle substance; the nidus of the Madrepora oculata. Class, Vermes; Order, Lithophyta. It is sometimes exhibited as an absorbent earth.

CORALLIUM RUBRUM. Acmo. Azur. The red coral is mostly employed medicinally. It is a hard, brittle, calcareous substance, resembling the stalk of a plant, and is the habitation of the Isis nobilis. Class, Vermes; Order, Zoophyta. When powdered, it is exhibited as an absorbent earth to children; but does

not appear to claim any preference to common chalk. CORALLODE'NDRON. (From κοραλλιον, coral, and ὀενδρον, a tree, resembling in hardness and colour a piece of coral.) The coral-tree of America; anti-

CORALLOI'DES. (From κοραλλιον, coral, and cos, likeness.) Coral-like. See Clavaria coralειδος, likeness.)

Co'rchoron. (From κορη, the pupil of the eye, and κορω, to purge; so called because it was thought to purge away rheum from the eyes.) The herb pimpernel, or chickweed.

corollum. (Corculum, a little heart; diminutive of cor, a heart.) An essential part of a germinating seed, called also the cmbryo, or germ. It lies between the cotyledons. It is the point from which the life and organization of the future plant originate. In some seeds it is much more conspicuous than in others. The walnut, bean, pea, and lupine show it in perfection. Its internal structure, before it begins to vegetate, is observed to be very simple, consisting of a uniformly medullary substance, enclosed in its appropriate bark or skin. Vessels are formed in it as soon as the vital principle is excited to action, and parts are then developed which seemed not previously to are then developed which seemed not previously to

exist. There are observed in it,

1. The rostellum, or little beak, which penetrates into the earth and becomes the root.

2. The plumula, which shoots above the ground, and becomes a tuft of young leaves, with which the young stem, if there be any, ascends. See Cotyledon.

Corda. See Chorda.

CORDA TYMPANI. See Chorda tympani.
CORDA TYMPANI. See Chorda tympani.
CORDATUS. Heart-shaped. Applied to leaves, petals, &c. which are ovate, hollowed out at the base, according to the vulgar idea of a heart: a form very frequent in leaves; as in those of Arctium lappa, and

A leaf is called obcordate, when the apex of the heart-shaped leaf is fixed to the petiole.

CO'RDIA. (So called by Plumier in honour of Euricius Cordius and his son Valerius, two eminent German botanists.) The name of a genus of plants. Class, Pentandria; Order, Monogynia.

CORDIA MYXA. The systematic name of the Sebesten plant. Sebesten; Sebestina; Cordia—foliis ovatis, supra glabris; coryumbis lateralibus; calveibus

tis, supra glabris; corymbis lateralibus; calycibus decemstriatis of Linnæus. The dark black fruit pos sesses glutinous and aperient qualities, and is exhibited in form of decoction in various diseases of the chest, hoarseness, cough, difficult respiration, &c.

CORDIAL. Cardiacus. Medicines are generally so termed, which possess warm and stimulating pro-

Perties, and that are given to raise the spirits.

Cordine M. (From καρα, the head, and διντω, to move about.) A headache attended with a vertigo.

Cordo Lium. (From cor, the heart, and dolor, pain.) A name formerly applied to cardialgia, or heaviers. heartburn

CORDUS, VALERIUS, was born in 1515, of a Hessian family. After studying in some of the German universities, he travelled through Italy, chiefly engaged in botanical researches. He died at the enry age of 29, leaving several works; a "History of Plants," many of them never before described; "Annotations on Dioscorides;" a Nuremberg Dispensatory, &c. CO'RE. Kopp. The pupil of the eye.

on Dioscorides;" a Nuremberg Dispensatory, &c. CO'RE. Κορη. The pupil of the eye. Core Mata. (From κορεω, to cleanse.) Medicines for cleansing the skin.

CORIACEUS. Leathery. Applied to leaves and pods that are thick and tough without being pulpy, or succulent; as in the leaves of Magnolia grandiflora, Aucuba, &c. and the pods of the Lupin.

CORIANDER. See Coriandrum.

CORIANDRUM. (Coriandrum, i. n.; from κορη, a pupil, and ανηρ, a man: because of its roundness, like the pupil of a man's eye; or probably so called from κορες, cimez, a bug, because the green herb, seed and all, stinks intolerably of bugs.) Coriander.

1. The name of a genus of plants in the Linnean

The name of a genus of plants in the Linnean system. Class, Pentandria; Order, Dygynia.
 The pharmacopæial name of the officinal corian-

2. The pharmacopæial name of the officinal coriander. See Coriandrum sativum.

CORLANDRUM SATIVUM. The systematic name of the plant called coriandrum in the pharmacopæias. Cassibor; Corianon. The Coriandrum—fructibus globosis, of Linnæus. This plant is a native of the South of Europe, where, in some places, it is said to grow in such abundance as frequently to choke the growth of wheat and other grain. From being cultivated here as a medicinal plant, it has for some time become naturalized to this country, where it is usually become naturalized to this country, where it is usually found in corn fields, the sides of roads, and about dung-hills. Every part of the plant, when fresh, has a very offensive odour, but, upon being dried, the seeds have a tolerably grateful smell, and their taste is moderately warm and slightly pungent. They give out their virtue totally to rectified spirit, but only partially to water. In distillation with water, they yield a small quantity of a yellowish essential oil, which smells strongly and pretty agreeably of the coriander

Dioscorides asserts, that the seeds, when taken in a considerable quantity, produce deleterious effects; and, in some parts of Spain and Egypt, where the fresh herb is eaten as a cordial, instances of fatuity, letharherb is eaten as a cordial, instances of faturty, icunargy, &c. are observed to occur very frequently; but these qualities seem to have been unjustly ascribed to the coriander; and Dr. Withering informs us, that he has known six drachms of the seeds taken at once, without any remarkable effect. These seeds, and indeed most of those of the umbelliferous plants, possess a stomachic and carminative power. They are different seems. rected in the infusum amarum, the infusum sennæ tartarizatum, and some other compositions of the pharmacopæias; and according to Dr. Gullen, the principal use of these seeds is, "that infused along with senna, they more powerfully correct the odour and taste of this than any other aromatic that I have employed, and are, I believe, equally powerful in obviating the griping that senna is very ready to produce."

CORIA'NON. See Coriandrum.

OO'RIS. (From κειρω, to cleave, or cut; so called

Tamus communis, and the petals of the Sium Selinum.

Aum.

A leaf is called obcordate, when the apex of the heart-shaped leaf is fixed to the petiole.

CO'RDIA. (So called by Plumier in honour of Euricius Cordius and his son Valerius, two eminent German botanists.) The name of a genus of plants.

Cordinate in the self of the Sium Selinum Se

apparently, an action in syphilis.

CORK. Suber. The bark of the Quercus suber of Linnæus, formerly employed as an astringent, but now disused. By the action of nitric acid it is acidified. See

Suberic acid.

Cork has been recently analyzed by Chevreuil by digestion, first in water and then in alkohol. By distildigestion, first in water and then in alkohol. By distillation there came over an aromatic principle, and a little acetic acid. The watery extract contained a yellow and a red colouring matter, an undetermined acid, gallic acid, an astringent substance, a substance containing azot, a substance soluble in water and insoluble in alkohol, gallate of iron, lime, and traces of magnesia. 20 parts of cork treated in this way, left 17.15 of insoluble matter. The undissolved residue being treated a sufficient number of times with alkohol, yielded a variety of bodies, but which seem reducible to three; namely, cerin, resin, and an oil. The ligneous portion of the cork still weighed 14 parts, which are called suber. are called suber.

[CORK, when burnt and reduced to a black coal, may be pulverized and given as a medicine. It produces a light and delicate carbon, which may be given by the tea-spoonful, in a little syrup or milk, to children with cholera infantum or sour stomach. It is an excellent corrector of acidity, and is a useful domestic remedy for complaints of the bowels in children during warm

weather. A.]

Cork, fossil. See Asbestos.

CORN. Clavus. A hardened portion of cuticle, produced by pressure: so called because a piece can be picked out like a corn of barley.

Corn salad. See Valeriana locusta.

CORNACHINI PULVIS. Scammony, antimony, and

CORNARIUS, John, was born in Upper Saxony, in the year 1500. According to Haller his real namewas Haguenbot, or Hanbut. He is said to have been led to the study of medicine from the delicacy of hisown constitution. He graduated at Padua, after attending several other universities. Besides translating Hip-pocrates, and some other Greek writers into Latia, he was author of several works on medicine; and is said to have had an extensive practice. He died in 1558, leaving a son, Diomede, who succeeded him, and was afterward professor of medicine at Vienna, and physician to Maximilian II.

CORNARO, Lewis, of a noble Venetian family, was born in 1467. Having impaired his constitution by a debauched and voluptuous life, and brought on at last a severe illness, on recovering from this, at the age of more than 40, he adopted a strict, abstemious regimen, limiting himself to twelve ounces of solid food, and fourteen of wine, daily; which quantity he rather diminished in the latter part of his life. He carefully avoided also the extremes of heat or cold, with all vioavoided also the extremes of heat or cold, with all vio-lent exercise; and took care to live in a pure dry air. He thus preserved a considerable share of health and activity to the great age of 98. His wife, by whom he had an only child, a daughter, when they were both advanced in years, survived him, and attained nearly the same period. When he was 83, he published a short treatise in commendation of temperance, which has been repeatedly translated, and printed in every country of Europe. He then states himself to have been able to mount his horse, without assistance, from any rising ground. He wrote three other discourses on similar subjects at subsequent periods, the last only three years before his death. The best English trans-lation is said to be that of 1779. lation is said to be that of 1779.

CO'RNEA. The sclerotic membrane of the eye is

so called, because it is of a horny consistence.

Sclerotic coat.

CORNEA OPACA. See Sclerotic coat.
CORNEA TRANSPARENS. Sclerotica ceratoides. The transparent portion of the sclerotic membrane, through which the rays of light pass, is so called, to distinguish it from that which is opaque. See Sclerotic

["Cornea Tunica. (From cornu, a horn.) The an-

texture, is tough like horn. It has a structure peculiar to itself, being composed of a number of concentric cellular lamellæ, in the cells of which is deposited a particular sort of fluid. It is covered externally by a continuation of the conjunctiva, which belongs to the class of mucous membranes, and it is lived by a constitution of the conjunctival which belongs to the class of mucous membranes. class of mucous membranes; and it is lined by a membrane, the tunica humoris aquei, which seems to be-long to the serous class."—Cooper's Surg. Dict. A.] CORNE'STA. A chemical retort. CORNFLOWER. See Centaurea cyanus.

CORNICULA. (From cornu, a horn.) A cupping instrument, made of horn.

CORNICULA'RIS. (From cornu, a horn.) Shaped like a horn; the coracoid process of the scapula.

CORNIFORMIS. (From cornu, a horn, and forma resemblance)

resemblance.) Horn-shaped: applied to the nectary of plants:—nectarium corniforme, in the orchis tribe. CO'RNU. A horn. This term is used both in ana-

tomy, surgery, and materia medica. 1. A wart. See

2. A corn or horny induration of the cuticle. See Carn.
3. The horn of the stag.

4. The cavities of the brain.

CORNU AMMONIS. Cornu arietis. When the pes hippocampi of the human brain is cut transversely through, the cortical substance is so disposed as to re-semble a ram's horn. This is the true cornu ammo-nis, though the name is often applied to the pes hippo-

[This name is also applied to the chambered shells found in a petrified state, and designated among the organic relics of another world as Ammonites. They are very abundant in Yorkshire, England, and have been found in some places in this country. A.]

CORNU ARIETIS. See Cornu ammonis.

CORNU CRYVI. Hartshorp. The horns of several

species of stag, as the Cervus alces, Cervus dama, Cervus elaphus, and Cervus taranda, are used meditimally. Boiled, they impart to the water a nutritious jelly, which is frequently served at table. Hartshorn jelly is made thus:—Boil half a pound of the shavings of hartshorn, in six pints of water, to a quart; to the strained liquor add one ounce of the juice of lemon, or of Seville orange, four ounces of mountain wine and half a pound of sugar; then boil the whole to a pro-per consistence. The chief use of the horns is for calcination, and to afford the liquor volations cornu cervi and subcarbonate of ammonia.

CCRNU CERVI CALCINATUM. See Cornu ustum.
CCRNU USTUM. Cornu cervi calcinatum. Burn
pleces of hartshorn in an open fire, till they become thoroughly white; then powder, and prepare them in the same manner as is directed for chalk. Burnt hartshorn shavings possess absorbent, antacid, and ad-stringent properties, and are given in the form of decetion, as a common drink in diarrheas pyrosis, &c.

CORNUA UTERL. Plecteng. In comparative anatomy, the horns of the womb; the womb being in some animals triangular, and its angles resembling horns.

CORNUMU'SA. A retort.
CO'RNUS. 1. The name of a genus of plants in the
Linnean system. Class, Tetrandria; Order, Mono-

gynia.

2. The pharmacopæial name of the cornel-tree. See

Cormis sanguinea.

"CORNUS FLORIDA. Dogwood. This is a small native tree, well known for its ornamental flowers in most parts of the country, but more particularly in the middle and southern states. The bark of the trunk is rough externally, and of a brownish colour within. Its taste is a strong bitter, with some astringent and aromatic flavour. It appears to contain a bitter extractive substance, tannin, gallic acid, and a small portion of resin. This bark has been much employed as a tonic in various parts of the interior country. It is particularly used in intermittent fevers, and is applied to various other cases of debility, in which tonics are to various other cases of debuity, in which tonics are indicated. When fresh, it is sometimes liable to disorder the stomach and bowels, which tendency it is thought to lose by age. It may be given in powder in doses of one or two scruples. Although this species has been most attended to, there are several others of the same genus, which, from their bitterness, promise quite as much efficacy."—Big. Mat. Med. A.]
["Cornus circinata. Round-leafed dogwood. This

terior transparent convex part of the eye, which, in texture, is tough like horn. It has a structure peculiar to itself, being composed of a number of concentric cellular lamellæ, in the cells of which is deposited a any other in bitterness, and unites with this property the chemical and sensible evidences of astringency. It is highly valuable as a tonic and stomachic, and appears to be largely in use in some parts of the United States, particularly in Connecticut, where it is em-ployed as a substitute for cinchona, and has become an officinal article. It is exhibited in the same way as Cornus florida."—Big. Mat. Med. A.]

COR

["Cornus sericea. Swamp dogwood. This is another of the bitter cornels, native in the United States. Its properties resemble the preceding so much, that it is unnecessary to repeat them. Indeed, the genus Cornus in the northern hemisphere, like Cinchona in the southern, appears to have the same medical character pervading all its species, differing only in degree."—Big. Mat. Med. A.]

CORNUS SANGUINEA. The fruit is moderately cooling and astringent.

CORNU TA. (From cornu; from its resemblance to

a horn.) A retort.

COROLLA. (From coronula, a little crown.) The leaves of a flower which consist of those more delease. and dilated, generally more coloured leaves, which are always internal with respect to the calyx, between it and the internal organs of the flower, and which constitute its chief beauty. It always consists of one or more coloured leaves, which are termed *petals*. A coloured calyx is to be distinguished from a co-

rolla, which may be readily done in the Allyssum alpestre, and Lamium orvala.

There are four general divisions of corols.

1. Monopetalous, which consists of one petal, as in Nicotiana tabacum.

2. Polypetalous, having many; as in Lillium candi-

3. Compound, consisting of many corolla, which are not calyculated, and are on a common receptacle, and calyx; as in Helianthus annuus.

4. Aggregate, consisting of many calyculated corolla placed on a common calyx; as in Scabiosa arven

sis, and Echinops sparocephalus.

A. Corolla monopetala, formed of one petal, which, for the most part, forms a cavity, and is divided into, a. Limbus, the limb, which is the margin, or horizontal spreading portion.

Tubus, the tube, which is the cylindrical and inferior part, and is enclosed in the calyx.

 Fauces, or the orifice of the tube.
 From the figure of a regular or uniform limb are derived the following terms

1. Corolla campanulata, bell-shaped; as in Campanula and Atropa.

2. C. globosa, globular; as in Hyacynthus botryoides and Erica ramentacca.

3. C. Tubulosa, tubular, as in Primula and Erica Massoni.

4. C. claviculata; as in Erica tubiflora.

5. C. cyathiformis, cup-shaped; as in Sympathum officinale.

6. C. infundibuliformis, funnel-shaped; as in Nicotiana tabacum, and Datura stramonium.
7. C. hypocrateriformis, salver-shaped, a flat limb
upon a long tube; as in Vinca rosea.
8. C. rotata: wheel-shaped, that is, salver-shaped,

with scarcely any tube; as in Borago-officinalis, and Physalis alkekengi.

9. C. urccolata, saucer-like; as in Evolvulus alci-

10. C. contorta, obliquely bent; as in Vinca minor

and Norium oleander. 11. C. ligulata, the tube very short, and ending sud denly in an oblong petal; as in the corolla of the ra-

dius of the Helianthus annuus.

From the figure of an unequal limb:

 Corolla ringens, irregular and gaping like the mouth of an animal; as in Lamium album, and Salvia sclarea.

2. C. personata, irregular and closed by a kind of palate; as in Antirrhinum majus.

In the ringent and personate corollæ are to be no ticed the following parts:

a. Tubus, the inferior part.

b. Rictus, the space between the two lips. Faux, the orifice of the tube in the rectus. d. Galea, the helmet or superior arched lip.

e. Labellum or barba, the inferior lip.
f. Palatum, the palate, an eminence in the inferior lip which shuts the rictus of a personate corolla.
g. Calcar, the spur which forms an obtuse or acute

bag at the side of the receptacle.

3. C. bilabiata, two-lipped, the tube divided into two irregular lips opposite each other, without any visible rictus; as in Aristolochia bilabiata.

In the bilabiate corolla are to be noticed,

a. The tubus. b. The faux.

c. The superior lip, formed of one or two lobes.
d. The inferior lip, mostly three-lobed.
e. One-lipped, the upper or lower wanting, as in Aristolochia elematitis, and Tenerium.
Corolla infera, means that it is below the germen, which is the most common place of the corolla; and corolla supera, above the germen, as in roses

B. Corolla polypetala, formed of many petals.

In the petal of this division are noticed,

 a. The unguis, the claw, the thin inferior part.
 b. The lamina or border, the broader and superior part ; example, Dianthus caryophyllis.

From the number of uniform petals, the corol of

this division is named,

1. Dipetalous; as in Euphorbia graminea.
2. Tripetalous: as in Tradescantia virginica.
3. Tetrapetalous; as in Chieranthus incanus. Pentapetalous; as in Pæonia officinalis.
Hexapetalous; as in Lilium candidum.
Polypetalous; as in Rosa centifolia.

From the figure,

1. Malvaceous; pentapetalous, with its claws united laterally, so that it appears monopetalous; as in Malva sylvestris, and Alcea.

Rosaccous, spreading like a rose, pentapetalous, almost destitute of claws; as in Rosa canina, and

Paonia officinalis.

3. Liliaccous; six-petalled, sometimes three without a calyx; as in Lilium candidum.
4. Caryophyllaccous: five-petalled, with a long claw, spreading border, and a monophyllous tubular calyx; as in Dianthus caryophyllus, and Saponaria officinalis.

5. Cruciform; three-petalled, like a cross; as in Sinapis alba, and Lunaria alba.
6. Manifold, many corols lying one on another; as

in Cactus flagelliformis.

From the figure of unequal petals:

1. Orchideal, five petals, three of which are bent backward, and two are lateral and in the middle of these: the labellum is bent back on the nectary.

2. Papilionaceous, four petals, irregular and spreading, somewhat like a butterfly; as in Lathyrus latifolius, and Robinii pseudacacia.

In a papilionaceous corolla, observe, a. The vexillum, the standard or large concave one at the bark.

b. Ala, the wings or two side-petals, placed in the middle.

c. The carina, or keel, consisting of two petals, united or separate, embracing the internal organs.

3. Calcarate or spurred, pentapetalous, one petal formed into a spur-like tube.

C. Compound corolla; consisting of numerous flores, not calyculate, and within a common perianthium.

It affords,

a. The discus, disk, or middle.
b. The radius, which forms the circumference.
The marginal white florets of the daisy exemplify the rays, and the central yellow ones the disk.

From the difference in the florets of a compound

flower it is said to be,

a. Tubulate, when all the florets are cylindrical.
b. Ligalate or semiflosculose, shaped like a strap or riband; as in Leontodon taraxacum.

c. Radiate, if the florets in the radius are ligulate, and those in the disk tubular.

d. Semiradiate, the radius consisting of only a few ligulate florets on one side; as in Bidens. See also

COROLLULA. (A diminutive of corolla, a little wreath or crown.)

The partial petal, or floret of a compound flower.

CORO'NA. A crown. This term is used in ana-

tomy to designate the basis of some parts; and in bo-tany, to parts of plants, from their resemblance. In the writings of some botanists, it is synonymous with

CORONA CILIARIS. The ciliar ligament.
CORONA GLANDIS. The margin of the glans penis.
CORONA IMPERIALIS. A name for crown-imperial.
The Turks use it as an emetic. The whole plant is

CORONA REGIA. The melilotus.
CORONA SOLIS. See Helianthus annuus.
CORONA VENERIS. Venereal blotches on the forehead are so termed.

CORONAL. (Coronalis; from corona, a crown or garland.) Belonging to a crown or garland: so named because the ancients wore their garlands in its direction.

CORONAL SUTURE. Sutura coronalis; Sutura ar-cualis. The suture of the head, that extends from one temple across to the other, uniting the two parietal bones with the frontal.

CORONA'RIUS. See Coronary.
CORONARIÆ. The name of an order of plants in
Linnæus's Fragments of a Natural Method, consisting of such as have beautiful flowers, thus forming a

CORONARY. (Coronarius; from corona, a crown.) This term is applied to vessels and nerves, which supply the corona or basis of parts, or because they spread round the part like a garland or crown.

CORONARY LIGAMENTS. (From corona, a crown.) Ligaments uniting the radius and ulna. The term ligamentum coronarium is also applied to a ligament of the liver.

CORONARY VESSELS. Vasa coronaria. The arteries and veins of the heart and stomach.

CORONATUS. Little crown-like eminences on

the surface of the petal; or in Nerium oleander.

CORONATI. Coronaticus. The name of a class of plants in Linnæus's Fragments of a Natural Method, consisting of plants which have the seed-bud placed

under the flower-cup which serves it for a crown. CORO'NE. (Κορωνη, a crow: so named from its supposed likeness to a crow's bill.) The acute process

of the lower jaw-bone.

CORONOID. (Coronoideus; from κορωνη, a crow, and ωδος, likeness. Processes of bones are so called, and ειδος, likeness. Processes of bones are so called, that have any resemblance to a crow's beak; as coronoid process of the ulna, jaw, &c.

CORONO PUS. (From κορωνη, a carrion crow, and που, a foot; the plant being said to resemble a crow's foot.) See Plantago.

CORONULA. The hemor border which surrounds

the seeds of some flowers in the form of a crown.

CO'RPUS. 1. The body. See Body.

2. Many parts and substances are also distinguished by this name: as corpus callosum, corpus luteum, &c. Corpus albicans. Two white eminences in the basis of the brain, discovered by Willis, and called corpora albicantia Willisii.

A synonyme of the pons Va-CORPUS ANNULARE.

rolii. See Pons Varolii.

CORPUS CALLOSUM. Commissura magna cerebri.
The white medullary part joining the two hemispheres of the brain, and coming into view under the falx of the dura mater when the hemispheres are drawn from each other. On the surface of the corpus callosum two lines are conspicuous, called the raphe.

Corpus cavernosus clittoribis. See Clitoris.

CORPUS CAVERNOSUS CLITGRIDIS.

CORPUS CAVERNOSUS PENIS. See Penis.

CORPUS FIMBRIATUM. The flattened terminations of the posterior crura of the fornix of the brain, which turn round into the inferior cavity of the lateral ventri-

cle, and end in the pedes hippocampi.

CORPUS GLANDULOSUM. The prostate gland.

CORPUS LOBOSUM. Part of the cortical part of the

kidney

CORPUS LUTEUM. A yellow spot found in that part of the ovarium of females, from whence an ovum has proceeded; hence their presence determines that the female has been impregnated. The number of the corpora lutea corresponds with the number of impregnations. It is, however, asserted by a modern writer, that corpora lutea have been detected in young virgins, where no impregnations could possibly have taken place. taken place.

CORPUS MUCOSUM. See Rete mucosum.

CORPUS NERVEO-SPONGIOSUM. The cavernous substance of the penis.

CORPUS NERVOSUM. The cavernous substance of

the clitoris.

CORPUS OLIVARE. Two external prominences of the medulla oblongata, shaped somewhat like an olive, are called corpora olivaria.

CORPUS PAMPINIFORME. Applied to the spermatic chord and thoracic duct; also to the plexus of veins surrounding the spermatic artery in the cavity of the

adbomen. CORPUS PYRAMIDALE. Two internal prominences of the medulla oblongata, which are of a pyramidal shape, are called corpora pyramidalia.

CORPUS QUADRIGEMINUM. See Tubercula quadri-

gemina.

CORPUS RETICULARE. See Rete mucosum.
CORPUS SESAMOIDEUM. A little prominence at the
entry of the pulmonary artery.

CORPUS SPONGIOSUM URETHRE. Substantia spongiosa urethra. Corpus spongiosum penis. This sub-stance originates before the prostate gland, surrounds the urethra, and forms the bulb; then proceeds to the end of the corpora cavernosa, and terminates in the glans penis, which it forms.

CORPUS STRIATUM. So named from its appearance.

See Cerebrum.

CORPUS VARICOSUM. The spermatic chord.

CORRA'GO. (From cor, the heart; it being supposed to have a good effect in comforting the heart.) See

Borago officinalis. Corrs. (From κτιρω, to shave.) The temples. That part of the jaws where the beard grows, and

which it is usual to shave.

CORROBORANT. (Corroborans.) Whatever gives strength to the body; as bark, wine, beef, coldbath, &c. See Tonic.

CORROSIVE. (Corrosivus; from corrodo, to eat away.) See Escharotic.

Corrosive sublimate. The oxymuriate of mercury.

See Hydrargyri oxymurias.

CORRUGA'TOR. (From corrugo, to wrinkle.)

The name of muscles, the office of which is to wrin-

kle or corrugate the parts they act on.

CORRUGATOR SUPERCILLI. A small muscle situated on the forehead. Musculus supercilii of Winslow; Musculus frontalis verus, seu corrugator contenti of Douglas; and Catanio sourcillier of Dumas. When one muscle acts, it is drawn towards the other, and projects over the inner canthus of the eye. When both muscles act, they pull down the skin of the forehead, and make it wrinkle, particularly between the eyebrows.

CORTEX. (Cortex, icis. m. or f.) This term is generally, though improperly, given to the Peruvian bark. It applies to any rind, or bark.

CORTEX ANGELINE. The bark of a tree growing in Grenada. A decoction of it is recommended as a ver-It excites tormina, similar to jalap, and ope-

rates by purging.

CORTEX ANGUSTURE. See Cusparia.

CORTEX ANTISCORBUTICUS. The canella alba. See Winteria aromatica.

CORTEX AROMATICUS. See Winteria aromatica. CORTEX BELA-AYE. See Nerium antidysenteri-

CORTEX CANELLE MALABARICE. See Laurus

CORTEX CARDINALIS DE LUGO. The Peruvian bark : so called, because the Cardinal Lugo had testimonials of above a thousand cures performed by it in the year 1653.

CORTEX CEREBRI. The cortical substance of the brain. See Cerebrum.

CORTEX CHINE REGIUS. See Cinchona. CORTEX CHINE SURINAMENSIS. This bark is remarkably bitter, and preferable to the other species in intermittent fevers.

CORTEX CHINCHINE. See Cinchona.
CORTEX ELUTHERIE. See Croton cascarilla.
CORTEX GEOFFROY E JAMAICENSIS. See Geoffroya jamaicensis.

CORTEX JAMAICENSIS. See Acras sapota.

CORTEX LAVOLA. The bark bearing this name is supposed to be the produce of the tree which affords the Anisum stellatum Its virtues are similar.

CORTEX MAGRILLANICUS. See Winteria aromatica.

CORTEX MASSOY. The produce of New Guinea, where it is beaten into a pultaceous mass with water, and rubbed upon the abdomen to allay pain of the bowels. It has the smell and flavour of cinnamon. The produce of New Guinea,

CORTEX PATRUM. See Cinchona. CORTEX PERUVIANUS. See Cinchona.

CORTEX PERUVIANUS FLAVUS. See Cinchona. CORTEX PERUVIANUS RUBER. See Cinchona.

CORTEX POCGEREBE. A bark sent from America; said to be serviceable in diarrheas, and dysenteries.

CORTEX QUASSIX. See Quassia amara. CORTEX WINTERIANUS. See Winteria aromatica. CO'RTICAL. Corticalis. 1. Belonging to the bark of a plant or tree.

2. Embracing or surrounding any part like the bark of a tree; as the cortical substance of the brain, kid

ney, &c.
CORTICO'SUS. Like bark or rind. Applied to
the hard pod of the Cassia fistularis.
CORTU'SA. See Sanicula europaa.

Co'RU CANARICA. A quince-like tree of Malabar;

it is antidysenteric.

CORUNDUM. A genus of minerals, which, according to Jameson, contains three species; the octo-

hedral, rhomboidal, and prismatic.

CORYDALES. (From koous, a helmet.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants which have flowers somewhat resembling a helmet or hood. CO'RYLUS. (Derivation uncertain: according to

some, from καρυα, a wainut.) 1. The name of a genus of plants in the Linnaan system. Class, Monacia; Order, Polyandria.

2. The pharmacopæial name of the hazel-tree. See

Corylus avellana.

CORYLUS AVELLANA. The hazel-nut tree. The nuts of this tree are much eaten in this country; they are hard of digestion, and often pass the bowels very little altered; if, however, they are well chewed, they give out a nutritious oil. An oil is also obtained from the wood of this tree, Corylus avellana stipulis ovatis, obtusis, of Linnæus; which is efficacious against the toothache, and is said to kill worms.

CORYMBIFERÆ. (From corymbus; a species of florescence, and fero, to bear.) Plants which bear corymbal flowers.

corymbal flowers.

CORYMBUS. (Κορυμβον, οτ κορυμβος, a branch or cluster crowning the summit of a plant; from κορυς, a helmet.) A corymb. That species of inflorescence formed by many flowers, the partial flower-stalks of which are gradually longer, as they stand lower on the common stalk, so that all the flowers are nearly on a level; as in the Crysanthemum corymbosum. It is said to be simple, when not divided into branches; as in Thlaspi arcense, and Gnaphalium dentatum: and compound, when it has branches; as in Gnaphalium stachas.

Co'RYPHE. Kopvon. The vertex of the head .-

CORY'ZA. (Kopvía; from kapa, the head, and ¿tw, to boil.) An increased discharge of mucus from the nose. See Catarrh. Dr. Good makes this a genus of disease; running and the nose. It has two species,

Coryta entonica, and atonica.
Coscu'lla. The grains of kermes.
COSME'TIC. Cosmeticus. A term applied to remedies against blotches and freckles.

Co'snos. A regular series. In Hippocrates it is the order and series of critical days.

Co'ssis. A little tubercle in the face, like the head of a worm. Co'ssum. A malignant ulcer of the nose, men-

tioned by Paracelsus.

COSTA. A rib. 1. The rib of an animal. See Ribs.

2. The thick middle nerve-like cord of a leaf, which

proceeds from its base to the apex. See Lcaf.

Costa Herba. The Hypocharis radicata.

COSTALIS. (From costa, a rib.) Belonging to a

rib: applied to muscles, arteries, nerves, &c.

Costa pulmonaria. Very probably the Hypocharis
radicata, or long-rooted hawk-weed, which was used

in pulmonary affections, and pains of the side.

COSTA'TUS. Ribbed. Applied to leaves, and is synonymous with nervous: the leaf having simple lines extended from the base to the point. See Leaf.

Costo-Hyoldeus. A muscle, so named from its origin and insertion. See Omohyoideus.

CO'STUS. (From kasta, Arabian.) The name of a genus of plants in the Linnman system. Class, Monandria; Order, Monogynia.

COSTUS AMARUS. See Costus arabicus.

COSTUS ARABICUS. The systematic name of the Costus indicus; amarus; dulcis; orientalis. Sweet and bitter costus. The root of this tree possesses bitter and aromatic virtues, and is considered as a good ter and aromatic virtues, and is considered as a good stomachic. Formerly there were two other species, the bitter and sweet, distinguished for use. At present, the Arabic only is known, and that is seldom employed. It is, however, said to be stomachic, diaphoretic, and diuretic.

Costus corticosus. The canella alba. Costus hortorum minor. The Achilla ageratum.

COSTUS MIGRA. The artichoke.
COTARO'NIUM. A word coined by Paracelsus, implying a liquor into which all bodies, and even their

elements, may be dissolved.

Co'τιs. (From κοτ/η, the head.) The back part of the head; sometimes the hollow of the neck.

CO'TULA. (Cotula, diminutive of cos, a whetstone, from the resemblance of its leaves to a whetstone; or from κο/νλη, a hollow.) Stinking chamomite.

["COTULA. Mayweed. The anthemis cotula is an annual weed imported from Europe, and now very common by road sides throughout the United States. Its taste is strong, disagreeable, and bitter. In small quantities it is tonic, stimulating, and diaphoretic; in large ones emetic and sudorific. It is commonly given in infusion."—Big. Mat. Med. A.]

CO'TULE. (Κοτυλη, the name of an old measure.)

CO'TULE. (Κοτυλη, the name of an old measure.)
The socket of the hipbone. See Actabulum.
COTTULA FŒTIDA. See Anthemis cotula.
COTYLEDON. (Cotyledon, onis. f.; from κοτυλη, a cavity.) Seed-lobe, or cotyledon. The cotyledones are the two halves of a seed, which, when germinating, become two pulpy leaves, called the seminal leaves. These leaves are often of a different form from those which are about to appear; as in the Raphanus sativus; and sometimes they are of another colour; as in Cannabis sativa, the seminal leaves of which are white.

Almost all the cotyledons wither and fall off, as the

Almost all the cotyledons wither and fall off, as the

plant grows up.

These bodies are spoken of in the plural, because it it is much doubted whether any plant can be said to have a solitary cotyledon, so that most plants are dicotyledonous. Plants without any, are called acotyledones. Those with more than two, polycotyledo-

Between the two cotyledons of the germinating seed, is seated the *embryo*, or germ of the plant, called by Linneus, *corculum*, or little heart, in allusion to the heart of the walnut. Mr. Knight denominates it the germen: but that term is appropriated to a very dif-ferent part, the rudiment of the fruit. The expanding embryo, resembling a little feather, has, for that reason, been called by Linnæus, plumula: it soon becomes a tuft of young leaves, with which the young stem ascends. See Corculum.

COTYLOID. (Cotyloides; from κοτυλη, the name of an old measure, and ειδος, resemblance.) Resembling the old measure, or cotule.

COTYLOID CAVITY. The acetabulum. See Innominatum of

COTYLOIDES .- See Cotyloid.

COUCHING. A surgical operation that consists in removing the opaque lens out of the axis of vision, by means of a needle constructed for the purpose.

Couch-grass. See Triticum repens. COUGH. Tussis. A sonorous co A sonorous concussion of the thorax, produced by the sudden expulsion of the air from the chest through the fauces. Co'um. The meadow-saffron. See Catarrh.

COUNTER-OPENING. COUNTER-OPENING. Contra-apertura. An opening made in any part of an abscess opposite to one already in it. This is often done in order to afford a readier egress to the collected pus.

Coup de soleil. The French for an crysipelas or appoplery, or any affection produced instantaneously.

apoplexy, or any affection produced instantaneously from a scorching sun.

Cou Rap. (Indian.) The provincial name of a disease of the skin common in Java, and other parts of the East Indies, accompanied by a perpetual itching and discharge of matter.

Cou'RBARIL. The tree which produces the gum anime. See Anime.

COURO'NDI. An evergreen tree of India, said to be antidysenteric.

COURDY MORLLI. A shrub of India, said to be antivenomous.

Cou'scous. An African food, much used about the river Senegal. It is a composition of the flour of millet, with some flesh, and what is there called lalo.

millet, with some flesh, and what is there called lalo.

COVOLA'M. See Cratava marmelos.

COWHAGE. See Dolichos pruriens.

COW-ITCH. See Dolichos pruriens.

COWPER, WILLIAM, was born about the middle of the 17th century, and became distinguished as a surgeon and anatomist in this metropolis. His first work, entitled "Myotomia Reformata," in 1694, far excelled any which preceded it on that subject in correctness, though since surpassed by Albinus. Three years after, he published at Oxford "the Anatomy of Human Bodies," with splendid plates, chiefly from Bidloo; but forty of the figures were from drawings made by himself; he added also some ingenious and made by himself; he added also some ingenious and useful anatomical and surgical observatious. Having been accused of plagiarism by Bidloo, he wrote an apology, called "Eucharistia;" preceded by a description of some glands, near the neck of the bladder, which have been called by his name. He was also author of several communications to the Royal Society, and some observations inserted in the anthropologia of Drake. He died in 1710. Drake. He died in 1710.

COWPER'S GLANDS. (Cowperi glandulæ; named from Cowper, who first described them.) Three large muciparous glands of the male, two of which are situated before the prostate gland under the accelerator muscles of the urine, and the third more forward, before the bulb of the urethra. They excrete a fluid, similar to that of the prostate gland, during the vene-

real orgasm.

COWPE'RI GLANDULE. See Comper's glands.
CO'XA. The ischium is sometimes so called, and sometimes the os coccygis.

COXE'NDIX. (From coza, the hip.) The ischi-

um; the hip-joint.

Crablouse. A species of pediculus which infests the axillæ and pudenda.

[The crab-louse is not a pediculus, but belongs to the genus of acarus. If the parts infested by them be washed with an infusion of tobacco, it will soon kill these vermin. A.]

Crab-yaws. A name in Jamaica for a kind of ulcer

Crab-yazes. A name in Jamaica for a king of uncer-on the soles of the feet, with callous lips, so hard that

it is difficult to cut them.

["CRAIK, JAMES, M.D. Dr. Craik was born in Scotland, where he received his education for the medical service of the British army. He came to the colony of Virginia in early life, and had the nonour to accompany the youthful Washington in his expedition against the French and Indians in 1754, and returned in safety after the hattle of the Meadows, and surrender of Fort Necessity. In 1755, he attended Braddock in his march through the wilderness, and on the 9th of July, assisted in dressing the wounds of that brave, but neffectively commender. At the close of the but unfortunate commander. At the close of the French war, the subject of this article resumed and continued his professional labours till the commence-ment of the Revolution in 1775. By the aid of his early and fast friend, General Washington, he was transferred to the Medical Department in the Conti nental army, and rose to the first rank and distinction. In 1777, he had an opportunity, which he gladly embraced, to show his fidelity to his General, and to his braced, to show his fidelity to his General, and to his adopted country, by taking an active part in the developement of a nefarious conspiracy, the object of which was the removal of the commander in chief. In 1780, he was deputed to visit Count de Rochambeau, then recently arrived at Rhode-Island, and to make arrangements for the establishment of Hospitals to accommodate the French army. Having performed this difficult duty, he continued in the army to the end of the war, and was present at the surrender of Cornwallis, on the memorable 19th October, 1781.

After the cessation of hostilities, the Doctor settled as a physician in Charles County, in Maryland, but soon removed to the neighbourhood of his illustrious friend and companion, the farmer of Mount Vernon, at his particular, repeated, and urgent request. In

at his particular, repeated, and urgent request. In 1798, when, like a guardian angel, the never to be for-

gotten Washington again stepped forth to redress the wrongs of his country; the venerable Craik was once more appointed to his former station in the medical staff. With the disbandment of the army, then called into service, ceased the public professional labours of the subject of this memoir, whose life, for nearly half a century, has been devoted with zeal and high repu-

tation to the cause of his country.

One trying duty yet remained to be performed; it was to witness the closing scene, and to receive the last sigh of his revered commander, the most distinguished man of his age. Their youthful commissions had been signed on the same day; they had served together in the ranks of war; their friendship was cemented by a social intercourse of fifty years' continuous and they were greatly endeared to each other by ance, and they were greatly endeared to each other by common toils, privations, and honours. At length the moment of parting arrived; it was tender, affectionate, solemn, and impressive. In reference to that painful event, the Doctor is said to have expressed himself in this manner: "I, who was bred amid scenes of human calamity, who had so often witnessed death in its direst and most awful forms, believed that its terrors were

and most awful forms, believed that its terrors were too familiar to my eye to shake my fortitude; but when I saw this great man die, it seemed as if the bonds of my nature were rent asundet, and that the pillar of my country's happiness had falien to the ground."

As a physician, Dr. Craik was greatly distinguished by his skill and success, and his professional merits were highly and justly appreciated. In the various relations of private life, his character was truly estimable, and his memory is precious to all who had the happiness and the honour of his acquaintance. He was one, and what a proud eulogy it is, of whom the immortal Washington was pleased to write, "my compatriot in arms, my old and intimate friend." He departed this life at the place of his residence in Fair-

compatriot in arms, my old and intimate friend." He departed this life at the place of his residence in Fairfax county, on the 6th February, 1814, in the 84th year of his age."—Thach. Med. Biog. A.] CRA'MBE. (Κοαμδη, the name given by Dioscorides, Galen, and others, to the cabbage; the derivation is uncertain.) The name of a genus of plants in the Linnæan system. Class, Tetradynamia; Order, Siticulosa. Cabbage.

CRAMBE MARITIMA. The systematic name for the sea-cole, or sea-kale. A delicious vegetable when forced and blanched. It is brought to table about Christmas, has a delicate flavour, and is much esteemed. Like to all oleraceous plants, it is flatulent and watery.

CRAMP. (From krempen, to contract. Germ.)

CRANESBILL. See Geranium.

Cranesbill, bloody. See Geranium sanguineum. CRA'NIUM. (Koavov, quasi карачоv; from кара, the head.) The skull or superior part of the head.

CRANTE RES. (From κραινω, to perform.) A name given to the dentes sapientiæ and other molares, from

their office of masticating the food.

CRA'PULA. (Κραιπυλα:) A surfeit; drunkenness.

CRA'SIS. (From κτραννυμτ, to mix.) Mixture.

A term applied to the numburs of the body, when there is such an admixture of their principles as to constitute a healthy state: hence, in dropsies, scurvy, kc. the crasis, or healthy mixture of the principles of the blood, is said to be destroyed.

Caa spedon. (Κρασπεδον, the hem of a garment; from κρεμαω, to hang down, and πεδον, the ground.) A relaxation of the uvula, when it hangs down in a thin, long membrane, like the hem of a garment.

CRASSAME NTUM. (From crassus, thick.) See

CRA'SSULA. (From crassus, thick: so named from the thickness of its leaves.) See Sedum tele-

CRATE'GUS. (From \$\sigma a705\$, strength: so called from the strength and hardness of its wood.) The wild service-tree, of which there are many, are all species of the genus Pranus. The fruits are most of them

CRATEVA. (So called from Cratevas, a Greek physician, celebrated by Hippocrates for his knowledge

of the tree strengthens the stomach, and relieves hy-

pochondriac languors.

CRATI'CULA. (From crates, a hurdle.) The bars or grate which covers the ash-hole in a chemical fur-

CRATON, John, called also Craffthem, was born at Breslaw in 1519. He was intended for the church, at Breslaw in 1519. He was intended for the church, but preferring the study of medicine, went to graduate at Padua, and then settled at Breslaw. But after a few years he was called to Vienna, and made physician and aulic counsellor to the Emperor Ferdinand I.: which offices also he held under the two succeeding emperors, and died in 1585. His works were numerous: the principal are, "A Commentary on Syphilis;" "A Treatise on Contagious Fever;" another on "Therapeutics;" and seven volumes of Epistles and Consultations. sultations.

Cream of tartar. See Potassæ supertartras.
CREMA'STER. (From κοιμαω, to suspend.) A
muscle of the testicle, by which it is suspended, and
drawn up and compressed, in the act of coition. It drawn up and compressed, in the act of coulon. It arises from Poupart's ligament, passes over the spermatic chord, and is lost in the cellular membrane of the scrotum, covering the testicles.

CRE'MNUS. (From κρημνος, a precipice, or shelving place.) 1. The lip of an ulcer.

2. The labium pudendi.

CRE'MOR. 1. Cream. The oily part of milk which rises to the surface of that liquid mixed with a

CRE'MOR. 1. Cream. The oily part of milk which rises to the surface of that liquid, mixed with a little curd and serum. When churned, butter is ob tained. See Milk.

2. Any substance floating on the top, and skimmed off.

CRENATUS. Crenate or notched, applied to a leaf or petal, when the indentations are blunted or rounded, and not directed toward either end of the leaf; as in Glecoma hederacea. The two British species of Salvia are examples of doubly crenate leaves.

cies of Salvia are examples of doubly crenate leaves. The petals of the Linum usitatissimum are crenate. CRE'PITUS. (From crepo, to make a noise.) A puff or little noise. The word is generally employed to express the pothognamonic symptoms of air being collected in the cellular membrane of the body; for when air is in these cavities, and the part is pressed, a little cracking noise, or crepitus, is heard.

CREPITUS LUPI. See Lycoperdon bovista.

Crescent shaped. See Leaf.

CRESS. There are several kinds of cresses eaten at the table, and used medicinally, as antiscorbutics.

at the table, and used medicinally, as antiscorbutics.

Cress, water. See Sisymbrium nasturtium aquati-

CRE'TA. Chalk. An impure carbonate of lime.

CRETA PRAPARATE. Take of chalk a pound; add a little water, and rub it to a fine powder. Throw this into a large vessel full of water; then shake them, and after a little while pour the still turbid liquor into another vessel, and set it by that the powder may subanother vessel, and set it by that the powder may subside; lastly, pouring off the water, dry this powder. Prepared chalk is absorbent, and possesses antacid qualities: it is exhibited in form of electuary, mixture, or bolus, in pyrosis, cardialgia, diarrhæa, acidities of the primæ viæ, rachitis, crusta lactea, &c. and is said by some to be an antidote against white arsenic.

Cretaceous acid. See Carbonic acid.

Cretaceous acid. See Carbonic acid.
Crete, dittany of. See Origanum dictamnus.
CRETINISMUS. Cretinism. A species of Cyrtosis in Dr. Good's Nosology: a disease affecting chiefly the head and neck; countenance vacant and stupid; mental faculties feeble, or idiotic; sensibility obtuse, mostly with enlargement of the thyroid gland.
CRIBRIFO'RM. (Cribriformis; from cribrum, a sieve, and forma, likeness; because it is perforated like a sieve.) Perforated like a sieve. See Ethmoid bone.

CRICHTONITE. A mineral named after Dr. Crichton, which Jameson thinks is a new species of titanium ore. It is of a splendent velvet black colour. CRI'CO. Names compounded of this word belong

to muscles which are attached to the cricoid cartilage. CRICO-ARYTENOIDEUS LATERALIS. Crico-lateri arithenaidien of Dumas. A muscle of the glottis, that opens the rima by pulling the ligaments from each

of plants.) The name of a genus of plants. Class, other.

Polyandria; Order, Monogymia.

CRATEVA MARMELOS. The fruit is astringent while unripe; but when ripe, of a delicious taste. The bark opens the rima glottidis a little, and by pulling back

the thyroid cartilage, or elevates and draws backwards the cricoid cartilage.

the cricoid cartilage.

CRICOI'D. (Cricoides; from κρικος, a ring, and κόος, resemblance.) A round ring-like cartilage of the larynx is called the cricoid. See Larynx.

CRIMNO'DES. (From κριμνον, bran.) A term applied to urine, which deposites a sediment like bran.

CRINA'TUS. (From κριμνον, the lily.) A term given to a suffumigation mentioned by P. Ægineta, composed chiefly of the roots of lilies.

chiefly of the roots of lilies.

CRI'NIS. The hair. See Capillus.

CRINOMY RON. (From κρινον, a lily, and μυρον, ointment.) An ointment composed chiefly of lilies.

CRINONES. (From crinis, the hair.) Malis gordii of Good. Morbus pilaris of Hotst. Malis à cridii of Good. Morbus pilaris of Horst. Malis a cri-nonibus of Elmuller and Sauvages. Collections of a sebaceous fluid in the cutaneous follicles upon the face and breast, which appear like black spots, and when pressed out, look like small worms, or, as they are commonly called, maggots.

CRIO'GENES. An epithet for certain troches, mentioned by P. Ægineta, and which he commends for cleansing ulcers.

CRIPSO'RCHIS. (From κρυπ7ω, to conceal, and ορχις, a testicle.) Having the testicle concealed, or not yet descended from the abdomen into the scrotum. tum.

CRI'SIS. (From κρινω, to judge.) The judgment. The change of symptoms in acute diseases, from which the recovery or death is prognosticated or judged of.

CRISPATU'RA. (From crispo, to curl.) A spas-modic contraction or curling of the membranes and

fibres CRISPUS. Curled. Applied to a leaf, when the border is so much more dilated than the disk, that it necessarily becomes curled and twisted; as in Malva

crispa, &c.
CRI'STA. (Quasi cerista; from κερας, a horn, or εarista; from καρα, the head, as being on the top of the head.) Any thing which has the appearance of a crest, or the comb upon the head of a cock. 1. In anatomy it is thus applied to a process of the ethmoid bone, christa galli, and to a part of the nympha; crista clitoridis.

2. In surgery, to excrescences, like the comb of a

cock, about the anus.

3. In botany, to several accessary parts or appendages, chiefly belonging to the antherw of plants; as the pod of the Hedysarum crista galli, &c.

CRISTA GALLI. An eminence of the ethmoid bone, so called from its resemblance to a cock's comb. See

CRISTATUS. Crested. Applied to several parts

of plants.
CRI'THAMUM. See Crithmum.

CRI'THE. (Κριθη, barley.) A stye or tumour on the eyelid, in the shape and of the size of a barley-

CRITHE'RION. (From κρινω, to judge.) The same

CRITHMUM. (From κρινω, to secrete; so named from its supposed virtues in promoting a discharge of

the urine and menses.) Samphire or sea-fennel.

CRITHMUM MARITIMUM. The Linnman name of the samphire or sea-fennel. Crithmum of the pharmacopæias. It is a low perennial plant, and grows macopeias. It is a low perennial plant, and grows about the sea-coast in several parts of the island. It has a spicy aromatic flavour, which induces the common people to use it as a pot-herb. Pickled with vine-gar and spice, it makes a wholesome and elegant condiment, which is in much esteem.

CRITHO DES. (From κριθη, barley, and ειδος, resemblance.) Resembling a barley-corn. It is applied to small protuber access.

CRITICAL (Criticals from crisis) from κείνει.

CRITICAL. (Criticus; from crisis; from κείνω, to judge.) Determining the event of a disease. Many physicians have been of opinion, that there is something in the nature of fevers which generally determining the property of the control of the cont mines them to be of a certain duration; and, therefore,

the arytenoid cartilage, stretches the ligament so as to make it tense.

CRICO-PHARYNGEUS. See Constrictor pharyngis inferior.

CRICO-THYPOIDEUS. Crico-thyroidien of Dumas.
The last of the second layer of muscles between the os hyoides and trunk, that pulls forward and depresses on hyoides and trunk, that pulls forward and depresses on the continued fevers especially to happen, are the third, and twentieth.

CROCIDIXIS. (From κροκιδιξω, to gather wool.) Floccilation. A fatal symptom in some diseases, where the patient gathers up the bed-clothes, and seems to pick up substances from them.

CRO'CINUM. (From крокоς, saffron.) A mixture of oil, myrrh, and saffron.

CROCO'DES. (From κροκος, saffron; so called from the quantity of saffron they contain.) A name of some old troches.

CROCOMA'GMA. (From κροκος, saffron, and μαγμα, the thick oil or dregs.) A troch made of oil of saffron and spices

CRO'CUS. (Kpokos of Theophrastus. The story of the young Crocus, turned into this flower, may be seen in the fourth book of Ovid's Metamorphoses. Some derive this name from κροκη or κροκις, a thread; whence the stamens of flowers are called κροκιδες. Others, again, derive it from Coriscus, a city and mountain of Cilicia, and others from crokin, Chald.) Saffron.

1. The name of a genus of plants in the Linnaan system. Class, Triandria: Order, Monogynia. Saf-

2. The pharmacopæial name of the prepared stig-

mata of the saffron plant. See Crocus sativus.

3. A term given by the older chemists to several preparations of metallic substances, from their resemblance: thus, Crocus martis, Crocus veneris.
CROCUS ANTIMONII. A sulphuretted oxide of an-

timony.

CROCUS GERMANICUS. See Carthamus. CROCUS INDICUS. See Curcuma. CROCUS MARTIS. Burnt green vitriol.

CROCUS METALLORUM. A sulphuretted oxide of antimony.

CROCUS OFFICINALIS. See Crocus satious.
CROCUS SARACENICUS. See Carthamus.
CROCUS SATIVUS. The systematic name of the

saffron plant. Crocus:—spatha univalvi radicali, corolla tubo longissimo, of Linnæus. Saffron has a powerful, penetrating, diffusive smell, and a warm, pungent, bitterish taste. Many virtues were formerly attributed to this medicine, but little confidence is now placed in it. The Edinburgh College directs a tincture, and that of London a syrup of this drug.

CROCUS VENERIS. Copper calcined to a red powder.

CROCHS VENERIS. Copper calculated a real powder. Cro'mmyon. (Παρα το τας κορας μυειν, because it makes the eyes wink.) An onion.

Crommyontre gma. (From κρομμυον, an onion, οξυς, acid, and ρηγνυμι, to break out.) An acid eructation accompanied with a taste resembling onions.

CROONE, William, was born in London, where he settled as a physician, after studying at Cambridge. In 1659, he was chosen rhetoric professor of Gresham. In 1659, he was chosen rhetoric professor of Gresham College, and soon after register of the Royal Society, which then assembled there. In 1662, he was created doctor in medicine by mandate of the king, and the same year elected fellow of the Royal Society, and of the College of Physicians. In 1670, he was appointed lecturer on anatomy to the Company of Surgeons. On his death, in 1684, he bequeathed them 1904; his books on Medicine to the College of Physicians, as also the profits of a house, for Lectures, to be read annually, on Muscular Motion; and donations to seven of the colleges at Cambridge, to found Mathematical Lectures. He left several papers on philosophical subjects, but his only publication was a small tract, "De jects, but his only publication was a small tract, "De Ratione Motus Musculorum."

CROSS-STONE. Harmotome; Pyramidal zeolite.

A crystallized grayish-white mineral, harder than fluor-spar, but not so hard as apatite, found only in mineral veins and agate balls in the Hartz, Norway,

and Scotland.

CROTALUS. The name of a genus of reptiles. CROTALUS HORRIDUS. The rattle-snake; the stone out of the head of which is erroneously said to be an antidote to the poison of venomous animals. A name also of the Cobra de capella, the Coluber naje of Linnæus.

CHOTA PHICA ARTERIA. The tendon of the tempo-

CROTAPHITES. (From \$607a805, the temple.)

See Temporalis.

CROTA PHIUM. (From κροζεω, to pulsate; so named from the pulsation which in the temples is eminently discernible.) Crotaphos. Crotaphus. A pain in the

CRO TAPHOS. See Crotaphium. CROTCHET. A curved insur-

A curved instrument with a sharp hook to extract the fœtus.

CRO TON. (From $\kappa\rho\sigma 7\epsilon\omega$, to beat.)

1. An insect called a tick, from the noise it makes by beating its head against wood.

2. A name of the ricinus or castor-oil berry, from its

likeness to a tick.

Inkeness to a tick.

3. The name of a genus of plants in the Linnman system. Class, Monacia; Order, Monadelphia.
CROTON BENZOE. See Styraz benzoe.
CROTON CASCARILLA. The systematic name of the plant which affords the Cascarilla bark. Cascarilla; Chocarilla; Elutheria; Elutria. The bark comes to us in quills, covered upon the outside with a rough, whitish matter, and brownish on the inner side, exwhitish matter, and brownish on the inner side, exhibiting, when broken, a smooth, close, blackish-brown surface. It has a light agreeable smell, and a moderately bitter taste, accompanied with a considerable aromatic warmth. It is a very excellent tonic, adstringent, and stomachic, and is deserving of a more general use than it has hitherto met with.

CROTON LACCIFERUM. The systematic name of the plant upon which gum-lac is deposited. See

CROTON TIGLIUM. The systematic name of the tree which anords the pavana wood, and tiglia seeds.

Croton-folis ovatis glabris acuminatis serratis, caule arborco of Linnæus.

1. Pavana wood. Lignum pavanæ; Lignum pavanum; Lignum moluccense. The wood is of a light spongy texture, white within, but covered with a grayish bark: and possesses a pungent, caustic taste, and a disagreeable smell. It is said to be useful as a

purgative in hydropical complaints.
2. Grana tiglia. Grana tilli. Grana tiglii. The grana tiglia are seeds of a dark gray colour, in shape very like the seed of the ricinus communis. abound with an oil which is far more purgative than castor-oil, which has been lately imported from the East Indies, where it has been long used, and is now admitted into the London pharmacopæia. One drop proves a drastic purge, but it may be so managed as to become a valuable addition to the materia me-

(The oil of Croton is the produce of a shrub or arborescent plant well known to botanists, and the oil when taken into the stomach acts as a powerful ca-thartic. The shrub belongs to the Class Monacia, and

Order, Monadelphia, of Linnaus's sexual system.

Persoon enumerates 82 species of this genus of plants. The specific character of the Tilgium is, that "The leaves are ovate, smooth, acuminated, serrated, and the stem arborescent." It is a native of the East Indies, China, and other Australasian islands. Ceylon, The specific character of the Tilgium is, that and the Moiuccas are particularly quoted as affording this species of Croton. It is also well known in Am-boyna and Batavia, and, indeed, generally through the distant east. Several parts of the plant possess medicinal virtue.

1. Radix, the root, or pulvis radicis croti. The powdered root of Croton is a drastic cathartic, when exhibited in the small quantity of even a few grains, on which account it has been considered by the Asiatics as a grand remedy for dropsy, upon the same principle by which the operation of scammony and gamboge is

explained. 2. The Wood of the Croton. Lignum croti tiglii. This is also efficacious, for in small doses it acts as a sudorific, by relaxing the pores of the skin; while in

large ones it purges severely.
3. The Leaves. Folia croti tiglii. Pulvis foliorum tiglii siccatorum. The dried leaves when powdered are reputed an antidote against the bite of that formidable and venomous serpent the Cobra de Capello.

4. The Seeds. Semina vel grana croti tiglii. They are the part of the plant most known and employed in medicine. They are of a date at least as old as the

age of Serapion, one of the earliest physicians of Arabia who wrote on the Materia Medica, and he flourished about 1000 years ago, or probably in the 8th century. When they were introduced into Europe long since, they were known by the name of "Molucca and as the writes of seeds of Tilliam. grains or seeds, and as the grains or seeds of Tilium

or Tiglium. It appears that they were freely administered, not merely for the purpose as a cathartic, but for the accomplishment of mischievous and deleterious ends. It is even stated by the accomplished Rumphius, the Dutch physician and botanist, that a dose of four grains had been administered for the working of destruction by women who wished to kill their husbands. Though the seeds were freely administered at that age and after, the extreme violence of their operation scores to be a president of the control of tion seems to have induced a very unfavourable opinion of them. This no doubt arose from injudicious doses; as, under similar circumstances, the digitalis purpurea, or purple fox-glove, had undergone a similar fate. It had been frequently administered, and was even popular, but from the bad consequences of injudictious prescription, was condemned as noxious, and was neglected as unfit for use. So, cubebs (amonum cubeba) were once in use, then discontinued from a supposed want of rough and letterly recorded. supposed want of power, and latterly revived and rendered fashionable. It nevertheless appears, that molucca grains are still used in the East Indies as an effectual cathartic.

5. The baked Seeds. Semina tosta vel furno cocta. The baked or roasted seeds of the Croton Tiglium. By these operations the shell or hull was removed, the seed rendered capable of being powdered, and, according to Ainslie's Materia Medica of Hindostan, the acrimonious and vehement qualities very much mo-

derated.

The medicinal history of this plant seems to have rested a long time. At length, however, as the seeds were replete with oil, it occurred to somebody to exwere replete with oil, it occurred to somebody to express it, and this oil was known to the celebrated pharmacians, Lemery and Geoffroy. Yet it lay dormant, until a revival was made by Mr. E. Conwell, of the Eaglish East India Company's service on the Madras Establishment. Having prescribed the Croton oil for many years with advantage, he sent a parcel of it to London for experiment.

6. The Oil of Tiglium, or oil of Croton. Oleum, croti tiglii expressum. The oil has a yellowish hue, but a faint smell, and an acrimonious taste. Though

but a faint smell, and an acrimonious taste. Though these qualities have some variation, caused probably by the degree of heat, or torrefaction, employed in the

process for obtaining it.

7. Gustus olci tiglii. Touching the tongue with the oil. It is reported, that in some constitutions the mere application of a particle to the tongue, is sufficient to produce a cathartic effect, thereby evincing an extraordinary power of sympathy between the organ of taste and the alimentary canal. There are, however, very striking analogies to illustrate its action. Tobacco, for example, in the form of a segar, applied to the mouth of some persons, moves the intestines to evacuation. A drop of the Prussic acid applied to the mouth of a rat causes instant death. The poison of a rattlesnake, as witnessed by Dr. Mitchill, infused in a wound, destroys the life of a rat, or other small animal in an exceedingly short time. It is reported, that a man who had been in the babit of using enemas, had been brought to a stool by the sight of a clystercient to produce a cathartic effect, thereby evincing an had been brought to a stool by the sight of a clyster-

8. Pills of the Oil of Tiglium. Pillulæ olei tiglii. A single drop, or at most two, is a sufficient dose. A safe method is to take the pills, to contain each one drop, with a crumb of bread; or, for more expeditious practice, the prescriber may prepare them containing two drops. He can thus administer with an assurance that the laxative effect will be produced without the fear of exciting any alarming commotion. In cases where there is an aversion to taking medicines, and where the bulk and repetition of the doses are objectionable, this remedy therefore possesses advantages which highly recommend it. The quantity of even half a drop, or in other words half a grain, will frequently move the intestines to discharge; and the ef-fect, which is generally speedy, more resembles that of the saline cathartics than the other drastics, such as elaterium, gamboge, and scammony.

9. Tincture of the Oil of Tigliam. Solutio olei

100

The latter has been denominated Tiglin, in the modern nomenclature. Alkohol is capable of decomposing this native oil; the tiglin being dissolved with a minute quantity only of the fixed oil, and the rest of it left un-combined. This discovery enables us to form a tineture upon a well-ascertained principle. It is accordingly proposed to form the tincture, by adding two drops of the oil (as it comes to us) to a fluid drackm of rectified spirit. After digesting long enough to secure the minon between the spirit and the tiglin, the tincture must be filtered. Yet, as a fluid so volatile as the must be filtered. Yet, as a fluid so volatile as the spirit will suffer some loss by evaporation, it is calcu-lated that half a fluid drachm of the tincture is equal to a drop and an half of the oil. It is found that the alkohol does not impair the cathartic power of the tiglin. This solution may therefore be exactly apportioned to the nature of the disorder, and the wish of the physician, and thus be regulated with the greatest exact-If taken in quantity corresponding to the number of drops decomposed, experience has decided that, the same effects were produced as by the same quantity

the same effects were produced as by the same quantity of undecompounded and entire oil. —

An article so expensive as this in comparison with other fixed oils, holds out a strong temptation for fraud by adulteration. This has been practised to a considerable extent by mixing it with the cheaper kinds. A method, however, has been proposed for detecting such vitiation by Dr. Nimmo, by means of alkohol, a phial, a balance, and an evaporating process, of hol, a phial, a balance, and an evaporating process, of which an abstract will be found in the Pharmacologia of Dr. Paris, vol. 2, p. 338. New-York edit. by Dr. Ives. This writer's opinion is, on the whole matter, "that this oil does not appear to produce any effects which cannot be commanded by other drastic purgatives. Its value depends upon the facility with which tives. Its value depends upon the facility with which it may be administered.—Notes from Dr. Mitchill's

Lectures on Mat. Med. A]
CROTON TINCTORIUM. The systematic name of the lucmus plant. Croton—feliis rhombeis repandis, capsulis pendulis, caule herbaceo, of Linnaus. Bezetta
carulea. This plant yields the Succus heliotropii;
Lacmus seu torna; Lacca carulea; Litmus. It is
much used by chemists as a test.
Chorulus. (From as a test.

CROTO'NE. (From κρογον, the tick.) A fungus on trees produced by an insect like a tick; and by metaphor applied to tumours and small fungous excres-

cences on the periosteum.

CROTOPUS. (From kporos, pulsus.) Painful pulsa-

CROTOPHIUM. (From Kgoros, the pulse.) Painful pulsation

CROUP. See Synanche.

CROUSIS. (From κρουω, to beat, or pulsate.) Pul-

CROU'SMATA. (From κρουω, to pulsate.) Rheums or defluxions from the head.
CROWFOOT. See Ranunculus.
Crowfoot-cranesbill. See Geranium pratense.
CRUCIAL. (Crucialis; from crus, the leg.) 1.
Cross-like. Some parts of the body are so called when they cross one another, as the crucial ligaments of the thigh. of the thigh.

A name of the mugweed or crosswort.

CRUCIALIS. See Orucial. CRUCIBLE. (Crucibulum; from crucio, to tor-CRUCIBLE. ment: so named, because, in the language of old ment: so named, because, in the language of old chemists, metals are tormented in it, and tortured, to yield up their powers and virtues.) A chemical vessel made mostly of earth to bear the greatest heat. They are of various shapes and composition.

CRUCIFORMIS. Cross-like. Applied to leaves, flowers, &c. which have that shape.

CRUDITAS. (From crudus, raw.) It is applied to undigested substances in the stomach, and formerly to humours in the body unprepared for concoction.

CRUICKSHANK, WILLIAM, was born at Edinburgh, in 1746. He was intended for the church, and

Doctor. He contsibuted largely to enrich the Museum, particularly by his curious injections of the lympathic vessels. He published, in 1795, a work on this subject, which is highly valued for its correctness. In 1795, he communicated to the Royal Society an Account of the Regeneration of the Nerves; and the same year published a pamphlet on Insensible Perspiration; and in 1797, an Account of Appearances in the Ovaria of Rabbits in different Stages of Pregnancy. He died in 1800.

CRU'NION. (From κρουνος, a torrent.) A medicine mentioned by Ačiius, and named from the violence of its operations as a diuretic.

CRU'OR. (From κρους, frigus, it being that which appears like a coagulum as the blood coels.) The red part of the blood. See Elood.

CRU'RA. The plural of crus.

CRU'RA. The pullar of Crura Clitoris. See Clitoris. The roots of the

medulia oblongata. CRURÆUS. (From crus, a leg; so named, because it covers almost the whole foreside of the upper part of the leg or thigh.) Cruralis. A muscle of the feg, situated on the forepart of the thigh. It arises, fleshy, from between the two trochanters of the os femoris, but nearer the lesser, firmly adhering to most the forepart of the os femoris, and is inverted then. of the forepart of the os femoris; and is inserted, ten-dinous, into the upper part of the patella, belvind the rectus. Its use is to assist the vasti and rectus muscles in the extension of the leg.

GRURAL. (Cruralis; from crus, the leg.) Belonging to the crus, leg, or lower extremity.

CRURAL HERNIA. See Hernia cruralis.

CRURA'LIS. See Cruraus.

CRUS. 1. The leg.

2. The root or origin of some parts of the body, from their recombinates to a leg or root. from their resemblance to a leg or root; as Crura cerebri, Crura cerebelli; Crura of the diaphragm, &c.

CRU'STA. 1. A shell.

2. A scab.

The scum or surface of a fluid.

3. The scum or surface of a fluid.

CRUSTA LACTEA. A disease that mostly attacks some part of the face of infants at the breast. It is known by an eruption of broad pustules, full of a glutinous liquor, which form white scabs when they are ruptured. It is cured by mineral alteratives.

CRUSTA VILLOSA. The inner coat of the stomach and intestines has been so called.

CRUSTULA. (Dim. of crusta, a shell.) A discoloration of the flesh from a bruise, where the skin is entire, and covers it over like a shell.

CRUSTUMINATOR. (From Crustuminum, a town

CRUSTUMINA'TUM. (From Crustuminum, a town where they grew.) 1. A kind of Catherine pear.

2. A rob or electuary made of this pear and apples boiled up with honey.

CRYMO'DES. (From κρυος, cold.) An epithet for a fever, wherein the external parts are cold.

CRYOLITE. A white or yellowish brown mineral, composed of alumina, soda, and fluoric acid. It is curious and rare, and found hitherto only at West

CRYOPHORUS. (From Epues, cold, and proce, to bear.) The frost-bearer, or carrier of cold; an elegant instrument invented by Dr. Wolfaston, to demonstrate the relation between evaporation at low temperature.

ratures, and the production of cold.

CRYPSO RCHIS. (From κρυπ7ω, to conceal, and ορχις, a testicle.) A term applied to a man whose testicles are hid in the belly, or have not descended into

CRYPTA. (From κουπτω, to hide.) The little rounded appearances at the end of the small arteries of the cortical substance of the kidneys, that appear as if formed by the artery being convoluted upon itself. the scrotum.

CRYPTOGAMIA. (From κουπτω, to conceal, and yauos, a marriage.) The twenty-fourth and last class of the sexual or Linnean system of plants, containing several numerous genera, in which the parts essential to their fructification have not been sufficiently ascertained to admit of their being referred to the other

cession of one of the testicies.

2. See Crypsorchis.
CRYSTAL. See Crystallus.
CRYSTALLINE. (Crystallinus; from its crystal-like appearance.) Crystal-like.
CRYSTALLINE LENS. A lentiform pellucid part of the eye, enclosed in a membranous capsule, called the capsule of the crystalline lens, and situated in a peculiar demonstalline lens, and situated in a peculiar demonstalline lens. liar depression in the anterior part of the vitreous hu-mour. Its use is to transmit and refract the rays of mour. Its use light. See Eye.

CRYSTALLINUM . (From κρυςαλλος, a crystal: so called from its transparency.) White arsenic.
CRYSTALLIZATION. (Crystallizatio; from

crystallus, a crystal.) A property by which crystallizable bodies tend to assume a regular form, when placed in circumstances favourable to that particular disposition of their particles. Almost all minerals possess this property, but it is most eminent in saline substances. The circumstances which are favourable to the crystallization of salts, and without which it cannot take place, are two: 1. Their particles must be divided and separated by a flower particles may meet and unite. responding faces of those particles may meet and unite.

2. In order that this union may take place, the fluid which separates the integrant parts of the salt must be gradually carried off, so that it may no longer divide them.

[" Crystallization, in the most limited extent of the term, is that process by which the particles of bodies unite in such a manner as to produce determinate and regular solids. But it is equally true, that those minerals, which possess a foliated or fibrous structure, are the products of crystallization, under circumstances which have rendered the process more or less imperfect, and prevented the appearance of distinct and

regular forms.

The ancients believed crystallized quartz (rock crystal) to be water, congealed by exposure to intense cold; and accordingly applied to it the term κρυς αλλος, which signified ice. Hence the etymology of the word crystal. Now, as a beautiful regularity of form is one of the most striking properties of crystallized quartz, the name crystal has been extended to all mineral and other inorganic substances, which exhibit themselves under the form of regular geometrical solids.

A crystal may therefore be defined an inorganic body, which, by the operation of affinity, has assumed the form of a regular solid, terminated by a number of plane and polished faces. The corresponding faces of all crystals, which possess the same variety of form, and belong to the same substance, are inclined to each other in angles of a constant quantity. This con-stancy of angles remains, even in those cases where the faces themselves, from some accidental causes, have changed their dimensions or number of sides. have changed their dimensions or number of sides. Transparency, though many crystals possess it in a greater or less degree, is not a necessary property. But plane surfaces, bounded by right lines, are so essential to the crystalline form, that their absence decidedly indicates imperfection in the process of crystallization. The lustre and smoothness of the faces may also be diminished by accidental causes."—

Cleav. Min. A.] CRYSTA'LLUS. (Crystallus, i. m.; from κρυος, cold, and σελλω, to contract: i. e. contracted by cold into ice.) A crystal. "When fluid substances are suffered to pass with adequate slowness to the solid state, the attractive forces frequently arrange their state, the attractive forces frequently arrange their ultimate particles, so as to form regular polyhedral figures or geometrical solids, to which the name of crystals has been given. Most of the solids which compose the mineral crust of the earth are found in the crystallized state. Thus granite consists of crystals of quartz, felspar, and mica. Even mountain masses like clay-slate, have a regular tabulated form. Perfect mobility among the corpuscles is essential to crystallization. The chemist produces it either by igneous fusion, or by solution in a liquid. When the temperature is slowly lowered in the former case, or the liquid slowly abstracted by evaporation in the lat-ter, the attractive forces resume the ascendency, and arrange the particles in symmetrical forms. Mere approximation of the particles, however, is not alone suf-

class. It is divided by Linnæus into four orders, Filicient, Musci, Algæ, and Fungi.

Cryso'rchis. Kousooris.

2. See Crypsorchis.

CRYSTAL. See Crystallius.

CRYSTALLINE. (Crystallinæ; from its crystallike.

CRYSTALLINE. (Crystalline.; from its crystallike.

CRYSTALLINE. Lens. A lentiform pellucid part of contract to distance.) solid state.

This reversion of the poles may be effected, 1st, By contact of any part of the fluid with a point of a solid, of similar composition, previously formed. 2d, Vibratory motions communicated, either from the atmosphere or any other moving body, by deranging, however slightly, the fluid polar direction, will instantly determine the solid polar arrangement, when the balance had been rendered nearly even by previous removal of the interstitial fluid. On this principle we explain the regular figures which particles of dust or explain the regular figures which particles of dust or iron assume, when they are placed on a vibrating plane, in the neighbourhood of electrized or magnetized bodies. 3d, Negative or resinous voltaic electricity instantly determines the crystalline arrangement, while

instantly determines the crystalline arrangement, while positive voltaic electricity counteracts it. Light also favours crystallization, as is exemplified with camphor dissolved in spirits, which crystallizes in bright and redissolves in gloomy weather.

It might be imagined, that the same body would always concrete in the same, or at least in a similar crystalline form. This position is true, in general, for the salts crystallized in the laboratory; and on this uniformity of figure, one of the principal criteria between different salts depends. But even these forms are liable to many modifications, from causes apparently slight; and in nature we find frequently the same chemical substance crystallized in forms apparently very dissimilar. Thus, carbonate of lime assumes the form of a rhomboid, of a regular hexaédral prism, of a solid terminated by 12 scalene angles, or of a dodecahedron with pentagonal faces, &c. Bisulphuret of iron or martial pyrites produces sometimes cubes and sometimes regular octohedrons, at one time dodecasometimes regular octohedrons, at one time dodecahedrons with pentagonal faces, at another icosahedrons

with triangular faces, &c.
While one and the same substance lends itself to so any transformations, we meet with very different substances, which present absolutely the same form. Thus fluate of lime, muriate of soda, sulphuret of iron, sulphuret of lead, &c. crystallize in cubes, under cer-tain circumstances; and in other cases, the same mi-nerals, as well as sulphate of alumina and the diamond, assume the form of a regular octohedron.

Romé de l'Isle first referred the study of crystallization to principles conformable to observation. He arranged together, as far as possible, crystals of the same nature. Among the different forms relative to each species, he chose one as the most proper, from its sim-plicity, to be regarded as the primitive form; and by supposing it truncated in different ways, he deduced the other forms from it, and determined a gradation, a series of transitions between this same form and that of polyhedrons, which seem to be still further removed from it. To the descriptions and figures which he gave of the crystalline forms, he added the results of the mechanical measurement of their principal angles, and showed that these angles were constant in each variety

The illustrious Bergmann, by endeavouring to pene-trate to the mechanism of the structure of crystals, considered the different forms relative to one and the same substance, as produced by a superposition of planes, sometimes constant and sometimes variable, planes, sometimes constant and sometimes variable, and decreasing around one and the same primitive form. He applied this primary idea to a small number of crystalline forms, and verified it with respect to a variety of calcareous spar by fractures, which enabled him to ascertain the position of the nucleus, or of the primitive form, and the successive order of the laminæ covering this nucleus. Bergmann, however, stopped here, and did not trouble himself either with determining the laws of structure, or applying calculation to it. It was a simple sketch of the most prominent point of view in mineralogy, but in which we see the hand of the same master who so successfully filled up the outlines of chemistry

In the researches which Haüy undertook, about the same period. on the structure of crystals, he proposed

combining the form and dimensions of integrant molecules with simple and regular laws of arrangement, and submitting these laws to calculation. This work produced a mathematical theory, which he reduced to analytical formulæ, representing every possible case, and the application of which to known forms leads to valuations of angles, constantly agreeing with observation."—Ure's Chem. Dict.

2. An eruption over the body of white transparent

pustules.

pustules.

["CRYSTALLOGRAPHY. Of the physical properties of minerals, no one is so important in itself, and extensive in its influence and application, as that by which crystals or regular solids are produced. To in vestigate and describe these solids is the object of crystallography, and constitutes, without doubt, the most interesting branch of mineralogical research."—Cleav. Mineralogy. A.]

Cre'pones. (From κ]ηδων, a rake.) The fibres are so called from their pectinated course.

CTEIS. KTUS. A comb or rake. Ctenes, in the plural number, implies those teeth which are called incisores, from their likeness to a rake.

CUBE ORE. Hexaedral olivenite. Wurfelerz of

Werner. A mineral arseniate of iron, of a pistachiogreen colour.

CUBE SPAR. See Anhydrite. CUBEB. See Piper cubeba. CUBEBA. (From cubabah, Arab.) See Piper

CUBITÆUS EXTERNUS. An extensor muscle of the fingers. See Extensor digitorum communis

CUBITALS INTERNUS. A flexor muscle of the fingers. See Flexor sublimis, and profundus.

CUBITAL. (Cubitalis; from cubitus, the forearm.) Belonging to the forearm.

CUBITAL ARTERY. Arteria cubitalis; Arteria ul-maris. A branch of the brachial that proceeds in the forearm, and gives off the recurrent and interosseals, and forms the palmary arch, from which arise branches going to the fingers, called digitals.

CUBITAL NERVE. Nervus cubitalis; Nervus ulnaris. It arises from the brachial plexus, and pro-

CUBITALIS MUSCULUS. An extensor muscle of the

CUBITUS. (From cubo, to lie down; because the ancients used to lie down on that part at their meals.)

1. The forearm, or that part between the elbow and

2. The larger bone of the forearm is called os cubiti.

See Ulna.

CUBOLDES OS. (From κυδος, a cube or die, and ειδος, likeness.) A tarsal bone of the foot, so called from its resemblance.

CUCKOW FLOWER. See Cardamine.

CUCUBALUS. The name of an herb mentioned by Pliny. The name of a genus or family of plants in the Linnæan system. Class, Decandria; Order Trymania.

CUCUBALUS BACCIFERUS. The systematic name of the berry-bearing chick-weed, which is sometimes

used as an emollient poultice.

CUCUBALUS BEHEN. The systematic name of the Behen officinarum, or spatling poppy, formerly used as a cordial and alexipharmic.

CUCULLA'RIS. (From encullis, a hood: so

CUCULLA'RIS. (From cucullis, a hood: so named, because it is shaped like a hood.) See Tra-

CUCULLATUS. Hooded. Applied to a leaf, when the edges meet in the lower part, and expand in the upper, forming a sheath or hood, of which the genus Sarcacenia are an example; to the nectary of the aconite tribe, &c.
CUCU'LLUS. 1. A hood.

2. An odoriferous cap for the head.
CUCUMBER. See Cucumis.
Cucumber, bitter. See Cucumis colocynthis.

Cucumber, bitter. See Cucums colocyntais.
Cucumber, squirting. See Momordica elaterium.
Cucumber, wild. See Momordica elaterium.
CUCUMIS. (Oucemis, mis. m.; also cucumer, ris.; quasi curvimeres, from their curvature.) The cucumber.
1. The name of a genus of plants in the Linman system. Class, Monacia; Order, Syngenesia.
The curvives.

The cucumber.

2. The pharmacopaial name of the garden cucumber. See Cucumis sativus.

CUCUMIS AGRESTIS.* See Momordica claterium.
CUCUMIS COLOCYNTHIS. The systematic name for the officinal bitter apple. Colocynthis; Alhandula of the Arabians. Coloquintida. Bitter apple; bitter gourd; bitter cucumber. The fruit, which is the medicinal part of this plant, Cucumis—foliis multifidis, pomis globosis glabris, of Linnaus, is imported from Turkey. Its spongy membranous medulia or pith, is directed for use; it has a nauseous, acrid, and intensely bitter taste; and is a powerful irritating cathartic. In doses of ten or twelve grains, it operates with great vehemence, frequently producing violent gripes, bloody stools, and disordering the whole system. It is recommended in various complaints, as worms, mania, dropsy, epilepsy, &c.; but is seldom worms, mania, dropsy, epilepsy, &c.; but is seldom resorted to, except where other more mild remedies have been used without success, and then only in the form of the extractum colocynthidis compositum, and the pilulæ ez colocynthide cum alor of the pharmaco-

CUCUMIS MELO. The systematic name of the melon plant. Melo. Musk-melon. This fruit, when ripe, has a delicious refrigerating taste, but must be eaten moderately, with pepper, or some aromatic, as all this class of fruits are obnoxious to the stomach, producing spasms and colic. The seeds possess muci-

laginous qualities.

CUCUMIS SATIVUS. The systematic name of the cucounter plant. Cucumis. Cucumis—foliorum angu-lis rectis; pomis oblongis scabris of Linneus. It is cooling and aperient, but very apt to disagree with bilious stomachs. It should always be eaten with pep-per and oil. The seeds were formerly used medicinally.

CUCUMIS SYLVESTRIS. See Momordica elaterium.
CU'CUPHA. A hood. An odoriferous cap for the head, composed of aromatic drugs.
CUCU'RBITA. (A survitate, according to Scaliger, the first syllable being doubled; as in Cacula, Populus, &c.) 1. The name of a genus of plants in the Linnwan system. Class, Monacia; Order, Syngene-

sia. The pumpion.

2. The pharmacopæial name of the common gourd.

See Cucurbita pepo.

3. A chemical distilling vessel, shaped like a gourd.

Cucurbita citrullus. The systematic name of the water-melon plant. Citrullus; Angura; Jace brasilientibus; Tetranguria. Sicilian citrul, or water-melon. The seeds of this plant, Cucurbita—foliis multipartitis of Linnaus, were formerly used medicipally, but now only to reproduce the plant. Watercinally, but now only to reproduce the plant. Water-melon is cooling and somewhat nutritious; but so soon begins to ferment, as to prove highly noxious to some stomachs, and bring on spasms, diarrheas, cholera, colics, &c.

lera, colics, &c.

Cucurbita Lagenaria. The systematic name of the bottle-gourd plant. See Cucurbita pepo.

Cucurbita pepo. The systematic name of the common pumpion or gourd. Cucurbita. The seeds of this plant, Cucurbita—foliis lobatis, pomis lavibus, are used indifferently with those of the Cucurbita lagenaria—foliis subangulatis, tomentosis, basi subtus biglandulosus; pomis lignosis. They contain a large proportion of oil, which may be made into emulsions; but is superseded by that of sweet almonds.

Cucurbitaer. (From cucurbita, a gourd.) The

Cucurbitace z. (From cucurbita, a gourd.) The name of an order of Linnaus's Fragments of a Natural Method, consisting of plants which resemble the

CUCURBITINUS. A species of worm, so called from its resemblance to the seed of the gourd. See

CUCURBITULA. (A diminutive of cucurbita, a gourd; so called from its shape.) A cupping-glass.
Cucurbitula cruenta. A cupping-glass, with

CULILA WAN. See Laurus culilawan.

CULI'NARY. (Culinarius, from culina,'a kitchen.) Any thing belonging to the kitchen, as salt, pot-herbs,

CULLEN, WILLIAM, was born at Lanark, Scotland, in 1712, of respectable, but not wealthy parents. After the usual school education, he was apprenticed to a surgeon and apothecary at Glasgow, and then, made several voyages, as surgeon, to the West Indies. He afterward settled in practice at Hamilton, and formed a connexion with the celebrated William Hunter; but their business being scanty, they agreed to pass a winter alternately at some university. Cullen went first to Edinburgh, and attended the classes so len went first to Edinburgh, and attended the classes so diligently, that he was soon after able to commence teacher. Hunter came the next winter to London, and engaged as assistant in the dissecting-room of Dr. William Douglas, who was so pleased with his assiduity and talent, as to offer him a share in his lectures: but though the partnership with Cullen was thus dissolved, they continued ever after a friendly correspondence. Cullen had the good fortune, while at Hamilton, to assist the Duke of Argyle in some chemical pursuits: and still more of being sent for to the Duke of Hamilton, in a sudden alarming illness, which he speedily relieved by his judicious treatment, and gained the entire approbation of Dr. Clarke, who afterward arrived. About the same time he married the daughter of a neighbouring clergyman, who bore him several children. In 1746 he took the degree of doctor in medicine, and was appointed teacher of chemistry at Glasgow. His talents were peculiarly fitted for this office; his systematic genius, distinct enunciation, lively manner, and extensive knowledge of the subject, represent his lectures highly interesting. In the mean rendered his lectures highly interesting. In the mean time his reputation as a physician increased, so that he was consulted in most difficult cases. In 1751, he was chosen professor in medicine to the university; and, five years after, the chemical chair at Edinburgh was offered him, on the death of Dr. Plummer, which was too advantageous to be refused. He soon became equally popular there, and his class increased, so as to exceed that of any other professor, except the anatomical. This success was owing not only to his assi-duity, and his being so well qualified for the office, but also in a great measure to the kindness which he showed to his pupils, and partly to the new Views on the Theory of Medicine, which he occasionally introduced into his lectures. He appears also, about this time, to have given Clinical Lectures at the Infirmary. On the death of Dr. Alston, Lecturer on the Materia Medica, he was appointed to succeed him: and six years afterward, jointly with Dr. Gregory, to lecture on the Theory and Practice of Medicine, when he resigned the Chemical Chair to his pupil, Dr. Black. Dr. signed the Chemical Chair to his pupil, Dr. Black. Dr. Gregory having died the following year, he continued the Medical Lectures alone, till within a few months of his death, which happened in February 1790, in his seventy-seventh year; and he is said, even at the last, to have shown no deficiency in his delivery, nor in his memory, being accustomed to lecture from short notes. His Lectures on the Materia Medica being surreptitiously printed, he obtained an injunction against their being issued until he had corrected them, which was accomplished in 1772: but they were afterward much improved, and appeared in 1789, in two quarto volumes. Fearing a similar fate to his Lectures on Medicine, he published an outline of them in 1784, in four volumes, octavo, entitled "First Lines of the Practice of Physic." He wrote also the "Institutions of Medicine," in one volume, octavo: and a "Letter to Lord Cathcart, on the Recovery of drowned Persons" But his most celebrated work is his "Synopsis Nosologia Methodica," successively improved in different logiæ Methodicæ," successively improved in different editions; the fourth, published in 1785, in two octavo volumes, contains the Systems of other Nosologists till that period, followed by his own, which certainly, as a practical arrangement of diseases, greatly surpasses

CULMUS, Culm. Straw. The stem of grasse rushes, and plants nearly allied to them. It bears both leaves and flowers, and its nature is more easily understood than defined. Its varieties are,

1. Culmus teres, round; as in Carez uliginosa.
2. C. tetragonus; as in Festuca ovina.
3. C. triangularis; as in Eriocaulon triangulare.
4. C. capillaris; as in Scirpus capillaris.
5. C. prostratus; as in Agrostis canina.
276

6. C. repens; as in Agrostis stolonifera.

7. C. nudus, as in Carez montana.

C. enodis, without joints; as in Juncus conglo meratus.

9. C. articulatus, jointed; as in Agrostis alba. 10. C. geniculatus, bent like the knee; as in Alo-10. C. geniculatus.

pecurus geniculatus.

It is also either solid or hollow, rough or smooth, sometimes hairy or downy, scarcely woolly.

CULMIFERE. Plants which have smooth soft

CULPEPER, Nicholas, was the son of a clergy-man, who put him apprentice to an apothecary; after serving his time, he settled in Spitalfields, London, about the year 1642. In the troubles prevailing at that period, he appears to have favoured the Puritans; but his decided warfare was with the College of Physicians, whom he accuses of keeping the people in ignorance, like the Popish clergy. He therefore published rance, like the Popish cfergy. He therefore published a translation of their Dispensary, with practical remarks; also an Herbal, pointing out, among other matters, under what planet the plants should be gathered; and a directory to midwives, showing the method of ensuring a healthy progeny, &c. These works were for some time popular. He died in 1654.

CULTER. (From colo, to cultivate.)

A knife or shear.
 The third lobe of the liver is so called from its

supposed resemblance. CU'LUS. (From (From κουλος.) The anus or funda-

See Piper cubeba.

CU'MAMUS. See Piper cubeba. CUMIN. See Cuminum. CU'MINUM. (From κυω, to bring forth; because

it was said to cure sterility.)

1. The name of a genus of plants in the Linnaan estem. Class, Heptandria; Order, Digynia. The

2. The pharmacopæial name of the cumin plant.

See Cuminum cyminum.

CUMINUM ATHIOPICUM. A name for the ammi verum. See Sison ammi.

CUMINUM CYMINUM. The systematic name of the cumin plant. Cuminum; Faniculum orientale. A native of Egypt and Ethiopia, but cultivated in Sicily and Malta, from whence it is brought to us. The seeds of cumin, which are the only part of the plant in use, have a bitterish taste, accompanied with an aromatic flavour, but not agreeable. They are generally pre-ferred to other seeds for external use in discussing in-dolent tumours, as the encysted scrofulous, &c. and give name both to a plaster and cataplasm in the pharmacopœias.

macopenas.

CUNEA'DIS SUTURA. The suture by which the ossphenoides is joined to the os frontis.

CUNEIFORMIS. (From cuneus, a wedge, and forma, likeness.) Cuneiform, wedge-like. Applied to bones, leaves, &c. which are broad and abrupt at the extremity. See Sphenoid bone; Tarsus, and Carpus; Leaf; Petalum.

CUNE'OLUS. (From cuneo, to wedge.) A crooked tent to put into a fistula.

CUNE OLUS. (From cuneo, to wedge.) A crooked tent to put into a fistula.

["CUNILA. Pennyroyal. The plant called pennyroyal, in England, is a species of mint, Mentha pulegiam; while the American plant, which bears the same common appellation, belongs to the genus Cunila, of Linnæus, and Hedeoma, of Persoon. American pennyroyal is a warm aromatic, possessing a pungent flavour, which is common to many of the labiate plants of other genera. Like them, it is heating, carminative, and diaphoretic. It is in popular repute as an emmenagogue. —Big. Mat. Med. A.]

Cup of the flower. See Calyx.

CUPEL. (Kuppel, a cup, German.) Copella; Catellus cinereus; Cineritium; Patella docimastica; Testa probatrix, exploratrix, or docimastica. A shallow earthen vessel like a cup, made of phosphate of lime, which suffers the baser metals to pass through it, when exposed to heat, and retains the pure metal.

lime, which suffers the baser metals to pass through it, when exposed to heat, and retains the pure metal. This process is termed cupellation.

CUPELLATION. Cupellatio. The purifying of perfect metals by means of an addition of lead, which, at a due heat, becomes vitrified, and promotes the vitrification and calcination of such imperfect metals as may be in the mixture, so that these last are carried off in the fusible glass that is formed, and the perfect metals are left nearly pure. The name of this opera-

tion is taken from the vessels made use of, which are called cupels.

Cu'rhos. Kovoos. Light. When applied to aliments, it imports their being easily digested; when to distempers, that they are mild.

[Cupring. Topical bleeding. "This is done by means of a scarificator, and a glass, shaped somewhat like a bell. The scarificator is an instrument containing a number of largets continues as many as ing a number of lancets, sometimes as many as twenty, which are so contrived, that when the instrument is applied to any part of the surface of the body, and a spring is pressed, they suddenly start out, and make the necessary punctures. The instrument is so constructed, that the depth, to which the lancets penetrate, may be made greater or less, at the option of the practitioner. As only small vessels can be thus opened, a very inconsiderable quantity of blood would be discharged; were not some method taken to probe discharged, were not some method taken to promote the evacuation. This is commonly done with a cupping-glass, the air within the cavity of which is rarefied by the flame of a little lamp, containing spirit of wine, and furnished with a thick wick. This plan is preferable to that of setting on fire a piece of tow, dipped in this fluid, and put in the cavity of the glass. The larger the glass, if properly exhausted, the less pain does the patient suffer, and the more freely does the blood flow. When the mouth of the glass is placed over the scarifications, and the rarefied air in it becomes condensed as it cools, the glass is forced down on the skin, and a considerable suction takes place."—Cooper's Surg. Dict. A.1

Cooper's Surg. Dict. A.]
CUPRE'SSUS. (So called, απο του κυειν παρισους τους ακρεμονας, because it produces equal branches.)

Cypress.

1. The name of a genus of plants in the Linnwan system. Class, Monacia; Order, Monadelphia. The cypress-tree.

2. The pharmacopoial name of the cypress-tree.

2. The pharmacopeiar name of the cypressure. See Cupressus sempervirens. The systematic name of the cupressus of the shops. Cupressus—foliis imbricatis squamis quadrangulis, of Linneus; called also cyparissus. Every part of the plant abounds with a bitter, aromatic, terebinthinate fluid; and is said to be a remedy against intermittents. Its wood is extremely durable, and constitutes the cases of Egyptian mammins. tian mummies.

CUPRI AMMONIATI LIQUOR. Solution of ammoni ated copper. Aqua cupri ammoniati of Pharm. Lond. 1787, and formerly called Aqua sapphirina. Take of ammoniated copper, a drachm; distilled water, a pint. Dissolve the ammoniated copper in the water, a pint.

Dissolve the ammoniated copper in the water, and filter the solution through paper. This preparation is employed by surgeons for cleansing foul ulcers, and disposing them to heal.

CUPRI RUBIGO. Verdigris.

CUPRI SULPHAS. Vitriolum cupri; Vitriolum ca-

CUPRI RUBHIAS. Vitriolum cupri; Vitriolum carulcum; Vitriolum Romanum; Cuprum vitriolatum. Sulphate of copper. It possesses acrid and styptic qualities; is esteemed as a tonic, emetic, adstringent, and escharotic, and is exhibited internally in the cure. of dropsies, hamorrhages, and as a speedy emetic. Ex-ternally it is applied to stop hamorrhages, to hamorrhoids, leucorrhoa, phagedænic ulcers, proud flesh, and condylomata. CU'PRUM. (Quasi as Cyprium; so called from

CUPRUM. (Quasi as Cyprium; so called from the island of Cyprus, whence it was formerly brought.) See Copper,

CUPRUM AMMONIACALE. See Cuprum ammonia-

CUPRUM AMMONIATUM. Cuprum ammoniacale. Ammoniated copper. Ammoniacal sulphate of copper Take of sulphate of copper, half an ounce; subcar bonate of ammonia, six drachms; rub them together in a glass mortar, till the effervescence ceases; then In a glass mortar, till the effervescence ceases; then dry the ammoniated copper, wrapped up in bibulous paper, by a gentle heat. In this process the carbonic acid is expelled from the ammonia, which forms a triple compound with the sulphuric acid and oxide of copper. This preparation is much milder than the sulphate of copper. It is found to produce tonic and astringent effects on the human body. Its principal internal use has been in enilepsy, and other obstinate internal use has been in epilepsy, and other obstinate spasmodic diseases, given in doses of half a grain, gradually increased to five grains or more, two or three times a day. For its external application, see Cupri ammoniati figuor. CUPRUM VITRIOLATUM. See Cupri sulphas.
CUPULA. An accidental part of a seed, being a rough calyculus, surrounding the lower part of a gland,

as that of the oak, of which it is the cup.

CURA AVANACEA. A decoction of oats and succory roots, in which a little nitre and sugar were dissolved, was formerly used in fevers, and was thus

CU'RCAS. See Jatropha curcas. Cu'RCULIO. (From Larkarah, Hebrew.) The throat and the aspera arteria.

Also the name of a genus of coleopterous insects, according to Linnaus's system. A.]

CU'RCUM. See Cheledonium majus.

CURCU'MA. (From the Arabic curcum or hercum.)

Turmeric. 1. The name of a genus of plants in the Linnaun system. Class, Monandria; Order, Mono-

2. The pharmacopæial name of the turmeric-tree.

See Curcuma longa.

CURCUMA LONGA. The systematic name of the turmeric plant. Crocus Indicus; Terra marita; Cannacorus radice erocco; Curcuma rotunda; Mayella; Kua kāha of the Indians. Curcuma—foliis lanceolatis; nervis lateralibus numerossimis of Linneus. The Arabians call every root of a saffron colour by the name of curcum. The root of this plant is imported here in its dried state from the East Indies, in various forms. Externally it is of a pale yellow colour, wrinkled, solid, ponderous, and the inner substance of a deep saffron or gold colour: its odour is somewhat fragrant; to the taste it is bitterish, slightly acrid, exciting a moderate degree of warmth in the mouth, and on being chewed, it linges the saliva yellow. It is an ingredient in the composition of Curry powder, is valuable as a dying dru and furnishes a chemical test of the presence of uncombined alkalies. It is now very seldom used medicinally, but retains a place in our pharmacopeias.

CURD. The coagulum, which separates from milk, upon the addition of acid or other substances.

["CURETTE. (French.) An instrument shaped like a minute spoon, or scoop, invented by Daviel, and used in the extraction of the cataract, for taking away any opaque matter, which may remain behind the pull imprediately after the crystalline has been taken pil, immediately after the crystalline has been taken

out."—Cooper's Surg. Dict. A.]

Curled leaf. See Leaf.

CU'RMI. (From κεραω, to mix.) Ale. A drink made of barley, according to Dioscorides.

CU'RSUMA. Curtuma. The Ranuhculus ficaria of Linnaus.

Linnaus.

CURSU'TA. (Corrupted from cassuta, kasuth, Ara-an.) The root of the Gentiana purpurea of Lin-

CURVA'TOR COCCYGIS. A muscle bending the coc-

cyx. See Coccygeus.

CURVATUS. (From curvus, a curve.) Curvate,
bent. Applied to the form of a pepo or gourd seed-

vessel; as in Cucumi flexuosus.

CUSCU'TA. (According to Linnæus, a corruption from the Greek Kasv/as, or Kašv/as, which is from the Arabic Chessuth, or Chasuth.) Bodder. 1. The name of a genus of plants in the Linnæan system. Class, Tetrandria; Order, Digynia.

2. The pharmacopeial name of dodder of thyme.

See Cuscuta epithymum.
Cuscuta epithymum. The systematic name of dodder of thyme. Epythymum. Cuscuta—foliis ses-silibus, quinquifidis, bracteis obvallaiis. A parasiti-cal plant, possessing a strong disagreeable smell, and a pungent taste, very durable in the mouth. Recom-mended in melancholia, as cathartics. Cuscuta europæa. The systematic name of a species of dodder of thyme. Cuscuta—floribus sessi-libus, of Linneus.

species of dodder of thyme. Cuscuta—floribus sessilibus, of Linnæus.

CUSPA'RIA. The name given by Messrs. Humboldt and Bonpland to a genus of plants in which is
the tree we obtain the Angustura bark from.

Cusparia ferrifuga. This is the tree said to
yield the bark called Angustura.—Cortex cusparia,
and imported from Angustura in South America. Its
external appearances vary considerable. The best is
not fibrous, but hard, compact, and of a yellowishbrown colour, and externally of a whitish hue. When

reduced into powder, it resembles that of Indian rhu- | the mixture of the ore with lead, by which litharge is reduced into powder, it resembles that of Indian rhubarb. It is very generally employed as a febrifuge, tonic, and adstringent. While some deny its virtue in curing intermittents, by many it is preferred to the Peruvian bark; and it has been found useful in diarrhosa, dyspepsia, and scrofula. It was thought to be the bark of the Brucea antidysenterica, or ferruginea. Wildenow suspected it to be the Magnalia plumieri; but Humboldt and Bonpland, the celebrated travellers in South America, have ascertained it to belong to a tree not before known, and which they promise to detree not before known, and which they promise to describe by the name of Cusparia febrifuga.

CUSPIDA'TUS. (From cuspis, a point.) 1. Four of the teeth are called cuspidati, from their form. See

Teeth.

2. Sharp-pointed. Applied to leaves which are tipped with a spine, as in thistles. See Leaf.

CU'SPIS. (From cuspa, Chaldean, a shell or bone, with which spears were formerly pointed.) 1. The glans penis was so called, from its likeness to the point

of a spear.

2. The name of a bandage.

Cc'stos oculi. An instrument to fix the eye during an operation.

CUTA MBULUS. (From cutis, the skin, and ambulo, to walk.) 1. A cutaneous worm.
2. Scorbutic itching.
CUTANEOUS. (Cutaneus; from cutis, the skin.)

Belonging to the skin.

CUTA'NEUS MUSCULUS. See Platysma myoides.

CUTICLE. Cuticula. (A diminutive of cutis, the skin.) Epidermis. Scari-skin. A thin, pellucid, insensible membrane, of a white colour, that covers and defends the true skin, with which it is connected by the hairs, exhaling and inhaling vessels, and the rete mucosum.

CUTICULA. See Cuticle.

CUTICULA. See Caticle.

CUTIS. (Cutis, tis. form.) See Skin.

CUTIS ANSERINA. The rough state the skin is sometimes thrown into from the action of cold, or other cause, in which it looks like the skin of the goose.

CUTIS VERA. The true skin under the cuticle.

CYANIA. The trivial name in Good's arrangement of diseases of a species called Exangua cyania, or blue skin. Class, Hamatica; Order, Struma.

CYANIC ACID. Acidum cyanicum. See Prussic acid.

CYANITE. Kyanite. Disthene of Haüy. A mi-neral of a Berlin blue colour, found in India and Eu-

CYANOGEN. (From κυανος, blue, and γινομαι, to form.) Production of blue. See Prussine.

CY'ANUS. (Κυανος, cærulean, or sky-blue; so called from its colour.) Blue-bottle. See Centauria CY'AR. (From κεω, to pour out.) 1. The lip of a

2. The eye of a needle.
3. The orifice of the internal ear, from its likeness to the eye of a needle.

CYA'SMA. Spots on the skin of pregnant women.
CYATHI'SCUS. (From κυαθος, a cup.) The hollow
part of a probe, formed in the shape of a small spoon, as an ear-picker.

as an ear-picker.

Cy'bitos. See Cubitus.

Cy'bitos. See Cubitus.

Cy'bitos. See Cubitus.

Cybot'des. See Cubitus.

Cycas. (Kukas, of Theophrastus. The name of a palm, said to grow in Ethiopia.) The name of a genus of plants, one of the Palma pinnatifolia, of Linneus; but afterward removed by him to the felices.

Cycas ctrcinalis. The systematic name of a palm-tree which affords a sago, called also Sagus; Sagu:—a dry fecula, obtained from the pith of this palm, in the islands of Java, Molucca, and the Philippines. The same substance is also brought from the West Indies, but it is inferior to that brought from the East. Sago becomes soft and transparent by boiling in water, and forms a light and agreeable liquid, much recommended in febrile, phthisical and calculous discussions. recommended in febrile, phthisical and calculous disorders, &c. To make it palatable, it is customary to add to it, when boiled or softened with water, some lemon juice, sugar, and wine.

CYCLUM. (From κυκαω, to mix.) Cyclon. A

Cy'ceum. (From κυκαω, to mix.) Cyceon. A mixture of the consistence of pap.

CY'CIMA. (From κυκαω, to mix.) So called from

made.
CYCLAMEN. (From κυκλος, circular; either on account of the round form of the leaves, or of the roots.) Cyclamen.

1. The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Monogynia.

2. The pharmacopæial name of the sow-bread. See

Cyclamen Europæum

Cyclamen Europaum. The systematic name of the sow-bread. Arthanita of the pharmacopæias. The root is a drastic purge and errhine; and by the common people it has been used to procure abortion. Cycli'scus. (From κυκλος, a circle.) An instrument in the form of a half-moon, formerly used for

Cyclopho'ria. (From κυκλος, a circle.) A lozenge. Cyclopho'ria. (From κυκλος, a circle, and φερω, to bear.) The circulation of the blood, or other

Cyclo'Pion. (From $\kappa \nu \kappa \lambda o \omega$, to surround, and $\omega \psi$, the eye.) The white of the eye. CY'CLOS. Cyclus. A circle. Hippocrates uses this word to signify the cheeks, and the orbits of the

cyclus METASYNCRITICUS. A long protracted course of remedies, persisted in with a view of restoring the particles of the body to such a state as is necessary to health.

CYDO'NIA. (From Cydon, a town in Crote whealth the tree grows and the contract of the tree grows and the contract of the cross services and the contract of the cross services are contracted to the cross services and contract of the cross services are contracted to the cross services and contracted to the cross services are contracted to the cross services are contracted to the co

CYDO'NIA. (From Cydon, a town in Crete, where the tree grows wild.) The quince-tree. See Pyrus

cydonia.

CYDONIUM MALUM. The quince. See Pyrus cydonie

CYE'MA. (From κυω, to bring forth.) Parturition. CYLI CHNIS. (From κυλίξ, a cup.) A gallipot or

Cyli chnis. (From κυλιξ, a cup.) A gallipot or vessel to hold medicines.

Cylindrical Leaf. See Leaf.

CYLI'NDRUS. (From κυλιω, to roll round.) A cylinder. A tent for a wound, equal at the top and bottom.

Cyllo'sis. (From κυλλοω, to make lame.) A tibia

Cyllo'sis. (From κυλλοω, to make lame.) A tibia or leg bending outwards.

Cy'lus. (From κυλλοω, to make lame.) In Hippocrates, it is one affected with a kind of luxation, which bends outwards, and is hollowed inward. Such a defect in the tibia is called Cyllosis, and the person to whom it belongs, is called by the Latins Varus, which term is opposed to Valgus.

CYMA. A cyme. A species of inflorescence of plants, consisting of several flower-stalks, all springing from one centre or point, but each stalk is variously subdivided; and in this last respect, a cyme differs essentially from an umbel, the subdivisions of the latter being formed like its primary divisions, of several ter being formed like its primary divisions, of several stalks springing from one point. This difference is of great importance in nature. The mode of inflores-cence agrees also with a corymbus in general aspect; but in the latter the primary stalks have no common centre, though the partial ones may sometimes be um-bellate, which last case is precisely the reverse of a cyme.

From its division into primary stalks or branches, it

is distinguished into,

 Trifid; as in Sedum acre.
 Quadrifid; as in Crassula rubens.
 Tripartite, having three less cymes; as in Sambucus ebulus.

4. Quinquipartite; as in Sambucus nigra

5. Sessile, or without stalk; as in Gnaphalium fru-

Comus sanguinea and sericea afford examples of the

Cyma nuda.
Cyma To'des. Is applied by Galen and others to an

unequal fluctuating pulse.

unequal fluctuating pulse.

CY'MBA. (From \$\epsilon\u00edbos\u00eb

be subject to it.) Sore throat. be subject to it.) Sore throat. A genus of disease in the class Pyrexia, and order Phleymasia of Cullen. It is known by pain and redness of the throat, attended by the control of the con ed with a difficulty of swallowing and breathing.

The species of this disease are:—

1. Cynanche trachealis; Cynanche laryngea; Suffocatio stridula; Angina perniciosa; Asthma infantum; Cynanche stridula; Morbus strangulatorius; Catarrhus suffocatius; Barbadensis; Angina polyposa sive membranacea. The croup. A disease that mostly attacks infants, who are suddenly seized with a difficulty of breathing and a crouping noise: it is an inflammation of the mucous membrane of the trachea that induces the secretion of a very tenacious coagu-lable lymph, which lines the trachea and bronchia, and impedes respiration. The croup does not appear and impedes respiration. The croup does not appear to be contagious, whatever some physicians may think to the contrary; but it sometimes prevails epidemically: It seems, however, peculiar to some families; and a child having once been attacked, is very liable to its returns. It is likewise peculiar to young children, and has never been known to attack a person

arrived at the age of puberty.

The application of cold seems to be the general cause which produces this disorder, and therefore it occurs more frequently in the winter and spring, than in the other seasons. It has been said, that it is most prevalent near the sea-coast; but it is frequently met with in inland situations, and particularly those which

are marshy.

Some days previous to an attack of the disease, the child appears drowsy, inactive, and fretful; the eyes are somewhat suffused and heavy; and there is a cough, which, from the first, has a peculiar shrill sound; this, in the course of two days, becomes more violent and troublesome, and likewise more shrill. Every fit of coughing agitates the patient very much; the face is flyshed and swelled the eyes are republic. the face is flushed and swelled, the eyes are protuberant, a general tremor takes place, and there is a kind of convulsive endeavour to renew respiration at the close of each fit. As the disease advances, a constant difficulty of breathing prevails, accompanied some-times with a swelling and inflammation in the tonsils, times with a swelling and inflammation in the tonsils, uvula, and velum pendulum palati; and the head is thrown back, in the agony of attempting to escape suffocation. There is not only an unusual sound produced by the cough, (something between the yelping and barking of a dog,) but respiration is performed with a hissing noise, as if the trachea was closed up by some slight spongy substance. The cough is generally dry; but if any thing is spit up, it has either a purulent appearance, or seems to consist of films resembling portions of a membrane. Where great nausea and frequent retchings prevail, coagulated matter sea and frequent retchings prevail, coagulated matter of the same nature is brought up. With these symptoms, there is much thirst, an uneasy sense of heat over the whole body, a continual inclination to change from place to place great realization. from place to place, great restlessness, and frequency of the pulse.

In an advanced stage of the disease, respiration becomes more stridulous, and is performed with still greater difficulty, being repeated at longer periods, and

with greater exertions, until at last it ceases entirely.

The croup generally proves fatal by suffocation, induced either by spasm affecting the glottis, or by a quantity of matter blocking up by the trachea or bronchia; but when it terminates in health, it is by a resolution of the inflammation, by a ceasing of the spasms, and by a free expectoration of the matter exuding from the trachea, or of the crusts formed there.

The disease has, in a few instances, terminated fatally within twenty-four hours after its attack; but it more usually happens, that where it proves fatal, it runs on to the fourth or fifth day. Where considerable portions of the membranous films, formed on the surface of the trachea, are thrown up, life is sometimes protracted for a day or two longer than would otherwise because

wise have happened

Dissections of children who have died of the croup, have mostly shown a preternatural membrane, lining the whole internal surface of the upper part of the trachea, which may always be easily separated from the proper membrane. There is likewise usually found a good deal of mucus, with a mixture of pus, in the trachea and its ramifications.

The treatment of this disease must be conducted on the strictly antiphlogistic plan. It will commonly be

proper, where the patient is not very young, to begin by taking blood from the arm, or the jugular vein; several leeches should be applied along the forepart of the neck. It will then be right to give a nauseating emetic, ipecacuanha with tartarized antimony, or with contill in divided desert this may be followed up by caemetic, ipecacuanha with tartarized antimony, or with squill in divided doses; this may be followed up by cathartics, diaphoretics, digitalis, &c. Large blisters ought to be applied near the affected part, and a discharge kept up by savine cerate, or other stimulant dressing. Mercury, carried speedily to salivation, has in several instances arrested the progress of the discase, when it appeared proceeding to a fatal termination. As the inflammation is declining, it is very important that free expectoration should take place; this may be promoted by nauseating medicines, by inhaling steam, and by stimulating gargles; for which the desteam, and by stimulating gargles; for which the de-coction of senna is particularly recommended. Where coction of senna is particularly recommended. Where there is much wheezing, an occasional emetic may relieve the patient considerably, and under symptoms of threatening suffocation, the operation of bronchotomy has sometimes saved life.—Should fits of spasmodic difficulty of breathing occur in the latter periods of the disease, opium joined with diaphoretics would be most likely to do good.

2. Cynanchetonsillaris. The inflammatory quinsy, called also angina inflammatoria. In this complaint, the inflammation principally occupies the tonsils: but

the inflammation principally occupies the tonsils; but often extends through the whole mucous membrane of the fauces, so as essentially to interrupt the speech,

the fauces, so as essentially to interrupt the speech, respiration, and deglutition of the patient.

The causes which usually give rise to it are, exposure to cold, either from sudden vicissitudes of weather, from being placed in a partial current of air, wearing damp linen, sitting in wet rooms, or getting wet in the feet; all of which may give a sudden check to perspiration. It principally attacks those of a full and plethoric habit, and is chiefly confined to cold climates, occurring usually in the spring and autumn; whereas the ulcerated sore throat chiefly attacks those of a weak irritable habit, and is most prevalent in warm climates. The former differs from the latter likewise in not being contagious. In many people there seems to be a particular tendency to this disease; as from every considerable application of cold it is readily induced.

An inflammatory sore throat discovers itself by a difficulty of swallowing and breathing, accompanied by a redness and tumour in one or both tonsils, drynessof the throat, foulness of the tongue, lancinating pains in the parts affected, a frequent but difficult excretion of mucus, and some small degree of fever. As the disease advances, the difficulty of swallowing and breathing becomes greater, the speech is very indistinct, the dryness of the throat and thirst increases, the tongue swells and is incrusted with a dark (ur, and the pulse is full and frequent. In some cases, a few white, sloughy spots are to be observed on the tonsils. If the inflammation proceeds to such a height as to put a total stop to respiration, the face will become livid, the pulse will sink, and the patient will quickly be destroyed.

The chief danger arising from this species of quinsy is, the inflammation occupying both tonsils, and proceeding to such a degree as to prevent a sufficient quantity of nourishment for the support of nature from being taken, or to occasion suffocation; but this seldom being taken, or to occasion suffocation; but this seldom being taken, or to occasion suffocation; but this seldom happens, and its usual termination is either in resolution or suppuration. When proper steps are adopted, it will in general readily go off by the former.

Where the disease has proved fatal by suffocation, little more than a highly inflamed state of the parts affected, with some morbid phenomena in the head, have been observed on dissection.

been observed on dissection.

This is usually a complaint not requiring very active This is usually a complaint not requiring very active treatment. If, however, the inflammation run high, in a tolerably strong and plethoric adult, a moderate quantity of blood should be drawn from the arm, or the jugular vein: but still more frequently leeches will be required; or scarifying the tonsils may afford will be required; An emetic will often be very more effectual relief. An emetic will often be very beneficial, sometimes apparently check the progress of the complaint: likewise cathartics must be employed, diaphoretics, and the general antiphlogistic regimen. A blister to the throat, or behind the neck, sometimes has a very excellent effect: but in milder cases, the linimentum ammoniæ, or other rubefacient application, mentum ammoniæ, or other rubefacient application, applied every six or eight hours, and wearing flannel

found the throat, may produce a sufficient determina-tion from the part affected. The use of proper gargles generally contributes materially to the cure. If there be much tension and pain in the fauces, a solution of nitrate of potassa will be best; otherwise dilute acids, a weak solution of alum, &c. Should the disease proa weak solution of alum, &c. Should the disease proceed to suppuration, warm emollient gargles ought to be employed, and perhaps similar external applications may be of some service: but it is particularly important to make an early opening into the abscess for the discharge of the pus. When deglutition is prevented by the tumefaction of the tonsils, it is recommended to exhibit nutritious clysters; and when suffocation is threatened, an emetic or inhaling ather may cause a rupture of the abscess, or this may be opened; but if relief be not thereby obtained, bronchotomy will become necessary. come necessary.

3. Cynanche pharyngea. This species is so called when the pharynx is chiefly affected. Dr. Wilson, in his Treatise on Febrile Diseases, includes in his defihis Treatise on Febrile Diseases, includes in his definition of cynanche tonsillaris, that of cynanche pharyngea. These varieties of cynanche differ considerably when they are exquisitely formed. But the one is seldom present in any considerable degree, without being attended with more or less of the other. Dr. Cullen declares, indeed, that he never saw a case of true cynanche pharyngea; that is, a case in which the inflammation was confined to the pharynx; it constantly spread in a greater or less degree to the tonsits and neighbouring parts. Besides, the mode of treatment is, in almost every instance, the same in both cases. And if we admit the cynanche pharyngea to be a distinct variety, we must admit another, the cynanche œsophagea; for inflammation frequently attacks the œsophagus, and is sometimes even confined to it.

4. Cynanche parotidea. The mumps. A swelling on the cheek and under the jaw, extending over the neck, from inflammation of the parotid and other salivary glands, rendering deglutition, or even respiration, sometimes difficult, declining the fourth day. Epidemic and contagious.

mic and contagious.

The disease is subject to a metastasis occasionally, in females to the mammæ, in males to the testes; and in a few instances, repelled from these parts, it has affected the brain, and even proved fatal. In general, however, the disease is without danger, and scarcely calls for medical aid. Keeping a fiannel over the part, and the antiphlogistic regimen, with mild laxatives, will be sufficient. Should the mammæ, or the testes, will be sufficient. Should the maintax, or the testes, be affected, more active evacuations may be necessary to prevent the destruction of those organs, bleeding general and topical, &c. but avoiding cold applications, lesi it should be driven to the brain. And where this part is unfortunately attacked, besides the means explained under Phrenitis; it may be useful to endeavour to recall the inflammation to its former seat by warm formentations, stimulant liminears. &c.

plained under Phrenitis, it may be useful to endeavour to recall the inflammation to its former seat by warm fomentations, stimulant liniments, &c.

5. Cynanche maligna. The malignant, putrid, or ulcerous sore throat. Called also Cynanche gangrænosa; Angina ulcerosa; Febris epidemica cum angina ulcusculosa; Angina epidemica; Angina gangrænosa; Angina suffocativa; Angina maligna. This disease is readily to be distinguished from the inflammatory quincy, by the soreness and specks which appear in the fauces, together with the great debility of the system, and small flutering pulse, which are not to be observed in the former. In the inflammatory sore throat there is always great difficulty of swallowing, a considerable degree of tumour, with a tendency in the parts affected to suppurate, and a hard, full pulse. Moreover in the former affection the disease is seated principally in the mucous membrane of the mouth and throat; whereas in the latter the inflammation chiefly occupies the glandular parts.

The putrid sore throat often arises from a peculiar state of the atmosphere, and so becomes epidemical; making its attacks chiefly on children, and those of a weak relaxed habit. It is produced likewise by contagion, as it is found to run through a whole family, when it has once seized any person in it; and it proves often fatal, particularly to those in an infantile state.

It appears, however, that under this head two different complaints have been included; the one, especially

often fatal, particularly to those in an inhandle state.

It appears, however, that under this head two different complaints have been included; the one, especially fatal to children, is an aggravated form of scarlatina; the other, a combination of inflammation of the fauces with typhus fever; the former is perhaps always, the policy of the English galangale. Cyperus—culmo 280

latter certainly often, contagious. See Scarlatina and

Typhus. CYNA'NCHICA. (Cinanchicus; from κυναγχη

CYNA NCHICAL CHARACTER (From κυων, a dog, and ανθρωπος, a man.) It is used by Bellini, De Morbis Capitas, to express a particular kind of melancholy, when menfancy themselves changed into dogs, and imitate their

CYNARA. See Cinara.

CYNAROCEPHALUS. (From κιναρα, the artichoke, and κεφαλη, a head.) Having a head like the Cinara, or artichoke; as the thistle, globe thistle, burdock, blue bottle.

CYNCHNIS. KUYXVIS. A vessel of any kind to

hold medicines in.

CYNOCRA'MBE. (From κυων, a dog, and κραμβη, cabbage; an herb of the cabbage tribe, with which dogs are said to physic themselves.) See Mercurialis pe-

CYNO'CTANUM. (From κυων, a dog, and κζεινω, to kill.) A species of aconitum, said to destroy dogs. See Aconitum napellus.

CYNOCY'TISIS. (From κυων, a dog, and κυζισος, the cytisis: so named because it was said to cure the distemper of dogs.) The dog-rose. See Rosa canina. CYNODE CTOS. (From κυων, à dog, and δακνω, to bite.) So Dioscorides calls a person bit by a mad dog.

to bite.) So Dioscornes cans a person of dog.

Cynope'smion. (From κυων, a dog, and δεω, to bind; so named because in dogs it is very discernible and strong.) A ligature by which the prepuce is bound to the glands. See Frænum.

CYNODO'NTES. (Κυνοδοντες: from κυων, a dog, and οδονες a tooth.) The canine teeth. See Teeth.

CYNOGLO'SSUM. (From κυων, a dog, and γλωσσα, a tongue; so named from its supposed resemblance.) Hound's tongue.

1. The name of a genus of plants in the Linnæan

1. The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Monogynia.

2. The pharmacopeial name of the hound's tongue. See Cynoglossum officinale.

Cynoglossum officinale. The systematic name for hound's tongue. Cynoglossum; Lingua canina; Cynoglossum—staminibus corolla brevioribus; foliis lato lanceolatis tomentosis, sessilibus, of Linnæus. It possesses narcotic powers, but is seldom employed medicinally. Acids are said to counteract the ill effects of an over-dose more speedily than any thing

else, after clearing the stomach.

Cyno'lorhus. (From κυων, a dog, and λοφος, a protuberance: so called because in dogs they are peculiarly eminent.) The asperities and prominences of

CYNOLY'SSA. (From κυων, a dog, and λυσση, madness.) Canine madness.

CYNOMO'RIUM. The name of a genus of plants

the Linnwan system. Class, Monacia; Order, Monandria.

Mondatria.

Cynonorium coccineum. The systematic name of the Fungus melitensis; improperly called a fungus It is a small plant which grows only on a little rock ad joining Malta. A drachm of the powder is given for a dose in dysenteries and hæmorrhages, and with remarkable success.

CYNORE XIA. (From κυων, a dog, and ορεξις, appetite.) A voracious or canine appetite. See Bu

limia.

CYNO'SBATOS. See Cynosbatus.

CYNO'SBATUS. (From κυων, a dog, and βαζος, a thorn: so called because dogs are said to be attracted by its smell.) The dog-rose. See Rosa canina.

CYNOSPA'STUM. (From κυων, a dog, and σπαω, to attract.) See Rosa canina.

CYOPHO'RIA. (From κυος, a fœtus, and φερω, to hear.) Prognancy.

CYOPHO RIA. (From κυος, a lectus, and φερω, to bear.) Pregnancy.

CYPARI'SSUS. See Cupressus.

CYPERUS. (From κυπαρος, a little round vessel, which its roots are said to resemble.) Cyperus. The name of a genus of plants in the Linnæan system.

Class, Triandria; Order, Monegynia.

CYPERUS RECULENTUS. The rush-nut. This plant is a native of Italy, where the fruit is collected and eaten, and said to be a greater delicacy than the chesnut.

triquetro folioso, umbella foliosa supra decomposita; pedunculis nudis, spicis alternis, of Linnæus. The smell of the root of this plant is aromatic, and its taste warm, and sometimes bitter. It is now totally fallen

CYPERUS ROTUNDUS. This species, the round cyperus, Cyperus—culmo triquetro subnudo, umbella de-composita; spicis alternis linearibus, of Linnæus, is generally preferred to the former, being a more grate-fully aromatic bitter. It is chiefly used as a stomachic.

CYPHELLA. A peculiar sort of pit or pore on the under side of the frond, in that section of lichens

CAPHO'MA. (From κυπ7ω, to bend.) A gibbosity, or curvature of the spine.

CYPHO'SIS. An incurvation of the spine.

CYPRESS. See Cyprus.

Cypress spurge. See Esula minor.

CYPRINUM OLEUM. Flowers of cypress, calamus,

cardamoms, &c. boiled in olive oil, now fallen into

Cy'PRIUM. (From κυπρος, Cyprus, an island where

it is said formerly to have abounded.) Copper.
CY'PRUS. (So called from the island of Cyprus,
where it grew abundantly.) The cypress-tree, or

Eastern privet.

[CYPRCEITE. Petrifaction of a Cyprcea or Cowrey. See Organic relics. A.]

CY'PSELIS. (From κυψελη, a beehive.) The aperture of the ear, also the wax of the ear.

CYRCNE'SIS. (From κυρκναω, to mix.) A mixture,

or composition. CYRTO'MA. (From Kup7os, curved.) I. An unna-

tural convex tumour. 2. Tympanites.

Cyrtono'sus. (From κυρ/ος, curved, and νοσος, a disease.) 1: The rickets.
2. Curved spine.
CYRTOSIS. (Cyrtosis, is. f.; from κυρτος, curvus,

incurvus, gibbosus, and among the ancients particularly imputed recurvation of the spine, or posterior larly imputed recurvation of the spine, or posterior crookedness, as \$\lambda op\tilde{a}\sigma_{\sigma \text{i}}\$ (imputed procurvation of the head and shoulders, or anterior crookedness.) The name of a genus of diseases in Good's Nosology. Class, Eccritica; Order, Mesotica. Contortion of the bones; defined, head bulky, especially anteriorly; stature short and incurvated; flesh flabby, pale, and wrinkled. It has two species, Cyrtosis rhachia, and Contentions of the procure of the

C. cretenismus, cretenism.
Cy'ssarus. (From κυσος, the anus.) The intestinum rectum is so called, because it reaches to the

Cysso'TIS. (From KUGOS, the anus.) An inflamma-

tion of the anus

CYSTEOLI'THUS. (Prom $\kappa v_5 \iota_5$, the bladder, and θ_{05} , a stone.) A stone in the bladder, either urinary λιθος, a stone.) or gall-bladder.

CYSTIUS. Κυσθος. The anus. CYSTIC. (Cysticus; from κυςις, a bag.) Belong-

CYSTIC (Cysticus; from keyts, a bag.) Belonging to the urinary or gall-bladder.
Cystic buct. See Ductus cysticus.
Cystic oxide. A peculiar animal product discovered by Dr. Wollaston. See Calculus, urinary.

Cy'stica. (Cysticus; from kuçıs, the bladder.)
Remedies for diseases of the bladder.

CY'STIDES. (Cystis, idis. f.; from kuşıç, a bag.)

Encysted tumours

CYSTIPHLO'GIA. (From kugis, the bladder, and

φλεγω, to burn.) An inflammation in the bladder See Cystitis.

CYSTIRRHA'GIA. (From κυςις, the bladder, and ρηγνυμι, to burst forth.) A discharge from the bladder. CYSTIS. (Κυςις, a bag.) 1. Cyst or bladder. 2. The urinary bladder.

3. The membranous or cyst surrounding or contain

ing any morbid substance.

ing any morbid substance.

Cystis choledocha. See Gall-bladder

Cystis fellea. See Gall-bladder.

Cystis urinaria. See Urinary bladder.

Cystis urinaria. See Urinary bladder.

Cystif Tis. (From kuşiş, the bladder.) Inflammation of the bladder. A genus of disease arranged by Cullen in the class Pyrexia, and order Phlegmasia. It is known by great pain in the region of the bladder, attended with fever and hard pulse, a frequent and painful discharge of urine, or a suppression, and generally tenesmus. This is rarely a primary disease, and when it occurs, the above character of it will readily point it out. There also is frequently nausea and yomiting, and, in some cases, delirium. It most point it out. There also is frequently nausea and vomiting, and, in some cases, delirium. It most generally arises in consequence of inflammation of the adjacent parts, or from calculi in the bladder. The treatment is very similar to that of Nephritis; which When suppression of urine attends, the catheter must be occasionally introduced.

CYSTOGE'LE. (From κυζις, the bladder, and λη, a tumour.) A hernia formed by the protusion

CYSTOGE'LE. (From κυςις, the bladder, and κηλη, a tumour.) A hernia formed by the protusion of the urinary bladder.

CYSTOLI'THICUS, (From κυςις, the bladder, and λιθος, a stone.) Having a stone in the bladder.

CYSTOPHLE'GICUS. (From κυςις, the bladder, and φλεγω, to burn.) An inflammation of the bladder.

CYSTOPHLEGMA'TICUS. (From κυςις, the bladder, and φλεγμα, phiegm.) Having matter or mucus in the bladder.

CYSTOPRO'CTICUS. (From κυςις, the bladder, and ωρωκ7ος, the anus, or rectum.) A disease of the bladder and rectum.

CYSTOPTO'SIS. (From κυςτς, the bladder, and ωιπ7ω, to fall.) A protrusion of the inner membrane of the bladder, through the urethra.

CYSTOSPA'STICUS. (From κυςτς, the bladder, and σπασμα, a spasm.) A spasm in the sphincter of the bladder. the bladder.

CYSTOSPYICUS. (From κυςις, the bladder, and πυον, pus.) Purulent matter in the bladder.

CYSTOTHROMBOLDES. (From κυςις, the bladder, and θρομβος, a coagulation of blood.) A concretion of grumous blood in the bladder.

CYSTOTO MIA. (From κυςις, the bladder, and 7εμνω, to cut.) The operation of cutting or piercing the bladder.

the bladder.

Cy'THON. An eye-wash.
Cy'TINUS. (Perhaps, as Martyn suggests, from κυζινοι, a name given by Theophrastus to the blossoms of the pomegranate, the calyx of which the flower in question resembles in shape.) The name of a genus of plants. Class, Gynandria; Order, Octandria of Linguis. Linnæus.

CYTINUS HYPOCISTIS. Rape of Cystus. pale-yellowish plant, parasitical on the roots of several species of cystus in the south of Europe, from which the succus hypocistidus is obtained.

CYTISO-GENISTA. Common broom. See Spartium

CYZEMER. A swelling of the wrists.

CYZICE'NUS. A plaster for wounds of the nerves.

. .

DAUNE'RUS. (From δακνω, to bite.) Biting. Pungent. An epithet for a sharp eye-wash, composed of burnt copper, pepper, cadmia, myrrh, and opium. DACRY DIUM. (From δακου, a tear.) The inspisated juice of scammony, in small drops, and therefore called a tear.

fore called a tear.

DACRYGELO'SIS. (From δακρυω, to weep, and γελαω, to laugh.) A species of insanity, in which the patient weeps and laughs at the same time.

DACRYO'DES. (From δακρυω, to weep.) A sanious, or weeping ulcer.

DACRYO'MA. (From δακρυω, to weep.) of one or more of the puncta lachrymalia, causing an effusion of tears.

DACTYLE THRA (From ¿aκ?νλος, a finger.) A species of bougies shaped like a finger, to excite vomiting.

DACTYLE'TUS. (From čak 7 v λος, the date.) The

DACTYLE TUS. (From caκ/υλος, the date.) The hermodactyl. See Hermodactylus.

DA'CTYLIUS. (From δακ/υλος, a finger.) A round pastil, troche, or lozenge, shaped like a finger. DA'CTYLUS. (From δακ/νλος, a finger; so called from the likeness of its fruit to a finger.) 1. A finger.

See Digitus.

2. The date. See Phanix dactylifera.

DÆ DIUM. (From ŏais, a torch. A small torch or

candle. A bougle.

DÆMONOMA'NIA. (From δαιμων, a dæmon, and μανια, madness.) That species of melancholy where the patient supposes himself to be possessed by

devils.

DAISY. See Bellis perennis.

Daisy, oz-eye. See Chrysanthemum leucanthemum.

DALE, SAMUEL, was born in 1659. After practising as an apothecary, he became a licentiate of the college of physicians, and settled at Bocking, where he continued till his death in 1739. He was also chosen a fellow of the Royal Society. In 1693, he published his "Pharmacologia," an Introduction to the Materia Medica, which he afterward much enlarged and improved; the work was well received, and passed through many editions. He also gave a good account of the natural productions about Harwich and Dover Court.

Damask rose. See Rosa centifalia.

Damna'TUS. (From damno, to condemn.) The dry useless faces, left in a vessel after the moisture has been distilled from it, is called terra damnata, or caput

DAMSON. The fruit of a variety of the Prunus

domestica.

[DANA, James Freeman, M. D., was the oldest son of Luther Dana, Esq., and was born in Amherst, in the state of New-Hampshire, in September 1793. After his graduation, he commenced the study of medicine under Dr. John Gorham, at that time Professor of Chemistry in Harvard University. In the year 1815, before he had completed his professional studies, he had become so well known as a practical chemist, that he was selected by the University to go to London, as an agent, for the purpose of procuring a new appathat he was selected by the University to go to London, as an agent, for the purpose of procuring a new apparatus for the chemical department. While in England, where he remained several mouths, he prosecuted the study of chemistry in the Laboratory of Acum, a celebrated operative chemist.

With Dartmouth College he remained connected, in the capacity of Lecturer on Chemistry, until the year 1820, when he received the appointment of Professor

1820, when he received the appointment of Professor of Chemistry and Mineralogy in the same institution. This office he held until the year 1826; and those who enjoyed the privilege of hearing his admirable lectures, will long remember with what ability and success he will long remember with what ability and success he discharged its duties. In 1826 he was appointed one of the Board of Visiters of the Military Academy at West Point; and, immediately after his return from the discharge of this duty, he was appointed Professor of Chemistry in the University of New-York. This appointment, which opened a wide field for the exertion of his talents, he readily accepted, and removed with his family to the city, in the autumn of the same year. About six months after his removal to New-York, he sunk under an attack of ervinelax at the

York, he sunk under an attack of crysipelas, at the carly age of 33, and when just entering upon an extended sphere of usefulness and honour.

His principal publications were the following, viz. "Outlines of the Mineralogy and Geology of Boston and its Vicinity:" "Epitome of Chemical Philosophy:" "Report on a singular Disease of horned Cathers in the Town of Burton, New-Hampshire." Besides these publications, he contributed several papers to the the, in the Town of Burton, New-Hampshire." Besides these publications, he contributed several papers to the American Journal of Science, the New-England Journal of Medicine, and the Annals of the Lyceum of Natural History of New-York, some of them of very considerable merit, and some of which have been reprinted in Europe."—Thatch. Med. Biog. A.]

DANDELION. See Learning of Pathyling See Pittyring 12.

DANDELION. See Leontodon Taraxacum.
DANDRIF. See Pityriasis.
DANEWORT. See Sambucus Ebulus.
DAOURITE. A variety of red schord from Siberia.
DAPHNE. (Dapane, δαφνη; from δαω, to burn, and φωνη, a noise: because of the noise it makes when burnt.) The name of a genus of plants in the Linnæan system. Class, Octandria; Order, Monogynia. The laurel, or bay-tree.
DAPHNE ALPINA. Chamælea; Chamelæa. This species of dwarf olive-tree is said to be purgative in the dose of 3 jj, and is sometimes given by country leople. The French chemists have lately examined it chemically. See Daphnin.

chemically. See Daphnin.

2. The mezereon is also so called, because it has leaves like the olive-tree. See Daphne mezereum. Daphne, flax-leaved. See Daphne gnidium. Daphne onidium. The systematic name of the tree which affords the Garou bark. Daphne:—panicula terminali foliis lineari-lanceolatis acuminatis of Linnaus. Thymelwa; Oneoron. Spurge-flax; Flax-leaved Daphne. Garou bark, which very much resembles that of our mezereum, is to be immersed in vinegar for about an hour before it is wanted; a small vinegar for about an hour before it is wanted; a small vinegar for about an hour before it is wanted; a small piece, the size of a sixpence, thus steeped, is applied to the arm or any other part, and renewed once a day in winter and twice in summer. It produces a serous exudation from the skin without irritating or blistering. It is recommended, and is in frequent use in France and Russia, against some diseases of the eyes.

Daphne Laureola. The systematic name of the spurge-laurel. Laureola daphnoides. The bark of this plant is recommended to excite a discharge from the skin, in the same way as that of the Daphne grai-

the skin, in the same way as that of the Daphne gni-

DAPHNE MEZEREUM. The systematic name of the mezereon. Spurge-olive; Widow-wail. Mezereum. Daphne-floribus sessilibus ternis caulinis, foliis lanceolatis deciduis, of Linnæus. This plant is extremely acrid, especially when fresh, and, if retained in the ly acrid, especially when fresh, and, if retained in the mouth, excites great and long-continued heat and in-flammation, particularly of the mouth and fauces; the berries, grana cnidii of old writers, also have the same effects, and, when swallowed, prove a powerful corrosive poison, not only to man, but to dogs, wolves, and foxes. The bark of the root is the part employed medicinally in the decoctum sarsaparilla compositum, intended to assist mercury in resolving nodes and other obstinate symptoms of synhilits. The antisynhilities obstinate symptoms of syphilis. The antisyphilitic virtues of mezereum, however, have been by many writers very justly doubted. "The result of my own experience (says Mr. Pearson, of the Lock Hospital) by no means accords with the representation given of this root by former writers. this root by former writers. From all that I have been able to collect, in the course of many years' observation, I feel myself authorized to assert, unequivocally, that the mezereum has not the power of curing the venereal disease in any one stage, or under any one form. If a decoction of this root should ever reduce a venereal node, where no mercury has been previously given, yet the patient will by no means be exempted from the necessity of employing mercury for as long a space of time, and in as large a quantity, as if no mezereum had been taken. With respect to the power it is said to possess, of alleviating the pain, and diminishing the bulk of membraneous nodes, nothing peculiar and appropriate can be ascribed to the mezereum on these accounts, since we obtain the same good effects from sarsaparilla, guaiacum, volatile alkali, blistering plasters, &c. Nevertheless, venereal nodes. blistering plasters, &c. Nevertheless, venereal nodes, which have subsided under the use of any of these articles of the materia medica, will appear again, and often with additional symptoms, if a full and efficacious course of mercury be not submitted to. It has, indeed, been alleged, that mezereum always alleviates the pain occasioned by a venereal node, and generally reduces it, where the periosteum only is affected; and that it seldom fails of removing those enlargements of the periosteum which have not yielded during the administration of mercury.

That some instances of success in cases like these

That some instances of success, in cases like these, may have fallen to the share of those who made the assertion, it would not become me to deny; but I have met with few such agreeable evidences of the efficacy met with few such agreeable evidences of the efficacy of this medicine. I have given the mezereum in the form of a simple decoction, and also as an ingredient in compound decoctions of the woods, in many cases, where no mercury had been previously employed, but never with advantage to a single patient. I have also tried it, in numerous instances, after the completion of a course of mercury; yet, with the exception of two cases, where the thickened state of the periosteum was removed during the exhibition of it, I never saw the least benefit derived from taking this medicine. In a few cases of anomalous pains, which I supposed were derived from irregularities during a mercurial course, the mezereum was of service, after I had tried the the mezereum was of service, after I had tried the common decoction of the woods without success; but even in this description of cases, I have always found it a very uncertain remedy. I have made trial of this vegetable in a great number of scrofulous cases, where

the membranes covering the bones were in a diseased state, and I am not sure that one single patient obtained any evident and material benefit from it.

The late Dr. Cullen, whose reports may justly claim The late Dr. Cullen, whose reports may justly claim attention from all medical men, when treating of the mezereum, in his Materia Medica, says, "I have frequently employed it in several cutaneous affections, and sometimes with success." It were to have been wished, that the professor of medicine had specified what those diseases of the skin were, in which the mezereum was sometimes employed with success; for, if I except an instance or two of lepra, in which the description of this plant conferred a temporary benefit. decoction of this plant conferred a temporary benefit, I have very seldom found it possessed of medicinal virtue, either in syphilis, or in the sequelæ of that disease, in scrofula or in cutaneous affections. Indeed the mezereum is of so acrimonious a nature, often producing heat and other disagreeable sensations in the fauces, and, on many occasions, disordering the prime viæ, that I do not often subject my patients, to the certain inconveniences which are connected with the primary effects of this medicine, as they are rarely com-

mary effects of this medicine, as they are rarely compensated by any other important and useful qualities."

DAPHNELÆ'ON. (From δαφνη, the laurel, and ελαιον, oil.) The oil of bay-berries.

DAPHNIN. The bitter principle of the Daphne alpina, discovered by Vauquelin. From the alkoholic infusion of this bark, the resin was separated by its concentration. On diluting the tincture with water, filtering and adding acetate of lead, a yellow daphnate of lead fell, from which sulphuretted hydrogen separated the lead, and left the daphnin in small transparent crystals. They are hard, of a grayish colour, a bitter taste when heated, evaporate in acrid acid vapours, sparingly soluble in cold, but moderately in a other taste when heated, evaporate in acrid acid vapours, sparingly soluble in cold, but moderately in boiling water. It is stated, that its solution is not precipitated by acctate of lead; yet acctate of lead is employed in the first process to throw it down.

Daphni'tis. (From δαφνη, the laurel.) A sort of cassia resembling the laurel.

DAPHNOI'DES. (From δαφνη, the laurel, and ειδος, a likeness.) The herb spurge laurel. See Daphne laureola.

The grosser Da'rsin. (From darzin, Arabian.)

sort of cinnamon.

DA'RSIS. (From δερω, to excoriate.) An excoria-

DA'RTOS. (From δερω, to excoriate: so called from its raw and excoriated appearance.) The part so called, under the skin of the scrotum, is by some anatomists considered as a muscle, although it appears to be no more than a condensation of the cellular membrane lining the scrotum. It is by means of the dartos that the skin of the scrotum is corrugated and relaxed

DARWIN, ERASMUS, was born at Elton, in Nottinghamshire, in 1731. After studying at Cambridge
and Edinburgh, and becoming doctor of medicine, he
went to settle at Litchfield. He had soon after the
good fortune to succeed in the cure of a gentleman in
the neighbourhood, who was so ill of a fever, as to
have been given over by the physician previously in
attendance: this speedily procured him very extensive
practice. He soon after married, and by his first wife
had three sons, of whom only one survived him. At had three sons, of whom only one survived him. At the age of 50, he married again, and removed to Derby, where he continued till his death in 1802, leaving six children by his second wife. The active life he led, and his very temperate habits, preserved his health and faculties in a great degree unimpaired. He distinguished himself more as a poet, than by professional improvements: though he certainly suggested some ingenious methods of practice; but, warned by prece-ding examples, he avoided publishing any material ding examples, he avoided publishing any material poem, till his medical fame was thoroughly established. His "Botanic Garden," and "Zoonomia," are well known, but they have long ceased to be popular: and the philosophy of the latter work, which advocates materialism, is justly censured. He communicated to the College of Physicians an account of his successful use of digitalis in dropsy, and some other diseases, which was published in their Transactions. His son Charles, who died while studying at Edinburgh, obtained a gold medal by an Essay on the distinction of Pus and Mucus; and left another unfinished on the Retrograde Action of the Absorbents: which were published after his death by his father. Dasy'mna. (From δασυς, rough.) A scabby roughness of the eyelids.

DA'SYS. (Δασυς, rough.) 1. A dry, parched tongue,
2. Difficult respiration.

DATE. See Dactylus.

Date plum, Indian. See Dyospyrus lotus.

DATOLYTE. Datholit of Werner. A species of silicious ore divided into common datolyte and botroldal fatchets. dal datolyte.

This is the silicious borate of lime, called Datho [This is the silicious borate of lime, called Datho-Lit, by Werner and Brogniart. It was discovered by Esmark. "It is sometimes in prismatic crystals, with ten sides, having two opposite solid angles on each base truncated. The primitive form is a right prism, whose bases are rhombs, with angles of 1099 28' and 70° 32'. It also appears in large granular concretions, which frequently discover indications of a prismatic form; also in grains or amorphous. The surface of the concretions is rough and glimmering.

Its hardness enables it to scratch fluate of lime, and its specific gravity is 2.98. Its fracture is imperfectly conchoidal, shining, and nearly vitreous. Its colour is white, shaded with gray or green, often very de-

When exposed to the flame of a candle, it assumes a dull white colour, and becomes very brittle, even be-tween the fingers. Before the blowpipe it swells into a milk-white mass, and then melts into a pale rose-coloured glass. It is composed of

Cleav. Min. A.]
DATU'RA. (Blanchard says, it is derived from the Indian word datiro, of which he knows not the meaning.) The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Monogynia.

DATURA STRAMONIUM. The systematic name of the thorn-apple. Stramonium; Dutray; Barryo coccalon; Solanum maniacum of Dioscorides. Stramonium spinosum of Gerard. Solanum fatidum of Bauhin. Stramonium majus album. Common thorn-apple. Datura—pericarpiis spinosis erectis ovatis, foliis onahin. Stramonium majus album. Common thorn-apple. Datura—pericarpiis spinosis erectis ovatis, foliis ovatis glabris, of Linnæus. This plant has been long known as a powerful narcotic poison. In its recent state it has a bitterish taste, and a smell somewhat resembling that of poppies, especially if the leaves be rubbed between the fingers. Instances of the deleterious effects of the plant are numerous, more particularly of the seed. An extract prepared from the seeds is recommended by Baron Stoerek in maniacal, epileptic, and convulsive affections; and is said by some to is recommended by Baron Stoerck in maniacal, epilep-tic, and convulsive affections; and is said by some to succeed, while, in the hands of others, it has failed. In this country, says Dr. Woodville, we are unac-quainted with any practitioners whose experience tends to throw light on the medical character of this plant. It appears to us, continues Dr. Woodville, that its effects as a medicine are to be referred to no other power than that of a narcotic. And Dr. Cullen. power than that of a narcotic. And Dr. Cullen, speaking on this subject, says, "I have no doubt that narcotics may be a remedy in certain cases of mania and epilepsy; but I have not, and I doubt if any other person has, learned to distinguish the cases to which such remedies are properly adapted. It is therefore that we find the other negative as well as the stage. that we find the other narcotics, as well as the stramonium, to fail in the same hands in which they had in

mium, to fail in the same hands in which they had in other cases seemed to succeed. It is this consideration that has occasioned my neglecting the use of stramonium, and therefore prevented me from speaking more precisely from my own experience on this subject."

The extract of this plant has been the preparation usually employed from one to ten grains and upwards a day; but the powdered leaves, prepared after the manner of those of hemiock, would seem to be more certain and convenient. Greding found the strength of the extract to vary exceedingly; that which he obtaintained from Ludwig was much more powerful than that which he had of Stoerck. Externally, the leaves of stramonium have been applied to inflammatory themours and burns, and it is said with success, and of late, the dried leaves have been smoked as a remedy in asthma; but it does not appear that they have been more efficacious in this way than tobacco.

[The Stramonium is known in different parts of the United States, by the name of Thorn-apple, Jamestown-283

wheed, Stink-weed, &c. All parts of the plant appear to be poisonous. Some soldiers died, during the revobe poisonous. Some soldiers died, during the revolutionary war, by eating the young plants, for greens, early in the spring. I have seen children labouring under the effects of the poison from having swallowed the seeds, and from drinking a decoction of herbs in which some of the young seed-vessels, and small leaves, of the stramonium had been accidentally mixed.

The poison of the stramonium produces, in children, a peculiar spasmodic delirium, attended with dilatation of the pupils of the eyes, heat of the skin, and a flush of the face. The ripe or unripe seeds, or the leaves, produce the same effect, and the only remedy is to discharge them from the stomach by emetics, as

is to discharge them from the stomach by emetics, as soon as possible. A.]

DAUBENTON, Lewis Mary, was born in Burgundy, 1716. Having become doctor in medicine at the age of 24, he went to Paris, and being very zealous in the study of comparative anatomy, the office of keeper of the royal cabinet of natural history was procured for him by the celebrated Buffon. He contributed materially to enrich the splendid work of that eminent naturalist, by furnishing the anatomy both of man and animals. He was a member of several distinguished societies, among others of the Royal Academy of Sciences at Paris, to which he made some useful communications. Having escaped the revolutionary horrors in France, he was chosen, in 1799, a member of the Conservative Senate: but he died towards ber of the Conservative Senate: but he died towards the end of the same year.

Wild-carrot seeds, steeped in

DAU'CUS. A nov row daucer, from its relieving the colic, and discussing flatulencies.) The carrot. 1. The name of a genus of plants in the Linnwan system. Class, Pentandria; Order, Digynia.

2. The pharmacopæial name of the garden carrot:

See Daucus carota.

DAUCUS ALSATICUS. The Oreoselinum pratense, of Linnaus.

DAUCUS ANNUUS MINOR. The Caucalis anthriscus,

of Linnæus.

of Linnæus.

Daucus carota. The systematic name of the carrot plant. Daucus; Daucus sylvestris; Pastinaca sylvestris tenuifolia officinarum; Daucus—seminibus hispidis, petiolis subtus nervosis, of Linnæus. The cultivated root, scraped, and applied in the form of a poultice, is a useful application to phagedænic ulcers, and to cancers and putrid sores. The seeds, which obtain a place in the materia medica, have a light aromatic smell, and a warm acrid taste, and are esteemed for their diuretic qualities, and for their ritility in calculous and perphritic complaints in which utility in calculous and nephritic complaints, in which an infusion of three spoonfuls of the seeds, in a pint of boiling water, has been recommended; or the seeds may be fermented in malt liquor, which receives from them an agreeable flavour, resembling that of lemon-peel. The boiled root is said by many to be difficult of peel. The boiled root is said by many to be difficult of digestion; but this is the case only when the stomach is weak. It contains a considerable quantity of the saccharine principle, and is very nutritious.

DAUCUS CRETICUS. See Athamanta cretensis.

DAUCUS SATIVUS. A variety of the Daucus carota, the seeds of which are preferred by some practitioners,

DAUCUS SEPRINUS. Common chervil.

DAUCUS SYLVESTRIS. Wild carrot, or bird's nest.

The seeds of the wild plant are said to be more efficacious than those of the garden carrot; they possess demulcent and aromatic qualities, and are given, in in-

The name of a class, and also of an order of plants in the sexual system. See Plants.

Decide Nila. (From decido, to fall down.) Any change prolonging acute diseases.

DECI'DUA. (Deciduus; from decido, to fall off.) Membrana decidua. A very thin and delicate membrane or tunic, which adheres to the gravid uterus, and is said to be a reflection of the chorion, and, on that account, is called decidua reflexa. The tunica decidua comes away after delivery, in small pieces, mixed with the lochia.

DECI'DUUS. (From decido, to fall off, or down: to die.) Deciduous; falling off. Applied to trees and shrubs, which, in most European countries, lose their leaves as winter approaches, and to the perianthium of Tilia europæa, which does not fall off until after the flower is expanded.

the flower is expanded.

This term is expressive of the second stage of duration, and, like caducous, has a different application according to the particular part to which it refers: thus leaves are deciduous which drop off in the autumn, petals which fall off with the stamina and pistils; and calyces are deciduous which fall off after the eventsion, and before the dropping of the flower. the expansion, and before the dropping of the flower.

DECIMA'NUS. (From decem, ten, and mane, the morning.) Returning every tenth day, applied to some erratic fevers.

DECLEMES. (Proceedings)

some erratic fevers.

DECLI'VIS. (From de, and elivis, a hill.) De clining, descending. A name of an abdominal muscle, because of its posture.

DECO'CTUM. (From decoguo, to boil.) A decoction. Any medicine made by boiling in a watery fluid. In a chemical point of view, it is a continued ebullition with water, to separate such parts of bodies as are only soluble at that degree of heat. The following are

only soluble at that degree of heat. The following are among the most approved decoctions.

DECOCTUM ALBUM. See Mistura cornu usti.

DECOCTUM ALOES COMPOSITUM. Compound de coction of aloes. Take of extract of liquorice, half an ounce; subcarbonate of potassa, two scruples; extract of spiked aloe powdered, myrrh powdered, saffron stigmata, of each a drachm; water, a pint. Boil down to twelve fluid ounces, and strain; then add compound tincture of cardamoms, four fluid ounces. This decoction, now first introduced into the London Pharmacopeia, is analogous to an article in very frequent use. pæia, is analogous to an article in very frequent use, invented by the late Dr. Devalingin, and sold under the name of Beaume de vie. By the proportion of tincture which is added, it will keep unchanged for any length of time.

of time.

Decoctum ALTHEE. Decoction of marsh mallows.

Take of dried marsh-mallow roots, 3 iv; raisins of the sun, stoned, 3 ij; water lbvij. Boil to five pounds; the sun, stoned, \(\frac{3}{3}\) ij; water lbvij. Boil to five pounds; place apart the strained liquor, till the faces have subsided, then pour off the clear part. This preparation, directed in the Edinburgh Pharmacopæia, may be exhibited as a common drink in nephralgia, and many diseases of the urinary passages, with advantage.

DECOCTUM ANTHEMIDIS. See Decoctum chama-

Take of the root of the DECOCTUM ASTRAGALI. astragalus escapus, 3 j; distilled water, biij. These are to be boiled, till only a quart of fluid remain. The whole is to be taken, a little warmed, in the course of 24 hours. This remedy was tried very extensively in Germany, and said to evince very powerful effects, as an antisyphilitic.

DECOCTUM BARDANE. Take of bardana root, 5 vj; of distilled water, lbvj. These are to be boiled till only two quarts remain. From a pint to a quart in a day is given, in those cases where sarsaparilla and other remedies, that are called alterative, are supposed

DAY-MARE. See Ephialtes.

DAY-MARE. See Ephialtes.

DAY-SIGHT. See Paropsis noctifuga.

Dead nettle. See Lamium album.

DEAFNESS. Surditas. See Paracusis.

DEAFNESS. Surditas. See Paracusis.

DEAFTICULA'TIO. (From de, and articulus, a joint.)

Articulation admitting evident motion.

DEAGY'NIA. (From δεκα, ten, and γυνη, a woman.) The name of an order of the class Decandria, of the sexual system of plants. See Plants.

DECAGY'NIA. (From δεκα, ten, and μυρον, an ointment.) An aromatic ointment, mentioned by Oribasius, containing ten ingredients.

DECA'NDRIA. (From δεκα, ten, and ανηρ, a man.)

DECA'NDRIA. (From δεκα, ten, and ανηρ, a man.)

lages, as being less dense than either of the others, and as being employed in larger doses, like other mucilaginous decoctions. In addition to gum, it contains other constituent parts of the seeds, and is, therefore, more apt to spoil than common mucilage, over which it possesses no other advantages, than that it is more grateful, and sufficiently thin, without further dilution, to form the bulk of appelloying medicing. He wither to form the bulk of any-liquid medicine. Its virtues are demulcent. Joined with syrup of mulberry and a little borax, it is useful against aphthæ of the mouth and

DECOCTUM DAPHNES MEZEREI. Decoction of mezereon. Take of the bark of mezereon root, \$\frac{3}{2}ij; liquorice root, bruised, \$\frac{3}{2}ss; water, bijj. Boil it, with a gentle leat, down to two pounds, and strain it. From four to eight ounces of this decoction may be given four times a day, in some obstinate venereal and rheumatic affections. It operates chiefly by per-

spiration. DECOCTUM DULCAMAR &. Decoction of woody nightshade. Take of woody nightshade stalks, newly gathered, 3j; distilled water, fbiss. These are to be boiled away to a pint, and strained. The dose is half an ounce to two ounces, mixed with an equal quantity of milk. This remedy is employed in inveterate cases of scrofula; in cancer and phagedæna; in lepra, and other cutaneous affections; and in anomalous local diseases, originating in venereal lues.

DECOCTUM GEOFFRÆÆ INERMIS. Decoction of cabbage-tree plant. Take of bark of the cabbage-tree, powdered, § j; water, bij. Boil it, with a gentle fire, down to one pound, and strain. This is a powerful anthelmintic. It may be given in doses of one table-spoonful to children, and four to adults. If disagreeable symptoms should arise from an over-dose, or from drinking cold water during its action, we must immediately drinking cold water during its action, we must immediately purge with castor oil, and dilute with acidulated drinks.

DECOCTUM GUALACI OFFICINALIS COMPOSITUM. Decoctum lignorum. Compound decoction of guaia-cum, commonly called decoction of the woods. Take cum, commonly called decoction of the woods. Take of guaiacum raspings, \(\frac{7}{2} \) iij; raisins, stoned, \(\frac{7}{2} \) ij; sassafras root, liquorice, each, \(\frac{7}{2} \) j; water, tbx. Boil the guaiacum and raisins with the water, over a gentle fire, to the consumption of one half; adding, towards the end, the sassafras and liquorice. Strain the liquor without expression. This decoction possesses stimulant and diaphoretic qualities, and is generally exhibited in rheumatic and cutaneous diseases, which are decorded to a vitiated state of the humours. It may pendent on a vitiated state of the humours. It may be taken by itself, to the quantity of a quarter of a pint, twice or thrice a day, or used as an assistant in a course of mercurial or antimonial alteratives; the patient, in either case, keeping warm, in order to promote the operation of the medicine.

DECOCTUM HELLEBORI ALBI. Decoction of white hellebore. Take of the root of white hellebore, powdered, by weight, \(\frac{3}{3}\)j; water, two pints; rectified spirits of wine, \(\frac{3}{3}\)j, by measure. Boil the water, with the root, to one pint; and the liquor being cold and strained, add to it the spirit. This decoction, in the last London Pharmaconomia, is called decoctum verastrained, add to it the spirit. This decoction, last London Pharmacopœia, is called decoctum veratri. It is a very efficacious application, externally, as a wash, in tinea capitis, lepra, psora, &c. When the skin is very tender and irritable, it should be diluted

with an equal quantity of water.

with an equal quantity of water.

Decoctum hordel. Decoctum hordel distichi.

Aqua hordeata. Take of pearl barley, 3 jj; water, four pints and a half. First wash away any adhering extraneous substances with cold water; next, having poured upon the barley half a pint of water, boil for a few minutes. Let this water be thrown away, and add the remainder of the water boiling; then boil down to two pints, and strain. Barley-water is a nutritive and softening drink, and the most proper of all

the lancifolia, or quilled; which is here directed. This way of administering the bark is very general, as all the other preparations may be mixed with it, as necessity requires. It is a very proper fomentation for prolapsus of the uterus and rectum.

DECOCTUM CORNU. See Mistura cornu usti.

DECOCTUM HORDET COMPOSITUM. Decoctum pectorale. Compound decoction of barley. Take of decoction of barley, two pints; figs, sliced, 3 ij; liquorice root, sliced and bruised, 3 ss; raisins, stoned, 3 ij; was ter, a pint. Boil over a gentle fire for ten minutes, then strain. This decoction, in the new London Pharmacopæia, has been removed from among the mucilages, as being less dense than either of the others, and lages, as being less dense than either of the others, and

DECOCTUM HORDET CUM GUMMI. Barley-water, fbij; gum arab., \$\frac{7}{3}j. The gum is to be dissolved in the barley decoction, while warm. It then forms a suitable diluent in strangury, dysury, &c. for the gum, finding a passage into the bladder, in an unaltered state, mixes with the urine, and prevents the action of its neutral salts on the urinary canal.

DECOCTUM LICHEMIS. Decoction of Iceland moss or liverwort. Take of liverwort, one ounce; water, a pint and a half. Boil down to a pint, and strain. The dose is from \$\frac{7}{3}iv.

[The Iceland moss was once in great repute as a remedy in consumption, the decoction being made

remedy in consumption, the decoction being made with milk, but it is no longer in repute, being considered a weak mucilagious bitter of little or no effi-

cacv.

DECOCTUM LOBELLE. Take a handful of the roots of the Lobelia syphilitica; distilled water, ibxij. These are to be boiled in the usual way, till only four quarts remain. The very desirable property of curing the venereal disease has been attributed to this medicine; but it is not more to be depended on than guaiacum, or other vegetable substances, of which the same thing has been alleged. The effects of this decoction are purgative, and the manner of taking it, as described by Swediaur, is as follows:—The patient is to begin with half a pint, twice a day. The same quantity is then to be taken, four times a day, and continued so long as its purgative effect is not too considerable. When the case is otherwise, it is to be discontinued for three or four days, and then had recourse to again till the cure is completed. As this is a remedy on the old system, and not admitted into our pharmacopæias, little confidence ought to be placed in it.

DECOCTUM LUSITANICUM. Take of sliced sarsaparilla, lignum sassafras, lignum santalum rubrum, officinal lignum guaiacum, of each one ounce and a half; of the roof of mezereon, coriander seed, of each half an ounce; distilled water, ten pounds. These are to be boiled till only half the fluid remains. The dose is a

quart or more in a day.

Take of sliced sarsaparilla, lignum santalum rubrum, lignum santalum citrinum, of each, 3 iss; of the root of glycirrhiza and mezereon, of each, 3 ij; of lignum rhodii, officinal lignum guaiacum, and lignum sassafras, of each, 3ss; of antimony, 3j; distilled water, by. These ingredients are to be macerated for twenty-four hours, and afterward boiled, till the fluid is reduced to half its original quantity. From one to

four pints are given daily.

The late Mr. Hunter notices this, and also the following formula, in his Treatise on the Venereal Dis-

Take of sliced sarsaparilla, of the root of China, of each \$\frac{3}{2}\$; walnut peels dried, xx; antimony, \$\frac{3}{2}\$; pumice-stone, powdered, \$\frac{3}{2}\$; distilled water, lbx. The powdered antimony and pumice-stone are to be tied in separate pieces of rag, and boiled, along with the other ingredients. This last decoction is reckoned to be the genuine Lisbon diet drink, the qualities of which have been the subject of so much encomium.

Decoctum Malv& compositum. Decoctum proenemate. Decoctum commune pro elystere. Compound decoction of mallows. Take of mallows dried, an ounce; chamomile flowers dried, half an ounce; water, a pint. Boil for a quarter of an hoor, and strain. A very excellent form for an emollient clyster. A variety of medicines may be added to answer particular indications.

ticular indications.

DECOCTUM MEZEREI. See Decoctum daplaces me-

DECOCTUM PAPAVERIS. Decoctum pro fomento.

Fotus communis. Decoction of poppy. Take of white poppy capsules bruised, 3 iv; water, four pints Boll for a quarter of an hour, and strain. This pre

paration possesses sedative and antiseptic properties, and may be directed with advantage in sphacelus, &c.

DECOCTUM PRO ENEMATE. See Decoctum malva

compositum.

DECOCTUM PRO FOMENTO. See Decoctum papaveris.
DECOCTUM QUERCUS. Decoction of oak bark. Take
of oak bark, 31; water, two pints. Boil down to a
pint, and strain. This astringent decoction has lately
been added to the Lond. Pharm., and is chiefly used
for external purposes. It is a good remedy in prolapsus ani, and may be used also in some cases as an injection.

Decoction sarsaparilla. Decoction of sarsaparilla. Take of sarsaparilla root, sliced, 5 iv; boiling water, four pints. Macerate for four hours, in a vessel lightly covered, near the fire; then take out the sarsaparilla and bruise it. After it is bruised, put it again into the liquor, and macerate it in a similar manner for two hours more; then boil it down to two pints, and strain pints, and strain.

This decoction is much extolled by some practitioners, in phthisis, and to restore the strength after a long

course of mercury.

DECOCTUM SARSAPARILLE COMPOSITUM. Compound decoction of sarsaparilla. Take of decoction of sarsaparilla boiling, four pints; sassafras root sliced, guaiacum wood shavings, liquorice root bruised, of each an ounce; mezereon root bark, 3 iij. Boil for a quarter of an hour, and strain. The alterative property of the compound is very great; it is generally given after a course of mercury, where there have been nodes and indolent ulcerations, and with great benefit. The dose is from half a pint to a pint in twenty-four hours.

Decoctum senege. Decoction of senega. Take

DECOCTUM SENEGE. Decoction of senega. of senega root, 3j; water, two pints. Boil down to a pint, and strain. This is now first introduced into the Lond. Pharm as being a useful medicine, especially in affections of the lungs, attended with debility

and inordinate secretion.

DECOCTUM ULMI. Decoction of elm bark. Take of fresh elm bark bruised, four ounces; water, four pints. Boil down to two pints, and strain. This may be employed with great advantage as a collyrium in chronic ophthalmia. It is given internally in some cutaneous eruptions.

DECOCTUM VERATRI. See Decoctum hellebori albi. [The Pharmacopæia of the United States contains

the following decections.

DECOCTUM ARALIE NUDICAULIS. Decection of false sarsaparilla.

DECOCTUM CINCHONE. Decoction of Peruvian

DECOCTUM COLOMBIE COMPOSITUM. Compound decoction of Columbo.

DECOUTUM DULCAMAR E. Decoction of bitter-sweet.

DECOCTUM GUAIACI. Decoction of guaiacum.
DECOCTUM HORDEI. Decoction of barley.
DECOCTUM HORDEI COMPOSITUM. Compound de-

DECOCTUM MEZEREI. Decoction of Iceland moss.
DECOCTUM MEZEREI. Decoction of mezercon.
DECOCTUM SARSAPARILLE. Decoction of sarsapa-

DECOCTUM SARSAPARILLE COMPOSITUM.

pound decoction of sarsaparilla.

DECOCTUM SCILLE. Decoction of squill.

DECOCTUM SENEGE. Decoction of seneca snake root.

DECOCTUM VERATRI. Decoction of white helle-

DECOLLA'TIO. (From decollo, to behead.) The

DECORDER 110. (From aecono, to benead.) The loss of a part of the skull.

DECOMPOSITA. The name of a class in Sauvage's Methodus Foliorum, consisting of such as have twice compounded leaves; that is, have a common footstalk supporting a number of less leaves, each of which is common and the supporting a number of less leaves, each of which is common and the supporting a number of less leaves, each of which is compounded; as in Fumaria, and many un-

belliferous plants.

DECOMPOSITION. Decompositio. The separation of the component parts or principles of bodies from each other. The decomposition of bodies forms a very large part of chemical science. It seems probable, from the operations we are acquainted with, that it, the part of some comit seldom takes place but in consequence of some combinations or composition having been effected. It would be difficult to point out an instance of the sepa-

been effected, unless in consequence of some new combination. The only exceptions seem to consist in those separations which are made by heat, and voltaic

electricity.

DECOMPOSITUS. A term applied to leaves, and means doubly compound. Sir James Smith observes, that Linnaus, in his Philosophia Botanica, gives an erroneous definition of this term which does not agree with his own use of it. The Ægopodium podagraria and Fulmaria claviculata, afford examples of the decomposite leaves. Supra decompositum, means thrice compound, or more; as in Caucalis anthriscus. The

compound, or more; as in Caucalis anthriseus. The decomposite flowers are such as contain within a common calyx a number of less or partial flower-cups, each of which is composed of many florets.

DECORTICATION. (Decorticatio; from de, from, and cortex, bark.) The stripping of any thing of its bark, husk, or shell; thus almonds, and the like, are decorticated, that is, deprived of their pelliele, when ordered for medicinal numbers.

decorticated, that is, deprived of their pelliele, when ordered for medicinal purposes.

[There is a natural and artificial decortication performed on certain trees. The shag-bark hickory-tree (juglans alba) throws off its bark by a natural and spontaneous decortication. So does the button-wood (platanus occidentalis) or plane-tree. The cork-tree is deprived of its bark artificially every few years, and lives longer than those trees which are suffized to grow without molestation. Those not decorticated become shaggy and hide-bound, while the others form a new bark and improve in appearance and vigour. These facts suggested the idea of improving fruit-trees that had become hide-bound and shaggy, and appeared to be in a state of decay. Dr. Mitchill first tried the experiment on an old apple-tree, and by removing the old bark, in the warm season, from the body of the tree, and protecting it from external injury for a time, he succeeded in producing a new bark and in regenehe succeeded in producing a new bark and in regene-rating a tree which was considered as past bearing. The tree became vigorous, again put forth blossoms and bore fruit. Since that experiment, it has become common in apple orchards to improve old trees by a

similar process. A.]

DECREPITATION. (Decrepitatio; from decrepo, to crackle.) A kind of crackling noise, which takes place in some bodies, when heated: it is peculiar to some kinds of salts, as muriate of soda, sulphate of

barytes, &c.
DECUMBENS. (From decumbo, to lie down.)
Drooping: a term applied to flowers which incline to

Drooping: a term applied to flowers which incline to one side and downwards.

DECURRENS. Decurrent. A term applied by botanists to leaves which run down the stem or leafy border or wing; as in Onapordium acanthium, and many thistles, great mullein, and comfrey: and to leaf-stalks; as in Pisum ochrus.

DECURSIVE: Decurrently. Applied to leaflets that run down the stem; as in Eryngium campestre.

DECUSSATION. (Decussatio; from decutio, to divide.) When nerves, or muscular-fibres cross one another, they are said to decussate each other.

DECUSSATUS. Decussated. Applied to leaves and spines which are in pairs, alternately crossing each other; as in Veronica decussata, and Genista lucitanica.

DECUSSO RIUM. (From decusso, to divide.)
An instrument to depress the dura mater, after trepanning.

DEFENSI'VA. (From defendo, to preserve.) Cordial

medicines, or such as resist infection.

DE FERENS. (From defero, to convey; because it conveys the semen to the vesiculæ seminales.) See

Vas deferens.

DEFLAGRATION. (Deflagratio; From deflagro, to burn.) A chemical term, chiefly employed to express the burning or setting fire to any substance; as nitre, sulphur, &c.

DEFLUXION. (Defluxio; from defluo, to run off.) A falling down of humours from a superior to an inferior part. Many writers mean nothing more by it then inflammation.

than inflammation.

DEFOLIATIO. (From de, and folium, a leaf.) The fall of the leaf. A term opposed to frondescentia, or the renovation of the leaf.

DEGLUTITION. (Deglutitio; from deglutio, to swallow down.) A natural action. "It is understood to be the passage of a substance, either sollid, ration of any of the principles of bodies which has liquid, or gaseous, from the mouth to the stomach

Though deglutition is very simple in appearance, it is arrives at the assophagus; in the the third it passes nevertheless the most complicated of all the muscular through this tube and enters the stomach. actions that serve for digestion. It is produced by the contraction of a great number of muscles, and requires

the concurrence of many important organs.

All the muscles of the tongue, those of the velum of the palate, of the pharynx, of the larynx, and the muscular layer of the œsophagus, are employed in deglu-

The velum is a sort of valve attached to the posterior edge of the roof of the palate; its form is nearly quadrilateral; its free or inferior edge is pointed, and quadrilateral; its free or inferior edge is pointed, and forms the uvula. Like the other valves of the intestinal canal, the velum is essentially formed by a duplicature of the digestive mucous membrane; there are many mucous follicles that eater into its composition, particularly in the uvula. Eight muscles move it; it is raised by the two internal pterygoid; the external pterygoid hold it transversely; the two palatopharyngei, and the two constrictores isthmi faucium carry it downwards. These four are seen at the bottom of the throat, where they raise the mucous memtom of the throat, where they raise the mucous mem-brane, and form the pillars os of the velum of the palate, between which are situated the amygdala, a mass of mucous follicles. The opening between the base of the tongue below, the velum of the palate above, and the pillars laterally, is called the isthmus of the throat. By means of its muscular apparatus, the velue of the order to the palate many changes of vertices of the order to the palate many changes of vertices. throat. By means of its muscular apparatus, the ve-lum of the palate may have many changes of posi-tion. In the most common state it is placed vertically, one of its faces is anterior, the other posterior; in cer-tain cases it becomes horizontal: it has then a superior and inferior aspect, and its free edge corresponds to the concavity of the pharynx. This last posi-tion is determined by the contraction of the elevating

The pharynx is a vestibule into which open the nostrils, the Eustachian tubes, the mouth, the larynx, and the esophagus, and which performs very important functions in the production of voice, in respiration, hearing, and digestion.

The pharynx extends from top to bottom, from the basilar process of the occipital bone, to which it is attached, to the level of the middle part of the

Its transverse dimensions are determined by the os hyoides, the larynx, and the pterygo-maxillary aponeurosis, to which it is fixed. The mucous membrane which covers it interiorly is remarkable for the development of its veins, which form a very apparent plexus. Round this membrane is the muscular layer, the circular fibres of which form the three constrictor muscles of the pharynx, the longitudinal fibres of which are represented by the stylo-pharyngeus and constrictores isthmi faucium. The contractions of these different muscles are not generally subject to the

The asophagus is the immediate continuation of the pharynx, and is prolonged as far as the stomach, where it terminates. Its form is cylindrical; it is united to the surrounding parts by a slack and extending cellular tissue, which gives way to its dilatation and its motions. To penetrate into the abdomen the esophamotions of the dispharent heads of the dispharent with gus passes between the pillars of the diaphragm, with which it is closely united. The mucous membrane of the esophagus is white, thin, and smooth; it forms longitudinal folds very proper for favouring the dilata-tion of the canal. Above it is confounded with that

of the pharynx.

There are found in it a great number of mucous follicles, and at its surface there are perceived the orifices of many excretive canals of the mucous glands.

The muscular layer of the esophagus is thick, its tissue is denser than that of the pharynx; the longitudinal fibres are the most external and the least numerous; the circular are placed in the interior and are very numerous.

Round the pectoral and inferior portion of the œso-phagus, the two perves of the eighth pair form a plexus which embraces the canal, and sends many filaments

into it. The contraction of the œsophagus takes place with-

out the participation of the will.

Mechanism of Deglutition. Deglutition is divided into three periods. In the first, the food passes from the mouth to the pharynx; in the second, it passes the opening of the glottis, that of the nasal canals, and

through this tube and enters the stomach.

Let us suppose the most common case, that in which we swallow at several times the food which is in the mouth, and according as mastication takes

As soon as a certain quantity of food is sufficiently chewed, it is placed, by the effects of the motions of mastication, in part upon the superior face of the tongue, without the necessity, as some think, of its being collected by the point of the tongue from the different parts of the mouth. Mastication then stops; the tongue is raised and applied to the roof of the The portion of food, or the alimentary bolus placed upon its superior surface, having no other way to escape from the force that presses, is directed towards the pharynx; it soon meets the velum of the plate applied to the base of the tongue and raises it; the velum becomes horizontal, so as to make a continua-tion of the palate. The tongue, continuing to press the food, would carry it towards the nasal canals, if the velum did not prevent this by the tension that it receives from the external peristaphyline muscles, and particularly by the contraction of its pillars; it thus becomes capable of resisting the action of the tongue, and of contributing to the direction of the food towards the pharynx.

The muscles which determine more particularly the application of the tongue to the top of the palate, and to the velum of the palate, are the proper muscles of the organ, aided by the mylo-hyoideus. Here the first time of deglutition terminates. Its motions are voluntary, except those of the velum of the palate. The phenomena happen slowly and in succession; they

are few and easily noticed.

The second period is not the same; in it the pheno mena are simultaneous, multiplied, and are produced with such promptitude, that Boerhaave considered

them as a sort of convulsion:

The space that the alimentary bolus passes through in this time is very short, for it passes only from the middle to the inferior part of the pharynx; but it was necessary to avoid the opening of the glottis and that of the nasal canals, where its presence would be inju-rious. Besides, its passage ought to be sufficiently rapid, in order that the communication between the larynx and the external air may not be interrupted, except for an instant.

Let us see how nature has arrived at this important result. The alimentary bole no sooner touches the pharynx than every thing is in motion. First, the pharynx contracts, embraces and retains the bole; the relum of the palate, drawn down by its pillars, acts in the same way. On the other hand, and in the same instant, the base of the tongue, the os hyoides, the larynx, are raised and carried forward to meet the bole, in order to render its passage more rapid over the opening of the glottis. While the os hyoides, and the larynx are raised, they approach each other, that is, the superior edge of the thyroid cartilage engages itself behind the body of the os hyoides: the epiglottic gland is pushed back; the epiglottis descends, inclines downwards and backwards, so as to cover the en-trance of the larynx. The cricoid cartilage makes a motion of rotation upon the inferior horns of the thy-roid, whence it results that the entrance of the larynx becomes oblique downwards and backwards. The bole slides along its surface, and being always pressed by the contraction of the pharynx and of the velum of

the palate, it arrives at the esophagus.

It is not long since the position that the epiglottis It is not long since the position that the epiglottis takes in this place was considered as the only obstacle opposed to the entrance of the food into the larynx, at the instant of deglutition; but Dr. Magendie has shown, by a series of experiments, that this cause ought to be considered as only accessary. In fact, the epiglottis may be entirely taken away from an animal without deglutition suffering any injury from it. What without deglutition suffering any injury from it. What is the reason, then, that no part of the food is introduced into the larynx the instant that we swallow? The reason is this. In the instant that the larynx is raised and engaged behind the os hyoides, the glottis shuts with the greatest closeness. This motion is prospect to the same muscles that press the glottis in the raised and engaged befind the os. This motion is proshuts with the greatest closeness. This motion is produced by the same muscles that press the glottis in the production of the voice; so that if an animal has the recurrents and nerver of the larynx divided, while the recurrents

epiglottis is untouched, its deglutition is rendered very difficult, because the principal cause is removed which coposes the introduction of food into the glottis.

Immediately after the alimentary bole has passed the glottis, the larynx descends, the epiglottis is raised, and the glottis is opened to give passage to the air.

After what has been said, it is easy to conceive why the food reaches the esophagus without entering any of the openings which end in the pharynx. The velum of the palate, which, in contracting, embraces the pharynx, protects the posterior nostrils, and the orifices of the Eustachian tubes; the epiglottis, and particularly the motion by which the glottis shuts, preserves the larynx.

Thus, the second period of deglutition is accomplished; by the effects of which the alimentary bole passes the pharynx, and is engaged in the superior part of the æsophagus. All the phenomena which concurrence is the place simultaneously, and with great promptior the esophagus. All the phenomena which concur in it take place simultaneously, and with great promptitude: they are not subject to the will; they are then different in many respects from the phenomena that belong to the first period.

The third period of deglutition is that which has been studied with the least care, probably on account of the situation of the esophagus, which is difficult to be observed except in its cervical portion.

The phenomena which are connected with it are not

The phenomena which are connected with it are not The phenomena which are connected with it are not complicated. The pharynx, by its contraction, presses the alimentary bole into the esophagus with sufficient force to give a suitable dilatation to the superior part of this organ. Excited by the presence of the bolus, its superior circular fibres very soon contract, and press the food towards the stomach, thereby producing the distension of those more inferior. These contract in their turn, and the same thing continues in succession until the bolus arrives at the stomach. In the sion until the bolus arrives at the stomach. In the upper two-thirds of the esophagus, the relaxation of the circular fibres follows immediately the contraction by which they displaced the alimentary bolus. It is not the same with the inferior third; this remains some moments contracted after the introduction of food into

All the extent of the mucous surface that the alimentary bolus passes in the three periods of deglutition is lubricated by an abundant mucosity. In the way that the bolus passes, it presses more or less the follicles that it meets in its passage, it empties them of the fluid that they contain, and slides more easily upon the mucous membrane. We remark that in those places where the bolus passes more rapidly, and is pressed with greater force, the organs for secreting mucus are much more abundant. For example, in the narrow space where the second period of deglutition takes place, there are found the tonsils, the fungous papilla of the base of the tongue, the follicles of the velum of the palate, and the uvula, those of the epiglottia, and the arytenoid glands. In this case the saliva and the mucosity fulfil uses analogous to those of the synovia. All the extent of the mucous surface that the ali-

of the synovia.

The mechanism by which we swallow the succeeding mouthfuls of food does not differ from that which we have explained.

we have explained.

Nothing is more easy than the performance of deglutition, and, nevertheless, all the acts of which it is composed are beyond the influence of the will and of instinct. We cannot make an empty motion of deglutition. If the substance contained in the mouth is not sufficiently chewed, if it has not the form, the consistence, and the dimensions of the alimentary bolus, if the motions of mastication which immediately precede deglutition have not been made, we will frequently find it impossible to swallow it, whatever efforts we make. How many people do we not find who cannot swallow a pill, or medicinal bolus, and who are obliged to fall upon other methods to introduce it into the esophagus?—Magendie.

DE'GMUS. (From darry, to bite.) A biting pain in the orifice of the stomach.

DEHISCENTIA. (From dehisco, to gape wide.) A spitting, or bursting open. Applied to capsules, anthery, &c. of plants.

DEIDIER, Anthony, was son of a surgeon of Montpelier. Having graduated in medicine in 1691, he was six years after made professor of chemistry. In 1732, heing amounted physician to the galleys, he went

was six years after made professor of chemistry. In 1732, being appointed physician to the galleys, he went to Marseilles, where he died in 1746. He published, among many other works on different branches of me-

dicine, "Experiments on the Bile, and the Bodies of those who died of the Plague," which occurred while he was at Marseilles. He states that he tried mercu-rial inunctions, but they had no effect on the disease. There are three volumes of consultations and observations by him deserving of perusal. The rest of his works are scarcely now referred to.

DEINO'SIS. (From ¿ctrow, to exaggerate.) An enlargement of the supercilia.

DEJE'CTIO. A discharge of any excrementitious matter; generally applied to the fæees: hence dejectio

DEJECTO'RIA. (From dejicio, to cast out.)

Purging medicines.

DELACHRYMATI'VA. (From de, and lachryma, a ear.) Medicines which dry the eyes, first purging

(From delabor, to slip down.) DELA'PSIO. falling down of any part, as the anus, uterus, or intes-

tines.

DELETERIOUS. (Deleterius; from δηλεω, to hurt or injure.) Of a poisonous nature; as opium, hemlock, henbane, &c.

[Deliquesce. To deliquesce is that action by which certain-bodies become liquid by absorbing moisture from the atmosphere. Potash for instance by exposure to the air will absorb so much water as to change from a solid to a fluid state. This is common to many saline bodies. A.]

Deliquescence. Deliquation, or the spontaneous assumption of the fluid state of certain saline bodies, when left exposed to the air, in consequence

bodies, when left exposed to the air, in consequence of their attracting water from it.

DELI'QUIUM. (Deliquium; from delinquo, to leave.) A fainting. See Syncope.

DELI'RIUM. (From deliro, to rave.) A febrile symptom, consisting in the person's acting of talking unreasonably. It is to be carefully distinguished from an alienation of the mind, without fever.

DELIVERY. See Parturition.

DELOCA'TIO. (From de, from, and locus, a place.)

A dislocation.

A dislocation.

DELPHIA. See Delphinia.

DELPHINE. See Delphinia.

DELPHINIA. Delphia. Delphine. A new-vegetable alkali, recently discovered by Lasseigne and Feneulle, in Stavesacre. See Delphinium staphysa-

DELPHINIC ACID. Acidum delphinicum. The name of an acid, extracted from the oil of the dolphin. It resembles a volatile oil; has a light lemon colour, and a strong aromatic odour, analogous to that of rancid butter. Its taste is pungent, and its vapour has a sweetened taste of wher. It is slightly soluble in water, and very soluble in alkohol. The latter solution strongly reddens litmus. 100 parts of delphinic acid neutralize a quantity of base, which contains 9 of oxygen, whence its prime equivalent appears to be 11.11.

DELPHINITE. See Enidate.

DELPHINITE. See Epidote.

DELPHINIUM (From δελφινος, the dolphin.)

Larkspur; so called from the likeness of its flower to the dolphin's head. The name of a genus of plants in the Linnman system. Class, Polyandria; Order, Tri-

the Linearn system. Class, Polyandria; Order, Trigyaia.

["Delphinum or Larkspur. The botanical alliance of the larkspur of our gardens with aconite and some other poisonous plants, would justify, a priori, a belief, that it possesses active properties. This is found on experiment to be the case. A tincture formed by infusing an ounce of the bruised seeds in a pound of spirit has been found an antispasmodic in asthma, and an active diuretic in dropsy. The dose is from ten to twenty drops. Larger doses are liable to nauseate, and would, not improbably, produce narcotic symptoms."—Big. Mat. Med. A.]

Delphinium consolida. The systematic name of the Consolida regalis. Calcatrippa. Delphinium—mectariis monophyllis, caule subdiviso, of Linnaus. Many virtues have been attributed to this plant. The flowers are bitter, and a water distilled from them is recommended in ophthalmia. The herb has been administered in calculous cases, obstructed menses, and visceral diseases.

foilis palmatis, lobis obtusis, of Linnæus. The seeds, which are the only parts directed for medicinal use, are usually imported here from Italy; they are large, rough, of an irregular triangular figure, and of a blackish colour on the outside, but yellowish within; their smell is disagreeable, and somewhat feetid; to the taste they are very bitter, acrid, and nauseous. It was formerly employed as a masticatory, but is now confined to external use, in some kinds of cutaneous eruptions, but more especially for destroying lice and other insects: hence, by the vulgar, it is called louse-wort.

A new vegetable alkali has lately been discovered in this plant by Lasseigne and Feneulle. It is thus

in this plant by Lasseigne and Feneulle. It is thus obtained:

obtained:
The seeds, deprived of their husks, and ground, are to be boiled in a small quantity of distilled water, and then pressed in a cloth. The decoction is to be filtered, and boiled for a few minutes with pure magnesia. It must then be-refiltered, and the residuum left on the filter is to be well washed, and then boiled with highly rectified alkohol, which dissolves out the alkali. By evaporation, a white pulverulent substance, presenting a few crystalline points, is obtained.

It may also be procured by the action of dilute substance acid, on the bruised but unshelled seeds. The solution of sulphate thus formed, is precipitated by

colution of sulphate thus formed, is precipitated by subcarbonate of potassa. Alkohol separates from this precipitate the vegetable alkali in an impure state. Pure delphinia obtained by the first process, is crys-

Pure delphinia obtained by the first process, is crystalline while wet, but becomes opake on exposure to air. Its taste is bitter and acrid. When heated it melts; and on cooling becomes hard and brittle like resin. If more highly heated, it blackens and is decomposed. Water dissolves a very small portion of it. Alkohol and wither dissolve it very readily. The alkoholic solution renders syrup of violets green, and restores the blue tint of litmus reddened by an acid. It forms soluble neutral salts with acids. Alkalies precipitate the delphinia in a white gelatinous state. precipitate the delphinia in a white gelatinous state, like alumina.

Sulphate of delphinia evaporates in the air, does not

Sulphate of delphinia evaporates in the air, does not crystallize, but becomes a transparent mass like gum. It dissolves in alkohol and water, and its solution has a bitter acrid taste. In the voltaic circuit it is decomposed, giving up its alkali at the negative pole.

Nitrate of delphinia, when evaporated to dryness, is a yellow crystalline mass. If treated with excess of nitric acid, it becomes converted into a yellow matter, little soluble in water, but soluble in boiling alkohol, This solution is bitter, is not precipitated by potassa, ammonia, or lime-water, and appears to contain no nitric acid, though itself is not alkaline. It is not destroyed by further quantities of acid, nor does it form oxalic acid. Strychnia and morphia take a red colour from nitric acid, but delphinia never does. The muriate is very soluble in water.

The acetate of delphinia does not crystallize, but forms a hard transparent mass, bitter and acrid, and readily decomposed by cold sulphuric acid. The oxalate forms small white plates, resembling in taste the preceding salts.

preceding salts.

preceding salts.

Delphinia, calcined with oxide of copper, gave no other gas than carbonic acid. It exists in the seeds of the stavesacre, in combination with malic acid, and associated with the following principles: 1. A brown bitter principle, precipitable by acetate of lead. 2. Volatile oit. 3. Fixed oil. 4. Albumen. 5. Animalized matter. 6. Mucus. 7. Saccharine mucus. 8. Yellow bitter principle, not precipitable by acetate of ead. 9. Mineral salts.—Annales de Chimic et de Physique, vol. xii. p. 358.

DE'LPHYS. Δελφυς. The uterus, or pudendum muliebre.

DE'LTA. (The Greek letter, Δ.) The external pudendum muliebre is so called, from the triangular

shape of its hair. DELTOUDES.

shape of its hair.

DELTOIDES. (From ōɛ\ra, the Greek letter \(\Delta\), and \(\alpha \) of the superior extremity, situated on the shoulder. \(Sous-acromio-clavi-humeral\) of Dumas. It arises exactly opposite to the trapezius, from one-third part of the clavicle, from the acromion and spine of the scapula, and is inserted, tendinous, into the middle of the os humeri, which bone it lifts up directly; and it assists with the supraspinatus and coracobrachialis in all the actions of the humerus, except the depression; it being convenient that the arm should be sion; it being convenient that the arm should be

DEME'NTIA. (From de, and mens, without mind.)
Absence of intellect; madness; fatuity.
DEMERSUS. A leaf which is naturally under water, and different from those above, is so called; folia immersa, and submersa, are the same as demersa. See

Natans.

DEMULCENT. (Demulcens; from demulceo, to soften.) Medicines suited to obviate and prevent the action of acrid and stimulant matters; and that not by correcting or changing their acrimony, but by involving it in a mild and viscid matter, which prevents it from acting upon the sensible parts of our bodies, or by covering the surface exposed to their action.

Where these substances are directly applied to the parts affected, it is easy to perceive how benefit may be derived from their application. But where they are received by the medium of the stomach, into the circulating system, it has been supposed that they can be

circulating system, it has been supposed that they can be of no utility, as they must lose that viscidity on which their lubricating quality depends. Hence it has been concluded that they can be of no service in gonorrhoa, concluded that they can be of no service in gonorrhoa, and some similar affections. It is certain, however, says J. Murray, in his Elements of Materia Medica and Pharmacy, that many substances which undergo the process of digestion are afterward separated, in their entire state, from the blood, by particular secreting organs, especially by the kidneys; and it is possible, that mucilaginous substances, which are the principal demulcents, may be separated in this manner. There can be no doubt, however, but that a great share of the relief demulcents afford, in irritation or inflammation of the urinary passages, is owing to the large quantities of water in which they are diffused, by which the urine is rendered less stimulating from diluwhich the urine is rendered less stimulating from dilu-tion. In general, demulcents may be considered merely as substances less stimulating than the fluids usually

Catarrh, diarrhœa, dysentery, calculus, and gonor-rhœa, are the diseases in which demulcents are em-ployed. As they are medicines of no great power, they may be taken in as large quantities as the stomach

can bear.

The particular demulcents may be reduced to the two divisions of mucilages and expressed oils. The principal demulcents are, the acacia vera, astragalus, tragacanthe, linum usitatissimum, althea officinalis, malva, sylvestris, glycyrrhiza glabra, cycas circinalis, orchis mascula, maranta arundinacea, triticum hyber-puro ichthroscula clea electronic area arundinacea, triticum hyber-puro ichthroscula clea electronic area arundinacea.

num, ichthyocolla, olea Europæa, amygdalus communis, cetaceum, and cera.
[Dendritic. (From δενδραι, a tree.) A term used in mineralogy to designate those appearances frequently found in minerals resembling trees or clusters

DENDROLI BANUS. (From δενδρον, a tree, and ολιδανος, frankincense.) Frankincense-tree. See Ros-

marinus officinalis.

DENS. (Dens, tis. m.: quasi edens; from edo, to eat, or from obovs, obov/os.)

1. A tooth. See Teeth.

2. Many herbs have this specific name, from their fancied resemblance to the tooth of some animal, the dandeling. Dens capis, dog's as Dens leonis, the dandelion; Dens canis, dog's tooth, &c.

tooth, &c.

Dens caninus. See Teeth.

Dens incisor. See Teeth.

Dens lacteus. See Teeth, and Dentition.

Dens lacteus. See Leontodon Tarazacum.

Dens molaris. See Leontodon Tarazacum.

Denta'GRA. (Dentagra, οδονταγρα; from οδους, a tooth, and αγρα, a seizure.) 1. The toothache.

2. An instrument for drawing the teeth.

DENTA'RIA. (Dentaria; from dens, a tooth: so called because its root is denticulated.) See Plumbaga enropæa.

europæa.

DENTARPA'GA. (From οδους, a tooth, and αρπαζω, to fasten upon.) An instrument for drawing of teeth.

DENTATA. Sec Dentatus.

DENTA'TUS. (From dens, a tooth; from its tooth-like process.) 1. The second vertebra of the neck. Dentata; Epistrophaus. It differs from the other cervical vetebra, by having a tooth-like process at the upper part of the body. See Vertebra.

2. Toothed: applied to roots, leaves, petals, &c. which are beset with projecting, horizontal, rather distant teeth of its own substance; as in the leaf of Atriplex leaves and the perianthium of Marrahium nulgare.

lacinata, and the perianthium of Marrubium vulgare, and Ercca denticulata, and the petals of the Silence lucitanica. The Ophris corallorhiza has a toothed

DENTELLA'RIA. (From dentella, a little tooth; so

DENTIELLA'RIA. (From dentella, a little tooth; so called because its root is denticulated.) The herb tooth-wort. See Plumbago europæa.

DENTIDU'CUM. (From dens, a tooth, and duco, to draw.) An instrument for drawing of teeth.

DENTIFRICE. (Dentifricus; from dens, a tooth, and frigo, to rub.) A medicine to clean the teeth.

DENTISCA'LPIUM. (From dens, a tooth, and scalpo, to scrape.) An instrument for scaling teeth.

DENTITION. (Dentitio; from dentio, to breed teeth.) Odontiasis; Odontophica. The breeding or cutting of the teeth. The first dentition begins about the sixth or seventh month, and the teeth are termed the sixth or seventh month, and the teeth are termed the primary or milk teeth. About the seventh year, these fall out, and are succeeded by others, which remain during life, and are called the secondary or percential teeth. The last dentition takes place between the ages of twenty and five and twenty, when the four last grinders appear; they are called dentes sapientia. See also Teeth.

DENTODU'CUM. See Dentiducum.
DENUDATE PLANTE. The name of an order of Linneus's Fragments of a Natural Method, embracing those plants, the flowers of which are naked, or with-

out a flower-cup.

DENUDA'TIO. (From denudo, to make bare.)
The laying bare any part; usually applied to a

DENUDATUS. (From denudo, to strip naked.)

Denude; naked. DEOBSTRUENT. DEOBSTRUENT. (Deobstruens; from de, and obstrue, to obstruct.) A medicine that is exhibited with a view of removing any obstruction.

DEOPPILA'NTIA. (From de, and oppilo, to stop.)

Deoppilativa. Medicines which remove obstructions.

DEPART! TIO. (From de, and partier, to divide.)

Separating metals.

Dependent of the form dependent of the undue loss of the fortus.

Dependent of the fortus.

Dependent of the fortus of the second of the rough

DEPHLEGMA'TION. (Dephlegmatio; from de, and phlegma, phlegma.) The operation of rectifying or freeing spirits from their watery parts, or any method by which bodies are deprived of their water.

DEPHLOGISTICATED. A term of the old chemistry, implying deprived of phlogiston or the inflammable principle.

mistry, implying deprived of phiogiston or the inflammable principle.

Dephlogisticated air. See Oxygen gas.
Dephlogisticated muriatic acid. See Chlorine.
DEPILATORY. (Depilatorius; from de, of, and
pilus, the hair.) Any application which removes the
hairs from any part of the body; thus, a pitch cap
pulls the hairs of the head out by the roots.

[A denilatory quintment is sometimes used to remove

[A depilatory ointment is sometimes used to remove hairs from inconvenient places. The French call it Pate depilatoire, a depilatory paste. It is made with quick lime, lapis calaminaris, and arsenic, lutimately united and made into a thin paste with a little water, and a thin coat spread upon the surface. The hairs are removed by the action of the arsenic as a caustic, but its action is modified by the other ingredi-

but its action is modified by the other ingredients. A.]

Deplu Matio. (From de, and pluma, a feather.) A disease of the eyelids, which causes the hair to fall off. DEPREHE'NSIO. (From deprehendo, to catch unawares.) The epilepsy is so called, from the suddenness with which persons are seized with it.

DEPRESSION. (Depressio; from deprimo, to press down.) When the bones of the skull are forced inwards by fracture, they are said to be depressed.

DEPRE SSOR. (From deprimo, to press down.)

A muscle is so termed, which depresses the part on

A muscle is so termed, which depresses the part on which it acts.

DEPRESSOR ALE NASI. See Depressor labii supsrioris alæque nasi.

Defressor anguli oris. A muscle of the mouth and lip, situated below the under lip. Triangularis, of Winslow. Depressor labiorum.communis, of Douglas. Depressor labiorum, of Cowper. Sous-maxillolabial of Dumas. It arises broad and fleshy, from the lower edge of the lower jaw, near the chin; and is inserted into the angle of the mouth, which it pulls downwards. downwards.

Depressor Labii inferioris. A muscle of the mouth and lip. Quadratus, of Winslow. Depressor labii inferioris proprius, of Douglas and Cowper. Mentonier labial, of Dumas. It pulls the under lip and skin of the side of the chin downwards, and a little outwards.

DEPRESSOR LABII SUPERIORIS ALÆQUE NASL. muscle of the mouth and lip. Depressor ala nasi, of Albinus. Incisivus medius, of Winslow. Depressor labii superioris proprius, of Douglas. Constrictores alarum nasi, ac depressores labii superiores, of Cowper. Maxillo-alveoli nasal, of Dumas. It is situated above the mouth, draws the upper lip and ala nasi downwards and backwards. It arises, thin and fleshy, from the superior maxillary bone, immediately above the joining of the gums, with the two incisor teeth and cuspidatus; from thence it runs upwards, and is inscrted into the upper lip and root of the ala of the

Depressor labit superioris proprius. See De-pressor labit superioris alæque nasi.

Depressor labiorum communis. See Depressor

DEPRESSOR OCULI. See Rectus inferior oculi. DEPRESSUS. Depressed; flattened vertically, as the leaves of the Mesembryanthemum linguiforme. Folia depressa is applied also to radical leaves which are pressed close to the ground, as is seen in *Plantago media*; but when applied to stem leaves, it regards their shape only, as being vertically flattened in op-

position to compressa.

DE PRIMENS. See Rectus inferior oculi.

DEPURA'NTIA. (Depurans; from depuro, to make clean.) Medicines which evacuate impurities.

DEPURA TION. Depuratio. The freeing a liquor

or solid from its foulness.

DEPURATO'RIUS. (From de, and purus, pure.)
Depuritory: applied to fevers, which terminate in

perspiration.

DERBYSHIRE SPAR. A mineral formed of cal-careous earth with fluoric acid.

DE RIS. (Δερις; from δερω, to excoriate.) The

DERIVATION. (Derivatio; from derivo, to drain off.) The doctrines of derivation and revulsion talked of by the ancients, are now, in their sense of the terms, wholly exploded. Derivation means the drawing away any disease from its original seat to another

DE'RMA. Δερμα. The skin. See Skin.

DERMATO'DES. (From δερμα, skin, and ειδος, a likeness.) Resembling skin, or leather; applied to the

dura mater.

DERMATOLO GIA. (From δερμα, the skin, and λογος, a discourse.) A discourse or treatise on the skin.

DE'RTRON. (From ¿cos, skin.) The omentum, and peritongum, are so named, from their skin-like

DESAULT, Peter, was a native of Bordeaux, where he graduated, and became distinguished as a practitioner in medicine about the beginning of the practitioner in medicine about the beginning of the last century. He was author of some popular and useful dissertations on medical subjects. In syphilis he maintained that a cure could be effected without salivation; and in calculous complaints, by the patient drinking the Bareges water, this being also injected into the bladder; but it probably merely palliated the symptoms. He exposed also some of the prevailing errors concerning hydrophobia; as that the patient barked like a dog, and had a propensity to bite his attendants. The precise period of his death is not mentioned. mentioned.

DESAULT, PETER JOSEPH, was chief surgeon to the Hôtel-Dieu at Paris. He published several numbers of a surgical journal, in 1791, &c.; also, jointly with Chopart, in 1794, "A Treatise on Chirurgical

DESICCATI'VE. (Desications; from desicco, to dry up.) An application to dry up the humours and moisture running from a wound or ulcer. DESICCATI'VE.

DESIPIE'NTIA. (From desipio, to dote.) A de-

fect of reason.

DESIRE. Will. We give the name of will to that modification of the faculty of perception by which we form desires. It is generally the effect of our judgment; but what is remarkable, our happiness or our misery are necessarily connected with it. When we satisfy our desires we are happy; but we are miserable if our desires be not fulfilled; it is then necessary to give such a direction to our desires that we may be enabled to obtain happiness. We ought not to desire things which cannot be obtained; we ought to avoid, even with greater care, those things which are hurtful. For with greater care, those things which are hurtful; for in such cases we must be unhappy, whether our de-sires are satisfied or not. Morality is a science which tends to give the best possible direction to our desires.

DE'SME. (From δεω, to bind up.) A bandage, or

ligature.

DESMI'DION. (From δεσμη, a bandful.) A small bundle, or little bandage.

DE'sMos. (From δεω, to bind up.) 1. A bandage. 2. An inflammatory stricture of a joint, after luxa-

DE'SPUMATION. (Despumatio; from despumo, to clarify.) The clarifying a fluid, or separating its foul parts from it.

DESQUAMATION. (Desquamatio; from desquamo, to scale off.) The separating of laminæ, or scales, from a bone. Exfoliation.

DESQUAMATO'RIUM. (From desquame, to scale off.) trepan, or instrument to take a piece out of the

DESTHLATION. See Distillation.
DESUDA'TIO. (From desudo, to sweat much.)

An unnatural and morbid sweating.

Dete'ntio. (From detineo, to stop, or hinder.)
Epilepsy is so called, from the suddenness with which
the patient is seized.

DETERGENT. (From detergo, to wipe away.)

1. A medicine which cleanses and removes such viscid humours as adhere to and obstruct the vessels.

2. An application that clears away foulness from

ulcers.

DETERMINATE`. Applied by botanists to branches and stems: determinate ramosus is abruptly branched, when each branch, after terminating in flowers, produces a number of fresh shoots, in a circular order, from just below the origin of those flowers. The term occurs frequently in the latter publication of Linnaus, particularly the second Mantissa; but he does not appear to have any where explained its meaning. appear to have any where explained its meaning.-

DETONATION. (Detonatio; from detono, to make a noise.) A sudden combustion and explosion. DETRACTOR. (From detraho, to draw.) Applied to a muscle, the office of which is to draw the part to which it is attached.

DETRAHENS. (From detraho, to draw.) The name of a muscle, the office of which is to draw the part it is attached to.

part it is attached to.

DETRHENS QUADRATUS. See Platysma myoides.
DETRU'SOR URINÆ. (From detrudo, to thrust
out.) 1. The name of a muscle, the office of which is to squeeze out the urine.

2. The muscular coat of the urinary bladder was

formerly so called.

DEU TERI. (From dev 7c905, second: because it is discharged next after the fætus.) The secundines, or after-birth.

DEUTEROPA THIA. (From δευ Γερος, second, and scaθος, a suffering.) An affection or suffering by con-

Diseases, and the Operations required in their Cure;" which is allowed to have considerable merit. He attended the young King of France, Lewis XVII., in the temple; and died under suspicious circumstances, shortly before his royal patient, in 1795.

DESCENSO'RIUM. (From descendo, to move downwards.) A vessel in which the distillation by descent is performed.

DESCE'NSUS. (From descendo, to move downwards.) The same chemists call it a distillation per descensum, by descent, when the fire is applied at the top and round the vessel, the orifice of which is at the bottom. the part originally affected, as where the stomach is disturbed through a wound in the head.

DEUTOXIDE. See Oxide.

Deutoxide of azot. See Nitrogen.

DEVENTER, HENRY, was born in Holland, toward the end of the 17th century. He took a degree in medicine, but his practice was principally in surgery, and at last almost confined to midwifery. He distinguished himself much by his improvements in this art, as well as by his mechanical inventions for obviating deformities in children. He published some obstetrical works several years prior to his death, which stetrical works several years prior to his death, which occurred in 1739; after which appeared a Treatise on the Rickets in his native language, of which Haller makes favourable mention.

Devil's dung. See Ferula assafatida.

Devilerry. See Blackberry.

DIA. Δια. Many terms in medicine, surgery, and pharmacy, commence with this word, when they signify composition and mixture; as Diacassia, Diacastoreum, &c.

[DIABASE. The Diabase of some French mineralogists is the greenstone of Werner and Jameson. Greenstone abounds in the United States. There is a long ridge of this kind of rock in Connecticut running northward from New-Haven. There are several ridges of this formation of superincumbent rocks in New-Jersey. The most remarkable is the ridge bordering that Hudson river on the west side running. New-Jersey. The most remarkable is the ridge bordering the Hudson river on the west side, running north from New-York city to the extent of thirty or forty miles, and known by the common appellation of the Palisado Rocks. There is a sublime show of this kind of rock on the south side of Lake Superior.

Diabase or "Greenstone is essentially composed of the palisado and follower in the state of regime received.

Diabase or "Greenstone is essentially composed of hornblende and felspar, in the state of grains, or sometimes of small crystals. The proportions are somewhat various; but the hornblende predominates, and very frequently gives to this aggregate more or less of a greenish tirge, especially when it is moistened. Hence the name of this rock (Greenstone). Sometimes the tinge of green is considerably lively, and may arise either from the hornblende, or from Epidote disseminated through the mass. Sometimes also its colour is dark gray, or grayish black. In fine, its colour, especially at the surface, is often modified by the presence of oxide of iron. of oxide of iron.
"This rock presents a considerable variety of as-

pect, depending on the general structure, or on the size, proportion, disposition, and more or less intimate mixture of its constituent parts.

"In some of the more common varieties, the two ingredients are in distinct grains of considerable size, like those of granite; and the foliated structure both of the hornblende and felspar is often distinctly visible. The proportion of felspar is sometimes very

"From Greenstone with a coarse granular structure. to those varieties whose texture is so finely granular that the two ingredients can scarcely be perceived, there is a gradual passage, exhibiting every intermediate step. Indeed the grains are sometimes so minute, and so uniformly and intimately mingled, that the mass is altogether homogeneous, and the different ingredients are hardly perceptible, even with a glass. Hence the texture of this rock is sometimes distinctly crystalline, and sometimes almost compact and

"Greenstone, like basalt, sometimes presents itself in prisms, or columns of various sizes. These prisms may have from three to seven sides, and are sometimes

may have from three to seven sides, and are sometimes as regular as those of basait.

"The general aspect of Greenstone is sometimes much diversified by the foreign ingredients, which it admits into its composition. Among these are quartz, epidote, mica, talc, carbonate of lime, and almost always sulphuret of iron, which is sometimes magalways sulphuret into the composition of this rock. Hence quently enters into the composition of this rock. Hence by exposure to the weather, its exterior becomes brownish or reddish brown; and sometimes Greenstones are gradually decomposed.

"Many Greenstones are susceptible of a polish;—and that variety which admits cpidote into its composition, often forms a very beautiful mineral, when polished, especially if it be porphyritic. Its colour is

DIA DIA

often a fine dark green, resembling serpentine. The epidote, either crystallized or compact, is sometimes in very narrow veins; and sometimes it is uniformly disseminated in very minute grains. In other cases, the epidote and felspar form a kind of base, containing acicular crystals of hornblende; or the three ingredients are distinct, as in granite."—Cleaveland's Mineral. A.1

DIADE'CUS. (From ¿iabcbaiow, to strengthen; so called, as affording the chief support to the foot.) The

DIABETES. (From ôta, through, and βatves, to pass.) An immoderate flow of urine. A genus of disease in the class Neuroses, and order Spasmi of Cullen.

There are two species in this complaint:

1. Diabetes insipidus, in which there is a superabundant discharge of limpid urine, of its usual urinary tasts.

2. Diabetes mellitus, in which the urine is very sweet, and contains a great quantity of sugar.

Great thirst, with a voracious appetite, gradual emaciation of the whole body, and a frequent discharge of urine, containing a large proportion of saccharine and other matter, which is voided in a quantity even exceeding that of the aliment or fluid introduced, are the characteristics of this disease. Those of a shattered constitution, and those who are in the decline of life, are most subject to its attacks. It not unfrequently attends on hysteria, hypochondriasis, dyspepsia, and asthma: but it is always much milder when symptomatic, than when it appears as a primary

Diabetes may be occasioned by the use of strong di-uretic medicines, intemperance of life, and hard drinkthe blood, or general debility. It has, however, taken place, in many instances, without any obvious cause.

That which immediately gives rise to the disease, has ever been considered as obscure, and Various the place in many instances, without any obvious cause.

ories have been advanced on the occasion. It has been usual to consider diabetes as the effect of relaxation of usual to consider diabetes as the effect of relaxation of the kidneys, or as depending on a general colliquation of the fluids. Dr. Richter, professor of medicine in the university of Gottingen, supposes the disease to be generally of a spasmodic nature, occasioned by a stimulus acting on the kidneys; hence a secretio aucta urina, and sometimes perversa, is the consequence. Dr. Darwin thinks that it is owing to an inverted action of the urinary branch of the lymphatics; which doctrine, although it did not escape the censure of the best anatomists and experienced physiologists, met. doctrine, although it did not escape the censure of the best anatomists and experienced physiologists, met, nevertheless, with a very favourable reception on its being first announced. The late Dr. Cullen offered it as his opinion, that the proximate cause of this disease might be some fault in the assimilatory powers, or in those employed in converting alimentary matters into the proper animal fluids, which theory has since been adopted by Dr. Pobson, and still later by Dr. Rolla, surgeon-general to the royal artillery. The liver has been thought, by some, to be the chief source of the disease; but diabetes is hardly ever attended with any affection of this organ, as has been proved by frequent dissections; and when observed, it is to be considered as accidental.

The primary seat of the disease is, however, far from being absolutely determined in favour of any hypothesis yet advanced; and, from the most attentive consideration of all the circumstances, the weight of evidence appears to induce the majority of practi-tioners to consider diabetes as depending on a primary affection of the kidneys.

Diabetes sometimes comes on slowly and impercep Diabetes cometimes comes on slowly and imperceptibly, without any previous disorder; and it now and then arises to a considerable degree, and subsists long without being accompanied with evident disorder in any particular part of the system; the great thirst which always, and the voracious appetite which frequently occur in it, being often the only remarkable symptoms; but it more generally happens, that a considerable affection of the stomach precedes the coming on of the disease; and that, in its progress, besides the on of the disease; and that, in its progress, besides the symptoms already mentioned, there is a great dryness in the skin, with a sense of weight in the kidneys, and a pain in the ureters, and the other urinary passages.

Under a long continuance of the disease, the body becomes much emaciated, the feet ædematous, great

insipid, clear, and colourless, soon acquires a sweetish or saccharine taste, its leading characteristic; and, when subjected to experiment, a considerable quantity of saccharine matter is to be extracted from it. Sometimes it is so loaded with sugar, as to be capable of being fermented into a vinous liquor Upwards of one-twelfth of its weight of sugar was extracted from some diabetic urine, by Cruickshank, which was at the rate of twenty-nine ounces troy a day, from one patient.

In some instances, the quantity of urine in diabetes is much greater than can be accounted for from all the sources united. Cases are recorded, in which 25 to 30 pints were discharged in the space of a natural day, for many successive weeks, and even months; and in which the whole ingesta, as was said, did not amount to half the weight of the urine. To account for this overplus, it has been alleged that water is absorbed from the air by the surface of the body; as also that a quantity of water is compounded in the lungs them-

selves

Dissections of diabetes have usually shown the kid-Dissections of diabetes have usually shown the kidneys to be much affected. In some instances, they have been found in a loose flabby state, much enlarged in size, and of a pale ash colour; in others, they have been discovered much more vascular than in a healthy state, approaching a good deal to what takes place in inflammation, and containing, in their infundibula, a quantity of whitish fluid, somewhat resembling pus, but without any sign of ulceration whatever. At the same time that these appearances have been observed. same time that these appearances have been observed same time that these appearances have been observed in their interior, the veins on their surface were found to be much fuller of blood than usual, forming a most beautiful net-work of vessels, the larger branches of which exhibited an absorbent appearance. In many cases of dissection, the whole of the mesentery has been discovered to be much diseased, and its glands remarkably enlarged; some of them being very hard, and of an irregular texture; others softer, and of a uniform spherical shape. Many of the lacteals have likewise been seen considerably enlarged. The liver. likewise been seen considerably enlarged. The liver, pancreas, spleen, and stomach, are in general perceived to be in a natural state; when they are not so, the oc-currence is to be considered as accidental. The bladder, in many cases, is found to contain a considerable quantity of muddy urine.

A great variety of remedies has been proposed for this disease; but their success is generally precarious, or only temporary, at least in the mellitic form of the complaint. The treatment has been generally concomplaint. The treatment has been generally conducted on the principles of determining the fluids to other outlets, particularly the skin, and of increasing the tone of the kidneys. Diaphoretics are certainly very proper remedies, especially the combination of opium with ipecacuanha, or antimonials, assisted by the warm bath, suitable clothing, and perhaps removal to a milder climate: in the insipid form of diabetes, this plan has sometimes effected a cure; and it appears that the large use of opium has even the power of correcting, for the time, the saccharine quality of the urine. Cathartics are hardly of service, farther than to keep the bowels regular. Tonics are generally indicated by obvious marks of debility; and if the patient be troubled with acidity in the primæ viæ, alkaline medicines will be properly joined with them, preferring those which have no diuretic power. Astringents have been highly extolled by some practitioners, but do not appear likely to prevail, except those which pass off by the urine, as uva ursi; or the milder stimulants, which can be directed to the kidneys, as copaiba, &c. may correct the laxity of those organs, if the disease depend on this cause. The tinctura lytter must be used with great caution, and its efficacy is not well established: and blisters to the loins can only be useful as counter-irritants, though not the most suitable. Frequent friction, especially over the kidneys. ducted on the principles of determining the fluids to useful as counter-irritants, though not the most suitable. Frequent friction, especially over the kidneys, able. Frequent friction, especially over the kidneys, wearing a tight belt, and gentle exercise, may assist the recovery of the patient; and when the function of the skin is restored, using the bath gradually of a lower temperature, will tend greatly to obviate its suppression afterward. It is likewise highly important to regulate the diet, especially in the mellitic diabetes. Dr. Rolla first pointed out the advantage derived from

restricting the patient to a diet principally of animal food, avoiding especially those vegetables which might afford saccharine matter, the urine becoming thereby of a more healthy quality, and diminishing in quantity: but unfortunately the benefit appears but temporary, and the plan is not persevered in without distress to the patient. The same gentleman recommended also the sulphuret of potassa, and still more the hydrosulphuret of ammonia; but they are very nau-seous medicines, and of doubtful efficacy. Another plan of treating the disease has been more recently proposed, namely, by bleeding, and other antiphlogistic measures; and some cases of its success have been recorded: but farther experience is certainly required, before we should be justified in relying much upon it.

DIA BOLUS METALLORUM. Tin.

DIABO'TANUM. (From δια, and βοτανη, an herb.) A plaster made of herbs.

DIACA'DMIAS. (From δια, and καδμια, cadmia.) The mame of a plaster, the basis of which is cadmia.

DIACALAMI'NTHES. (From δια, and καλαμινθη, calamint.) The name of an antidote, the chief ingredient in which is calamint.

Diaca RCINUM. (From δια, and καρκινός, a crab.)
The name of an antidote prepared from the flesh of crabs and cray-fish.

DIACA'RYON. (From oca, and kapver, a nut.) Rob

of nuts, or walnuts.

DIACA'ssia. (From dia, and κασσια, cassia.) Electuary of cassia.

Diacasto rium. (From δια, and καςωρ, castor.) An antidote, the basis of which is castor.

Diacatho Licon. (From δια, and καθολικος, universal.) The name of a purge, so called from its versal.) The nan general usefulness.

(From δια, and κεν Jaupiov, cen-DIACENTAU'RIUM.

DIACENTAU RIUM. (From δια, and κεν/αυρίον, centaury.) The Duke of Portland's powder is so called, because its chief ingredient is centaury.

DIACENTRO TUM. (From δια, and κεν/ροω, to prick.) A collyrium, so called from its pungency and stimulating qualities.

DIACHALCI'TIS. (From δια, and χαλκιζις, chalcitis.) A plaster, the chief ingredient in which is chalcitis. DIACHA'LSIS. (From διαχαλω, to be relaxed.) 1.

2. The opening of the sutures of the head.

DIACHEIRI'SMUS. (From δια, and χειρ, the hand.)
Any operation performed by the hand.
DIACHELIDO'NIUM. (From δια, and χελιδωνιον, telandine.) A plaster, the chief ingredient in which was the herb celandine.

Diachoresis. Any excretion, or excrement, but chiefly that by stool.

DIACHORE'SIS. See Diachorema. Diachri'sTa. (From dia, and xpie, to anoint.)

Diacher's Ta. (From dia, and xoise to anoint.)
Medicines to anoint parts.
Diacher's um. (From dia, and xouses, gold.) A
plaster for fractured limbs; so named from its yellow

DIA'CHYLUM. (From &a, and xvlos, juice.) A plaster formerly made of certain juices, but it now means an emollient digestive plaster.

DIA'CHYSIS. (From δια, and χυω, to pour out.)

Fusion or melting.

DIACHY TICA. (From διαχυω, to dissolve.) Medicines which discuss tumours.

DIACINE'MA. (From &a, and servess, to move.) A slight dislocation.

DIACT'SSUM. (From &a, and steeges, ivy.) An application composed of ivy leaves.

Dia CLASIS. (From δια, and χλαω, to break.) A

DIACLY SMA. (From διακλυζω, to wash out.) gargle or wash for the mouth.

DIACOCCYME'LON. (From δια, and κοκκυμηλου, a plum.) An electuary made of prunes.

Diaco' DIUM. (From dea, and κωdea, a poppy head.)

A composition made of the heads of poppies.

DIACOLOCY'NTHIS. (From δια, and κολοκυνθις, the colocynth.) A preparation, the chief ingredient of

which is colocynth.

Diaco'mma. (From διακοπ/ω, to cut through.)

Diacope. A deep cut or wound.

Diacope. See Diacomma.

Diacope. See Diacomma.

Diacope. (From δια, κοπρος, dung, and αιξ, a

goat.) A preparation with goat's dung.

Diacora'llow. (From δια, and ποραλλιον, coral.) A preparation in which coral is a chief ingredient.

DIA'CRISIS. (From διακρινω, to distinguish.) The distinguishing diseases one from another by their symptoms.

DIACRO'CIUM. (From ¿ta, and κροκός, saffron.) A

collyrium in which is saffron.

Diacurcu'ma. (From δια, and κυρκουμα, turmeric.) An antidote in which is turmeric or saffron.

DIACYDO'NIUM. (From δια, and κυδωνια, a quince.)
Marmalade of quinces.

Marmalade of quinces.

DIADAPHN'DION. (From δια, and δαφμις, the laureltree.) A drawing plaster in which were bay-berries.

DIADE LPHIA. (From δις, twice, and αδελφις, a

brotherhood; two brotherhoods.) The name of a

class in the sexual system of plants, embracing those
the flowers of which are hermaphrodites, and have the male organs united below in two sets of cylindrical fila-

DIADE'MA. (From διαδεω, to surround.) 1. A diadem or crown.

2. A bandage to put round the head.

Diade'xis. (From διαδεχομαι, to transier.) Dia-doche. A transposition of humours from one place to another.

DIA DECRE. See Diadexis.

DIA POSIS. (From διαδιδωμι, to distribute.) The remission of a disorder.

DIÆ RESIS. (From διαιρεω, to divide or separate.)

A solution of continuity of the soft parts of the human

DIERE'TICA. (From διαιρεω, to divide.) Corrosive medicines

DLE'TA. (From διαιζαω, to nourish.) Diet; food. It means also the whole of the non-naturals. See

Diaglau'cium. (From Jia, and ylaukiov, the blue juice of an herb.) An eye-water made of the purging thistle.

DIAGNO'SIS. (From ciayavwarw, to discern or distinguish.) The science which delivers the signs by which a disease may be distinguished from another disease; hence those symptoms which distinguish such affections are termed diagnostic.

DIAGRY'DICM. Corrupted from dacrydium or scammony.

DIAHERMODA'CTYLUN. (From ¿i.a., and τρμοδακ/υλος, the hermodactyl.) A purging medicine, the basis of which is the hermodactyl.

DIAT'REON. (From 612, and 1915, the lily.) An antidote in which is the root of the lily.

DIAI'UM. (From dea, and cov, a violet.) A pastil, the chief ingredient of which is violets. DIALA'CCA. (From dea, and hakke.) An antidote

in which is the lacca.

Dialago'um. (From δια, and λαγως, a hare.) A medicine in which is the dung of a hare.

DIALE'MMA. (From διαλαμβανω, to interrupt.) The

remission of a disease.

DIALE'PSIS. (From dialaphave, to interrupt.) 1. An intermission.

2. A space left between a bandage.

Diali Banum. (From dia, and hisavov, frankin-cense.) A medicine in which frankincense is a chief

ingredient.

DIALLAGE. Smaragdite of Saussure. Verde di Corsica duro of artists. A species of the genus Schiller spar. It is a mineral of a greenish colour, composed of silica, alumina, magnesia, lime, oxide of iron, oxide of copper, and oxide of chrome. It is found principally in Corsica.

DIA LOES. (From bia, and alon, the aloe.) A me-

Dia loes. (From δια, and αλοη, the aloe.) A medicine chiefly composed of aloes.

Dialthæa. (From δια, and αλβαια, the mallow.) An ointment composed chiefly of marsh-mallows.

DIA LYSIS. (From διαλυω, to dissolve.) A solution of continuity, or a destruction of parts.

Dia lyses. The plural of dialysis. The name of an order in the class Locales of Cullen's Nosology.

Dialy tica. (From διαλυω, to dissolve.) Medicines which heal wounds and fractures.

Diamargari ton. (From δια, and μαργαμίζες, pearl:) An antidote in which pearls are the chief ingredient.

gredient.

DIAMASSE'MA. (From dia, and passopat, to chew.) A masticatory, or substance put into the mouth, and chewed to excite a discharge of the saliva.

to the ancients, is principally found in the western peninsula of India, on the coast of Coromandel, in the kingdoms of Golconda and Visapour, in the island of Borneo, and in the Brazils. It is the most valued of all minerals.

Diamonds are generally found bedded in yellow ochre or in rocks of freestone, or quartz, and sometimes in the beds of running waters. When taken out of the earth, they are incrusted with an exterior earthly covering, under which is another, consisting of carbo-nate of time.

In the Brazils, it is supposed that diamonds might be obtained in greater quantities than at present, if the sufficient working of the diamond-mines was not prohibited, in order to prevent that diminution of their commercial value, which a greater abundance of them might occasion.

Brazilian diamonds are, in commercial estimation,

inferior to the oriental ones.

In the rough, diamonds are worth two pounds sterling the carat, or four grains, provided they are without blemish. The expense of cutting and polishing amounts to about four pounds more. The value however is far above what is now stated when they become considerable in size. The greatest sum that has been given for a single diamond is one hundred and fifty thousand pounds.

The usual method of calculating the value of diamonds is by squaring the number of carats, and then multiplying the amount by the price of a single carat: thus supposing one carat to be 2t. a diamond of 8 carats

is worth 128t. being 8 × 8 × 2.

The famous Pigot diamond weighs 188 1-8th grains.

The famous Pigot diamond weighs 188 1-8th grains.

Physical Properties of Diamond.

Diamond is always crystallized, but sometimes so imperfectly, that, at first sight, it might appear amorphous. The figure of diamond, when perfect, is an eight-sided prism. There are also cubical, flat, and round diamonds. It is the oriental diamond which crystallizes into octohedra, and exhibits all the varieties of this primitive figure. The diamond of Region ties of this primitive figure. The diamond of Brazil crystallizes into dodecahedra.

The texture of the diamond is lamellated, for it may

be split or cleft with an instrument of well-tempered steel, by a swift blow in a particular direction. There are however some diamonds which do not appear to be formed of lamina, but of twisted and interwoven fibres, like those of knots in wood. These exceed the others greatly in hardness, they cannot be cut or polished, and are therefore called by the lapidaries dia-

monds of nature.

The diamond is one of the bardest bodies known. It resists the most highly-tempered steel file, which cir-cumstance renders it necessary to attack it with diacumstance renders it necessary to attack it with diamond powder. It takes an exquisite and lasting polish. It has a great refractive power, and hence its lustre, when cut into the form of a regular solid, is uncommonly great. The usual colour of diamonds is a light gray, often inclining to yellow, at times lemon colour, violet, or black, seldomer rose-red, and still more rarely green or blue, but more frequently pale brown. The purest diamonds are perfectly transparent. The colourless diamond has a specific gravity which is in proportion to that of water as 3.512 to 1.000, according to Brisson. This varies however considerably. When Brisson. This varies however considerably. When rubbed it becomes positively electric, even before it has been cut by the lapidary.

Diamond is not acted upon by acids, or by any chemical agent, oxygen excepted; and this requires a very great increase of temperature to produce any

effect.

The diamond burns by a strong heat, with a sensible flame, like other combustible bodies, attracting oxy-gen, and becoming wholly converted into carbonic

acid gas during that process

It combines with iron by fusion, and converts it, like common charcoal, into steel; but diamond requires a much higher temperature for its combustion than common charcoal does, and even then it consumes but slowly, and ceases to burn the instant its temperature is lowered.

"From the high refractive power of the diamond,

Dia'mbra. (From δια, and αμδρα, amber.) An aromatic composition in which was ambergris.

Diame'lon. (From δια, and μηλον, a quince.) A composition of quinces.

Diamond. The diamond, which was well known to the ancients, is principally found in the western to the ancients, is principally found in the western the fluoric compounds, he three out the idea, that it remains all of India. The content of Compounds the fluoric compounds, he three out the idea, that it remains all of India. might be the carbonaceous principle, combined with some new, light, and subtle element of the oxygenous and chlorine class

This unrivalled chemist, during his residence at Florence in March 1814, made several experiments on the combustion of the diamond and of plumbago, by means of the great lens in the cabinet of natural history; the same instrument as that employed in the first trials on the action of the solar heat on the diamond, instituted in 1694 by Cosmo III. Grand Duke of Tuscany. He subsequently made a series of researches on the combustion of different kinds of charcoal at Rome. His mode of investigation was peculiarly ele-

gant, and led to the most decisive results.

He found that diamond, when strongly ignited by the lens, in a thin capsule of platinum, perforated with many orifices, so as to admit a free circulation of air, continued to burn with a steady brilliant red light, visible in the brightest sunshine, after it was withdrawn from the focus. Some time after the diamonds were after the diamonds. were removed out of the focus, indeed, a wire of platina that attached them to the focus, indeed, a wife of platina that attached them to the tray was fused, though their weight was only 1.84 grains. His apparatus consisted of clear glass globes of the capacity of from 14 to 40 cubic inches, having single apertures to which stop-cocks were attached. A small hollow cylinder of platinum was attached to one end of the stop-cock, and was mounted with the little perforated capsule for containing the diamond. When the experiment was to be made, the globe containing the capsule and the substance to be burned was exhausted by an excellent air-pump, and pure oxygen, from chlorate of potassa, was then introduced. The change of volume in the gas after combustion was estimated by means of a fine gas after combission was estimated by means of a line tube connected with a stop-cock, adapted by a proper screw to the stop-cock of the globe, and the absorption was judged of by the quantity of mercury that entered the tube which afforded a measure so exact, that no alteration however minute could be overlooked. He had previously satisfied himself that a quantity of moisture, less than 1-100th of a grain, is rendered evident by deposition on a polished surface of glass; for a piece of paper weighing one grain was introduced into a tube of about four cubic inches' capacity, whose exterior was slightly heated by a candle. A dew was immediately perceptible on the inside of the glass, though the paper, when weighed in a balance turning with 1-100th of a grain, indicated no appreciable diminution.

The diamonds were also heated to redness before they were introduced into the capsule. During their combustion, the glass globe was kept cool by the appli-cation of water to that part of it immediately above the capsule, and where the heat was greatest. From the results of his different experiments, con-

ducted with the most unexceptionable precision, it is demonstrated, that diamond affords no other substance demonstrated, that diamond altords no other substance by its combustion than pure carbonic acid gas; and that the process is merely a solution of diamond in oxygen, without any change in the volume of the gas. It likewise appears, that in the combustion of the dif-ferent kinds of charcoal, water is produced; and that from the diminution of the volume of the oxygen, from the diminution of the volume of the oxygen, there is every reason to believe that the water is formed by the combustion of hydrogen existing in strongly ignited charcoal. As the charcoal from oil of turpentine left no residuum, no other cause but the presence of hydrogen can be assigned for the diminution of the reason of the reaso tion occasioned in the volume of the gas during its combustion.

The only chemical difference perceptible between diamond and the purest charcoal is, that the last contains a minute portion of hydrogen; but can a quantity of an element, less in some cases than 1-50,000th part of the weight of the substance, occasion so great a difference in physical and chemical characters? The opinions of Tennant, that the difference depends on crystallization, seems to be correct. Transparent on crystallization, seems to be correct. Transparent solid bodies are in general non-conductors of electricity; and it is probable that the same corpuscular arrangements which give to matter the power of trans-

witting and polarizing light, are likewise connected with its relations to electricity. Thus water, the hy-drates of the alkalies, and a number of other bodies which are conductors of electricity when fluid, become

non-conductors in their crystallized form.

That charcoal is more inflammable than the diamond, may be explained from the looseness of its texture, and from the hydrogen it contains. But the diamond appears to burn in oxygen with as much facility as plumbago, so that at least one distinction supposed to exist between the diamond and common supposed to exist between the diamond and common carbonaceous substances is done away by these researches. The power possessed by certain carbonaceous substances of absorbing gases, and separating colouring matters from fluids, is probably mechanical and dependent on their porous organic structure; for it belongs in the highest degree to vegetable and animals. mal charcoal, and it does not exist in plumbago, coke, or anthracite.

The nature of the chemical difference between the diamond and other carbonaceous substances, may be demonstrated by igniting them in chlorine, when mu-riatic acid is produced from the latter, but not from the former. The visible acid vapour is owing to the moisture present in the chlorine uniting to the dry muriatic gas. But charcoal, after being intensely ignited in chlorine, is not altered in its conducting power of colour. This circumstance is in favour of the opinion, that the minute quantity of hydrogen is not the cause of the great difference between the physical properties of the diamond and charcoal." See Carbon.

Diamond-shaped. See Leaf. Diamo'Ron. (From δια, and μωρον, a mulberry.) A

Diamora-snapea. See Leaf.

Diamo'ron. (From δia, and μωρον, a mulberry.) A preparation of mulberries.

Diamo'schum. (From δia, and μοσχος, musk.) An antidote in which musk is a chief ingredient.

Diamoτο'sis. (From δia, and μογος, lint.) The introduction of lint into an ulcer or wound.

DIA'NA. 1. The moon.

The chemical name for silver from its white shining appearance.

DIANANCA SMUS. (From δια, and αναγκαζω, to force.) 1. The forcible restoration of a luxated part into its proper place.

2. An instrument to reduce a distorted spine.

DIA'NDRIA. (From δις twice, and ανηρ, a man.)

The name of a class in the sexual system, consisting of

hermaphrodite plants which have flowers with two

DIA'NTHUS. (From Δις, διος, Jove, and ανθος, a flower: so called from the elegance and fragrance of its flower.) The name of a genus of plants in the Linnæan system. Class, Decandria; Order, Di-

DIANTHUS CARYOPHYLLUS. The systematic name DIANTHUS CARYOPHYLLUS. The systematic name of the clove-pink. Caryophyllum rubrum; Tanica; Vetonica; Betonica; Coronaria; Caryophyllus hortensis. Clove gilliflower. Clove July flower. This fragrant plant, Dianthus—floribus solitariis, squamis calycinus subovatis, brevissimus, corollis crenatis, of Linguus, grows wild in several parts of England; but the flowers, which are pharmaceutically employed, are usually produced in gardens: they have a pleasant aromatic smell, somewhat allied to that of clovespice; their taste is bitterish and sub-adstringent. These flowers were formerly in extensive use, but are now merely employed in form of syrup, as a useful and pleasant vehicle for other medicines.

DIAPA'SMA. (From διαπασσω, to sprinkle.) A medicine reduced to powder and sprinkled over the body,

or any part.

DIAPEDE'SIS. (From διαπηδαω, to leap through.)
The transudation or escape of blood through the coats of an artery.

DIAPE'GMA. (From διαπηγνυω, to close together.)
A surgical instrument for closing together broken

DIAPE'NTE. (From dea, and meyer, five.) A medi-

cine composed of five ingredients.
DIAPHANOUS. (Diaphanosus; from ¿a, through, and φαινω, to shine.) A term applied to any substance which is transparent; as the hyanoid membrane covering the vitreous humour of the eye, which is as transparent as glass.

Diapher'Nicum. From čia, and φοινίξ, a date.)

DIA PHORA. (From διαφερω, to distinguish.) The

distinction of diseases by their characteristic marks and symptoms.

DIAPHORE'SIS (From διαφορεω, to carry through.)

DIAPHORETIC. (Diaphoreticus; from diapopew, to carry through.) That which, from being taken internally, increases the discharge by the skin. When this is carried so far as to be condensed on the surface, it forms sweat: and the medicine producing it is named sudorific. Between diaphoretic and sudorific, there is no distinction; the operation is in both cases the same, and differs only in degree from augmentation of dose, or employment of assistant means. This class of medicines comprehends five orders.

1. Pungent diaphoretics, as the volatile salts, and essential oils, which are well adapted for the aged; those in whose system there is little sensibility; those who are difficultly affected by other diaphoretics; and those whose stomachs will not bear large doses of me-

dicines.

2. Calefacient diaphoretics, such as serpentaria contrayerva, and guaracum: these are given in cases where the circulation is low and languid.

3. Stimulant diaphoretics, as antimonial and mercurial preparations, which are best fitted for the vigorous

and plethoric.

4. Antispäsmodic diaphoretics, as opium, musk, and camphire, which are given to produce a diaphoresis, when the momentum of the blood is increased.

5. Diluent diaphoretics, as water, whey, &c. which are best calculated for that habit in which a predisposition to sweating is wanted, and in which no diaphoresis takes place, although there be evident causes to produce it.

DIAPHRA'GMA. (Diaphragma, matis. n.; from δια, and φρατ7ω, to divide.) Septum transversum. The midrit, or diaphragm. A muscle that divides the thorax from the abdomen. If is composed of two muscles; the first and superior of these arises from the sternum, and the ends of the last ribs on each side. Its fibres, from this semicircular origination, tend towards their centre, and terminate in a tendon, or aponeurosis, which is termed the centrum tendinosum. The se-cond and inferior muscle comes from the vertebræ of the loins by two productions, of which that on the right side comes from the first, second, and third ver-tebræ of the loins; that on the left side is somewhat shorter, and both these portions join and make the lower part of the diaphragm, which joins its tendons with the tendon of the other, so that they make but one muscular partition. It is covered by the pieura on its upper side, and by the peritonæum on the lower side. It is pierced in the middle for the passage of the vena cava; in its lower part for the œsophagus, and the nerves, which go to the upper orifice of the stomach, and between the productions of the inferior muscle, passes the aorta, the thoracic duct, and the vena azygos. It receives arteries and veins called phrenic or It receives arteries and veins called phrenic or diaphragmatic, from the cava and aorta: and sometimes on its lower part two branches from the vena adiposa, and two arteries from the lumbares. It has two nerves which come from the third vertebra of the neck, which pass through the cavity of the thorax, and are lost in its substance. In its natural situation, the diaphragm is convex on the upper side towards the breast, and concave on its lower side towards the belly; therefore, when its fibres swell and contract, it pust become plain on each side, and consequently the cavity of the breast is enlarged to give liberty to the lungs to receive air in inspiration; and the stometh and intestines are pressed for the distribution of their contents; hence the use of this muscle is very considerable; it is the principal, and the principal contents is the principal contents. hence the use of this muscle is very considerable; it is the principal agent in respiration, particularly in inspiration; for when it is is action the cavity of the thorax is enlarged, particularly at the sides, where the lungs are chiefly situated; and as the lungs must always be contiguous to the inside of the thorax and upper side of the maphragm, the air rushes into them, in order to fill up the increased space. In expiration it is relaxed and pushed up by the pressure of the abdominal muscles apon the viscera of the abdomen; and at the same time that they press it upwards, they pull down the ribs, by which the cavity of the thorax is dimainshed, and the air suddenly pushed out of the lungs. DIAPHRAGMATITIS. (From διαφραγμα, the diaphragm.) Inflammation of the diaphragm. See Paraphrenettis.

raphrenitis.

Dia PHTHORA. (From διαφθειρω to corrupt.) abortion where the fætus is corrupted in the womb.

Diaphyla'cTica. (From διαφυλασσω, to preserve.) Medicines which resist putrefaction or prevent infec-

Dia Privata. (From διαφυω, to divide.) An interstice or partition between the joints.

Diapisselæ'um. (From δια, and πισσελαιον, the oil of pitch, or liquid pitch.) A composition in which is liquid pitch.

Dia Plasis. (From διαπλασσω, to put together.) The replacing a luxated or fractured bone in its proper

situation.

DIAPLA'SMA. (From διαπλασσω, to anoint.) An unction or fomentation applied to the whole body or any part.

DIA PNE. (From διαπνεω, to blow through, or pass gently as the breath does.) An insensible discharge

of the urine

DIAPNOE. (From διαπνεω, to breathe through.) The transpiration of vapour through the pores of the skin.

(From διαπνεω, to transpire.) Diaphoretics or medicines which promote perspiration. DIAPORE'MA. (From διαπορεω, to be in doubt.)

Nervous anxiety

DIAPORON. (From δια, and οπωρα, autumnal fruits.) A composition in which are several autumnal fruits, us quinces, mediars, and services.

DIAPRA'SSIUM. (From δια, and πρασσιον, hoarhound.) A composition in which hoarhound is the principal transaction. ingredient.

DIAPRU'NUM. (From δια, and προυνη, a prune.) An

clectuary of prunes.

Diaprso'ricum. (From δια, and ψωρα, the itch or scurvy.) A medicine for the itch or scurvy.

Diaprz'rnes. (From δια, and π/ερνα, the heel.)

A composition of cow heel and cheese.

Diaptero'sis. (From $\delta \iota a$, and $\pi / \epsilon \rho o \nu$, a feather.) The cleaning the ears with a feather.

DIAPYE'MA. (From dia, and muov, pus.) A suppuration or abscess.

(From διαπυημα, a suppuration.) DIAPYE'MATA. Suppurating medicines. DIAPYE'TICA. (From διαπυημα, a suppuration.)

Suppurating applications.

DIARHO CHA. (From δια, and ρηχος, a space.) The space between the foldings of a bandage. DIA'RIUS. (From dies, a day.) A term applied to

fevers which last but one day.
DIAROMA'TICUM. (From ¿ia, and αρομαζικον, an

Diaroma'ticum. (From δια, and αρομα/ικον, an aromatic.) A composition of spices.

Dia'rrhage. (From διαρρηγνυμι, to break asunder.) A fracture.

Diarrhodo'mell. (From δια, ροδον, a rose, and μιλι, honey.) Scammony, agaric, pepper, and honey.

Dia'rrhodon. (From δια, and ροδον, a rose.) A composition of roses.

Diarrhodo'mell. (From διαρρεω, to flow through.)

A purging. It is distinguished by frequent stools with the natural excrement, not contagious, and seldom atthe natural excrement, not contagious, and seldom attended with pyrexia. It is a genus of disease in the class Neuroses, and order Spasmi of Cullen, containing the following species:

1. Diarrhaa crapulosa. The feculent diarrhaa, from crapulus, one who overloads his stomach.
2. Diarrhaa biliosa. The bilious, from an increased

secretion of bile.

3. Diarrhaa mucosa. The mucous, from a quantity of slime being voided.
4. Diarrhaa hepatirrhaa. The hepatic, in which there is a quantity of serous matter, somewhat resembling the washings of flesh, voided; the liver being primarily affected.

5. Diarrhaa lienterica. The lientery; when the

food passes unchanged.
6. Diarrhaa caliaca. 6. Diarrhwa caliaca. The coliac passion: the food passes off in this affection in a white liquid state

like chyle.
7. Diarrhæa verminosa. Arising from worms.
Diarrhæa seems evidently to depend on an increase of the peristaltic motion, or of the secretion of the intestines; and besides the causes already nothed, it may arise from many others, influencing the system generally, or the particular seat of the disease. Of the former kind are cold, checking perspiration, certain passions of the mind, and other disorders; as den-

An tition, gout, fever, &c. To the latter belong various acrid ingests, drastic cathartics, spontaneous acidity, eve.) &c. In this complaint each discharge is usually pre-&c. In this complaint each discharge is usually pre-ceded by a murmuring noise, with a sense of weight and uncasiness in the hypogastrium. When it is pro-tracted, the stomach usually becomes affected with sickness, or sometimes vomiting, the countenance grows pale or sallow, and the skin generally dry and rigid. Ultimately great debility and emaciation, with dropsy of the lower extremities, often supervene. Dis-sections of diarrhos, where it terminated fatally, have sections of diarrhoa, where it terminated fatally, have shown ulcerations of the internal surface of the intestines, sometimes to a considerable extent, especially about the follicular glands; in which occasionally a cancerous character has been observable. The treatment of this complaint must vary greatly according to circumstances: sometimes we can only hope to palliate, as when it occurs in the advanced period of phthisis pulmonalis; sometimes it is rather to be encoursis pulmonalis; sometimes it is rather to be encouraged, relieving more serious symptoms, as a bilious diarrhœa coming on in fever, though still some limits must be put to the discharge. Where, however, we are warranted in using the most speedy means of stopping it, the objects are, 1. To obviate the several causes. 2. To lessen the inordinate action, and give tone to the intestine.

causes. 2. To lessen the inordinate action, and give tone to the intestine.

I. Emetics may sometimes be useful, clearing out the stomach, and liver, as well as determining to the skin. Cathartics also, expelling worms, or indurated faces; but any acrimony in the intestine would probably cause its own discharge, and where there is much irritability, they might aggravate the disease: however, in protracted cases, the alvine contents speedily become vitiated, and renew the irritation; which may be best obviated by an occasional mild aperient, particularly rhubarb. If, however, the liver do not perform its office, the intestine will hardly recover its healthy condition: and that may most probably be effected by the cautious use of mercury. Likewise articles which determine the fluids to other outlets, diuretics, and particularly diaphoretics, in many cases contribute materially to recovery; the latter perhaps assisted by bathing, warm clothing, gentle exercise, &c. Diluent, demulcent, antacid, and other chemical remedies, may be employed to correct acrimony, according to its particular nature. In children teething, the gums should be lanced; and if the bowels have been attacked on the repulsion of some other disease, it may often be proper to endeavour to restore this. But a matter of the greatest importance is the due regulation of the diet, carefully avoiding those articles, which are likely to disagree, or irritate the bowels, and preferring such as have a mild astringent effect. ticles, which are likely to disagree, or irritate the bowels, and preferring such as have a mild astringent effect. Eis, and pretering such as nave a man as a series, bread, Fish, milk, and vegetables, little acescent, as rice, bread, &c. are best; and for the drink, madeira or brandy, sufficiently diluted, rather than malt liquors.

II. Some of the means already noticed will help to

II. Some of the means already noticed will help to fulfil the second indication also, as a wholesome diet, exercise, diaphoretics, &c.: but there are others of more power, which must be resorted to in urgent cases. At the head of these is opium, a full dose of which frequently at once effects a cure; but where there is some more fixed cause, and the complaint of any standing, moderate quantities repeated at proper intervals will answer better, and other subsidiary means ought not to be neglected; aromatics may prevent its disordering the stomach, rhubarb obviate its causing permanent constipation, &c. Tonics are generally proper, the discharge itself inducing debility, and where there is a deficiency of bile particularly, the lighter forms of the aromatic bitters, as the infusum calumbae, &c. will materially assist; and mild chalybeates are &c. will materially assist; and mild chalybeates are sometimes serviceable. In protracted cases astringents come in aid of the general plan, and where opium disagrees, they may be more necessary: but the milder ones should be employed at first, the more powerful only where the patient appears sinking. Chalk and lime-water answer best where there is acidity; otherwise the nomegrapate rind, logwood extract, catechy. wise the pomegranate rind, logwood extract, catechu, kino, tormentil, &c. may be given: where these fail, alum, sulphate of zinc, galls, or superacetate of lead.

DIARTHRO'SIS. (From διαρθροω, to articulate.)

A moveable connexion of bones. This genus has five

species, viz. enarthrosis, arthrodia, ginglymus, trochoides, and amphiarthrosis

DIASAPO'NIUM. (From dia, and gawwy, soap.) An ointment of soap.

Diasaty'rium. (From δια, and σα/υριον, the orchis.) An ointment of the orchis-root.

Diasci'llum. (From δια, and σκιλλα, the squill.) DIASATY RIUM.

Oxymel and vinegar of squills.

Diasci'ncus. (From δια, and σκιγκος, the crocodile.) A name for the mithridate, in the composition of which there was a part of the crocodile.

Diasco' RDIUM. (From δια, and σκορδιον, the water germander.) Electuary of scordium.

Diask' NA. (From δια, and sena.) A medicine in which is sonna.

which is senna.

Diasmy'rnum. (From dia, and suppry, myrrh.)
Diasmyrnes. A wash for the eyes, composed of myrrh.

Diaso'sticus. (From διασωζω, to preserve.) That which preserves health.

Which preserves health.

Diaspe'rmatum. (From δια, and σπερμα, seed.)

A medicine composed chiefly of seeds.

Dia'sphage. (From διασφαζω, to separate.) Diasphaxis. The interstice between two veins.

DIA'SPHAGE. (From ἀιασφαζω, to separate.) Diasphazis. The interstice between two veins.

DIASPHY'XIS. (From ὁια, and σφυζω, to strike.)
The pulsation of an artery.
[Diaspore, of Haiy, Brogniart, Cleaveland, &c.
"This mineral is but little known. It is composed of laminæ, somewhat curved, easily separable from each other, and possessing a pearly gray colour, with considerable lustre. These laminæ according to the natural joints, which they present, when examined by a light, seem to have separated in the direction of the smaller diagonals of the bases of a rhomboidal prism. The edges or angles of its fragments are capable of scratching glass. Its specific gravity is 3.43.

"A small fragment, placed in the flame of a candle,

A small fragment, placed in the flame of a candle, "A small fragment, placed in the flame of a candle, almost instantly decrepitates, and is dispersed in numerous little spangles. Hence its name from the Greek Διαδπειρω. It is composed of alumine 80, water 17, iron 3. Nothing is known of its geological situation. Its gangue, is a rock, both argiliaceous and ferruginous."—Cleav. Min. A.]

DIA'STASIS. (From διιστημι, to separate.) Diastema. A separation. A separation of the ends of the bones; as that which occasionally happens to the bones of the cranium, in some cases of hydrocephalus.

DIASTE'ATON. (From δια, and εταρ, fat.) An oint-

DIASTE'ATON. (From δια, and ςεαρ, fat.) An ointment of the fat of animals.

DIASTE'MA. See Diastasis.
DIASTOLE. (From δια, and στελλω, to stretch.)
The dilatation of the heart and arteries. See Circu-Lation.

Diastomo'sis. (From διαςομοω, to dilate.) Any dilatation, or dilating instrument.

Diastre'mma. (From διαςρεφω, to turn aside.)

Diastrophe. A distortion of any limb or part.

Diastrophe. A distortion of any limb or part.

Diastrophe. See Diastromma.

Diastrophe. See Diastromma.

Diastrophe. Grow διατεινω, to distend.) The extension of a fractured limb, in order to reduce it.

Diatecolisthum. (From δια, and Τηκολιθος, the Jew's stone.) An antidote containing lapis judaicus.

DIATERE'SIS. (From δια, and Τερεω, to perforate.) A perforation or aperture.

Diaterestica. (From δια and Τερεω, to preserve.)

Medicines which preserve health and prevent disease.

Diate'ssaron. (From δια, and τεσσαρες, four.) A

Medicines which preserve health and prevent disease.

Diate'ssaron. (From δια, and τεσσαρες, four.) A medicine compounded of four simple ingredients.

Diate'trioum. (From δια, and 7ετ7ιγων, a grasshopper.) A medicine in the composition of which were grasshoppers, given as an antidote to some nephritic complaints, by Æginetus.

Dia'THESIS. (From διατιθημι, to dispose.) Any particular state of the body: thus, in inflammatory fever, there is an inflammatory diathesis, and, during putrid fever, a putrid diathesis.

Diathe'smus. (From διαθεω, to run through.) A

DIATHE'SMUS. (From διαθεω, to run through.) A rupture through which some fluid escapes.

DIATRAGACA'NTHUM. From δια, and τραγακανθα, tragacanth.) A medicine composed of gum-traga-

Canth.

DIA TRIUM. (From δια, and 7ρεις, three.) A medicine composed of three simple ingredients.

DIAXYLA LOES. (From δια, and ξυλαλοη, the lignum aloes.) A medicine in which is lignum aloes.) A medicine in which is lignum aloes.) The diatory was a surround; because it surrounds the cavity of the thorax.) The diaphragm.

Diazo'ster. (From διαξωννυμι, to surround; because, when the body is girded, the belt usually lies upon it.) A name of the twelfth vertebra of the back.

DICENTE TUM. (From δια, and κεν τω, to stimu-late.) A pungent or stimulating wash for the eyes. DICHASTE RES. (From διχαζω, to divide, because they divide the food.) A name of the foreteeth. DICHOPHY'IA. (From διχα, double, and φνω, to grow.) A distemper of the hairs, in which they split and grow forked.

and grow forked.

DICHOTOMUS. (From &c., twice, and τεμνω, to cut; that is, cut into two.) Dichotomous or bifurcated. Applied to stems, styles, &c. which are forked or divided into two.

DICHROITE. A species of iolite.

DICOTYLEDONES. Two cotyledons. See Co-

tyledon.

DICROTIC. (Dicroticus; from δις, twice, and κρονω, to strike.) A term given to a pulse in which the artery rebounds after striking, so as to convey the sensation of a double pulsation.

DICTAMNI'TES. (From δικ]αμνος, dittany.) A wine medicated with dittany.

DICTA'MNUS. (From Dictamnus, a city in Crete, on whose mountains it grows.) The name of a genus of plants in the Linnman system. Class, Decandria; Order, Monogunia. Dittany.

candria; Order, Monogynia. Dittany.
DICTAMNUS ALBUS. White fraxinella, or bastard DICTAMNUS ALBUS. White fraxinella, or bastard dittany. Fraxinella. Dictamnus albus—foliis pinnatis, caule simplici, of Linnæus. The root of this plant is the part directed for medicinal use; when fresh, it has a moderately strong, not disagreeable smell. Formerly it was much used as a stomachic, tonic, and alexipharmic, and was supposed to be a medicine of much efficacy in removing uterine obstructions, and destroying worms; but its medicinal pow-ers became so little regarded by modern physicians, that it had fallen almost entirely into disuse, till Baron that it had fallen almost entirely into disuse, till Baron Stoerck brought it into notice, by publishing several cases of its success, viz. in tertian intermittents, worms, (lumbrici) and menstrual suppressions. In all these cases, he employed the powdered root to the extent of a scruple twice a day. He also made use of a tincture, prepared of two ources of the fresh root digested in 14 ounces of spirit of wine; of this 20 to 50 drops, two or three times a day, were successfully employed in epilepsies, and, when joined with steel, this root, we are told, was of great service to chlorotic pages. root, we are told, was of great service to chlorotic patients. The dictamnus undoubtedly, says Dr. Woodtients. The dictamnus undoubtedly, says Dr. Woodville, is a medicine of considerable power; but notwithstanding the account of it given by Stoerck, who
seems to have paid little attention to its modus operandi, we may still say with Haller, "nondum autem
vires pro dignitate exploratus est," and it is now
fallen into disuse.

DICTAMNUS CRETICUS. See Origanum dictamnus.
DIDYMÆ'A. (From διδυμος, double.) A cataplasm;
so called by Galen, from the double use to which he

Dl'DYMI. (From διόυμος, double.) Twins. An old name of the testicles, and two eminences of the

DIDYMI. (From διδυμος, double.) Twins. An old name of the testicles, and two eminences of the brain, from their double protuberance.

DIDYNAMIA. (From δις, twice, and δυναμις, power, two powers.) The name of a class in the sexual system of plants, consisting of those with hermaphrodite flowers, which have four stamina, two of which are long, and two short.

Diecro'lium. (From δια, and εκβαλλω, to cast out.) A medicine causing an abortion.

Diele'ctron. (From δια, and ελεκ γρον, amber.) A name of a troche, in which amber is an ingredient. DIEMER BROECK, Iserand, was born near Utrecht, in 1609. After graduating at Angers, he went to Nimeguen in 1636, and for some years continued freely attending those who were ill of the plague, which raged with great violence, and of which he subsequently published an account. This obtained him much credit: and, in 1642, he was made professor extraordinary in medicine at Utrecht; when he gave lectures on that subject, as well as on anatomy, which rendered him very popular. He received also other endered him very popular. He received also other distinctions at that university, and continued in high esteem till his death, in 1674. He was author, besides, of a system of anatomy, and several other works in medicine and surgery; part of which were published after his death by his son, especially his treatise on the measles and smallpox.

DIERVI'LLA. (Named in honour of Mr. Dierville,

the measles and smallpox.

DIERVI'LLA. (Named in honour of Mr. Dierville, who first brought it from Arcadia.) See Lonicera

diervilla.

DIET. Diata. The dietetic part of medicine is no inconsiderable branch, and seems to require a much greater share of regard than it commonly meets with. A great variety of diseases might be removed by the observance of a proper diet and regimen, without the assistance of medicine, were it not for the impatience of the sufferers. However, it may on all occasions come in as a proper assistant to the successions. casions come in as a proper assistant to the cure, which sometimes cannot be performed without a due observance of the non-naturals. That food is, in general, thought the best and most conducive to long life, neral, thought the best and most conducive to long life, which is most simple, pure, and free from irritating qualities, and such as approaches nearest to the nature of our own bodies in a healthy state, or is capable of being easiest converted into their substance by the vis vitæ, after it has been duly prepared by the art of cookery; but the nature, composition, virtues, and uses of particular aliments, can never be learnt to satisfaction, without the assistance of practical chemistry.

Diet drink. An alterative decoction employed daily in considerable quantities, at least from a pint to a quart. The decoction of sarsaparilla and mezereon, the Lisbon diet drink, is the most common and most useful.

DIETE'TIC. Dieteticus. That part of medicine which considers the way of living with relation to

food, or diet, suitable to any particular case.

Die xopos. (From δια, and εξοδος, a way to pass out.) Diodos. In Hippocrates it means evacuation

by stool.
DIFFLA'TIO. (From diffle, to blow away.) Per-

DIFFUSUS. Diffused; spreading. Applied to panicles and stems. Panicula diffusa, that is, lax and spreading; as in Saxifraga umbrosa; the London pride, so common in our gardens; and many grasses, especially the common cultivated out. The Bunias

especially the common cultivated out. The Bunias kakile, or sea rocket, has the caulis diffusus.

BIGA'STRICUS. (From &c., twice, and yaarno, a belly: so called from its having two bellies.) Biventer maxillæ of Albinus. Mastoido-hygenien of Dumas. A muscle situated externally between the lower jaw and os hyoides. It arises, by a fleshy belly, from the upper part of the processus mastoideus, and descending, it contracts into a round tendon, which passes through the stylohyoideus, and an annular ligament which is fastened to the os hyoides: then it grows fleshy again, and assends towards the middle of the fleshy again, and ascends towards the middle of the nesny again, and ascends towards the middle of the edge of the lower jaw, where it is inserted. Its use is to open the mouth by pulling the lower jaw downwards and backwards; and when the jaws are shut, to raise the larynx, and consequently the pharynx, upwards, as in deglutition.

DIGERENTIA. (From digero, to digest.) Medicines which promote the secretion of proper pus in wounds and ulcera.

would and theers.

DIGESTER. A strong and tight iron kettle or copper, furnished with a valve of safety, in which bodies may be subjected to the vapour of water, alkohol, or ather, at a pressure above that of the atmosphere.

DIGESTION. (Digestio; from digero, to dis-

An operation in chemistry and pharmacy, in which such matters as are intended to act slowly on each other, are exposed to a heat, continued for some

2. In physiology, the change that the food under-goes in the stomach, by which it is converted into

chyme.

"The immediate object of digestion is the formation of chyle, a matter destined for the reparation of the continual waste of the animal economy. The digestive organs contribute also in many other ways to nutrition.

If we judge of the importance of a function by the number and variety of its organs, digestion ought to be placed in the first rank; no other function of the animal economy presents such a complicated appa-

There always exists an evident relation between the sort of aliment proper for an animal and the disposition of its digestive organs. If, by their nature, the aliments are very different from the elements which compose the animal: if, for example, it is graminivorous, the dimensions of the apparatus will be more complicated, and more considerable; if, on the contrary, the animal feeds on ficsb, the digestive organs 298

will be fewer and more simple, as is seen in the carnivorous animals. Man, called to use equally animal and vegetable aliments, keeps a mean between the graminivorous and carnivorous animals, as to the disposition and complication of his digestive apparatus, without deserving, on that account, to be called omni-

We may represent the digestive apparatus as a long canal differently twisted upon itself, wide in certain points, narrow in others, susceptible of contracting or enlarging its dimensions, and into which a great quantity of fluids are poured by means of different ducts.

The canal is divided into many parts by anatomists;

The mouth.

The pharynx.

The asophagus.

The stomach.
The small intestines.

The great intestines.

The anus.

Two membranous layers form the sides of the diges tive canal in its whole length. The inner layer, which is intended to be in contact with the aliments, consists is intended to be in contact with the alments, consists of a nucous membrane, the appearance and structure of which vary in every one of the portions of the canal, so that it is not the same in the pharynx as in the mouth, nor is it in the stomach like what it is in the asophagus, &c. In the lips and the anus this membrane becomes confounded with the skin. The second brane becomes confounded with the skin. The second layer of the sides of the digestive canal is muscular; it is composed of two layers of fibres, one longitudinal, the other circular. The arrangement, the thickness, the nature of the fibres which enter into the composition of these strata are different, according as they are observed in the mouth, in the esophagus, or in the large intestine, &c. A great number of blood-vessels go to, or come from the digestive canal; but the abdominal portion of this canal receives a quantity incomparably greater than the superior parts. This presents only what are necessary for its nutrition, and the inconsiderable secretion, of which it is the seat; while the number and the volume of the vessels that belong to the abdominal portion show that it must be the to the abdominal portion show that it must be the agent of a considerable secretion. The chyliferous vessels arise exclusively from the small intestine.

vessels arise exclusively from the small intestine. As to the nerves, they are distributed to the digestive canal in an order inverse to that of the vessels; that is, the cephalic parts, cervical and pectoral, receive a great deal more than the abdominal portion, the stomach excepted, where the two nerves of the eighth pair terminate. The other parts of the canal scarcely receive any branch of the cerebral nerves. The only nerves that are observed, proceed from the subdiaphragmatic ganglions of the great sympathetic. We will see, farther on, the relation that exists between the mode of distribution of the nerves, and the functions of the superior and inferior portions of the digestive canal.

The bodies that pour fluids into the digestive canal,

1. The digestive mucous membrane.
2. Isolated follicles that are spread in great numbers in the whole length of this membrane.
3. The agglomerated follicles which are found at the isthmus of the throat, between the pillars of the velum of the palate, and sometimes at the junction of the asophagus and the stomach.

4. The mucous glands which exist in a greater or less number in the sides of the cheeks, in the roof of

less number in the sides of the cheeks, in the roof of the palate, around the esophagus.

5. The parotid, the submaxillary, and sublingual glands, which secrete the saliva of the mouth, the liver, and the panereas; the first of which pours the bile, the second the panereatic juice, by distinct canals, into the superior part of the small intestine, called duodenum.

All the digestive organs contained in the abdominal All the digestive organs contained in the abdominal cavity are immediately covered, more or less completely, by the serous membrane called the peritonæum. This membrane, by the manner in which it is disposed, and by its physical and vital properties, is very useful in the act of digestion, by preserving to the organs their respective relations, by favouring their changes of volume, by rendering easy the shding motions which they perform upon each other, and upon the adjoining parts. adjoining parts.

The surface of the mucous digestive membrane is

always lubrified by a glutinous adhesive matter, more or less abundant, than is seen in greatest quantity where there exist no follicles,—a circumstance which seems to indicate that these are not the only secreting seems to indicate that these are not the only secreting organs. A part of this matter, to which is given generally the name of mucus, continually evaporates, so that there exists habitually a certain quantity of vapours in all the points of the digestive canal. The chemical nature of this substance, as taken at the intestinal surface, is still very little known. It is transparent, with a light gray tint; it adheres to the membrane which forms it; its taste is salt, and its acidity is shown by the re-agents: its formation still continues some time after death. That which is formed in the mouth, in the pharvax, and in the essential surface. formed in the mouth, in the pharynx, and in the eso-phagus, goes into the stomach mixed with the saliva, and the fluids of the mucous glands, by movements of and the fluids of the mucous glands, by movements of deglutition, which succeed each other at near intervals. According to this detail, it would appear that the stomach ought to contain, after it has been some time empty of aliments, a considerable quantity of a mixture of mucus, of saliva, and follicular fluid. This observation is not proved, at least in the greatest number of individuals. However, in a number of persons, who are evidently in a particular state, there exist, in the morning, in the stomach, many ounces of this who are evidently in a particular state, there exist, in the morning, in the stomach, many ounces of this mixture. In certain cases it is foamy, slightly troubled, very little viscous, holding suspended some flakes of mucus; its taste is quite acid, not disagreeable, very sensible in the throat, acting upon the teeth, so as to diminish the polish of their surface, and rendering their motion upon each other more difficult. This liquid reddens paper stained with turnsol.

In the same individual, in other circumstances, and with the same appearances as to colour, transparence.

with the same appearances as to colour, transparency, with the same appearances as to colour, transparency, and consistency, the liquid of the stomach had no savour, nor any acid property; it is a little salt: the solution of potassa, as well as the nitric and sulphuric acids, produced in it no apparent change.

When we examine the dead bodies of persons killed by accident, the stomach not having received any aliments are desired.

ments nor drink for some time, this organ contains only a very few acid mucosities adhering to the coats of the stomach, port of which, in the pyloric portion of that viscus, appears reduced to chyme. It is, then, very probable, that the liquid which ought to be in the stomach is digested by this viscus as an alimentary substance, and that this is the reason why it does not accumulate there.

In animas the organization of which approaches to that of man, such as dogs and cats, there is no liquid found in the stomach after one, or many days of complete abstinence; there is seen only a small quantity of viscous mucosity adhering to the sides of the organ, towards its splenic extremity. This matter has the greatest analogy, both chemical and physical, with that which is found in the stomach of man. But, if we make these animals swallow a body which is not susceptible of being digested, as a pebble for example, there forms, after some time, in the cavity of the stomach, a certain quantity of an acid liquid mucus of a grayish colour, sensibly salt, which, in its composition, is nearly the same as that found sometimes in man. In animas the organization of which approaches to

This liquid, resulting from the mixture of the mucosities of the mouth, of the pharynx, of the œsophagus and the stomach, with the liquid secreted by the follicles of the same parts and with the saliva, called by physiologists the gastric juice, and to which they have attributed particular properties.

In the small intestine there is also formed a great quantity of mucous matter, which rests habitually attached to the sides of the intestine; it differs little from that of which we have spoken above; it is viscid, tough, and has a salt and acid savour; it is reneweld, tough, and has a salt and acid savour; it is renewed with great rapidity. If the mucous membrane of this intestine is laid bare, in a dog, and the layer of mucus absorbed by a sponge, it will appear again in a minute. This observation may be repeated as often as we please, until the intestine becomes inflamed by the contact of the air, and foreign bodies.

The mucus of the stomach penetrates into the cavity of the small intestine only under the form of a pulpous matter, grayish and opaque, which has all the appear-

ance of a particular chyme.

It is at the surface of this same portion of the digestive canal that the bile is delivered as well as the liquid

secreted by the pancreas. In animals, such as dogs, the flowing of these liquids takes place at intervals; that is, about twice in a minute, there is seen to spring from the orifice of the ductus choledochus, or biliary canal, a drop of bile, which immediately spreads itself uniformly in a sheet upon the surrounding parts, which are already impregnated with it; there is, also, constantly found a certain quantity of bile in the small stantly found a certain quantity of bile in the small intestine.

The flowing of the liquid formed by the pancreas takes place much in the same manner, but it is much slower; sometimes a quarter of an hour passes before a drop of this fluid springs from the orifice of the canal which pours it into the intestine

The different fluids deposited in the small intestine, which are, the chymous matter that comes from the stomach, the mucus, the follicular fluid, the bile, and the pancreatic liquid, all mix together; but, on account of its properties, and perhaps of its proportions, the bile predominates, and gives to the mixture its proper taste and colour. A great part of this mixture de-scends towards the large intestine, and passes into it; in this passage, it becomes more consistent, and the clear yellow colour which it had before becomes dark, and afterward greenish. There are, however, in this respect, strong individual differences.

In the large intestine, the mucous and follicular secretion appears less active than in the small intestine; the mixture of fluids which comes from the small intestine acquires in it more consistence; it contracts a fortid odour, analogous to that of ordinary excrements: it has, besides, the appearance of it, by its colour,

odour, &c.

The knowledge of these facts enables us to understand how a person who uses no aliments can continue to produce excrements, and how, in certain diseases, their quantity is very considerable, though the sick person has been long deprived of every alimentary substance, even of a liquid kind. Round the anus exist follicles, which secrete a fatty matter of a singu-

larly powerful odour.
We find gas almost always in the intestinal canal; We find gas almost always in the intestinal canal; the stomach contains only very little. The chemical nature of these gases has not yet been examined with care; but as the saliva that we swallow is always more or less impregnated with atmospheric air, it is probably the atmospheric air, more or less changed, which is found in the stomach. At least, it contains carbonic acid. The small intestine contains only a small quantity of gas; it is a mixture of carbonic acid, of azote and hydrogen. The large intestine contains carbonic acid, azote, and hydrogen, sometimes carburetted, sometimes sulphuretted. Twenty-three per cent. of this gas was found in the rectum of an individual, whose large intestine contained no excredividual, whose large intestine contained no excrement.

The muscular-layer of the digestive canal deserves to be remarked, in respect to the different modes of contraction it presents. The lips, the jaws, in most cases the tongue, the cheeks, are moved by a contraction, entirely like that of the muscles of locomotion. The roof of the palate, the pharynx, the œsophagus, and the tongue in certain particular circumstances, offer many motions, which have a manifest analogy with muscular contraction, but which are very different from it, because they take place without the participation of the will.

This does not imply that the motions of the parts just named are beyond the influence of the nerves; experience proves directly the contrary. If, for example, the nerves that come to the œsophagus are cut, this tube is deprived of its contractile faculty.

The muscles of the velum of the palate, those of the pharynx, the superior two-thirds of the œsophagus, scarcely contract like digestive organs, but when they act in permitting substances to pass from the mouth into the stomach. The inferior third of the æsophagus presents a phenomenon which is important to be known: this is an alternate motion of contraction and relaxation which exists in a constant manner. The contraction commences at the union of the superior two-thirds of the canal with the inferior third; it is continued, with a certain rapidity, to the insertion of the esophagus into the stomach: when it is once produced, it continues for a time, which is variable, the duced, it continues for a time, which is variable; its mean duration is, at least, thirty seconds. Being so contracted in its inferior third, the assophagus is hard

and elastic, like a cord strongly stretched. The re-laxation which succeeds the contraction happens all at once, and simultaneously in all the contracted fibres;

The first mouthfuls of food swallowed are easily in certain cases because it and the contracted fibres; in certain cases, however, it seems to take place from the superior to the inferior fibres. In the state of re-laxation, the esophagus presents a remarkable flac-cidity, which makes a singular contrast with its state of contraction.

This motion of the esophagus depends on the nerves of the eighth pair. When these nerves of an animal are cut, the esophagus no longer contracts, but neither is it in the relaxed state that we have described; its fibres being separated from nervous influence, shorten themselves with a certain force, and the canal is found in an intermediate state between contraction and relaxaan intermediate state between contraction and relaxa-tion. The vacuity, or distention of the stomach, has an influence upon the duration and intensity of the

contraction of the esophagus.

From the inferior extremity of the stomach to the end of the intestine rectum, the intestinal canal presents a mode of contraction which differs, in almost sents a mode of contraction which differs, in almost every respect, from the contraction of the sub-diaphragmatic portion of the canal. This contraction always takes place slowly, and in an irregular manner; sometimes an hour passes before any trace of it can be perceived; at other times many intestinal portions contract at once. It appears to be very little influenced by the nervous system: for example,—it continues in the stomach after the section of the nerves of the eighth pair; it becomes more active by the weakness of animals, it becomes more active by the weakness of animals, and even by their death; in some, by this cause it becomes considerably accelerated; it continues though the intestinal canal is entirely separated from the body. The pyloric portion of the stomach, the small intes-tine, are the points of the intestinal canal where it is presented oftenest, and most constantly. This motion, which arises from the successive or simultaneous con-traction of the longitudinal or circular fibres of the intestinal canal, has been differently denominated by authors: some have named it vermicular, others peris-taltic, others again, sensible organic contractility, &c. Whatever it is, the will appears to exert no sensible influence upon it.

Influence upon it.

The muscles of the anus contract voluntarily.

The supra-diaphragmatic portion of the digestive canal is not susceptible of undergoing any considerable dilatation; we may easily see, by its structure, and the mode of contraction of its muscular coat, that it is not intended to allow the aliments to remain in its cavity, but that it is rather formed to carry these substances from the mouth into the stomach: this last organ, and the large intestine, are evidently prepared to undergo a very great distention; substances, also, which are introduced into the alimentary canal, accumulate, and

remain for a time, more or less, in their interior.

The diaphragm, and the abdominal muscles, produce a sort of perpetual agitation of the digestive or-gans contained in the abdominal cavity; they exert, upon them, a continual pressure, which becomes sometimes very considerable.

The digestive actions which by their union consti-

tute digestion, are-

1. The apprehension of aliments.

2. Mastication.

3. Insalivation. Deglutitiog.

The action of the stomach.

The action of the small intestines. The action of the large intestines. The expulsion of the focal matter.

All the digestive actions do not equally contribute to the production of chyle; the action of the stomach and that of the small intestines, are alone absolutely

The digestion of solid food requires generally the eight digestive actions; that of drinks is much more simple; it comprehends only apprehension, deglutition, the action of the stomach, and that of the small intestine.

The mastication and deglutition of the food being effected, we have now to notice the action of the sto-mach on the aliment: chemical alterations will now present themselves to our examination. In the stomach the food is transformed into a matter proper to

animals, which is named chyme.

Before showing the changes that the food undergoes in the stomach, it is necessary to know the phenomena 300

local and general elects that result from it.

The first mouthfuls of food swallowed are easily lodged in the stomach. This organ is not much compressed by the surrounding viscera; its sides separate easily, and give way to the force which presses the alimentary bole; but its distention becomes more difficult in presention as new food agricus for this is account. in proportion as new food arrives, for this is accompanied by the pressing together of the abdominal viscera, and the extension of the sides of the abdomen. This accumulation takes place particularly towards the right extremity and the middle part: the pyloric half gives way with more difficulty.

While the stomach is distended, its form, its rela-

While the stomach is distended, its form, its relations, and even its positions, undergo alterations: in place of being flattened on its aspects, of occupying only the epigastrium and a part of the left hypochondrium, it assumes a round form; its great cul de sac is thrust into this hypochondrium, and fills it almost completely; the greater curvature descends towards the umbilicus, particularly on the left side; the pylorus, alone, fixed by a fold of the peritonæum, preserves its motion and its relations with the surrounding parts. On account of the resistance that the vertebral column presents behind, the posterior surface of the stomach cannot distend itself on that side: for that reason this viscus is wholly carried forward; and as the pylorus and the œsophagus cannot be displaced in this direction, it makes a motion of rotation, by which its great curve is directed a little forward; its posterior aspect inclines downwards, and its superior upwards.

Though it undergoes these changes of position and relation, it, nevertheless, preserves the recurved conoid form which is proper to it. This effect depends on the manner in which the three tunics contribute to its dilatation. The two plates of the serous membrane separate and give place to the stomach. The muscular layer suffers a real distention; its fibres are prolonged, but so as to preserve the particular form of the stomach. Lastly, the mucous membrane gives way, particularly in the points where the folds are multiplied. It will be noticed that these are found particularly along the larger curve, as well as at the splenic extremity.

The dilatation of the stomach alone produces very important changes in the abdomen. The total volume of this cavity augments; the belly juts out; the abdominal viscera are compressed with greater force; often the necessity of passing urine, or faces, is felt. Though it undergoes these changes of position and

dominal viscera are compressed with greater force; often the necessity of passing urine, or faces, is felt. The diaphragm is pressed towards the breast, it descends with some difficulty; thence the motions of respiration, and the phenomena which depend on it, are more incommoded, such as speech, singing, &c. In certain cases, the dilatation of the stomach may be carried so far that the sides of the abdomen are

painfully distended, and respiration becomes difficult.

To produce such effects, the contraction of the esophagus, which presses the food in the stomach, must be very energetic. We have remarked above the considerable thickness of the muscular layer of this canal, and the great number of nerves which go to it; nothing less than this disposition is necessary to account for the force with which the food distends the stomach. For more certainty, the finger has only to be introduced into the assophagus of an animal by the cardiac ori-fice, and the force of the contraction will be found

But if the food exerts so marked an influence upon the sides of the stomach and the abdomen, they ought the sides of the stomach and the abdomen, they ought themselves to suffer a proportionate reaction, and tend to escape by the two openings of the stomach. Why does this effect not take place? It is generally said that the cardia and pylorus shut; but this pheno-menon has not been submitted to any particular re-searches. Here is what Dr. Magendie's experiments

have produced in this respect.

The alternate motion of the œsophagus prevents the return of the food into this cavity. The more the sto-mach is distended, contraction becomes the more in-tense and prolonged, and the relaxation of shorter duration. Its contraction generally coincides with the instant of inspiration, when the stomach is most forci-bly compressed. Its relaxation ordinarily happens at the instant of expiration. the instant of expiration.

We may have an idea of this mechanism by laying bare the stomach of a dog, and endeavouring to make the food pass into the œsophagus by compressing the stomach with both hands. It will be nearly impossible

to succeed, whatever force is used, if it is done at the instant when the assophagus is contracted: but the passage will take place, in a certain degree, of itself; if the stomach is compressed at the instant of relaxa-

The resistance that the pylorus presents to the passage of the aliments is of another kind. In living animals, whether the stomach is empty or full, this opening is habitually shut, by the constriction of its fibrous ring, and the contraction of its circular fibres. There is frequently seen another constriction in the stomach, at the distance of one or two inches, which appears intended to prevent the food from reaching the pylorus; we perceive, also, irregular and peristaltic contractions, which commence at the duodenum, and are continued into the pyloric portion of the stomach, the effect of which is to press the food towards the splenic part. Besides, should the pylorus not be naturally shut, the food would have little tendency to enter it for it contracted and the pylorus and place where it, for it only endeavours to escape into a place where the pressure is less; and this would be equally great in

the pressure is less; and this would be equally great in the small intestine as in the stomach, since it is nearly equally distributed over all the abdominal cavity.

Among the number of phenomena produced by the food in the stomach, there are several, the existence of which, though generally admitted, do not appear sufficiently demonstrated; such is the diminution of the volume of the spleen, and that of the blood-vessels of the liver, or the omeata, &c.; such is also a motion of the stomach, which should preside over the reception of the food, distribute it equally by exerting upon it a gentle pressure, so that its dilatation, far from being it a gentle pressure, so that its dilatation, far from being a passive phenomenon, must be essentially active. Dr.

a passive phenomenon, must be essentially active. Dr. Magendie has frequently opened animals the stomachs of which were filled with food; he has examined the bodies of executed persons, a short time after death, and has seen nothing favourable to these assertions.

The accumulation of food in the stomach is accompanied by many sensations, of which it is necessary to take account:—at first, it is an agreeable feeling, or the pleasure of a want satisfied. Hunger is appeased by degrees; the general weakness that accompanied it is replaced by an active state, and a feeling of new force. If the introduction of food is continued, we experience a sensation of fulness and satiety which indicates that a sensation of fulness and satiety which indicates that the stomach is sufficiently replenished; and if, contrary to this instinctive information, we still persist to make use of food, disgust and nausea soon arrive, and they are very soon followed by vomiting. These different impressions must not be attributed to the volume of the aliments alone. Every thing being equal in other respects, food very nutritive occasions, more promptly, the feeling of satiety. A substance which is not very nourishing does not easily calm hunger, though it is taken in great quantity.

is not very nourishing does not easily calm hunger, though it is taken in great quantity.

The mucous membrane of the stomach, then, is endowed with considerable sensibility, since it distinguishes the nature of substances which come in contact with it. This property is very strongly marked if an irritating poisonous substance is swallowed: intolerable pain is then felt. We also know that the stomach is sensible to the temperature of food.

We cannot doubt that the presence of the atiments

We cannot doubt that the presence of the aliments of the stomach causes a great excitement, from the redness of the mucous membrane, from the quantity of fluid it secretes, and the volume of vessels directed there; but this is favourable to chymification. This excitement of the stomach influences the general state of the functions.

The time that the aliments remain in the stomach is considerable, generally several hours; it is during this stay that they are transformed into chyme.

Changes of the aliments in the stomach:

It is more than an hour before the food suffers any

apparent change in the stomach, more than what re-sults from the perspiratory and mucous fluids with which they are mixed, and which are continually re-

The stomach is uniformly distended during this time; but the whole extent of the pyloric portion afterward contracts, particularly that nearest the splenic portion, into which the food is pressed. Afterward, there is nothing found in the pyloric portion but chyme, mixed with a small quantity of unchanged

A. There are as many sorts of chyme as there are different sorts of food, if we judge by the colour, consistence, appearance, &c.; as we may easily ascertain, by giving different simple alimentary substances to dogs to eat, and killing them during the operation of digestion. He frequently found the same result in man, in the dead bodies of criminals, or persons dead by accident. by accident.

by accident.

B. Animal substances are generally more easily and completely changed than vegetable substances. It frequently happens that these last traverse the whole intestinal canal without changing their apparent properties. He has frequently seen in the rectum, and in the small intestine, the vegetables which are used in soup, spinage, sorrel, &c., which had preserved the most part of their properties: their colour alone appeared sensibly changed by the contact of the bile.

Chyme is formed particularly in the pyloric portion. The food appears to be introduced slowly into it, and during the time they remain they undergo transformation. The Doctor believes, however, that he has observed frequently chymous matter at the surface of the mass of aliments which fill the splenic portion; but the aliments in general preserve their properties in

but the aliments in general preserve their properties in

this part of the stomach.

It would be difficult to tell why the pyloric portion is better adapted to the formation of chyme than the rest better adapted to the formation of chyme than the rest of the stomach; perhaps the great number of follicles that are seen in it modify the quantity or the nature of the fluid that is there secreted. The transformation of alimentary substances into chyme takes place generally from the superficies to the centre. On the surface of portions of food swallowed, there is formed a soft layer easy to be detached. The substances seem to be attacked and corroded by a reagent capable of dissolving them. The white of a hard egg, for instance, becomes in a little time as if plunged in vinegar, or in a solution of potassa. or in a solution of potassa.

C. Whatever is the alimentary substance employed,

C. Whatever is the alimentary substance employed, the chyme has always a sharp odour and taste, and reddens paper coloured with turnsol.

D. There is only a small quantity of gas found in the stomach during the formation of chyme; sometimes there exists none. Generally, it forms a small bubble at the superior part of the splenic portion. Once only in the body of a criminal a short time after death he gathered with proper precautions a quantity sufficient to be analyzed. Chevreuil found it composed of: posed of:

Oxygen, 11.00
Carbonit acid, 14.00
Pure hydrogen, 3.55
Azote, 71.45

Total,.....100.00

There is rarely any gas found in the stomach of a dog. We cannot then believe, with Professor Chaus-sier, that we swallow a bubble of air at every motion of deglutition, which is pressed into the stomach by the alimentary bole. Were it so, there ought to be found a considerable quantity of air in this organ after

found a considerable quantity of air in this organ after a meal: now the contrary is to be seen.

E. There is never a great quantity of chyme accumulated in the pyloric portion: the most that the Doctor ever saw in it was scarcely equal in volume to two or three ounces of water. The contraction of the stomach appears to have an influence upon the production of chyme. The following is what he observed in this respect. After having been some time immoveable, the extremity of the duodenum contracts, the pylorus and the pyloric portion contract also; this motion presses the chyme towards the splenic portion; but it afterward presses it in a contrary direction, that is, after being distended, and having permitted the chyme-to enter again into its cavity, the pyloric portion contracts from left to right, and directs the chyme towards the duodenum, which immediately passes the pylorus and enters the intestine.

chyme, mixed with a small quantity of unchanged food.

The best authors have agreed to consider the chyme as a homogeneous substance, pultaceous, grayish, of times. When the stomach contains much food, this

motion is limited to the parts of the organ nearest the pylorus; but in proportion as it becomes empty, the motion extends farther, and is seen even in the splenic portion when the stomach is almost entirely empty. It becomes generally more strong about the end of chymification. Some persons have a distinct feeling of it at this moment.

The pylorus has been made to play a very important part in the passage of the chyme from the stomach to the intestine. It judges, they say, of the chymification of the food; it opens to those that have the required qualities, and shuts against those that have not. However, as we daily observe substances not digestible traverse it easily, such as stones of cherries, it is added, that becoming accustomed to a substance not chymified, which presents itself repeatedly, it at last opens a passage. These considerations, consecrated in a certain degree by the word pylorus, a porter, may please the fancy, but they are purely hypothetical.

F. All the alimentary substances are not transformed into chyme with the same promptitude.

Generally the fat substances, the tendons, the cartilages, the concrete albumen, the mucilaginous and sweet vegetables, resist more the action of the stomach qualities, and shuts against those that have not.

sweet vegetables, resist more the action of the stomach than the caseous, fibrinous, and glutinous substances. Even some substances appear refractory: such as the bones, the epidermis of fruits, their stones, and whole

In determining the digestibility of food, the volume of the portions swallowed ought to be taken into account. The largest pieces, of whatever nature, remain longest in the stomach; on the contrary, a substance which is not digestible, if it is very small, such

as grape stones, does not rest in the stomach, but passes quickly with the chyme into the intestine.

In respect of the facility and quickness of the formation of chyme, it is different in every different individual. It is evident, after what has been said, that to fix the necessary time for the chymification of all the food contained in the stomach, we ought to take into account their quantity, their chemical nature, the man-ner in which the mastication acts upon them, and the individual disposition. However, in four or five hours after an ordinary meal, the transformation of the whole

The nature of the chemical changes that the food undergoes in the stomach is unknown. It is not because there have been no attempts at different periods cause there have been no attempts at different periods to give explanations of them more or less plausible. The ancient philosophers said that the food became putrified in the stomach; Hippocrates attributed the digestive process to coction; Galen assigned the stomach attractive, retentive, concoctive, expulsive faculties, and by their help he attempted to explain digestion. The doctrine of Galen reigned in the schools until the middle of the seventeenth century, when it was attacked and overturned by the fermenting chemists who established in the stomach an effernescence. mists, who established in the stomach an effer a particular fermentation, by means of which the food

a particular fermentation, by means of which the food was macerated, dissolved, precipitated, &c.

This system was not long in repute; it was replaced by ideas much less reasonable. Digestion was supposed to be only a trituration, a bruising performed by the stomach; an Innumerable quantity of little worms was supposed to attack and divide the food. Boerhaave thought he had found the truth, by combining the different opinions that had reigned before him. Haller did not follow the ideas of his master; he considered digestion a simple maceration. He knew that vegetable and animal matters, plunged into water, are soon covered with a soft homogeneous layer; he besoon covered with a soft homogeneous layer; he be-lieved that the food underwent a like change, by ma-cerating in the saliva and fluids secreted by the

Reaumur and Spallanzani made experiments on animals, and demonstrated the falsity of the ancient systems; they showed that food, contained in hollow metallic balls pierced with small holes, was digested the same as if it was free in the cavity of the stomach. They proved that the stomach contains a particular fluid which they call greaters in the and that this fluid. They proved that the stomach contains a particular fluid, which they call gastric juice, and that this fluid was the principal agent of digestion; but they much exaggerated its properties, and they were mistaken when they thought to have explained digestion in considering it as a solution: because, in not explaining this solution, they did not explain the changes of food in the stomach. in the stomach.

In the formation of chyme, it is necessary to consider, 1st, The circumstances in which the food is found in the stomach. 2dly, The chemical nature of it.

The circumstances affecting the food in the stomach,

The circumstances affecting the food in the stomach, during its stay there, are not numerous: 1st, it suffers a pressure more or less strong, either from the sides of the abdomen, or from those of the stomach; 2dly, the whole is entirely moved by the motions of respiration; 3dly, it is exposed to a temperature of thirty to thirty-two degrees of Reaumur; 4thly, it is exposed to the action of the saliva, of the mucosities proceeding from the mouth and the esophagus, as well as the fluid secreted by the mucous membrane of the stomach.

It will be remembered that this fluid is slightly viscous that it contains much water, mucus, salts, with a

cous, that it contains much water, mucus, salts, with a base of soda and ammonia, and lactic acid of Ber-

With regard to the nature of the food, we have already seen how variable it is, since all the immediate principles, animal or vegetable, may be carried into the stomach, in different forms and proportions, and serve usefully in the formation of chyme. Now, making allowance for the nature of the food, and the circumstances in which it is placed in the stomach, shall we be able to account for the known phenomena of the formation of chyme? The temperature of thirty to thirty-two degrees, R. = 100 to 104 F.; the pressure, and the tossing that the food sustains, cannot be considered as the principal cause of its transformation into chyme; it is probable that they only co-operate in this; the action of the saliva and that of the fluid secreted in the stomach remain; but after the known composition of the saliva, it is hardly possible that it can attack and change the nature of the food; at most, it can only serve to divide, to imbibe it in such a manner as to separate its particles: it must then be the action of the fluid formed by the internal membrane of the stomach. mach. It appears certain that this fluid, in acting chemically upon the alimentary substances, dissolves them from the surface towards the centre.

To produce a palpable proof of it, with this fluid of

To produce a palpable proof of it, with this fluid of which we speak, there have been attempts made to produce what is called in physiology, artificial digestions, that is, after having macerated food, it is mixed with gastric juice, and then exposed in a tube, or any other vase, to a temperature equal to that of the stomach. Spallanzani advanced, that these digestions succeeded, and that the food was reduced to chyme; but, according to the researches of de Montegre, it appears that they are not; and that, on the contrary, the substances employed undergo no alteration analogous to chymification; this is agreeable to experiments made by Reaumur. But because the gastric juice does not dissolve the food when put with it into a tube, we ought not to conclude that the same fluid cannot dissolve the food when it is introduced into the stomach; the circumstances are indeed far from being the same: in the stomach, the temperature is constant, the food is pressed and agitated, and the saliva and the same; in the stopach, the temperature is constant, the food is pressed and agitated, and the saliva and gastric juice are constantly renewed; as soon as the chyme is formed, it is carried away and pressed in the duodenum. Nothing of this takes place in the tube or vase which contains the food mixed with gastric juice; therefore, the want of success in artificial digestions, proves nothing which tends to explain the footmarked of chymne.

formation of chyme.

But how does it happen that the same fluid can act in a manner similar upon the great variety of alimentary substances, animal and vegetable? The acidity which characterizes it, though fit to dissolve certain

matters, as albumen, for example, would not be suita-ble for dissolving fat.

To this it may be answered, that nothing proves the To this it may be answered, that housing proves the gastric juice to continue always the same; the small number of analyses that have been made of it demonstrate, on the contrary, that it presents considerable varieties in its properties. The contact of different sorts of food upon the mucous membrane of the stomach, may possibly influence its composition; it is at least contain, that this varies in the different animals. least certain, that this varies in the different animals. For example, that of man is incapable of acting on bones; it is well known that the dog digests these substances perfectly.

Generally speaking, the action by which the chyme is formed prevents the reaction of the constituent elements of the food upon each other; but this effort takes place only in good digestions; in bad digestion,

fermentation, and even putrefaction may take place: this may be suspected by the great quantity of inodor-ous gases that are developed in certain cases, and the sulphuretted hydrogen which is disengaged in others.

The nerves of the eighth pair have long been considered to direct the act of chymification: in fact, if these nerves are cut, or tied in the neck, the matters these nerves are cut, or fied in the neck, the matters introduced into the stomach undergo no alteration. But the consequence, (says Dr. Magendie) that is deduced from this fact, does not appear to me to be rigorous. Is not the effect produced upon the stomach by the injury done to respiration, confounded here with the direct influence of the section of the nerves of the eighth pair upon this organ? I am inclined to believe it: for, as I have many times done, if the two eighth pairs be cut in the breast below the branches which go to the lungs, the food which is introduced afterward into the stomach is transformed into chyme, and ultimately furnishes an abundant chyle.

Some persons imagine that electricity may have an influence in the production of chyme, and that the nerves we mention may be the conductors: there is no established fact to justify this conjecture. The most probable use of the nerves of the eighth pair is, to esta-blish intimate relations between the stomach and the brain, to give notice whether any noxious substances have entered along with the food, and whether they

are capable of being digested.

In a strong person, the operation of the formation of chyme takes place without his knowledge; it is merely perceived that the sensation of fulness, and the difficulty of respiration produced by the distention of the stomach, disappear by degrees; but frequently, with people of a delicate temperament, digestion is accompanied with feebleness in the action of the senses, with a general coldness, and slight shiverings; the activity of the mind diminishes, and seems to become drowsy, and there is a disposition to sleep. The vital powers are then said to be concentrated in the organ that acts, and to abandon for an instant the others. To those general effects are joined the production of the gas that escapes by the mouth, a feeling of weight, of heat, of giddiness, and sometimes of burning, followed by an analogous sensation along the esophagus, &c. These effects are felt particularly towards the end of the effects are felt particularly towards the end of the chymification. It does not appear, however, that these laborious digestions are much less beneficial than the

From the stomach, the food is received into the small intestine, which is the longest portion of the diestive canal; it establishes a communication between the stomach and the large intestine. Not being sus-ceptible of much distention, it is twisted a great many times upon itself, being much longer than the place in which it is contained. It is fixed to the vertebral column by a fold of the peritonsum, which limits, yet aids its motions; its longitudinal and circular fibres are not separated as in the stomach; its mucous membrane, which presents many villi, and a-great number of mucous follicles, forms irregular circular folds, the number of which are greater in proportion as the intes-tine is examined nearer the pyloric orifice: these folds

are called valvula conniventes.

The small intestine receives many blood-vessels; its nerves come from the ganglions of the great sympa-thetic. At its internal surface, the numerous orifices

of the chyliferous vessels open.

This intestine is divided into three parts, called the duodenum, jejunum, and ileum. The mucous mem-brane of the small intestine, like that of the stomach, secretes abundance of mucus; viscous, thready, of a salt taste, and reddens strongly turnsol paper; all which properties are also in the liquid secreted by the sto-mach. Haller gave this fluid the name of intestinal juice; the quantity that is formed in twenty-four hours he estimated at eight pounds.

Not far from the gastric extremity of this intestine is the common orifice of the biliary and pancreatic canals, by which the fluid secreted by the liver and the pancreas flow into the intestinal cavity. If the formation of the chyme is still a mystery, the nature of the phenomena that take place in the small intestine are little better known.

In the experiments which have been made on dogs and rabbits, the chyme is seen to pass from the stomach into the duodenum. The phenomena are these. At intervals, more or less distant, a contractile motion

commences towards the middle of the duodenum; it is propagated rapidly to the site of the pylorus: this ring contracts itself, as also the pyloric part of the stomach; by this motion, the matters contained in the duodenum are pressed back towards the pylorus, where they are stopped by the valve, and those that are found in the pyloric part, are partly pressed towards the splenic part; but this motion, directed from the intestine towards the stomach, is very soon replaced by another in a contrary direction, that is, which propagates itself from the stomach towards the duodenum, the result of which is to make a considerable quantity the result of which is to-make a considerable quantity of chyme pass the pylorus.

This fact seems to indicate that the valve of the

pyiorus serves as much to prevent the matters con-tained in the small intestine from flowing back into the

tained in the small intestine from flowing back into the stomach, as to-retain the chyme and the food in the cavity of this organ.

The motion that we have described, is generally repeated many times following, and modified as to the rapidity, the intensity of the contraction, &c.; it then ceases to begin again after some time. It is not very marked in the first moments of the formation of the chyme; the extremity only of the pyloric part participates in it. It augments in proportion as the stomach pates in it. It augments in proportion as the stomach becomes empty; and, towards the end of chymifica-tion, it often takes place over the whole stomach. It is not suspended by the section of the nerves of the

eighth pair.

Thus the entrance of chyme into the small intestine is not perpetual. According as it is repeated, the chyme accumulates in the first portion of the intestine, it distends its sides a little, and presses into the intervals of the valves; its presence very soon excites the organ to contract, and by this means one part advances into the intestine; the other remains attached to the surface of its membrane, and afterward takes the same The same phenomenon continues down to the large intestine; but, as the duodenum receives new portions of the chyme, it happens at last that the small intestine is filled in its whole length with this matter. It is observed only to be much less abundant near the cocum than at the pyloric extremity.

The motion that determines the progress of the

chyme through the small intestine, has a great analogy with that of the pylorus: it is irregular, returns at periods which are variable, is sometimes in one direction, sometimes in another, takes place sometimes in many parts at once; it is always slow, more or less; it causes relative changes among the intestinal circumvolutions. It is beyond the influence of the will.

We should form a false idea of it were we merely to examine the intestine of an animal recently dead;

it has then a much greater activity than during life Nevertheless, in weak digestions it appears to acquire

more than ordinary energy and velocity.

In whatever manner this motion takes place, the chyme appears to move very slowly in the small intestine: the numerous valves that it contains, the multitude of asperities that cover the mucous membrane, the many bendings of the canal, are so many circumstances that ought to contribute to retard its progress, but which could to force it mixture with the floids. but which ought to favour its mixture with the fluids contained in the intestine, and the production of the chyle which results from it.

Changes that the chyme undergoes in the small in-testine.—It is only about the height of the orifice of the choledochus and pancreatic canal that the chyme begins to change its properties. Before this, it preserves its colour, its semi-fluid consistence, its sharp odour, its slightly acid savour; but, in mixing with the bile and the pancreatic juice, it assumes new qualities: its colour becomes yellowish, its taste bitter, and its sharp odour diminishes much. If it proceeds from animal or vegetable matters, which contained grease or oil, irregular filaments are seen to form here and there on, irregular hiaments are seen to form here and there upon its surface; they are sometimes flat, at other times rounded, attach themselves quickly to the surface of the valve, and appear to consist of crude chyle. This matter is not seen when the chyme proceeds from matter that contained no fat; it is a grayish layer, more or less thick, which adheres to the mucous membrane, and appears to contain the closester. brane, and appears to contain the elements of chyle. The same phenomena are observed in the two superior thirds of the small intestine: but in the inferior third, the chymous matter is more consistent; its yellow co-lour becomes more deep; it ends sometimes by becoming of a greenish brown, which pierces through the intestinal parietes, and gives an appearance to the ileum, distinct from that of the duodenum and jejunum. When it is examined near the cocum, there are few or no whitish chylous strise seen; it seems, in this place, to be only the remainder of the matter which has served in the formation of the chyle.

After what has been said above, upon the varieties that the chyme presents, we may understand that the changes it undergoes in the small intestine are variable according to its properties; in fact, the phenomena of digestion in the small intestine, vary according to the nature of the food. The chyme, however, preserves its acid property; and if it contains small quantities of food or other bodies that have resisted the action of the stomach, they traverse the small intestine without undergoing any alteration. The same phenomena appear when the same substances have been used. Dr. Magendie has ascertained this fact upon the bodies of Magendie has ascertained this fact upon the bodies of two criminals, who, two hours before death, had taken an ordinary meal, in which they had eaten the same food nearly in equal quantity; the matters contained in the stomach, the chyme in the pyloric portion and in the small intestine, appeared to him exactly the same as to consistence, colour, taste, odour, &c.

There is generally gas found in the small intestine during the formation of chyle. Drs. Magendie and Chevreuil have made experiments upon the bodies of criminals opened shortly after death, and who, being young and vigorous, presented the most favourable conditions for such researches. In a subject of twenty-four years, who had eaten, two hours before his death,

four years, who had eaten, two hours before his death, bread, and some Swiss cheese, and drank water red-dened with wine, they found in the small intestine:

Carbonic acid	24.39
Pure hydrogen	55.53
Total1	

In a second subject, aged twenty-three years, who had eaten of the same food at the same hour, and whose punishment took place at the same time:

Carbonic acid 4	
Pure hydrogen 5	
Azote	8.85
Total10	00.00

In a third experiment, made upon a young man of twenty-eight years, who, four hours before death had eaten bread, beef, lentiles, and drank red wine, they found in the same intestine:

Oxygen	0.00
Carbonic acid	25.00
Pure hydrogen	8.40
Azote	
	100000000

They never observed any other gases in the small intestine. These gases might have different origins. They might possibly come from the stomach with the chyme; or they were, perhaps, secreted by the intes-tinal mucous membrane; they might arise from the reciprocal action of the matters contained in the intestine; or perhaps they might come from all these sources

However, the stomach contains oxygen, and very little hydrogen, while they have almost always found much hydrogen in the small intestine, and never any oxygen. Besides, it is a daily observation, that the little gas that the stomach contains is generally passed by the mouth towards the end of chymification, probably, because at this instant it can more easily ad-

vance into the esophagus.

The probability of the formation of gases by the secretion of the mucous membrane could not be at all admissible, except for carbonic acid, which seems to be formed in this manner in respiration. With regard to the action of matters contained in the intestine, Dr. Magendie says he has many times seen the chymous matter let bubbles of gas escape very rapidly. This took place from the orifice of the ductus choledochus to the commencement of the iloum; there was no trace of it perceived in this last intestine, nor in the superior part of the duodenum, nor the stomach. He made this observation again upon the body of a criminal four hours after death; it presented no traces of putre-

The alteration which chyme undergoes in the sma'l intestine is unknown; it is easily seen to be the result of the action of the bile, of the pancreatic juice, and of the fluid secreted by the mucous membrane, upon the chyme. But what is the play of the affinities in this real chemical operation, and why is the chyle precipitated against the surface of the valvula conniventes, while the rest remains in the intestine to be after-ward expelled? This is completely unknown.

We have learned something more of the time that is necessary for this alteration of the chyme. The phenomenon does not take place quickly: in animals, it often happens that we do not find any chyle formed

three or four hours after the meal.

After what has been said, we see that in the small intestine, the chyme is divided into two parts: the one which attaches itself to the sides, and which is the chyle still impure; the other the true refuse, which is destined to be thrown into the large intestine, and afterward entirely carried out of the body.

The manner in which drinks accumulate in the sto-mach differs little from that of the aliments; it is generally quicker, more equal, and more easy; probably because the liquids spread, and distend the stomach more uniformly. In the same manner as the food, they occupy more particularly its left and middle portion; the pyloric, or right extremity, contains always much less

The distention of the stomach must not, however, be carried to a great degree, for the liquid would be expelled by vomiting. This frequently happens to persons that swallow a great quantity of drink quickly. When we wish to excite vomiting in persons who have taken an emetic, one of the best means is to make them drink a number of glasses of liquid quickly. The presence of drinks in the stomach produces

The presence of drinks in the stomach produces local phenomena like those which take place from the accumulation of the aliments; the same changes in the form and position of the organ, the same distention of the abdomen, the same contraction of the pylorus and

the osophagus, &c.

The general phenomena are different from those produced by the aliments: this depends on the action of the liquids upon the sides of the stomach, and the quickness with which they are carried into the

Potations, in passing rapidly through the mouth and the œsophagus, preserve more than the food their proper temperature until they arrive in the stomach. We therefore prefer them to those, when we wish to experience in this organ a feeling of heat or of cold: hence arises the preference that we give to hot drinks in winter, and cold drinks in summer.

Every one knows that the drinks remain a much shorter time in the stomach than the aliments; but the manner of their passage out of this viscus is still very ittle known. It is generally supposed that they traverse the pylorus and pass into the small intestine, where they are absorbed with the chyle; nevertheless a ligature applied round the pylorus in such a manner as to hinder it from penetrating into the duodenum, does not much retard its disappearance from the cavity of the stomach.

Alteration of drinks in the stomach.—Fluids, in respect of the alterations that they prove in the stomach, may be divided into two classes: the one sort do not form any chyme, and the other are chymified

wholly or in part.

To the first class belong pure water, alkohol, suffi-ciently weak to be considered as a drink, the vegetable acids, &c. During its stay in the stomach, water assumes an equilibrium of temperature with the sides of this viscus: it mixes at the same time with mucus, the gastric juice, and the saliva which are found in it; the gastric juice, and the sanva which are found in it; it becomes muddy, and afterward disappears slowly without suffering any other transformation. One part passes into the small intestine; the other appears to be directly absorbed. There remains after its disappearance a certain quantity of mucus, which is very soon reduced to chyme like the aliments. By observation we know that water deprived of atmospheric air, a distilled water, or water charged with a great quantity

Alkohol acts quite in a different manner. We know the impression of burning heat that it causes at first in its passage through the mouth, the pharynx, the eso-phagus; and that which it excites when it enters the stomach: the effects of this action determine the contraction of this organ, irritate the mucous membrane, and augment the secretion of which it is the seat; it coagulates at the same time all the albuminous parts with which it is in contact; and as the different liquids in the stomach contain a considerable proportion of this matter, it happens that a short time after alkohol has been swallowed, there is in this viscus a certain quantity of concrete albumen. The mucus undergoes a modification analogous to that of the albumen; it becomes hard, forms irregular elastic filaments, which

preserve a certain transparency.

In producing these phenomena, the alkohol mixes with the water that the saliva and the gastric juice contain; probably it dissolves a part of the elements that enter into their composition, so that it ought to be much weakened by its stay in the stomach. It disappears very quickly; its general effects are also very rapid, and drunkenness or death follow almost immediately the introduction of too great a quantity of alkodiately the introduction of too great a quantity of alko-

hol into the stomach.

The matters coagulated by the action of the alkohol are, after its disappearance, digested like solid ali-

Among the drinks that are reduced to chyme, some

are reduced in part and some wholly.

Oil is in this last case; it is transformed, in the pyloric part, into a matter analogous in appearance with that which is drawn from the purification of oils by sulphuric acid; this matter is evidently the chyme of oil. On account of this transformation, oil is perhaps the liquid that remains longest in the stomach.

Every one knows that milk curdles soon after it is swallowed; this curd then becomes a solid aliment, which is digested in the ordinary manner. Whey only

can be considered as drink

The greatest number of drinks that we use are formed of water, or of alkohol, in which are in suspension or dissolution, immediate animal or vegetable principles, such as gelatine, albumen, osmazome, sugar, gum, fecula, colouring or astringent matters, &c. These drinks contain salts of lime, of soda, of potassa, &c.

The result of several experiments that have been made upon animals, and some observations that have been made on man, is, that there is a separation of the water and the alkohol in the stomach from the matters that these liquids hold in suspension or solution. These matters remain in the stomach, where they are transformed into charge like the aliments: while the transformed into chyme, like the aliments; while the liquids with which they were united are absorbed, or pass into the small intestine; lastly, they are conducted, as we have just now seen, in treating of water and

Salts that are in solution in water do not abandon Salts that are in solution in water do not abandon this liquid, and are absorbed with it. Red wine, for example, becomes muddy at first by its mixture with juices that are formed in, or carried into the stomach; it very soon coagulates the albumen of these fluids, and becomes flaky; afterward, its colouring matter, carried perhaps by the mucus and the albumen, is deposited upon the mucous membrane: there is a certain quantity of it seen at least in the pyloric portion; the watery and alkoholic parts disappear with rapidity.

rapidity.

The broth of meat undergoes the same changes. The water that it contains is absorbed; the gelatine, the albumen, the fat, and probably the osmazome, remain in the stomach, where they are reduced into

Action of the small intestine upon drinks.—After what has been read, it is clear that fluids penetrate, under two forms, into the small intestine: 1st, under that of liquid; 2dly, under that of chyme.

The liquids that pass from the stomach into the intestine remain but a short time, except under particular circumstances; they do not appear to undergo any other alteration than their mixture with the intestinal juice, the chyme, the paperreatic liquid, and the bale. other alteration than their intitute properties of the chyme, the pancreatic liquid, and the bile; they do not form any sort of chyle; they are generally absorbed in the duodenum, and the commencement of digitalis, when the remedy is designed to act as a nar-

of salts, as well-water, remain long in the stomach and produce a feeling of weight.

Alkohol acts quite in a different manner. We know this last case does not happen except in the state of sickness. of sickness; for example, during the action of a pur-

The chyme that proceeds from drinks follows the same rule, and appears to undergo the same changes as that of the food; it therefore produces chyle.

Such are the principal phenomena of the digestion of drinks: we see how necessary it was to distinguish them from those that belong to the digestion of the aliments.

But we do not always digest the aliments and the drinks separately, as we have supposed; very frequently the two digestions take place at the same

Drink favours the digestion of the aliments; effect is probably produced in various manners. Those that are watery, soften, divide, dissolve even certain foods; they aid in this manner their chymification and

their passage through the pylorus.

Wine fulfils analogous uses, but only for the sub-stances that it is capable of dissolving; besides, it excites by its contact the mucous membrane of the stomach, and causes a greater secretion of the gastric juice. Alkohol acts much in the same manner as wine, only it is more intense. It is thus that those liquors which are used after meals, are useful in exciting the action of the stomach."—Magendie's Phy-

DIGESTIVE. Digestivus; from digere, to dissolve.) A term applied by surgeons to those substances which, when applied to an ulcer or wound, promote suppuration: such are the ceratum resina,

unguentum elemi, warm poultices, fomentations, &c
Digestive salt. The muriate of potassa.
Digestive salt of Sylvius. The muriate of potassa.

DIGESTI'VUM SAL. See Potassa murias.
DIGITA'LIS. (From digitus, a finger; because its flower represents a finger.)

1. The name of a genus of plants in the Linnman stem. Class, Didynamia; Order, Angiospermia. system.

Fox-glove.

2. The pharmacopaial name of the common fox-glove. See Digitalis purpurea.

DIGITALIS PURPUREA. The systematic name of the glove. See Digitalis purpurea.

DIGITALIS PURPUREA. The systematic name of the fox-glove. Digitalis—calycinis foliolis ovatis acutis, corollis obtusis, labio superiore integro, of Linnaus. The leaves of this plant have a bitter nauseous taste, but no remarkable smell; they have been long used externally to ulcers and scrofulous tumours with considerable advantage. When properly dried, their colour is a lively green. They ought to be collected when the plant begins to blossom, to be dried quickly before the fire, and preserved unpowdered.

Of all the narcotics, digitalis is that which diminishes most powerfully the actions of the system; and it does so without occasioning any previous excite-

it does so without occasioning any previous excitement. Even in the most moderate dose, it diminishes the force and frequency of the pulse, and, in a large dose, reduces it to a great extent, as from 70 beats to 40 or 35 in a minute, occasioning, at the same time, vertigo, indistinct vision, violent and durable sickness, with vomiting. In a still larger quantity, it induces convulsions, coldness of the body, and insensibility; symptoms which have sometimes terminated fatally. As a narcotic, fox-glove has been recommended in epilepsy, insanity, and in-some acute inflammatory dis-As a narcotic, fox-glove has been recommended in epilepsy, insanity, and in some acute inflammatory diseases. Lately it has been very extensively employed in phthisis, and the beneficial effects which it produces in that disease, are probably owing to its narcotic power, by which it reduces the force of the circulation through the lungs and general system. It is administered so as to produce this effect. One grain of the powdered leaves, or ten drops of the saturated administered so as to produce this effect. One grain of the powdered leaves, or ten drops of the saturated tincture, may be given night and morning. This dose is increased one-half every second day, till its action on the system becomes apparent. As soon as the pulse begins to be diminished, the increase of dose must be made with more caution: and, whenever nausea is induced, it ought rather to be reduced, or, if necessary, intermitted for a short time. If the sickness become urgent, it is best relieved by stimulants, particularly large doses of brandy, with arounaities. The incrure large doses of brandy, with aromatics. The tincture has been supposed to be the best form of administering

cotic: it is also more manageable in its dose, and more uniform in its strength, than the dried leaves.

Besides its narcotic effects, digitalis acts as one of the most certain diuretics in dropsy, apparently from its power of promoting absorption. It has frequently succeeded where the other diuretics have failed. Dr. Withering has an undoubted claim to this discovery; and the numerous cases of dropsy related by him, and other practitioners of established reputation, afford incontestable evidence of its diuretic powers, and of its practical importance in the cure of those disorders. From Dr. Withering's extensive experience of the use of the digitalis in dropsies, he has been able to judge of its success by the following circumstances;—"It seldom succeeds in men of great natural strength, of tense fibre, of warm skin, of florid complexion, or in those with a tight and cordy pulse. If the belly in ascites be tense, hard, and circumscribed, or the limbs in anasarca solid and resisting, we have but little hope. On the contrary, if the pulse be feeble, or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, the anasarcous limbs readily pitting under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner." Of the inferences which he deduces, the fourth is, "that if it (digitalis) fails, there is but little chance of any other medicine succeeding." Although the digitalis is now generally admitted to be a very powerful diuretic, yet it is but justice to acknowledge that this medicine has more frequently failed than could have been reasonably expected, from a comparison of the facts stated by Dr. Withering. The dose of the dried leaves in powder is from one to three grains, twice a day. But if a liquid medicine be preferred, a drachm of the dried leaves is to be infused for four hours, in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. One hours, in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. One ounce of this infusion, given twice a day, is a medium dose. It is to be continued in these doses till it either acts upon the kidneys, the stomach, the pulse (which, as has been said, it has a remarkable power of lowering.) or the bowels.

The administration of this remedy requires to be

The administration of this remedy requires to be conducted with much caution. Its effects do not immediately appear; and when the doses are too frequent, or too quickly augmented, its action is concentrated so as to produce frequently the most violent symptoms. The general rules are, to begin with a small dose, to increase it gradually, till the action is apparent on the kidneys, stomach, intestines, or vascular system; and immediately suspending its exhibition, when its effects on any of these parts take place.

The symptoms arising from too large a dose of digi-The symptoms arising from too large a dose of diginalist are, extreme sickness, vertigo, indistinct vision, incessant vomiting, and a great reduction of the force of the circulation, terminating sometimes in syncope, or convulsions. They are relieved by frequent and small doses of opium, brandy, aromatics, and strong bitters, and by a blister applied to the region of the

biomach.

DIGITATUS. Digitate or fingered. A leaf is called folium digitatum, when several leaflets proceed from the summit of a common footstalk, as in Potentilla verna; and reptans.

DIGITIFORMIS. Finger-like. Applied to the receptacle of the Arum maculatum, and Calla athio-

Digitum. (From digitus, a finger.)

1. A contraction of the finger-joint.

2. A whitlow, or other sore upon the finger.
DIGITUS. (From digero, to direct.) A finger.
Digitus manus, is the finger, properly so called; and digitus pedis, the toe.

DIGITUS MANUS. A finger. The fingers and thumb in each hand consist of fourteen bones, there being three to each finger, and two to the thumb; they are a little convex and round towards the back of the hand, but hollow and plain towards the palm, except the last, where the nails are. The order of their disposition is called first, second, and third phalanz. The first is longer than the second, and the second longer than the third. What has been said of the fingers, applies to the toes also.

DIGITUS PEDIS. A toe. See Digitus Manus.

DIGITUS PEDIS. A toe. See Digitus Manus.
DIGLO'SSUM. (From δις, double, and γλωσσα, a tongue: so called because above its leaf there grows a 396

cotic: it is also more manageable in its dose, and more less leaf, like two tongues.) 1. The Laurus alexandring.
2 Galen makes mention of a man born with two

DIGNO'TIO. (From dignosco, to distinguish.) See

Diagnosis.

Diagnosis.

DiGY'NIA. (From dis, twice, and youn, a woman.) The name of an order of several classes of the sexual system of plants, embracing those plants which to the character of the class, whatever it may be, add the circumstance of having two styles.

Diha'maton. (From dia and alia, blood.) An antidote in which is the blood of many animals.

Diha'lon. (From dia and als, salt.) A plaster prepared with salt and nitre, adapted to foul ulcers.

Dit'petes. (From Zeus, dios heaven, and wintig, to fall: i. e. falling as rain.) An epithet applied by Hippocrates to semen, when it is discharged like a shower of rain.

shower of rain.
DILATA'TIO. (From dilato, to enlarge.)

1. Dilatation, or enlargement.
2. The diastole of the heart.
DILA'TOR. (From dilato, to enlarge.) The name of some muscles, the office of which is to open and enlarge parts. -

enlarge parts.

DILATOR ALE NASI. See Levator labit superioris.
DILATORIUM. (From dilato, to enlarge.) A
surgical instrument for enlarging any part.
DILL. See Ancthum.
DILUENT. (Diluens; from diluo, to wash away.)
Those substances which increase the proportion of fluid in the blood. It is evident that this must be done
by watery liquors. Water is, indeed, properly speaking, the only diluent. Various additions are made to
it, to render it pleasant, and frequently to give it a it, to render it pleasant, and frequently to give it a slightly demulcent quality. But these are not suffi-ciently important to require to be noticed, or to be classed as medicines.

Diluents are merely sccondary remedies. They are given in acute inflammatory diseases, to lessen the sti-mulant quality of the blood. They are used to promote the action of diuretics in dropsy, and to favour the operation of sweating.

Di'Nica. (From δινος, giddiness.) Medicines which relieve a giddiness.

Di'Nos. See Dinus.

Di'NUS. (From δινεω, to turn round.) Dinos.

Dizziness. The name of a genus of disease in Good's Nosology. Class, Neurotica; Order, Systatica. It has only one species. Dinus vertigo. Vertigo, or middiness.

Dio'cres. The name of a lozenge.
Di'oros. (From δια, and οδος, the way through.)
Evacuation by stool.
DIŒ'CIA. (From δις, double, and οικια, a house.)
The name of a class of plants in the sexual system of Linnæus, containing such as have barren, or male, flowers on one individual, and fertile, or female, ones on another of the same species.

flowers on one individual, and fertile, or female, ones on another of the same species.

DICENA'NTHES. (From δια, and οινανθη, the flower of the vine.) A remedy said to be good for cholera, in which was the flower of the vine-tree.

DIO'GMUS. (From διωχια, to persecute.) A distressing palpitation of the heart.

DIOI'CUS. (From δις, double, and οικια, a house.) Dioecious. Plants and flowers are so called when the barren and fertile flowers grow from two separate roots.

DIONIS, Peter, was born about the middle of the 17th century, and educated to the practice of surgery. He was appointed to read the lectures in anatomy, &c. in the royal gardens at Paris, instituted by Lewis XIV., and after this, surgeon to the queen, and other branches of the royal family, which offices he held, with great credit, till his death, in 1718. His first publication gave an account of a woman who died in the with great credit, till his death, in 1718. His first publication gave an account of a woman who died in the sixth month of pregnancy, of what he considered to be a ruptured uterus; but as he states that there were two uteri, it is suspected that the ruptured part was one of the Fallopian tubes much enlarged. He afterward gave a useful epitome of anatomy, which was very favourably received, passed through several editions, and was even translated into the Tartar language, hy order of the emperor of China. His next work, a course of surrical operations, obtained still more celecourse of surgical operations, obtained still more celebrity, which it even now in some degree retains, especially as commented upon by Heister. Besides these

wifery, were published by this author-

Dronysi'scus. (From Διονυσος, Bacchus, who was of old represented as having horns.) Certain bony

of old represented as having horns.) Certain bony excrescences, near the temples, were called dionysisci. Dionysony'mphas. (From Διονωσος, Bacchus, and νυμφα, a nymph.) An herb which, if bruised, smells of wine, and yet resists drunkenness.

Diopo'rum. (From δια, and οπωρα, autumnal fruits.) A medicine composed of ripe fruits for quinsy.

DIOPSIDE. A subspecies of oblique-edged augite, found near Piedmont.

DIOPTASE. Emerald, copper ore.

Dio'PTRA. (From διοπ'λομαι, to see through.) Dioptron. 1. Specularis.

2. The lapis specularis.

DIO'PTRICS. (Dioptricus; from διοπ'λομαι, to see through.) The doctrine of the refraction of light.

DIOPTRI'SMUS. (From διοπ'λομαι, to see through.) Dioptri'smus. (From διοπ 7ομαι, to see through.) Dilatation of any natural passage.

Dio'ROBUM. (From ¿ta, and ocobos, a vetch.) A medicine, in the composition of which there are

vetches.

Diorrho'sis. (From ¿ia, and opoos, the serum.)

Diorosis. 1. A dissolved state of the blood.

2. A conversion of the humours into serum and

water.

DIORTHRO'SIS. (From διορθροω, to direct.) The reduction of a fracture.

DIOSCO'REA. (Named in honour of Dioscorides.)
The name of a genus of plants in the Linnæan system.
Class, Dioscore; Order, Hezandria.
DIOSCOREA ALATA. The name of the plant which affords the esculent root, called the yam. It is obtained, however, from three species; the alata, bulbifera, and sativa. They grow spontaneously in both Indies, and their roots are promiscuously eaten, as the potato is with us. There is great variety in the colour size. and their roots are promiscuously eaten, as the potato is with us. There is great variety in the colour, size, and shape of yams; some are generally blue or brown, round or oblong, and weigh from one pound to two. They are esteemed, when dressed, as being nutritious and easy of digestion, and are preferred to wheaten bread. Their taste is somewhat like the potato, but more luscious. The negroes, whose common food is yams, boil and mash them. They are also ground and made into bread and puddings.

When they are to be kept for some time, they are exposed upon the ground to the sun, as we do onions.

When they are to be kept for some time, they are exposed upon the ground to the sun, as we do onions, and when sufficiently withered, they are put into dry sand in casks, and placed in a dry garret, where they remain often for many seasons without losing any of their primitive goodness.

DIOSCOREA BULBIFERA. See Dioscorea alata.

DIOSCOREA SATIVA. HE DIOSCOREA BULBIFERA SEE DIOSCOREA BULBIFERA SEE DIOSCOREA BULBIFERA SEE DIOSCOREA BULBIFERA SEE DIOSCOREA BARTIVA. SEE DIOSCOREA BARTIVA SEE DIOSCOREA BAR medica, in five books, chiefly considering plants; also two books on the composition and application of medicines, an essay on antidotes, and another on ve-nomous animals. His works have been often printed in modern times, and commented upon, especially by Matthiolus. He notices about 600 plants, but his de-scriptions are often so slight and superficial, as to leave their identity a matter of conjecture; which is perhaps of no very great medical importance; though their virtues the useful to ascertain which particular plants

they meant.

Dioscu'ri. (i. c. Διος, Κουροι, the sons of Jupiter, or Castor and Pollux.) The parotid glands were so named from their twin-like equality in shape and po-

sition.
["Diospyros. Persimmon. The persimmon-tree is very common in the middle and western states, and grows also in the southern parts of our country. The bark is bitter, and has been added to our numerous list of native tonics. It is recommended in intermittents and ulcerated sore throats, and may be exhibited U2

Med. A.]
Diospy Ros Lorus. The Indian date plum. The fruit, when ripe, has an agrecable taste, and is very

DIOXELE'UM. (From ¿ia, očus, acid, and ¿λαιον, oil.) A medicine composed of oil and vinegar

Oil.) A medicine composed of oil and vinegar Dro'xos. (From δια, and οξυς, acid.) A collyrium composed chiefly of vinegar.

DIPHYLLUS. (From δις, double, and φυλλον, a leaf.) Diphyllous, or two-leaved. Applied to the perianthium of flowers, when there are two calyces; as in Papaver rhaas.

DIPLASIA'SMUS. (From re-exacerbation of a disease. (From διπλοω, to double.) The

re-exacerbation of a disease.

DIPLOE. (From διπλοω, to double.) The spongy substance between the two tables of the skull.

DIPLOPIA. (From διπλοως, double, and οπτομαι, to see.) Visus duplicatus. A disease of the eye, in which the person sees an object double or triple. Dr. Cullen makes it a variety of the second species of pseudoblepsis, which he calls mutans, in which objects appear changed from what they really are: and ects appear changed from what they really are; and the disease varies according to the variety of the remote causes.

mote causes.

Di'pnoos. (From δις, twice, and πνεω, to breathe.)

A wound which is perforated quite through, and admits the air at both ends.

Dipple's animal oil. See Animal oil.

DI'PSACUS. (From διψα, thirst; so called from the concave situation of its leaves, which hold water, by which the thirst of the traveller may be relieved.)

1. The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia. The

teasel.

2. A diabetes, from the continual thirst attend-

DIPSOSIS. (From διψα, thirst.) The name of a genus of diseases in Good's Nosology, known by the desire for drinking being excessive or impaired. It

has two species, Dipsosis avens, and Dipsosis expers.
DIPYRE. Schmelstein. A mineral found in white
or reddish steatite in the Western Pyrenees, composed

or reddish steatile in the Western Pyrenees, composed of silica, alumina, and lime.

Dippyre'sum. (From δις, twice, and πυρην, a ber ry.) 1. A berry, or kernel.

2. A probe with two buttons.

Dippyres. (From δις, twice, and πυρ, fire.) Dippyres. An epithet given by Hippocrates to bread twice baked, and which he recommended in dropsies.

DIRECTOR. (From dirigo, to direct.)

1. A hollow instrument for guiding an incisor-knife.

2. The name of a muscle.

2. The name of a muscle.

Director Penis. (From dirigo, to direct.) The same as erector penis.

Director Penis.

Director Penis.

Director Penis.

Director Penis.

See Acorus calamus.

Disce'ssus. (From discedo, to depart.) The separation of any two bodies, before united, by chemical experition.

ration of any two bodies, before united, by chemical operation.

DISCIFO'RMIS. (From discus, a quoit, and forma, likeness.) Resembling a disk, or quoit, in shape. It is applied to the knee-pan.

DISCOI'DES. (From δισκος, a quoit, and ειδος, resemblance.) Resembling a disk, or quoit, in shape, It is applied to the crystalline humour of the eye Discar'men. 1. A small roller.

2. The diaphragm.

DISCUS. (From δισκος, a quoit and disk, and from

DISCUS. (From δισκος, a quoit and disk, and from its flat and round appearance like the circumference of the sun.) The disk, or central part of a leaf, and of a compound flower. In the common daisy, the white leaflets of the flower surround the disk.

The disk of a leaf is the whole flat surface within

the margin

the margin.

DISCUTIENT. (Discutions; from discutio, to shake in pieces.) Discusorius; Dischyticus. A term in surgery, applied to those substances which possess a power of repelling or resolving tumours.

DISEASE. Morbus. Any alteration from a perfect state of health. A disease is variously termed: when it pervades the whole system, as fever does, it is called a general disease, to distinguish it from inflammation of the eye, or any other viscus, which is a partial, or local one. When it does not depend on 307

another disease, it is termed idiopathic, which may be either general or partial, to distinguish it from a symptomatic one, which depends upon another disease. See A DISTORTOR ORIS. See Zygomaticus minor.

also Endemic, Epidemic, Sporadic, &c.
[DISINTEGRATION. This is a geological term, and means the crumbling down of rock by their decomposition, and the consequent formation of alluvial

DISK. See Discus.

DISLOCA'TION. (Dislocatio; from disloco, to put out of place.) Luxation. The secession of a bone of a moveable articulation from its natural ca-

DISPE'NSARY. (Dispensarium; from dispendo, to distribute.) 1. The shop or place in which medicines are prepared.

cines are prepared.

2. The name of an institution, in which the poor are supplied with medicines and advice.

DISPE'NSATORY. (Dispensatorium; from dispendo, to distribute.) Antidotarium. A book which treats of the composition of medicines.

DISSE'CTION (Dissectio; from disseco, to cut asunder.) The cutting to pieces of any part of an animal, or vegetable, for the purpose of examining its structure. See Anatomy.

DISSECTUS. Cut. A term used by botanists synonymously with incised and laciniated, to leaves which are cut, as it were, into numerous irregular portions. See Leaf.

DISSEPIMENTUM. (From dissepio, to separate.) A partition. Applied by botanists to partitions which

portions. See Leaf.

DISSEPIMENTUM. (From dissepio, to separate.)
A partition. Applied by botanists to partitions which separate the cells of a capsule. See Capsula.

DISSEPTUM. (From dissepio, to enclose round.)
The diaphragm, or membrane, which divides the cavity of the thorax from the abdomen.

DISSOLVENTIA. (From dissolvo, to loosen.)
1. Medicines which loosen and dissolve morbid concretions in the body.
2. In chemistry, it means menstrua.

DISSOLUTUS. (From dissolvo, to loosen.) Loose, morbas dissolutus. An epithet applied to dysentery.

Dissolutus. An epithet applied to dysentery.
DISTANS. Distant. Applied to petals from their direction; as in Cucubalus bacciferus.
DISTE'NTIO. (From distendo, to stretch out.) 1.
Distention, or dilatation.
2. A convulsion.

2. A convulsion:
DISTHENE. See Cyanite.
DISTI'CHIA. See Distichiasis.
DISTICHI'ASIS. (From διστιχια: from δις, double, and 51205, a row.) Districtiasis; Distictia. A disease of the eyelash, in which there is a double row of hairs, the one row growing outwards, the other in-

wards towards the eye.
DISTICHUS. Two-ranked.

wards towards the eye.

DISTICHUS. Two-ranked. Applied to stems, leaves, &c. when they spread in two horizontal directions; as the branches of the Pinus picca, or silver fur, and the leaves of the Tazus baccata, or yew.

DISTILLATION. (Distillatio; from distillo, to drop little by little.) Alsacta; Catastagmos. A chemical process, very similar to evaporation, instituted to separate the volatile from the fixed principles, by means of heat. Distillatory vessels are either alembics or retorts; the former consist of an inferior vessel called a cucurbit designed to contain the matter to sel called a cucurbit designed to contain the matter to sel called a cucurbit designed to contain the matter to be examined, and having an upper part fixed to it, called the capital, or head. In this last, the vapours are condensed by the contact of the surrounding air, or, in other cases, by the assistance of cold water surrounding the head, and contained in a vessel called the refrigeratory. From the lower part of the capital proceeds a tube called the nose, beak, or spout, through which the vapours, after condensation, are, by a proper figure of the capital, made to flow into a vessel called the receiver, which is usually spherical. These per figure of the capital, made to flow into a vessel called the receiver, which is usually spherical. These receivers have different names, according to their figure, being called mattresses, balloons, &c. Retorts are a kind of bottle of glass, pottery, or metal, the bottom being spherical, and the upper part gradually diminishing into a neck, which is turned on one side.

Distilled vinegar. See Acctum.

DISTO'RTION. (Distortio; from distorqueo, to wrest aside.) A term applied to the eyes, when a person seems to turn them from the object he would look at and is then called squinting, or strabismus. It also

at, and is then called squinting, or strabismus. It also signifies the bending of a bone preternaturally to one side; as distortion of the spine, or vertebræ.

DISTO'RTOR. (From distorquee, to wrest aside.)

DISTORTOR ORIS. See Zygomaticus minor.
DISTRICHI'ASIS. See Distichiasis.
DISTRIX. (From & dist, double, and fort, the hair.)
A disease of the hair, when it splits and divides at the

Dittany, bastard. See Dictamnus albus.
Dittany of Crete. See Origanum dictamnus.
Dittany, white. See Dictamnus albus.
DIURE SIS. (From dia, through, and over, to make water.) An increased secretion of urine. It is also applied to a diabetes.

DIURETIC. (Diureticus. Alovontikos; from diovonos, a discharge of urine.) That which, when taken internally, augments the flow of urine from the kidneys. It is obvious that such an effect will be produced by any substance capable of stimulating the secreting vessels of the kidneys. All the saline diuretics seem to act in this manner. They are received into the circulation; and passing off with the urine, stimulate the vessels, and increase the quantity secreted.

There are other diuretics, the effect of which appears not to arise from direct application, but from an action excited in the stomach, and propagated by nervous communication to the secreting urinary vessels.

The diuretic operation of squill, and other vegeta-

The diuretic operation of squill, and other vegetables, appears to be of this kind.

There is still, perhaps, another mode in which certain substances produce a diuretic effect; that is, by promoting absorption. When a large quantity of watery fluid is introduced into the circulating mass, it stimulates the secreting vessels of the kidneys, and is carried off by urine. If, therefore, absorption be promoted, and if a portion of serous fluid, perhaps previously effused, be taken up, the quantity of fluid secreted by the kidneys will be increased. In this way digitalis seems to act: its diuretic effect, it has been said, is greater when exhibited in dropsy than it is in is greater when exhibited in dropsy than it is in

On the same principle (the effect arising from stimu-lating the absorbent system) may probably be explained the utility of mercury in promoting the action of several diuretics.

The action of these remedies is promoted by drink-ing freely of mild diluents. It is also influenced by the state of the surface of the body. If external heat be applied, diuresis is frequently prevented, and dia-phoresis produced. Hence the doses of them should be given in the course of the day, and the patient, if

be given in the course of the day, and the patient, if possible, be kept out of bed.

The direct effects of diuretics are sufficiently evident. They discharge the watery part of the blood; and, by that discharge, they indirectly promote absorption over the whole system.

Dropsy is the disease in which they are principally employed; and when they can be brought to act, the disease is removed with less injury to the patient than it can be by exciting any other evacuation. Their it can be by exciting any other evacuation. Their success is very precarious, the most powerful often failing; and, as the disease is so frequently connected with organic affection, even the removal of the effused fluid, when it takes place, only palliates without effectives. ing a cure.

Diuretics have been likewise occasionally used in

Diuretics have been likewise occasionally used in calculous affections, in gonorrhea, and with a view of diminishing plethora, or checking profuse perspiration.

Murray, in his Elements of Materia Medica, classes the supertartrate of potassa, or cream of tartar, and nitrate of potassa, or nitre, the muriate of ammonia, or crude sal-ammoniac, potassa, and the acetate of potassa, or kali acetatum, among the saline diuretics; and selects the following from the vegetable kingdom:—scilla maritima, digitalis purpurea, nicotiana tabacum, solanum dulcamara, lactuca virosa, colchicum autumnale, gratiola officinalis, spartium scoparium, juniperis communis, copaifera officinalis, pinus balsamea, and pinus larix; and the lytta vesicutoria from the animal kingdom.

In speaking of particular diuretics, Dr. Cullen save

the animal kingdom.

In speaking of particular diuretics, Dr. Cullen says, the diuretic vegetables, mentioned by writers, are of very little power, and are employed with very little success. Of the umbellate, the medicinal power resides especially in their seeds; but he never found any

of them very efficacious. The semen dauci sylvestris has been commended as a diurctic; but its powers as such are not very remarkable. In like manner, some of the planta stellata have been commended as diurctics; but none of them deserve our notice, except the rubia tinctorium, the root of which passes so much by the kidneys as to give its colour to the urine. Hence it may fairly be supposed to stimulate the secretories; but Dr. Cullen found its diurctic powers did not always appear, and never to any considerable denot always appear, and never to any considerable de-gree; and as, in brute animals, it has always appeared hurtful to the system, he does not think it fit to be em-ployed to any extent in human diseases. The bardana, lithospermum, ononis, asparagus, enula campa-na, are all substances which seem to pass, in some measure, by the kidneys; but their diuretic powers are hardly worth notice.

The principal articles included by Dr. Cullen, in his catalogue of diuretics, are dulcamara, digitalis, scilla; some of the alliaceæ and siliquosæ; the balsams and

resins; cantharides, and the diuretic salts.

Divapora Tio. Evaporation.

DIVARICATION. The crossing of any two things: thus when the muscular or tendinous fibres intersect each other at different angles, they are said to divaricate.

Divellent affinity. See Affinity quiescent.
Diverso'Rium. (From diversor, to resort to.) The

receptaculum chyli.
DIVERTI'CULUM. A mal-formation or diseased appearance of a part, in which a portion goes out of the regular course; and thereby forms a diverticulum, or deviation from the usual course. It is generally

or deviation from the usual course. It is generally applied to the alimentary canal.

DIVERTICULUM NUCKII. The opening through which the round ligaments of the uterus pass. Nuck asserted that it remained open a long time after birth; to these openings he gave the name of diverticula.

DIVI'NUS. A pompous epithet of many compositions, from their supposed excellence.

DIVU'LSIO. (From divello, to pull asunder.) Urine with uneven sediment.

DOCIMASTIC. Ars docimastica. The art of examining fossils, in order to discover what metals, &c. they contain.

DOCK. See Rumex.

DOCK. See Rumez.

Dock, cresses. See Lapsana.

Dock, sour. See Rumez acetosa.

Dock, water. See Rumez hydrolapathum.

DODDER. See Cuscuta epithymum.

Dodecada crylus. (From δωδεκα, twelve, and δακ 7υλος, a finger; so named because its length is about the breadth of twelve fingers.) The duodenum, an intestine so called. It must be observed, that at the time this same was given anatomy consisted in the time this name was given, anatomy consisted in the dissection of brutes; and the length was therefore probably adjudged from the gut of some animal, and

not of man.

DODECA'NDRIA. (From δωδεκα, twelve, and ανηρ, a man.) The name of a class of plants in the sexual system, embracing those with hermaphrodite

BODECAPHA'RMACUM. (From δωδεκα, twelve, and φαρμακον, a medicine.) An ointment consisting of twelve ingredients, for which reason it was called the ointment of the twelve apostles.

DODECA'THEON. (From δωδεκα, twelve, and 7ιθημι, to put.) An antidote consisting of twelve simples.

DODONÆUS, Rembertus, (or Dodoens,) was born at Mechlin, in 1517. He became physician to two succeeding emperors, and, in 1582, was appointed professor of physic in the newly-founded University of Leyden, the duties of which he performed with credit, till his death, three years after. His fame at present chiefly rests on his botanical publications, particularly his "Pemptades," or 30 books of the history of plants. The "Frugum Historia," "Herbarium Belgicum," &c. are of much inferior merit.

DOG. See Canis.

Dog's-bane, Sgrian. See Asclepias syriaca.

Dog's-bee Canis.

Dog's-bane, Sgrian. See Asclepias syriaca.

Dog's-grass. See Triticum repens.

Dog's-mercury. See Mercurialis perennis.

Dog-rose. See Rosa canina.

Dogrestones. See Orchis mascula.
[Dogresod. See Cornus Florida. A.]
DO GMA. (From δοκεω, to be of opinion.) A dogma, or opinion, founded on reason and experience.

DOLERFTE. When volcanic masses are composed of grains distinct from each other, and contain besides felspar, much pyroxene, black oxide of iron, ampibole, &c., they are called, by the French geologist,

DO'LICHOS. (From δολιχος, long: so called from its long shape.) 1. The name of a genus of plants in the Linnæan system. Class, Diadelphia; Order, De-

2. The pharmacopæial name of the cowhage. See

2. The pharmacopæial name of the cowhage. See Dolichos pruviens.

Dolichos Pruviens. The systematic name of the cowhage. Dolichos; Dolichos—volubilis, leguminibus racemosis, valoulis subcarinatis kirtis, pradunculis ternis, of Linnæus. The pods of this plant are covered with sharp hairs, which are the parts employed medicinally in form of electuary, as anthelmintics. The manner in which these hairy spicula act, seems to be purely mechanical: for neither the tincture, nor the docoction, possess the least anthelmintic power.

Dollchos sola. The plant which affords the soy.

Dollenos soja. The plant which affords the soy. It is much cultivated in Japan, where it is called da-

It is much cultivated in Japan, where it is called daidsu: and where the pods supply their kitchens with various productions; but the two principal are, a sort of butter, termed miso, and a pickle called sooju.

DOLABRIFORMIS. (From dolabella, a hatchet, and forma, resemblance.) Hatchet-shaped. A term applied to a leaf, which is compressed with a very prominent dilated keel, and a cylindrical base; as in Misembryanthemum dolabriforme.

DOLOMITE. A calcareo-magnesian carbonate.
DO'LOR. (Dolor, oris. f.) Pain.
DOLOR FACIEI. See Tic douloureuz.
DORO'NICUM. (From dorongi, Arab.) Leopard's bane. See Arnica montana.

DORONICUM GERMANICUM. See Arnica montana.

DORONICUM ROMANUM. The pharmacopæial name of the Roman leopard's bane. See Doronicum pardalianches.

Doronicum pardalianches. The systematic name of the Roman leopard's bane. Doronicum romanum; Doronicum—folius cordatis, obtucis, denticulatis; radicalibus petiolatis; caulinis amplexicaulibus, of Linnæus. The root of this plant, if given in a full dose, possesses poisonous properties; but instances are related of its efficacy in epileptical and other nervous diseases.

DO'RSAL. (Dorsalis; from dorsum, the back.)
Belonging to the back.
Dorsalis nervus. The nerve which passes out

Dorsalts Nervus. The nerve which passes out from the vertebræ of the back.

[DORSEY, John Syng, M.D., Professor of anatomy in the university of Pennsylvania, was born in the city of Philadelphia, in December, 1783. In early life he received an excellent elementary and classical education at a school in Philadelphia, of the society of Friends, then in high repute, and here manifested the same vivacity of genius and onickness in learning, with same vivacity of genius and quickness in learning, with the mild and gracious dispositions, for which he was subsequently so conspicuous. At the age of 15 years, he entered the office of his relation, the celebrated Dr.

Physick. Not long after receiving his degree, the yellow fever reappeared in the city, and prevailed so widely that an hospital was opened for the accommodation exclusively of the sick with this disease, to which he was appointed resident physician. So great was the value attached to his services, that it is difficult to speak too highly of the manner in which he discharged the duties of his office of hazardous benevolence. At the close of the same season, he proceeded to Europe, for the purpose of improving his medical knowledge. In December, 1804, he returned home, and immediately entered on the practice of his profession. The repu-tation he brought with him, his amiable temper, and popular manners, his fidelity and attention, speedily introduced him into a large share of business. From introduced him into a large share of business. From this period professional honours were heaped on him with profusion. He was appointed surgeon to the dispensary, the alms-house, and hospitals, and in all our medical associations he held some elevated office. But there was reserved for him a still higher and more dignified station. In 1807 he was elected adjunct professor of surgery, in which office he continued till he was raised to the chair of anatomy, by the lamented death of the venerable Dr. Wistar.

"Considering himself now placed for the first time."

"Considering himself now placed for the first time

In the proper sphere for the exercise of his talents and the gratification of a generous ambition, the appointment gave him much delight; and with ample preparation, he opened the session by one of the finest exhibitions of eloquence ever heard within the walls of the college. But here his bright and prosperous career ended, and the expectations of success thus created were not permitted to be realized. Elevated to a position above which he could hardly ascend, and surrounded by all that we most value, Providence seems to have selected him as an instance to teach a salutary lesson of the shortness of life, the insignificance of lesson of the shortness of life, the insignificance of lesson of the shortness of life, the Insignificance of things transitory, and the importance of that eternity which absorbs all being and all time. On the evening of the same day that he pronounced his introductory lecture, and while the praises of it still resounded, he was attacked with a fever of such vehemence, that in one short week it closed his existance, leaving to us only his enviable name and inestimable example. He died in November, 1818, aged 35 years."—Thack.

died in November, 1818, aged 35 years."—Thack. Med. Biog. A.]

DORSTE'NIA. (Named in honour of Dr. Dorsten.) The name of a genus of plants in the Linnman system. Class, Tetrandria; Order, Monogynia.

DORSTENIA BRAZILIENSIS. The root of this plant is used by the natives of Brazil, internally and externally. They call it Caa apia. When chewed, it has the same effects as ipecacuanha. The wounds from poisoned darts are said to be cured with the juice of the root, which they pour into the wound.

the root, which they pour into the wound.

DORSTENIA CONTRAVERVA. The systematic name of the plant which affords the contrayerva root; Contrayerca; Drakena; Cyperus longus, odorus, perua-nus; Bezoardica radix. The contrayerva root was first brought into Europe about the year 1581, by Sir Francis Drake, whence its name Drakena. It is the root of a small plant found in Peru, and other parts of the Spanish West Indies. Dr. Houston observes, that the roots of different species of dorstenia are promiscuously gathered and exported for those of the contraverva, and, as all the species bear a great resemblance to each other, they are generally used for medical purposes in this country. The tuberous parts of these roots are the strongest, and should be chosen for use. They have an agreeable aromatic smell: a rough, bit-They have an agreeable aromatic smell; a rough, bitter, penetrating taste; and, when chewed, they give out a sweetish kind of acrimony.

out a sweetish kind of acrimony.

It is diaphoretic and antiseptic; and was formerly used in low nervous fevers, and those of the malignant kind; but its use is superseded by the cinchona.

Dr. Cullen observes, that this and serpentaria are powerful stimulants; and both have been employed in fevers in which debility prevailed. However, he thinks, wine may always supersede the stimulant powers of these medicines; and that debility is better remedied by the tonic and antiseptic powers of cold and Peruvian bark, than by any stimulants.

remedied by the tonic and antiseptic powers of cold and Peruvian bark, than by any stimulants.

By the assistance of heat, both spirit and water extract all its virtues; but they carry little or nothing in distillation; extracts made by inspissating the decoction, retain all the virtues of the root.

The London College forms the compound powder of contrayerva, by combining five ounces of contrayerva root with a pound and a half of prepared shells. This powder was formerly made up in balls, and called lapis contrayerve, employed in the decline of ardent fevers, and through the whole course of low and nervous ones. The radix serpentarize virginiensis, in all vous ones. The radix serpentariæ virginiensis, in all cases, may be substituted for the contrayerva.

Dorstenia drakena. The systematic name for one

sort of the contraverva.

DORSTENIA HOUSTONII. See Dorstenia contra-

DO'THIEN. A name for the furunculus.

DOUGLAS, JAMES, M. D. was born in Scotland in
1675. After completing his education, he came to
London, and applied himself diligently to the study of London, and applied himself diligently to the study of anatomy and surgery, which he both taught and practised several years with success. Haller has spoken very highly of his preparations, to show the motion of the joints, and the structure of the bones. He patronised the celebrated William Hunter; who assisted him shortly before his death in 1742. He was reader of Anatomy to the Company of Surgeons, and a Fellow of the Royal Society, to which he made several communications. He published, in 1707, a more correct description of the muscles than had before appear-

ed; eight years after, a tolerable account of preceding anatomical writers; in 1726, a History of the lateral Operation for the Stone; and in 1730, a very accurate Description of the Peritonzum, &c.

DOUGLAS, John, brother of the preceding, was surgeon to the Westminster Infirmary, and author of several controversial pieces. In one of them, called a Remarks on a late pompous Work," he censures, with no small degree of severity, Cheselden's Anatomy of the Bones; in another, he criticises, with equal asperity, the works of Chamberlen and Chapman; and in a third, he decries the new forceps of Dr. Smellie. He also wrote a work on the high operation for the stone, which he practised; a Dissertation on the Venereal Disease; and an Account of the Efficacy of Bark in stopping Gangrene.

in stopping Gangrene.

DOVE'S FOOT. See Geranium rotundifolium.

Dover's powder. See Pulvis ipecacuanhæ compo-

Down of seed. See Pappus.

DRA'BA. (From δρασσω, to seize; so called from its sudden effect upon the nose of those who eat it.) The name of a genus of plants in the Linnæan system. Class, Tetradynamia; Order, Siliculosa.

Draba verna. A common plant on most walls.

The seed is hot and stimulating, and might be used for

pepper.
DRA'CO. (Draco, onis. m. Δρακων, the dragon.) The dragon.

Draco mitigatus. The submuriate of mercury.
Draco sylvestris. See Achillea Ptarmica.
DRACOCE'PHALUM. (From δρακων, a dragon, and κεφαλη, a head.) The name of a genus of plants in the Linnæan system. Class, Didynamia; Order,

Gymnospermia.

Gymnospermia.

Dracoccephalum canariense. The systematic name of the balm of Gilead. Turkey-balsam; Canary balsam; Balsam of Gilead. Moldavica; Melissa Turcica. Dracoccephalum moldavica—floribus verticellatis, bracteis lanceolatis, serraturis capillaceis of Linnaus. This plant affords a fragrant essential oil, by distillation, known in Germany by the name of oleum syriæ. The whole herb abounds with an aromatic smell, and an agreeable taste joined with an oleum syriæ. The whole herb abounds with an aromatic smell, and an agreeable taste, joined with an aromatic flavour; it is recommended to give tone to the stomach and nervous system.

DRACONIS SANGUIS. Dragon's blood. See Calamus

DRACONTIA. The dracontia of the Greeks, according to Pliny, was the Guinea-worm, or dracunculus. See Medinensis vena.

DRACO'NTIUM. (From δρακων, a dragon; so called because its roots resemble a dragon's tail.) See Arum

["Dracontium. Skunk Cabbage. The skunk cabbage is an indigenous plant, very common in wet meadows throughout the United States, and well known for its offensive odour, perfectly resembling that of the animal whose name it bears. Its odour resides in a volatile substance not easily obtained in a separate state, and soon dissipated by heat or by drying. It contains likewise an acrid principle like that of the genus gram, also a portion of resin and many of the genus arum; also a portion of resin and mu-

of the genus arum; also a portion of resin and muciage.

"This plant in small doses is a stimulant and antispasmodic, and in large doses a narcotic. Thirty grains of the powdered root, if freshly prepared, will bring on vertigo, nausea, and frequently vomiting. Age and exposure, however, diminish its activity. In medicine this vegetable has been found of important use in certain forms of asthma, and in chronic catarrh, in which diseases it has succeeded, even when the cases had previously been of great obstinacy. It has also been recommended in rheumatism, in hysteria, and in dropsy.

and in dropsy

"A popular form of using this medicine is that of a syrup. This is an uncertain preparation, owing to the volatility of the active ingredients. It is better given in powder made from the dried root a short time before it is wanted. Ten grains may be taken at a dose, in honey or treacle, and the quantity gradually increased as long as the stomach and head remain unaffected."—Big. Mat. Med. A.]

DRACUNCULUS. (From δρακων, a serpent.) Gordius medinensis; Vermis medinensis; Vena medinensis; Vermiculus capillaris. The Guinea worm. This animalcule is common in both Indies, in most

parts of Arrica, occasionally at Genoa, and other hot countries. It resembles the common worm, but is much larger; is commonly found in the legs, but sometimes in the muscular part of the arms. It principally affects children, and its generation is not unlike that of the broad worms of the belly. While it moves under the skin, it creates no trouble; but, in length of time, the place near the descence was supportates, and time, the place near the dracunculus suppurates, and the animal puts forth its head. If it be drawn, it excites considerable uneasiness, especially if drawn so forcibly as to break it; for the part left within creates intolerable pain. These worms are of different lengths. In the Edin Med. Essays, mention is made of one that was three yards and a half in length.

Descripting PRATERIES. See Achilles ntarmical

DRACUNCULUS PRATENSIS. See Achillea ptarmica.

DRAGACA'NTHAL See Astragalus.

DRAGACA'NTHAL See Astragalus.

DRAGON. See Dracs.

Dragon's blood. See Calamus rotang.

Dragon's wort. See Arum dracunculus.

DRAKE, JAMES, M.D. Fellow of the College of Physicians, and of the Royal Society, published, in 1707, "A New System of Anatomy," which, though taken principally from Cowper, being on a reduced plan, and more within the reach of students, was pretty favourably received. In the third edition, it was styled "Anthropologia Nova." In abscesses of the antrum maxillare, he advised drawing one of the molar teeth, to let out the matter. The description of the internal nostrils, and of the cavities entering them, is new; as are also the plates of the abominal viscera. viscera.

Viscera.

DRAKE'NA. See Dorstonia contrayerva.

DRA'STIC. (Drasticus. Δραστικος, active, brisk; from δραφ, to effect.) A term generally applied to those medicines which are very violent in their action; thus, drastic purges, emetics, &c.

Drawing state. See Chalk, black.

DRELINGCOURT, Charles, was born at Paris in 1633; and after studying some years at Saumur, he went to graduate at Montpelier. He soon after attended the celebrated Turenne in his campaigns, and was by him made physician to the army. He was also appointed one of the physicians to Lewis XIV. But in 1688 he was chosen to succeed Vander Linden, as professor of medicine at Leyden; and two years after he was advanced to the chair of anatomy. He was also made physician to William, then Prince of Orange, and his consort; and on their accession to the throne of England, he spoke the congratulatory ora-Orange, and his consort; and on their accession to the throne of England, he spoke the congratulatory oration to them, as rector of the university. He continued in his professorship, giving general satisfaction, to the period of his death in 1697. He was a voluminous and learned, but hardly an original writer; yet his works were very much read at the time. In one of his orations, he exculpates medical men from the charge of impiety, observing that the contemplation of the works of God tends to blind them more to religion. In his "Apologia Medica," he refutes the notion, that physicians were excluded from Rome for six hundred years. He strenuously opposed the introduction of chemical preparations into medicine, which was then very prevalent. His son, Charles, succeeded him in practice, but has left no publication, except his thesis "De Lienosis."

Dro'MA. The name of a plaster described by Myrepsus.

Myrepsus.

Dropaci'smus. (From δρεπω, to remove.) Dropax. A stimulant plaster of pitch, wax, &c. to take off hair.

DRO'FAX. See Dropacismus.
DRO'FAX. See Dropacismus.
DRO PSY. Hydrops. A collection of a serous fluid in the cellular membrane; in the viscera and the circumscribed cavities of the body. See Hydrops, Ascites, Anasarca, Hydrocephalus, Hydrothorax, Hy-

drocele.

Dropsy of the belly. See Ascites.

Dropsy of the brain. See Hydrocephalus.

Dropsy of the chest. See Hydrothorax.

Dropsy of the ovary. See Ascites.

Dropsy of the skin. See Anasarca.

Dropsy of the testicle. See Hydrocele.

DROPWORT. See Enanthe, and Spiræa.

Dropwort, hemlock. See Enanthe.

Dropwort, water. See Enanthe.

DRO'SERA. (From δροσερα, dewy; which is from δροσερα, dewy; drops hanging on the leaves like dew.)

The name of a genus of plants. Class, Pentandria?

Order, Hexagynia. Sun-dew.
DROSERA ROTUNDIFOLIA. The sytematic name of the sun-dew. Ros solis; Roscila. Sun-dew. Drosera rotundifolia—scapis radicatis; foliis orbiculatis of Linnaus. This elegant little plant is said to be so acrid as to ulcerate the skin, and remove warts and corns; and to excite a fatal coughing and delirium in sheep who eat it. It is seldom given medicinally in sheep who eat it. It is seldom given medicinally in this country but by the lower orders, who esteem a decoction of it as serviceable in asthmas and

COUGHS.

DROSOBO TANUM. (From δροσος, dew, and βο Γανη, an herb: so called from its being covered with an aromatic dew.) The herb betony. See Betonica.

DROSSO MELL. (From δροσος, dew, and μελι, honey.) Honey-dew. Manna.

DRUPA. (Drupæ, unripe olives.) A stone fruit formed of a fleshy or coriaceous seed-vessel, enclosing

It is distinguished into,

1. Drupa succosa, when of a succulent fleshy consistence; as the cherry, plum, peach, and nectarine.

2. D. fibrosa, the nut being fibrose; as in Cocus nu-

3. D. exsicea, dry and subcoriaceous; as the almond and horse-chesnut. 4. D. dehiscens, opening; as in Juglans regia, and Myristica moschata.

From the number of nuts it contains, the drups is said to be monosperma, when there is but one, as in the olive and pistachia; and disperma when there are two,

as in Styraz.

DRUPACEUS. Drupaceous; resembling a drupe, or stone fruit. Applied to the pod of Erugago and

Bunnas.

DUCT. See Ductus.

Duct, biliary. See Biliary duct.

DUCTI'LITY. Ductilitas. A property by which bodies are elongated by repeated or continued pressure. It is peculiar to metals. Most authors confound the words malleability, laminability, and ductility, together, and use them in a loose indiscriminate way; but they are very different. Malleability is the property of a body which enlarges one or two of its three dimensions, by a blow or pressure very suddenly apdimensions, by a blow or pressure very suddenly ap-plied. Laminability belongs to bodies extensible in dimension by a gradually applied pressure; and duc-tility is properly to be attributed to such bodies as can be rendered longer and thinner by drawing them through a hole of less area than the transverse section

of the body so drawn.

DUCTUS. A canal or duct.

DUCTUS ARTERIOSUS. A great artery-like canal found only in the fætus, and very young children, between the pulmonary artery and the aorta. In adults it is closed up.

DUCTUS AURIS PALATINUS. The Eustachian tube. DUCTUS BILIARIS. See Choledochus ductus.

DUCTUS COMMUNIS CHOLEDOCHUS. See Choledochus ductus.

DUCTUS CYSTICUS. The trunk of the biliary ducts in the liver which carries the bile from them into the gall-bladder.

DUCTUS HEPATICUS. See Hepatic duct.
DUCTUS LACHRYMALIS. See Lachrymal ducts.
DUCTUS LACTIFERUS. Ductus galactophorus. The
excretory ducts of the glandular substance composing
the female breast. The milk passes along these ducts

DUCTUS AD NASUM. See Canalis nasalis.
DUCTUS PANCREATICUS. The pancreatic duct. It is white and small, and arises from the sharp extremity of the pancreas, runs through the middle of the gland towards the duodenum, into which it pours its contents by an opening common to it and the ductus communis choledochus.

DUCTUS SALIVALES. The excretory ducts of the salivary glands, which convey the saliva into the

DUCTUS STENONIS. The Stenonian duct, which was so called after its discoverer, Steno. It arises from all the small excretory ducts of the parotid gland, from all the small excretory ducts of the paroua grand, and passes transversely over the masseter muscle, penetrates the buccinator, and opens into the mouth.

DUCTUS THORACICUS. See Thoracic duct.

DUCTUS VENOSUS. When the vena cava passes the

DUCTUS WARTHONIANUS. The excretory duct of the maxillary glands; so named after its discoverer. Dulca'cidum. (From dulcis, sweet, and acidus, sour.) A medicine composed of a sweet and sour in-

DULCAMA'RA. (From dulcis, sweet, and amarus, bitter.) Bitter-sweet. See Solanum dulcamara.

Dumbness. See Aphonia and Paracusis.

DUMOSUS. (From dumus a bush.) Bushy.

DUMOSE. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of Decision of the sea with irregular.

shrubby plants, which are thick set with irregular branches, and bushy.

DUNCAN, DANIEL, was born at Montaubon, in Languedoc, in 1649, son of a professor of physic in that city, but of a family originally Scotch. Having lost both his parents in early infancy, he was taken under the protection of his maternal uncle, and at a proper age sent to study medicine at Montpelier, where he took his degree. He afterward resided seven years he took his degree. He afterward resided seven years at Paris, where he published his first work, upon the principle of motion in animal bodies. He then visited London, partly to arrange some family affairs, partly to obtain information concerning the plague, and in-tended to have settled there; but after two years he was summoned to attend his patron, the great Colbert. Was summoned to attend his patron, the great Colhert. He soon after made public two works, in which he attempted to explain the Annual Functions on Chemical and Mechanical Principles. On the death of Colhert, he resided for some years in his native city; but the persecution of the Protestants in 1690 drove him to Switzerland, and he was appointed Professor of Anatomy and Chemistry at Berne, where he got into considerable practice. In 1699 he was sent for to attend the Princess of Hesse-Cassel, who had symptoms of siderable practice. In 1639 he was sent for to attend the Princess of Hesse-Cassel, who had symptoms of threatening consumption, induced by the excessive use of tea, and other hot liquors; which led him to write a Treatise against that practice, published subsequently by the persuasion of his friend, Boerhaave. He remained there three years, affording meanwhile much relief to the French refugees; and the fame of his liberality procured his invitation to the court of Berlin: but a regard to his health and to economy soon complished his favourite object of settling in London, and when he reached his 70th year, put in practice his previous resolution of giving his professional services only gratuitously: in which he steadily persevered during the remaining sixteen years of his life, though, in 1721, he lost the third part of his property by the South-sea scheme.

DUNG. See Fext.

Dung, depiles. See Fexula resolution. obliged him to remove to the Hague. In 1714 he ac-

Dung, devil's. See Ferula assafatida.

DUO. (Δνω, two.) Some compositions consisting of two ingredients, are distinguished by this term; as

pilulæ ex duobus. DUODE'NUM. DUODE NUM. (From duodenus, consisting of twelve; so called because it was supposed not to ex-ceed the breadth of twelve fingers; but as the ancients dissected only animals, this does not hold good in the human subject.) The first portion of the small intes-tines. See Intestines.

DUPLEX. (From duo, two, and plice, to fold.)

Double or two-fold. In botany applied to leaves, petals, perianths, &c. The perianthum duplex is seen petals, perianths, &c. The perian Malva althau and Hibiscus.

Duplica'na. (From duplex, double.) A name of the double tertian fever.

DUPLICATUS. (From duplex, double.) This term is applied to a flower which has two series or

DU'RA MATER. (From durus, hard, and mater, a mother: called dura, from its comparative hardness with the pia mater; and mater, from its being supposed to be the source of all the other membranes. Other parts have received the trivial name of dura, from their comparative hardness; as portio dura, from their comparative hardness; as portio dura, arbranch of the seventh pair of nerves.) Dura meninz; Dermatodes. A thick and somewhat opaque and insensible membrane formed of two layers, that sursensible membrane, formed of two layers, that sur-rounds and defends the brain, and adheres strongly to the internal surface of the cranium. It has three considerable processes, the falciform, the tentorium, and the ceptum cerebelli; and several sinuses, of which

liver in the fœtus, it sends off the ductus venosus, which communicates with the sinus of the vena portæ; but, in adults, it becomes a flat ligament.

The process we require the communicates with the sinus of the vena portæ; but, in adults, it becomes a flat ligament.

The process we require the communicates with the sinus of the vena portæ; but, in adults, it becomes a flat ligament. mater, there are inthe noise, from which emerge fleshycoloured papillæ, and which, upon examining the
skull-cap, will be found to have corresponding foveæ.
These are the external glandulæ Pacchioni. They are
in number from ten to fifteen on each side, and are
chiefly lateral to the course of the longitudinal sinus.
The arteries which supply this membrane with chiefly lateral to the course of the longitudinal sinus. The arteries which supply this membrane with vessels for its own nourishment, for that of the contiguous bone, and for the perpetual exudation of the fluid, or halitus rather, which moistens or bedews its internal surface, may be divided into an erior, middle, and posterior. The first proceeds from the ophthalmic and ethmoidal branches; the second from the internal maxillary and superior pharyngeal; the posterior from the occimital and vertebral arteries.

the occipital and vertebral arteries.

the occipital and vertebral arteries.

The principal artery of the dura mater, named, by way of distinction, the great artery of the dura mater, is derived from the internal maxillary artery, a branch of the external carotid. It is called the spinalis, or spheno-spinalis, from its passing into the head through the spinous hole of the sphenoid bone, or meninga media, from its relative situation, as it rises in the great middle fossa of the skull. This artery, though it sometimes enters the skull in two branches, usually enters in one considerable branch, and divides, soon after it reaches the dura mater, into three or four branches, of which the anterior is the largest; and these spread their ramifications beautifully upon the dura mater, over all that part which is opposite to the dura mater, over all that part which is opposite to the anterior, middle, and posterior lobes of the brain. Its larger trunks run upon the internal surface of the parietal bone, and are sometimes for a considerable spa buried in its substance. The extreme branches of this artery extend so as to inosculate with the anterior and posterior arteries of the dura mater; and through the bones (chiefly parietal and temporal bones), they inosculate with the temporal and occipital arteries. The meningeal artery has been known to become aneurismal, and distended at intervals; it has formed an

mal, and distended at intervals; it has formed an aneurism, destroying the bones and causing epilepsy. Dura Meniax. See dura mater.

DWALE. See Atropa belladonna.

Dwarf elder. See Sambucus ebulus.

Dvo'ta. (From δυω, two, and συς, ωγος, an ear.) A chemical instrument with two ears, or handles.

DYSÆSTHE'SIA. (From δυς, difficulty, and αισθανομαι, to feel or perceive.) Impaired feeling.

Dysæsthesiæ. (The plural of Dysæsthesia.) The name of an order in the class Locales of Dr. Cullen's Nosology, containing those diseases, in which the senses are deprayed, or destroyed, from a defect of the external organs. external organs.

senses are deprayed, or destroyed, from a defect of the external organs.

Dysanago'gus. (From δυς, with difficulty, and avayω, to subdue.) Viscid expectoration.

DYSCATAPO'TIA. (From δυς, and κα/απινω, to drink.) A difficulty of swallowing liquids, which Dr. Mead thinks a more proper term than that generally used for canine madness, viz. hydrophobia; as it is more particularly descriptive of the affection under which the unhappy patients labour; for, in reality, they dread water from the difficulty of swallowing it.

DYSCINE'SIA. (From δυς, bad, and κιντω, to move.) Bad or imperfect motion.

Dyscinesiæ. (The plural of dyscinesia.) Applied to an order in the class Locales of Cullen's Nosology; embracing diseases in which the motion is impeded, or deprayed, from an imperfection of the organ.

DYSCOPHO'SIS. (From δυς, with difficulty, and κωφωω, to be deaf.) A defect in the sense of hearing.

DYSCRA'SIA. (From δυς, with difficulty, and κεραννυμι, to mix.) A bad habit of body.

DYSECE'A. (From δυς, difficulty, and ακοη, hearing). Cophosis. Deafness. Hearing diminished, or destroyed. A genus of disease in the class Locales and order, Dyscathesias of Cullen, containing two spends

destroyed. A genus of disease in the class Locales and order Dysasthesia of Cullen, containing two spe and order Dysæsthesiæ of Cullen, containing two species: Dysecæa organica, which arises from wax in the meatus, injuries of the membrane, or inflammation and obstruction of the tube: Dysecæa atonica, when without any discernible injury of the organ.

Dyse'lcia. (From δυς, with difficulty, and ελκος, an ulcer.) An inveterate ulcer, or one difficult to heal-Dyse'metus. (From δυς, with difficulty, and εμεω, to vomit.) A person not easily made to vomit.

Dysenteria. See Dysentery

Dysentery. (Dysenteria; from δυς, difficulty

and ev7epa, the bowels.) Dissolutus morbus. Diarrhaa carnosa. 'The flux. A genus of disease in the class Pyrexia, and order Proflucia of Cullen's Nosoloclass Pyrexia, and order Profacta of Cunion's Nosology. It is known by contagious pyrexia; frequent griping stools; tenesmus; stools, chiefly mucous, sometimes mixed with blood, the natural faces being retained or voided in small, compact, hard substances, known by the name of scybala, loss of appetite, and nausea. It occurs chiefly in summer and autumn, and in other pressional, by many pointing succeeding nausea. It occurs chiefly in summer and autumn, and is often occasioned by much moisture succeeding quickly intense heat, or great drought; whereby the perspiration is suddenly checked, and a determination made to the intestines. It is likewise occasioned by the use of unwholesome and putrid food, and by noxious exhalations and vapours; hence it appears often in armies encamped in the neighbourhood of low marshy ground, and proves highly destructive; but the cause which most usually gives rise to it, is a specific contagion; and when it once makes its appearance, where numbers of people are collected together. ance, where numbers of people are collected together, it not unfrequently spreads with great rapidity. A pe-culiar disposition in the atmosphere seems often to predispose, or give rise to the dysentery, in which case it prevails epidemically.

It frequently occurs about the same time with au-

these, it is often complicated.

The disease, however, is much more prevalent in Warm climates than in cold ones; and in the months of August, September, and October, which is the rainy season of the year in the West Indies, it is very apt to break out and to become very general among the negroes on the different plantations in the colonies. The body having been rendered irritable by the great heat of the summer, and being exposed suddenly to heat of the summer, and being exposed suddenly to much moisture with open pores, the blood is thereby thrown from the exterior vessels upon the interior, so

as to give rise to dysenteries.

An attack of dysentery is sometimes preceded by loss of appetite, costiveness, flatulency, sickness at the stomach, and a slight vomiting, and comes on with chills, succeeded by heat in the skin, and frequency of the pulse. These symptoms are in general the forerunners of the griping and increased evacuations which

afterward occur.

When the inflammation begins to occupy the lower part of the intestinal tube, the stools become more frequent, and less abundant; and, in passing through the inflamed parts, they occasion great pain, so that every evacuation is preceded by a severe griping, as also a rumbling noise.

The motions vary both in colour and consistence The motions vary both in colour and consistence, being sometimes composed of frothy mucus, streaked with blood, and at other times of an acrid watery humour, like the washings of meat, and with a very fœtid smell. Sometimes pure blood is voided; now and then lumps of coagulated mucus, resembling bits of cheese, are to be observed in the evacuations, and in some instances a quantity of purulent matter is passed.

Sometimes what is voided consists merely of a mucous matter, without any appearance of blood, exhibiting that disease which is known by the name of dysenteria alba, or morbus mucosus.

senteria alba, or morbus mucosus.

While the stools consist of these various matters, and are voided frequently, it is seldom that we can perceive any natural faces among them, and when we

perceive any natural faces among them, and when we do, they appear in small hard balls, called scybala, which being passed, the patient is sure to experience some temporary relief from the griping and tenesmus. It frequently happens, from the violent efforts which are made to discharge the irritating matters, that a portion of the gut is forced beyond the verge of the anus, which, in the progress of the disease, proves a troublesome and distressing symptom; as does likewise the tenesmus, there being a constant inclination to go to stool, without the ability of voiding any thing, except perhaps a little mucus. except perhaps a little mucus

except perhaps a little mucus.

More or less pyrexia usually attends with the symptoms which have been described, throughout the whole of the disease, where it is inclined to terminate fatally; and is either of an inflammatory or putrid tendency. In other cases, the febrile state wholly disappears after a time, while the proper dysenteric symptoms probably will be of long continuance. Hence the distinction into acute and chronic dysentery.

When the symptoms run high, produce great loss of strength and are accompanied with a putrid tendency

strength and are accompanied with a putrid tendency

and a feetid and involuntary discharge, the disease often terminates fatally in the course of a few days; but when they are more moderate, it is often protracted to a considerable length of time, and so goes off at last by a gentle perspiration, diffused equally over the whole body; the fever, thirst, and griping then ceasing, and the stools becoming of a natural colour and consistence. When the disease is of long standing, and has become habitual, it seldom admits of any cure; and when it attacks a person labouring under an advanced stage of scurvy, or pulmonary consumption, or whose constitution has been much impaired by any other disorder, it is sure to prove fatal. It sometimes appears at the same time with autumnal intermittent and remittent fevers, as has been observed, and is then more complicated and difficult to remove.

Upon opening the bodies of those who die of dysentery, the internal coat of the intestines (but more parti-cularly of the colon and rectum) appears to be affected with inflammation and its consequences, such as ul-ceration, gangrene, and contractions. The perito-

ceration, gangrene, and contractions. The peritonæum, and other coverings of the abdomen, seem likewise, in many instances, to be affected by inflammation.

In the treatment of the acute dysentery, when not
arising from contagion, but attended by considerable
pyrexia and pain, in persons of a strong and full habit,
it will be right to commence by a moderate venæsection; but in general, leeches to the abdomen will abstract a sufficient quantity of blood followed by fomentations, or the warm bath, which may produce a
powerful determination to the surface as well as counteract spasm; also blisters or rubefacients should not be neglected. With regard to internal remedies, a brisk emetic will often be advisable, particularly where the tongue is very foul, the stomach loaded, or marks of congestion in the liver appear: it may also, by inducing diaphoresis, materially check the violence of the symptoms, nay sometimes cut short the disease at once.* The next object is effectually to clear out the bowels: for which purpose calonel, joined with opium in quantity sufficient to relieve the pain may be given, and followed up by castor oil, neutral saits, &c. till they operate. In the mean time, mucilaginous demulcents may help to moderate the irritation. When the cents may help to moderate the irritation. When the bowels have been thoroughly evacuated, it will be important to procure a steady determination to the surface, and the compound powder of ipecacuanha is perhaps the best medicine; assisted by warm clothing, friction, exercise, &c. Should the liver not perform its office properly, the continued use of mercury may be necessary; to restore the strength, and relieve dyspeptic symptoms, tonics and antacids will be useful, with a mild nutritious diet; and great care must be taken to tic symptoms, tonics and antacids will be useful, with a mild nutritious diet; and great care must be taken to obviate accumulation of faces. In the chronic form of the disease, demulcents and sedatives may be freely employed by the mouth, or in the form of clyster; the bowels may be occasionally relieved by rhubarb, or other mild aperients; mercury should be cautiously employed, where the discharge of bile is indicated, or if that cannot be borne, nitric acid may be tried; and besides great attention to regimen as in the decline of besides great attention to regimen, as in the decline of acute dysentery, mild astringents, with tonics, &c. may

contribute materially to the recovery of the patient.

Dysepulo'Ticus. (From δυς, with difficulty, and επυλοω, to cicatrize.) Dysepulotus. An inveterate ulcer difficult to be healed.

Dyshæmorrho'is. (From δυς, with difficulty, and αιμοοροις, the piles.) Suppression of the bleeding from

DYSLO'CHIA. (From δυς, difficulty, and λοχια, the lochia.) A suppression of the lochia.

DYSMENORRHÆ'A. (From δυς, with difficulty, and μηνορροια, the menses.) A difficult or painful menstruation, accompanied with severe pains in the back, loins, and bottom of the belly.

Dyso pes. (From cus, bad, and oξω, to smell.)

1. A bad smell. Fœtid.

2. Hippocrates applies it to a fætid disorder of the small intestines.
3. The name of a malagma and acopon in Galen

and Paulus Ægineta.

and Paulus Argineta.
DYSO'PIA. (From δυς, bad, and ωψ, an eye.)
Parorasis. Difficult sight. Sight deprayed, requiring
one certain quantity of light, one particular distance,
or one position. A genus of disease in the class Locales, and order Dysasthesia of Cullen, containing the five following species:

1. Dysopia tenebrarum, called also Amblyopia cre-puscularis, requiring objects to be placed in a strong

2. Dysopia luminis, likewise termed Amblyopia meridiana, objects only discernible in a weak light.
3. Dysopia dissitorum, in which distant objects are

not perceived.

4. Dysopia proximorum, or Dysopia amblyopia, in which objects too near are not perceived.
5. Dysopia lateralis, called also Amblyopia luscorum, in which objects are not seen, unless placed in an oblique position. DYSORE'XIA.

(From ous, bad, and opeges, appe-

tite.) A depraved appetite.

Dysorexiz. (The plural of Dysorexia.) The name of an order in the class Locales of Cullen's Nosology, which he divides into two sections, appetitus erronei and deficientes.

DYSPERIA (Prop. L. bad order 2

DYSPE'PSIA. (From δυς, bad, and πεπ7ω, to concoct.) Apepsia. Indigestion. Dr. Cullen arranges this genus of disease in the class Neuroses, and order Adynamia. It chiefly arises in persons between thirty Adynamia. It chiefly arises in persons between unity and forty years of age, and is principally to be met with in those who devote much time to study, or who lead either a very sedentary or irregular life. A great lead either a very sedentary or irregular life. A great singularity attendant on it is, that it may and often does continue a great length of time, without any aggravation or emission of the symptoms.

Great grief and uneasiness of mind, intense study, profuse evacuations, excess in venery, hard drinking, particularly of spirituous liquors, and of tea, tobacco, opium, and other narcotics, immoderate repletion, and over distention of the stomach, a deficiency in the secretion of the bile, or gastric juice, and the being much exposed to moist and cold air, when without exercise, are the causes which usually occasion dyspepsla.

A long train of nervous symptoms generally attend

A long train of nervous symptoms generally attend on this disease, such as a loss of appetite, nausea, heart-burn, flatulency, acid, fætid, or indorous cructa-tions, a gnawing in the stomach when empty, a sense of constriction and uneasiness in the throat, with pain in the side, or sternum, so that the patient at times can only lie on his right side; great costiveness, habitual chilliness, paleness of the countenance, languor, unwillingness to move about, lowness of spirits, palpitations and distributed about tions, and disturbed sleep.

The number of these symptoms varies in different cases, with some, being felt only in part; in others, being accompanied even with additional ones, equally unpleasant, such as severe transient pains in the head

and breast, and various affections of the sight, as blindness, double vision, &c.

Dyspepsia never proves fatal, unless when, by a very long continuance, it produces great general debility and weakness; and so passes into some other disease, such as dropsy; but it is at all times very difficult to remove, but more particularly so in warm climates.

The morbid appearances to be observed on dissections of this disease, are principally confined to that part of the stomach which is called the pylorus; which is often found either in a contracted, scirrhous, or ulcerated state. In every instance, the stomach is perceived to be considerably distended with air.

The treatment of dyspepsia consists, 1. In obviating the several exciting causes. 2. In relieving urgent symptoms, some of which may tend to prolong the disease. 3. In restoring the tone of the stomach, or of the general system, and thus getting rid of the liability

I. In fulfilling the first indication, we are often much circumscribed by the circumstances or habits of the patient; and particularly when they have been accuspatient; and particularly when they have been accustomed to drink spirits, which they can hardly relinquish, or only in a very gradual manner. The diet must be regulated by the particular form of the disease; in those who are liable to acidity, it should be chiefly of an animal nature, with the least acescent vegetable substances, and for drink, toast and water, or soda water, adding a little brandy, if really necessary; where the opposite, or septic tendency appears, which happens especially in persons of a florid complexion, it should consist principally of vegetable matter, particularly the ripe subacid fruits, with the meat of young animals occasionally, and if plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in those of the phlegmatic temperament the most larly the ripe subacid fruits, with the meat of young animals occasionally, and if plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in these of the phlegmatic temperament the most occasionally, and if plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable, table-beer, cider, &c. may be allowed for drink; and in the occasional plain water be not agreeable discharge.

nutritious and digestible articles must be selected, mostly of an animal nature, assisted by the warmer condiments, and the more generous fermented liquors in moderation. It will be generally better to take food oftener, rather than to load the stomach too much at once; but more than four meals a day can hardly be requisite: if at any other time a craving should occur, a crust of bread or a piece of biscuit may be eaten.

II. Among the symptoms requiring palliation, heartburn is frequent, resulting from acrimony in the sto-mach, and to be relieved by antacid, or antiseptic remedies, according to circumstances, or diluents and demulcents may answer the purpose. A sense of weight at the stomach, with nausea, may occasionally indicate a gentle emetic; but will be less likely to occur if the bowels are kept regular. Flatulence may be relieved by aromatics, wther, &c.; and these will be proper for spasmodic, or nervous pains; but if ineffectual, opium should be had recourse to. Vomiting is generally best checked by carbonic acid. When diarrhea occurs, the aromatic confection is mostly proper, some-times with a little opium. But the bowels are much more commonly confined, and mild cathartics should be frequently exhibited, as castor oil, rhubarb, aloes, be frequently exhibited, as castor oil, rhubarb, aloes, &c.; sometimes the more active, where these do not answer. In those of a florid complexion a laxative diet, with the supertartrate of potassa, or other saline cathartic occasionally, may agree better: and where the liver is torpid, mercurials should be resorted to.

III. The third object is to be attempted by tonics, particularly the aromatic bitters, the mineral acids, or the preparations of iron; by the cold bath prudently regulated; by gentle evergise steadily personned in

regulated; by gentle exercise steadily persevered in, particularly walking or riding on horseback; by a careful attention to the diet; by seeking a pure mild air, keeping regular hours, with relaxation and amusement

seed.) Agenesia. Slow, or impeded emission of semen, during coition, insufficient for the purpose of generation. A genus of disease in the class Locales, and order Epischeses of Cullen. The species are:

1. Dyspermatismus urethralis, when the obstruction is in the urethra.

2. Dyspermatismus nodosus, when a tumour is formed in either corpus cavernosum penis.

3. Dyspermatismus præputialis, when the impediment is from a straightness of the orifice of the præ-

4. Dyspermatismus mucos obstructed by a viscid mucus. rmatismus mucosus, when the urethra is

4. Dyspermatismus hypertonicus, when there is an excess of erection of the penis.
6. Dyspermatismus epilepticus, from epileptic fits coming on during coition.

7. Dyspermatismus apractodes, from a want of vi-gour in the genitals.

8. Dyspermatismus refluus, in which the semen is thrown back into the urinary bladder.

DYSPHA'GIA. (From δυς, with difficulty, and φαγω, to eat.) A difficulty of deglutition. A genus of disease in Good's Nosology, embracing five species, Dysphagia constricta; atonica; globosa; uvulosa;

DYSPHO'NIA. (From &v5, bad, and \$\phi \psi \psi_1\$, the voice.) A difficulty of speaking. Dissonant voice. The sound of the voice imperfect or deprayed. A genus of disease in Good's Nosology, embracing three species Dysphonia susurrans, puberans, and immodulate.

dulata.

DYSPHORIA. (From δυς, and φοριω, gesto.)
Restlessness. A genus of disease in Good's Nosology, it has two species, Dysphorea simplex and anxietas.

DYSPNŒ'A. (From δυς, difficult, and πνιω, to breathe.) Dyspnoon. Difficult respiration, without sense of stricture, and accompanied with cough through the whole course of the disease. A genus of disease in the class Neuroses, and order Spasmi of Cullen. He distinguishes eight species.

1. Dyspnæa catarrhalis, when with a cough there are copious discharges of viscid mucus, called also asthma catarrhale, pneumodes, pneumonicum, and

asthma catarrhale, pneumodes, pneumonicum, and

pituitosum.

4. Dyspnæa terrea, when earthy or calculous mat-

5. Dyspnaa aquosa, when there is a scarcity of urine and ædematous feet, without the other symptoms of a dropsy in the chest.

6. Dyspnaa pinguedinosa, from corpulency.
7. Dyspnaa thoracica, when parts surrounding the chest are injured, or deformed.
8. Dyspnaa| extrinseca, from manifest external

Dy'spnoon. See Dyspnæa.

DYSTHETICA. (Δυσθετικα, an ill-conditioned state of the body.) The name of the fourth order of the class Hamatica in Good's Nosology. Cachexies. Its genera are Plethora; Hamorrhagia; Marasmus; Struma; Carcinus; Lues; Elephantius; Bucnemia; Catacausis; Porphyra; Exangia; Gangrena; Ulcus. DYSTHY'MIA. (From δυς, bad, and θυμος, mind.) Insanity.

DYSTHY MIA. (From δυς, bad, and θυμος, mind.)
Insanity.

DYSTO'CHIA. (From δυς, with difficulty, and
τικ 7ω, to bring forth.) Difficult labour.

DYSTCECHI'ASIS. (From δυς, bad, and ξοιχος, order.) An irregular disposition of the hairs in the eyelids.

DYSU'RIA. (From δυς, difficulty, and συρου, urine.)

Stillicidium; Ardor urinæ; Culbicio. A suppression
or difficulty in discharging the urine. A total suppression is called ischuria; a partial suppression, dysuria: and this may be with or without heat. When there are frequent, painful, or uneasy urgings to discharge the
urine, and it passes off only by drops, or in very small
quantities, the disease is called strangury. When a
sense of pain, or heat, attends the discharge, it passes
with difficulty, and is styled ardor urinæ, heat of the
urine. The dysuria is acute, or chronic. Dr. Cullen
places this disease in the class Locales, and order Epischeses, containing six species:

1. Dysuria ardens, with a sense of heat, without
any manifest disorder of the bladder.

2. Dysuria spasmodica, from spasm.

3. Dysuria compressionis, from a compression of the neighbouring parts.

4. Dysuria phlogistica, from violent inflammation.

5. Dysuria calculosa, from stone in the bladder.

6. Dysuria mucosa, from an abundant secretion of

6. Dysuria mucosa, from an abundant secretion of mucus.

The causes which give rise to these diseases are, an inflammation of the urethra, occasioned either by venereal sores, or by the use of acrid injections, tumour, uicer of the prostate gland, inflammation of the kidneys, or bladder, considerable enlargements of the hemorrhoidal veins, a lodgment of indurated faces in the rectum, spasm at the neck of the bladder, the absorption of cantharides, applied externally or taken internally, and excess in drinking either spirituous or vineus liquors; but particles of gravel, sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. Gouty matter falling on the neck of the bladder, will sometimes occasion these complaints.

In dysury, there is a frequent inclination to make water, with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceeds from a calculus in the kidney or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the loins and region of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and the stream of water will either be divided into two, or be discharged in a twisted manner, not unlike a corkscrew. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, unattended with any acute pain, may readily be felt in the perinæum, or by introducing the finger into the rectum.

D

EAR. Auris. The ear is the organ of hearing. It is situated at the side of the head, and is divided into external and internal ear. The auricula, or pinna, commonly called the ear, constitutes the external part. It is of a greater or less size, according to the individual. Its external face, which, in a well-formed ear, is a little anterior, presents five eminences, the helix, anti-helix, tragus, anti-tragus, lobula; and three cavities, those of the helix, fossa navicularis,

The pinna is formed of a fibrous cartilage, elastic and pliant; the skin which covers it is thin and dry; adheres to the fibro-cartilage by a cellular tissue, which is compact, and contains very little adipose substance: the lobule alone contains it in considerable quantity. There are seen under the skin a number of sebaceous cellicits, which formick a price server.

There are seen under the skin a number of sebaceous follicles, which fernish a micaceous white matter, that produces the polish and suppleness of the skin.

There are also seen, upon the different projections of the cartilaginous ear, certain muscular fibres, to which the name of muscles have been given, but which are only vestigia. The pinna, receiving many vessels and nerves, is very sensible, and easily becomes red. It is fixed to the head by the cellular tissue, and by muscles, which are called according to their position, anterior, superior, and posterior. These muscles are anterior, superior, and posterior. These muscles are anterior, superior, and posterior. These muscles are much developed in many animals: in man they may be considered as simple vestiges.

The meatus auditorius extends from the concha to the membrane of the tympanum; its length, variable according to age, is from ten to twelve lines in the adult; it is narrower in the middle than at the ends; it presents a slight curve above, and in front. Its external orifice is commonly covered with hairs, like the entrance to the other cavities. It is composed of an osseous part, of a fibro-cartilaginous substance, which is confounded with that of the pinna, of a fibrous part, which completes it above. The skin sinks into it, becoming thinner, and terminates in covering the exter-The meatus auditorius extends from the concha to

matter.

The middle ear comprehends the cavity of the tympanum, the little bones which are contained in this cavity, the mastoid cells, the Eustachian tube, &c.

this cavity, the mastoid cells, the Eustachian tube, &c.
The tympanum is a cavity which separates the external from the internal ear. Its form is that of a portion of a cylinder, but a little irregular. Its external
partition presents, on the upper part, the fenestra ovalis,
which communicates with the vestibule, and which
is formed by a membrane; immediately below, a projection which is called promontory; below this projection, a little groove, which lodges a small nerve; still
lower, an opening called the fenestra rotunda, which jection which is called promontory; below this projection, a little groove, which lodges a small nerve; still lower, an opening called the fenestra rotunda, which corresponds to the external winding of the cochlea; and which is also shut by a membrane. The external side presents the membrana tympani. This membrane is directed obliquely downward and inward; it is bent, very slender and transparent, covered on the outside by a continuation of the skin, on the inside by the narrow membrane which covers the tympanum; it is also covered on this side by the nerve called chorda tympani: its centre serves as a point of fixation for the extremity of the handle of the malleus; its circumference is fixed to the bony extremity of the meatus auditorius: it adheres equally in every point, and presents no opening that might admit a communication between the external and middle ear. Its tissue is dry, brittle, and has nothing analogous in the animal economy; there are neither fibres, vessels, nor nerves, found in it. The circumference of the tympanum presents, in the forepart, 1st, The opening of the Eustachian tube, by which the cavity communicates with the superior part of the pharynx; 2dly, The opening by which the tendon of the internal muscle of the malleus enters. Behind are seen, 1st, The opening of the mastoid cells,—irregular winding cavities, which are formed in the mastoid process, and which are alEAR EAU

ways filled with air; 2dly, The pyramid, a little hollow projection, which lodges the muscle of the stapes; 3dly, The opening by which the chorda tympani enters into the hollow of the tympanum. Below, the tympanum presents a slit, called glenoid, by which the tendon of the anterior muscle of the malleus enters, and the chorda tympani passes out, and goes to unite itself with the lingual nerve of the fifth pair.

Above, the circumference presents only a few small openings, by which blood-vessels pass. The cavity of the tympanum, and all the canals which end there, are covered with a very slender mucous membrane: this

the tympanum, and all the canals which end there, are covered with a very slender mucous membrane: this cavity, which is always full of air, contains besides four small bones, (the malleus, incus, os orbiculare, and stapes,) which form a chain from the membrana tympani to the fenestra ovalis, where the base of the stapes is fixed. There are some little muscles for the purpose of moving this osseous chain, of stretching and stackening the membranes to which they are attached: thus, the internal muscle of the malleus draws it forward, bends the chain in this direction, and stretches the membranes; the anterior muscle produces the contrary effect: it is also supposed that the small muscle which is placed in the pyramid, and which is attached to the neck of the stapes, may give a slight tension to the chain, in drawing it towards a slight tension to the chain, in drawing it towards itself

The internal ear, or labyrinth, is composed of the cochlea, of the semicircular canals, and of the ves-

The cochlea is a bony cavity, in form of a spiral, from which it has taken its name. This cavity is divided into two others, called the gyri of the cochlea, and which are distinguished into external and internal. The partition which separates them is a plate set edgeways, and which in its whole length is partly bony, and partly membranous. The external gyration communicates by the feneral gyration ends in the vestical gyration is the type of the type of the gyration gyration ends in the year. the tympanum; the internal gyration ends in the ves-

The semicircular canals are, three cylindrical cavi-ties, bent in a semicircular form, two of which are

ties, bent in a semicircular form, two of which are disposed horizontally, and the others vertically. These canals terminate by their extremities in the vestibule. They contain bodies of a gray colour, the extremities of which are terminated by swellings.

The vestibule is the central cavity, the point of union of all the others. It communicates with the tympanum by the feneral avails, with the internal gyration of the cochies, with the semicircular capals, and with of the cochlea, with the semicircular canals, and with the internal meatus auditorius, by a great number of

little openings.

The whole of the cavities of the internal ear are hollowed out of the hardest part of the petrous portion of the temporal bone: they are covered with an extremely thin membrane, and are full of a very thin and limpid fluid, called Liquor of Cotunnius, which can flow out by two narrow apertures, known by the name of the arealysis of the scalled the restriction.

flow out by two narrow apertures, known by the name of the aquaducts of the cochlea, and of the vestibule: they contain, besides, the acoustic nerve.

The acoustic nerve proceeds from the fourth ventricle; it enters into the labyrinth by the holes that the internal auditory meatus presents in its bottom. Having entered into the vestibule, it separates itself into a number of branches, one of which remains in the vestibule, another enters into the cochlea, and two go to the semicircular canals. Scarpa has very minutely described the distribution of these different branches in the cavities of the internal ear.

in the cavities of the internal ear.

In terminating this short description, we remark that the internal and middle ear are traversed by that the internal and middle ear are traversed by several nervous threads, the presence of which is, perhaps, useful to hearing. It is known that the facial nerve proceeds a considerable space in a canal of the petrous portion. In this canal it receives a small thread of the vidian nerve; it furnishes the chorda tympani, which attaches itself to this membrane. There are two other nervous inosculations in the ear; to one of which Ribes called the attention of anatomists not long since: the other was recently discovered. mists not long since; the other was recently discovered by Jacobson.

Earwax. See Cerumen aurium.

EART'TES. Hæmatites, or blood-stone.

EARTH. Terra. Although there seems to be an almost infinite variety of earthy substances scattered on the surface of this globe, yet when we examine them with a chemical eye, we find, not without sur-

prise, that all the earth and stones which we tread under our feet, and which compose the largest rocks, as well as the numerous different specimens which adorn the cabinets of the curious, are composed of a very few simple or elementary earths. "Analysis has shown, that the various stony or pulverulent masses, which form our mountains, valleys, and plains, might be considered as resulting from the combination or intermixture, in various numbers and proportions, of nine primitive earths, to which the following names were given:

1. Barytes. 2. Strontites. 3. Lime. 4. Magnesia. 5. Alumina, or clay. 6. Silica. 7. Glucina. 8. Zirconia. 9. Yttria.

Alkalies, acids, metallic ores, and native metals, were supposed to be of an entirely dissimilar consti-

The brilliant discovery by Sir H. Davy, in 1808, of the metallic bases of potassa, soda, barytes, strontites, and lime, subverted the ancient ideas regarding the

earths, and taught us to regard them as all belonging, by most probable analogies, to the metallic class.

To the above nine earthy substances, Berzelius has lately added a tenth, which he calls thorina. Whatever may be the revolutions of chemical nomenclature, manking will never cease to consider as carths. ever may be the revolutions of chemical nomenclature, mankind will never cease to consider as earths, those solid bodies composing the mineral strata, which are incombustible, colourless, not convertible into metals by all the ordinary methods of reduction, or when reduced by scientific refinements, possessing but an evanescent metallic existence, and which either alone, or at least when combined with carbonic acid, are insipid and insoluble in water.

Earth, absorbent. See Absorbent.

Earth, animal calcarcous. This term is applied to crab's-claws, &c. which contain calcareous earth, and are obtained from the animal kingdom.

Earth, argillaceous. See Alumina.

Earth, argillaceous. See Alumina. Earth-bath. A remedy recommended by some

Earth-bath. A remedy recommended by some writers on the continent, as a specific in consumption. Earth, bolar. See Bole.

Earth, fullers'. Cimolia purpurescens. A compact bolar earth, commonly of a grayish colour. It is sometimes applied by the common people to inflamed breasts, legs, &c. with a view of cooling them.

Earth, heavy. See Barytes.

Earth, Japan. See Acacia catechu.

Earth, mineral calcarcous. Those calcareous earths which are obtained from the mineral kingdom. The term is applied in opposition to those obtained from

term is applied in opposition to those obtained from animals.

Earth-nut. See Bunium bulbocastanum.

Earth, scaled. Terra sigillata. Little cakes of earths, which are stamped with impressions. They were formerly in high estimation as absorbents, but now fallen into disuse.

Earth-worm. See Lumbricus terrestris

Euton's styptic. French brandy highly impreg-nated with calcined green vitriol. A remedy for

nated with calcined green vitriol. A remedy for checking hæmorrhages.

[EATON, Amos, professor in the Rensselaer school, at Troy, in the state of New-York. Although Professor Eaton is still living, we deem it but justice to say, that he is one of the most industrious and indefatigable votaries of natural science in the state. He has lectured a number of years at Albany and Troy, on botany, mineralogy, and geology. He has published a valuable Manual of Botany for the Northern States, a Geological Section of the Country from Boston to Lake Erie, and a pamphlet, containing a "Geological Nomenclature for North America." He has been employed for seven years past, under the direcological Nomenclature for North America." He has been employed for seven years past, under the direction of the Hon. Stephen Van Rensselaer, in travelling over different parts of the state of New-York, and those adjoining, and in making geological surveys and examinations of strata. He has probably done more in this way than any geologist in the country. He promises to publish a System of American Geology, in which will be displayed some peculiarities of the formations in this country, and show how they differ from those of the Eastern continent. A.]

Eau-de-luce. See Spiritus ammoniæ succinatus.

Eau-de-rabel. This is composed of one part of sulphurous acid to three of rectified spirit of wine. It s much used in France, when diluted, in the cure of igonorrhœas, leucorrhœa, &c.

Ent'scus. See Hibiscus abelmoschus.
EBULLITION. (Ebullitio. From ebullio, to bubble up.) Boiling. This consists in the change which a fluid undergoes from a state of liquidity to that of an elastic fluid, in consequence of the application of heat, which dilates and converts it into

(From ebullio, to make boil: so called because of its supposed use in purifying the humours of the body.) See Sambucus chulus.

Ecbo Lica. (From εκβαλλω, to cast out.) Medi-

cines which cause abortion.

Ευβο'Lios. (From εκδαλλω, to cast out.) Miscar-

riage.

Echra'smata. (From εκδραζω, to be very hot.)

Ecchymata. Painful fiery pimples in the face, or surface of the body.

(From εκδραζω, to become hot.) Fer-

ECBRA'SMUS. (From εκδραζω, to become hot.) Fer-

Ecryrso'MATA. (Prom $\epsilon \kappa$, and $\beta \nu \rho \epsilon a$, the skin.) Protuberances of the bones at the joints, which appear through the skin.

ECCHYLO'MA. (From ex, and xulos, juice.) An

extract.

ECCHY MATA. (From εκχυω, to pour out.) See

Ecbrasmata

ECCHVMO'MA. (Εκχυμωμα; from εκχυω, to pour out.) Ecchymosis; Crustula; Sugillatio. Extravasation. A black and blue swelling, either from a bruise or spontaneous extravasation of blood. A genus of disease in the class Locales, and order Tumores of Cullen.

ECCHYMOMA ARTERIOSUM. The false aneurism. ECCHYMO'SIS. See Ecchymoma. E'CCLISIS. (From εκκλινω, to turn aside.) A luxation or dislocation.

E'CCOPE. (From εκκοπ 7ω, to cut off.) The cut-

ECCOPE. (From εκκοπ/ω, to cut off.) The cutting off any part.

Ecco'PĒUS. (From εκκοπ/ω, to cut off.) An ancient instrument, the raspatory, used in trepanning.

ECCOPRO'TIC. (Eccoproticus; from εκ, and κοπρος, dung.) An opening medicine, the operation of which is very gentle; such as manna, senna, &c.

ECCRINOCRI'TICA. (From εκκρινω, to secrete, and κρινω, to judge.) Judgments formed from the secretions.

ECCRINOLOGIA. (From εκκρινω, to secrete, and eyes, a discourse.) Eccrinologica. The doctrine of λογος, a discourse.) Eccrinologica.

E'CCRISIS. (From εκκρινω, to secrete.) A secretion of any kind.

ECCRITICA. (From εκκρινω, to secern, or strain off.) Dr. Good applies this name to a class of diseases of the excernent system. It has three orders, viz. Mesotica, Catotica, Acrotica.

ECCYESIS. (From εκ, and κυησις, gravidity.)

ECCYESIS. (From εκ, and κυησις, gravidity.)
Extra-uterine fortation. The name of a genus of diseases in Good's Nosology. It has three species: Eccyesis ovariæ, tubalis, abdominalis.
ECCYMO'SIS. See Ecchymoma.
ECDORA. (From εκότρω, to excoriate.) An excoriation: and particularly used for an excoriation of

the urethra.

Ecdo Ria. (From εκδερω, to excoriate.) Medicines which excoriate and burn through the skin.

ECHECO'LLON. (From εχω, to have, and κολλα, glue.) Echecollum. Any topical glutinous remedy.
ECHETRO'SIS. So Hippocrates calls the white

briony.

ECHINATUS. Bristly. Applied in botany to any thing beset with bristles, as the pod of Glycyrrhiza echinata, and to the gourd seed-vessel, or pepo.

ECHINI'DES. In Hippocrates it is mentioned as what he used for purging the womb with.

ECHINOPHTHA'LMIA. (From εχινος, a hedgehog, and οφθαλμια, an inflammation of the eye.) An inflammation of that part of the eyelids, where the hairs bristle out like the quills of an echinus, or hedgehog.

ECHINOPO DIUM. (From εχιτος, a hedge-hog, and πους, a foot; so named because its flowers resemble the foot of an urchin.) A species of broom or

ECHI'NOPS. (From extros, as beset with prickles.)
The name of a genus of plants. Class, Syngenesia;
Order, Polygamia segregata.

ECHINOPS SPHEROCEPHALUS. The systematic name

of the globe-thistle. Crocodilion; Acanthairuca; Scabiosa carduifolia; Spharocephala elatis; Echinopus. It is raised in our gardens. The root and seeds are moderately diuretic, but not used.

ECHINUS. 1. The hedge-hog, or Erinaceus Eu-

ropaus of Linnaus.

2. A genus in the Linnaus system, included in the molusca order of vermes.

 The calcareous petrifaction of the sea hedge-hog.
 The prominent points on the surface of the pileus, or upper part of the mushroom tribe, are called echini.

See Fungus.

ECHIOIDES. (From εχις, a viper, and ειδος, resemblance.) The trivial name of some plants, from their supposed resemblance to the Echium.

E'CHIUM. (From εχις, a viper; so called because it was said to heal the stings of vipers.) The name of a genus of plants in the Linnæan system. Class, Fentandria; Order, Monogynia. Viper's bugloss.

ECHIUM EGYPTIACUM. Wall bugloss. The Asperugo ægyptiaca, the root of which is sudorific, and is used with oil as a dressing for wounds.

E'CHOS. Ηχος. Sound. In Hippocrates, it signifies the same as the tinnitus aurlum, or noise in the ears.

E'CHYSIS. (From εχυω, to pour out.) A fainting

ECLA MPSIA. (From εκλαμπω, to shine.

ECLA'MPSIS. (From εκλαμπω, to shine. Eclamp sia. It signifies a splendour, brightness, effulgence, flashing of light, scintillation. It is a flashing light, or those sparklings which strike the eyes of epileptic patients. Culius Aurelianus calls them circuli ignei, scintillations, or fiery circles. Though only a symptom of the epilepsy, Hippocrates puts it for epilepsy

ECLE CTIC. (Eclecticus; from εκλεγω, to select.) Archigenes and some others selected from all other sects what appeared to them to be the best and most rational; hence they were called Edectics, and their

medicine Eclectic medicine.

ECLE CTOS. (From εκλειχω, to lick up. A linctus, or soft medicine, like an electuary, to be licked up.

ECLE GMA. (From εκλειχω, to lick.) A linctus, or form of medicine made by the incorporation of oils with syrups, and which is to be taken upon a liquor-

ice stick. E'CLYSIS. (From εκλυω, to dissolve.) A uni-

versal faintness.

ECMA'GMA. (From εκμασσω, to form together.)

A mass of substances kneaded together.

ECPEPIE'MENOS. (From εκπιεζω, to press out.)

An ulcer with protuberating lips.

ECPHLYSIS. (Εκφλυσις; from εκφλυζω, to boil, or bubble up, or over.) A blain, or vesicular eruption. The name of a genus of disease in Good's Nosology. It has four species, viz. Ecphlysis pompholex, herpes,

It has four species, VIZ. Exphiysis pomphotex, herpes, rhypia, and eczema.

ECPHRA'CTIC. (From εκφρασσω, to remove obstructions. That which attenuates tough humours, so as to promote their discharge.

ECPHRA'XIS. (From εκφρασσω, to remove obstruction.) A perspiration, an opening of obstructed

ECPHRONIA. (Εκφρωνε, οτ εκφροσυνη, from εκφρων, extra mentem, out of one's mind.) The name of a genus in Good's Nosology. Insanity and craziness. It has two species: Ecphronia melancholia, and Ecphronia mania.

E'CPHYAS. (From ex, and ovo, to produce.) 1.

An appendix, or excrescence.

2. The appendicula cæci vermiformis.

ECPHYMA. (From εκφυω, educo, egero.) A cutaneous excrescence. The name of a genus of diseases in Good's Nosology. Class, Eccritica; Order, Acrotia. It has four species, viz. Ecphyma caruncula, verruca, clavus, and callus.

E/CEPYSE. (From exchanges to blow out.) Flatus

E'cphyse. (From εκφυσαω, to blow out.) Fiatus from the bladder through the urethra, and from the wound through the vagina.

ECPHYSE'SIS. (From εκφυσαω, to breathe through.)
A quick expulsion of the air from the lungs.
E'CPHYSIS. (From εκφυω, to produce.)
1. An apophysis, or appendix.

2. A process.

Ecpie'sma. (From εκπιεζω, to press out.) A fracture of the skull, in which the bones press inwardly. Ecpie'smos. (From εκπιεζω, to press out.) A disorder of the eye, in which the globe is almost pressed out of the socket by an afflux of humours.

Ecplero'ma. (From εκπληροω, to fill.) In Hippocrates they are hard balls of leather, or other substances, adapted to fill the arm-pits, while by the help of the heels, placed against the balls, and repressing the same, the luxated os humeri is reduced into its place.

ECPLE'XIS. (From εκπλησω, to terrify or astonish.) A stupor, or astonishment, from sudden external acci-

E'CPNOE. (From εκπρεω, to breathe.) Expiration; that part of respiration in which the air is expelled from

ECPTO'MA. (From εκπιπ7ω, to fall out.) 1. A

luxation of a bone.

2. The expulsion of the secundines. The falling off of gangrenous parts.
 A hernia in the scrotum.

A herma in the scrotum.
 A falling down of the womb.
 Ecry'ctica. (From εκπυκαζω, to condense.) Medicines that render the fluids more solid.
 ECPYE'MA. (From εκ, από πυον, pus.) A collection of pus, from the suppuration of a tumour.
 ECPYESIS. (From εκπυω, to suppurate.) The name of a genus of diseases in Good's Nosology.
 Class, Eccritica; Order, Acrotica. Humid scalp. It has four species, Ecpyesis impetigo, porrigo, ecthyma, scabies.

ECRE'GMA. (From εκρηγνυμι, to break.) A rup-

ECRE'XIS. (From εκρηγυρμι, to break.) A rupture. Hippocrates expresses by it a rupture or laceration the womb.

ECHRY THMOS. (From εκ, and ρυθμος, harmony.) A term applied to the pulse, and signifies that it is irre-

E'CROE. (From εκρεω, to flow out.) An efflux, or the course by which any humour which requires purging is evacuated.

Ecrucles. The French for scrofula.

E'CRYSIS. (From εκρεω, to flow out.) In Hippocrates it is an efflux of the semen before it receives the conformation of a fœtus, and therefore is called an efflux, to distinguish it from abortion.

ECSARCO'MA. (From ex, and σαρξ, flesh.)

fleshy excrescence

ECSTASIS. (Ecstasis, eos. f. Εκςασις; from εξιςα-μαι, to be out of one's senses.) An ecstasy, or trance. In Hippocrates it signifies a delirium.

Ecstro' Phius. (From εκςρεφω, to invert.) An epithet for any medicine, that makes the blind piles

appear outwardly.

ECTHELY'NSIS. (From εκθελυνω, to re nder effeminate.) Softness. It is applied to the skin and flesh, when lax and soft, and to bandages, when not sufficiently tight.

ECTHLI'MMA. (From εκθλίδω, to press out against.)
An ulceration caused by pressure of the skin.

ECTHLI'PSIS. (From εκθγίδω, to press out against.)
Elision, or expression. It is spoken of swelled eyes, when they dart forth sparks of light.

E'CTHYMA. (Ecthyma, atis. n. εκθυειν, to rage, or press forth with fury.)

A pustule or cutaneous graph.

break forth with fury.) A pustule or cutaneous erup-

ECTILLO ΤΙCA. (From εκ 7ελλω, to pull out.) Medicines which eradicate tubercles or corns, or destroy superfluous hair.

ECTO PIA. (From εκ 7οπος, out of place.) Dis-

placed.

ECTOPIE. (The plural of ectopia.) Parts displaced. An order in the class locales of Cullen's Nosology. See Nosology.

ECTRAPELOGA'STROS. (From εκ ζοεπομαι, to degenerate, and γαςηρ, a belly.) One who has a monstrous belly, or whose appetite is voraciously large.

ECTRI MMA. (From εκ ζρεδω, to rub off.) An excoriation. In Hippocrates it is an exulceration of the

skin about the os sacrum.

E'CTROPE. (From εκ/οεπω, to divert, pervert, or invert.) It is any duct by which the humours are diverted and drawn off. In P. Ægineta it is the same as Ectro-Pium. ECTRO'PIUM. (From εκ/ρεπω, to evert.)

eversion of the eyelids, so that their internal surface is outermost.

There are two species of this disease: one produced by an unnatural swelling of the lining of the eyelids, which not only pushes their edges from the eyeball, but also presses them so forcibly, that they become everted; the other arising from a contraction of the skin covering the eyelid, or of that in the vicinity, by which means the edge of the eyelid is first removed for some distance from the eye, and afterward turned completely outward, together with the whole of the affect ed eyelid.

The morbid swelling of the lining of the eyelids, which causes the first species of ectropium, arises mostly from a congenital laxity of this membrane, afterward increased by chronic ophthalmies, particularly of a scrofulous nature, in relaxed, unhealthy subjects; or else the disease originates from the small-pay affecting the eyes

pox affecting the eyes

While the disease is confined to the lower eyelid, as it most commonly is, the lining of this part may be ob-served rising in the form of a semilunar fold, of a pale red colour like the fungous granulations of wounds, and intervening between the eye and eyelid, which lat-ter it in some measure everts. When the swelling is afterward occasioned by the lining of both the eyelids, the disease assumes an annular shape, in the centre of which the eyeball seems sunk, while the circumtre of which the eyebair seems sunk, while the circum-ference of the ring presses and everts the edges of the two eyelids, so as to cause both great uneasiness and deformity. In each of the above cases, on pressing the skin of the eyelids with the point of the finger, it be-comes manifest that they are very capable of being elongated, and would readily yield, so as entirely to cover the eyeball, were they not prevented by the intervening swelling of their membranous lining.

Besides the very considerable deformity which the disease produces, it occasions a continual discharge of tears over the cheek, and, what is worse, a dryness of the eyeball, frequent exasperated attacks of chronic ophthalmy, incapacity to bear the light, and, lastly opacity and ulceration of the cornea.

The second species of ectropium, or that arising from a contraction of the integuments of the eyelids, are neighbouring parts, is not unfrequently a consequence of the eyelids.

from a contraction of the integuments of the eyelids, or neighbouring parts, is not unfrequently a consequence of puckered scars, produced by a confluent small-pox, deep burns, or the excision of cancerous or encysted tumours, without saving a sufficient quantity of skin; or, lastly, the disorder is the effect of malignant carbuncles, or any kind of wound attended with much loss of substance. Each of these causes is quite enough to bring on such a contraction of the skin of the eyelids as to draw the parts towards the arches of the eyelids as to draw the parts towards the arches of the orbits, so as to remove them from the eyeball, and turn their edges outward. No sooner has this circumstance happened, than it is often followed by another one equally unpleasant, namely, a swelling of the internal membrane of the affected eyelids, which afterward has a great share in completing the eversion. The lining of the eyelids, though trivially everted, being continually exposed to the air, and irritation of extraneous substances, soon swells, and rises up like fungus. One side of this fungous-like tumour covers a part of the eyeball; the other pushes the eyelid so considerably outwards, that its edge is not unfrequently in contact with the margin of the orbit. The complaints induced by this second species of ectropium are the same as those brought on by the first; it being noticed, however, that in both cases, whenever the disease is very inveterate, the fungous swelling of the inside of the eyelids becomes hard, and as it were callous.

Although, in both species of ectropium, the lining of the eyelids seems equally swollen, yet the surgeon can easily distinguish to which of the two species the disease belongs. For, in the first, the skin of the eyelids, and adjoining parts, is not deformed with scars; and by pressing the everted eyelid with the point of the finger, the part would with ease cover the eye, were it not for the intervening fungous swelling. But in the second species of ectropium, besides the obvious cicatrix and contraction of the skin of the cyclids, or adjacent parts, when an effort is made to cover the eye with the everted eyelid, by pressing upon the latter part with the point of the finger, it does not give way so as completely to cover the globe, as it ought to do, only yielding for a certain extent: or it does not move in the least from its unnnatural position, by reason of the the eyelids as to draw the parts towards the arches of the orbits, so as to remove them from the eyeball, and

least from its unnnatural position, by reason of the

integuments of the eyelids having been so extensively destroyed, that their margin has become adherent to the arch of the orbit. ECTROSIS. (Εκτρωσις; from εκζιζρωσκω, to mis-

carry.) A miscarriage.

Ectro'tica. (From εκλίλρωσκω, to miscarry.) Ectyrotica; Ectylotica. Medicines which cause abor-

ECTYLO'TICA. See Ectillotica.
ECTYRO'TICA. See Ectrotica.
ECZE'MA. (From εκζεω, to boil out.) Eczesma. A hot, painful eruption, or pustule,
EDE'LPHUS. The prognosis of a disease from the nature of elements.

EDULCORA'NTIA. (From edulco, to make sweet.) Edulcorants. Medicines which purify the fluids, by

depriving them of their acrimony.

EFFERVESCENCE. (Effervescentia; from effervesco, to grow hot.) 1. That agitation which is produced by mixing substances together, which cause the

evolution of a gas.

2. A small degree of ebullition.

E'ffila. Freckles.

EFFLORESCENCE. (Efflorescentia; from effloresce, to blow as a flower.) T. In pathology, it is used to express a morbid redness of the skin, and is generally

rally synonymous with exanthema.

2. In chemistry, it means that effect which takes place when bodies spontaneously become converted into a dry powder. It is almost always occasioned by the loss of the water of crystallization in saline bodies.

3. In botany, it is applied to express the blooming of flowers, and the time of flowering.

EFFLU'VIUM. (From effuo, to spread abroad.)

See Contagion.

EFFRACTU'RA. (From effringe, to break down.) A fracture, in which the bone is much depressed by the blow

blow.

EFFUSION. (Effusio; from effundo, to pour out.)
In pathology it means the escape of any fluid out of
the vessel, or viscus, naturally containing it, and its
lodgment in another cavity, in the cellular substance,
or in the substance of parts. Effusion also sometimes
signifies the morbid secretion of fluids from the vessels; thus physicians frequently speak of coagulable
lymph being effused on different surfaces.

EGERAN. A sub-species of pyramidal garnet of a
reddish-brown colour.

reddish-brown colour.

EGERAN. A sub-species of pyramidal garnet of a reddish-brown colour.

Ege'ries. (From egero, to carry out.) Egestio. An excretion, or evacuation.

EGG. Ovum. The eggs of hens, and of birds in general, are composed of several distinct substances.

1. The shell or external coating, which is composed of carbonate of time .72, phosphate of lime .2, gelatine .3. The remaining .23 are perhaps water. 2. A thin white and strong membrane, possessing the usual characters of animal substances. 3. The white of the egg, for which, see Albumen. 4. The yelk, which appears to consist of an oil of the nature of fat oils, united with a portion of serous matter, sufficient to render it diffusible in cold water, in the form of an emulsion, and concrecible by heat. Yelk of egg is used as the medium for rendering resins and oils diffusible in water. The eggs of poultry are chiefly used as food, the different parts are likewise employed in pharmacy and in medicine. The calcined shell is esteemed as an absorbent. The oil is softening, and is used externally to burns and chaps. The yelk renders oil miscible with water, and is triturated with the same view with resinous and other substances. Raw eggs have been much recommended as a popular remedy for jaundice.

Eggerof page. (From syggregores, to watch.) A jaundice.

EGREGO'RSIS. (From εγρηγορεω, to watch.) A watchfulness, or want of sleep.
Ει' LAMIS. (From ειλεω, to involve.) A membrane

involving the brain.

ELLE'MA. (From ειλεω, to form convolutions.) In Hippocrates, it signifies painful convolutions of the intestines from flatulence. Sometimes it signifies a covering. Vogel says, it is a fixed pain in the bowels, as if a nail was driven in.

El'LEON. (From ειλεω, to wind.) Gorræus says it is a name of the intestinum ileum.

El'LEOS. (From ειλεω, to form convolutions.) The

Et'LEOS. (From ειλεω, to form convolutions.) The

Er'sBole. (From εις, into, and βαλλω, to cast.) It

signifies strictly an injection, but is used to express the access of a distemper, or of a particular paroxysm.

Et'spnoe. (From es, into, and nrew, to breathe.) Inspiration of air.

EJACULA'NTIA. (From ejaculo, to east out.)

Ejaculatoria. The vessels which convey the seminal matter secreted in the testicles to the penis. These are the epididymis, and the vasa deferentia; the vesiculæ seminales are the receptacles of the semen.

EJE'CTIO. (From ejicio, to cast out.) Ejection, or the discharging of any thing from the body.

ELACA'LLI. The Indian name of a cathartic shrub, the Euphorbia mervifolia, of Linnæus.

the Euphorbia mervifolia, of Linnaus. ΕLEA'GNON. (From ελαιον, oil, and αγνος, chaste.)

See Vitez agnus castus.

ELÆO'MELL (From ελαιον, oil, and μελι, honey.)
A sweet purging oil, like honey.
ELÆOSA'CCHARUM. (From ελαιον, oil, and σακχαφον, sugar.) A mixture of an essential oil with sugar.

ELEOSELI'NUM. See Eleoselinum.
ELAIN. The oily principle of solid fats, so named by its discoverer, Chevreuil, who dissolves tallow in very pure hot alkohol, separates the stearin by crystallization, and then procures the elain by evaporation tallization, and then procures the claim by evaporation of the spirit. Braconnot has adopted a simpler, and probably a more exact method. By squeezing tallow between the folds of porous paper, the claim soaks into it, while the stearin remains. The paper being then soaked in water, and pressed, yields up its oily impregnation. Elain has very much the appearance and properties of vegetable oil. It is liquid at the temperature of 60°. Its smell and colour are derived from the solid fats from which it is extracted.

["Mr. Pictet" method, of procuring claims, consists

["Mr. Pictet's method of procuring elaine, consists in pouring upon oil a concentrated solution of caustic soda, stirring the mixture, heating it slightly to separate the elaine from the soap of the stearine, pouring it on a cloth, and then separating by decantation the elaine from the excess of alkaline solution.—Webster's

Man. of Chemistry. A.]

ELAIS GUINEZ'NSIS. A species of palm which grows spontaneously on the coast of Guinea, but is much cultivated in the West Indies. It is from this tree that the oil, called in the West Indies Mackaw fat, is obtained: and, according to some, the palm-oil, which is considered as an emollient and strengthener of all kinds of weakness of the limbs. It also is recommended against bruises, strains, cramps, pains, swellings, &c. ELAMBICA'TIO. A method of analyzing mineral

ELAOLITE. A subspecies of pyramidal felspar. ELAPHOBO SCUM. (From ελαφος, a stag, and βοσκω, to eat: so called, because deer eat them greedily.) See Pastinaca.

iy.) See Pastinaca.

ELAPHOSCO'RODON. (From ελαφος, the stag, and σκοροδον, garlic.) Stag's or viper's garlic.

ELA'SMA. (From ελαννω, to drive.) A lamina of any kind. A clyster-pipe.

ELASTIC. (Elasticus; from ελαςης, impulsor, or of ελαννειν, to impel, to push.) Springy; having the power of returning to the form from which it has been forced to deviate, or from which it is withheld; thus, a blade of steel is said to be elastic, because if it is bent to a certain degree, and then let go, it will of itself return to its former situation; the same will happen to the branch of a tree, a piece of Indian rubber, pen to the branch of a tree, a piece of Indian rubber,

&c. See Elasticity.

Elastic fluid. See Gas.

Elastic gum. See Caoutchouc.

ELASTICITY. Elasticitas. A force in bodies, by
which they endeavour to restore themselves to the posture from whence they were displaced by any ex-ternal force. To solve this property, many have re-course to the universal law of nature, attraction, by which the parts of solid and firm bodies are caused to cohere together: whereby, when hard bodies are struck or bent, so that the component parts are a little moved from one another, but not quite disjoined or broken off, nor separated so far as to be out of the power of the attracting force, by which they cohere together; they certainly must, on the cessation of the external violence, spring back with a very great velocity to their former state. But in this circumstance, the atmospherical pressure will account for it as well; which the parts of solid and firm bodies are caused to because such a violence, if it he not great enough to

separate the constituent particles of a body far enough to let in any foreign matter, must occasion many vacuola between the separated surfaces, so that upon the removal of the external force, they will close again by the pressure of the aerial fluid upon the external parts, i. e. the body will come again into its natural posture. The included air, likewise, in most bodies, gives that power of resilition upon their percussion.

If two bodies perfectly elastic strike, one against another, there will be or remain in each the same relative velocity as before, i. e. they will recede with the same velocity as they met together. For the compressive force, or the magnitude of the stroke in any given bodies, arises from the relative velocity of those bodies, and is proportional to it, and bodies perfectly elastic will restore themselves completely to the figure they had before the shock; or, in other words, the restihad before the shock; or, in other words, the resti-tutive force is equal to the compressive, and therefore must be equal to the compressive, and therefore must be equal to the force with which they came together, and consequently they must, by elasticity, recede again from each other with the same velocity. Hence, taking equal times before and after the shock, the distances between the bodies will be equal: and therefore the distances of them from the common central transfer will in the same times be equal. tre of gravity will, in the same times, be equal. And hence the laws of percussion of bodies perfectly elastic are easily deduced.

(From ελαυνω, to stimulate or ELATE RIUM. agitate; so named from its great purgative qualities.)

agitate: so named from its great purgative qualities.) See Momordica elaterium.

["The Momordica elaterium is a perennial plant, growing spontaneously in the south of Europe. The fruit, which is botanically allied to the cucumber and melon, has the curious property of separating itself, when ripe, from its stalk, and ejecting its seeds with great force through an opening in the base, where the stalk was attached. The medicinal property resides chiefly in the juice at the centre of the fruit, and about the seeds. The drug called Elaterium in our Pharmacopeia, and which the London College have, with some latitude of application, called an extract, is the sediment which subsides from the juice of the fruit after it has been drawn out. The quantity of genuine elaterium contained in a single fruit is extremely small, as it appears that only six grains were obtained by as it appears that only six grains were obtained by Dr. Clutterbuck from forty of the cucumbers.

plant might be raised in this country.
"Elaterium is sold in small, thin cakes, or fragments of a greenish colour, and a bitter and somewhat acrid taste. It is liable to vary in strength, according to the mode of its preparation. If the juice has been extracted with much pressure, the sediment contains portions of the fruit which are comparatively inactive, and which, of course, tend to lessen its activity. In selecting elaterium, those specimens which have a very dark colour, are compact and heavy, and break with a shining resinous fracture, are to be rejected as

"This drug is one of the most violent cathartics. It was employed by the ancients as a hydragogue in dropsy, in a form not dissimilar to that used at the present day. It was also used by the Arabians, and in more modern times by Boerhaave, Sydenham, and Lister. Quite recently it has been highly recommended in dropsy by some distinguished English physicians, and their practice has been successfully imitated in this country; although the great uncertainty of its operation has repeatedly caused it to be abandoned. It has the peculiar property of not only nor "This drug is one of the most violent cathartics. of its operation has repeatedly caused it to be abandoned. It has the peculiar property of not only purging, but at the same time exciting a febrile action, which Lister describes as attended with a throbbing that is felt to the fingers' ends. Orfila found that a large dose, given to a dog, brought on inflammation of the stomach, but when injected in two cases into the cellular texture of the thigh, the rectum was the only part of the canal which became inflamed. Hence he concludes, that the medicine has some peculiar action concludes, that the medicine has some peculiar action

on that organ. "The uncertainty arising from the different prepa-"The uncertainty arising from the different preparations of this medicine may be inferred from the circumstance, that Fallopius gave it in doses of a drachm, while Dr. Clutterbuck found one-eighth of a grain to purge violently. The strength of any particular parcel ought always to be tested by small doses, before it is ventured on in any considerable quantity. Of the article imported into this country, I have given from one to two grains in a pill three times a day, without any

excessive operation resulting from it."-Big. Mat

Med. A.]

ELATHE'RIA. A name for the cascarilla bark.

ELATIN. The active principle of elaterium. See

Momordica elaterium.

ELATINE. (From ελα]των, smaller, being the

smaller species.) See Antirrhinum elatine.

ELATIO. Elevated, exalted. This term is applied in Good's Nosology, to a species of the genus

Alusio, to designate mental extravagance.

ELATITES. Bloodstone.

ELCO'SIS. (From the ELCO'SIS. (From ελκος, an ulcer.) A disease attended with fœtid, carious, and chronic ulcers. The term is seldom used. ELDER. See Sambucus.

Elder, dwarf. See Sambucus Ebulus. ELECAMPANE. See Inula helenium.

ELECTIVE. That which is done, or passes, by

ELECTIVE. That which is done, or passes, by election.

Elective affinity, double. See Affinity double.

Elective attraction. See Affinity.

Elective attraction, double. See Affinity double

ELECTRICITY. (Electricitas; from electrum, ηλεκτρον, from ηλεκ/ωρ, the sun, because of its bright shining colour; or from ελκω, to draw, because of its magnetic power.) A property which certain bodies possess when rubbed, heated, or otherwise excited, whereby they attract remote bodies, and frequently emit sparks or streams of light. The ancients first observed this property in amber, which they called Electrum, and hence arose the word electricity.

"If a piece of sealing-wax and of dry warm flannel be rubbed against each other, they both become capable of attracting and repelling light bodies. A dry and warm sheet of writing-paper, rubbed with India rubber, or a tube of glass rubbed upon silk, exhibit the same phenomena. In these cases, the bodies are said to be electrically excited; and when in a dark room, they always appear luminous. If two pith-balls be electrified by touching them with the sealing-wax, or with the flannel, they repel each other; but if one pith-ball be electrified by the wax, and the other by the flannel, they attract each other. The same applies to the glass and silk: it shows a difference in the electricities of the different bodies, and the experiment leads to the conclusion, that bodies similarly electrified renet cities of the different bodies, and the experiment leads to the conclusion, that bodies similarly electrified repel each other; but that when dissimilarly electrified, they attract each other.

The term electrical repulsion is here used merely to denote the appearance of the phenomenon, the separation being probably referrible to the new attractive power which they acquire, when electrified, for the air and other surrounding bodies.

If one ball be electrified by sealing-wax rubbed by flannel, and another by silk rubbed with glass, those balls will repel each other; which proves that the electricity of the silk is the same as that of the sealingwax. But if one ball be electrified by the sealing-wax and the other by the glass, they then attract each other, showing that they are oppositely electrified.

other, showing that they are oppositely electrified.

These experiments are most conveniently performed with a large downy feather, suspended by a silken thread. If an excited glass tube be brought near it, it will receive and retain its electricity; it will be first attracted and then repelled; and upon re-exciting the tube, and again approaching it, it will not again be attracted, but retain its state of repulsion; but upon approaching it with excited sealing-wax, it will instantly be attracted, and remain in contact with the wax till it has acquired its electricity, when it will be repelled. be attracted, and remain in contact with the wax intit has acquired its electricity, when it will be repelled, and in that state of repulsion it will be attracted by the glass. In these experiments, care must be taken that the feather remains freely suspended in the air, and touches nothing capable of carrying off its elec-

The terms vitreous and resinous electricity were applied to these two phenomena; but Franklin, observing that the same electricity was not inherent in serving that the same electricity was not inherent in the same body, but that glass sometimes exhibited the same phenomena as wax, and viceversa, adopted another term, and instead of regarding the phenomena as dependent upon two electric fluids, referred them to the presence of one fluid, in excess in some cases, and in deficiency in others. To represent these states, he used the terms plus and minus, positive and negative. When glass is rubbed with silk, a portion of electricity leaves the silk, and enters the glass; it becomes poeitive, therefore, and the silk negative: but when sealing-wax is rubbed with flannel, the wax loses, and the flannel gains; the former, therefore, is negative, and the latter positive. All bodies in nature are thus regarded as containing the electric fluid, and when its equilibrium is disturbed, they exhibit the phenomena just described. The substances enumerated in the following table become positively electrified when rubbed with those which follow them in the list; but with those which precede them they become negatively electrical.—Biot, Traité de Physique, tom ii. p. 220.

Cat's-skin.

Paper.

Polished glass.

Silk.

Cat's-skin. Polished glass. Woolen cloth. Silk. Gum lac: Feathers. Rough glass.

Feathers. Rough glass.

Very delicate pith-balls, or strips of gold leaf, are usually employed in ascertaining the presence of electricity; and by the way in which their divergence is effected by glass or sealing-wax, the kind or state of electricity is judged of. When properly suspended or mounted for delicate experiments, they form an electrometer or electroscope. For this purpose, the slips of gold leaf are suspended by a brass cap and wire in a glass cylinder: they hang in contact when unelectrified, but when electrified they diverge.

When this instrument, as usually constructed, becomes in a small degree damp, its delicacy is much diminished, and it is rendered nearly useless.

The kind of electricity by which the gold leaves are

The kind of electricity by which the gold leaves are diverged may be judged of by approaching the cap of the instrument with a stick of excited sealing-wax; if the leaves will collapse, upon the principle of the mu-tual annihilation of the opposite electricities, or that bodies similarly electrified repel each other, but that when dissimilarly electrified, they become mutually attractive.

Some bodies suffer electricity to pass through their Some bodies suffer electricity to pass through their substance, and are called conductors. Others only receive it upon the spot touched, and are called nonconductors. The former do not, in general, become electrified by friction, and are called non-electrics: the latter, on the contrary, are electrics, or acquire electricity by friction. They are also called insulators. The metals are all conductors; dry air, glass, sulphur, and resins, are non-conductors. Water, damp wood, spirit of wine, damp air, and some oils, are imperfect conductors. conductors.

Rarified air admits of the passage of electricity; so does the Jarricellian vacuum; hence, if an electrified body be placed under the receiver of the air-pump, it

body be placed under the receiver of the air-pump, it loses its electricity during exhaustion. So that the air, independent of its non-conducting power, appears to influence the retentive properties of bodies, in respect to electricity, by its pressure.

There appears to be no constant relation between the state of bodies and their conducting powers: among solids, metals are conductors; but gums and resins are non-conductors: among liquids, strong alkaline acid, and saline solutions, are good conductors; pure water is an imperfect conductor, and oils are non-conductors: is an imperfect conductor, and oils are non-conductors; solid wax is almost a non-conductor; but when melted

a good one.

Conducting powers belong to bodies in the most opposite states; thus, the flame of alkohol and ice are equally good conductors. Glass is a non-conductor when cold, but conducts when red-hot: the diamond is a non-conductor; but pure and well-burned char-coal is among the best conductors.

There are many mineral substances which show signs of electricity when heated, as the tourmalin, topaz, diamond, boracite, &c., and in these bodies the different surfaces exhibit different electrical states.

Whenever one part of a body, or system of bodies, is positive, another part is invariably negative; and these opposite electrical states are always such as exactly to neutralize each other. Thus, in the common electrical machine, one conductor receives the electricity of the glass-cylinder, and the other that of the silk-rubber, and the former conductor is positive, and the latter negative; but, if they be connected, all electrical phenomena cease. trical phenomena ceas

Electricians generally employ the term quantity to indicate the absolute quantity of electric power in any body, and the term intensity, to signify its power of passing through a certain stratum of air, or other ill-conducting medium.

If we suppose a charged Leyden phial to furnish a spark, when discharged, of one inch in length, we should find that another uncharged Leyden phial, the should find that another uncharged Leyden phial, the inner and outer coating of which were communicated with those of the former, would, upon the same quantity of electricity being thrown in, reduce the length of the spark to half an inch; here the quantity of electricity remaining the same, its intensity is diminished by one-half, by its distribution over the larger surface. It is obvious that the extension of surface alluded to in the last paragraph will be attended with a greater superficial exposure to the unelectrified air; and hence it might be expected that a similar diminution of in

in the last paragraph will be attended with a greater superficial exposure to the unelectrified air; and hence it might be expected that a similar diminution of intensity would result from the vicinity of the electrified surface to the ground, or to any other body of sufficient magnitude in its ordinary state. That this is the case, may be shown by diverging the leaves of the gold leaf electrometer, and in that state approaching the instrument with an uninsulated plate, which, when within half an inch of the electrometer plate, will cause the leaves to collapse; but, on removing the uninsulated plate, they will again diverge, in consequence of the electricity regaining its former intensity. The same fact is shown by the condensing electrometer.

The power of the Leyden jar is proportioned to its surface; but a very large jar is inconvenient and difficult to procure; the same end is attained by arranging several jars, so that by a communication existing between all their interior coatings, their exterior being also united, they may be charged and discharged as one jar. Such a combination is called an electrical battery, and is useful for exhibiting the effect of accumulated electricity.

The discharge of the battery is attended by a considerable report, and if it be passed through small animals, it instantly kills them; if through fine metallic wires, they are ignited, melted, and burned; and gunpowder, cotton sprinkled with powdered resin, and a variety of other combustibles, may be inflamed by the same means.

There are many other sources of electricity than

same means.

There are many other sources of electricity than those just noticed. When glass is rubbed by mercury, it becomes electrified; and this is the cause of the luminous appearance observed when a barometer is agitated in a dark room, in which case flashes of light are seen to traverse the empty part of the tube. Even the friction of air upon glass is attended by electrical excitation: for Wilson found, that by blowing upon a dry plate of glass-with a pair of bellows, it acquired a positive electricity. Whenever bodies change their forms, their electrical states are also altered. Thus, the conversion of water into vapour, and the congelation of melted resins and sulphur are processes in which electricity is also rendered sensible.

When an insulated plate of zinc is brought into

which electricity is also rendered sensible.

When an insulated plate of zinc is brought into contact with one of copper or silver, it is found, after removal, to be positively electrical, and the silver or copper is left in the opposite state.

The most oxidisable metal is always positive, in relation to the least oxidisable metal, which is negative, and the more opposite the metals in these respects the greater the electrical excitation; and if the metals he placed in the fullowing order, each will become be placed in the following order, each will become positive by the contact of that which precedes it, and negative by the contact of that which follows it; and the greatest effect will result from the contact of the most distant metals.

Platinum. Mercury. Tin. Lead. Gold. Copper. Iron. Zinc. Silver.

Silver. Iron. Zinc.

If the nerve of a recently killed frog be attached to a silver probe, and a piece of zinc be brought into the contact of the muscular parts of the animal, violent convulsions are produced every time the metals thus connected are made to touch each other. Exactly the same effect is produced by an electric spack, or the discharge of a very small Leyden-phial.

If a piece of zinc be piaced upon the tongue, and a piece of silver under it, a peculiar sensation will be perceived every time the two metals are made to touch.

In these cases the chamical properties of the metals are observed to be acceted. If a silver and zinc wire be put into a wise glass full of dilute sulphuric acid, the zinc wire will only evolve gas; but upon bringing the two wires in contact with each other, the silver will also copiously produce air bubbles.

If a number of alterations be made of copper or silver.

ver leaf, zinc leaf, and thin paper, the electricity ex-cited by the contact of the metals will be rendered evident to the common electrometer.

If the same arrangement be made with the paper moistened with brine, or a weak acid, it will be found, on bringing a wire communicating with the last copper plate into contact with the first zine plate, that a spark is perceptible, and also a slight shock, provided the number of alternations be sufficiently numerous. This

number of alternations be sufficiently numerous. This is the voltaic apparatus.

Several modes of constructing this apparatus have been adopted, with a view to render it more convenient or active. Sometimes double plates of copper and zinc soldered together, are cemented into wooden troughs in regular order, the intervening cells being filled with water, or saline, or acid solutions.

Another form consists in arranging a row of glasses, containing dilute sulphuric acid, in each of which is placed a wire, or plate of silver, or copper, and one of zinc, not touching each other, but so connected by metallic wires, that the zinc of the first cup may communicate with the copper of the second; the zinc of the second with the copper of the third; and so on throughout the series.

When the poles of the Voltaic apparatus are con-

When the poles of the Voltaic apparatus are connected by a steel wire, it requires magnetic properties, and if by a platiaum, or other metallic wire, that wire exhibits numerous magnetic poles, which attract and repel the common magnetic needle. This very curious fact was first observed by Professor Oersted, of Copen-

On immersing the wires from the extremes of this apparatus into water, it is found that the fluid suffers decomposition, and that oxygen gas is liberated at the positive wire or pole, and hydrogen gas at the negative

All other substances are decomposed with similar phenomena, the inflammable element being disengaged at the negatively electrical surface; hence it would appear, upon the principle of similarly electrified bodies repelling each other, and dissimilarly electrified bodies attracting each other, that the inherent or natu-ral electrical state of the inflammable substances is ral electrical state of the inflammable substances is positive, for they are attracted by the negative or oppositely electrified pole; while the bodies, called supporters of combustion, or acidifying principles, are attracted by the positive pole, and, therefore, may be considered as possessed of the negative power.

When bodies are thus under the influence of electrical decomposition, their usual chemical energies are suspended, and some very curious phenomena are observed.

The most difficult decomposable compounds may be thus resolved into their component parts by the electrical agency; by a weak power the proximate ele-ments are separated, and by a stronger power these

are resolved into their ultimate constituents.

All bodies which exert powerful chemical agencies upon each other when freedom of motion is given to their particles, render each other oppositely electrical when acting as masses. Hence Sir H. Davy, the great and successful investigator of this branch of chemical and successful investigator of this branch of chemical and chemical statements. philosophy, has supposed that electrical and chemical phenomena, though in themselves quite distinct, may be dependent on one and the same power, acting in the former case upon masses of matter, in the other upon

former case upon masses of matter, in the other upon its particles.

The power of the Voltaic apparatus to communicate divergence to the electrometer, is most observed when it is well insulated, and filled with pure water; but its power of producing ignition and of giving shocks, and of producing the other effects observed when its poles are connected, are much augmented by the interposition of dilute acids, which act chemically upon one of the places; here the insulation is interfered with by the producting of vapour, but the quantity of electricity is much increased, a circumstance which may, perhaps, he referred to the increase of the positive energy of the most oxidisable metal by the contact of the acid. In experiments made with the great battery of the Royal Institution, it has been found that 120 plates rendered active by a mixture of one part of nitric acid, and three of water, produces effects equal to 480 plates rendered active by one part of nitric acid, and fifteen of water. and fifteen of water

In the Voltaic pile, the intensity of the electricity increases with the number of alternations, but the

quantity is increased by extending the surface of this plates. Thus, if a battery, composed of thirty pairs of plates, two inches square, be compared with another battery of thirty pairs of twelve inches square charged in the same way, no difference will be perceived in their effects upon bad or imperfect conductors; their powers of decomposing water, and of giving shocks, will be similar; but upon good conductors the effects of the large plates will be considerably greater than those of the small: they will ignite and fuse large quantities of platinum wire, and produce a very brilliant spark between charcoal points. The following experiment well illustrates the different effects of quantity and intensity in the Voltaic apparatus.

Immerse the platinum wires connected with the extremity of a charged battery composed of twelve-inch plates into water, and it will be found that the evolution of gas is nearly the same as that occasioned by a similar number of two-inch plates. Apply the moistened fingers to the wires, and the shock will be the same as if there were no connexion by the water. While the circuit exist through the human body and the water let a wire strached to a thin slip of char-

same as if there were no connexion by the water. While the circuit exists through the human body and the water, let a wire attached to a thin slip of charcoal he made to connect the poles of the battery, and the charcoal will become vividly ignited. The water and the animal substance discharge the electricity of a surface, probably, not superior to their own surface of contact with the metals; the wires discharge all the residual electricity of the plates; and if a similar experiment be made on plates of an inch square, there will scarcely be any sensation when the hands are made to connect the ends of the battery, a circuit being previously made through water; and no spark, when charcoal is made the medium of connexion, imperfect conductors having been previously applied. perfect conductors having been previously applied. These relative effects of quantity and intensity were admirably illustrated by the experiments instituted by Children, who constructed a battery, the plates of which were two feet eight inches wide, and six feet high. They were fastened to a beam, suspended by counterpoises, from the ceiling of his laboratory, so as to be easily immersed into, or withdrawn from the cells of acid. The effects upon metallic wires, and

cells of acid. The effects upon metallic wires, and perfect conductors, were extremely intense; but upon imperfect conductors, such as the human body, and water, they were feeble.—Phil. Trans. 1815, p. 363.

When the extremes of a battery composed of large plates are united by wires of different metals, it is found that some are more easily ignited than others, a circumstance which has been referred to their conducting powers: thus platinum is more easily ignited than silver, and silver than zinc. If the ignition be supposed to result from the resistance to the passage of electricity, we should say that the zinc conducted better than silver, and the silver than platinum.

An important improvement has been suggested in

An important improvement has been suggested in the construction of the Voltaic apparatus, by Dr. Wollaston, (Annals of Philosophy, Sept. 1815.) by which great increase of quantity is obtained, without inconvenient augmentation of the size of the plates; it consists in extending the copper plate, so as to oppose it to every surface of the zinc.

With the single pair of plates, of very small dimensions, constructed upon this principle, Dr. Wollaston succeeded in fusing and igniting a fine platinum wire. This is the most economical and useful form of the Voltaic apparatus; certainly, at least, it is so for all those researches in which there is an occasional demand for quantity as well as intensity of electricity.

The theory of the Voltaic pile is involved in many difficulties. The original source of electricity appears to depend upon the contact of the metals, for we know that a plate of silver and a plate of zinc, or of any other difficulty and easily oxidisable metals, become negative and positive on contact. The accumulation must be referred to induction, which takes place in the elective and positive on contact. The accumulation must be referred to induction, which takes place in the electrical column, through the very thin stratum of air, or paper, and through water, when that fluid is interposed between the plates. Accordingly, we observe, that the apparatus is in the condition of the series of conductors, with interposed air, and of the Leyden phials. When the electric column is insulated, the extremities exhibit feeble negative and positive powers, but if exhibit feeble negative and positive powers, but if either extremity be connected with the ground, the electricity of its poles or extremities is greatly increased, as may be shown by the increased divergence of the leaves of the electrometer which then ensues.

As general changes in the form and constitution of matter are connected with its electrical states, it is obvious that electricity must be continually active in nature. Its effects are exhibited on a magnificent scale in the thunder-storm, which results from the accumulation of electricity in the clouds, as was first experimentally demonstrated by Dr. Franklin, who also first showed the advantage of pointed conductors as safeguards to buildings. In these cases, the conducting and or rods should be of conner or iron, and from half matter are connected with its electrical states, it is obvious that electricity must be continually active in nature. Its effects are exhibited on a magnificent scale in the thunder-storm, which results from the accumulation of electricity in the clouds, as was first experimentally demonstrated by Dr. Franklin, who also first showed the advantage of pointed conductors as safeguards to buildings. In these cases, the conducting rod, or rods, should be of copper, or iron, and from half to three-fourths of an inch diameter. Its upper end should be elevated three or four feet above the highest part of the building, and all the metallic parts of the roof should be connected with the rod, which should be perfectly continuous throughout, and passing down the side of the building, penetrate several feet below its foundation, so as always to be immersed in a moist stratum of soil, or if possible, into water. The leaden water pipes attached to houses, often might be made to answer the purpose of conductors, especially when to answer the purpose of conductors, especially when thick enough to resist fusion. During a thunder-storm the safest situation is in the

burning a mindle start has a start in the satest situation is in the standing upon a woollen rug, which is a nonconductor. Blankets and feathers being nonconductors, bed is a place of comparative safety, provided the bell-wires are not too near, which are almost always melted in houses struck by lightning. When out of doors, it is dangerous to take shelter under trees: the safest situation is within some varies of them and more the ation is within some yards of them, and upon the

dryest spot that can be selected.

The discharge of electricity in a thunder-storm is sometimes only from cloud to cloud; sometimes from the earth to the clouds; and sometimes from the clouds to the earth to the clouds; and sometimes from the clouds to the earth; as one or the other may be positive or negative. When aqueous vapour is condensed, the clouds formed are usually more or less electrical; and the earth below them being brought into an opposite state, by induction, a discharge takes place when the clouds approach within a certain distance, constituting lightning; and the indulation of the air, produced by the discharge, is the cause of thunder, which is more the discharge, is the cause of thunder, which is more or less intense, and of longer or shorter duration, according to the quantity of air acted upon, and the distance of the place, where the report is heard from the point of the discharge. It may not be uninteresting to give a further illustration of this idea. Electrical effects take place in no sensible time. It has been found that a discharge through a circuit of four miles is instantaneous; but sound moves at the rate of about twelve miles a minute. Now suppose the lightning to is instantaneous; but sound moves at the rate of about twelve miles a minute. Now, suppose the lightning to pass through a space of some miles, the explosion will be first heard from the point of the air agitated nearest to the spectator: it will gradually come from the more distant parts of the course of electricity, and last of all, will be heard from the remote extremity, and the different degrees of the agitation of the air, and likewise the difference of the distance, will account for the different intensities of the sound, and its anaaron. the different intensities of the sound, and its apparent reverberations and changes

In a violent thunder-storm, when the sound instartly

succeeds the flash, the persons who witness the circumstance are in some danger; when the interval is a quarter of a minute, they are secure.

A variety of electrical apparatus has been devised to illustrate the operation of conductors for lightning, and the advantage of points over balls; the simplest consists of a model of a house having a conductor with consists of a model of a house having a conductor with a break in it, in which some inflammable matter should be placed; the lower end of the conductor should be communicated with the exterior of a charged Leyden phial, the knob of which, brought over its upper end, will then represent a thunder cloud. If the conductor be pointed, it will be slowly discharged, if surrounded by a ball, there will be an explosion, and the combustibles probably inflamed.

The coruscations of the Autora borealis are also probably electrical, and much resemble flashes of elec-

probably electrical, and much resemble flashes of elec-tric light traversing rarefied air. The water-spout may be referred to the same source, and is probably the result of the operation of a weakly electrical cloud, at an inconsiderable elevation above the sea, brought into an opposite electrical state; and the attraction of the lower part of the cloud, for the surface of the water, may be the immediate cause of this extraordinary phenomenon.

In the gymnotus, or electric eel, and in the torpedo,

That arrangements of different organic substances are capable of producing electrical effects, has been shown by various experimentalists. If the hind-legs of a frog be placed upon a glass plate, and the crural nerve dissected out of one made to communicate with another, it will be found on making occasional contacts with the remaining crural nerves that the light of the communicate with the remaining crural nerves that the light of the communicate with the remaining crural nerves that the light of the communicate with an order of the communicate with the communicate with an order of the communicate with a communicate with the communicat

ther, it will be found on making occasional contacts with the remaining crural nerve, that the limbs of the animal will be agitated at each contact. These circumstances have induced some physiologias to suppose, that electricity may be concerned in some of the most recondite phenomena of vitality, and Dr. Wollaston, Sir E. Home, and myself, have made some experiments tending to confer probability on this idea.

We have as yet no plausible hypothesis concerning the cause of electrical phenomena, though the subject has engaged the attention of the most eminent philosophers of Europe. They have been, by some, referred to the presence of a peculiar fluid existing in all matter, and exhibiting itself by the appearances which have been described wherever its equilibrium is disturbed, presenting negative and positive electricity, when deficient, and when redundant. Others have plausibly argued for the presence of two fluids, distinct from each other. Others have considered the effects from each other. Others have considered the effects as referrible to peculiar exertions of the attractive powers of matter, and have regarded the existence of any distinct fluid, or form of matter, to be as unnecessary to the explanation of the phenomena, as it is in

the question concerning the cause of gravitation.

When the flame of a candle is placed between a positive and negative surface, it is urged towards the latter; a circumstance which has been explained upon the supposition of a current of electrical matter passing from the positive to the perative role, indeed it. ing from the positive to the negative pole; indeed, it has been considered as demonstrating the existence of such a current of matter. But if the flame of phosphorus be substituted for that of a candle, it takes an phorus be substituted for that of a candle, it takes an opposite direction; and instead of being attracted towards the negative, it bends to the positive surface. It has been shown that inflammable bodies are always attracted by negative surfaces; and acid bodies, and those in which the supporters of combustion prevail, are attracted by positive surfaces. Hence the flame of the candle throwing off carbon, is directed to the negative pole, while that of phosphorus forming acid matter goes to the positive, consistently with the ordinary laws of electro-chemical attraction.

There are other experiments opposed to the idea that

There are other experiments opposed to the idea that electricity is a material substance. If we discharge a electricity is a material substance. If we discharge a Leyden phial through a quire of paper, the perforation is equally burred upon both sides, and not upon the negative side only, as would have been the case if any material body had gone through in that direction. The power seems to have come from the centre of the paper, as if one half of the quire had been attracted by the positive, and the other by the negative surface.

When a pointed metallic wire is presented towards the conductor of the electrical machine, in a darkened room, a star of light is observed when the conductor is positive, but a brush of light when it is negative.

positive, but a brush of light when it is negative; a circumstance which has been referred to the reception of the electric fluid in the one case, and its escape in the other. In the Voltaic discharge the same appearances are evident upon the charcoal point; rays appearing to diverge from the negative conductor, while from the positive a spot of bright light is perceptible. But these affections of light can scarcely be considered as indicating the omission, or reception of any specific form of matter.

The efficacy of electricity in the cure of several diseases has been supported by many very respectable authorities, especially in paralytic diseases. It considerably augments the circulation of the blood, and excites the action of the absorbents."—Brande's Che-

ELECTRO-MAGNETISM. The name given to a class of very interesting phenomena, first observed by Oersted, of Copenhagen, in the winter of 1819-20, and which have since received great illustration from the

facts.

Let the opposite poles of a voltaic battery be connected by a metallic wire, which may be left of such length as to suffer its being bent or turned in various directions. This is the conjunctive wire of Oersted. Let us suppose that the rectilinear portion of this wire is extended horizontally in the line of the magnetic meridian. If a freely suspended compass-needle be now introduced, with its centre under the conjunctive wire, the needle will instantly deviate from the magnetic meridian; and it will decline towards the west, under that part of the conjunctive wire which is nearest the negative electric pole, or the copper end of the est the negative electric pole, or the copper end of the voltaic apparatus. The amount of this declination depends on the strength of the electricity, and the sensibility of the needle. Its maximum is 30°.

We may change the direction of the conjunctive wire, out of the magnetic meridian, towards the east or the west, provided it remains above the needle, and parallel to its plane without any change is the above.

or the west, provided it remains above the needle, and parallel to its plane, without any change in the above result, except that of its amount. Wires of platinum, gold, silver, brass, and iron, may be equally employed; nor does the effect cease, though the electric circuit be partially formed by water. The effect of the conjunctive wire takes place across plates of glass, metal, wood, water, resin, pottery, and stone.

If the conjunctive wire be disposed horizontally beneath the needle, the effects are of the same nature as those which occur when it is above it; but they operate

those which occur when it is above it; but they operate in an inverse direction; that is to say, the pole of the needle under which is placed the portion of the conjunctive wire which receives the negative electricity of the apparatus, declines in that case towards the

To remember these results more readily, we may employ the following proposition: The pole, above which the negative electricity enters, declines towards

the west; but if it enters beneath it, the needle de-clines towards the East.

If the conjunctive wire (always supposed horizon-tal) is slowly turned about, so as to form a graddally increasing angle with the magnetic meridian, the de-clination of the needle increases, if the movement of the wire be towards the line of position of the dis-turbed needle; it diminishes, on the contrary, if it recede from its position.

When the conjunctive wire is stretched alongside of the needle in the same horizontal plane, it occasions no declination either to the east or west; but it causes it merely to incline in a vertical line, so that the pole adjoining the negative influence of the pile on the wire dips when the wire is on its west side, and rises

when it is on the east.

If we stretch the conjunctive wire, either above or beneath the needle, in a plane perpendicular to the magnetic meridian, it remains at rest, unless the wire be very near the pole of the needle; for, in this case, it rises when the entrance takes place by the west part of the wire, and sinks when it takes place by the east

When we dispose the conjunctive wire in a vertical line opposite the pole of the needle, and make the upper extremity of the wire receive the electricity of the negative end of the battery, the pole of the needle moves towards the cast; but if we place the wire opposite a point between the pole and the middle of the needle, it moves to the west. The phenomena are presented in an inverse order, when the upper extremity of the conjunctive wire receives the electricity of the positive side of the apparatus.

of the positive side of the apparatus.

It appears from the preceding facts, says Oersted, that the electric conflict (action) is not enclosed within that the electric conflict (action) is not enclosed within the conducting wire, but that it has a pretty extensive sphere of activity round it. We may also conclude from the observations, that this conflict acts by revolution; for without this supposition we could not comprehend how the same portion of the conjunctive wire, which, placed beneath the magnetic pole, carries the needle towards the east, when it is placed above this pole, should carry it towards the west. But such is the nature of the circular action, that the movements which it produces take place in directions prements which it produces take place in directions pre-cisely contrary to the two extremities of the same diameter. It appears also, that the circular movement,

labours of Ampère, Arago, Sir H. Davy, Wollaston, Faraday, de la Rive, and several other philosophers. The following is a short outline of the fundamental facts.

Let the opposite poles of a voltaic battery be conlength as to suffer its being bent or turned in various directions. This is the conjunctive wire of Oersted since the conjunctive wire of the conjunctive wire, ought to form a kind of action, which operates spirally around this wire as an axis. For further information, Faraday's able and original paper, in the Journal of Scince the conjunctive wire, ought to form a kind of action, which operates spirally around this wire as an axis. For further information, Faraday's able and original paper, in the Journal of Scince the conjunctive wire, ought to form a kind of action, which operates spirally around this wire as an axis.

ELECTRO'DES. (From ηλεκ'ρον, amber.) An epithet for intestinal faces which shine like amber.

ELECTROMETER. (From ηλεκ/ρον, and μετρον, See Electricity

ELECTROSCOPE. (From ελεκ/ρον, and σκοπεω,

ELECTROSCOPE. (From ελεκ/ρον, and σκοπτω, to see.) See Electricity.

ELECTRUM. Ελεκ/ρον. Amber.

ELECTRUM MINERALE. The tincture of metals. It is made of tin and copper, to which some add gold, and double its quantity of martial regulus of antimony melted together; from these there results a metallic mass, to which some chemists have given the name of electrum minerale. This mass is powdered and detonated with nitre and charcoal to a kind of scoria; it is powdered again while bot, and then digested in spirit of wine, whence a tincture is obtained of a fine spirit of wine, whence a tincture is obtained of a fine

red colour.

ELECTUA'RIUM. An electuary. The London
Pharmacopæia refers those articles which were formerly called electuaries to confections. See Confectio.

ELECTUARIUM ANTIMONII. R. Electuarii sennæ, 3j; guaiaci gummi, hydrargyri cum sulphure, antimonii ppti. sing. 3s; syrupi simplicis q. s. misce. Of this electuary, from a drachm to about two drachms is given twice a day, in those cutaneous diseases which go under the general name of scorbutic. It is usually accompanied with the decoctions of elm bark or sarsaparilla.

ELECTUARIUM CASSIM. See Confectio cassia.

ELECTUARIUM CATECHU. Confectio Japonica. Electuary of catechu, commonly called Japonic confection. Take of mimosa catechu, four ounces; kino, Electuary of catechu, commonly called Japonic confection. Take of mimosa catechu, four ounces; kino, three ounces; cinnamon, nutmeg, each one ounce; opium diffused in a sufficient quantity of Spanish white wine one drachm and a half; syrup of red roses boiled to the consistence of honey, two pounds and a quarter. Reduce the solids to powder, and, having mixed them with the opium and syrup, make them into an electuary. A very useful astringent, and perhaps the most efficacious way of giving the catechu to advantage. Ten scruples of this electuary contain one grain of onium.

ELECTUARIUM CINCHONÆ CUM NATRO. ppti. 3 ij.; pulyeris cinchonæ unc.: mucilaginis gummi arabici q. s. misce. In this composition, mucilage is preferred to syrup on account of its covering the taste of the bark much more advantageously. It should, for this purpose, however, be made thin, otherwise it will increase the bulk of the electuary too much.

This remedy will be found an excellent substitute.

This remedy will be found an excellent substitute for the burnt sponge, the powers of which, as a remedy in scrofula, are known solely to depend on the proportion of natron contained in it. The dose is two

drachms, twice or thrice a day.

ELECTUARIUM OPIATUM. See Confectio opii.

ELECTUARIUM OPIATUM. See Confectio opii.

ELELL'SPHACOS. (From ελελιζω, to distort, and σφακος, sage: so named from the spiral coiling of its leaves and branches.) A species of sage.

ELEMENT. Radical. First principles. A substance which can no further be divided or decomposed

stance which can no further be divided or decomposed by chemical analysis.

E'LEMI. (It is said this is the Ethiopian name.) Gum elemi. The parent plant of this resin is supposed to be an amyris. See Amyris elemifera.

ELEN'GI. A tree of Malabar, which is said to possess cordial and carminative properties.

ELEOCHRY'SUM. (From ηλιος, the sun, and χρυσος, gold: so called from its gold-like, or shining yellow appearance.) Goldilocks. See Gnaphalium stachas.

ELEOSELI'NUM (From elos, a lake, and oche-

νον, parsley.) See Apium.
ELEPHA NTIA. (From ελεφας, an Jelephant: so called from the great enlargement of the body in this disorder.) See Elephantiasis.

ELEPHANTIA ARABUM. In Dr. Cullen's Nosology it is synonymous with elephantiasis. The term is, however, occasionally confined to this disease when it affects the feet.

ELEPHANTI'ASIS. (From ελεφας, an elephant: so named from the legs of people affected with this disorder growing scaly, rough, and wonderfully large, at an advanced period, like the legs of an elephant. Elephas; Elephantia; Lazari morbus vel malum; Phaniceus morbus. A disease that attacks the whole body, but mostly affects the feet, which appear somewhat like those of the elephant. It is known by the skin being thick, rough, wrinkly, unctuous, and void of hair, and mostly without the sense of feeling. It is said to be contagious. Cullen makes it a genus of disease in the class Cachezia, and order Impetigines. Elephantiasis has generally been supposed to arise in consequence of some slight attack of fever, on the cessation of which the morbid matter falls on the leg, and occasions a distention and tumefaction of the

and occasions a distention and tumefaction of the limb, which is afterward overspread with uneven lumps, and deep fissures. By some authors it has been considered as a species of leprosy; but it often subsists for many years without being accompanied with any of the symptoms which characterize that disease

It sometimes comes on gradually, without much pre-It sometimes comes on gradually, without much previous indisposition; but more generally, the person is seized with a coldness and shivering, pains in the head, back, and loins, and some degree of nausea. A slight fever then ensues, and a severe pain is felt in one of the inguinal glands, which, after a short time, becomes hard, swelled, and inflamed. No suppuration, however, ensues; but a red streak may be observed running down the thigh from the swelled gland to the leg. As the inflammation increases in all the served running down the thigh from the swelled gland to the leg. As the inflammation increases in all the parts, the fever gradually abates; and, perhaps, after two or three days' continuance, goes off. It, however, returns again at uncertain periods, leaving the leg greatly swelled with varicose turgid veins, the skin rough and rugged, and a thickened membrana cellulosa. Scales appear also on the surface, which do not fall off, but are enlarged by the increasing thickness of the membranes; uneven lumps, with deep fissures, are formed, and the leg and foot become at last of an apparatus size. enormous size.

A person may labour under this disease many years without finding much alteration in the general health, except during the continuance of the attacks; and perhaps the chief inconvenience he will experience is the enormous bulky leg which he drags about with him. The incumbrance has, indeed, induced many who have laboured under this disease to submit to an amputation; but the operation seldom proves a radical cure, as the other leg frequently becomes affected. Hilary observes, that he never saw both legs swelled at the same time. Instances where they have alike A person may labour under this disease many years

at the same time. Instances where they have alike acquired a frightful and prodigious size, have, however, frequently fallen under the observation of other physicians.

ELEPHANTI'NUM EMPLASTRUM. A plaster described by Oribasius. Celsus describes one of the same name,

but very different in qualities.

E'LEPHAS. (Ελεφας, the elephant.)

1. The name of an animal.

2. The name of a disease of the skin. See Elephantiasis.

3. Aqua fortis was so called in some old chemical

ELE'TTARI PRIMUM. The true amomum.

ELETTARI PRIMON. The true amonum. See Elettaria cardamomum.

ELETTARIA. (From elettari.) The name of a new genus of plants formed by Dr. Maton, to which the less cardamom is referred. Class, Monandria;

Order, Monogynia.

ELETTARIA CARDAMONUM. Cardamomum minus. Less or officinal cardamom. Amomum repens; or le cardamome de la côte de Malabar, of Sonnerat. Elet-taria cardamomum, of Maton, in Act. Soc. Lin. The seeds of this plant are imported in their capsules or seeds of this plant are imported in their capsules or husks, by which they are preserved, for they soon lose a part of their flavour when freed from this covering. On being chewed, they impart a glowing aromatic warmth, and grateful pungency; they are supposed gently to stimulate the stomach, and prove cordial, carminative, and antispasmodic, but without that irritation and heat which many of the other spicy aromatics are apt to produce. Simple and compound spirituous tinctures are prepared from them, and they are ordered as a spicy ingredient in many of the officinal compositions.

ELEUTHE'RIA. See Croton cascarilla-

ELEVA'TIO. (From elevo, to lift up.) Elevation. Sublimation.

ELEVA'TOR. (From elevo, to lift up.)
1. A muscle is so called, the office of which is to lift up the part to which it is attached.

2. A chirurgical instrument, elevatorium, with which surgeons raise any depressed portion of bone, but chiefly those of the cranium.

ELEVATOR LABII INFERIORIS PROPRIUS. See Le-

vator labii inferioris.

ELEVATOR LABII SUPERIORIS PROPRIUS. See Lo-

vator labii superioris alæque nasi.

ELEVATOR LABIORUM. See Levator anguli oris.

ELEVATOR NASI ALARUM. See Levator labii superioris alæque nasi.

ELEVATOR OCULI. See Rectus superior oculi. ELEVATOR PALPEBRÆ SUPERIORIS. See Levator palpebræ superioris.

ELEVATOR SCAPULE. See Levator scapulæ. ELEVATO'RIUM. (From elevo, to lift up.) instrument to raise a depression in the skull.

Instrument to raise a depression in the skull.

ELI'BANUM. See Juniperus lycia.

ELICHRY'SUM. (From ηλιος, the sun, and χρυσος, gold; so called from its gold-like, or shining yellow appearance.) See Gnaphalium stæchas.

ELI'BANUM. See Gnaphalium stæchas.

ELI'GMA. A linctus.

ELIOSELI'NUM. See Eleoselinum.

ELIPTICUS. Eliptic. Applied to leaves and receptacles, which are of a somewhat oval form, but broader at each end; as in the leaf of the Convallaria majalis, and the receptacle of the Dorstenia drakenia.

ELIQUATION. - An operation, by means of which a more fusible substance is separated from another, which is less fusible. It consists in the application of a degree of heat, sufficient to fuse the former, but not the latter.

[" If lead be heated so as to boil and smoke, it soon dissolves pieces of copper thrown into it; the mixture when cold is brittle. The union of these two metals is remarkably slight; for upon exposing the mass to a heat no greater than that in which lead melts, the lead almost entirely runs off by itself. This process is called *cliquation*. The coarser sorts of lead, which owe their brittleness and granulated texture to an ad-

owe their brittleness and granulated texture to an admixture of copper, throw it up to the surface on being melted by a small heat."—Web. Man. of Chem. A.]

ELITHROI'DES. The vaginal coat of the testicle. See Elythroides and Testis.

ELIXA'TIO. (From elixo, to boil.) The act of seething or boiling.

ELI'XIR. (From elekser, an Arabic word, signifying quintessence.) A term formerly applied to many preparations similar to compound tinctures. It is now very little employed. very little employed.

Elixir of health. Elixir salutis. A term formerly applied to tincture of senna.

ELIXIR PAREGORICUM. See Tinctura camphoræ ELIXIR PROPRIETATIS. A preparation like the

compound tincture of aloes.

ELIXIR SACRUM. A tincture of rhubarb and aloes.

ELIXIR SALUTIS. See Tinctura sennæ.

ELIXIR STOMACHICUM. See Tinctura gentianæ

composita. ELIXIVA'TIO. (From elizo, to boil, or from lixivium,

ELIXIVA'TIO. (From elizo, to boil, or from lizivium, lye.) The extraction of a fixed salt from vegetables, by an affusion of water. See Liziviation

ELLAGIC ACID. (Acidum ellagicum; so named by Braconnot, by reversing the word galle.) The deposite which forms in infusion of nut-galls, left to itself, is not composed solely of gallic acid and a matter which colours it. It contains, besides, a little gallate and sulphate of lime, and a new acid, which was pointed out for the first time by Chevreuil, in 1815, an acid on which Braconnot made observations, in 1818, and which he proposed to call acid ellagic, from the word galle reversed. Probably this acid does not exist ready formed in nut-galls. It is insoluble; and, carrying down with it the greater part of the gallic acid, forms the yellowish crystalline deposite. But boiling water removes the gallic acid from the ellagic; whence the means of separating them from one anowhence the means of separating them from one another. Ann. de Chim. et de Phys. ix. 181.

Elleborum. See Helleborus and Veratrum.

ELM. See Ulmus.

Elm'leaved sumach. See Rhus coriaria.

ELMI'NTHES. (From thew, to involve, from its contortions.) A worm.

ELO'DES. (From they, a swamp.) A term given to a sweating fever, from its great moisture.

ELORA'TIO. (From clongo, to lengthen out.) An imperfect luxation, where the ligament is only lengthened, and the bone not put out of its socket.

ELOY, Nicholas Francis Joseph, was born at Mons, in 1714, and died in 1788, having practised as a physician with great ability and humanity. He had the honour of attending Prince Charles of Lorraine. He was a man of extensive learning, and, notwithstanding his professional avocations, was author of several publications. The principal of these, an Historical Medical Dictionary, was originally in two octavo volumes; but in 1788, it appeared greatly improved and enlarged in four volumes quarto. An Introduction to Midwifery; a Memoir on Dysentery; Reflections on the Use of Tea; and a Medico-Political Tract on Coffee; were likewise written by this author. The latter work procused him the reward of a severth sputh but the reward of a severth sputh between the latter work procused him the reward of a severth sputh but its severth sputh but fee; were likewise written by this author. The latter work procured him the reward of a superb snuff-box from the estates of Hainault, inscribed "Ex dono

ELUTRIATION. (Elutriatio; from elutrio, to cleanse.) Washing. It is the pouring a liquor out of one vessel into another, in order to separate the lighter earthy parts, which are carried away while the heavier

metallic parts subside to the bottom.

ELUVIES. (From eluo, to wash out.) The effluvium from a swampy place. Also the humour discharged in fluor albus.

charged in fluor albus.

ELUXA'TIO. (From cluzo, to put out of joint.) A luxation, or dislocation.

ELYMAGRO'STIS. (From clupos, the herb panic, and appears, wild.) Wild panic.

ELY'MUS. Elupos. The herb panic, or panicum of Dioscorides, but now the name of a new genus of grasses, in the Linnean system.

ELYOT, Sir Thomas, was born of a good family in Suffolk, about the beginning of the sixteenth century. After studying at Oxford, and improving himself by travelling, he was introduced at court: and Henry by travelling, he was introduced at court; and Henry VIII. conferred upon him the honour of knighthood, and employed him in several embassies. He distin-guished himself in various branches of learning, as well as by patronising learned men; and was generally beloved by his contemporaries for his virtues and ac-complishments. He died in 1546, and was buried in Cambridgeshire, of which he had been sheriff. Among Cambridgeshire, of which he had been sheriff. Among other studies, he was partial to medicine, and made himself master of the ancient authors on that subject, though he never exercised the profession. He published a work about the year 1541, called "The Castell of Health," which was much admired, even by some of the faculty: in this he is a strong advocate for temperance, especially in sexual pleasures. He also notices, that catarrhs were much more common than they had been forty years before; which he ascribes chiefly to free living, and keeping the head too much covered. He also wrote and translated several other works, but not on medical subjects:

ELYTROCE LE. (From ελυτρον, the vagina, and κηλη, a tumour.) A hernia in the vagina. See Hernia vaginalis.

ELYTROI'DES. (Elytroides; from ελυτρον, a sheath, and ειδος, form.) Like a sheath. The tunica vaginalis is so called by some writers, because it includes the testis like a sheath

ELYTRON. (From ελυω, to involve.) The vagina. A sheath. The membranes which involve the spinal marrow are called ελυγρα.

EMACIATION. See Atrophia and Marasmus.

EMARGINATIO. (From emargino, to cleanse the edges.) The cleansing of the edges of wounds from scurf and filth.

EMARGINATUS. Emarginate, nicked, that is, having a small acute notch at the summit; as the leaf of the bladder senna, Colutea arborescens, the petals of the Allium roseum, and Agrostema flos jovis.

EMASCULA'TUS. (From emasculo, to render impotent.) Having the testicles in the belly, and not fallen into the scretum.

fallen into the scrotum.

EMBA'MMA. (From εμβαπ7ω, to emerge in.) A medicated pickle to dip the food in.

E'MBOLE. (From εμβαλλω, to put in.) The setting of a dislocated bone.

E'MBOLUM. (From εμβαλλω, to cast out: 50 named because it ejects the semen.) The penis.

Embre ama. (From εμβρεχω, to make wet.) A fluid application to any part of the body.

EMBROCA'TIO. (From εμβρεχω, to moisten or soak in.) Embroche. An embrocation. A fluid application to rub any part of the body with. Many use the term bowever, as synonymous with liniment. the term; however, as synonymous with liniment.
The following embrocations are in general use.

EMBROCATIO ALUMINIS. R. Aluminis 3 ij. Aceti,

spiritus vinosi tenuloris, sing. ibss. For chilblains and

diseased joints.

Embrocatio ammoniæ. B. Embrocationis ammoniæ acetatis 3 ij. Aquæ ammoniæ puræ 3 ij. For sprains and bruises.

EMBROCATIO AMMONIÆ ACETATIS. R. Aquæ amoniæ acetatæ. Solutionis saponis sing. 5 j M. For moniæ acetatæ. Solutioni bruises with inflammation.

EMBROCATIO AMMONIÆ ACETATIS CAMPHORATA. B. Solutionis saponis cum camphora, aque ammonise acetate sing. § j. Aque ammonise pure § ss. For sprains and bruises. It is also frequently applied to disperse chilblains which have not suppurated. It is said to be the same as Steer's opodeldoc.

EMBROCATIO CANTHARIDIS CUM CAMPHORA. R. Tinct, cantharidis. Spiritus camphoræ sing. 3 j M. This may be used in any case in which the object is to stimulate the skin. The absorption of cantharides,

The absorption of Canadatuces however, may bring on a stranguary.
 E'mbroche. See Embrocatio.
 E'MBRYO. (From εμδρυω, to bud forth.) 1. The germ of a plant; called by Linnaeus the corculum.
 See Corculum and Cotyledon.

2. The fatis in utero is so called before the fifth month of pregnancy, because its growth resembles that of the budding of a plant.

EMBRYOTHLA STES. (From εμδρυον, the fœtus, and θλαω, to break.) Embryorectes. A crotchet or instrument for breaking the bones of a dead fœtus to promote its deliveres.

EMBRYO'TOMY. (Embryotomia; from εμβρυον, a feetus, and τεμνω, to cut.) The separating of any part of the fœtus while in utero, to extract it.

Embryo'lcus. (From εμβρυον, a fœtus, and ελκω, to draw.) A blunt hook or forceps, for drawing the child from the womb.

EMERALD. A beautiful genus of minerals, which

contains two species.

1. The prismatic emerald, Euclase of Haüy. This is of a green and sky-blue colour, and is found in Peru and Brazil.

2. Rhomboidal emerald, of which there are two subspecies, the precious emerald and the beryl. The first is well known by its emerald green colour. The most beautiful emeralds come from Peru. As a gem, it is

valued next to ruby.

["This mineral is by no means uncommon in the United States. It occurs in the primitive range, and particularly in granite, in which it is imbedded. In the State of Maine, it has been found remarkably clear and transparent, and in every respect resembling

the State of Maine, it has been found remarkably clear and transparent, and in every respect resembling the Siberian Beryl, particularly that discovered at Topsham by Professor Cleveland, of Brunswick College. The crystals are well defined hexaædral prisms, and are often imbedded in the smoky quartz which abound in the large-grained granite. In some instances, in point of colour, it equals the finest Peruvian emerald.

"At Chesterfield, in Massachusetts, it occurs in great abundance. Dr. J. F. Waterhouse, who has carefully examined this locality, informs us that crystals, in hexangular prisms, from an ounce and under to 6lb. in weight, are found singly disseminated through the granite. They are of various dimensions, from a small size to that of a foot in diameter; their colour light green. The Chesterfield emerald greatly resembles that lately discovered in France. If the new earth glacine should be required for the arts or manufactures, this emerald would furnish it in abundance; as such is the quantity occurring at this place, that Dr. Waterhouse obtained upwards of 70lb. within a very small space. The emerald occurs in other parts of Massachusetts. To the politeness of Dr. David Hunt, we are indebted for several specimens found by that indefatigable mineralogist, in the vicinity of Northampton and Goshen.

"At Haddam, in Connecticut, this mineral occurs in ampton and Goshen

"At Haddam, in Connecticut, this mineral occurs in abundance; the crystals are from a very small size to

everal inches in length; they are generally of a light yellowish-green, and sometimes of an amber colour, resembling topaz. Col. Gibbs has in his possession a crystal of a deep green an inch in diameter, and several in length, it bears a strong resemblance to the Peruvian emerald. Mr. Mather, a young mineralogist of great promise, discovered one seven inches in length, by nine inches in the diagonal diameter: it is in the cabinet of Professor Silliman.

"New-York affords but few instances of the production of emerald. It now and then, though rarely, occurs in the granite veins which traverse the gneiss on the island, about four miles from the city.

"The emerald is found in the vicinity of Philadelphia, and at Chester. These are the principal localities of this mineral in the United States, which have as yet come to our knowledge. As others occur, we shall with pleasure notice them."—Bruce's Min. Journal.

EMERSUS. (From emergo, to rise up or appear out of the water.) Raised above the water, as the upper leaves accompanying the flowers of the Meriophyllum verticillatum, while its lower ones are de-

E'MERUS. Scorpion senna. A laxative.
EMERY. A sub-species of rhomboidal corundum, found in quantities in the isle of Naxor, and at Smyrna. Its fine powder, which is used for polishing hard minerals and metals, is made by trituration and elu-

EMESIA. (From τμεω, to vomit.) Emesma; mesis. The act of vomiting. Medicines which Emesis.

Emests. The act of volunting cause vomiting.

EME'TIC. (Emeticus; from εμιω, to vomit.) That which is capable of exciting vomiting, independently of any effect arising from the mere quantity of matter introduced into the stomach, or of any nauseous taste or flavour.

The susceptibility of vomiting is very different in different individuals, and is often considerably varied by disease

Emetics are employed in many diseases.

When any morbid affection depends upon, or is connected with, over-distention of the stomach, or the presence of acrid, indigestible matters, vomiting gives speedy relief. Hence its utility in impaired appetite, acidity in the stomach, in intoxication, and where poi-

From the pressure of the abdominal viscera in vo-miting, emetics have been considered as serviceable in jaundice, arising from biliary calculi obstructing the

The expectorant power of emetics, and their utility in catarrh and phthisis, have been ascribed to a similar pressure extended to the thoracic viscera.

In the different varieties of febrile affections, much advantage is derived from exciting vomiting, especially in the very commencement of the disease. In high inflammatory fever it is considered as dangerous, and in the advanced stage of typhus it is prejudicial.

Emetics given in such doses, as only to excite nausea, have been found useful in restraining hamorphage.

Different species of dropsy have been cured by vomiting, from its having excited absorption. To the same effect, perhaps, is owing the dispersion of swelled testicle, bubo, and other swellings, which has occasionally resulted from this operation.

The operation of vomiting is dangerous, or burtful, in the following eases: where there is determination.

The operation of vomiting is dangerous, or hurtful, in the following cases: where there is determination of the blood to the head, especially in plethoric habits; in visceral inflammation; in the advanced stage of pregnancy; in hernia and prolapsus uteri; and wherever there exists extreme general debility. The frequent use of emetics weakens the tone of the stone of mach. An emetic should always be administered in the fluid form. Its operation may be promoted by drinking any tepid diluent, or bitter infusion.

The individual emetics may be arranged under two heads, those derived from the vegetable, and those from the mineral kingdom. From the vegetable, and those from the mineral kingdom. From the vegetable kingdom are numbered ipecacuanha, scilla maritima, anthemis nobilis, sinapis alba, asarum Europæum, nicotiana tabacum. From the mineral kingdom, antimony, the sulphates of zinc and copper, and the subacetate of copper. To these may be added ammonia and its hydro-sulphuret.

EMETIN. Emetine. Digest ipecacuan root, first in a:ther and then in alkohol. Evaporate the alkoholis infusion to dryness, redissolve in water, and drop in acetate of lead. Wash the precipitate, and then differented hydrogen gas Salehura Current of sulphuretted hydrogen gas sulphu

fusing it in water, decompose by a current of sulphuretted hydrogen gas. Sulphuret of lead falls to the bottom, and the emetin remains in solution. By evaperating the water, this substance is obtained pure. Emetin forms transparent brownish-red scales. It has no smell, but a bitter acrid taste. At a heat somewhat above that of boiling water, it is resolved into carbonic acid, oil, and vinegar. It affords no ammonia. It is soluble both in water and alkohol, but not in æther; and uncrystallizable. It is precipitated by protonitrate of mercury and corrosive sublimate, but not by tartar emetic. Half a grain of emetin acts as a powerful emetic, followed by sleep; six grains vomit violently, and produce stupor and death. The lungs and intestines are inflamed."—Pelletier and Magendie. gendie.

Emetine. See Emetin.
EMETOCATHA'RTICUS. (From εμεω, to vomit, and καθαιρω, to purge.) Purging both by vomit and

EMINE'NTLE QUADRIGEMINE. See Tuber-

eula quadrigemina.
ENMENAGOGUE. (Emmenagogus; from zupprua,
ENMENAGOGUE.) Whatever possesses the menses, and $\alpha y \omega$, to move.) Whatever possesses the power of promoting that monthly discharge by the uterus, which, from a law of the animal economy, should take place in certain conditions of the female system. The articles belonging to this class may be referred to four ordres:-

Stimulating emmenagogues, as hydrargyrine and antimonial preparations, which are principally adapted for the young, and those with peculiar insensibility of

2. Irritating emmenagogues, as aloes, savine, and panish flies: these are to be preferred in torpid and Spanish flies: chlorotic habits.

3. Tonic emmenagogues, as ferruginous prepara-tions, cold bath, and exercise, which are advanta-geously selected for the lax and phlegmatic.

4. Antispasmodic emmenagogues, as as afatida, castor, and pediluvia: the constitutions to which these are more especially suited are the delicate, the weak, and the irritable.

EMME'NIA. (From εν, in, and μην, a month.)
The menstrual flux.
EMO'LLIENT. (Emolliens; from emollio, to soften.) Possessing the power of relaxing the living and animal fibre, without producing that effect from any mechanical action. The different articles belonging to this class of medicines may be comprehended under

the following orders:—
1. Humectant emollients, as warm water, and tepid vapours, which are fitted for the robust and those in

the prime of life.

2. Relaxing emollients, as althwa, malva, &c. These may be employed in all constitutions, while at the same time they do not claim a preference to others from any particular habit of body.

3. Lubricating emollients, as bland oils, fat, and lard. The same observation will hold of this order as lard. The same observation will hold of this order as

was made of the last mentioned.

Atonic emollients, as opium and pediluvia. These are applicable to any constitution, but are to be pre-ferred in habits where the effects of this class are re-

quired over the system in general.

EMPATHEMA. (Έμπαθης; from παθημα, passio, affectio.) Ungovernable passion. A genus of disease in Good's Nosology. Class, Neurotica; Order,

Phrenica

It has three species, Empathema entonicum, atoni-cum, insane, and innumerable varieties. ΕΜΡΕΙ΄ RIA. (From εν, and πειρω, to endeavour.)

Professional experience.

Professional experience.

EMPHERO'MENUS. (From εμφερω; to bear.) Urine, or other substances which have a sediment.

EMPHLYSIS. (From εμ, in, and φλυσες, a vesicular tumour or eruption.) The name of a genus, ichorous exanthem, of Good's Nosology, which includes six species: Emphlysis miliaria; Aphtha; Vaccinia; Varicella; Pemphigus; Erystpelas.

EMPHER'CTICA. (From εμφρατ?ω, to obstruct.) Medicines which, applied to the skin, shut up the

EMP EMP

EMPHYMA. This term, applied by Good to a genus of disease, Class, Eccritica; Order, Mesotica, of his arrangement, imports (in contradiction to Phy-ma, which, in his system, is limited to cutaneous tu-mours, accompanied with inflammation,) a tumour originating below the integuments, and unaccompanied with inflammation, at least in its commencement. It embraces three species, viz. Emphyma sarcoma; En-

EMPHYSE'MA. (Emphysema, atis, n.; from

EMPHYSE MA. (Emphysema, atis, n.; Irom εμφυσαω, to inflate.) See Pneumatosis.

EMPIRIC. (Empiricus. Εμπειρικος; from εν, in, and πειρα, experience.) One who practises the healing art upon experience, and not theory. This is the true meaning of the word empiric; but it is now applied, in a very opposite sense, to those who deviate from the line of conduct pursued by scientific and regular practitioners, and vend nostrums, or sound their own praise in the public papers. own praise in the public papers.

ΕΜΡΙΑ΄ STICA. (From εμπλασσω, to obstruct.) Me-

EMPLASTICA. (From εμπλασσω, to obstruct.) Aledicines which, spread upon the skin, stop the pores.

EMPLA'STRUM. (Emplastrum, i. n.; from εμπλασσω, to spread upon.) A plaster. Plasters are composed of unctuous substances, united either to powders or metallic oxides, &c. They ought to be of such a consistence as not to stick to the fingers when cold, but to become soft, so as to be spread out in a moderate degree of heat, and in that of the human moderate degree of heat, and in that of the human body, to continue tenacious enough to adhere to the skin. They owe their consistence either to metallic oxides, especially those of lead, or to wax, resin, &c. They are usually kept in rolls wrapped in paper, and spread, when wanted for use, upon thin leather; if the plaster be not of itself sufficiently adhesive, it is to be surrounded at its margin by a boundary of resin

EMPLASTRUM AMMONIACI. Take of purified aumoniacum, five ounces; acetic acid, half a pint. Dissolve the ammoniacum in the acid, then evaporate the liquor in an iron vessel, by means of a water-bath, constantly stirring it, until it acquires a proper consistence. This plaster is now first introduced into the sistence. This plaster is now first introduced into the London Pharmacopæia; it adheres well to the skin, without irritating it, and without producing inconve-nience by its smell.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. Take of purified ammoniacum, a pound; purified mercury, three ounces; sulphuretted oil, a fluid drachm. Rub the mercury with the sulphurated oil until the globules disappear; then add by degrees the ammoniacum, previously melted, and mix the whole together.

This composition is said to possess resolvent virtues; and the plaster is recommended with this view to be applied to nodes, tophs, indurated glands, and tumours.

EMPLASTRUM ASAFŒTIDÆ. Emplastrum antihys-tericum. Plaster of asafætida. Take of plaster of semi-vitrified oxide of lead, asafætida, each two parts: galbanum, yellow wax, each one part. This plaster is said to possess anodyne and antispasmodic virtues. It is, therefore, occasionally directed to be applied to the umbilical region in hysterical cases.

EMPLASTRUM CANTHARIDIS. Blistering-fly plaster.

Emplastrum vesicalorium. Take of blistering flies,

in very fine powder, a pound; wax plaster, a pound and a half; prepared fat, a pound. Having melted the plaster and fat together, and removed them from the fire, a little before they become solid sprinkle in the blistering flies, and mix the whole together. See Blister and Cantharis.

EMPLASTRUM CERE. Wax plaster. Emplastrum attrahens. Take of yellow wax, prepared suet, of each three pounds; yellow resin, a pound. Melt them together and strain. This is a gently-drawing preparation, calculated to promote a moderate discharge from the blistered surface, with which intention it is mostly used. Where the stronger preparations irritate, this will be found in general to agree.

EMPLASTRUM CUMINI: Cumin plaster. Take of cumin-seeds, caraway-seeds, bay-berries, of each three ounces; dried pitch, three pounds; yellow wax, three ounces. Having melted the dry pitch and wax together, add the remaining articles previously powdered, EMPLASTRUM CERE. Wax plaster. Emplastrum

ther, add the remaining articles previously powdered, and mix. A warm stomachic plaster, which, when applied to the stomach, expels flatulency. To indolent scrofulous tumours, where the object is to promote suppuration, this is an efficacious plaster.

EMPLASTRUM GALBANI COMPOSITUM. Compound Galbanum plaster, formerly called emplastrum lithargyri compositum and diachylon magnum cum gummi. Take of galbanum gum resin purified, eight ounces; lead plaster, three pounds; common turpentine, ten drachms; resin of the spruce fir, three ounces. Having melted the galbanum gum resin with the turpentine, mix in first the powdered resin of the spruce fir, and then the lead plaster, previously melted by a slow fire, and mix the whole. This plaster is used as a warm digestive and suppurative, calculated to promote maturation of indolent or scirrhous tumours, and to allay the pains of sciatica, arthrodynia, &c.

mote maturation of indolent of schribous tumodis, and to allay the pains of sciatica, arthrodynia, &c.

EMPLASTRUM HYDRARGYRI. Mercurial plaster.

Emplastrum lithargyri cum hydrargyro. Take of purified mercury, three ounces; sulphurated oil, a fluid drachm; lead plaster, a pound. Rub the mercury with the sulphurated oil, until the globules disappear; then add by degrees the lead plaster, melled, and my the add by degrees the lead plaster, melted, and mix the

EMPLASTRUM LADANI COMPOSITUM. Take of soft labdanum, three ounces; of frankincense, one ounce; cinnamon and expressed oil of mace, each half an ounce; essential oil of mint, one drachm: add to the frankincense, melted first, the labdanum a little heated, till it becomes soft, and then the oil of mace; afterward mix in the cinnamon with the oil of mace; afterward mix in the cinnamon with the oil of solutions. ward mix in the cinnamon with the oil of mint, and beat them together into a mass, in a warm mortar, and keep it in a vessel well closed. This may be used with the same intentions as the cumin-plaster, to which it is in no way superior, though composed of more expensive materials. Formerly, it was considered as a very elegant stomach plaster, but is now dis-

EMPLASTRUM LITHARGYRI. See Emplastrum plumbi.

EMPLASTRUM LITHARGYRI COMPOSITUM. See Emplastrum Galbani compositum.

EMPLASTRUM LITHARGYRI CUM RESINA: See Em-

plastrum resinæ.

EMPLASTRUM LYTTE. See Emplastrum cantha-

EMPLASTRUM OPH. Plaster of opium. Take of hard opium, powdered, half an ounce; resin of the spruce fir, powdered, three ounces; lead plaster, a pound. Having melted the plaster, mix in the resin of the spruce fir, and opium, and mix the whole. Opium is said to produce somewhat, though in a smaller degree, its specific effect when applied externally.

EMPLASTRUM PICIS COMPOSITUM. Compound pitch plaster. Emplastrum picis Burgundicæ. Take of dried pitch, two pounds; resin of spruce fir, a pound; yellow resin, yellow wax, of each four ounces; expressed oil of nutmegs, an ounce. Having melted together the pitch, resin, and wax, add first the resin of the spruce fir, then the oil of nutmegs, and mix the whole together. From the slight degree of redness this stimulating application produces, it is adapted to gently irritate the skin, and thus relieve rheumatic pains. Applied to the temples, it is sometimes of use in pains of the head.

Emplastrum plumbi. Lead plaster. Emplastrum EMPLASTRUM PICIS COMPOSITUM. - Compound pitch

pains. Applied to the temples, it is sometimes of use in pains of the head.

Emplastrum flumni: Lead plaster. Emplastrum lithargyri; Emplastrum commune; Diachylon simplex. Take of semi-vitreous oxide of lead, in very fine powder, five pounds; olive oil, a gallon; water, two pints. Boil them with a slow fire, constantly stirring until the oil and litharge unite, so as to form a plaster. Excoriations of the skin, slight burns, and the like, may be covered with this plaster: but is in more general use, as a defensive, where the skin becomes red from lying a long time on the part. This plaster is also of great importance, as forming the basis, by addition to which many other plasters are prepared.

Emplastrum resine. Resin plaster. Emplastrum adhassivum; Emplastrum lithargyri cum resina. Take of yellow resin, half a pound; lead plaster, three pounds. Having melted the lead plaster over a slow fire, add the resin in powder, and mix. The adhesive, or sticking plaster, is chief; used for keeping on other dressings, and for retaining the edges of recent wounds together.

wounds together.

EMPLASTRUM SAPONIS. Soap plaster. Take of hard soap sliced, half a pound; lead plaster, three pounds. Having melted the plaster, mix in the soap; then boil it down to a proper consistence. Discutient properties are attributed to this elegant plaster, with which view, it is applied to lymphatic and other, indewhich view, it is applied to lymphatic and other indo-

EMPLASTRUM THURIS COMPOSITUM. Compound frankincense plaster. Take of frankincense, half a pound; dragon's blood, three ounces; litharge plaster, two pounds. To the melted lead plaster, add the rest powdered. This plaster is said to possess strengthening, as well as adhesive powers. By keeping the skin firm, it may give tone to the relaxed muscles it surrounds, but cannot, in any way, impart more strength rounds, but cannot, in any way, impart more strength than the common adhesive plaster.

[The pharmacopæia of the United States admits the

following plasters: Emplastrum ammoniaci.

Do. asafœtidæ. Do. ferri. Do. hydrargyri. plumbi. Do.

plumbi subcarbonatis compositum.

Do. resinosum.

Do. resinosum cantharidum. A.] EMPREUMATO'SIS. From εν, in, and πνεω, to blow.)
An inflation of the stomach, or any other viscus.

EMPO'RIUM. (From εμπορεω, to negotiate.) A mart. The brain is so called, as being the place where

all rational and sensitive transactions are collected.

EMPRESMA. Good revives this term (used in its

simple form both by Hippocrates and Galen, to express internal inflammation) to designate a genus of disease in his Class, *Hæmatica*; Order, *Phlogotica*. Visceral inflammation. It embraces inflammation of all the viscera: hence Empresma cephalitis; otitis; parotiriscela: hence Empresma exphantis; bitts; parotitis; paristhmitis; laryngitis; bronchitis; pneumonitis; pleuritis; carditis; peritonitis; gastritis;
enteritis; hepatitis; splenitis; nephritis; cystitis;
hysteritis; orchitis.

E'mprion. (From εν, and πρίων, a saw.) Serrated.
Formerly applied to a pulse, in which the artery at different times is unequally distended.

FMPROSTHOTONOS. (From expression before

EMPROSTHO TONOS. (From εμπροσθεν, before,

EMPROSTHO TONOS. (From εμπροσθεν, before, or forwards, and τεινω, to draw.) A clonic spasm of several muscles, so as to keep the body in a fixed position and bent forward. Cullen considers it as a species of tetanis. See Tetanus.

EMPTYSIS. (From εμπ/νω, to spit out.) A discharge of blood from the mouth.

EMPYE'MA. (From εν, within, and πνον, pus.) A collection of pus in the cavity of the thorax. It is one of the terminations of pleuritis. There is reason for believing that matter is contained in the cavity of the chest, when, after a pleurisy, or inflammation in the thorax, the patient has a difficulty of breathing, particularly on lying on the side opposite the affected one; and when an edematous swelling is externally perceptible.

EMPYE'MATA. (From Ev, and woov, pus.) Sup-

purating medicines.

EMPYESIS. (From εμπυοω, or εμπυεω, suppuro.)
Good has given this term (found in the fifth book of Hippocrates's aphorisms) to a genus of disease, class, Hamatica; order, Exanthematica, characterized by phlegmonous pimples, which gradually fill with a purulent fluid. It has only one species, small-pox— Empyesis variola.

Empyesis variola.

Empyreal air. Scheele gave this name to oxygen

EMPYREU'MA. (From εμπυρευω, to kindle, from πυρ, fire.) A peculiar and offensive smell that distilled waters and other substances receive from being exposed to heat in closed vessels, or when burned under circumstances which prevent the accession of air to a considerable part of the mass.

EMPYREUMA'TIC. Empyreumaticus; from εμπυρευω, to kindle.) Smelling as it were burnt; thus empyreumatic oils are those distilled with a great heat, and impregnated with a smell of the fire.

and impregnated with a smell of the fire.

EMU'LGENT. (Emulgens; from emulgeo, to melt out; applied to the artery and vein which go from the aorta and vena cava to the kidneys, because the ancients supposed they strained, and, as it were, milked the serum through the kidneys.) The vessels of the kidneys are so termed. The emulgent artery is a branch of the aorta. The emulgent vein evacuates its blood into the ascending cava.

EMU'LSIO. (Emulsio, onis. f.; from emulgeo, to milk 1. An emulgion. A soft and somewhat oils me.

milk) An emulsion. A soft and somewhat oily me-

fent tumours. It forms an admirable defensive and soft application, spread on linen, to surround a fractured limb.

dicine resembling milk. An imperfect combination of soft application, spread on linen, to surround a fractured limb. stances.

EMULSIO ACACIÆ. This is made in the same manner as the almond emulsion, only adding while beating the almonds, two ounces of gum arabic. This cooling the almonds, two ounces of gum arabic. This cooling and demulcent emulsion, ordered in the Edinburgh Pharmacopæia, may be drank ad libitum to mitigate ardor urina, whether from the venereal virus or any other cause. In difficult and painful micturition, and strangury, it is of infinite service. strangury, it is of infinite service.

Strangury, it is of infinite service.

EMULSIO AMYODALE. Almond emulsion. Take of almonds, one ounce; water, two pounds and a half. Beat the blanched almonds in a stone mortar, gradually pouring on them the water; then strain off the liquor. It possesses cooling and demulcent properties.

EMULSIO CAMPHORATA. Take of camphor, one scruple; sweet almonds, blanched, two drachms; double refined sugar, one drachm; water, six ounces. This is to be made in the same manner as the common emulsion. It is calculated for the stomache of those emulsion. It is calculated for the stomachs of those

who can only bear small quantities of camphire.

EMULSION. See Emulsio.

Emulsion, almond. See Emulsio amygdalæ.

Emulsion, Arabic. See Emulsio acaciæ.

Emulsion of asafatida. See Mistura asafatida. Emulsion, camphorated. See Emulsio camphorata. Emulsion of gum-ammoniac. See Mistura ammo-

EMU'NCTORY. (Emunctorium; from emungo, to drain off.) The excretory ducts of the body are so termed; thus the exhaling arteries of the skin constitute the great emunctory of the body.

Eng'ma. (From ey, and atha, blood.) Engmos. So Hippocrates and Galen call such object medicines

as are appropriated to bleeding wounds.

ENΞORΕ'ΜΑ. (From Σν, and αιωοεω, to lift up.) The pendulous substance which floats in the middle of the urine.

See Teeth.

ENANTHESIS. 1. (From ev, in, intra, and avbew, floreo; efflorescence from within, or from internal affection.) A genus of disease, Class, Hamatica; Order, Exanthematica, in Good's Nosology. Rash exanthem. It comprehends three species: viz. Enanthesis rosalia; rubeola; urticaria.

rubeola; urticaria.

2. (From $\varepsilon\nu$, and $a\nu/a\omega$, to meet.) The near approach of ascending and descending vessels.

ENARTHRO'SIS. (From $\varepsilon\nu$, in, and $a\rho\theta\rho\sigma\nu$, a joint.) The ball and socket-joint. A species of diarthrosis, or moveable connexion of bones, in which the round head of one is received into the deeper cavity of another, so as to admit of motion in every direction; as the head of the os femoris with the acetabulum of the os innominatum. See Articulation.

the os innominatum. See Articulation.

ENCA'NTHIS. (From v_{i} , and $\kappa a v \theta o_{i}$, the angle of the eye.) A disease of the caruncula lachrymalis, of which there are two species. Encanthis benigna, and Encanthis maligna seu inveterata. The encanthis its constant is such as the continuous conti and Encanthis maligna seu inveterata. The encanthis, at its commencement, is nothing more than a small, soft, red, and sometimes rather livid excrescence, which grows from the caruncula lachrymalis, and at the same time from the neighbouring semilunar fold of the conjunctiva. This excrescence on its first appearance is commonly granulated, like a mulberry, or is of a ragged and fringed structure. Afterward, when it has acquired a certain size, one part of it represents a granulated tumour, while the rest appears like a smooth, whitish, or ash-coloured substance, streaked with variouse vessels, sometimes advancing as far over with varicose vessels, sometimes advancing as far over the conjunctiva, covering the side of the eye next to the nose, as where the cornea and sclerotica unite.

The encanthis keeps up a chronic ophthalmy, impedes the action of the eyelids, and prevents, in particular, the complete closure of the eye. Besides, partly by compressing and partly by displacing the orifices of the puncta lachrymalia, it obstructs the free passage of the tears into the nose. The inveterate encanthis is ordinarily of a very considerable magnitude; its roots eytend beyond the caruncula lachrymalis and semiextend beyond the caruncula lachrymalis and semi-lunar fold to the membraneous lining of one or both eyelids. The patient experiences very serious incon-venience from its origin and interposition between the commissure of the cyclids, which it necessarily keeps asunder on the side towards the nose. Sometimes the disease assumes a cancerous malignancy. This character is evinced by the dull red, and, as it were, leaden colour of the excrescence; by its exceeding hardness, and the lancinating pains which occur in it, and extend to the forehead, the whole eyeball and the temple, especially when the tumour has been, though slightly, touched. It is also shown, by the propensity of the excrescence to bleed, by the partial ulcerations on its surface, which emit a fungous substance, and a thin and exceedingly acrid discharge.

ENCATALE PSIS. (From εν, and καγαλαμβανω, to seize.) A catalepsy.

to seize.) A catalepsy.

ENCATHI'SMA. (From εν, and καθιζω, to sit in.)

A semicupium, or bath for half the body.

ENCAU'MA. (From εν, in, and καιω, to burn.) A

arn. See Burn. ENCAU'SIS. (From &, and kato, to burn.)

ENCEPHALOCE'LE. (From ενκεφαλον, the brain, and κηλη, a tumour.) A rupture of the brain. ENCEPHALON. (From εν, in, and κεφαλη, the head.) Encephalum. By some writers the cerebrum head.) Encephalum. By some writers the cerebrum only is so called; and others express by this term the contents of the cranium.

ENCE'RIS. (From Ev, and knpos, wax.) A roll of

wax for making plasters.

Encero'sis. (From εν, and κεροω, to wax.) The covering of a plaster with wax.

ENCHARA'XIS. (From εν, and χαρασσω, to scarify.) A scarification.

rify.) A scarification.

ENCHEIRE'SIS. (From εν, and χειρ, the hand.)

Encheira. Galen uses this word as a part of the title
to one of his works, which treats of dissection. The word imports the manual treatment of any subject.

Enchei'ria. See Encheiresis. Enchilo'ma. See Enchyloma.

ENCHO'NDRUS. (From εν, and χονδρος, a cartilage.)

ENCHRIS'TA. (From εγχριω, to anoint.)

ENCHYLO'MA. (From εν, and χυλος, juice.) An inspissated juice. An elixir, according to Lemery. Ε'ΝCΗΥΜΑ. (From εν, and χεω, to infuse.) Επ-

chysis. 1. An infusion.

2. A sanguineous plethora. Enchy'mata. (From εγχυω, to infuse.) Injec-

tions for the eyes and ears.

ENCHYMO'MA. (From εν, and χυω, to pour in.) In the writings of the ancient physicians, it is a word by which they express that sudden effusion of blood into the cutaneous vessels, which arises from joy, anger, or shame; and, in the last instance, is what we usually call blushing.

ENCHYMO'SIS. Εγχυμωσις. 1. Blushing. 2. An extravasation of blood, which makes the part appear livid.

E'nchysis. See Enchyma.

ENCLY'SMA. (From εν, and κλυζω, to cleanse out.)

A clyster.
ENCŒ'LIA. (From εν, within, and κοιλια, the belly.) The abdominal viscera.
(From ενκολπεω, to insinuate.) A

uterine injection.

ENCRA'NIUM. (From sv, within, and κρανιον, the skull.) The cerebrum and the whole contents of the skull

Encrast'cholus. (From εν, in, κερας, the head, and χολη, bile; because it is said to have the gall in its head.) The anchovy. See Clupea.

Ε'ncris. Εγκρις. A cake of meal, oil, and honey.
Ε'ncymon. (From εν, and κυω, to conceive.)

Pregnancy. E'NCYSIS. (From εν, and κυω, to bring forth.)

ENCY'STED. Saccatus. A term applied to those tumours which consist of a fluid or other matter, en-

closed in a sac or cyst. ENCY'STIS. (From εν, in, and κυςις, a bag.) An

encysted tumour.

ENDE'MIC. (Endemicus, sc. morbus; from εν, in, and δημος, people.) A disease is so termed that is peculiar to a certain class of persons, or country; thus struma is endemial to the inhabitants of Derbyshire and the Alps; scurvy to seafaring people; and the plica polonica is met with in Poland.

E'ndesis. (From εν, and δεω, to tie up.) A ligature.

ENDIVE. See Cichorium.

ENDI'VIA. (Quasi cundo via, quia passim nasci-tur; named from the quickness of its growth.) Sec Cichorium.

(From ev, and διδωμι, to give.) A re-E'nposts.

ENDOSIS. (From Εν, and οιοωμι, to give.) A remission, disorder.

ENECIA. (From Ηνεκης, continued.) A genus of disease in Good's Nosology. Class, Hæmatica; Order, Pyretica: continued fever. It comprehends three species, Enecia cauma; typhus; synochus.

ENELLA'GMENUS. (From εναλλατζω, to interchange.) An epithet applied to the union of the

change.) An epithe

E'NEMA. (Enema, matis. neut.; from cymput, to inject.) A clyster. A well-known form of conveying both nourishment and medicine to the system, under certain morbid circumstances. The former takes place where obstruction of the passage to the stomach is so great as to render access to that organ impossible, such as occurs in lockjaw, diseased œsophagus, &c. By these means the body can be supported for a few weeks, while an attempt is made at effecting a cure. It is composed, in such cases, of animal broths, gruels It is composed, in such cases, of animal broths, grueis made of farinaceous seeds, mucilages, &c. As a form of medicine, clysters are no less useful; and, according to the intention with which they are prescribed, they are either of an emollient, anodyne, or purgative nature. The following forms are in general use.

Enema anodynum. Take of starch jelly, half a pint; tincture of opium, forty to sixty drops. Mix. The whole to be injected by means of a clyster-syringe, cases of dysentery or violent nurging, and pain in

in cases of dysentery or violent purging, and pain in

the bowels.

Enema antispasmodicum. Take of tincture of asafetida, half an ounce; tincture of opium, forty drops; gruel, half a pint. Mix. For spasmodic affections of the bowels. Take of tincture of

ENEMA LAXATIVUM. Take of sulphate of magne-sia, two ounces; dissolve in three quarters of a pint of warm gruel, or broth, with an ounce of fresh butter,

or sweet oil.

ENEMA NICOTIANÆ. Take of the infusion of to-bacco from a half to a whole pint. Employed in cases

of strangulated hernia.

Enema nutriens. Take of strong beef tea, twelve ounces; thicken with hartshorn shavings, or arrow-

root.

ENEMA TEREBINTHINE. Take of common turpentine, half an ounce; the yelk of one egg, and half a pint of gruel. The turpentine being first incorporated with the egg, add to them the gruel. This clyster is generally used, and with great good effect, in violent fits of the stone.

ENERGY: (From ενερειδω, to adhere to a compression.) A tight ligature.

E'NERGY. (Energia; from ενεργεω, to act.) The degree of force exercised by any power: thus, nervous energy, muscular energy, &c.

ENERVATING. The act of destroying the force,

use, or office of the nerves, either by cutting them, or breaking them by violence or abuse of the non-na-

turals.

ENEURE'SIS. See Enuresis.

ENERVIS. Ribless: applied to leaves which are without lines or ribs.

ENGALA'CTUM. (From εν, and γαλα, milk; so called, because it is eaten by nurses to increase their milk.) The herb saltwort. See Salsola.

ENGASTRIMY'THUS. (From εν, in, γαςηρ, the helly, and μνθεομαι, to discourse.) A ventriloquist;

belly, and μυθεομαι, to discourse.) A ventriloquist; one who appears to speak from his belly.

Engiso'MA. (From εγγιζω, to approach.)

1. An instrument for making the parts of a broken

clavicle meet

2. A fracture of the cranium.

English Mercury. See Mercurialis.
English Mercury. See Mercurialis.
ENGLOTTO-OASTOR. (From εν, γλωτ/η, the tongue, and γαςηρ, the belly.) A ventriloquist.
ENGOMPHO'SIS. (From εν, and γομφος, a nail, the species of articulation which resembles a nail driven into wood, as a tooth in its socket.

Engo'nios. (From εν, and γωνια, an angle.) The flexure, or angle made by the bending of a joint.

Eng'xum paracelsi. The caput mortuum of the

distillation of nitric acid, which is a super-sulphate of

potassa.
ENNEANDRIA. (From svesa, nine, and àvyo, a man.) The name of a class of plants in the sexual

system, containing such as have hermaphrodite flow- , the pulse, shrinking of the features, and distention of ers with nine stamina.

ENNEAPHA'RMACUM. (From EPPEA, Time, and Time and akov, a medicine.) simple ingredients.

ENNEAPHY'LLUM. ENNEAPHY'LLUM. (From εννεα, nine, and φυλλον, a leaf; because its flower consists of nine leaves.) A name for helleboraster, or bear's foot.

ENODIS. Without knots: applied to stems of plants, as Culmus enodis; that is, a smooth culm, as income common resheer.

in-our common rushes.

ENRY THMUS. (From εν, and ρυθμος, number.) A

pulse in some respect regular.

ENS. This word denoted in ancient chemistry the most efficacious part of any natural mixed body, whe-ther animal, vegetable, or fossil, wherein all the qua-lities or virtues of the ingredients of the mixed are comprehended in a small compass.

ENSATÆ. (From ensis, a sword.) The name of a natural order of plants, consisting of such as have

sword-shaped leaves.

E'NSIFORM. (Ensiformis; from ensis, a sword, and forma, resemblance.) Sword-like. 1. A term applied to some parts from their resemblance; as the ensiform cartilage.

In botany, a leaf is called folium ensiforme, which has two edges, and tapers to a point, like a sword.

See Leaf.

Ensta'ctum. (From εν, and ςαζω, to instil.) A liquid medicine, which is applied instillatim, or drop

hand medicine, which is applied instillatim, or drop by drop.

ENTASIA. (From evracus, intentio vehementia.)

A name of a genus of diseases in Good's Nosology.

Class, Neurotica; Order, Cinetica. Constrictive spasm. It has eight species, viz. Entasia priapismus; lozia; articularis; systremma; trismus; tetamus: lussa: aerotismus:

mus; lyssa; acrotismus.

Enta'tica. (From εν/ζεινω, to strain.) Provocatives, or whatever excites venereal inclination.

E'NTERA. (From εν/ζος, within.)

1. The bowels.

2. Hippocrates calls by this name the bags in which

2. Hippocrates calls by this name the bags in which medicines for fomentations were formerly enclosed. ENTERADE'NES. (From εν/ξοον, an intestine, and αόην, a gland.) The intestinal glands.

ENTERE'NCHYTA. (From εν/ξορα, the bowels, and εγχυω, to infuse into.) An instrument for administering clysters. A clyster-pipe.

ENTERICA. (From εντερον, intestinum, alvus.) The name of the first order, class Caliaca, of Good's Nosology. Diseases affecting the alimentary canal. Its genera are, Odontia: Ptualismus: Dushkagia:

Nosology. Diseases affecting the alimentary canal. Its genera are, Odontia; Ptyalismus; Dysphagia; Dipsosis; Limosis; Colica; Coprostasis; Diarrhaa; Cholera; Enterolithus; Helminthia; Proctica. ENTERI'TIS. (From 17/2001, an intestine.) Inflammation of the intestines. It is a genus of disease in the class Pyrexia, and order Phlegmasia of Cullen, and is known by the presence of pyrexia, fixed pain in the abdomen, costiveness, and vomiting. The causes of enteritis are much the same as those of gastritis, being occasioned by acrid substances, indurated faces, long-continued and obstinate costiveness, spasmodic colic, and a strangulation of any part of the intestinal canal; but another very general cause is the application of cold to the lower extremities, or to the belly itself. It is a disease which is most apt to occur at an advanced period of life, and is very liable to a at an advanced period of life, and is very liable to a

It comes on with an acute pain, extending in general over the whole of the abdomen; but more especially round the navel, accompanied with eructations, sickness at the stomach, a vomiting of bilious matter, ob-stinate costiveness, thirst, heat, great anxiety, and a quick and hard small pulse. After a short time the pain becomes more severe, the bowels seem drawn together by a kind of spasm, the whole region of the abdomen is highly painful to the touch, and seems drawn together in lumpy contractions; invincible cos-tiveness prevails, and the urine is voided with great difficulty and pain.

The inflammation continuing to proceed with vi-

olence, terminates at last in gangrene; or abating gradually, it goes off by resolution. Enteritis is always attended with considerable danger, as it often terminates in gangrene in the space of a few hours from its commencement; which event is marked by the sudden remission of pain, sinking of the belly, and it frequently proves fatal likewise, during the inflammatory stage. If the pains abate gradually, if natural stools be passed, if a universal sweat, attended with a firm equal pulse, comes on, or if a copious discharge of loaded urine, with the same kind of pulse takes place a resolution and favourable ter-

of pulse, takes place, a resolution and favourable termination may be expected.

Dissections of this disease show, that the inflammation pervades the intestinal tube to a very considerable tion pervades the intestinal tube to a very considerable extent; that adhesions of the diseased portion to contiguous parts are formed; and that, in some cases, the intestines are in a gangrenous state, or that ulcerations have formed. They likewise show, that, besides obstinate obstructions, introsusception, constrictions, and twistings, are often to be met with; and that, in most cases, the peritonæum is more or less affected, and is perceived, at times, to be covered with a layer of coagulable lymph. The treatment must be begun by taking blood freely from the arm, as far as the strength of the patient will allow; but the disease occurring more frequently in persons rather advanced in years, and of a constitution somewhat impaired, it becomes and of a constitution somewhat impaired, it becomes and of a constitution somewhat impaired, it becomes more important to limit this evacuation and rely in a great measure on the effects of a number of leeches, applied to the abdomen. Another very useful step is to put the patient into a hot bath, which may presently induce faintness; or where this cannot be procured, fomenting the abdomen assiduously. When the symptoms are thus materially relieved, an ample blister should be applied. It becomes also of the first importance to clear out the bowels: a copious laxative clyster ance to clear out the bowels: a copious laxative clyster will evacuate the inferior part of the canal, and solicit the peristaltic motion downwards; and the milder cathartics, as castor oil, neutral salts, &c. in divided cathartics, as castor oil, neutral salts, &c. in divided doses, may gradually procure a passage. But where the disease has been preceded by costiveness, more active articles will probably be necessary, as calomel, compound extract of colocynth, infusion of senna, with salts, &c. If the stomach be irritable, the effervescing saline draught may enable it to retain the requisite cathartics. Another plan, often very successful, is giving opium in a full dose, particularly in conjunction with calomel, taking care to follow it up by some of the remedies above mentioned, till the bowels are relieved; which effect it appears to promote by its soothing artispasmodic power. Afterward we may enare relieved; which effect it appears to promote by its soothing artispasmodic power. Afterward we may endeavour to keep up diaphoresis, and recruit the strength of the patient by a mild nourishing diet; taking care to guard against accumulation of faces, exposure to cold, or any thing else likely to occasion a relapse. ENTERO'. (From $\varepsilon_* / \varepsilon_p \rho_*$, an intestine.) Names compounded of this word belong to things which resemble an intestine; or to parts connected with, or diseases of some part of the intestine.

ENTEROCE LE. (From $\varepsilon_* / \varepsilon_p \rho_*$, an intestine, and $\varepsilon_\eta \lambda_\eta$, a tumour.) An intestinal rupture or hernia. Every hernia may be so called that is produced by the protrusion of a portion of intestine, whether it is in the

protrusion of a portion of intestine, whether it is in the groin, navel, or elsewhere.

ENTERO-EPIPLOCELE. (From εν/ερον, an intestine, επιπλοον, the epiploon, and κηλη, a tumour.) A rupture formed by the protrusion of part of an intestine,

with a portion of the epiploon.

ENTERO-HYDROCELE. (From εντερον, an intestine, υδωρ, water, and κηλη, a tumour.) This must mean a common scrotal hernia, with a good deal of water in the hernial sac; or else a hernia congenita, (in which the bowels descend into the tunica vaginalis testis,) attended with a collection of fluid in the cavity of this membrane

membrane.

ENTEROLITHUS. (From εντερον, an intestine, and λεθος, a stone.) The name of a genus of disease, Class, Caliaca; Order, Enterica, in Good's Nosology. Intestinal concretion. It embraces three species, viz.

Enterolithus bezoar; calculus; scybalum.

ENTERO'MPHALUS. (From εντερον, an intestine, and ομφαλος, the navel.) An umbilical hernia, produced by the protrusion of a portion of intestine.

ENTERO'PHYTUM. (From εν/ζερον, an intestine, and φη/λον, a plant.) A plant which grows in the form

ENTERO PHYTUM. (From εν/ερον, an intestine, and φυ/ον, a plant.) A plant which grows in the form of a gut, the sea-chitterling.

ENTERORA PHIA. (From εντερον, an intestine, and ραφη, a suture.) A suture of the intestines, or the sewing together the divided edges of an intestine.

ENTEROSCHEOCE LE. (From εν/τερον, an intestine, οσχεον, the scrotum, and κηλη, a rupture.) A

scrotal hernia, or rupture of the intestines into the

ENTHE MATA. (From εν 7ιθημι, to put in.) Anti-inflammatory styptics.

E'NTHLASIS. A contusion with the impression of the instrument by which it happened. Entire Leaf. See Integerrimus. ENTROCHI. A genus of extraneous fossils, made

up of round joints, which, when separate and loose,

are called trochita.

ENTROPIUM (Entropium, i. n.; from εν, and τρεπω, to turn.) A disease of the eyelids, occasioned by the eyelashes and cyclid being inverted towards the bulb of the eye.

ENTYPO'SIS. (From εν/νποω, to make an impres-on.) 1. The acetabulum.

sion.) 1. The acetabulum.
2. The scapula, or concave bone of the shoulder.
E'NULA. (A corruption of henula, or Helenium, from Helene, the island where it grew.) See Inula

ENULA CAMPANA. See Inula helenium.

ENU'LON. (From ev, and oulor, the gums.) The internal flesh of the gums, or that part of them which is within the mouth.

ENURE'SIS. (Eneuresis, is. f.; from ενουρεω, to make water.) An incontinency, or involuntary flow of urine. This disease usually proceeds either from relaxation or a paralytic affection of the sphincter of the bladder, induced by various debilitating causes, as too free a use of spirituous liquors, manustupration, and excess in venery; or it arises from compression on the bladder, from the diseased state of the organ, or from some irritating substance contained in its cavity. It is arranged in the class *Locales*, and order *Apocenoses* of Cullen, and contains two species: 1. Enuresis atonica, the sphincter of the bladder having lost its tone from some previous disease. 2. Enuresis ab irritatione, vel compressione vesice, from an irritation or compression of the bladder.

EPACMA'STICUS. (From επι, and ακμαζω, to increase.) A fever which is increasing in malignity.

EPA'CME. (From επακμαζω, to increase.) The increase, or exacerbation of a disease.

Erago' GIUM. (From επαγω, to draw over.) The prepuce, or that part of the penis which is drawn over the glans, according to Dioscorides.

Eranadido'stes. (From επαγαδιδωμε, to increase.) A term applied to fevers which continue to increase in their degree of heat.

EPANADIPLO SIS. (From επαναδιπλοω, to redupli-cate.) The reduplication of a fit of a semitertian fever; that is, the return of the cold fit before the hot fit is

EPANA'STASIS. (From επι, and ανιςημα, to excite.)
A tubercle, or small pustule upon the skin.
EPANCYLO'TUS. (From επι, and αγκυλος, crooked.)
A sort of crooked bandage in Oribasius.
EPANETUS. (From 'Επαντιμι, to return.) The name of a genus, Class Hæmatica; Order, Pyretica, in Good's Nosology. Remittent fever. It has three species, viz. Epanetus nutis; malignus; hectica.
EPA'RMA. (From επαιρω, to elevate.) Eparsis.
Any kind of tumour, but frequently applied to one of the parotid gland.

the parotid gland.

EPA'RSIS. See Eparma.
EPASMA'STIGA FEBRIS. A fever is so called by Bellini, and others, while it is in its increase. See Epac-

EPE'NCRANIS. (From επι, εν, in, and κρανιον, the skull.) The name of the cerebellum.

ΕΡΗΕΒΕ'UM. (From επι, and ηδη, the groin.) The hair upon the pubes.

Ε'ΡΗΕΡΚΑ. (From εφεζομαι, to sit upon.) Ephedrana.

1. The buttocks.

2. A species of here.

2. A species of horse-tail.

EPHE DRANA. See Ephedra.
EPHE LCIS. (From επι, upon, and ελκος, an ulcer.)
1. The crust of an ulcer.

The crust of an acces.
 Hardened purulent expectoration.
 EPHE'LIS. (Ephelis; from επι, and ηλιος, the sun.) A sun spot. A solitary, or aggregated spot, attacking most commonly the face, back of the hand, and breast, from exposure to the sun.

EPHE'MERA. (From επι, upon, and ημερα, a day.)
A disease of a day's duration.
2. A fever which begins, is perfectly formed, and runs through its course in the space of twelve hours.

332

EPHEME'RIDES. (Ephemeris, idis. f.: from εφημερις, an almanac: so called because, like the moon's age, they may be foretold by the almanac.) Diseases which return at particular times of the moon.

EPHIA'LTES. (From εφαλλομαι, to leap upon: so called because it was thought a dæmon leaped upon the breast.) Incubus, or nightmare. See Oneirodynia.

EPHIA'LTIA. (From ephialtes, the nightmare; so called because it was said to cure the nightmare.)

The herb peony. EPHIDRO'SIS. EPHIDRO'SIS. (From εφιδροω, to perspire.) Sudatio. Mador. A violent and morbid perspiration. A genus of disease in the class Locales, and order Approximates of Cullen.

EPHI PPIUM. A saddle, which it is thought to re-

semble. See Sella turcica.

E'rнороз. (From ext and odos, a way.) In Hippocrates it hath three significations

1. The ducts or passages, by which the excrements

of the body are evacuated.

2. The periodical attack of a fever, from the common use of it to express the attack of thieves.

3. The access of similar or dissimilar things, which may be useful or hurtful to the body.

EPIA'LTES. See Ephialtes.

EPI'ALUS. (From ηπιον, gently, and αλκαζω, to heat.) Epialos. An ardent fever, in which both heat and cold are felt in the same part at the same time. Galen defines it to be a fever in which the patient

labours under a preternatural heat and a coldness at the same time. The ancient Latins call it Quercera. Epi'bole. (From επιδαλλω, to press upon.) The

nightmare, or ephialtes.

EPICA'NTHIS. (From επι, and καιθος, the angle of the eye.) The angle of the eye.

EPICA'RPIUM. (From επι, upon, and καρπος, the wrist.) A medicine applied to the wrist.

EPICA'UMA. (From επι, and καιω, to burn.) A

burn.

EPICAU'SIS. A burn.
EPI'CERAS. (From επί, and κερας, a horn: so called because its pods are shaped like a horn.) See Trigo-

mella fanum gracum.

Epicera'stica. (From επι, and κεραννυμι, to mix.)

Medicines which, by mixing with acrimonious juices, temper them and render them less troublesome; as

emollients. (From emt, and xeep, the hand.) EPICHEIRE'SIS. A manual operation.

EPI'CHOLUS. (From em, and xohn, the bile.) Bilious.

EPICHO'RDIS. (From επι, upon, and χορόη, a gut.) The mesentery.

EPICHO'RIOS. (From επι, upon, and χορα, a region.)

The same as epidermis.

EPICHROSIS. (From επιχοωσις, a coloured or spotted surface.) The name of a genus of disease, Class, Eccritica; Order, Acrotica, in Good's Nosology. Macular skin, or simple discoloration of the surface. Macular skin, or simple discoloration of the surface. It embraces seven species, viz. Epichrosis leucasmus; spilus; lenticula; ephelis; aurigo; pacilia; alphosis. Epicœlis. (From επι, upon, and κοιλις, the eyelid.) The upper eyelid. EPICO'LIC. (Epicolicus; from επι, upon, and κωλον, the colon.) That part of the abdomen which lies over the head of the cocum and the sigmoid flexure of the colon, is called the epicolic region. Epicopho'sis. (From επι, and κωφος, deaf.) A total deafness.

total deafness

EPICRA'NIUM. (From em, and sparior, the cranium.) The common integuments, aponeurosis, and muscular expansion which lie upon the cranium.

and muscular expansion which he upon the cranium.

EPICRA'NIUS. See Occipito frontalis.

EPI'CRASIS. (From επι, and κεραννυμι, to temper.) A critical evacuation of bad humours, an attemperation of bad ones. When a cure is performed in the alterative way, it is called per Epicrasin.

EPICRISIS. (From επι, and κρινω, to judge from.) A judgment of the termination of a disease from present symptoms.

sent symptoms. sent symptoms.

EPICTE'NIUM. (From επι, about, and κ7ιις, the pubes.) The parts above and about the pubes.

EPICYE'MA. (From επι, upon, and κυω, to conceive.)

Epicyesis. Superfectation.

EPICYE'SIS. See Epicyema.

EPIDE'MIC. (Epidemicus; from επι, upon, and δημος, the people.) A contagious disease is so termed,

that attacks many people at the same season, and in the same place; thus, putrid fever, plague, dysentery, &c. are often epidemic.

EPIDE'NDRUM. (From επι, upon, and ἀενδρον, a tree; because all this genus of plants grow parasitically on the trunks or branches of trees.) The name of a genus of plants in the Linnæan system. Class, Gynandria; Order, Monandria.

EPIDENDRUM VANILLA. The systematic name of the vanelloe plant. Vanilla; Banlia; Banilas; Aracus aromaticus; Epidendrum—scandens, foliis ovato oblong is nervosis sessilibus caulinis, cirrhis spiralibus of Linnæus. The vanelloe is a long, flattish pod, containing, under a wrinkled brittle sheell, a reddish brown pulp, with small shining black seeds, which have an unctuous aromatic taste, and a fragrant smell like that of some of the finer balsams heightened with musk. Although chiefly used as perfumes, they are said to Although chiefly used as perfumes, they are said to possess approdisiac virtues.

EPI DERIS. (From em, and depas, the skin.) The

clitori

clitoris.

EPIDE'RMIS, (From επι, upon, and δερμα, the true skin.) The scarf-skin. See Cuticle.

EPI'DESIS. (From επι, upon, and δεω, to bind.) A bandage to stop a discharge of blood.

EPIDE'SMUS. (From επι, upon, and δεω, to bind.) A bandage by which splints, bolsters, &c. are secured. EPIDI'DYMIS. (From επι, upon, and δεῶνμος, a testicle.) A hard, vascular, oblong substance, that lies upon the testicle, formed of a convolution of the vas deferens. It has a thick end, which is convex, and situated posteriorly; and a thin end, which is rather flat, and situated inferiorly. The epididymis adheres to the testicle by its two extremities only, for its middle part is free, forming a bag, to which the tunica vagi-

part is free, forming a bag, to which the tunica vaginalis of the testicle is attached.

Ent'rosis. (From επιδιδωμι, to grow upon.) A preternatural enlargement of any part.

EPIDOTE. Pistacite of Werner. Acanticone from Norway. A sub-species of prismatoidal augite. A compounded one, containing silica, alumina, lime, oxide of iron, oxide of manganese, found in primitive beds and veins along with augite, hornblende, calcabeds and veins, along with augite, hornblende, calcareous spar, &cc.

(From επιδρεμω, to run upon.)

EPI'DROME. (F) afflux of humours. EPIGA'STRIC. EPIGA'STRIC. (Epigastricus; from $\varepsilon \pi \epsilon$, upon, or above, and $\gamma a_S \eta \rho$, the stomach.) That part of the abdomen that lies over the stomach, is called the epigastric region; it reaches from the pit of the stomach to an imaginary line above the navel, supposed to be drawn from one extremity of the last of the false ribs to the other. Its sides are called hypochondria, and are covered by the false ribs, between which lies the enigastrium.

epigastrium.

EPIGA'STRIUM. (From επι, upon, or above, and γαςηθ, the belly.)

The part immediately over the

EPIGENESIS. A name given by the ancients, to that theory of generation which consists in regarding the feetus as the joint production of matter afforded by

both sexes.

EPIGENNE'MA. (From επιγινομαι, to generate upon.) 1. The fur on the tongue.

2. An accessory symptom.

EPIGENNE'SIS. See Epigennema.

EPIGINO'MENA. (From επιγινομαι, to succeed or supervene.) Galen says, they are those symptoms which naturally succeed, or may be expected in the progress of a disease; but Foesius says, they are accessions of some other affection to diseases, which never happen but in stubborn and malignant diseases.

EPIGLO'SSUM. (From επι, upon, and γλωσσα, the tongue: so called because a less leaf grows above the larger in the shape of a tongue.) The Alexandrian

the larger in the shape of a tongue.) The Alexandrian laurel, a species of Ruscus. EPIGLO TTIS. (From $\iota\pi$, upon, and $\gamma \lambda \omega \tau / \iota \varepsilon$, the tongue.) The cartilage at the root of the tongue that falls upon the glottis or superior opening of the larynx. Its figure is nearly oval; it is concave poeteriorly, and convex anteriorly. Its apex or superior extremity is loose, and is always elevated upwards by its own elasticity. While the back of the tongue is drawn backwards in swallowing, the epiglottis is put over the aperture of the larynx, hence it shuts up the passage from the mouth into the larynx. The base of the epi-

A superfectation.

EPILE'MPSIS. See Epilepsy.

EPILE'NTIA. Corrupted from epilepsia.

EPILE'NTIA. Corrupted from epilepsia.

EPILEPSY. (Epilepsia, ω, f.; from επιλαμβανω, to seize upon: so called, from the suddenness of its attack.) It is also called falling sickness, from the patient suddenly falling to the ground on an attack of this disease. By the ancients it was termed, from its affecting the mind, the most noble part of the rational creature, the sacred disease. It consists of convulsions with sleep, and usually froth issuing from the mouth. It is a genus of disease in the class Neuroses, and order Spasmi, of Cullen, and contains three species:

Epilepsia cerebralis; attacking suddenly without manifest cause, and not preceded by any unpleasant sensation, unless perhaps some giddiness or dimness of

Epilepsia sympathica; without manifest cause, but preceded by a sensation of an aura ascending from

some part of the body to the head.

some part of the body to the head.

3. Epilepsio occasionalis; arising from manifest irritation, and ceasing on the removal of this. It comprehends several varieties:—R. Epilepsia traumatica, arising from an injury of the head: b. Epilepsia à dolore, from pain: c. Epilepsia verminosa, from the irritation of worms: d. Epilepsia à veneno, from poisons: e. Epilepsia exanthematica, from the repulsion of cutaneous eruptions: f. Epilepsia à cruditate ventriculi, from crudities of the stomach: g. Epilepsia ab inanitione, from debility: h. Epilepsia uterina, from hysterical affections: i. Epilepsia ex onanismo, from onanism, &c. onanism, &cc.

Epilepsy attacks by fits, and after a certain duration goes off, leaving the person most commonly in his usual state; but sometimes a considerable degree of stupor and weakness remain behind, particularly where the disease has frequent recurrences. It is oftener met with among children than grown persons, and boys seem more subject to its attacks than girls. Its returns are periodical, and its paroxysms commence more frequently in the night than in the day, being somewhat connected with sleep. It is sometimes counterfeited, in order to extort charity or excite com-

Epilepsy is properly distinguished into sympathetic and idiopathic, being considered as sympathetic, when produced by an affection in some other part of the

produced by an affection in some other part of the body, such as acidities in the stomach, worms, teething, &c. as idiopathic when it is a primary disease, neither dependent on nor proceeding from any other.

The causes which give rise to epilepsy are blows, wounds, fractures, and other injuries, done to the head by external violence, together with lodgments of water in the brain, tumours, concretions, and polypi. Violent affections of the nervous system, sudden frights, fits of passion, great emotions of the mind, acute pains in any part, worms in the stomach or intestines, teething, the suppression of long-accustomed evacuations, too any part, worms in the stomach or intestines, teething, the suppression of long-accustomed evacuations, too great emptiness or repletion, and poisons received into the body, are causes which likewise produce epilepsy. Sometimes it is hereditary, and at others it depends on a predisposition arising from mobility of the sensorium, which is occasioned either by plethora, or a state of debility.

An attack of epilepsy is now and then preceded by

of debility.

An attack of epilepsy is now and then preceded by a heavy pain in the head, dimness of sight, noise in the ears, palpitations, flatulency in the stomach and intestines, weariness, and a small degree of stupor, and in some cases, there prevails a sense of something like a cold vapour or aura arising up to the head; but it more generally happens that the patient falls down suddenly without much previous notice; his eyes are distorted, or turns so that only the whites of them can be seen; his fingers are closely clenched, and the trunk

EPI EFI

tion, or comes on after the age of puberty, or where the fits recur frequently, and are of long duration, it will be very difficult to effect a cure: but when its attacks are at an early age, and occasioned by worms, or any accidental cause, it may in general be removed with ease. In some cases, it has been entirely carried off by the occurrence of a fever, or by the appearance of a cutaneous eruption. It has been known to terminate in apoplexy, and in some instances to produce a loss of the powers of the mind, and to bring on idiotism.

The appearances usually to be observed on dissection, are serous and sanguineous effusion, a turgid tense state of the vessels of the brain without any effusion,

state of the vessels of the brain without any effusion, a dilatation of some particular part of the brain, excrescences, polypi, and hydatids, adhering to it, and obstructing its functions, and likewise ulcerations.

During the epileptic paroxysm in general, little or nothing is to be done, except using precautions, that the patient may not injure himself; and it will be prudent to remove any thing which may compress the veins of the neck, to obviate congestion in the head. Should there be a considerable determination of blood to this part, or the patient very plethoric, it may be proper, if you can keep him steady, to open a vein, or the temporal artery; and in weakly constitutions the most powerful antispasmodics may be tried in the form of clyster, as they could hardly be swallowed: but there is very seldom time for such measures. In the intervals, the treatment consists: 1. In obviating the intervals, the treatment consists: 1. In obviating the several exciting causes. 2. In correcting any observable predisposition. 3. In the use of those means, which are most likely to break through the habit of re-

I. The manner of fulfilling the first indication requires little explanation; after an injury to the head, or where there is disease of the bone, an operation may be necessary, to remove irritation from the brain; in children teething, the gums ought to be lanced: where children teething, the gums ought to be lanced: where the bowels are foul, or worms suspected, active purgatives should be exhibited, &c. In those instances in which the aura epileptica is perceived, it has been recommended to destroy the part, where it originates, or divide the nerve going to it, or correct the morbid action by a blister, &c.; such means would certainly be proper when there is any disease discoverable in It. Making a tight ligature on the limb above has sometimes prevented a fit; but, perhaps, only through the medium of the imagination.

medium of the imagination.

II. Where a plethoric state appears to lay the foundation of the disease, which is often the case, the patient must be restricted to a low diet, frequent purges exhibited, and the other excretions kept up, and he should take regular moderate exercise, avoiding what-ever may determine the blood to the head; and to ever may determine the blood to the head; and to counteract such a tendency, occasional cupping, blisters, issues, &c. may be useful, as well as the showerbath; but in urgent circumstances, the lancet ought to be freely used. If, on the contrary, there are marks of inanition and debility, a generous diet, with tonic medicines, and other means of strengthening the system, will be proper. The vegetable tonics have not been so successful in this disease as the metallic preparations, particularly the sulphate of zinc, the nitrate of silver, and the ammoniated copper, but this cannot perhaps be so safely persevered in: where the patient is remarkably exsanguineous, chalybeates may answer better; and, in obstinate cases, the arsenical solution might have a cautious trial. In irritable constitutions, sedatives are indicated, as digitalis, opium, &c.: but might have a cautious trial. In irritable constitutions, sedatives are indicated, as digitalis, opium, &c.: hut the free use of opium is restricted by a tendency to congestion in the head. Where syphilis appears to be concerned, a course of mercury is proper; in scrofulous habits, bark, or steel, with iodine, soda, and seabathing; and so on.

III. The third division of remedies comes especially

of his body, particularly on one side, is much agitated; he foams at the mouth, and thrusts out his tongue, which often suffers great injury from the muscles of the lower jaw being affected; he loses all sense of feeling, and not unfrequently voids both urine and faces involuntarily.

The spasms abating, he recovers gradually; but on coming to himself feels languid and exhausted, and retains not the smallest recollection of what has passed during the fit.

When the disease arises from an hereditary disposition, or comes on after the age of puberty, or where tion. Also long voyages have removed it, which might especially be hoped for at the age of puberty, particu-larly if a considerable change in the mode of life were larly if a considerable change in the mode of life were made in other respects; those who had lived indolently being obliged to exert themselves, the diet properly adapted to the state of the system, &c.

EPILO BIUM. (From επι λοβου τον, a violet or beautiful flower, growing on a pod.) The name of a genus of plants in the Linnæan system. Class, Octandria; Order, Monogynia.

ENTORING ANGESTINGLIAM, Rose-bay-willow herb.

EPILOBIUM ANGUSTIFOLIUM. Rose-bay-willow herb. The young tender shoots cut in the spring, and dressed as asparagus, are little inferior to it.

EPIME DIUM. The plant barren-wort.

EPIMO'RIUS. (Fro επι, and μειρω, to divide.) An obsolete term, formerly applied to an unequal pulse.

EPIMO'LIS. (From επι, and μυλη the knee.) The

EPIMY'LIS. (From επι, and μυλη, the knee.) The patella or knee-bone

EPINENEU'CUS. (From επινευω, to nod or incline.)

EPINENEU'CUS. (From επινευω, to nod or incline.) An unequal pulse.

EPINO TIUM. (From επι, upon, and νω/ος, the back.) The shoulder-blade.

EPINY CTIS. (From επι, and νυξ, night.) A pustule, which rises in the night, forming an angry tumour on the skin of the arms, hands, and thighs, of the size of a lupine, of a dusky red, and sometimes of a livid and pale colour, with great inflammation and pain. In a few days it breaks, and sloughs away.

'Epipa'ctis. (From επιπακ/οω, to coagulate.) A plant mentioned by Dioscorides; and so named because its juice was said to coagulate milk.

Epiparoxy'smus. (From επι, upon, and παροξυσμος, à paroxysm.) An unusual frequency of febrile exacerbation.

Epipa'stum. (From επι, upon, and πασσω, to

EPIPA'STUM. (From επι, upon, and πασσω, to sprinkle.) Any powdered drug sprinkled on the body.

EPIPE CHYS. (From επι, above, and πηχυς, the cubit.) That part of the arm above the cubit.

EPIPHLOGI'SMA. (From επι, upon, and φλογιζω, to inflame.) 1. Violent inflammation, or burning heat in any part, attended with pain, tumour, and redness.

2. A name given by Hippocrates to the shingles.
EPIPHORA. (From επιφέρω, to carry forcibly.)
The watery eye. An involuntary flow of tears. A su-The watery eye. An involuntary flow of tears. A superabundant flowing of a serous or aqueous humour from the eyes. A genus of disease in the class Locales, and order Apocenoses, of Cullen. The humour which flows very copiously from the eye in epiphora, appears to be furnished, not only by the lachrymal gland, but from the whole surface of the conjunctive membrane, Meibomius's glands, and the carancula lachrymalis; which increased and morbid secretion may be induced from any stimulus seated between the globe of the eye and lids, as sand, acrid fumes, and the like; or it may and lids, as sand, acrid fumes, and the like; or it may drise from the stimulus of active inflammation; or from the acrimony of scrofula, measles, small-pox, &c., or from general relaxation. The disease may also arise from a more copious secretion of tears, than the puncta lachrymalia can absorb, or, as is most common, from an obstruction in the lachrymal canal, in consequence of which the tears are prevented from passing freely

from the eye into the nose.

EPIPHRAGMA. The slender membrane which sometimes shuts the peristoma of mosses, as is seen

EPI PHYSIS. (From επι, upon, and φυω, to grow.) Any portion of bone growing upon another, but separated from it by a cartilage.

rated from it by K Cartinage.

EPIPLA'SMA. (From επι, upon, and πλασσαω, to spread.) 1. A poultice.

2. A name for an application of wheat meal, boiled in hydrelæum, to wounds.

EPIPLO. (From επιπλοογ, the omentum.) Names compounded of this word belong to parts connected with, or disease of, the epiploon.

EPIPLOCE'LE. (From επιπλοογ, the omentum.

and κηλη, a tumour.) An omental hernia. A rupture produced by the protrusion of a portion of the omentum. See Hernia omentalis.

This complaint is to be considered as of little constant and the omentum.

EPIPLOCOMI'STIS. (From επιπλοον, the omentum, and κομιζω, to carry.) One who has the omentum morbidly large.

Epiploic appendages. See Appendicula epiploica. EPIPLOLTIS. (From επιπλοον, the omentum.) An inflammation of the process of the peritonsum, that forms the epiploon or omentum. See Peritonitis. EPIPLOO MPHALON. (From επιπλοον, the omen-

tum, and $o\mu\phi\alpha\lambda_{05}$, the navel.) An omental hernia protruding at the navel.

EPI'PLOON. (From επιπλοω, to sail over, because it is mostly found floating, as it were, upon the intes-

tines.) See Omentum.
EPIPLOSCHEOCE'LE. (From επιπλοου, the omentum, οσχεου, the scrotum, and κηλη, a tumour or hernia.) A rupture of the omentum into the scrotum,

or a scrotal hernia containing omentum.

EPIPO LASIS. (From επιπολαζω, to swim on the top.)

1. A fluctuation of humours.

2. A species of chemical sublimation. EPIPO MA. (From $\varepsilon \pi_1$, upon, and $\pi \omega \mu a$, a lid.) An instrument to cover the shoulder in a luxation.

ΕΡΙΡΟΠΟ ΜΑ. (From επιπωρεω, to harden.) A hard

EPIPORO'MA. (From επιπωρεω, to harden.) A hard tumour about the joints.

EPIPTY'XIS. (From επιπ'/νοσω, to close up.) A spasmodic closing of the lips.

EPIPYRE'XIS. (From επι, and πυρετ'/ω, to be feverish.) A rapid exacerbation in a fever.

EPIRIGE SIS. (From επι, and ριγεω, to become cold.) An unusual degree of cold, or repetition of rigors.

EPI'RRHOE. (From επι, upon, and ρεω, to flow.) An influx or afflux of humours to any part.

EPISARCI'DIUM. (From επι, upon, and σαρξ, the flesh.) An anasarca, or dropsy, spread between the skin and flesh.

EPISCHE'SES. (From επισχιω, lo restrain.) A

EPISCHE'SES. (From επισχεω, to restrain.) A suppression of excretions. It is an order in the class Locales of Cullen's Nosology.

EPI'SCHIUM. (From επι, upon, and ισχιον, the hip-bone.) The os pubis.

EPISCOPA'L. (From episcopus, a bishop, or mitred dignitary.) Of, or belonging to a bishop: applied to a valve at the orifice between the left auricle and ventricle of the heart. See Mitral valve.

EPISPA'SMUS. (From episcopus, to draw together.)

EPISPA'SMUS. (From επισπαω, to draw together.)

A quick inspiration.

A quick inspiration.

EPISPA'STIC. (Epispasticus; from επισπαω, to draw together.) Those substances which are capable, when applied to the surface of the body, of producing a serous or puriform discharge, by exciting a previous state of inflammation. The term, though comprehending likewise issues and setons, is more commonly restricted to blisters—those applications which, exciting inflammation on the skin, occasion a thin serous citing inflammation on the skin, occasion a thin serous fluid to be poured from the exhalants, raise the cuticle, and form the appearance of a vesicle. This effect arises from their strong stimulating power, and to this stimulant operation and the pain they excite, are to be ascribed the advantages derived from them in the treatment of disease. The evacuation they occasion is too inconsiderable to have any material effect. See

EPISPHE'RIA. (From επι, and σφαισα, a sphere: so called from the spherical shape of the brain.) The windings of the exterior surface of the brain; or the winding vessels upon it.

EPISTA GMUS. (From em, and sagu, to trickle

down.) A catarrh.

down.) A catarrh.

EPISTAPHYLI'NUS. (From επι, and ςαφυλη, the uvula.) See Uvula.

EPISTA'XIS. (From επιςαζω, to distil from.) Bleeding at the nose, with pain or fulness of the head. A genus of disease arranged by Cullen in the class Pyrexiæ, and order Hamarrhagiæ.

Persons of a sanguine and plethoric habit, and not yet advanced to manhood, are very liable to be attacked with this complaint: females being much less subject to it than males, particularly after menstruation.

subject to it than males, particularly after menstruation. Epistaxis comes on at times without any previous

This complaint is to be considered as of little consequence, when occurring in young persons, being never attended with any danger; but when it arises in those who are advanced in life, flows profusely, and returns frequently, it indicates too great fulness of the vessels of the head, and not unfrequently precedes apoplexy, palsy, &c. and, therefore, in such cases, is to be regarded as a dangerous disease. When this hæmorrhage arises in any putrid disorder, it is to be considered as a fatal symptom.

considered as a fatal symptom.

In general, we need not be very anxious to stop a discharge of blood from the nose, particularly where there are marks of fulness of the vessels of the head: but if it occurs under a debilitated state of the head: but if it occurs under a debilitated state of the system, or becomes very profuse, means must be employed to suppress it. These are chiefly of a local nature; applying pressure to the bleeding vessels, introducing astringents into the nostriks, as solutions of alum, sulphate of zinc, sulphate of copper, &c. applying cold to the head, or to some very sensible part of the skin, as in the course of the spine, &c. At the same time the patient should be kept in the erect position. If the hæmorrhage be of an active character, the antiphlogistic regimen should be carefully observed: the patient kept cool and quiet: the saline the antiphiogistic regimen should be carefully observed: the patient kept cool and quiet; the saline cathartics, refrigerants, as nitrate of potassa and the acids, digitalis, diaphoretics, &c. administered internally; and blood may be taken from the temples by leeches, or even from the arm, if the patient be very plethoric. Sometimes, after the failure of other means, closing the posterior as well as anterior outlets from the nose, and preventing the escare of the blood for some closing the posterior as well as anterior outlets from the nose, and preventing the escape of the blood for some time mechanically, has been successful; and this might be particularly proper, where it was discharged copiously into the fauces, so as to endanger suffocation, on the patient falling asleep.

EPISTHO TONOS. (From επισθεν, forwards, and τεινω, to extend.) A spasmodic affection of muscles drawing the body forwards. See Tetanus.

EPISTO MION. (From επι, upon, and ςομα, a mouth.)

1. A stopper for a bottle.

A stopper for a bottle.
 A venthole of a furnace, called the register.

Eristro rhalus. (From επι, upon, and ςρεφω, to turn about.) Epistrophia, and Epistrophis. Applied to the first vertebra of the neck, because it turns about

upon the second as upon an axis.

Epi'strophe. (From επιςρεφω, to invert.) I. An inversion of any part, as when the neck is turned

2. A return of a disorder which has ceased.

EPI'STROPHEUS. (From επιςροφαω, to turn round, because the head is turned upon it.) The second cervical vertebra. See Dentatus.

EPI'STROPHIS. See Epistrophalus.

EPI'STROPHIS. (From επι and τεννω to extend.) The

EPI TASIS. (From επτ, and τεινω, to extend.) The beginning and increase of a paroxysm or disease. EPITHE LIUM. The cuticle on the red part of the

EPITHE'MA. (From επι, upon, and τιθημι, to apply.) A term formerly applied to a lotion, fomentation, or

any external application.

EPITHEMA'TIUM. The same.

EPI'THESIS. (From επι, and τιθημι, to cover, or lay upon.) The rectification of crooked limbs by means of instruments.

EPITHY'MUM. (From επι, upon, and θυμος, the herb thyme.) See Cuscuta epithymum.

Ero'de. (From επι, over, and ωδη, a song.) Epodos. The method of curing distempers by incantation.

EPOM'18. (From επι, upon, and ωμος, the shoulder.)
The acromion, or upper part of the shoulder.
EPOMPHA'LUM. (From επι, upon, and ομφαλος, the navel.) An application to the navel.
EPSOM. The name of a village in Surrey, about eighteen miles from London, in the neighbourhood of which is a considerable mineral spring, called Epsom water. Aqua Epsomensis. This water evaporated to dryness leaves a residuum, the quantity of which has been estimated from an ounce and a half in the gallon, Epistaxis comes on at times without any previous warning; but at others, it is preceded by a pain and heaviness in the head, flushing in the face, heat and itching in the nostrils, a throbbing of the temporal arteries, and a quickness of the pulse. In some instances a coldness of the feet, and shivering over the

tions. There is nothing sulphurous or metallic ever found in this spring. The diseases in which it is em-ployed are similar to those in which we use Seidlitz water. There are many other of the simple saline water. There are many other of the simple saline springs that might be enumerated, all of which agree with that of Epsom, in containing a notable proportion of some purging salt, which, for the most part, is either sulphate of magnesia, or sulphate of soda, or often a mixture of both, such as Acton, Kilburne, Bagnigge Wells, Dog and Duck, St. George's Fields, &c.

Epsom salt. A purging salt formerly obtained by boiling down the mineral water found in the vicinity of Epsom in Surrey. It is at present prepared from sea water, which, after being boiled down, and the muriate of soda separated, deposites numerous crystals, that consist chiefly of sulphate of magnesia, and sold in the shops under the name of sal catharticus amarus,

in the shops under the name of sal catharticus amarus,

or bitter purging salt. See Magnesiæ sulphas. EPU'LIS. (From επι, and ουλα, the gums.) A small tubercle on the gums. It is said sometimes to

small tubercle on the gums. It is said sometimes to become cancerous.

EPULO'TIC. (Epuloticus; from επουλοω, to cicatrize.) A term given by surgeons to those applications which promote the formation of skin.

EQUISE'TUM. (From equus, a horse, and seta, a bristle: so named from its resemblance to a horse's tail.) 1. The name of a genus of plants in the Linnæan system. Class, Cryptogamia; Order, Filices.

2. The pharmacopæial name of the Cauda equina. See Hippuris vulgaris.

See Hippuris vulgaris.
EQUISETUM ARVENSE. See Hippuris ulgaris.
EQUITANS. Equitant. This term is applied to leaves, which are disposed in two opposite rows, and clasp each other by their compressed base; as in Nar-

thecium ossijragum.

EQUIVALENTS. A term introduced into chemistry by Dr. Wollaston, to express the system of definite ratios, in which the corpuscular objects of this science reciprocally combine, referred to a common standard, reckoned unity. See Atomic system.

E'QUUS. 1. The horse.

The name of a genus of animals of the order

Bellua

EQUUS ASINUS. The systematic name of the animal called an ass; the female affords a light and nutritious milk. See Milk, asses.

ERA'NTHEMUS. (From ηρ, the spring, and ανθεμος, a flower: so called because it flowers in the spring.)

A sort of chamomile.

ERASIS TRATUS. A celebrated Greek physician, said to have been born in the island of Ceos, and cian, said to have been born in the island of Ceos, and to have been the most distinguished pupil of Chrysippus, of the Cnidian school. He was the first, in conjunction with Herophilus, to dissect human bodies, anatomy having been before studied only in brutes; but the Ptolemies having allowed them to examine malefactors, they were enabled to make many important discoveries. Celsus notices a very improbable report, that they opened the bodies of those persons alive, to observe the internal motions; they could hardly then have maintained, that the arteries and left ventriele, do not naturally contain blood, but air only hardly then have maintained, that the arteries and left ventricle, do not naturally contain blood, but air only. The works of Erasistratus, which were numerous, are lost; but, from the account of Galen, he appears to have very accurately described the brain, which he considered as the common sensorium; also the heart and large vessels; and pointed out the office of the liver and kidneys; but he supposed digestion performed by trituration. He imagined inflammation and fever to arise from the blood being forced through the minute veins into the corresponding arteries. He was averse to blood-letting, or the use of active medicines, but sometimes employed mild clysters; trusting, however, principally to abstinence, and proper exercise. Being tormented with an ulcer in the foot, at an extreme old age, he is said to have terminated his existence by poison.

extreme old age, he is said to have terminated ms existence by poison.

ERATE'VA MARMELOS. This plant, a native of several parts of India, affords a fruit about the size of an orange, and covered with a hard bony shell, containing a yellow viscus pulp, of a most agreeable flavour; which, when scooped out, and mixed with sugar and orange, is brought to the tables of the grandees in India, who eat it as a great delicacy. It is also esteemed as a sovereign remedy against dysentery.

dysentery. Erisi'n Thus. Ερεδίνθος. The vetch. 336

ERE'CTOR. The name of several muscles, the office of which is to raise up the part to which they are inserted.

ERECTOR CLITORIDIS. First muscle of the clitoris of Douglas. Ischio-cavernosus of Winslow, and Ischio-clitoridien of Dumas. A muscle of the clitoris that draws it downwards and backwards, and serves to make the body of the clitoris more tense, by squeezing the blood into it from its crus. It arises from the tuberosity of the ischium, and is inserted into the clitoris.

clitoris.

ERECTOR PENIS. Ischio-cavernosus of Winslow, and Ischio-caverneux of Dumas. A muscle of the penis that drives the urine or semen forwards, and, by grasping the bulb of the urethra, pushes the blood towards the corpus cavernosum and the glans, and thus distends them. It arises from the tuberosity of the ischium, and is inserted into the sides of the cavernous substance of the penis.

ERECTUS. Upright. Botanists use this to express the direction of the stem, branches, leaves, petals, stamens. pistils, &c.: as Caulis erectus, an upright

stamens, pistils, &c.; as Caulis erectus, an upright stem, as in Lysimackia vulgaris; folium erectum, forming an acute angle with the stem, as in Juncus articulatus, &c. The petals of the Brassica

ERETHI'SMUS. (From ερεθιζω, to excite or irritate.) Increased sensibility and irritability. It is variously applied by modern writers. Mr. Pearson has described a state of the constitution produced by has described a state of the constitution produced by mercury acting on it as a poison. He calls it the mercurial crithismus, and mentions that it is characterized by great depression of strength, anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small, quick, sometimes intermitting pulse, occasional vomiting, a pale, contracted countenance, a sense of coldness; but the tongue is seldom furred, nor are the vital and natural functions much disturbed. In this state, any sudden exertion will sometimes prove fatal. sometimes prove fatal.

ERGASTE RIUM. (From εργον, work.) A laboratory: that part of the furnace in which is contained the matter to be acted upon.

ERI'CA. (From ερεικω, to break; so named from its fragility, or because it is broken into rods to make besoms of.) The name of a genus of plants in the Linnæan system. Class, Octandria; Order, Monogynia. Heath. nia. Heath.

ERICE RUM. (From ερεικη, heath.) A medicine in which heath is an ingredient.

ERI'GERON. (Ηριγερων, of the ancient Greeks; from ηρ the spring, and γερων, an old man, because, in the spring, it has a white, hoary blossom, like the hair of an old man.) 1. The name of a genus of Class, Syngenesia; Order, Polygamia superflua.
2. The common chick-weed is so called in old books.

2. The common chick-ween's so can a more services.

See Senecio vulgaris.

ERIGERUM. See Senecio vulgaris.

ERO'SION. (Erosio; from erodo, to gnaw off.)

This word is very often used in the same sense as ulceration, viz. the formation of a breach or chasm in the substance of parts, by the action of the absorbance.

EROSUS. Jagged. A leaf is called folium crosum, the margin of which is irregularly cut or notched, especially when otherwise divided besides; as in Sc-

especially when otherwise divided besides; as in Senecio squalidus.

EROTIA'NUS, the author of a Glossary, containing an explanation of the terms in Hippocrates, lived in the reign of Nero. The work was printed at Venice, in 1566; and also annexed to Foesius's Edition of Hippocrates.

EROTOMA'NIA. (From tpos, love, and µavia, madness.) That melancholy, or madness, which is the effect of love.

the effect of love.

the effect of love.

E'RPES. (From ερπω, to creep: so named from their gradually increasing in size. See Herpes.

ERRA'TIC. (Erraticus; from erro, to wander.) Wandering; irregular. A term occasionally applied to pains, or any disease which is not fixed, but moves from one part to another, as gout, rheumatism, &c.

E'RRHINE. (Errhinus; ερρινα, from εν, in, and οιν, the nose.) By errhines are to be understood those medicines which, when topically applied to the internal membrane of the nose, excite sneezing, and increase the secretion, independent of any mechanical

irritation. The articles belonging to this class may be referred to two orders.

referred to two orders.

1. Sternutatory errhines; as nicotiana, helleborus, euphorbium, which are selected for the torpid, the vigorous, but not plethoric, and those to whom any degree of evacuation would not be hurtful.

2. Evacuating errhines; as asarum, &c. which are calculated for the phlegmatic and infirm.

E'RROR LOCI. Boerhaave is said to have introduced this term, from the opinion that the vessels were of different sizes, for the circulation of blood, lymph, and serum, and that when the larger sized globules were forced into the less vessels, they became obstructed, by an error of place. But this opinion does not appear to be well-grounded.

ERUCA. (From orugo, to make smooth; so named

ERU CA. (From crugo, to make smooth; so named from the smoothness of its leaves, or from uro, to burn, because of its biting quality.) See Brassica

ERUCA SYL'VESTRIS. The wild rocket. See Bras-

ERUCTATION. Belching.
ERUPTION. Eruptio. A discoloration, or spots on the skin; as the eruption of small-pox, measles, nettle-rash, &c.

ERUTHEMA. (From ερυθω, to make red.) A fiery

red tumour, or pustules on the skin.

E'RVUM. (Quasi arvum, a field, because it grows wild in the fields; or from erno, to pluck out, because it is diligently plucked from corn.) The tare. 1. The name of a genus of plants in the Linnæan system. Class, Diadelphia; Order, Decandria.

2. The pharmacopæial name of tare. See Errum

ervilia.

ERVUM ERVILIA. Orobus. The seeds of this plant, Ervum ervalia—germinibus undatoplicatis, folias imparipinnatis of Linnaus, have been made into bread in times of scarcity, which is not the most salubrious. The meal was formerly among the resolvent remedies by way of poultice.

ERVUM LENS. The systematic name of the lentillens. Φακος of the Greeks. Ervum—pedunculis subbifloris; seminibus compressis, convexis, of Linnaus. There are two varieties; the one with large, the other with small seeds. They are eaten in many places as we eat pease, than which they are more flatulent, and more difficult to digest. A decoction of these seeds is used as a lotion to the ulcerations after small-pox and, it is said, with success.

t is said, with success.
 ERY'NGIUM. (From τρυγγανω, to eructate.)
 Eryngo, or sea-holly. I. The name of a genus of plants in the Linnæan system. Class Pentandria;
 Order, Digynia.
 2. The pharmacopæial name of the sea-holly. See

Eryngium maritimum.

["ERYNGIUM AQUATICUM. Button snake-root. The Eryngium aquaticum is a native of the southern states. We are told in Mr. Elliott's botany, that the root is of a pungent, bitter, and aromatic taste. When chewed, it were sensibly excites a flow of saliva. A decoction it very sensibly excites a flow of saliva. A decection of it is diaphoretic and expectorant, and sometimes proves emetic. It is preferred by some physicians to the Seneca snake-root, which it much resembles in its effects." A.]

the Seneca snake-root, which it much resembles in its effects." A.]

ERYNGIUM CAMPESTRE. The root of this plant,
Eryngium—foliis radicalibus, amplexicaulibus, pinmato-lanceolatis, of Linnæus, is used in many places
for that of the sea-cryngo. See Eryngium.

ERYNGIUM MARITIMUM. The systematic name of
the sea-holly or eryngo. Eryngium—foliis radicalibus
subrotundis, plicatis spinosis, capitulis pedunculatis,
paleis tricuspidatis, of Linnæus. The root of this
plant is directed for medical use. It has no particular
smell, but to the taste it manifests a grateful sweetsmell, but to the taste it manifests a grateful sweetness; and, on being chewed for some time, it discovers a light aromatic warmth or pungency. It was formera light aromatic warmth or pungency. It was formerly celebrated for its supposed aphrodisiac powers, but it is now very rarely employed.

ERYNGO. See Eryngium.

Eryngo, sea. See Eryngium.

Eryngo-leaved lichen. See Lichen islandiens.

ERY SIMUM. (From epow, to draw, so called from its power of drawing and producing blisters. Others derive it from one row together, because the leaves are

derive it from απο του ερεικειν, because the leaves are much cut; others from ερετερον, precious.) 1. The name of a genus of plants in the Linnman system. Class, Tetradynamia; Order, Siliquosa.

2. The pharmacopæial name of the hedge-mustard-

See Erysimum officinale. Erysimum albiaria. The systematic name of Jack-in-the-hedge. Alliaria; Chamaplion of Oriba-sius. Sauce alone, or stinking hedge-mustard. The plant to which this name is given, is the Erysimum foliis cordatis, of Linnæus; it is sometimes exhibited in humid asthma and dyspnæn, with success. Its virtues are powerfully diaphoretic, diuretic, and anti-scorbutic.

ERYSIMUM BARBAREA. The systematic name of the barbarea of the shops. The leaves of this plant, Erysimum—foliis lyratis, extimo subrotundo of Linnæus, may be ranked among the antiscorbutics. They

are seidom used in practice.

ERYSIMUM OFFICINALE. The systematic name of the hedge-mustard. Erysimum—siliquis spica ad-pressis, foliis runcinatis, of Linnaus. It was former-ly much used for its expectorant and diuretic qualities, which are now forgotten. The seeds are warm and pungent, and very similar to those of mustard in their

sensible effects.

ERYSTPELAS. (From ερνω, to draw, and πελας, adjoining: named from the neighbouring parts being attented by the eruption.) Ignis sacer. The rose, or adjoining: named from the neighbouring parts being affected by the eruption.) Ignis sacer. The rose, or St. Anthony's fire. A genus of disease in the class Pyrexia, and order Exanthemata of Cullen. It is known by synocha of two or three days' continuance, with drowsiness, and sometimes with delirium; pulse commonly full and hard; then erythema of the face, or some other part, with continuance of synocha, tending either to abecess or gangrene. There are two species of this disease, according to Cullen: 1. Errorice

tending either to abscess or gangrene. There are two species of this disease, according to Cullen: 1. Erysipelas vesiculosum, with large bilsters: 2. Erysipelas phlyetanodes, the shingles or an erysipelas with phlyetanae, or small blisters.

This disease is an inflammatory affection, principally of the skin, when it makes its appearance externally, and of the mucous membrane when it is seated internally; and is more liable to attack women and children, and those of an irritable habit, than those of a niethoric and robust constitution. those of a plethoric and robust constitution

It is remarkable that erysipelas sometimes returns periodically, attacking the patient once or twice a year, or even once every month, and then by its repeated attacks it often gradually exhausts the strength, especially if he be old and of a bad habit.

When the inflammation is principally confined to the skin, and is unattended by any affection of the system, it is then called crythema; but when the system is affected, it is passed crysingles.

is affected, it is named erysipelas.

Every part of the body is equally liable to it, but it more frequently appears on the face, legs, and feet, than any where else, when seated externally; and it occurs oftener in warm climates than phicgmonous inflammation

It is brought on by all the causes that are apt to excite inflammation, such as injuries of all kinds, the external application of stimulants, exposure to cold, and obstructed perspiration; and it may likewise be occasioned by a certain matter generated within the body, and thrown out on its surface. A particular state of the atmosphere seems sometimes to render it

epidemical.

In slight cases, where it attacks the extremities, it In slight cases, where it attacks the extremities, it makes its appearance with a roughness, heat, pain, and reduces of the skin, which becomes pale when the finger is pressed upon it, and again returns to its former colour, when it is removed. There prevails likewise a small febrile disposition, and the patient is rather hot and thirsty. If the attack is mild, these symptoms will continue only for a few days, the surface of the part affected will become yellow, the cuticle or scarfskin will fall off in scales, and no further inconvepart affected will become yellow, the cuticle or scarf-skin will fall off in scales, and no further inconve-nience will perhaps be experienced; but if the attack has been severe, and the infiammatory symptoms have run high, then there will ensue pains in the head and back, great heat, thirst, and restlessness; the part affected will slightly swell: the pulse will become small and frequent; and about the fourth day, a num-ber of little vesicles, containing a limpid, and, in some cases, a yellowish fluid, will arise. In some instances, the fluid is viscid, and instead of running out, as gene-rally happens when the blister is broken, it adheres to and dries upon the akin.

In unfavourable cases, these blisters sometimes de-generate into obstinate ulcers, which now and then

generate into obstinate ulcers, which now and then

become gangrenous. This, however, does not happen frequently; for although it is not uncommon for the surface of the skin and the blistered places to appear livid, or even blackish, yet this usually disappears with the other symptoms.

The period at which the vesicles show themselves is very uncertain. The same may be said of the duration of the eruption. In mild cases, it often disappears gradually, or is carried off by spontaneous sweating. In some cases it continues, without showing any dis-

position to decline, for twelve or fourteen days, or

The trunk of the body is sometimes attacked with erysipelatous inflammation, but less frequently so than eryspetatous inhammation, but less frequently so than the extremities. It is not uncommon, however, for infants to be attacked in this manner a few days after birth; and in these it makes its appearance about the genitals. The inflamed skin is hard, and apparently very painful to the touch. The belly often becomes uniformly tense, and sphacelated spots sometimes are to be observed. From dissections made by Dr. Underwood, it appears, that in this form of the disease the inflammation frequently spreads to the abdominal the inflammation frequently spreads to the abdominal

Another species of erysipelatous inflammation, which most usually attacks the trunk of the body, is that vulgarly known by the name of shingles, being a corruption of the French word ceingle, which implies a belt. Instead of appearing a uniform inflamed surface, it consists of a number of little pimples extending round the body a little above the umbilicus, which have the little forced on them in a short time. which have vesicles formed on them in a short time. Little or no danger ever attends this species of erysi-

When erysipelas attacks the face, it comes on with chilliness, succeeded by heat, restlessness, thirst, and other febrile symptoms, with a drowsiness or tendency to coma or delirium, and the pulse is very frequent and full. At the end of two or three days, a fiery redness appears on some part of the face, and this extends at length to the scalp, and then gradually down the neck, leaving a tumefaction in every part the redness has occupied. The whole face at length becomes turgid, and the eyelids are so much swelled as to deprive the patient of sight. When the redness and swelling have continued for some time, blisters of different sizes, containing a thin colourless acrid liquor, arise on different parts of the face, and the skin puts on a livid appearance in the blistered places; but in those not affected with blisters, the cuticle, towards the close of the disease, falls off in scales.

No remission of the fever takes place on the appearance. When erysipelas attacks the face, it comes on with

No remission of the fever takes place on the appearance of the inflammation on the face; but, on the contrary, it is increased as the latter extends, and both will continue probably for the space of eight or ten days. In the course of the inflammation, the disposition to coma and delirium are sometimes so increased as to destroy the patient between the seventh and eleventh days of the disease. When the complaint is mild, and not leading to a fatal event, the inflammation and fever generally cease gradually without any

evident crisis.

If the disease arises in a bad habit of body, occupies a part possessed of great sensibility, is accompanied with much inflammation, fever, and delirium, and these take place at an early period, we may suppose the patient exposed to imminent danger. Where translations of the morbid matter take place, and the inflammation falls on either the brain, lungs, or abdometers. inflanimation falls on either the brain, lungs, or abdominal viscera, we may entertain the same unfavourable opinion. Erysipelas never terminates in suppuration, unless combined with a considerable degree of phlegmonous inflammation, which is, however, sometimes the case; but in a bad habit, it is apt to terminate in gangrene, in which case there will be also great danger. When the febrile symptoms are mild, and unaccompanied by delirium or coma, and the inflammation does not run high, we need not be appreflammation does not run high, we need not be apprehensive of danger.

Where the disease has occupied the face, and proves fatal, inflammation of the brain, and its consequences,

are in some cases met with on dissection.

The treatment of erysipelas must proceed on the antiphlogistic plan, varied however in its activity according to the type of the disease. When it occurs in robust plethoric constitutions, partaking of the phlegmonous character, with severe synochal fever, it will

be proper to begin by taking a moderate quantity of be proper to begin by taking a moderate quantity of blood, then direct cooling saline purgatives, antimonial diaphoretics, a light vegetable diet, &c. When the disorder attacks the face, it may be better to use cupping behind the neck, and keep the head somewhat raised. But if the disease exhibits rather the typhoid type, and particularly where there is a tendency to gaugrene, the patient's strength must be supported: after clearing out the prime via, and endeavouring to promote the other secretions by mild evacuants, when the oulse begins to fail, a more nutritious diet, with a the pulse begins to fail, a more nutritious diet, with a moderate quantity of wine, and the decoction of bark with sulphuric acid, or other tonic medicine, may be with sulphuric acid, or other tonic medicine, may be resorted to; nay, even the bark in substance, and the more powerful stimulants, as ammonia, &c. ought to be tried, if the preceding fail. Should the inflammation, quitting the skin, attack an internal part; a blister, or some rubefacient, may help to relieve the patient; and stimulants to the lower extremities will likewise be proper, where the head is severely affected. To the inflamed part of the skin, applications must not be too freely made: where there is much pain and heat, cooling it occasionally, with plain water, is perheat, cooling it occasionally, with plain water, is per-haps best; and where an acrid discharge occurs, wash-ing it away from time to time with warm milk and ing it away from time to time with warm milk and water. Should suppuration happen, it is important to make an early opening for the escape of the matter, to obviate the extensive sloughings otherwise apt to follow, and where gangrene occurs, the fermenting cataplasm may be applied.

ERYTHE MA. (From ερυθρος, red.) Inflammatory blush. A morbid redness of the skin, as is observed upon the cheeks of hectic patients after eating, and the skin covering bubo, phleguon, &c.

and the skin covering bubo, phlegmon, &c.

ERYTHRO DANUM. (From ερυθρος, red: so called from the colour of its juice.) See Rubia tinctorum.

ERYTHROET DES. (From ερυθρος, red, and ειδος, a likeness: so called from its colour.) A name given to

the tunica vaginalis testis.

ERYTHRO'NIUM. (From ερυθρος, red: so called from the red colour of its juice.) A species of satyrion.
["ΕπΥΤΗΚΟΝΙΟΜ ΑΜΕΚΙΚΑΝΟΜ. The Erythronium

Americanum is an emetic in its recent state, producing vomiting in the dose of thirty or forty grains. This property is impaired by drying. The affinity of the plant to Colchicum, and some others of known activity, renders, it deserving of further investigation. The bulbs should be dug when the leaves first appear, before flowering. A pure feenla may be obtained from fore flowering. A pure fecula may be obtained from them."—Big. Mat. Med. A.]
ERYTHRO XYLUM. (From ερυθρος, red, and ξυλον, wood: so named from its colour.). Logwood. See

Hamatoxylum.

E RYTHRUS. (From ερυθρος, red: so named from the red rolour of its juice.) The sumach. See Rhus

E'saphe. (From εσαφαω, to feel.) The touch; or feeling the mouth of the womb, to ascertain its condition

E'SCHAR. (Εσχαρα; from εσχαροω, to scab over.)

Eschara. The portion of flesh that is destroyed by the application of a caustic, and which sloughs away.

ESCHARO'TIC. (Escharoticus; from τεχαροω, to scab over.) Caustic; corrosive. A term given by surgeons to those substances which possess a power of destroying the texture of the various solid parts of the animal look to which they are directly applied. The animal body to which they are directly applied. The articles of this class of substances may be arranged under two orders:

1. Eroding escharotics; as blue vitriol, alumen ustum, &c.

2. Caustic escharotics; as lapis infernalis, argenta

2. Caustic escharotics; as tapis infernatis, argenti-nitras, acidum sulphuricum, nitricum, &c.
ESCULENT. Esculentus. An appellation given to such animals, fishes, and plants, or any part of them, that may be eaten for food.
E'SOX. The name of a genus of fishes. Class,

Pisces; Order, Abdominales.

Esox Lucius. The systematic name of the pike fish, from the liver of which an oil is separated sponfish, from the liver of which an oil is separated spontaneously, which is termed, in some pharmacopaias, oleum lucii piscis. It is used in some countries, by surgeons, to destroy spots of the transparent cornea. ESSENCE. Several of the volatile or essential oils are called by this name.

ESSENTIAL. Essentialis. Something that is necessary to constitute a thing, or that has such a con-

nexion with the nature of a thing, that is found wherever the thing itself is; thus the heart, brain, spinal marrow, lungs, stomach, &c. are parts essential to life.

In natural history, it is applied to those circumstances which mark or distinguish an animal or plant from all others in the same order or genus.

stances which mark or distinguish an animal of plans from all others in the same order or genus.

Esse'ntial oil. See Oil.

E'SSERA. (Essera, from Eshera, an Arabian word literally meaning papulæ.) A species of cutaneous eruption, distinguished by broad, shining, smooth, red spots, mostly without fever, and differing from the nettle-rash in not being elevated. It generally attacks the face and hands. attacks the face and hands.

ESTHIOMENOS. (From εσθιω, to eat.) A term for-merly applied to any disease which rapidly destroyed, or, as it were, are away the flesh, as some forms of

berpes, lupus, cancer.
E'SULA. (From esus, caten, because it is eaten by some as a medicine.) Spurge.
ESULA MAJOR. See Euphorbia palustris.
ESULA MINOR. See Euphorbia cyparissias.

ETHER. See Æther.

ETHER, ACETIC. Acetic naphtha. An ethereal fluid, drawn over from an equal admixture of alkohol and acetic neid, distilled with a gentle heat from a glass retort in a sand-bath. It has a grateful smell, is extremely light, volatile, and inflammable.

ETHER MURIATIC. Marine ather. Muriatic ather is obtained by fixing and distilling alkohol with extremely concentrated muriate of tin. It is stimulant,

antiseptic, and diuretic.

ETHER, NITROUS. Nitric naphtha. This is only a stronger preparation than the spiritus atheris nitrici of the London Pharmacopæia; it is produced by the distillation of two parts of alkohol to one part and a half of fuming nitric acid.

ETHER, SULPHURIC. See Æther sulphuricus.
ETHER, VITRIOLIC. See Æther sulphuricus.
ETHEREAL. A term applied to any highly rectified essential oil, or spirit. See Oleum æthereum.
Ethiops, antimonia. See Æthiops antimonialis.
Ethiops, martial. The black oxide of iron.
Ethiops mineral. See Hydrargyri sulphuretum ni-

Ethiops per se. See Hydrargyri oxydum cincreum. ETHMOID. (Ethmoides; from εφμος, a sieve, and ασός, form: because it is perforated like a sieve.)

ETHMOID BONE. Os ethmoideum; os athmoides. Cribriform bone. A bone of the head. This is, perhaps, one of the most curious bones of the human body. It apone of the most curious bones of the human-body. It appears almost a cube, not of solid bone, but exceedingly light, spongy, and consisting of many convoluted plates, which form a net-work, like honey-comb. It is curiously enclosed in the os frontis, between the orbitary processes of that bone. One horizontal plate receives the olfactory nerves, which perforate that plate with such a number of small holes, that it resembles a sieve; whence the bone is named cribriform, or ethmoid bone. Other plates dropping perpendicularly from this bone. Other plates dropping perpendicularly from this one, receive the divided nerves, and gave them an opone, receive the divided nerves, and gave them an opportunity of expanding into the organ of smelling; and these bones, upon which the olfactory nerves are spread out, are so much convoluted as to extend the surface of this sense very greatly, and are named spongy bones. Another flat plate lies in the orbit of the eye; and being very smooth, by the rolling of the eye, it is named the os planum, or smooth bone. So that the ethmoid bone supports the forepart of the brain, receives the olfactory nerves, forms the organ of smelling, and makes the chief part of the orbit of the eye; and the spongy bones, and the os planum, are neither of them distinct bones, but parts of this ethmoid bone. The cribriform plate is exceedingly delicate and thin; lies horizontally over the root of the nose; and

thin; lies horizontally over the root of the nose; and fills up neatly the space between the two orbitary plates of the frontal-bone. The olfactory nerves, like two small flat lobes, lie out upon this plate, and, adhering to it, shoot down like many roots through this bone, so as to perforate it with numerous small holes, as if it had been dotted with the point of a pin, or like a nutmeg-grater. This plate is horizontal; but its processes are perpendicular, one above, and three below.

1. The first perpendicular process is what is called crista galli; a small perpendicular projection, somewhat like a cock's comb, but exceedingly small, stand-

ing directly upwards from the middle of the cribriform plate, and dividing that plate into two; so that one olfactory nerve lies upon each side of the crista galli; and the root of the falx, or septum, between the two hemispheres of the brain, begins from this process. The foramen excum, or blind hole of the frontal bone, is formed partly by the root of the crista galli, which is very smooth, and sometimes, it is said, hollow, or is very smooth, and sometimes, it is said, hollow, or cellular.

3. Exactly opposite this, and in the same direction 3. Exactly opposite this, and in the same direction with it, i. e. perpendicular to the ethmoid plate, stands out the nasal plate of the ethmoid bone. It is sometimes called azygous, or single process of the ethmoid, and forms the beginning of that septum, or partition, which divides the two nostrils. This process is thin but firm, and composed of solid bone; it is commonly inclinated a little transmitted as the restriction. inclined a little to one side, so as to make the nostrils of unequal size. The azygous process is united with the vomer, which forms the chief part of the partition; so that the septum, or partition of the nose, consists of the azygous process of the ethnoid bone above, of the young helow, and of the cartilage in the fore or provomer below, and of the cartilage in the fore or pro-jecting part of the nose; but the cartilage rots away, so that whatever is seen of the septum in the skull must be part either of the ethmoid bone or vomer.

2. Upon either side of the septum, there hangs down a spongy bone, one hanging in each nostril. They are each rolled up like a scroll of parchment; they are very spongy; are covered with a delicate and sensible membrane; and when the olfactory nerves depart from the clibriform plate of the ethmoid bone, they attach themselves to the septum, and to these upper spongy bones, and expand upon them so that the convolutions of these bones are of material use in expanding the organ of swelling and detaining the organs. volutions of these bones are of material use in expanding the organ of swelling, and detaining the odorous effluvia till the impression be perfect. Their convolutions are more numerous in the lower animals, in proportion as they need a more acute sense. They are named spongy or turbinated bones, from their convolutions resembling the many folds of a turban.

The spongy bones have a great many honey-comblike cells connected with them, which belong also to the organ of smell, and which are useful perhaps by detaining the effluvia of odorous bodies, and also by

the organ of smell, and which are useful perhaps by detaining the effluvia of odorous bodies, and also by reverberating the voice. Thus, in a common cold, while the voice is hurt by an affection of these cells, the sense of smelling is almost lost.

4. The orbitary plate, of the ethmoid bone, is a large surface; consisting of a very firm plate of bone, of a regular square form: exceedingly smooth and polished; it forms a great part of the socket for the eye, lying on its inner side. When we see it in the detached bone, we know it to be just the flat side of the ethmoid bone; but while it is incased in the socket of the eye, we should believe it to be a small square bone; and from this, and from its smoothness, it has got the distinct name of os planum.

The cells of the ethmoid bone, which form so important a share of the organ of smell, are arranged in great numbers along the spongy bone. They are small neat cells, much like a honey-comb, and regularly arranged in two rows, parted from each other by a thin partition; so that the os planum seems to have one set of cells attached to it, while another regular set of cells belongs in like manner to the spongy bone.

one set of cells attached to it, while another regular set of cells belongs in like manner to the spongy bones. There are thus twelve in number opening into each

other, and into the nose.

These cells are frequently the scat of venereal ulcers; and the spongy bones are the surface where polypi often sprout up. And from the general connexions and forms of the bone, we can easily understand how the venereal ulcer, when deep in the nose, having got to venereal ulcer, when deep in the nose, having got to these cells, cannot be cured, but undermines all the face; how the venereal disease, having affected the nose, soon spreads to the eye; and how even the brain theelf is not safe. We see the danger of a blow upon the nose, which, by a force upon the septum, or middle partition, may depress the delicate criteriform plate, so as to oppress the brain with all the effects of a fractured skull, and without any operation which can give relief. And we also see the danger of pulling away polypi, which are firmly attached to the upper spongy bone.

ETHMOIDES. See Ethmoid bone.
ETMULLER, MICHAEL, was born at Leipsic, in 1644. He graduated there at the age of twenty-four, after going timough the requisite studies, and much im-

proving himself by travelling through different parts of Europe. Eight years after he was appointed professor of botany in that University, as well as extraordinary professor of surgery and anatomy. He fulfilled those offices with great applause, and his death, which happened in 1683, was generally regretted by the faculty of Leipsic. He was a very voluminous writer, and his works were considered to have sufficient merit to be translated into most European languages. be translated into most European languages

EUDIO METER. An instrument by which the quantity of oxygen and nitrogen in atmospherical air can be ascertained. Several methods have been employed, all founded upon the principle of decomposing common air by means of a body which has a greater affinity for the oxygen. See Eudiometry.

EUDIOMETRY. The method of ascertaining the purity of atmospheric air.

No sooner was the composition of the atmosphere

No sooner was the composition of the atmosphere known, than it became an inquiry of importance to find out a method of ascertaining, with facility and precision, the relative quantity of oxygen gas contained in a given bulk of atmospheric air. The instruments in which the oxygen gas of a de-

termined quantity of air was ascertained, received the name of Eudiometers, because they were considered as measures of the purity of air. They are, however, more properly called Oximeters.

The eudiometers proposed by different chemists, are

the following:

1. Priestley's Eudiometer.—The first eudiometer was made in consequence of Dr. Priestley's discovery, that when nitrous gas is mixed with atmospheric air over water, the bulk of the mixture diminishes rapidly, in consequence of the combination of the gas with the oxygen of the air, and the absorption of the nitric acid

s formed by the water.

When nitrous gas is mixed with nitrogen gas, no diminution takes place; but when it is mixed with oxygen gas, in proper proportions, the absorption is complete. Hence it is evident, that in all cases of a mixture of these two gases, the diminution will be proportional to the quantity of the oxygen. Of course it will indicate the proportion of oxygen in air; and, by mixing it with different portions of air, it will indicate the different quantities of oxygen which they contain, provided the component parts of air be susceptible of variation

Dr. Priestley's method was to mix together equal bulks of air and nitrous gas in a low jar, and then transfer the mixture into a narrow graduated glass tube about three feet long, in order to measure the diminu-dimension of bulk. He expressed this diminution by the number of hundredth parts remaining. Thus, suppose he had mixed together equal parts of nitrous gas and air, and that the sum total was 200 (or 2.00): suppose the residuum, when measured in the graduated tube, to amount to 104 (or 1.04), and of course that 96 parts of the whole had disappeared by denoted the partity

of the whole had disappeared, he denoted the purity of the air thus tried by 104.

This method of analyzing air by means of nitrous gas is liable to many errors. For the water over which the experiment is made may contain more or less carties of the content is contain more or less carties. bonic acid, atmospheric air, or other heterogeneous substance. The nitrous gas is not always of the same purity, and is partly absorbed by the nitrous acid which is formed; the figure of the vessel, and many

other circumstances are capable of occasioning considerable differences in the results.

Fontana, Cavendish, Ladriani, Magellan, Von Humboldt, and De Falence, Ladriani, Magellan, Magella boldt, and Dr. Falconer, have made series of laborious experiments to bring the test of nitrous gas to a state of complete accuracy; but, notwithstanding the exer-tions of these philosophers, the methods of analyz-ing air by means of nitrous gas are liable to so many anomalics, that it is unnecessary to give a particu-340

lar description of the different instruments invented

by them.

Scheele's Eudiometer .- This is merely a graduated glass cylinder, containing a given quantity of air, exposed to a mixture of iron filings and sulphur, formed into a paste with water. The substances may be made use of in the following manner:

Make a quantity of sulphur in powder, and iron filings, into a paste with water, and place the mixture in a saucer, or plate, over water, on a stand raised above the fluid; then invert over it a graduated beliglass, and allow this to stand for a few days. The air contained in the bell-glass will gradually diminish, as will appear from the ascent of the water.

When no further diminution takes place the vertical standard or the vertical standa

as will appear from the ascent of the water.

When no further diminution takes place, the vessel containing the sulphuret must be removed, and the remaining air will be found to be nitrogen gas, which was contained in that quantity of atmospheric air.

In this process, the moistened sulphuret of iron has a great affinity to oxygen; it attracts and separates it

from the atmospheric air, and the nitrogen gas is left behind; the sulphur, during the experiment, is con-verted into sulphuric acid, and the iron oxidized, and sulphate of iron results.

The air which is exposed to moistened iron and sul-phur, gradually becomes diminished, on account of its oxygen combining with a portion of the sulphur and iron, while its nitrogen remains behind. The quantity of oxygen contained in the air examined becomes thus obvious, by the diminution of bulk, which the volume of air submitted to examination has undergone.

A material error to which this method is liable, is that the sulphuric acid which is formed, acts partly on the iron, and produces hydrogen gas, which joins to some of the nitrogen forming ammonia; and hence it is that the absorption amounts in general to 0.27 parts, although the true quantity of oxygen is no more than

from 0.21 to 0.22.

from 0.21 to 0.22.

3. De Marti's Eudiometer.—De Marti obviated the errors to which the method of Scheele was liable. He availed himself, for that purpose, of an hydroguretted sulphuret, formed by boiling sulphur and liquid potassa, or lime water, together. These substances, when newly prepared, have the property of absorbing a minute portion of nitrogen gas; but they lose this property when saturated with that gas, which is easily effected by agitating them for a few minutes in contact with a small portion of atmospheric air.

with a small portion of atmospheric air.

The apparatus is merely a glass tube, ten inches long, and rather less than half an inch in diameter. open at one end, and hermetically sealed at the other. The close end is divided into one hundred equal parts. The close end is divided into one hundred equal parts having an interval of one line between each division. The use of this tube is to measure the portion of air to be employed in the experiment. The tube is filled with water; and by allowing the water to run out gradually, while the tube is inverted, and the open end kept shat with the finger, the graduated part is exactly filled with air. These hundredth parts of air are introduced into a glass bottle, filled with liquid sulphunettroduced into a glass bottle, filled with liquid su of lime previously saturated with nitrogen gas, and capable of holding from two to four times the bulk of the air introduced. The bottle is then to be closed with a ground glass stopper, and agitated for five minutes. After this, the stopper is to be withdrawn, while the mouth of the phial is under water; and, for the greater accuracy, it may be closed and agitated again. Lastly, the air is to be again transferred to the graduated glass tube, in order to ascertain the diminugraduated glass tube, in order to ascertain the diminu-tion of its bulk.

4. Humboldt's Eudiometer consists in decomposing a definite quantity of atmospheric air, by means of the combustion of phosphorus, after which, the portion of gas which remains must be measured.

Take a glass cylinder, closed at the top, and whose capacity must be measured into sufficiently small por-tions by a graduated scale fixed on it. If the instrument be destined solely for examining atmospheric air, it will be sufficient to apply the scale from the orifice of the cylinder down to about half its length, or to sketch that scale on a slip of paper pasted on the out-side of the tube, and to varnish it over with a trans-

parent varnish.

This half of the eudiometrical tube is divided into fifty equidistant parts, which in this case indicate hundredth parts of the whole capacity of the instru-

Into this vessel, full of atmospheric air, put a piece of dry phosphorus (one grain to every twelve cubic inches), close it air-tight, and heat it gradually, first the sides near the bottom, and afterward the bottom itself. The phosphorus will take fire and burn rapidly. After every thing is cold, invert the mouth of the eudiometertube into a basin of water, and withdraw the cork. The water will ascend in proportion to the loss of oxygen gas the air has sustained, and thus its quantity may be ascertained.

Analogous to this is,

5. Seguin's Eudiometer, which consists of a glass tube, of about one inch in diameter, and eight or ten inches high, closed at the upper extremity. It is filled with mercury, and kept inverted in this fluid in the mercurial trough. A small bit of phosphorus is introduced into it, which, on account of its specific gravity being less than that of mercury, will rise up in it to the top. The phosphorus is then melted by means of the top. The phosphorus is then mence by means of a red-hot poker, or burning coal applied to the outside of the tube. When the phosphorus is liquefied, small portions of air destined to be examined, and which have been previously measured in a vessel graduated to the cubic inch, or into grains, are introduced into the tube. As soon as the air which is sent up reaches the phosphorus, a combustion will take place, and the mercury will rise again. The combustion continues till the end of the operation; but, for the greater exactness, Seguin directs the residuum to be heated strongly. When cold, it is introduced into the graduated vessel to ascertain its volume. The difference of the two volumes gives the quantity of the oxygen gas contained in the air subjected to examination.

6. Berthollet's Eudiometer.—Instead of the rapid

combustion of phosphorus, Berthollet has substituted its spontaneous combustion, which absorbs the oxygen of atmospheric air completely; and, when the quan-tity of air operated on is small, the process is accom-

plished in a short time.

Berthollet's apparatus consists of a narrow graduated glass tube, containing the air to be examined, into which is introduced a cylinder, or stick of phosphorus, supported upon a glass rod, while the tube stands inverted in water. The phosphorus should be nearly as long as the tube. Immediately after the introduction of the phosphorus, white vapours are formed which fill the tube; these vapours gradually descend, and become absorbed by the water. When no more white vapours appear, the process is at an end, for all the oxygen gas which was present in the confined quantity of air, has united with the phosphorus: the residuum is the quantity of nitrogen of the air submitted to examination.

This eudiometer, though excellent of the kind, is nevertheless not absolutely to be depended upon; for, as soon as the absorption of oxygen is completed, the nitrogen gas exercises an action upon the phosphorus, and thus its bulk becomes increased. It has been asand thus its dulk becomes increased. It has been ascertained, that the volume of nitrogen gas is increased by 1-40th part; consequently the bulk of the residuum, diminished by 1-40th, gives us the bulk of the nitrogen gas of the air examined; which bulk, subtracted from the original mass of air, gives us the proportion of oxygen gas contained in it. The same allowance must be made in the eudiometer of Seguin.

7. Dann's Endiagrates — Until part lately the pro-

7. Davy's Eudiometer.—Until very lately, the pre-ceding processes were the methods of determining the relative proportions of the two gases which compose

our atmosphere.

Some of these methods, though very ingenious, are so extremely slow in their action, that it is difficult to ascertain the precise time at which the operation Others have frequently involved inaccuracies, not easily removed.

The eudiometer of Davy is not only free from these objections, but the result it offers is always constant; it requires little address, and is very expeditious; the

apparatus is portable, simple, and convenient.

Take a small glass tube, graduated into one hundred equidistant parts; fill this tube with the air to be exequidistant parts; fill this tube with the air to be examined, and plunge it into a bottle, or any other convenient vessel, containing a concentrated solution of green muriate or sulphate of iron, strongly impregnated with nitrous gas. All that is necessary to be done, is to move the tube in the solution a little backwards and forwards; under these circumstances, the oxygen gas contained in the air will be rapidly absorbed, and condensed by the nitrous gas in the solu-tion, in the form of nitrous acid.

N. B. The state of the greatest absorption should be marked, as the mixture afterward emits a little gas

which would alter the result.

This circumstance depends upon the slow decompo This circumstance depends upon the slow decomposition of the nitrous acid (formed during the experiment,) by the oxide of iron, and the consequent production of a small quantity of aeriform fluid (chiefly nitrous gas); which, having no affinity with the red muriate, or sulphate of iron, produced by the combination of oxygen, is gradually evolved and mingled with the residual nitrogen gas. However, the nitrous gas evolved might be abstracted by exposing the resigas evolved might be abstracted by exposing the residuum to a fresh solution of green sulphate or muriate of iron.

The impregnated solution with green muriate, is more rapid in its operation than the solution with green sulphate. In cases when these salts cannot be obtained in a state of absolute purity, the common sul-phate of iron of commerce may be employed. One cubic inch of moderately impregnated solution, is capable of absorbing five or six cubic inches of oxygen, in common processes; but the same quantity must never be employed for more than one experi-

In all these different methods of analyzing air, it is necessary to operate on air of a determinate density, and to take care that the residuum be neither more condensed nor dilated than the air was when first opecondensed nor dilated than the air was when first operated on. If these things are not attended to, no dependence whatever can be placed upon the result of the experiments, how carefully seever they may have been performed. It is, therefore, necessary to place the air, before and after the examination, into water of the same temperature. If this, and several other little circumstances, have been attended to, for instance, a change in the height of the barometer, &c. we find that air is composed of about 0.21 of oxygen we find that air is composed of about 0.21 of oxygen gas, and 0.79 of nitrogen gas by bulk. But as the weight of these two gases is not exactly the same, the proportion of the component parts by weight will differ a little; for as the specific gravity of oxygen gas is to that of nitrogen gas as 8 to 7 nearly, it follows that 100 parts of air are composed by weight of about 76 nitrogen gas and 24 oxygen gas.

100 parts of air are composed by weight of about 76 nitrogen gas, and 24 oxygen gas.

The air of this metropolis, examined by means of Davy's eudiometer, was found, in all the different seasons of the year, to contain 0.21 of oxygen: and the same was the case with air taken at Islington and Highgate; in the solitary cells in Cold-Bath-Fields prison, and on the river Thames. But the quantity of water contained in a given bulk of air from these places, differed considerably.

Eu'le. (From ευλαζω, to putrefy.) A worm bred in foul and putrid ulcers.

EUNU'CHIUM. (From eurouxos, a cunuch: so called because it was formerly said to render those who eat it impotent, like a cunuch.) The lettuce. See

EUPATORIOPHA'LACRON. (From ευπαζωριον, agrimony, and φαλακρος, bald.) A species of agrimony with naked heads.

EUPATO'RIUM. (From Eupator, its discoverer: or quasi hepatorium, from ηπαρ, the liver; because it was said to be useful in diseases of the liver.) 1. The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia aqualis.
2. The pharmacoposial name of the Eupatorium.

See Eupatorium cannabinum.
EUPATORIUM ARABICUM. See Eupatorium canna-

EUPATORIUM CANNABINUM. The systematic name of the hemp agrimony. Eupatorium; Eupatorium arabicum. The juice of this very bitter and strong-smelling plant, Eupatorium—foliis digitatis of Linnaus, proves violently emetic and purgative, if taken in sufficient quantity, and promotes the secretions generally. It is recommended in dropsies, jaundices, agues, &c. and is in common use in Holland among the lower orders as a purifier of the blood in pld ul-

agues, &c. and is in common use in Holland among the lower orders, as a purifier of the blood in old ulcers, scurvy, and anasarca.

EUPATORIUM MESUES. See Achillea ageratum.

["EUPATORIUM PERFOLIATUM. Thoroughwort. The Eupatorium perfoliatum is an indigenous vegetable, growing in wet meadows throughout the United States. The whole plant is medicinal, but the leaves and flowers are most active. The taste is intensely bitter, accompanied by a flavour peculiar to the plant, but without astringency or acrimony. A kind of extractive matter appears to contain its sensible and medicinal properties, and of this water is an adequate solvent.

"The medicinal powers of this plant are, such as its sensible qualities would seem to indicate, those of a tonic stimulant. Given in moderate quantities, either in substance, in cold infusion or decoction, it promotes in substance, in cold infusion or decoction, it promotes digestion, strengthens the viscera, and restores tone to the system. Like other vegetable bitters, if given in large quantities, especially in warm infusion or decoction, it proves emetic, cathartic, and sudorific. Even in cold infusion, it brings on diaphoresis more readily than most tonics. It is an efficacious article in the cure of intermittents, and is much employed for this use in districts where fever and ague prevail. Cures effected by it appear to have been as speedy as those from any of the medicines in common use. Thoroughwort has been employed in small does with benefit in from any of the medicines in common use. Thoroughwort has been employed in small doses with benefit in other febrile complaints attended with prostration of strength in their advanced stages. Its action upon the skin has acquired for it some confidence in the treatment of cutaneous disease

"As a tonic, twenty or thirty grains of the powder "As a tonic, twenty or thirty grains of the powder may be given in milk or wine, or two fluid ounces of the infusion. When intended to act as an emetic, a strong decoction may be made from an ounce of the plant in a quart of water boiled to a pint. The decoction is a disagreeable, but popular and effectual medicine in catarrhs, rheumatism, and febrile, attacks. It is powerfully emetic, cathartic, and sudorific."—Big.

Mat. Med. A.]

["EUPATORIUM PERFUREUM. Gravel root. This is a taller plant than the species already cited. Its taste is bitter, astringent, and atomatic. I am informed that it operates as a diuretic, and is employed by different country physicians as a palliative in dysury and calculous diseases."—Big. Mat. Med. A.]

["EUPATORIUM TEUCRIUM. Wild hourhound. Many of the species of Eupatorium, which nearly resemble Eupatorium perfoliatum, in botanical habit are likewise similar to it in medicinal properties. The present species is one of this kind. It is tonic, diaphoretic, and cathartic, and in small doses sits well on the stomach. It is extensively used in the southern states in 342

["EUPHORBIA IPECACUANHA. Ipecacuanha spurge. This is a low tufted plant, growing native in sandy soils in the middle and southern parts of the United States. It was at one time supposed to be the plant from which the officinal ipecacuanha is derived.

"The root is very large in proportion to the plant, fleshy, irregular, and branched. When dried, it is of a grayish colour outside, and white within. It is light

fleshy, irregular, and branched. When dried, it is of a grayish colour outside, and white within. It is light and brittle, without a ligneous centre, and has about the hardness of cork. To the taste it is sweetish, and not particularly unpleasant. It contains a substance of the nature of caoutchouc, which is soluble in ether, and precipitated by alkohol; likewise resin, mucus, and probably fœcula.

"Most of the species of the extensive genus Euphorbia, are violent emetics and cathartics. The lactescent juice, which they exude when wounded, is acrid and virulent, so as to blister and ulcerate the skin when externally applied. Taken internally in large doses, they produce the violent symptoms which are common to other acrid narcotics. The Euphorbia ipecacuanha is milder in its operation than many of the other species, and has lately been revived in practice as an effectual emetic. With a view of becoming acquainted with the mode of operation of this plant, I performed a series of experiments on its action, assisted by some medical gentlemen of the Boston Dispensary and Alms-house. These trials have led to the conclusion, that this root, in doses of from ten to twenty grains, is both an emetic and cathartic; that it is more active than ingeracuanha, in prepartion, to, the number of both an emetic and cathartic; that it is more active than ipecacuanha, in proportion to the number of grains administered; that in small doses it operates with as much case as most emetics in a majority of instances. If it fails, however, at first, it is not so safely repeated as many of the emetics in common use. If accumulated in the stomach to the amount of two or three scruples, it finally excites active and long continued vomiting, attended with a sense of heat, vertigo, indistinct vision, and great prostration of strength. Its operation seems exactly proportionate to the quantity taken, and vomiting is not checked by the powder being thrown off in the first efforts of the stomach. "From ten to twenty grains constitute an emetic, to be given at once. If this quantity fails to vomit, it generally purges. It may be quickened by a little tartarized antimony, but ought not to be repeated to the amount of more than twenty-five or thirty grains."—

Big. Mat. Med. A.]

EUPE PSIA. (From ευ, well, and πεπ/ω, to concoct.) A good digestion.

felspar and diallage.
EUPHO RBIA. The name of a genus of plants in
EUPHO RBIA. Class, Dodecandria; Order,

the Linnæan system. Class, Dodecandria; Order, Trigynia.

Euphorbia antiquorum. The systematic name of a plant supposed to produce the Euphorbium.

Euphorbia canariensis. In the Canary islands this species of spurge affords the gum euphorbium.

Euphorbia cyparissias. The systematic name of the cypress spurge. Esula minor; Tithymalus cyparissius. This, like most of the spurges, is very acrimonious, inflaming the eyes and esophagus after touching them. It is now fallen into disuse, whatever were its virtues formerly, which, no doubt, among some others, was that of opening the bowels, for among rustics, it was called poor man's rhubarb.

["Euphorbia corollata is a tall species, with a fiverayed umbel, and white flowers. It grows spontaneously in dry fields from Pennsylvania to Carolina.

"The soft brittle texture of the root, and its sweetish taste, are similar to those of Euphorbia ipecacuanha. Its chemical constitution is nearly the same, except that the quantity of resin is apparently somewhat greater.

"This is a very active medicine, of the evacuating class, operating in small doses as a cathartic, and in large ones as an emetic. It has been thought to possess about twice the strength of jalap. It exerts its cathartic efficacy in doses of less than ten grains, and if given to the amount of fifteen or twenty, it is as sure to vomit as other common emetics in their proper

EUS EVA

quantities. The only inconveniences attending these doses, which have come to my knowledge, are, that when given in small quantities, for a cathartic, it is liable to produce nausea; and in large ones, suitable for an emetic, it has sometimes induced a degree of hypercatharsis. But similar inconveniences may occur from jalap and tartarized antimony. The effects which large doses of this root may produce on the nervous system, I have not had occasion to witness. The Euphorbia corollata, like many others of its genus, if applied in a contused state to the skin, excites inflammation and vesication. Its volatile particles possess a mation and vesication. Its volatile particles possess a certain degree of virulence, so that inflammation of the face has been brought on by handling the root. It remains to be ascertained whether the vesicating powers of this and the other species are equally definite and manageable, with those of the more common epispastic substances."—Big. Mat. Med. A.]
EUPHORBIA LATHYRIS. The systematic name of

EUPHORBIA LATHYRIS. The systematic name of the plant which affords the less cataputia seeds. Ca-

the plant which affords the less cataputia seeds. Cataputia minor; Euphorbia—umbella quadrifida, dichotoma, foliis oppositis integerrimis of Linnæus. The seeds possess purgative properties; but if exhibited in an over dose, prove drastic and poisonous; a quality peculiar to all the Euphorbia.

Euphorbia officinarum. The systematic name of the plant which affords the euphorbium in the greatest abundance. Euphorbium is an inodorous gum-resin, in yellow tears, which have the appearance of being worm-eaten; said to be obtained from several species of euphorbiae, but principally from the Euphorbia officinarum; aculatea nuda multangularis, aculeis germinatis of Linnæus: it is imported from Ethiopia, Libya, and Mauritania. It contains an Ethiopia, Libya, and Mauritania. It contains an active resin, and is very seldom employed internally, but, as an ingredient, it enters into many resolvent and discutient plasters.

EUPHORBIA PALUSTRIS. The systematic name of EUPHORBIA PALUSTRIS. The systematic name of the greater spurge. The officinal plant ordered by the name, Esula major, in some pharmacopæias, is the Euphorbia palustris; umbella multifida, bifida, involucellis ovatis, foliis lanceolatis, ramis sterilibus of Linnæus. The juice is exhibited in Russia as a common purge; and the plant is given, in some places, in the cure of intermittents.

EUPHORBIA PARALIAS. Tithumalus paralies. Sea-

EUPHORBIA PARALIAS. Tithymalus paralios. Seapurge. Every part of this plant is violently cathartic and irritating, inflaming the mouth and fauces. It is seldom employed in the practice of this country; but where it is used, vinegar is recommended to correct its

irritating power.

EUPHO RBIUM. (From Euphorbus, the physician of king Juba, in honour of whom it was named.)

ee Euphorbia officinarum. EUPHRA'SIA. (Corru

See Euphorbia efficinarum.

EUPHRA'SIA. (Corrupted from Euphrosyne, ruφροσιωγ, from ευφρων, joyful: so called because it exhibitantes the spirits.)

1. The name of a genus of plants in the Linnæan system. Class, Didynamia; Order, Angiospermia.

2. The pharmacopæial name of eye-bright. See

Euphrasia officinalis.

EUPHRASIA OFFICINALIS. The systematic name of the eye-bright. This beautiful little plant, Euphrasia—folius ovatis, lineatis, argute dentatis of Linneus, has been greatly esteemed by the common people, as a remedy for all diseases of the eyes; yet, notwithstanding this, and the encomiums of some medical writers, it is now wholly fallen into disuse. It is an ingredient in the British herb-tobacco.

EUSTACHIAN TUBE. Tuba custuchiana. The tube so called was discovered by the great Eustachius. It begins, one in each ear, from the anterior extremity of the tympanum, and runs forwards and inwards in a bony canal, which terminates with the petrous portion of the temporal bone. It then goes on, partly cartila-

of the temporal bone. It then goes on, partly cartilaginous, and partly membranous, gradually becoming larger, and at length ends behind the soft palate. Through this tube the air passes to the tympanum. EUSTACHIAN VALVE. See Valvula Eustachii. EUSTACHIUS, BARTHOLOMEW, one of the most celebrated anatomists of the 16th century, was born at San Severino, in Italy. He studied at Rome, and made himself such a proficient in anatomy, that he was chosen professor of that branch of medicine there, where he died in 1574. He was author of several works, many of which are lost, especially his treatise "De Controversiis Anatomicorum," which is

much regretted. He made several discoveries in anatomy; having first described the renal capsules, and the thoracic duct; also the passage from the throat to the internal ear, named after him the Eustachian tube. A series of copperplates, to which he alludes in his "Opuscula," were recovered by Lancisi, and published in the beginning of the 18th century. He edited the Lexicon of Erotian with a commentary.

EUTHYPO'RIA. (From Ευθυς, straight, and πορος, a passage.) Euthiporos. An extension made in a straight line, to put in place a fracture, or dislocation. EVAPORA'TION. A chemical operation usually performed by applying heat to any compound substance, in order to dispel the volatile parts. "It differs from distillation in its object, which chiefly consists in preserving the more fixed matters, while the volatile substances are dissipated and lost. And the volatile substances are dissipated and lost. And the vessels are accordingly different; evaporation being commonly made in open shallow vessels, and distillation in an apparatus nearly closed from the external

The degree of heat must be duly regulated in eva-oration. When the fixed and more volatile matters do not greatly differ in their tendency to fly off, the heat must be very carefully adjusted; but in other

As evaporation consists in the assumption of the elastic form, its rapidity will be in proportion to the degree of heat, and the diminution of the pressure of the atmosphere. A current of air is likewise of service in this process.

Barry has lately obtained a patent for an apparatus, by which vegetable extracts for the apothecary may be made at a very gentle heat, and in vacuo.

be made at a very gentle heat, and in vacuo. From these two circumstances, extracts thus prepared differ from those in common use, not only in their physical, but medicinal properties. The taste and smell of the extract of hemlock made in this way are remarkably different, as is the colour both of the soluble and feculent parts. The form of apparatus is as follows:—

The evaporating-pan, or still, is a hemispherical dish of cast-iron, polished on its inner surface, and furnished with an air-tight flat lid. From the centre of this a pipe rises, and bending like the neck of a retort, it forms a declining tube, which terminates in a copper sphere of a capacity three (four?) times greater than that of the still. There is a stop-cock on that pipe, midway between the still and the globe, and another at the under side of the latter.

at the under side of the latter.

The manner of setting it to work is this :- The juice, or infusion, is introduced through a large opening into the polished iron still, which is then closed, made airtight, and covered with water. The stop-cock which leads to the sphere is also shut. In order to produce the vacuum, steam from a separate apparatus is made to rush by a pipe through the sphere, till it has expelled all the air, for which five minutes are commonly sufficient. This is known to be effected, by the steam issuing uncondensed. At that instant, the copper sphere is closed, the steam shut off, and cold water ad-mitted on its external surface. The vacuum thus prosphere is closed, the steam shut on, and cold water admitted on its external surface. The vacuum thus produced in the copper sphere, which contains four-fifths of the air of the whole apparatus, is now partially transferred to the still, by opening the intermediate stop-cock. Thus, four-fifths of the air in the still rush into the sphere, and the stop-cock being shut again, a second exhaustion is effected by steam in the same manner as the first was; after which a mo-mentary communication is again allowed between the iron still and the receiver; by this means, four-fifths of the air remaining after the former exhaustion, are expelled. These exhaustions, repeated five or six times, are usually found sufficient to raise the mercurial co-lumn to the height of 28 inches. The water-bath, in which the iron still is immersed, is now to be heated, until the fluid that is to be inspissated begins to boil, which is known by inspection through a window in the apparatus, made by fastening on, air-tight, a piece the apparatus, made by lastening on, air-light, a piece of very strong glass; and the temperature at which the boiling print is kept up, is determined by a thermometer. Ebullition is continued until the fluid is inspissated to the proper degree of consistence, which also is tolerably judged of by its appearance through the glass window. The temperature of the boiling fluid is usually about 100° F., but it might be reduced to nearly 900.

In the Medico-chirurgical Transactions for 1819,

(vol. x.) there is a paper by J. T. Barry on a new method of preparing Pharmaceutical Extracts. It consists in performing the evaporation in vacuo. For this purpose he employed apparatus which was found to answer so well, that, contemplating its application to other manufacturers, he was induced to take out a patent for it, that is to say, for the apparatus. As it has been erroneously supposed that the patent is for preparing extracts in vacuo, it may not be improper to correct the statement by a short quotation from the above paper. On that account, I have been induced to take out a patent for it (the apparatus). It is, howabove paper. 'On that account, I have been induced to take out a patent for it (the apparatus). It is, however, to be recollected by this society, that I have declined having a patent for its pharmaceutical products. Chemists, desirous of inspissating extracts in vacuo, are therefore at liberty to do it in any apparatus differing from that which has been made the subject of the parallel, and thus there substances may continue my patent; and thus these substances may continue the object of fair competition as to quality and price.' The apparatus combines two striking improvements.

The first consists in producing a vacuum by the agency of steam only, so that the use of air-pumps and the machinery requisite for working them, is superseded.

The other improvement is a contrivance for super-

seding the injection of water during the process of evaporation in vacuo.'

Evergreen leaf. See Sempervirens.
Exacerbatio. (Exacerbatio; from exacerbo, to become violent.) An increase of the force or violence of the symptoms of a disease. The term is generally applied to an increase of febrile symptoms.

Exacrresis. (From εξαιρεω, to remove.) One of the divisions of surgery adopted by the old surgeons; the term implies the removal of parts.

Exactron. (From εξαιλρεω, to lean out.) Hippo-

Exa LMA. (From εξαλλομαι, to leap out.) Hippo-crates applies it to the starting of the vertebræ out of

EXAMBLO MA. (From εξαμόλοω, to miscarry.)

An abortion. EXAMBLO'SIS. An abortion.

Exanastomo'sis. (From εξανασ Jομοω, to relax, or open.) The opening of the mouths of vessels, to discharge their contents.

EXANGIA. (Exangia; from εξ, and ανγειον, a vessel.) The name of a genus; class, Hæmatica; order, Dysthetica, in Good's Nosology. It embraces

three species, Exangia aneurisma, varix, cyania.

EXANTHE'MA. (Exanthema, atis. n.; from exacts, efforceso, to efforceso, or break forth on a surface.) Exanthisma. An eruption of the skin, called a rash. It consists of red patches on the skin, variously figured; in general confluent, and diffused irregularly over the body, leaving interstices of a natural colour. Portions of the cuticle are often elevated in a rash but the elevations are not acuminated. The a rash, but the elevations are not acuminated. eruption is usually accompanied with a general disorder of the constitution, and terminates in a few days by cuticular exfoliations.

ger of the constitution, and terminates in a few days by cuticular exfoliations.

EXANTHE'MATA. (The plural of exanthema.) The name of an order of diseases of the class Pyrexia in Cullen's Nosology. It includes diseases, beginning with fever, and followed by an eruption on the skin.

EXANTHEMATICA. The name of an order of diseases, class, Hamatica, in Good's Nosology. Eruptive fevers. It comprehends four genera, viz. Exanthesis, Emphlyis, Empyesis, Anthracia.

EXANTHESIS. (From εξ, extra, and ανθιω, floreo.) The name of a genus of disease, class, Eccritica; order, Acrotica, in Good's Nosology. Cutaneous blush. It affords only one species, Exanthema.

EXANTHE'SIA. (From εξ, without, and ανθρωπος, a man, i. e. having lost the faculties of a man.) A species of melancholy, in which the patient fancies himself some kind of brute.

EXARA'GMA. (From εξαρατ ω, to break.) A fracture.

Exara'oma. (From εξαρατ 7ω, to break.) A fracture. Exa'rma. (From εξαιρω, to lift up.) A tumour or

swelling. (From ¿{ap/aw, to suspend.) EXARTE'MA. charm, hung round the neck.

Exarther MA. (From εξαρθροω, to put out of int.) Exarthroma; Exarthrosis. A dislocation, or

Exarthro'ma. See Exarthrema. Exarthro'sis. See Exarthrema. 344

EXARTICULA'TIO. (From ez, out of, and articulus, a joint.) from its socket.

(From excipio, to receive.) A che-EXCLPULUM.

mical receives

EXCITABILITY. That condition of living bodies wherein they can be made to exhibit the functions and phenomena which distinguish them from inanimate

matter, or the capacity of organized beings to be af-fected by various agents called exciting powers.

Much confusion seems to have arisen in medical controversies from the application of the word stimuli, controversies from the application of the word stimuli, to denote the means necessary to the support of life; and particularly by Brown, in his celebrated attempt to reduce the varied and complicated states of the system to the reciprocal action of the exciting powers upon the excitability. By this hypothesis, instead of regarding life as a continued series of actions, which cannot go on without certain agents constantly ministering to them, we are to suppose a substance or quality, called excitability, which is superadded or assigned to every being upon the commencement of its living state. The founder of the Brunoffan school considers that this substance or quality is expanded considers that this substance or quality is expanded by the incessant action of the exciting powers. These are—air, food, and drink, the blood and the secretions, as well as muscular exertion, sensation, thought, and passions, or emotion, or other functions of the system itself; and these powers, which exhaust the excitabi-lity or produce excitement (according to the language of the school), are strangely enough called stimuli. We are told, that it is in the due balance between the exciting powers and the excitability that health con-sists: for if the exciting powers he in excess, indirect

exciting powers and the excitability that health consists: for if the exciting powers be in excess, indirect debility is produced; and where, on the other hand, the stimuli are deficient and the excitability accumulated, there ensues a state of direct debility.

EXCITATION. (Excitato; from excito, to excite.) The act of awakening, rousing, or producing some power or action: thus we say, the excitation of motion, excitation of heat, excitation of the passions, &c. In natural philosophy, it is principally used in the subjects of action of living parts, and in electricity and heat.

city and heat.

EXCITEMENT. According to the opinion of Brown, excitement is the continual exhaustion of the matter of life, or excitability by certain agents, which have received the name of stimuli or exciting powers. The due degree of this expension or excitement is the condition necessary to health: the excessive action of stimuli causing indirect debility and generating sthemic diseases, while the opposite state of deficient excitement produces direct debility, and gives birth to asthemic diseases: and death is said to result equally from complete exhaustion of the excitability, and from total absence of the exciting powers. Excitement is in this view equivalent to that forced state which is supposed by the Brunonian school to constitute life.

It has been objected to this hypothesis, that by simplifying too much the varied phenomena of healthy functions and of diseases, it necessarily classed together conditions of the system which have been considered as widely different, and of opposite tendencies, by the more patient observer. And though gladly caught at by many, as pointing out in a few general rules the mode of cure in all diseases, namely, by restoring the proper equilibrium between excitability rules the mode of cure in all diseases, namely, by restoring the proper equilibrium between excitability and the action of stimuli, the Brunonian theories seem now to be considered, by those who are suspicious of bold classifications, as an example of the observation, "that the most ingenious way of becoming foolish is by a system; and the surest way to prevent truth, is to set up something in the room of it."

EXCITING. That which has the power of impressing the solids, so as to alter their action, and thus produce disease.

EXCITING CAUSE. That which, when applied to

Exciting cause. That which, when applied to the body, excites a disease.

EXCORIATION. (Excoriatio; from excorio, to take off the skin.) An abrasion of the skin.

EXCREMENT. (Excrementum; from excerno, to separate from.) The alvine faces.

EXCRESCENCE. (Excrescentia; from excresco, to grow from.) Any preternatural formation of flesh, or any part of the body, as wens, warts, &c.

EXCRETION. (Excretio; from excerno, to separate from.) This term is applied to the separation of

those fluids from the blood of an animal, that are supposed to be useless, as the urine, perspiration, and alvine faces. The process is the same with that of secretion, except with the alvine faces; but the term excretion is applied to those substances which, when separated from the blood, are not applied to any useful parrosses in the animal secretion.

purposes in the animal economy.

EXCRETORY. (Excretorius; from excerno, to purge, sift, &c.) This name is applied to certain little ducts or vessels in the fabric of glands; thus the tubes which convey the secretion out of the testicle into the vesiculæ seminales are called the excretory ducts.

EXERCISE. See Æora.

EXFOLIA TION. (Exfoliatio; from exfolio, to cast the leaf.) The separation of a dead piece of bone from the living.

EXPOLIATI'VUM. (From exfolio, to shed the leaf.) A raspatory, or instrument for scraping exfoliating portions of bone.

Ext'schios. (From εξ, out of, and ισχιον, the ischium.) A luxation of the thigh-bone.

EXITU'RA. (From exeo, to come from.) A running

abscess.

E'xirus. (From ezeo, to come out.) A prolapsus, or falling down of a part of the womb or bowel.

Exoche. A tubercle on the outside of the anus.

E'xoche. See Exochas.

Exocy'stis. See Exocystis.
Exocy'stis. (From εξω, without, and κυςις, the bladder.) Exocyste. A prolapsus of the inner membrane of the bladder.

EXO'MPHALUS. (From εξ, out, and ομφαλος, the . An umbilical hernia. See navel.) Exomphalos. Hernia umbilicalis.

EXONCHO MA. (From εξ, and ογχος, a tumour.) A large prominent tumour. EXOPHTHA LMIA. (From εξ, out, and οφθαλμος,

EXOPHTHA LMIA. (From εξ, out, and οφθαλμος, the eye.) A swelling or protrusion of the builb of the eye, to such a degree that the eyelids cannot cover it. It may be caused by inflammation, when it is termed exophthalmia inflammatoria; or from a collection of pus in the globe of the eye, when it is termed the exophthalmia purulenta; or from a congestion of blood within the globe of the eye, exophthalmia sanguinea. EXORMIA. (Εξορμία; from εξορμάω, to break out.) The name of a genus of disease, class, Eccritica; order, Acrotica, in Good's Nosology. Papulous skin. It has four species, viz. Exormia strophalus, lichen, prurigo, milium.

EXOSTO'SIS. (From εξ, and οσζον, a bone.) Hyperostosis. A morbid enlargement, or hard tumour of a bone. A genus of disease arranged by Cullen in the class Locales, and order Tumores. The bones most frequently affected with exostosis, are those of the cranium, the lower jaw, sternum, humerus, radius, the cranium, the lower jaw, sternum, humerus, radius, ulna, bones of the carpus, the femur, and tibia. There is, however, no bone of the body which may not become the seat of this disease. It is not uncommon to find the bones of the cranium affected with exostosis, in their whole extent. The ossa parietalia sometimes become an inch thick.

The exostosis, however, mostly rises from the surface of the bone, in the form of a hard round tumour; and venereal exostoses, or nodes, are observed to arise chiefly on compact bones, and such of these as are only superficially covered with soft parts; as, for instance, the bones of the cranium, and the front surface

EXPANSION. The increase of surface, or of bulk,

to which natural bodies are susceptible.

EXPE'CTORANT. (Expectorans; from expectoro, to discharge from the breast.) Those medicines which increase the discharge of mucus from the lungs. The different articles referred to this class may be divided into the following orders:

1. Nauseating expectorants; as squill, ammonia-cum, and garlic, which are to be preferred for the aged

and phlegmatic.

Stimulating expectorants; as marrubium, which
is adapted to the young and irritable, and those easily
affected by expectorants.

3. Antispasmodic expectorants; as vesicatories, pediluvium, and watery vapours: these are best calculated for the plethoric and irritable, and those liable to spasmodic affections.

4. Irritating expectorants; as fumes of tobacco and

acid vapours. The constitutions to which these are chiefly adapted, are those past the period of youth, and those in whom there are evident marks of torpor, either in the system generally, or in the lungs in par-

[These are remedies which promote, or are adminis-tered to facilitate the discharge from the lungs both by

secretion or expectoration.

This secretion is of two kinds, first the Halitus or watery vapour, and secondly the Muscus or slime. In cases of disease there are other secretions, or rather fluids to be excreted; such as,

Blood or sanguineous mixtures.
 Pus or purulent mixtures.

Lymphatic or coagulated films, as in croup
 Stony or calculous concretions.

5. Hydatids.

There may be too little vascular or grandular action in consequence of which the organ of respiration may be too dry, or secrete less than it ought; and also there may be too little power to throw out the secreted matters. Under the title therefore of Expectorants, are comprehended all the remedies which promote secretion or excretion in the lungs.

Respiration may be considered as a perspiratory function, and acting in conjunction with, or vicariousto, the skin, and as having also a somewhat to perform analogous to the alimentary canal. For which purpose the lungs and intestines may be strictly and properly considered as external surfaces.

When the pulmonary and bronchial vessels are considered as to the amount of blood they convey, the importance of the function, the proximity of the heart, the frequency and seriousness of the diseases to which the lungs are subjected, it will be evident that this class of remedies is worthy of being well understood.

The function of respiration in my view has an analogy to respiration.

logy to respiration.

Remedies therefore which determine the fluids to the skin, or excite the cuticular surface to secretory action, may be considered as almost pari passu encouraging pulmonary exhalation. This argument decouraging pulmonary exhalation. This argument derives force from the common remark of the suppressed perspiration falling upon the lungs. There is no doubt that the pulmonic surface and the cuticular surface (both of which are to be considered as external) are frequently both disordered at once. But the true interpretation probably is, that the lungs do not suffer in consequence of the fluids repelled from the skin, but from the same cause which disturbs the skin: the cold, for example, which acts injuriously upon the former, produces a like mischief in the latter. They are cutaneous disorders, and are to be removed as far as the restoration of their respective secretions are

as the restoration of their respective secretions are concerned by corresponding means.

I therefore class Sudorifics among the expectorants.

Emetics are to be placed in the same class, and for a very good reason. Their action in inverting the motion of the stomach is favourable to the excretion of fluids from the trackers and breaching the motion. fluids from the trachea and bronchise, as well as from the stomach and fauces. This may be explained from the action of the belly, the diaphragm, and intercos-tals, and the compression they make upon the chest, and forcing out its contents. The same solution seems to apply, at least as far as secretion goes, to the opera-tion of nauseating doses. Upon the same principle that they relax the skin, they relax the pulmonary

Some expectorants are directly applied to the lungs; among which are,

1. Warm air, of a thermometric temperature to suit

the patient's case.

2. Respirable air, medicated by carbonic acid to dimi-

2. Respirable air, medicated by carbonic acid to diminish its too stimulant quality.

3. Respirable air, quickened by a mixture of oxygenous gas to excite the bronchiæ and rouse them from torpor. The same may be done by ether.

4. Air qualified and tempered by the vapour of water and infused herbs, as in Mudges inhaler.

5. Teas and medicated drinks, sipped slowly, and swallowed gradually, so that a portion of their vapour may enter the trachea with the breath.

6. Dry fumes, as those of tobacco, stramonium, &c., a part of which undoubtedly enters the trachea, and cannot be excluded, as of cinnabar, frankincense, &c.

7. A medicated atmosphere, into which the odours

EXT

of plants and flowers, as of geraniums and oranges, or of gums and drugs, such as camphor and musk, may be set loose and mingled.

Its office is to extend the toes.

EXTENSOR CARPI RADIALIS BREVIOR. An extensor

Other expectorants act upon the mouth and fauces by virtue of the sympathy between those parts and the

lungs; such as,

1. Saccharine substances, as honey, syrups, dry
sugars and their lozenges, liquorice, &c.

2. Mucilaginous substances, as gum arabic, gum tra-

gacanth, &c.

Gacanth, &c.

Others again act through the medium of the stomach, as any of the before-mentioned substances when they are swallowed, and others bringing the lungs by consent into a relaxed and expectorating state.

The rules recommended in the administration of expectorants may be reduced to two.

1. To keep the patient in a warm and comfortable temperature.

temperature.

2. To avoid the administration of such cathartics as seem to act contrariwise to expectorants. Can they not however be so employed as to supersede expectorants to a certain degree?

Excessive expectoration will frequently require

your interposition, as,

1. In catarrhal affections of the chronic kind, where the secreted mucus must be evacuated by hawking or coughing; and the quantity of slime in chronic cases is very considerable. The disease is troublesome, and sometimes ends in hemoptysis or phthisis.

2. In phthisis pulmonalis; in which the excretion of mucus, pus, &c. is one of the most distressing symptoms, and thus often without vomica or ulceration.

In occasional rushes or determination of fluids to the trachea and bronchia, where prodigious quan-tities of slime are effused and excreted, with great exertion and straining.

The course of proceeding in each case will depend upon the particular state of the constitution, the idiosyncrasy of the patient, the acquired habits of living and physicking; and the connexion of this particular symptom, with the other symptoms of the dominant

The following are the principal of the expectorants:
Lichen islandicus, Iceland moss. 2. Glycyrrhiza
abra, Liquorice. 3. Mimosa nilotica, Gum arabic. 1. Lichen islandicus, Iceland moss. 2. Glycyrrinza glabra, Liquorice. 3. Mimosa nilotica, Gum arabic. 4. Ulmus aspera, Slippery elm. 5. Heracleum gummosiferum, Gum ammoniac. 6. Scilla maritima, the Squill. 7. Allium sativum, Garlic. 8. Ferula, Assafœtida. 9. Arum tryphillum, March turnip. 10. Polygala Senega, Seneca snakeroot. 11. Carbonate of ammonia. 12. Carbonate of potash. 13. Carbonate of soda. 14. Colchicum-autumnale or meadow saffron. 15. Balsams of Tolu, Capivi, &c. 16. Inhalations of water, vinegar, medicated infusions. 17. Syrupa and saccharine compositions, as honey and vinerups and saccharine compositions, as honey and vine-

gar, molasses and vinegar, &c.—Notes from Dr.
Mitchill's Lect. on Mat. Med.
EXPERIENCE. A kind of knowledge acquired by long use, without any teacher. Experience consists in the ideas of things we have seen or read, which the judgment has reflected on, to form for itself a rule or

EXPERS. Wanting; destitute. The trivial name of some diseases; as dipsosis expers, in which the thirst is wanting.

thirst is wanting.

EXPIRA'TION. (Expiratio; from expiro, to breathe.) That part of respiration in which the air is thrust out from the lungs. See Respiration.

Expressed oil. Such oils as are obtained by pressing the substance containing them; as olives, which give out olive oil, almonds, &c.

Exsucca'Tio. (From ex, out of, and succus, humour.) An ecchymosis, or extravasation of humours, under the integuments.

EXTE'NSOR. (From extends, to stretch out)

EXTENSOR. (From extendo, to stretch out.) A term given to those muscles, the office of which is to extend any part; the term is in opposition to flexor.

EXTENSOR BREVIS DIGITORUM PEDIS. A muscle of the toes, situated on the foot. Extensor brevis, of Douglas. Calcano phalanginien commune, of Dumas. It arises fleshy and tendinous from the fore and upper part of the os calcis, and soon forms a fleshy belly, divisible into four portions, which send off an equal number of tendons that pass over the upper part of the foot, under the tendons of the extensor longus digito-

muscle of the wrist, situated on the forearm. Radialis externus brevior, of Albinus. Radialis secundus, of Winslow. It arises tendinous from the external conwinslow. It arises tendinous from the external con-nects the radius to it, and runs along the outside of the radius. It is inserted by a long tendon into the upper and back part of the metacarpal bone of the middle finger. It assists in extending and bringing the hand backward.

EXTENSOR CARPI RADIALIS LONGIOR. An extensor muscle of the carpus, situated on the forearm, that acts in conjunction with the former. Radialis externus longior, of Albinus. Radialis externus primus, of Winslow. It arises thin, broad, and fleshy, from the lower part of the external ridge of the os humeri, above its external condyle, and is inserted by a round tendon into the posterior and upper part of the metacarpal bone that sustains the foreingers.

EXTENSOR CARPI ULNARIS. Ulnaris externus, of Albinus and Winslow. It arises from the outer condule of the os humeri, and then receives an origin from EXTENSOR CARPI RADIALIS LONGIOR.

dyle of the os humeri, and then receives an origin from the edge of the ulna: its tendon passes in a groove be-hind the styloid process of the ulna, to be inserted into the inside of the basis of the metacarpal bone of the

little finger.

EXTENSOR DIGITORUM COMMUNIS. A muscle situated on the forearm, that extends all the joints of the tingers. Extensor digitorum communis manus, of Douglas and Winslow. Extensor digitorum communis, seu digitorum tensor, of Cowper, and Epichondylo-suspha-langettien commune, of Dumas. Cum extensore proprio auricularis, of Albinus. It arises from the external protuberance of the humerus: and at the wrist it divides into three flat tendons, which pass under the annular ligament, to be inserted into all the bones of the fore, middle, and ring fingers.

EXTENSOR DIGITORUM LONGUS. See Extensor landary. EXTENSOR DIGITORUM COMMUNIS. A muscle situ-

primi internodii.

primi internodii.

EXTENSOR OSSIS METACARPI POLLICIS MANUS. An extensor muscle of the wrist, situated on the forearm. Abductor longus pollicis manus, of Albinus. Extensor primi internodii, of Douglas. Extensor primi pollicis, of Winslow. Extensor primi internodii pollicis, of Cowper. Cubito-radisus metacarpien du pouce, of Dunas. It arises fleshy from the middle and posterior part of the ulna, from the posterior part of the middle of the radius, and from the interosseous ligament, and is inserted into the os trapezium, and upper part of the is inserted into the os trapezium, and upper part of the metacarpal bone of the thumb.

EXTENSOR POLLICIS PRIMUS. See Extensor primi

internodii.

Extensor pollicis secundus. See Extensor secundi internodii.

cundi internodii.

EXTENSOR PRIMI INTERNODII. A muscle of the thumb situated on the hand, that extends the first bone of the thumb obliquely outwards. Extensor minor pollicis manus of Albinus. This muscle, and the Extensor ossis metacarpi pollicis manus, are called Extensor pollicis primus by Winslow; Extensor secundi internodii by Douglas; Extensor secundi internodii ossis pollicis of Cowper. Cubito-susphalangien du pouce of Dumas. It arises fleshy from the posterior part of the ulna, and from the interosseous ligament, and is inserted tendinous into the posterior part of the first bone of the thumb.

Extensor Propries Pollicis Profs. An exterior muscle of the great toe, situated on the foot. Extensor longus of Douglas. Extensor pollicis longus of Winslow and Cowper. Peroneo susphalangien du pouce of Dumas. It arises by an acute, tendinous, and fleshy beginning, some way below the head, and anterior part of the fibula, along which it runs to near its lower extremity, connected to it by a number of fleshy fibres, which descend obliquely, and form a tendon, which is inserted into the posterior part of the first and last joint of the great toe. last joint of the great toe.

EXTENSOR SECUNDI INTERNODII. A muscle of the EXTENSOR SECUNDI INTERNODII. A muscie of the thumb, situated on the hand, that extends the last joint of the thumb obliquely backwards. Extensor major pollicis manus of Albinus. Extensor pollicis secundus of Winslow. Extensor tertii internodii of Douglas. Extensor internodii ossis pollicis of Cowper. Cubito susphalangettien du pouce of Dumas. It arises tendinous and fleshy from the middle part of the ulna, and interosseous ligament; it then forms a tendon, which runs through a small groove at the inner and back part runs through a small groove at the inner and back part of the radius, to be inserted into the last bone of the thumb. Its use is to extend the last phalanx of the thumb obliquely backwards.

EXTENSOR SECUNDI INTERNOMI INDICIS PROPRIUS. See Indicator.

EXTENSOR TARSI MINOR. See Plantaris.

EXTENSOR TARSI SURALIS. See Gastrocnemius

EXTENSOR TERTH INTERNODII INDICIS. See Prior indicis.

Extensor tertii internodii minimi digiti. See

Abductor minimi digiti manus.

EXTERNUS MALLEI. See Laxator tympani.

EXTIPULATUS. Without stipulæ. A botanical term. Applied to stems.

EXTIRPATION. (Extirpatio; from extirpo, to eradicate.) The complete removal or destruction of any part, either by cutting instruments, or the action of caustics.

EXTRACT. Extractum. 1. When chemists use this term, they generally mean the product of an aqueous decoction.

2. In pharmacy it includes all those preparations from vegetables which are separated by the agency of various liquids, and afterward obtained from such solutions, in a solid state, by evaporation of the menstruum. It also includes those substances which are held in solution by the natural juices of fresh plants, as well as those to which some menstruum is added at the time of preparation. Now, such soluble matters are various, and mostly complicated; so that chemical accuracy is not to be looked for in the application of the term. Some chemists, however, have affixed this name to one peculiar modification of vegetable matter, which has been called extractive, or extract, or extractive principle; and as this force one constitute that the same constitute of contractive and as this force one constitute that the same called extractive are constituted as the same called extractive. and, as this forms one constituent part of common extracts, and possesses certain characters, it will be proper to mention such of them as may influence its pharmaceutical relations. The extractive principle has a strong taste, differing in different plants: it is soluble in water, and its solution speedily runs into a state of putrefaction, by which it is destroyed. Repeated evaporations and solutions render it at last insoluble, in consequence of its combination with oxygen from the atmosphere. It is soluble in alkohol, but insoluble in ether. It unites with alumine, and if boiled with neutral salts thereof, precipitates them. It precipitates with strong acids, and with the oxides from solutions of most metallic salts, especially muriate of tin. It readily unites with alkalies, and forms compounds with them, which are soluble in water. No part, however, tracts, and possesses certain characters, it will be proper them, which are soluble in water. No part, however, of this subject has been hitherto sufficiently examined.

of this subject has been hitherto sufficiently examined. In the preparation of all the extracts, the London Pharmacopaia requires that the water be evaporated as speedily as possible in a broad, shallow dish, by means of a water-bath, until they have acquired a consistence proper for making pills; and, towards the end of the inspissation, that they should be constantly stirred with a wooden rod. These general rules require minute and accurate attention, more particularly in the immediate evaporation of the solution, whether prepared by expression or decoction, in the manner as well as the degree of heat by which it is performed, and the promotion of it by changing the surface by constant stirring, when the liquor begins to thicken, and even by directing a strong current of air over its surface, if it directing a strong current of air over its surface, if it

can conveniently be done. It is impossible to regulate the temperature over a naked fire, or, if it be used, to prevent the extract from burning; the use of a waterbath is, therefore, absolutely necessary, and not to be dispensed with, and the beauty and precision of extracts so prepared, will demonstrate their superiority.

EXTRACTION. (Extractio; from extraho, to draw out.) The taking extraneous substances out of the body. Thus bullets and splinters are said to be extracted from wounds; stones from the urethra, or bladder. Surgeons also sometimes apply the term extraction to the removal of tumours out of cavities, as, for instance, to the taking of cartilaginous tumours out of the joints. They seldom speak of extracting any diseased original part of the body; though they do so in one example, viz. the cataract.

EXTRACTIVE. See Extract.

EXTRACTUM. (From extraho, to draw out.)

(From extraho, to draw out.) EXTRA'CTUM. An extract. See Extract.

EXTRACTUM ACONITI. Extract of aconite. Take of aconite leaves, fresh, a pound; bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation of the sediment, evaporate it to a proper consistence. The dose is from one grain to five grains. For its virtues, see

EXTRACTUM ALOES PURIFICATUM. Purified extract of aloes. Take of extract of spike aloe, powdered, half a pound; boiling water, four pints. Macerate for three days in a gentle heat, then strain the solution, and set it by, that the dregs may subside. Pour off the clear solution, and evaporate it to a proper consistence.

dose, from five to iffteen grains. See Aloës.

EXTRACTUM ANTHEMIDIS. Extract of chamomile, formerly called extractum chamæmell. Take of chamomile flowers, dried, a pound; water, a gallon; boil down to four pints, and strain the solution while it is hot, then evaporate it to a proper consistence. The dose is ten grains to a scruple. For its virtues, see Anthemis rabilis. Anthemis nobilis.

EXTRACTUM BELLADONNE. Extract of belladonna. Take of deadly night-shade leaves, fresh, a pound. Bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and without any previous separation of the sediment, evaporate it to a proper consistence. The dose is from one to five grains.

For its virtues, see Atropa belladonna.

EXTRACTUM CINCHONE. Extract of bark. Take of lance-leaved cinchona bark, bruised, a pound; water a gallon; boil down to six pints, and strain the liquor, while hot. In the same manner, with an equal quantity of water, four times boil down, and strain. Lastly, consume all the liquors, mixed together, to a proper consistence. This extract should be kept soft, for making pills, and hard to be reduced to powder. making pills, and hard to be reduced to powder.

making pills, and hard to be reduced to powder.

Extractum cinchon resinosum. Resinous extract of hark. Take of lance-leaved cinchona bark, bruised, a pound; rectified spirit, four pints; macerate for four days and strain. Distil the tincture in the heat of a water-bath, until the extract has acquired a proper consistence. This is considered by many as much more grateful to the stomach, and, at the same time, producing all the effects of bark in substance, and by the distillation of it, it is intended that the spirit which passes over shall be collected and preserved. The dose is from ten grains to half a drachm. See Cinchona. is from ten grains to half a drachm. See Cinchona.

EXTRACTUM COLOGYNTHIDIS. Extract of colocynth.

Take of colocynth pulp, a pound; water, a gallon; boil down to four pints, and strain the solution while it is hot, and evaporate it to a proper consistence. The dose is from five to thirty grains. For its virtues, see Cucumis colocynthis.

Cucumis colocynthis.

Extractum colocynthis compositum. Compound extract of colocynth. Take of colocynth pulp, sliced, six drachms; extract of spike aloe, powdered, an ounce and half; scammony gum-resin, powdered, half an ounce; cardamom seeds, powdered, a drachm; proof spirit, a pint. Macerate the colocynth pulp in the spirit, for four days, in a gentle heat: strain the solution, and add it to the aloes and scammony; then, by means of a water-bath, evaporate it to a proper consistence, constantly stirring, and about the end of the inspissation, mix in the cardamom-seeds. The dose from five to thirty grains.

Extractum conn. Extract of hemlock, formerly called succus cicutæ spissatus. Take of fresh hemlock, a pound. Bruise it in a stone mortar, sprinkling

on a little water; then press out the juice, and, with-out any separation to the sediment, evaporate it to a proper consistence. The dose, from five grains to a

EXTRACTUM ELATERII. Extract of elaterium. Cut the ripe, wild cucumbers into slices, and pass the juice, very gently expressed, through a very fine hair sieve, into a glass vessel; then set it by for some hours, until the thicker part has subsided. Pour off, and throw away the thinner part, which swims at the top. Dry the thicker part which remains in a gentle heat. The dose, from half a grain to three grains. For its virtues, see from half a grain to three grains. For its virtues, see Momordica claterium.

EXTRACTUM GENTIANE. Extract of gentian. Take of gentian root, sliced, a pound; boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Dose, from ten to thirty grains. See

Gentiana.

EXTRACTUM GLYCYRRHIZE. Extract of liquorice. Take of liquorice root, sliced, a pound; boiling water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Dose, from one drachm to

half an ounce. See Glycyrrhiza

EXTRACTUM HEMATOXYLL. Extract of logwood, formerly called extractum ligni campechensis. Take of logwood, powdered, a pound; boiling water, a gailon; macerate for twenty-four hours; then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Dose, from ten grains to half a drachm. For its virtues, see Hengelength For its virtues, see Hamatoxylon campeckianum.

EXTRACTUM HUMULI. Extract of hops. Take of hops, four ounces; boiling water, a gallon; boil down to four pints; strain the hot liquor, and evaporate it to

to four pints; strain the hot liquor, and evaporate it to a proper consistence. This extract is said to produce a tonic and sedative power combined; the dose is from five grains to one scruple. See Humulus lupulus.

EXTRACTUM HYOSCYAMI. Extract of henbane. Take of fresh henbane leaves, a pound; bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without separating the faculencies, evaporate it to a proper consistence. Dose, from five to thirty grains. For its virtues, see Hyoschamus.

EXTRACTUM JALAPE. Extract of jalap. Take of pints; water, ten pints; macerate the jalap-root powdered, a pound; rectified spirit, four pints; water, ten pints; macerate the jalap-root in the spirits for four days, and pour off the tincture; boil the remaining powder in the water, until it be reduced to two pints; then strain the tincture and decoction separately, and let the former be distilled and the latter evaporated, until each begins to grow thick. Lastly, mix the extract with the resin and reduce it to a promix the extract with the resin, and reduce it to a proper consistence. Let this extract be kept in a soft state, fit for forming pills, and in a hard one, so that it it may be reduced to powder. The dose, from ten to twenty grains. For its virtues, see Convolvulus

EXTRACTUM OPH. Extract of opium, formerly called extractum thebaicum. Opium colatum. Take of opium, sliced, half a pound; water, three pints; pour a small quantity of the water upon the opium, and macerate it for twelve hours, that it may become soft; then, adding the remaining water gradually, rub them together until the mixture be complete. Set it by, that the faculencies may subside; then strain the liquor, and evaporate it to a proper consistence. Dose, from half a grain to five grains.

EXTRACTUM PAPAVERIS. Extract of white poppy.

Take of white poppy capsules bruised, and freed from
the seeds, a pound; boiling water a gallon. Macerate
for twenty-four hours, then boil down to four pints;

for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Six grains are about equivalent to one of opium. For its virtues, see Papaver album.

Extraction results. Extract of rhubarb. Take of rhubarb root, powdered, a pourd; proof spirit, a pint; water, seven pints. Macerate for four days in a gentle heat; then strain and set it by, that the faculencies may subside. Pour off the clear liquor, and evaporate to a proper consistence. This extract possesses the purgative properties of the root, and the fibrous and earthy parts are separated; it is therefore, a useful basis for pills, as well as given separately. Dose, from ten to thirty grains. See Rheum.

348

EXTRACTUM SARSAPARILLE. Extract of sarsaparilla. Take of sarsaparilla root, sliced, a pound; boil ing water, a gallon; macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. In practice this is much used, to render the common decoction of the same root stronger and more efficacious. Dose, from ten grains to a drachm. For its virtues, see Smilar sarsangrille. lax sarsaparilla.

EXTRACTUM SATURNI. See Plumbi acctatis liquor
EXTRACTUM TARAXACI. Take of dandelion root,
fresh and bruised, a pound; boiling water, a gallon;
macerate for twenty-four hours; boil down to four
pints, and strain the hot liquor; then evaporate it to a proper consistence. Dose, from ten grains to a drachm. For its virtues, see Leontodon taraxacum.

EXTRAFOLIACEUS. Applied to stipulæ, which are below the footstalk, and external with respect to the leaf; as in Astragalus anobrichis.

EXTRAVASATION. (Extravasatio; from extra, without, and vas, a vessel.) A term applied by surgeons to fluids, which are out of their proper vessels, or receptacles. Thus, when blood is effused on the surface, or in the ventricles of the brain, it is said that there is an extravasation. When blood is poured from the vessels into the cavity of the peritonaum, in wounds of the abdomen, surgeons call this accident extravasation. The urine is also said to be extravasated, when, in consequence of a wound, or of sloughing, or ulceration, it makes its way into the cellular ing, or ulceration, it makes its way into the cellular substance or among the abdominal viscera. When the bile spreads among the convolutions of the bowels, in wounds of the gall-bladder, it is also a species of

EXTREMITIES. This term is applied to the limbs, as distinguishing them from the other divisions of the animal, the head and trunk. The extremities are four in number, divided in man into upper and lower; in other animals into anterior and posterior. Each extremity is divided into four parts; the upper into the shoulder, the arm, the forearm and the hand: the lower into the hip, the thigh, the leg, and the foot.

EYE. Oculus. The parts which constitute the eye are divided into external and internal. The exter-

nal parts are:

The eyebrows, or supercilia, which form arches of hair above the orbit, at the lower part of the fore-

head. Their use is to prevent the sweat falling into the eyes, and for moderating the light above.

2. The eyelashes, or cilia, are the short hairs that grow on the margin of the eyelids; they keep external bodies out of the eyes and moderate the influx

3. The eyelids, or palpebræ, of which, one is superior or upper, and the other inferior, or under; where they join outwardly, it is called the external canthus; inwardly, towards the nose, the internal canthus; they cover and defend the eyes.

The margin of the eyesds, which is cartilaginous, is called the cartilaginous,

is called tarsus.

In the tarsus, and internal surface of the eyelids, small glands are situated, called glandulæ Meibomianæ, because Meibomias discovered them; they secrete an oily or mucilaginous fluid, which prevents the at trition of the eyes and eyelids, and facilitates their motions.

4. The lachrymal glands, or glandula lachrymales, which are placed near the external canthus, or corner of the eyes, in a little depression of the os frontis.

From these glands six or more canals issue, which are called lachrymal ducts, or ductus lachrymales, and they open on the internal surface of the upper. The chambers, or camera of the eyes are: eyelid.

5. The lachrymal caruncle, or caruncula lachrymalis, which is situated in the internal angle, or canthus of the eyelids.

6. Puncta lachrymalia, are two callous orifices or openings, which appear at the internal angle of the tarsus of the cyclids; the one in the superior, the other in the inferior eyelid.

7. The canales lachrymales, or lachrymal ducts, are two small canals, which proceed from the lachrymal points into the lachrymal sac.

8. The saccus lachrymalis, or lachrymal sac, is a membraneous sac, which is situated in the internal can-

10. The ductus nasalis, or nasal duct, is a membraneous canal, which goes from the inferior part of the lachrymal sac through the bony canal below, and a little behind, into the cavity of the nose, and opens under the inferior spongy bone into the noserial.

The membrana conjunctiva, or conjunctive mem-brane, which, from its white colour is called also albu-

brane, which, from its white colour is called also albuginea, or white of the eye, is a membrane which lines the internal superficies of the eyelids, and covers the whole forepart of the globe of the eye: it is very vascular, as may be seen in inflammations.

The bulb, or globe of the eye, is composed of eight membranes, or coverings, two chambers, or camera, and three humours, improperly so called.

The membranes of the globe of the eye, are, four in the hinder or posterior part of the bulb, or globe, viz. selerotica, choroidea, retina, and hyaloidea, or arachnoidea; four in the fore or anterior part of the bulb, viz. cornea transparens, iris, uvea, and capsule bulb, viz. cornea transparens, iris, uvea, and capsule

of the crystalline lens.

The membrana sclerotica, or the sclerotic or horny membrane, is the outermost. It begins from the optic nerve, forms the spherical or globular cavity, and terminates in the circular margin of the transparent

The membrana choroidea, or choroides, is the middle tonic of the bulb, of a black colour, beginning from the optic nerve, and covering the internal superficies of the sclerotica, to the margin of the transparent cornea. In this place it secedes from the cornea, and deflects transversely and inwardly, and in the middle forms a round foramen. This circular continuation of the choroidea in the anterior surface is called iris, in

The round opening in the centre is called the pupil, or pupilla. This foramen, or round opening, can be dilated, or contracted by the moving powers of almost

invisible muscular fibres.

The membrana retina, is the innermost tunic of a white colour, and similar to mucus, being an expansion of the optic nerve, chiefly composed of its medullary part. It covers the inward surface of the choroides,

The chambers, or camera of the eyes are:

1. Camera anterior, or fore-chamber; an open space, which is formed anteriorly, by the hollow surface of the cornea transparens, and posteriorly, by the surface

2. Camera posterior, that small space which is bounded anteriorly by the tunica uvca, and pupilla, or pupil; posteriorly by the anterior surface of the crystalline lens.

Both these chambers are filled with an aqueous humour. The humours of the eye, as they are called,

are in number three:

1. The aqueous humour, which fills both chambers.
2. The crystalline lens, or humour, is a pellucid body, about the size of a lentil, which is included in an exceedingly fine membrane, or capsula, and lodged in a concave depression of the vitreous

humour.

3. The vitreous humour, is a pellucid, beautifully transparent substance, which fills the whole built of the eye behind the crystalline lens. Its external surface is surrounded with a most pellucid membrane, which is called membrana hyaloidea, or arachnoidea. In the anterior part is a fovea, or bed, for the crystal-

The connexion of the bulb is made anteriorly, by means of the conjunctive membrane, with the inner surface of the eyelids, or palpebræ; posteriorly, by the adhesion of six muscles of the bulb and the optic nerve

with the orbit.

The optic nerve, or nerveus opticus, perforates the selerotica and choroides, and then constitutes the retina, by spreading itself on the whole posterior part of

the internal globe of the eye.

The muscles by which the eye is moved in the orbit, The muscles by which the eye is moved in the orbit, are six; much fat surrounds them, and fills up the cavities in which the eyes are seated. The arteries are the internal orbital, the central, and the ciliary arteries. The veins empty themselves into the external jugulars. The nerves are the optic, and branches from the third, fourth, fifth, and six pair.

The use of the eye is to form the organ of vision.

Externally, the globe of the eye and the transparent cornea are moistened with a most limpid fluid, called cornea are moistened with a most limpid fluid, called lackryma, or tears; the same pellucid subtile fluid exactly fills all the pores of the transparent cornea; for, deprived of this fluid, and being exposed to the air, that coat of the eye becomes dry, shrivelled, and cloudy, impeding the rays of light.

EYE-BRIGHT. See Euphrasia.

EYE-BROW. Supercilium. See Eye.

EYE-LID. Palpebra. See Eye.

Eye-tooth. The fangs of the two upper cuspidati are very much larger than those on each side, and ex-

are very much larger than those on each side, and extend up near to the orbit, on which account they have have been called eye-teeth. See Teeth.

P. or ft. In a prescription these letters are abbreviations of fiat, or fiant, let it, or them, be made; thus f. bolus, let the substance or substances prescribed be made into a bolus.

FA'BA. A bean. See Bean.

FABA CRASSA. See Sedum telephium. FABA EGYPTIACA. See Nymphæa nelumbo. FABA FEBRIFUGA. See Ignatia amara.

FABA INDICA. See Ignatia amara.
FABA MAJOR. The garden-bean. See Bean.
FABA MINOR. The horse-bean. It differs no otherwise from the garden-bean than in being less.

FABA PECHURIM. Faba pichurim; Faba pechuris. Brazilian bean. An oblong oval, brown, and ponderous seed, supposed to be the produce of a Laurus, brought from the Brazils. Their smell is like that of musk, between it and the scent of sassafras. They are exhibited as carminatives in flatulent colics, diarrhœas, and dysenteries.

FABRICIUS, HIERONYMUS, born at Aquapendente in Italy, 1537. He studied at Padua under Fallopius, whom he succeeded as professor of anatomy and surgery there; which office he held for nearly half a century with great credit, and died at the advanced age of gery there; which office he held for nearly half a century with great credit, and died at the advanced age of eighty-two, universally regretted. The republic of Venice also conferred many honours upon him. He is thought to have been the first to notice the valves of the veins, which he demonstrated in 1574. But his surgical works obtained him most reputation; indeed he has been called the father of modern surgery. His first publication in 1592 contained five Dissertations on Tumours, Wounds, Ulcers, Fractures, and Dislocations. He afterward added another part, treating of

all the diseases which are curable by manual opera-tion. This work passed through seventeen editions in

different languages.

FABRICIUS, JAMES, was born at Rostock, in 1577. After traveiling through different parts of Europe, he graduated at Jena, and soon gained extensive practice. He was professor of medicine and the mathematics at Rostock during forty years, and first physician to the Duke of Mecklenburgh; afterward went to Copenhagen, and was made physician to the kings of Norway and Denmark, and died there, in 1652. He has left several tracts on medical subjects.

FABRICIUS Prune Cover professor of medical subjects.

FABRICIUS, PHILIP CONRAD, professor of medicine at Helmstadt, was author of several useful works in anatomy and surgery. His first treatise, "Idea Anatomes Practica," 1741, contained some new directions in the Art of Injection, and described several branches of the Portio Dura, &c. In another work he has some good observations on the Abuse of Trepan-

PABRICIUS, WILLIAM, better known by the name of Hildanus, from Hilden, in Switzerland, where he wasborn in 1560. He repaired to Lausanne, to complete was born in 1560. He repaired to Lausanne, to complete his knowledge of surgery, at the age of twenty-six; and distinguished himself there by his assiduity, and the successful treatment of many difficult cases. He studied medicine also, and went to practise both arts at Payenne, in 1665; but ten years after was invited to Berne by the senate, who granted him a pension. In the latter part of his life, severe illness prevented his professional exertions, which had procured him general esteem and high reputation. His death occurred in 1634. His works were written in German, but have been mostly translated into Latin. He published five been mostly translated into Latin. He published five "Centuries of Observations," which present many curious facts, as also several instruments invented by

FACE. Facies. The lower and anterior part of

the cranium, or skull.

FA CIAL. F. facial nerve, &c. Facialis, Belonging to the face; as

FACIAL NERVE. Nervus facialis. Portio dura of the auditory nerve. These nerves are two in number, and are properly the eighth pair: but are commonly called the seventh, being reckoned with the auditory, which is the portio mollis of the seventh pair. They arise from the fourth ventricle of the brain, pass through the petrous portion of the temporal bone to the

FACIES. The face. See Face.

Facies hippocratica. That particular disposition of the features which immediately precedes the stroke of death is so called, because it has been so admirably described by Hippocratics. described by Hippocrates.

FACIES RUBRA. See Gutta rosacea.
FACTI TIOUS. A term applied to any thing which is made by art, in opposition to that which is native, or found already made in nature.

FA'CULTY. Facultas. The power or ability by which any action is performed.

Fx'CES. (The plural of fxx.) The alvine excre-

soft, of a pale yellowish or greenish colour, a bitterish aromatic taste, and a fragrant delightful smell, approaching to that of lavender and ambergris. The more common sort is in semi-transparent grains, of a whitish, yellowish, brownish, or greenish colour, and of a less grateful smell than the former. Tacamabaca was formerly in high estimation as an ingredient in warm stimulating plasters; and although seldom used internally, it may be given with advantage as a corroborant and astringent balsamic.

borant and astringent balsamic.

FAGARA PLEROTA. Fagara major; Castana Luzonis; Cubebis. This plant is found in the Philippine islands. The berries are aromatic, and, according to Avicenna, heating, drying, good for cold, weak stomachs, and astringent to the bowels.

FAGOPY'RUM. (From φαγος, the beech, and πυρος, wheat; because its seeds were supposed to resemble the mast, i. e. fruit of beech.) See Polygonum

fagopyrum.

FAGOTRI'TICUM. See Polygonum fagopyrum.
FA'GUS. (From φαγω, to eat; its nut being one of the first fruits used by man.)

1. The name of a genus of plants in the Linnæan system. Class, Monæcia; Order, Polyandria.

2. The pharmacopæial name of the beech See

2. The pharmacopeial mainters of the Fagus sylvatica.

Fagus sylvatica.

Fagus castanea. The systematic name of the chesnut-tree. Castanea; Lopima; Mota; Glans Jovis Theophrasti. Jupiter's acorn; Sardinian acorn; the common chesnut. The fruit of this plant, Fagus—foliis lanceolatis, acuminato-serratis, subtus nudis, of Linnæus, are much esteemed as an article of luxury poor dispar. Togsting renders them more easy of dispare. after dinner. Toasting renders them more easy of di-gestion; but, notwithstanding, they must be considered as improper for weak stomachs. They are moderately nourishing, as containing sugar, and much farinaceous substance.

FAGUS SYLVATICA. The systematic name of the beech-tree. Fagus; Oxya; Balanda; Valanida. The fruit and interior bark of this tree, Fagus—foliis ovatis, obsolete serratis, of Linneus, are occasionally used medicinally, the former in obstinate headache, and the latter in the cure of hectic fever. The oil ex-pressed from beech-nuts is supposed to destroy worms; a child may take two drachms of it night and morning; an adult an ounce. The poor people of Silesia use this oil instead of butter.

FAHLUMITE. A sub-species of octohedral corun-

FAIRBURN. The name of a village in the county of Ross, in the north of Britain, where there is a sul-

FA'LCIFORM. (Falciformis; from falz, a scythe,

and forma, resemblance.) Resembling a scythe.

FALCIFORM PROCESS. The falx. A process of the dura mater, that arises from the crista galli, separates the hemispheres of the brain, and terminates in the tentorium.

Is made by art, in opposition to that which is native, or found already made in nature.

FA'CULTY. Facultas. The power or ability by which any action is performed.

FE'CULA. (Diminutive of fax.) The alvine excretions.

FE'CULA. (Diminutive of fax.) A substance obtained by bruising or grinding certain vegetables in water. It is that part which, after a little, falls to the bottom. The facula of plants differs principally from gum or mucus in being insoluble in cold water, it which it falls with wonderful quickness. There are few plants which do not contain facula; but the seeds of gramineous and leguminous vegetables, and all tuberose roots contain it most plentifully.

FEX. (Faz, acis, I. an excretion.) The alvine excretions are called faces.

FAGA'RA. (From fagus, the breech, which it resembles.) The name of a genus of plants in the Limanus system. Class, Tetrandria; Order, Monagynia.

FAGARA OCTANDRA. The systematic name of the plant which affords Tacamahaca, which is a resinous substance that exudes both spontaneously, and when incisions are made into the stem of this tree: Fagara foliolis tomentosis, of Linnaus. and not, as was formerly supposed, from the Populus balsamifera. Two kinds of a tacamahaca are met with in the shops. The best, called, from its being collected in a kind of gourd-shell, tacamahaca in shells, is somewhat unctuous and store of which are evidently spurious.

FALX. See Falciform process. FA'MES. Hunger.

FARES CANINA. See Bulimia.

FAMIGERATI'SSIMUM EMPLASTRUM. (From famigeratus, renowned; from fama, fame, and gero, to bear: so named from its excellence.) A plaster used

tin intermittent fever, made of aromatic, irritating substances, and applied to the wrists.

FAMILY. Familia. A term used by naturalists to express a certain order of natural productions, agreeing in the principal characters, and containing numerous individuals not only distinct from one another, but in whole sets wavel products the sets of the set o but in whole sets, several members being to be col-lected out of the same family, all of which have the family character, and all some subordinate distinction peculiar to that whole number, or, though found in every individual of it, not found in those of any others. It has been too common to confound the words, class,

family, order, &c. in natural history; but the determi-nate meaning of the word family seems to be that larger order of creatures under which classes and or-

larger order of creatures under which classes and orders are subordinate distinctions.

FA'RFARA. (From farfarus, the white poplar: so called because its leaves resemble those of the white poplar.) See Tussilago farfara.

FARI'NA. (From far, corn, of which it is made.) Meal, or flour. A term given to the pulverulent and glutinous part of wheat, and other seeds, which is obtained by grinding and sifting. It is highly nutritious, and consists of gluten, starch, and mucilage. See Triticum.

FARINA'CEA. (From farina, flour.) This, term includes all those substances, employed as aliment, called cerealia, legumina, and nuces oleosæ.

FARINA'CEOUS. (Farinaccus; from farina,

FARINA CEOUS. (Farinaccus; from farina, flour.) A term given to all articles of food which contain farina. See Farina.

FARINA'RIUM. See Farina.

FARINA'RIUM. See Farina.

FA'RREUS. (From far, corn.) Scurfy. An epithet of urine, where it deposites a branny sediment.

FA'SCIA. (From fascis, a bundle; because, by means of a band, materials are collected into a bundle).

dle.) 1. A bandage, fillet, or roller.
2. The tendinous expansions of muscles, which bind parts together, are termed fasciæ. See Aponeu-

FASCIA LATA. A thick and strong tendinous expansion, sent off from the back, and from the tendons of the glutei and adjacent muscles, to surround the muscles of the thigh. It is the thickest on the outside of the thigh and leg, but towards the inside of both becomes gradually thinner. A little below the trochanter major, it is firmly fixed to the linea aspera; and, further down, to that part of the head of the tibia that is next the fibula, where it sends off the tendinous expansion along the outside of the leg. It serves to strengthen the action of the muscles, by keeping them firm in their proper places when in action, particularly the tendons that pass over the joints where this memthe tendons that pass over the joints where this membrane is thickest.

FASCIA'LIS. (From fascia, a fillet.) See Tensor

vacing femoris.
Fascia Tio. (From fascia, a fillet.) The binding up any diseased or wounded part with bandages.

FASCICULARIS. (From fascis, a bundle.) Applied to roots which are sessile at their base, and conist of bundles of finger-like processes; as the root of

the Ophris nidus avis.
FASCICULATUS. Fasciculate. Bundled or clustered. Applied to nerves, stems of plants, leaves, &c. See Leaf and Caulis.

FASCICULUS. (From fascis, a bundle. 1. In

See Leaf and Caulis.

FASCI'CULUS. (From fascis, a bundle. 1. In pharmacy, a handful.

2. In botany, a fascicule is applied to flowers on little stalks, variously inserted and subdivided, collected into a close bundle, level at the top; as in Sweet-william. It differs from,

1. A corymb, in the little stalks coming only from about the apex of the peduncle, and not from its whole

length.
2. An umbel, from the stalks not coming from a

common point.

3. A cyme, in not having its principal division umbellate.

FAT. Adeps. A concrete oily matter contained in the cellular membrane of animals, of a white, or yellowish colour, with little or no smell, or taste.

differs in different animals in solidity, colour, taste, &c. and likewise in the same animal at different ages. In infancy it is white, insipid, and not very solid; in the adult it is firm and yellowish, and in animals of an advanced age, its colour is deeper, its consistence various, and its taste in general stronger.

The fat appears to be useful in the animal economy principally by its physical properties; it forms a sort of elastic cushion in the orbit upon which the eye moves with facility; in the soles of the feet, and in the hips, it forms a sort of layer, which renders the pressure exerted by the body upon the skin and other soft parts less severe; its presence beneath the skin concurs in rounding the outlines, in diminishing the bony and muscular projections, and in beautifying the form; and as all fat bodies are bad conductors of caloric, it contributes to the preservation of that of the body. Full persons in general suffer little in winter by the cold.

fat bodies are bad conductors of caloric, it contributes to the preservation of that of the body. Full persons in general suffer little in winter by the cold.

Age, and the various modes of life, have much influence upon the developement of this fluid: very young children are generally fat. Fat is rarely abundant in the young man; but the quantity of it increases much towards the age of thirty years, particularly if the nourishment is succulent, and the life sedentary; the abdomen projects, the hips increase in size, as well as the breasts in women. The fat becomes more yellow in proportion as the age is more advanced. Fat meat is nourishing to those that have strong digestive powers. It is used externally, as a softening remedy, and enters into the composition of ointments and plas-

ters.
"Concerning the nature of this important product of animalization, nothing definite was known, till Chevreuil devoted himself with meritorious zeal and perseverance to its investigation. He has already published in the Annales de Chimie, seven successive me-moirs on the subject, each of them surpassing its pre-decessor in interest. We shall in this article give a brief abstract of the whole.

By dissolving fat in a large quantity of alkohol, and observing the manner in which its different portions were acted upon by this substance, and again separated from it, it is concluded that the fat is composed of an oily substance, which remains fluid at the ordinary temperature of the atmosphere; and of another fatty substance which is much less fusible. Hence it follows that fat is not to be revarded as a simple principle. lows, that fat is not to be regarded as a simple principle, but as a combination of the above two principles, which may be separated without alteration. One of these substances melts at about 45°, the other at 100° the same quantity of alkohol which dissolves 3.2 parts of the characteristic of the fatter of t of the oily substance, dissolves 1.8 only of the fatty substance; the first is separated from the alkohol in the form of an oil; the second in that of small silky

Each of the constituents of natural fat was then sabach of the constituents of natural lat was then sa-ponified by the addition of potassa; and an accurate description given of the compounds which were form-ed, and of the proportions of their constituents. The oily substance became saponified more readily than the fatty substance; the residual fluids in both cases con-tained the sweet oily principle; but the quantity that proceeded from the soap formed of the oily substance, was four or five times as much as that from the fatty substance. The latter soap was found to contain a much greater proportion of the pearly matter than the former, in the proportion of 7.5 to 2.9; the proportion of the fluid fat was the reverse, a greater quantity of this being found in the soap formed from the oily substance of the fat.

When the principles which constitute fat unite with potassa, it is probable that they experience a change in the proportion of their elements. This change devethe proportion of their elements. This change in lopes at least three bodies, margarine, fluid fat, and the sweet principle; and it is remarkable, that it takes place without the absorption of any foreign substance, or the disengagement of any of the elements which are separated from each other. As this change is effected by the intermedium of the alkali, we may conclude that the newly formed principles must have a strong affinity for salifiable bases, and will in many respects resemble the acids; and, in fact, they exhibit the leading characters of acids, in reddening litmus, in decomposing the alkaline carbonates to unite to their bases, and in neutralizing the specific properties of the alkalies.

Having already pointed out the avalors.

Having already pointed out the analogy between the

FAT FAT

properties of acids and the principles into which fat is converted by means of the alkalies, the next object was to examine the action which other bases have upon fat, and to observe the effect of water, and of the cohesive force of the bases upon the process of saponification. The substances which the author subjected to experiment, were soda, the four alkaline earths, alumina, and the oxides of zinc, copper, and lead. After giving a detail of the processes which he employed with these substances respectively, he draws the following general conclusions:—Soda, barytes, strontian, lime, the oxide of zinc, and the protoxide of lead, convert fat into margarine, fluid fat, the sweet principle, the yellow colouring principle, and the odorous principle, precisely in the same manner as potassa. Whatever be the base that has been employed, the products of saponification always exist in the same relative proportion. As the above mentioned bases form with margarine and the fluid fat compounds which are insoluble in water, it follows, that the action of this liquid, as a solvent of soap, is not essential to the pro-cess of saponification. It is remarkable that the ox-ides of zinc and of lead, which are insoluble in water, and which produce compounds equally insoluble, should give the same results with potassa and soda,— a circumstance which proves that those oxides have a strong alkaline power. Although the analogy of mag-nesia to the alkalies is, in other respects, so striking, yet we find that it cannot convert fat into soap under the same circumstances with the oxides of zinc and lead

It was found that 100 parts of hog's-lard were reduced to the completely saponified state by 16.36 parts of potassa.

The properties of spermaceti were next examined: it melts at about 112°; it is not much altered by distillation; it dissolves readily in hot alkohol, but separates as the fluid cools; the solution has no effect in changing the colour of the tincture of litmus, a circumstance, as it is observed, in which it differs from margarine, a substance which, in many respects, it resembles.-Spermaceti is capable of being saponified by potassa, with nearly the same phenomena as when we submit hogs-lard to the action of potassa, although the opera-tion is effected with more difficulty

The author's general conclusion respecting the fatty matter of dead bodies is, that even after the lactic acid, the lactates, and other ingredients which are less essential, are removed from it, it is not a simple, ammoniacal soap, but a combination of various fatty sub-stances with ammonia, potassa, and lime. The fatty substances which were separated from alkohol, had different melting points, and different sensible properties. It follows, from Chevreuil's experiments, that the sub-stance which is the least fusible, has more affinity for bases than those which are more so. It is observed, that adipocere possesses the characters of a saponified fat; it is soluble in boiling alkohol in all proportions, reddens litmus, and unites readily to potassa, not only without losing its weight, but without having its fu-

sibility or other properties changed.

Chevreuil has shown, that hog's-lard, in its natural state, has not the property of combining with alkalies; but that it acquires it by experiencing some change in the proportion of its elements. This change being in-duced by the action of the alkali, it follows that the bodies of the new formation must have a decided af-finity for the species of body which has determined it. If we apply this foundation of the theory of saponifi-cation to the change into fat which bodies buried in the earth experience, we shall find that it explains the process in a very satisfactory manner. In reality, the fatty matter is the combination of the two adipose substances with ammonia, lime, and potassa: one of these substances has the same sensible properties with mar-garine procured from the soap of hog's-lard; the other, the orange-coloured oil, excepting its colour, appears to have a strong analogy with the fluid fat. From these circumstances, it is probable that the formation of the fatty matter may be the result of a proper saponification produced by ammonia, proceeding from the decomposition of the muscle, and by the potassa and lime, which proceed from the decomposition of certain

The author remarks, that he has hitherto made use of periphrases when speaking of the different bodies that he has been describing, as supposing that their 352

nature was not sufficiently determined. He now, hownature was not sufficiently determined. He now, however, conceives, that he may apply specific names to them, which will be more commodious, and, at the same time, by being made appropriate, will point out the relation which these bodies bear to each other. The following is the nomenclature which he afterward adopted:—The crystalline matter of human biliary calculi is named cholesterine, from the Greek word $\chi_0\lambda\eta$, bile, and $\zeta_1\rho_0$, solid; spermaceti is named cetime, from $\kappa\eta\tau_0$, a whale; the fatty substance and the oily substance, are named respectively, stemping and chaine, from the words $\tau_1\rho_0$, and $\tau_2\rho_0$, and $\tau_3\rho_0$, and stearine and claime, from the words grap, and chator, oil; margarine, and the fluid fat obtained after sapo nification, are named margaric acid and oleic acid, while the term cetic acid is applied to what was named saponified spermaciti. The margarates, oleates, and cetates, will be the generic names of the soaps or combinations which these acids are canable of the minations which these acids are canable of the minations. binations which these acids are capable of forming by their union with salifiable bases.

Two portions of human fat were examined, one taken from the kidney, the other from the thigh: after some time they both of them manifested a tendency to some time they both of them manifested a tendency to separate into two distinct substances, one of a solid, and the other of a fluid consistence: the two portions differed in their fluidity and their melting point. These variations depend upon the different proportions of stearine and claime; for the concrete part of fat is a combination of the two with an excess of stearine, and the fluid part is a combination with an excess of elaine. The fat from the other animals was then examined, principally with respect to their melting point and their solubility in alkohol; the melting point was not always the same in the fat of the same species of animal.

Chevreuil next examines the change which is produced in the different kinds of fat respectively by the action of potassa. All the kinds of fat are capable of action of potassa. All the Ends of lat are capable of being perfectly saponified, when excluded from the contact of the air, in all of them there was the production of the saponified fat and the sweet principle; no carbonic acid was produced, and the soaps formed contained no acetic acid, or only slight traces of it. The saponified fats had more tendency to crystallize in needles than the fats in their natural state; they were soluble in all proportions in boiling alkohol of the specific gravity of 821. The solution, like that of the saponified fat of the hog, contained both the margaric saponned at of the nog, contained both the margaric and the oleic acids. They were less fusible than the fats from which they were formed: thus, when human fat, after being saponified, was melted, the thermometer became stationary at 95°, when the fluid began to congeal, in that of the sheep, the thermometer fell to 118.5°, and rose to 122°; in that of the ox it remained stationary at 118.50; and in that of the jaguar

The method of analysis employed was to expose the different kinds of fat to boiling alkohol, and to suffer the mixture to cool: a portion of the fat that had been dissolved was then separated in two states of combi-nation; one with an excess of stearine was deposited, the other with an excess of claine remained in solution. The first was separated by filtration, and by distilling the filtered fluid, and adding a little water towards the end of the operation, we obtain the second in the re-tort, under the form of an alkoholic aqueous fluid. The distilled alkohol which had been employed in the analysis of human fat, had no sensible ofour; the same was the case with that which had served for the analysis of the fat of the ox, of the hog, and of the goose. The alkohol which had been employed in the analysis of the fat of the sheep, had a slight odour of candlegrease.

All the soaps of stearine were analyzed by the same process as the soap of the fat from which they had been extracted: there was procured from them the pearly super-margarate of potassa and the oleate; but the first was much more abundant than the second. The margaric acid of the stearines had precisely the same capacity for saturation as that which was extracted from the soaps formed of fat. The margaric acid of the stearine of the sheep was fusible at 1449, and that of the stearine of the ox at 143.5°; while the margaric acids of the hog and the goose had nearly the same fusibility with the margaric acid of the fat of these animals.

Chevreuil technically calls spermaceti, cetine. In the fifth memoir, in which we have an account of many

of the properties of this substance, it was stated, that it is not easily saponified by potassa, but that it is con-verted by this reagent into a substance which is soluble in water, but has not the saccharine flavour of the sweet principle of oils; into an acid analogous to the margaric, to which the name of cetic was applied; and into another acid, which was conceived to be analogous to the oleic. Since he wrote the fifth memoir, the author has made the following observations on this subject:—1. That the portion of the soap of cetine which is insoluble in water, or the cetate of potassa, is in part gelatinous, and in part pearly: 2. The two kinds of crystals were produced from the cetate of potassa which had been dissolved in alkohol: 3. That the cetate of potassa exposed, under a bell glass, to the the cetate of potassa exposed, under a bell glass, to the heat of a stove, produced a sublimate of a fatty matter which was not acid. From this circumstance Chevreuil was led to suspect, that the supposed cetic acid might be a combination, or a mixture of margaric acid, and of a fatty body which was not acid. He accordingly treated a small quantity of it with barytic water, and boiled the soap which was formed in alkohol; the greatest part of it was not dissolved, and the alkoholic solution, when cooled, filtered, and distilled, recovered. solution, when cooled, filtered, and distilled, produced a residuum of fatty matter which was not acid. The suspicion being thus confirmed, Chevreuil determined to subject cetine to a new train of experiments. Being treated with boiling alkohol, a cetine was pro-cured which was fusible at 120°, and a yellow fatty matter which began to become solid at 89.5°, and which at 73.50 contained a fluid oil, which was separated by filtration.—Ure's Chem. Dic. FATULTAS. (From fatuus, silly.) Fatuity or

FAU'CES. (Faux, pl. fauces.) A cavity behind the tongue, palatine arch, uvula, and tonsils; from

which the pharynx and larynx proceed.

FAU'FEL. Terra japonica, or catechu.

[FAUSSE AVOINE. False oats. Indian rice. See Zizania aquatica. A.]

FAUX. (Faux, cis. f.) 1. The gorge, or mouth, or opening of the gullet.

2. Applied by botanists to the opening of the tube of more preclaims covering. See Coverla.

of monopetalous corals. See Corolla.

FAVA'GO AUSTRALIS. (From favus, a honey-comb;

from its resemblance to a honey-comb.) A species of

bastard sponge.

FAVOSUS. (From favus, a honey-comb.) Honey-comb-like, 1. Applied to some cruptive diseases; as Licken favosus, the secretion in which is cellular and honey-comb-like.

2. To parts of plants, as the receptacle of the ono-pordium which has cells like a honey-comb.

FAVUS. 1. A honey-comb. 2. A species of achor, or foul ulcer.

FEBRES. (The plural of febris.) An order in the class Pyrexia, of Cullen, characterized by the presence of pyrexia, without primary local

FEBRI'CULA. (Dim. of febris, a fever.) A term employed to express a slight degree of symptomatic

FERRIFUGA. (From febrem fugare, to drive away a fever.) The plant feverfew; less centaury.

FE BRIFUGE. (Febrifugus; from febris, a fever, and fugo, to drive away.) That which possesses the property of abating the violence of any fever.

FEBRIFUGUM CRENII. Regulus of antimony. FEBRIFUGUM OLEUM. Febrifuge oil. The flowers of antimony, made with sal-ammoniac and antimony sublimed together, and exposed to the air, when they

FERRIPUGES PULVIS. Pebrifuge powder. The Germans give this name to the pulvis stypticus Helvetii. In England, a mixture of oculi cancrorum and emetic tartar, in the proportion of half a drachm and two grains, has obtained the same name; in fevers it is given in doses of gr. iii. to iv.

FEBRIFUGUS SAL. Regenerated marine salt.
FEBRIS. (Febris, is. f.; from fervee, to burn.) A
fever. A disease characterized by an increase of heat,
an accelerated pulse, a foul tongue, and an impaired
state of several functions of the body.
FEBRIFUGUE. See Chloradia.

FEBRIS ALBA. See Chlorosis. FEBRIS AMPHIMERINA. A quotidian fever. FEBRIS ANGINOSA. See Scarlatina anginosa. FEBRIS APHTHOSA. See Apatha.

fevers, and several varieties.

2. Tertiana. A tertian ague. The paroxysms commonly come on at mid-day, at an interval of about forty-eight hours.

Quartana. A quartan ague. The paroxysms come on in the afternoon, with an interval of about seventy-two hours. The tertian ague is most apt to

prevail in the spring, and the quartan in autumn.

Of the quotidian, tertian, and quartan intermittents, there are several varieties and forms; as the double there are several varieties and forms; as the double tertian, having a paroxysm every day, with the alternate paroxysms, similar to one another. The double tertian, with two paroxysms every other day. The triple tertian, with two paroxysms on one day, and another on the next. The double quartan, with two paroxysms on the first day, none on the second and third, and two again on the fourth day. The double quartan, with a paroxysm on the first day, another on the second, but none on the third. The triple quartan, with three paroxysms every fourth day. The triple quartan, with a paroxysm every day, every fourth paroxysm being similar. paroxysm being similar.

When these fevers arise in the spring of the year,

they are called vernal; and when in the autumn, they

FEBRIS ARDENS. Fever attended by a very hotorburning state of the skin. A burning inflammatory fever. Februs assones. A tertian fever, with extreme restlessness

FEBRIS BULLOSA. See Pemphigus. FEBRIS CACATORIA. An intermittent fever, with diarrhœa.

FEBRIS CARCERUM. The prison fever. FEBRIS CASTRENSIS. A camp fever camp fever, generally

typhus.
FEBRIS CATARRHALIS. A fever, either typhoid, nervous, or synochal, attended with symptoms of ca-

FEBRIS CHOLERICA. A fever, attended throughout

with bilious diarrhea.

FEBRIS CONTINUA. A continued fever. A division of the order Febres, in the class Pyrcxia, of Cullen. Continued fevers have no Intermission, but exacerbations come on usually twice in one day. The genera of continued fever are

Synocha, or infiammatory fever, known by increased heat; pulse frequent, strong, and hard; urine high-coloured; senses not much impaired. See Sy-

2. Typhus, or putrid-tending fever, which is contagious, and is characterized by moderate heat; quick, weak, and is characterized by monerate neat; quick, weak, and small pulse; senses much impaired, and great prostration of strength. This genus has two species; Typhus petechialis, attended with petechiæ; and Typhus icterodes, or yellow fever; and of the former there are two varieties: Typhus mitior, or nervous fever; and Typhus gravior, or putrid fever. See Febris nervosa, and Typhus.

3. Synochus, or mixed fever. See Synochus.

France values of fever with continual and pro-

FEBRIS ELODES. A fever with continual and pro-

fuse sweating. FEBRIS EPIALA. A fever with a continual sense of coldness. See Epialus.

FEBRIS ERVSIPELATOSA. See Erysipelas. FEBRIS EXANTHEMATICA. A fever with an eruption. See Exanthema.

Februs Flava. See Typhus.

Februs Flava. See Typhus.

Februs Hectica. A genus of disease in the class Pyrexia, and order Februs, of Cullen. It is known by exacerbations at noon, but greater in the evening, with slight remissions in the morning, after nocturnal sweats; the urine depositing a furfuraceo-lateritious sediment; appetite good; thirst moderate. Hectic fever is symptomatic of chlorosis, scrofula, phthisis, diseased viscera, &c.

France Westers and Provided Head of the control of the cont

FEBRIS HUNGARICA. A species of tertian intermittent fever.

FEBRIS HYDRODES. A fever with profuse sweats.

Februs hydrodes. A lever with profuse sweats. Februs inflammatoria. See Synocha. Februs intermittens. An intermittent fever, or ague. A division of the order Febres, of Cullen, in the class Pyrexia. Intermittent fevers are known by cold, hot, and sweating stages, in succession, attending each paroxysm, and followed by an intermission or remission. There are three genera of intermitting foregree and several varieties.

FEB FEB

are known by the name of autumnal. Intermittents often prove obstinate, and are of long duration in warm climates; and they not unfrequently resist every mode of cure, so as to become very distressing to the patient; and by the extreme debility which they there-

by induce, often give rise to other chronic complaints.
It seems to be pretty generally acknowledged, that
marsh miasmata, or the effluvia arising from stagnant
water, or marshy ground, when acted upon by heat,
are the most frequent exciting causes of this fever. In are the most frequent exciting causes of this fever. In marshes, the putrefaction of both vegetable and animal matter is always going forward, it is to be presumed; and hence it has been generally conjectured, that vegetable and animal putrefaction imparted a peculiar quality to the effluvia arising from thence. We are not yet acquainted with all the circumstances, which are requisite to render marsh miasma productive of the intermittents; but it may be presumed that a moist atmosphere has a considerable influence in promoting its action. A watery poor diet, great in promoting its action. A watery poor diet, great fatigue, long watching, grief, much anxiety, exposure to cold, lying in damp rooms or beds, wearing damp linen, the suppression of some long-accustomed evacuation, or the recession of eruptions, have been ranked among the exciting causes of intermittents; but it is more reasonable to suppose that these circumstances act only by inducing that state of the body, which pre-disposes to these complaints. By some it has been imagined that an intermittent fever may be communi-cated by contagion; but this supposition is by no means consistent with general observation.

One peculiarity of this fever is, its great susceptibility of a renewal from very slight causes, as from the prevalence of an easterly wind, even without the repetition of the original exciting cause. It would appear that a predisposition is left in the habit, which favours the recurrence of the complaint. In this circumstance, intermittents differ from most other fevers, as it is well known, that after a continued fever has once occurred, and been removed, the person so affected is by no means so liable to a fresh attack of the disorder, as one in whom it had never taken place

We have not yet attained a certain knowledge of the proximate cause of an intermittent fever, but a deranged state of the stomach and primæ viæ is that which is most generally ascribed.

Each paroxysm of an intermittent fever is divided into three different stages, which are called the cold,

the hot, and the sweating stages or fits.

The cold stage commences with languor, a sense of debility and sluggishness in motion, frequent yawning and stretching, and an aversion to food. The face and extremities become pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted, as if cold had been applied to it. At length the patient feels very cold, and universal rigors come on, with pains in the head, back, loins, and joints, nausea, and vomiting of billious matter; the respiration is small, frequent, and anxious; the urine is almost colourless; sensibility is greatly impaired; the thoughts are somewhat confused; and the pulse is small, frequent, and often irregular. In a few instances, drowsingss and sturpour have prevailed the pulse is small, frequent, and often irregular. In a few instances, drowsiness and stupour have prevailed in so high a degree as to resemble coma or apoplexy; but this is by no means usual.

These symptoms abating after a short time, the se-cond stage commences with an increase of heat over the whole body, redness of the face, dryness of the skin, thirst, pain in the head, throbbing in the temples, anxiety and restlessness; the respiration is fuller and more free, but still frequent; the tongue is furred, and the pulse has become regular, hard, and full. If the attack has been very severe, then perhaps delirium

When these symptoms have continued for some time, a moisture breaks out on the forehead, and by degrees becomes a sweat, and this, at length, extends over the whole body. As this sweat continues to flow, the heat of the body abates, the thirst ceases, and most of the functions are restored to their ordinary This constitutes the third stage.

It must, however, be observed, that in different cases these phenomena may prevail in different degrees, and their mode of succession vary; that the series of them may be more or less complete; and that the several stages, in the time they occupy, may be in different proportions to one another.

Such a depression of strength has been known to take place on the attack of an intermittent, as to cut off the patient at once; but an occurrence of this kind

is very uncommon.

Patients are seldom destroyed in intermittents from general inflammation, or from a fulness of the vessels either of the brain or of the thoracic viscera, as hap-pens sometimes in a continued fever; but when they pens sometimes in a continued lever; but when they continue for any length of time, they are apt to induce other complaints, such as a loss of appetite, flatulency, schirrhus of the liver, dropsical swellings, and general debility, which in the end now and then prove fatal. In warm climates, particularly, intermittents are very apt to terminate in this manner, if not speedily removed; and in some cases, they degenerate into continued fevers. When the paroxysms are of short duration, and leave the intervals onlite free, we may exration, and leave the intervals quite free, we may expect a speedy recovery; but when they are long, vio-lent, and attended with much anxiety and delirium, the event may be doubtful. Relapses are very com-mon to this fever at the distance of five or six months, or even a year; autumnal intermittents are more diffi-cult to remove than vernal ones, and quartans more

so than the other types.

Dissections of those who have died of an intermittent, show a morbid state of many of the viscera of the thorax and abdomen; but the liver, and organs concerned in the formation of bile, as likewise the mesentery, are those which are usually most affected.

The treatment of an intermittent fever resolves itself

into those means, which may be employed during a paroxysm, to arrest its progress, or to mitigate its violence; and those, which may prevent any return, and effect a permanent cure: this forms of course the more important part of the plan; but it is sometimes necessary to palliate urgent symptoms; and it is always desirable to suspend a paroxysm, if possible, not only to prevent mischief, but also that there may be more time for the use of the most effectual remedies. When therefore a fit is commencing, or shortly expected, we may try to obviate it by some of those means, which excite moveobviate it by some of those means, which excite move-ments of an opposite description in the system; an emetic will generally answer the purpose, determining the blood powerfully to the surface of the body; or a full dose of opium, assisted by the pediluvium, &c.; ather also, and various stimulant remedies, will often succeed, but these may perhaps aggravate, should they not prevent the fit; the cold bath, violent exercise, strong impressions on the mind. &c. have likewise been occaimpressions on the mind, &c. have likewise been occasionally employed with effect. Should the paroxysm have already come on, and the cold stage be very severe, the warm bath, and cordial diaphotetics in repeated moderate doses, may assist in bringing warmth to the surface: when, on the contrary, great heat prevails, the antiphlogistic plan is to be pursued; and it may be sometimes advisable, when an organ of importance is much pressed upon, to take some blood locally, or even from the general system, if the patient is plethoric and robust: and where profuse perspirations occur, acidulated drink may be exhibited, with a little wine to support the strength, keeping the surface cool at the same time. In the intermissions in conjunction at the same time. In the intermissions, in conjunction with a generous diet, moderate exercise, and other means calculated to improve the vigour of the system; tonics are the remedies especially relied upon. At the head of these we must certainly place the cinchona, head of these we must certainly place the chichona, which, taken largely in substance, will seldom fail to cure the disease, where it is not complicated with visceral affection: in a quotidian an ounce at least should be given between the fits, in a tertian half as much more, and in a quartan two ounces. It will be generally better to clear out the primae vize before this remarks to become with any arrange additional contents. medy is begun with; and various additions may often be required, to make it agree better with the stomach and bowels, particularly aromatics and other stimulants, aperients or small doses of opium, according to circumstances. We must not be content with the omission of a single paroxysm, but continue it till the health appears fully established. In failure of the cinchona, other vegetable tonics may be tried, as the salix, gen-tian, calumba, and other bitters; or the astringents, as tormentil, galls, &c.; or these variously combined with each other, or with aromatics. The mineral acids are often powerfully tonic, and the sulphuric has been of late stated to have proved very successful in the removal of this disease. Some metallic preparations are also highly efficacious, particularly the liquor arsenicais,

which, however, is too hazardous a remedy to be employed indiscriminately; it must be given in small doses two or three times a day, and its effects assiduously watched. The sulphate of zinc, and chalybeates, may be used more freely alone, or preferably joined with bitters. Where visceral disease attends, we can hardly succeed in curing the ague, till this be removed; a state of congestion, or inflammatory tendency, may require local bleeding, blistering, purging, &c.; and when there is a more fixed obstruction, particularly in the liver, the cautious use of mercury will be most likely to avail.

Febris Lactea. Milk fever, which is mostly of the synochus-type attended with much irregularity of mind, and nervousness.

and nervousness.

FEBRIS LENTA. See Febris nervosa.
FEBRIS LENTICULARIS. A fever, either typhus or synochus, attended by an eruption like small lentils.
FEBRIS MALIONA. See Typhus.
FEBRIS MILIARIS. See Miliaria.

Februs Miliaris. See Miliaria.

Februs Morbillosa. See Miliaria.

Februs Morbillosa. See Rubeola.

Februs Mervosa. Febris lenta nervosa. The nervous fever. A variety of the typhus mitior of Cullen, but by many considered as a distinct disease. It mostly begins with loss of appetite, increased heat and vertigo; to which succeed nausea, vomiting, great languor, and pain in the head, which is variously described, by some like cold water pouring over the top, by others a sense of weight. The pulse, before little increased, now becomes quick, febrile, and tremulous; the tongue is covered with a white crust, and there is great anxiety about the præcordia. Towards the seventh or eighth day, the vertigo is increased, and tinnitus aurium, cophosis, delirium, and a dry and tremulous tongue, take place. The disease mostly terminates about the fourteenth or twentieth day. See Typhus.

Februs nosocomorum. The fever of hospitals, mostly the typhus gravior.

Februs palustris. The marsh fever

Februs petechialis. See Pestis.

Februs petechialis. See Typhus.

Febris Petechialis. See Typhus.
Febris Putrida. See Typhus.
Febris Remittens. A remittent fever: a fever with strong exacerbations, which approach in some cases to the nature of a paroxysm of an intermittent, and which follow each other so closely as to leave very little time between. In some, there is a great secretion of bile, when it is called a bilious remittent; in others, there is great putrescency, when it is termed a putrid remittent, and so on.

FELSPAR. An important mineral genus, distributed by Jameson into four species: prismatic felspar; pyra-midal felspar; prismato-pyramidal felspar; rhomboidal

The prismatic felspar has nine sub-species,
 Adularia.
 Glassy felspar.

- c. Ice spar.
 d. Common felspar.
 e. Labradore felspar.
 f. Compact felspar.
- Clink-stone.
- Earthy common spar. Porcelain earth.
- Pyramidal felspar. This embraces the scapolite

3. Prismato-pyramidal felspar. See Meionite.

4. Rhomboldal felspar. See Nepheline. Chiastolite and sodalite have also been annexed to this species.

[Fesite. Blue felspar of Stiria. A.]

FE'MEN. (Quasi ferimen; from fero, to bear: so called because it is the chief support of the body.)

FEMINEUS. A flower is termed a female, which is furnished with the pistillum, and not with the stamina; the pistil being considered as the female generative

(Femoralis; from femur, the thigh.)

organ.
FEMORAL. (Femoralis
Of or belonging to the thigh.
FEMORA'LIS ARTERIA. A A continuation of the external iliac along the thigh, from Poupart's ligament to

the ham.

FE'MORIS OS. The thigh-bone. A long cylindrical bone, situated between the pelvis and tibia. Its upper extremity affords three considerable processes; these are, the head, the trochanter major, and trochanter minor. The head, which forms about two-thirds of a sphere, is turned inwards, and is received into the acetabulum of the os innominatum, with which it is articulated by enarthrosis. It is covered by a cartilage, which is thick in its middle part, and thin at its edges, but which is wanting in its lower internal part, where a round spongy fossa is observable, to which the strong ligament, usually, though improperly, called the round one, is attached. This ligament is about an inch in length, flattish, and of a triangular shape, having its narrow extremity attached to the fossa just described, narrow extremity attached to the fossa just described, while its broader end is fixed obliquely to the rough surface near the inner and anterior edge of the acetabulum of the os innominatum, so that it appears shorter internally and anteriorly, than it does externally

tabulum of the os innominatum, so that it appears shorter internally and anteriorly, than it does externally and posteriorly.

The head of the os femoris is supported obliquely, with respect to the rest of the bone, by a smaller part, called the carvix, or neck, which, in the generality of subjects, is about an inch in length. At its basis we observe two oblique ridges, which extend from the trochanter major to the trochanter minor. Of these ridges, the posterior one is the most prominent. Around this neck is attached the capsular ligament of the joint, which likewise adheres to the edge of the cotyloid cavity, and is strengthened anteriorly by many strong ligamentous fibres, which begin from the lower and anterior part of the ilium, and spreading broader as they descend, adhere to the capsular ligament, and are attached to the anterior oblique ridge at the bottom of the neck of the femur. Posteriorly and externally, from the basis of the neck of the bone, a large unequal protuberance stands out, which is the trochanter major. The upper edge of this process is sharp and pointed posteriorly, but is more obtuse anteriorly. A part of it is rough and unequal, for the insertion of the muscles; the rest is smooth, and covered with a thin cartilaginous crust, between which and the tendon of the glutagus maximus that slides over it, a large bursa mucosa is interposed. Anteriorly, at the root of this process, and immediately below the bottom of the neck, is a small process called trachanter minor. Its basis is nearly triangular, having its two upper angles turned towards the head of the femur and the great trochanters, from the muscles that are inserted into them being the principal instruments of the rotatory motion of the thigh. Im mediately below these two processes the body of the bone may be said to begin. It is smooth and convex before, but is made hollow behind by the action of the muscles. In the middle of this posterior concave surface is observed a rough ridge, called linea aspera, which seems to originate fro which seems to originate from the trochanters, and extending downwards, divides at length into two branches, which terminate in the tuberosities near the condyles. At the upper part of it, blood-vessels pass to the internal substance of the bone by a hole that runs obliquely

upwards.

The lower extremity of the os femoris is larger than the upper one, and somewhat flattened, so as to form two surfaces, of which the anterior one is broad and convex, and the posterior one narrower and slightly concave. This end of the bone terminates in two large protuberances, called condyles, which are united before so as to form a pulley, but are separated behind by a considerable cavity, in which the crural vessels and nerves are placed secure from the compression to which they would otherwise be exposed in the action of bending the leg. Of these two condyles, the external one is the largest; and when the bone is separated from the rest of the skeleton, and placed perpendicularly, the internal condyle projects less forwards,

Z 2

FER FER

and descends nearly three-tenths of an inch lower than the external one; but in its natural situation, the bone is placed obliquely, so that both condyles are then nearly on a level with each other. At the side of each condyle, externally, there is a tuberosity, the situation of which is similar to that of the condyles of the os humeri. The two branches of the linea aspera terminate in these tuberosities, which are rough, and serve for attachment of ligaments and muscles.

FE'MUR. (Femur, moris. n.) The thigh.
FENE'STRA. (From \$\phi n v \text{if}, quasi phanestra.) A window, entry, or hole.

FENESTRA OVALIS. An oblong or elliptical foramen, between the cavity of the tympanum and the vestibulum of the ear. It is shut by the stapes.

FENESTRA ROTUNDA. A round foramen, leading from the tympanum to the cochlea of the ear. It is covered by a membrane in the fresh subject. and descends nearly three-tenths of an inch lower

vered by a membrane in the fresh subject.

FE'NNEL. See Anethum faniculum.

Fennel, hog's. See Peucedanum.

FE'RINE. (Ferinus, savage or brutal.) A term occasionally applied to any malignant or noxious dis-

FERMENTATION. (Fermentatio, onis. f.; from fermento, to ferment.) When aqueous combinations of vegetable or animal substances are exposed to ordinary atmospherical temperatures, they speedily undergo spontaneous changes, to which the generic term of fermentation has been given. There are several circumstances required in order that fermentation may proceed: such are, 1. A certain degree of fluidity: thus, dry substances do not ferment at all. 2. A certain degree of heat. 3. The contact of air. Chemists, after Boerhaave, have distinguished three kinds of fermentation. fermentation.

1. The vinous or spirituous, which affords ardent

The acctous, which affords vinegar, or acetic acid.
 The putrid fermentation, or putrefaction, which

produces volatile alkali.

produces volatile alkali.

I. The conditions necessary for vinous fermentation are: 1. A saccharine mucilage. 2. A degree of fluidity slightly viscid. 3. A degree of heat between 55 and 65 of Fahrenheit. 4. A large mass, in which a rapid commotion may be excited. When these four conditions are united, the vinous fermentation takes place, and is known by the following characteristic phenomena: 1. An intestine motion takes place. 2. The bulk of the mixture then becomes augmented. 3. The transparency of the fluid is diminished by opaque filaments. 4. Heat is generated. 5. The solid parts mixed with the liquor rise and float in consequence of the disengagement of elastic fluid. 6. A large quantity of carbonic acid gas is disengaged in bubbles. All these phenomena gradually cease in proportion as the liquor loses its sweet and mild taste, and it becomes liquor loses its sweet and mild taste, and it becomes brisk, penetrating, and capable of producing intoxication. In this manner, wine, beer, cider, &c. are made. All bodies which have undergone the spirituous fermentation are capable of passing on to the acid fermentation; but although it is probable that the acid fermentation never takes place before the body has gone through the spirituous fermentation, yet the duration of the first is frequently so short and imperceptible, that it cannot be ascertained. Besides the bodies which are proper for spirituous fermentation, this class includes all sorts of fæcula boiled in water.

II. The conditions required for the acid fermentaliquor loses its sweet and mild taste, and it becomes

includes all sorts of facula boiled in water.

II. The conditions required for the acid fermentation are, 1. A heat from 70 to 85 degrees of Fahrenheit.

2. A certain degree of liquidity.

3. The presence of atmospheric air.

4. A moderate quantity of fermentable matter. The phenomena which accompany this fermentation, are an intestine motion, and a considerable absorption of air. The transparent liquor becomes turbid, but regains its limpidity when fermentation is over. The fermented liquor now consists, in a great measure, of a peculiar acid, called the acctic acid, or vinegar. Not a vestige of spirit remains, it being entirely decomposed, but the greater the quantity of spirit in the liquor, previous to the fermentation, the greater will be the quantity of true vinegar obtained. As the ultimate constituents of vegetable matalon. tained. As the ultimate constituents of vegetable mat-ter are oxygen, hydrogen, and carbon; and of animal matter, the same three principles with azote, we can readily understand that all the products of fermentation must be merely new compounds of these three or

four ultimate constituents. Accordingly, 100 parts of real vinegar, or acetic acid, are resolvable, by Gay Lussac and Thenard's analysis, into 50,224 carbon + 46,911 hydrogen and oxygen, as they exist in water, + 2,863 oxygen in excess. In like manner, wines are all resolvable into the same ultimate components, in proportions somewhat different. The aëriform results of putrefactive fermentation are in like manner found

of putrefactive fermentation are in like manner found to be, hydrogen, carbon, oxygen, and azote, variously combined, and associated with minute quantities of sulphur and phosphorus. The residuary matter consists of the same principles, mixed with the saline and earthy parts of animal bodies.

Lavoisier was the first philosopher who instituted, on right principles, a series of experiments to investigate the phenomena of fermentation, and they were so judiciously contrived, and so accurately conducted, as to give results comparable to those derived from the more rigid methods of the present day. Since then, Thenard and Gay Lussac have each contributed most important researches. By the labours of these three illustrious chemists, those material metamorphoses, formerly quite mysterious, seem susceptible of a satisfactory explanation.

As sugar is a substance of uniform and determinate

As sugar is a substance of uniform and determinate As sugar is a substance of uniform and determining the changes which arise when its solution is fermented into wine or alkohol. Lavoisier justly regarded it as a true vegetable oxide, and stated its constituents to be, 8 hydrogen, 28 carbon, and 64 oxygen, in 100 parts. By two different analyses of Berzelius, we have,

6.891 42.704 50,405 100.000 100.000

Gay Lussac and Thenard's analysis gives,

Hydrogen 6.90 { 57.53 water,
Oxygen 50.63 }
Carbon 42.47 42.47 100.00 100.00

It has been said, that sugar requires to be dissolved in at least 4 parts of water, and to be mixed with some yest, to cause its fermentation to commence. But this is a mistake. Syrup stronger than the above will ferment in warm weather, without addition. If the temperature be low, the syrup weak, and no yest added, acetous fermentation alone will take place. To determine the vinous, therefore, we must mix certain proportions of saccharine matter, water, and yest, and

place them in a proper temperature.

To observe the chemical changes which occur, we To observe the chemical changes which occur, we must dissolve 4 or 5 parts of pure sugar in 20 parts of water, put the solution into a matrass, and add 1 part of yest. Into the mouth of the matrass a glass tube must be luted, which is recurved, so as to dip into the mercury of a pneumatic trough. If the apparatus be now placed in a temperature of from 70° to 80°, we shall speedtly observe the syrup to become muddy, and a multitude of air bubbles to form all around the ferment. These units and attaching themselves to parment. These unite, and attaching themselves to particles of the yest, rise along with it to the surface, forming a stratum of froth. The yesty matter will then disengage itself from the air, fall to the bottom of the vessel, to reacquire buoyancy a second time by attached air bubbles, and thus in succession. If we operate on 3 or 4 ounces of sugar, the fermentation will be very rapid during the first ten or twelve hours; it will then slacken, and terminate in the course of a few days. At this period the matter being deposited which disturbed the transparency of the liquor, this will become clear.

The following changes have now taken place: 1. The sugar is wholly, and the yest partially, decomposed. 2. A quantity of alkohol and carbonic acid, together nearly in weight to the sugar, is produced. 3. A white matter is formed, composed of hydrogen, oxygen, and carbon, equivalent to about half the weight of the decomposed ferment. The carbonic acid passes over into the pneumatic apparatus; the alkohol may be separated from the vinous liquid by distillation, and the white matter falls down to the bottom of the matrass with the remainder of the vest. trass with the remainder of the yest.

The quantity of yest decomposed is very small. 100

parts of sugar require, for complete decomposition, only two and a half of that substance, supposed to be in a dry state. It is hence very probable, that the ferment, which has a strong affinity for oxygen, takes a little of it from the saccharine particles, by a part of its hydrogen and carbon, and thus the equilibrium being broken between the constituent principles of the sugar, these so react on each other, as to be transformed into alkohol and carbonic acid. If we consider the composition of alkohol, we shall find no difficulty in tracing the steps of this transformation.

Neglecting the minute products which the yest fur-

Neglecting the minute products which the yest furnishes, in the act of fermentation, let us regard only the alkohol and carbonic acid. We shall then see, on comparing the composition of sugar to that of alkohol, that to transform sugar into alkohol, we must withthat to transform sugar into alkohol, we must withdraw from it one volume of vapour of carbon, and one volume of oxygen, which form by their union one volume of carbonic acid gas. Finally, let us reduce the volumes into weights, we shall find, that 100 parts of sugar ought to be converted, during fermentation, into 51.55 of alkohol, and 48.45 of carbonic acid.

When it is required to preserve fermented liquors in the state produced by the first stage of fermentation, it is usual to put them into casks before the vinous process is completely ended; and in these closed vessels a change very slowly continues to be made for many months, and perhaps for some years.

change very slowly continues to be made for many months, and perhaps for some years.

But if the fermentative process be suffered to proceed in open vessels, more especially if the temperature be raised to 90 degrees, the acetous fermentation comes on. In this, the oxygen of the atmosphere is absorbed; and the more speedily in proportion as the surfaces of the liquor are often changed by lading it from one vessel to another. The usual method consists in exposing the fermented liquor to the air in open casks, the bunghole of which is covered with a tile to prevent the entrance of the rain. By the absorption of oxygen which takes place, the inflammable spirit becomes converted takes place, the inflammable spirit becomes converted into an acid. If the liquid be then exposed to distilla-

tion, pure vinegar comes over instead of ardent spirit.

III. When the spontaneous decomposition is suffered to proceed beyond the acetous process, the vinegar becomes viscid and foul; air is emitted with an offensive smell; volatile alkali flies off; an earthy sediment is deposited; and the remaining liquid, if any, is mere water. This is the putrefactive process. See also Putrefaction.

FERME'NTUM. (Quasi fervimentum, from ferveo,

to work.) Yest. FERMENTUM CEREVISIÆ. FERMENTUM CEREVISE. Yest; Barm; the scum which collects on beer while fermenting, and has the property of exciting that process in various other substances. Medicinally it is antiseptic and tonic; and has been found useful internally in the cure of typhus fever attended with an obvious tendency to putrefaction in the system with petechiæ, vibices, and the like: the best way to administer it, is to mix a fluid ounce with seven of strong beer, and give three table spoonfuls to an adult every three or four hours. Externally,

fuls to an adult every three or four hours. Externally, it is used in the fermenting cataplasm.

FERN. See Filix and Polypodium.

Fern, male. See Polydodium filix mas.

Fern, female. See Pteris aquilina.

FERNEL, John, was born at Claremont, near the end of the 15th century. He went at the age of 19 to prosecute his studies at Paris, and distinguished himself so much that after the degree of master. self so much, that, after taking the degree of master of arts, he was chosen professor of dialectics in his college. His application then became intense, till a quartan ague obliged him to seek his native air: and on his return to Paris, he determined on the medical profession, and taught philosophy for his support, till in 1530, he took his doctor's degree. Soon after he in 15.30, he took his doctor's degree. Soon after he married, and speedily got into extensive practice; and at length was made physician to the Dauphin, who afterward became Henry II. He was obliged to accompany that monarch in his campaigns, yet he still, though at the age of sixty, seldom passed a day without writing. But in 1558, having lost his wife of a fever, he did not long survive her. His works are numerous on philipsenhies. merous on philosophical, as well as medical subjects; of the latter, the most esteemed were his "Medicina," dedicated to Henry IL, and a posthumous treatise on

FERRAME'NTUM. An instrument made of iron. FERRO-CHYAZIC ACID. Acidum ferro-chyazi-

cum; chyazicum, from the initial letters of carbon, hydrogen, and azote.) An acid obtained by Porrett by adding to a solution of ferro-cyanite of barytes, supphuric acid just enough to precipitate the barytes. It has a pale yellow colour, no smell, and is decomposed by gentle heat or strong light, in which case hydrocyanic acid is formed, and white hydrocyanite of iron is deposited, which becomes blue by exposure.

FERRO-CYANATE. A compound of ferro-prussic acid with salifiable bases.

FERRO-CYANIC ACID. See Ferro-prussic acid.

FERRO-PRUSSIC ACID. Acidum ferro-prussic acid.

Into a solution of the

Acidum ferro-prussi-Into a solution of the FERRO-PRUSSIC ACID. Acidum ferro-prussicum. Acidum ferro-cyanicum. Into a solution of the aniber-coloured crystals, usually called prussiates of potassa, pour hydro-sulphuret of barytes, as long as any precipitate falls. Throw the whole on a filter, and wash the precipitate with cold water. Dry it; and having dissolved 100 parts in cold water, add gradually thirty of concentrated sulphuric acid; agitate the mixture, and set it aside to repose. The supernatant liquid is ferro-prussic acid, called by Porrett, who had the merit of discovering it, ferruretted chyazic acid.

It has a pale lemon-yellow colour, but no smell. Heat and light decompose it. Hydrocyanic acid is then formed, and white ferro-prossiate of iron, which soon becomes blue. Its affinity for the bases enables it to displace acetic acid, without heat, from the acetates,

and to form ferro-prussiates.

FE'RRUM. (Ferrum, i. neut.; the etymology uncertain.) Iron. See Iron.

FERRUM AMMONIATUM. Ammoniated iron; for-FERRUM AMMONIATUM. Ammoniated iron; for-merly known by the names of flores martiales; flores salls ammoniaci martiales; ens martis; ens veneris Boylei; sal martis muriaticum sublimatum, and lately by the title of ferrum ammoniacale. Take of subcarbonate of iron, muriate of ammonia, of each a pound. Mix them intimately, and sublime by immediate exposure to a strong fire; lastly, reduce the sublimed ammoniated iron to powder. This preparation is astringent and deobstruent, in doses from three to fifteen grains, or more, in the form of bolus or pills, prepared with some gum. It is exhibited in most cases of debility, in chlorosis, asthenia, menorrhagia, intermittent fevers, &c. This or some other strong preparation of iron, as the Tinct. ferri muriatis, Mr. Cline is wont to recommend in schirrhous affections of the

breast. See Tinctura ferri ammoniati.

FERRUM TARTARIZATUM. Tartarized iron. A tartrate of potassa and iron; formerly called tartarus chalybeatus; mars solubilis; ferrum potabile. Take of iron, a pound; supertartrate of potassa, powdered, two pounds; water, a pint. Rub them together; and expose them to the air in a broad glass vessel for eight days then day the residue in a sand both and reduce it. days, then dry the residue in a sand bath, and reduce it to a very fine powder. Add to this powder a pint more water, and expose it for eight days longer, then dry it, and reduce it to a very fine powder. Its virtues are astringent and tonic, and it forms in solution an averallant tonic forms and tonic and tonic forms. excellent tonic fomentation to contusions, lacerations, distortions, &c. Dose from ten grains to half a

drachm.

FERRI ALKALINI LIQUOR. Solution of alkaline iron. Take of iron, two drachins and a half; nitric acid, Take of iron, two drachms and a balf; nitric acid, two fluid ounces; disilled water, six fluid ounces; solution of subcarbonate of potassa, six fluid ounces. Having mixed the acid and water, pour them upon the iron, and when the effervescence has ceased, pour off the clear acid solution; add this gradually, and at intervals, to the solution of subcarbonate of potassa, occasionally shaking it, until it has assumed a deep brown-red colour, and no further effervescence takes place. Lastly, set it by for six hours, and pour off the clear solution. This preparation was first described by Stael, and called tinctura martis alkalina, and is now introduced in the London Pharmacopæia as affording a combination of iron distinct from any other, and ing a combination of iron distinct from any other, and often applicable to practice. The dose is from half a drachm to a drachm.

FERRI CARBONAS. See Ferri subcarbonas.
FERRI LIMATURA PURIFICATA. Purified iron filings.
These possess tonic, astringent, and deobstruent virtues, and are calculated to relieve chlorosis and other diseases in which steel is indicated, where acidity in the prime vie abounds.

the prime vie abounds.

Ferri subcarbonas.

Ferri subcarbonas.

pracipitatum, formerly called chalybis rubigo prapa-

FIB FER

each in four pints of water; then mix the solutions together and set it by, that the precipitated powder may subside; then having poured off the supernatant liquor, wash the subcarbonate of iron with hot water, and dry it was hibsides. and dry it upon bibulous paper in a gentle heat. It possesses mild corroborant and stimulating properties, and is exhibited with success in leucorrhoa, ataxia, asthenia, chlorosis, dyspepsia, rachitis, &c. Dose from two to ten grains.

FERRI SULPHAS. Sulphate of iron; formerly called sal martis, vitriolum martis, vitriolum ferri, and ferrum vitriolatum: Green vitriol. Take of iron, sulphuric acid, of each by weight, eight ounces; water, four pints. Mix together the sulphuric acid and water in a glass vessel, and add thereto the iron; then after the effervescence has ceased, filter the solution through paper, and evaporate it until crystals form as it cools. Having poured away the water, dry these upon bibulous paper. This is an excellent preparation of iron. lous paper. This is an excellent preparation of iron, and is exhibited, in many diseases, as a styptic, tonic, astringent, and anthelmintic. Dose from one grain to

five grains.

[FERRILITE. Common trap of Kitwan. Amor-phous basalt of Cleaveland. The Ferrilite, and perhaps the Mullen stone of Kirwan, may be referred to this variety of basalt. A.] FERRURETTED CHYAZIC ACID. See Ferro-

prussic acid. FERSÆ. The measles.

Fersæ. The measles.

Fertile flower. See Flos.

FE'RULA. The name of a genus of plants in the Linnæan system. Class Fentandria; Order, Digynia.

Ferula africana Galbanifera. The galbanum plant. See Bubon galbanum.

Ferula assafætida. The systematic name of the assafætida plant. Assafætida. Hingiseh of the Persians. Altiht of the Arabians. By some thought to be the σιλφιου, vel οπος σιλφιου of Dioscorides, Theophrastus, and Hippocrates. Laser et laserpitium of the Latins. Ferula assafætida—foliis alternatim simuatis, obtusis, of Linnæus. This plant, which affords us the assafætida of the shops, grows plentifully on the mountains in the provinces of Chorassan and Laar, in Persia.

The process of obtaining it is as follows: the earth is cleared away from the top of the roots of the oldest plants; the leaves and stalks are then twisted away, and made into a covering, to screen the root from the sun; in this state the root is left for forty days, when the covering is removed, and the top of the root cut off transversely; it is then screened again from the sun for forty-eight hours, when the juice it exudes is scraped off, and exposed to the sun to harden. A second transverse section of the root is made, and the exudation suffered to continue for forty-eight hours, and then scraped off. In this manner it is eight times and then scraped off. In this manner it is eight times repeatedly collected in a period of six weeks. The juice thus obtained has a bitter, acrid, pungent taste, and is well known by its peculiar nauseous smell, the strength of which is the surest test of its goodness. This odour is extremely volatile, and of course the drug loses much of its efficacy by keeping. It is brought to us in large irregular masses, composed of various little shining lumps, or grains, which are partly of a whitish colour, partly reddish, and partly of a violet hue. Those masses are accounted the best which violet hue. Those masses are accounted the best which are clear, of a pale reddish colour, and variegated with a great number of elegant white tears. This concrete juice consists of two-thirds of gum, and one-third of resin and volatile oil, in which its taste and smell reside. It yields all its virtues to alkohol. Triturated with water, it forms a milk-like mixture, the resin being diffused by the medium of the gum. Distilled with water, it affords a small quantity of essential oil. It is the most powerful of all the fætid gums, and is a most valuable remedy. It is most commonly employed in hysteria, hypochondriasis, some symptoms of dyspepsia, flatulent colics, and in most of those diseases termed nervous, but its chief use is derived from its antispasmodic effects; and it is thought to be the most powerful remedy we possess, for those violet hue. Those masses are accounted the best which

rata and ferri rubigo. Subcarbonate of iron. Take of sulphate of iron, eight ounces; subcarbonate of soda, six ounces; boiling water, a gallon. Dissolve the sulphate of iron and subcarbonate of soda separately, four pints of water, the subcarbonate of soda separately, and anodyne. Dr. Cullen prefers it as an expectorant to gum ammoniacum. Where we wish it expectorant to gum ammoniacum. expectorant to gum ammoniacum. Where we wish it to act immediately as an antispasmodic, it should be used in a fluid form, as that of tincture, from half a drachm to two drachms. When given in the form of a pill, or triturated with water, its usual dose is from five to twenty grains. When in the form of enema, one or two drachms are to be diffused in eight ounces of warm milk or water. It is sometimes applied externally as a plaster and stimulating remedy, in hysteria, &c.

Ferula minor. All-heal of Æsculapius. This plant is said to be detergent.

Ferula coa. See Buhon gelbanum.

FERULA'CCA. See Bubon galbanum.
FEVER. See Febris.
FEVERFEW. See Matricaria.
FI'BER. (From fiber, extreme, because it resides in the extremities of lakes and rivers.) The beaver.

See Castor fiber.

FIBRE. Fibra. A very simple filament. It is owing to the difference in the nature and arrangements of the fibres that the structure of the several parts of animals and vegetables differ: hence the barks, woods, animals and vegetables differ: hence the barks, woods, leaves, &c. of vegetables, and the cellular structure, membranes, muscles, vessels, nerves, and, in short, every part of the body, has its fibres variously constituted and arranged, so as to form these different parts. Fibre muscular. See Muscular fibre. FiBRIL. (Fibrila, diminutive of fibra.) A small thread-like fibre: applied to the little roots which are given off from radicles.

thread-like fibre: applied to the little roots which are given off from radicles.

FI'BRIN. "A peculiar organic compound found both in vegetables and animals. Vauquelin discovered it in the juice of the papaw-tree. It is a soft solid, of a greasy appearance, insoluble in water, which softens in the air, becoming viscid, brown, and semi-transparent. On hot coals it melts, throws out greasy drops, crackles, and evolves the smoke and odour of roasting meat. Fibrin is procured, however, in its most characteristic state from animal matter. It exists in chyle; it enters into the composition of blood; of it, the chief part of muscular flesh is formed; and hence it may be regarded as the most abundant constituent of the soft regarded as the most abundant constituent of the soft solids of animals.

solids of animals.

To obtain it, we may beat blood as it issues from the veins with a bundle of twigs. Fibrin soon attaches itself to each stem, under the form of long reddish filaments, which become colourless by washing them with cold water. It is solid, white, insipid, without smell, denser than water, and incapable of affecting the hue of litmus or violets. When moist it possesses a species of elasticity; by desiccation it becomes yellowish, hard, and brittle. By distillation we can extract from it much carbonate of ammonia, some acetate, a fortid it much carbonate of ammonia, some acetate, a fætid brown oil, and gaseous products; while there remains in the retort a very luminous charcoal, very brilliant, difficult of incineration, which leaves, after combus-tion, phosphate of lime, a little phosphate of magnesia, carbonate of lime, and carbonate of soda. Cold water has no action on fibrin. Treated with

Cold water has no action on fibrin. Treated with boiling water, it is so changed as to lose the property of softening and dissolving in acetic acid. The liquor filtered from it, yields precipitates with infusion of galls, and the residue is white, dry, hard, and of an

agrecable taste

When kept for some time in alkohol of 0.810, it gives rise to an adipocerous matter, having a strong and disagreeable odour. This matter remains dissolved in the alkohol, and may be precipitated by water. Æther makes it undergo a similar alteration, but more slowly. When digested in weak muriatic acid, it evolves a lit-When digested in weak muriatic acid, it evolves a lit-tle azote, and a compound is formed, hard, horny, and which, washed repeatedly with water, is transformed into another gelatinous compound. This seems to be a neutral muriate, soluble in hot water; while the first is an acid muriate, insoluble even in boiling water. Sulphuric acid, diluted with six times its weight of water, has similar effects. When not too concentrated, nitric acid has a very different action on fibrin. For example, when its sp. gr. is 1.25, there results form it. employed in hysteria, hypochondriasis, some symptoms of dyspepsia, flatulent colics, and in most of those diseases termed nervous, but its chief use is derived from its antispasmodic effects; and it is thought to be the most powerful remedy we possess, for those peculiar convulsive and spasmodic affections, which often recur in the first of these diseases, both taken

bined with the malic and nitric or nitrous acids. In tion, and are more easily discernible before than be-fact, if we put this mass on a filter, and wash it copi-hind. Below this the fibula is lengthened out, so as offset with the malic and nitric or nitrous acids. In fact, if we put this mass on a filter, and wash it copicusly with water, it will part with a portion of its acid, will preserve the property of reddening litmus, and will take an orange hue. On treating it afterward with boiling alkohol, we dissolve the fatty matter; and putting the remainder in contact with chalk and water, an effervescence will be occasioned by the escape of caybonic acid, and malate or nitrate of lime escape of carbonic acid, and malate or nitrate of lime

will remain in solution.

Concentrated acetic acid renders fibrin soft at ordinary temperatures, and converts it by the aid of heat into a jelly, which is soluble in hot water, with the disengagement of a small quantity of azote. This solution is colourless, and possesses little taste. Evaporated to dryness, it leaves a transparent residue, which reddens litmus paper, and which cannot be dissolved even in boiling water, but by the medium of more acetic acid. Sulphuric, nitric, and nuriatic acids, precipitate the animal matter, and form acid combinations. Potassa, soda, ammonia, effect likewise the precipitation of this matter, provided we do not use too great an excess of alkali; for then the precipitated matter would be redissolved. Aqueous potassa and soda gradually dissolve fibrin in the cold without or soda gradually dissolve fibrin in the cold, without oc-casioning any perceptible change in its nature; but with heat they decompose it, giving birth to a quantity of ammoniacal gas, and other usual animal products. Fibrin does not putrefy speedily when kept in water. It shrinks on exposure to a considerable heat, and emits the smell of burning horn. It is composed, ac-cording to the analysis of Gay Lussac, and Thenard,

> Carbon, 53,360 Azote, 19.934

Oxygen, 19.685) 22.14 water.
Hydrogen, 7.021 (4.56 hydrogen.
FIBROLITE. A crystallized mineral harder than quartz, of a white or gray colour, found in the Carnatic, and composed of alumina, silica, and iron.

FIBROSUS. (From fibre, a fibre.) Fibrous. A term frequently used in anatomy to express the texture of parts. In botany, its meaning is the same, and is applied to roots and other parts, as those of grasses,

FIBULA. (Quasi figilula; from figo, to fasten: so named because it joins together the tibia and the muscles.) A long bone of the leg, situated on the outer side of the tibia, and which forms, at its lower end, the outer ankle. Its upper extremity is formed into an irregular head, on the inside of which is a slightly concave articulating surface, which, in the recent subjects, is covered with cartilage, and receives the circular flat surface under the edge of the external cavity of the tibia. This articulation is surrounded by a capsular ligament, which is farther strengthened by other strong ligamentous fibres, so as to allow only a small motion backwards and forwards.—Externally, the head of the fibula is rough and protuberant, serving for the attachment of figaments, and for the insertion of the biceps cruris muscle.—Immediately below it, on its inner side, is a tubercle, from which a part of the gastrocnemius internus has its origin. Immediately below this head the body of the bone begins. It is of a triangular shape, and appears as if it were slightly twisted at each end, in a different direction. It is likewise a little curved inwards and forwards. This curvature is in part owing to the action of muscles; and in part perhaps to the carelessness of nurses.—Of the three angles of the bone, that which is turned towards the tibia is the most prominent, and serves for the attachment of the interesseous ligament, which, in its structure and uses, resembles that of the forearm, and, like that, is a little interrupted above and below. The three surfaces of interrupted above and below. The three surfaces of the bone are variously impressed by different muscles. the bone are variously impressed by different muscles. About the middle of the posterior surface is observed a passage for the medullary vessels, slanting downwards. The lower end of the fibula is formed into a spongy, oblong head, externally rough and convex, internally smooth and covered with a thin cartilage, where it is received by the external triangular depression at the lower end of the tibia. This articulation, which resembles that of its upper extremity, is furnished with a capsular ligament, and farther strengthened by ligamentous fibres, which are stronger and more considerable than those before described. They extend from the tibia to the fibula, in an oblique direcextend from the tibia to the fibula, in an oblique direc-

to form a considerable process, called malleolus exter nus, or the outer ankle. It is smooth and covered with cartilage on the inside, where it is contiguous to the astragalus, or first bone of the foot. At the lower and inner part of this process, there is a spongy cavity, filled with fat; and a little beyond this, posteriorly, is a cartilaginous groove, for the tendons of the peroneus longus and peroneus brevis, which are here bound down by the ligamentous fibres that are extended over

The principal uses of this bone seem to be, to afford origin and insertion to muscles, and to contribute to the articulation of the leg with the foot.

the articulation of the leg with the foot.

FICA'RIA. (From ficus, a fig; so called from its likeness.) See Ranneulus ficaria.

FICA'TIO. (From ficus, a fig.) A tuberculous disease, near the anus and pudenda.

FICOIDE'A. Ficoides. Resembling a fig. A name of the house-lock. See Sempercivum tectorium.

FICUS. 1. A fleshy substance about the anus, in figure resembling a fig.

2. The name of a genus of plants in the Linnæan system. Class, Polygamia; Order, Diacia. The figtree.

Ficus carica. The systematic name of the fig-tree. Carica; Ficus; Ficus vulgaris; Ficus com-munis. Ευκη of the Greeks. French figs are, when completely ripe, soft, succulent, and easily digested, unless eaten in immoderate quantities, when they are unless eaten in immoderate quantities, when they are apt to occasion flatulency, pain of the bowels, and diarrhœa. The dried fruit, which is sold in our shops, is pleasanter to the taste, and more wholesome and nutritive. They are directed in the decoctum hordei compositum, and in the confectio sennæ. Applied externally, they promote the suppuration of tumours; hence they have a place in maturating cataplasms; and are very convenient to apply to the gums, and, when boiled with milk, to the throat.

Figure 1 page 2.

Ficus indica. See Lacca. Fiddle-shaped. See Leaf.

FIDICINA'LES. (Fidicinalis, Sc. musculus.) See

FIDICINALES. (Fidicinalis, SC. musculus.) See Lumbricales.

FIENUS, Thomas, was son of a physician of Antwerp, and born in 1567. After studying at Leyden and Bologna, he was invited, at the age of 26, to be one of the medical professors at Louvaine, where he took his degrees. With the exception of one year, during which he attended the Duke of Bavaria, he remained in that office till his death in 1631. Besides his great abilities in medicine and surgery, he was distinguished for his knowledge of natural history, the learned languages, and the mathematics. He has left several works: the chief of which is termed "Libri Chirurgici XII.," treating of the principal operations; it passed through treating of the principal operations; it passed through many editions. His father, John, was author of a well-received treatise, "De Flatibus."

FIG. See Ficus carica.

FIGURESTONE. Bildstein. Agalmatolite. A massive mineral of a gray colour, or brown flesh-red, and sometimes spotted, or with blue veins; unctuous to the touch, and yielding to the nail. It comes from China, cut into grotesque figures. It differs from steatite in wanting the magnesia. It is also found in Transplyania and in Wales.

FIGWORT. See Ranunculus ficaria.

FILA'GO. (From filum, a thread, and ago, to produce or have to do with, in allusion to the cottony web connected with every part of the plant.) Cud or cot-

connected with every part of the plant.) Cud or cotton-weed; formerly used as an astringent.

FILA'MENT. (Filamentum; from filum, a thread.)

1. A term applied in anatomy to a small thread-like portion adhering to any part, and frequently synonymous with fibre. See Fibre.

2. The stamen of a flower consists of the filament, anther, and pollen. The filament is the column which supports the anther.

From its figure it is called,

1. Capillary; as in Plantago.

2. Filiform; as in Scilla maritima.

3. Flat; as in Allium cepa.

4. Dilatate, spreading laterally; as in Ornithog alum umbellature.

umbellatum.
5. Pedicellate, affixed transversely to a little stalk;

as in Salvia.
6. Bifid, having two; as in Stemedia.

7. Bifurced; as in Prunella.
8. Multifid; as in Carolina princeps.
9. Dentate; as in Rosmarinus oficinalis.
10. Nicked; as in Allium cepa.
11. Lanceolate; as in Ornithogalum pyrenaicum.
12. Castrate, the auther naturally wanting; as in Gratiola officinalis.

13. Subulate; as in Tulipa gesneriani.
From the pubescence,
1. Barbate, bearded; as in Lycium.

 Lanate, woolly; as in Verbascum thapsus.
 Pilose; as in Anthericum frutescens.
 Gland-bearing; as in Laurus and Rheum. From its direction,

1. Erect; as in Tulipa gesneriana.
2. Incurved; curved inward, and a little bent.
3. Declinate; as in Hemerocalis fulva.
4. Connivent; as in Physalis alkekengi.

From its concretion,

1. Liberate, free, nowhere adhering; as in Nicotiana tabacum.

2. Connate, adhering at their base; as in Malva sylvestris, and Alcea rosea.

From its insertion,

Receptaculine, inserted into the receptaculum; as in Papaver somniferum.

2. Corolline, as in Verbaseum thapsus, and Nerium

3. Calicine; as in Pyrus malus, and Mespilus ger-

4. Styline; as in the Orchides.
5. Nectorine; as in Pancratium declinatum.
From its length, it is said to be very long; as in Plantago major: very short in Jasminum and Vinca; and unequal, some long, some short; as in Cheiranthus

FILARIA. The name of a genus of intestinal

FILE'LLUM. (From filum, a thread; because it resembles a string.) The frænum of the penis and

File'TUM. (From filum, a thread; named from its string-like appearance.) The frænum of the tongue

and penis

FILICES. (Filix, cis. f.; from filum, a thread.)
Ferns. One of the families, or natural tribe into which
the whole vegetable kingdom is divided. They are
defined plants which bear their flower and fruit on the

back of the leaf or stalk, which is termed frons.

FILI'CULA. (Dim. of filix, fern; a small sort of fern: or from filum, a thread, which it resembles.)

Common maiden-hair. See Adianthum capillus ve-

FILIFORMIS. Filiform, thread-like: applied to many parts of animals and vegetables from their re-semblance.

FILIPE'NDULA. (From filum, a thread, and pen-deo, to hang; so named because the numerous bulbs of its roots hang, as it were, by small threads.) See Spiraa filipendula.

FILIPENDULA AQUATICA. Water-dropwort; the CENARTHE FISHULOSA OF LIMBRUS.

FILIUS ANTE PATREM. Any plant, the flower of which comes out before the leaf; as collsfoot.

FILIX. (From filum, a thread; so called from its being cut, as it were, in slender portions, like threads.) Fern. See Polypodium.

FILIX ACULEATA. See Polypodium aculeatum.
FILIX FLORIDA. See Osmunda regalis.
FILIX FLORIDA. See Polypodium filix mas.
FILIX FLORIDA. See Polypodium filix mas.
FILIX MAS. See Polypodium filix mas.
FILTRA'TION. (Filtratio; from filtrum, a strainer.) An operation, by means of which a fluid is mechanically separated from consistent particles merely mixed with it. It does not differ from straining.
An apparatus fitted up for this purpose is called a filter. The form of this is various, according to the intention of the operator. A piece of tow, or wool, or cotton, stuffed into the pipe of a funnel, will prevent the passage of grosser particles, and by that means render the fluid clearer which comes through. Sponge is still more effectual. A strip of linea rag wetted and hung over the side of a vessel containing a fluid, in such a manner as that one end of the rag may be immersed in the fluid, and the other end may remain It mixed with it. It does not differ from straining.

may eitner be fastened over the mouths of proper ves sels, or fixed to a frame, like a sieve, for the purpose of filtering. All these are more commonly used by cooks and apothecaries than by philosophical chemists, who, for the most part, use the paper called cap paper, made up without size.

As the filtration of considerable quantities of fluid could not be effected at once without breaking the filter of paper, it is found requisite to use a linen cloth, upon which the paper is applied and supported.

Precipitates and other pulverulent matters are collected more speedily by filtration than by subsidence. But there are many chemists who disclaim the use of this method, and avail themselves of the latter only. this method, and avail themselves of the latter only, which is certainly more accurate, and liable to no objection, where the powders are such as will admit of edulcoration and drying in the open air.

edulcoration and drying in the open air.

Some fluids, as turbid water, may be purified by filtering through sand. A large earthen funnel, or stone bottle with the bottom beaten out, may have its neck loosely stopped with small stones, over which smaller may be placed, supporting layers of gravel increasing in fineness, and lastly covered to the depth of a few inches with fine sand all thoroughly cleansed by washing. This apparatus is superior to a filtering stone, as it will cleanse water in large quantities, and by washing. This apparatus is superior to a filtering stone, as it will cleanse water in large quantities, and may readily be renewed when the passage is obstructed, by taking out and washing the upper stratum of sand.

A filter for corrosive liquors may be constructed, on the same principles, of broken and pounded glass.— Ure's Chem. Dict.

FI'LTRUM. A filter, straining or filtering instru-

FILUM. A thread or filament.

FILUM ARSENICALE. Corrosive sublimate.
FI'MBRIA. (A fringe, quasi finibria; from finis, the extremity.) A fringe. 1. A term used by anatomists to curled membraneous productions. See Fim-

2. In botany, it is applied to the dentate or fringe-like ring of the operculum of mosses, by the elastic power of which the operculum is displaced. See Peistomium.

FINERIE. (Fimbria, a fringe. Quasi finibria; from finis, the extremity.) The extremities of the Fallopian tubes. See Uterus.

FINCKLE. See Anethum faniculum.

FIRE. Ignis. A very simple and active element, the principal agent in nature to balance the power and natural effect of attraction. The most useful acceptation of the word fire comprehends heat and light. tion of the word fire comprehends heat and light. There have been several theories proposed respecting fire, but no one as yet is fully established. See Caloric

[FFRTH, Dr. S. of Salem, in New-Jersey, published a dissertation on malignant fever in 1805, with lished a dissertation on malignant fever in 1805, with an attempt to prove that yellow fever is not contagious. The experiments he tried with the matter of black-romit are bold and decisive. He proves by his experiments, that neither the black-romit, serum, nor saliva of persons labouring under yellow fever, are capable of communicating that disease. He dropped the matter of black-romit in his eye, inoculated himself with, and even swallowed it. For the particulars of these and other experiments see Black-romit. these and other experiments, see Black-vomit. A.]

[FISHERY, SEAL. Vessels belonging to the United tates, employed in voyages for catching seals, usually ass round Cape-Horn, and visit the islands of Juan States, employed in voyages for catching seals, usually pass round Cape-Horn, and visit the islands of Juan Fernandez and Massafuero. At the latter of these, seals were formerly very numerous. They are also taken at Falkland's Islands, Southern Georgia, Tristan d'Acunha, St. Paul's, and Amsterdam islands. But of late years they have been found to be much more rare. Even at Massafuero, and the islands in its vicinity, they are no longer found in that abundance which prethey are no longer found in that abundance which pre-

The sea-elephant belongs to the same family with the seal. He is found on many of the uninhabited islands of the great southern ocean, particularly at Kerguelan's Land, which they frequent in great herds. They make little resistance, and of course are easily killed. Several of our vessels are said to have been engaged in their destruction. Their oil is found to be

of an excellent quality; and not only answers for home consumption, but makes a valuable article of

"FISHERY, WHALE. This branch of business seems be less inviting and profitable than it formerly was. Whether this is owing to a scarcity of whales, to greater exertions of other nations, or to the inferiority of the market at home, and high duties abroad, we need not examine particularly here. The decline of the whale-fishery among the people of the United States, is probably to be ascribed to the operation of all these causes, as well as to bounties and immunities granted by some of the European powers so generously as to tempt many of our most enterprising whalemen to engage themselves and their capitals in foreign serto engage themselves and their capitals in foreign ser--Med. Repos.

These observations were made in 1805, since which there has been a great increase in the amount of capi-tal, number of ships, and seamen engaged in the whale fishery from the United States. The greatest number of ships in this business are fitted out at New-Bedford of ships in this business are fitted out at New-Bedford in Massachusetts, the island of Nantucket, and Sag-Harbour, on the east end of Long-Island, of the state of New-York. Some few are fitted out from this city, and some from ports in Connecticut. Few or none of our vessels pursue this business in the Arctic seas. Some take the right whale on the coast of Brazil, but most of those engaged in this employment from the United States resort to the Pacific ocean, where they take both the spermaceti and the right whale.

Vessels are fitted out on shares; the owners, master, and seamen dividing the proceeds of the voyage ac-

and seamen, dividing the proceeds of the voyage acvoyage commences, and which generally lasts about voyage commences, and which generally lasts about two years. The success depends upon the skill and enterprise of the officers and crew, which generally consists of hardy and active young men. The greater their success the greater their share of the profits. The spermaceti-whale is the great object of their search in the Pacific, as from this animal is derived the pharmacopeial substance called sperma ceti. Ambergris is also occasionally found in the intestines of this whale. A.]

of this whale. A.]
[FISHERY, cop. "This employment appears to be on the increase. Notwithstanding the abundance of business which might be followed on shore, in a country having so many millions of unappropriated acres, there are found plenty of people who prefer the catching of fish along the coasts of the United States, and on the Banks of Newfoundland. Government allows a bounty on the tonnage of the vessels engaged in the cod-

fishery, in lieu of a drawback upon the salt used in curing the fish."—Med. Rep.

The cod taken along our shores and on the Banks of Newfoundland is the Gadus morhua, though some of the other species are also taken. On the rocky shores of Maine, the hake (Gadus merluccius) is abundantly taken. The fish is not so good as the Gadus morhua, but it has a very large sound from which icthyocolla, or fish glue, of a good quality, may

be prepared in any quantity. A.]

Fish-glue. See Ichthyocolla.

FLE'MEN. (From flecto, to incline downwards.)

Flegma. A tumour about the ankles.

FLERE'SIN. Gout.

FLESH. 1. The muscles of animals.

2. A sulgar term for all the soft parts of an animal.

2. A vulgar term for all the soft parts of an animal. 3. It is also applied to leaves, fruit, &c. which have the appearance or consistence of flesh.

FLE'XOR. The name of several muscles, the office of which is to bend parts into which they are in-

serted.

FLEXOR ACCESSORIUS DIGITORUM PEDIS. Flexor longus digitorum pedis.

Flexor brevis digitorum pedis, Perforatus, sublimis. A flexor muscle of the toes, situated on the foot. Flexor brevis digitorum pedis, perforatus of 361

Albinus. Flexor brevis of Douglas. Flexor digitorum brevis, sive perforatus pedis of Winslow. Perforatus, seu fexor secundi internodii digitorum pedis of Cowper; and Calcano sus-phalangettien commun of Dumas. It arises by a narrow, tendinous, and fleshy beginning, from the inferior protuberance of the os calcis. It likewise derives many of its fleshy fibres from the adjacent aponeurosis, and soon forms a thick belly, which divides into four portions. Each of these portions terminates in a flat tendon, the fibres of which decussate, to afford a passage to a tendon of the long flexor, and afterward reuniting, are inserted into the second phalanx of each of the four less toes. This muscle serves to bend the second joint of the toes.

Flexor brevis minimi digiti pedis. Parathenar

FLEXOR BREVIS MINIMI DIGITI PEDIS. Parathenar minor of Winslow. This little muscle is situated minor of Winslow. This little muscle is situated along the inferior surface and outer edge of the metatarsal bone of the little toe. It arises tendinous from the basis of that bone, and from the ligaments that connect it to the os cuboides. It soon becomes fleshy, and adheres almost the whole length of the metatarsal bone at the apparent of which it forms to be a state of the saturation of the metatarsal than a state of the saturation of the metatarsal than a state of the saturation of the sat bone, at the anterior extremity of which it forms a small tendon, that is inserted into the root of the first joint of the little toe. Its use is to bend the little

Flexor brevis pollicis manus. Flexor secundi internodii of Douglas. Thenar of Winslow. Flexor primi et secundi ossis pollicis of Cowper; and Carpophalangien du pouce of Dumas. This muscle is divided into two portions by the tendon of the flexor longus pollicis. The outermost portion arises tendinous from the anterior part of the os trapezoides and internal annular ligament. The second, or innermost, and thickest portion, arises from the same bone, and likewise from the os magnum, and os cuneiforme.

and thickest portion, arises from the same bone, and likewise from the os magnum, and os cuneiforme. Both these portions are inserted tendinous into these sesamoid bones of the thumb. The use of this muscle is to bend the second joint of the thumb.

FLEXOR BREVIS FOLLICIS FEDIS. A muscle of the great toe, that bends the first joint of that part. Flexor brevis of Douglas. Flexor brevis pollicis of Cowper; and Tarsophalangien du pouce of Dumas. It is situated upon the metatarsal bone of the great toe, arises tendinous from the under nant anterior part of the os caleis, and from the under part of the os cuneiforme

ated upon the metatarsal bone of the great toe, arises tendinous from the under and anterior part of the os calcis, and from the under part of the os cuneiforme externum. It soon becomes fleshy and divisible into two portions, which do not separate from each other till they have reached the anterior extremity of the metatarsal bone of the great toe, where they become tendinous, and then the innermost portion unites with the tendon of the abductor, and the outermost with that of the abductor pollicis. They adhere to the external os sesamoideum, and are finally inserted into the root of the first joint of the great toe. These two portions, by their separation, form a groove, in which passes the tendon of the flexor longus pollicis.

Flexor carpi radialis. A long thin muscle, situated obliquely at the inner and anterior part of the forearm, between the palmaris longus and the pronator teres. Radialis internus of Albinus and Winslow; and Epitrochlo metacarpien of Dumas. It arises tendinous from the inner condyle of the os humeri, and, by many fleshy fibres, from the adjacent tendinous fascia. It descends along the inferior edge of the pronator teres, and terminates in a long, flat, and thin tendon, which afterward becomes narrower and thicker, and, after passing under the internal annular ligament, in a groove distinct from the other tendons of the wrist, it spreads wider again, and is inserted into the fore and upper part of the metacarpal bone that sustains the fore-finger. It serves to bend the hand, and its oblique direction may likewise enable it to assist in its pronation.

Flexor carpi ulnaris. Ulnaris internus of

FLEXOR CARPI ULNARIS. Ulnaris internus of Winslow and Albinus. Epitrochli cubito carpien of Dumas. A muscle situated on the cubit or forearm, that assists in bending the arm. It arises tendinous from the inner condyle of the os humeri, and, by a small fleshy origin, from the anterior edge of the olecranon. Between these two portions, we find the ulnar nerve passing to the forearm. Some of its fibres arise likewise from the tendinous fascia that covers the muscles of the forearm. In its descent, it soon becomes tendinous, but its fleshy fibres do not entirely disappear till it has reached the lower extremity of the ulna, where its tendon spreads a little, and after sending off a few fibres to the external and

internal and annular ligaments, is inserted into the to pisiforme.

pisiforme.

FLEXOR LONGUS DIGITORUM PEDIS PROFUNDUS PERFORANS. A flexor muscle of the toes, situated along the posterior part and inner side of the leg. Perforans seu flexor profundus of Douglas. Flexor digitorum longus, sive perforans pedis, and perforans seu flexor tertii internodii digitorum pedis of Cowper; and Tibio phalangetien of Dumas. It arises fleshy from the back part of the tibia, and, after running down to the internal ankle, its tendon passes under a kind of annular figament, and then through a sinuosity at the inside of the os calcis. Soon after this it receives a inside of the os calcis. Soon after this it receives a small tendon from the flexor longus pollicis pedis, and about the middle of the foot it divides into four tendons, which pass through the slits of the flexor brevis digitorum pedis, and are inserted into the upper part of the last bone of all the less toes. About the mid-dle of the foot, this muscle unites with a fleshy por-tion, which, from the name of its first describer, has tion, which, from the name of its first describer, has been usually called massa carnea Jacobi Sylvii: it is also termed Flezor accessorius digitorum pedis. This appendage arises by a thin fleshy origin, from most part of the sinuosity of the os calcis, and likewise by a thin tendinous beginning from the anterior part of the external tubercle of that bone; it soon becomes all fleshy, and unites to the long flexor just before it divides into its four tendons. The use of this muscle is to bend the last joint of the toes.

FLEXOR LONGUS POLITIES MANUS. Flexor longuest.

vides into its four tendons. The use of this muscle is to bend the last joint of the toes.

Flexor Longus Pollicis Manus. Flezor longus pollicis of Albinus. Flexor tertii internodii of Douglas; Flexor tertii internodii sive longissimus pollicis of Cowper; and radio-phalangetien du pouce of Dumas. A muscle of the thumb placed at the side of the flexor longus digitorum, profundus, perforans, and covered by the extensores carpi radiales. It arises fleshy from the anterior surface of the radius, immediately below the insertion of the biceps, and is continued down along the oblique ridge, which serves for the insertion of the supinator brevis, as far as the pronator quadratus. Some of its fibres spring likewise from the neighbouring edge of the internal annular ligament. Its tendon passes under the internal annular ligament of the wrist, and, after running along the inner surface of the first bone of the thumb, between the two portions of the flexor brevis pollicis, goes to be inserted into the last joint of the thumb, being bound down in its way by the ligamentous expansion that is spread over the second bone. In some subjects we find a tendinous portion arising from the inner condyle of the os humeri, and forming a fleshy slip that commonly terminates near the upper part of the origin of this muscle from the radius. The use of this muscle is to bend the last joint of the thumb.

Flexor longus Pollicis Pedis. A muscle of the great loe, situated along the posterior part of the lear

FLEXOR LONGUS POLLICIS PEDIS. A muscle of the great toe, situated along the posterior part of the leg. It arises tendinous and fleshy a little below the head of the fibula, and its fibres continue to adhere to that of the fibula, and its nores continue to adhere to that bone almost to its extremity. A little above the heel it terminates in a round tendon, which, after passing in a groove formed at the posterior edge of the astragalus, and internal and lateral part of the os calcis, in which it is secured by an annular ligament, goes to be inserted into the last bone of the great toe, which it

serves to bend.

FLEXOR OSSIS METACARPI POLLICIS. Opponens pollicis of Innes. Opponent pollicis manus of Albinus. Flexor primi internodii of Douglas. Antithenar sive semi-interosseus pollicis of Winslow; and Carpophalangien du pouce of Dumas. A muscle of the thumb, situated under the abductor brevis pollicis, which it resembles in its shape. It arises tendinous and fleshy from the os scaphoides, and from the anterior and inner part of the internal annular ligament. It is inserted tendinous and fleshy into the under and anterior part of the first bone of the thumb. It serves to turn the first bone of the thumb upon its axis, and at the same time to bring it inwards opposite to the other fingers. other fingers.

other ingers.

FLEXOR PARVUS MINIMI DIGITI. Abductor minimi digiti, Hypothenar Riolani of Douglas. Hypothenar minimi digiti of Winslow; and second carpo-phalangien du petit doigt of Dumas. A muscle of the little finger, situated along the inner surface of the metacarpal bone of the little finger. It arises tendinous and fleshy from the hook-like process of the unciform bone, and likewise from the auterior surface of the adjacent and likewise from the anterior surface of the adjacent

part of the annular ligament. It terminates in a flat tendon, which is connected with that of the abductor minimi digiti, and inserted into the inner and anterior part of the upper end of the first bone of the little finger. It serves to bend the little finger, and likewise to assist the abductor.

FLEXOR PROFUNDUS PERFORANS. Profundus, of Albinus. Perforans, of Douglas. Perforans vulgo profundus, of Winslow; Flezor tertii internedii digitorum manus, vel perforatus manus, of Cowper; and Cubito phalangetien commun, of Dumas. A muscle of the fingers situated on the forearm, immediately under the perforatus, which it greatly resembles in its shape. It arises fleshy from the external side, and upper part of the ulna, for some way downwards, and from a large portion of the interrosseous ligament. It splits into four tendons a little before it nasses under splits into four tendons a little before it passes under the annular ligament of the wrist, and these pass through the slit in the tendons of the flexor sublimis, to be inserted into the fore and upper part of the third or last bone of all the fore-fingers, the joint of which

they bend. they bend.

FLEXOR SUBLIMIS PERFORATUS. This muscle, which is the perforatus of Cowper, Douglas, and Winslow, is, by Albinus and others, named sublimis. It has gotten the name of perforatus, from its tendons being perforated by those of another flexor muscle of the finger, called the perforans. They who give it the appellation of sublimis, consider its situation with respect to the latter, and which, instead of perforans, they name profundus. It is a long muscle, situated most commonly at the anterior and inner part of the forearm, between the palmaris longus and the flexor earpi ulnaris; but, in some subjects, we find it placed under the former of these muscles, between the flexor carpi ulnaris and the flexor carpi radialis. It arises, tendinous and fleshy, from the inner condyle of the os humeri, from the inner edge of the coronoid process of tendinous and fleshy, from the inner condyle of the os humeri, from the inner edge of the coronoid process of the ulna, and from the upper and forepart of the radius, down to near the insertion of the pronator teres. A little below the middle of the forearm, its fleshy belly divides into four portions, which degenerate into as many round tendons, that pass all together under the internal annular ligament of the wrist, after which they separate from each other, become thinner and flatter, and running along the palm of the hand, under the appreurosis nalmaris, are inserted into the upper the aponeurosis palmaris, are inserted into the upper part of the second bone of each finger. Previous to this insertion, however, the fibres of each tendon de-cussate near the extremity of the first bone, so as to afford a passage to a tendon of the perforans. Of these four tendons, that of the middle finger is the largest, that of the forefinger the next in size, and that of the little finger the smallest. The use of this muscle is to bend the second joint of the fingers.

FLEXOR TERTII INTERNODII. See Flexor longus

FLEXUOSUS. Flexuous; full of turnings or windings. A stem is so named which is zigzag, form-ing angles alternately from right to left, and from left

to right; as in Smilaz aspera.

FLINT. A hard stone, found in beds of chalk, and in primitive, transition, secondary, and alluvial mountains. Its constituents are silica, lime, alumina, and oxide of iron.

FLINTY SLATE. Basanite. A mineral, of which

there are two kinds.

1. Common flinty slate, of an ash-gray colour, with other colours, in flamed, striped, and spotted delineations. It is found in different parts of the great tract of clay-slate and gray-wacke which extends from St.

Abb's head to Portpatrick.

2. Lydian stone, of a grayish-black and velvet-black colour. It is found frequently along with common flinty slate, in beds of clay-slate. It occurs in Bohemia and the Pentland hills, near Edinburgh. It is sometimes used as a touchstone for ascertaining the purity of gold and silver.

FLOATSTONE. The spongiform quartz of

FLOCCILATION. (Floccilatio; from floccus, the map of clothes.) Picking the bedclothes. A symptom of great danger in acute diseases.

FLORAL. (Floralis; from flos, a flower.) Belonging to a flower; as floral leaf. See Bractea.

[FLORA OF NORTH AMERICA. "Before the revolutionary struggle began in France, Louis 16th had

patronized a botanical inquiry into the vegetable productions of North America. In the sixth volume of our Medical Repository, we gave an account of the establishments formed for that purpose, and of the history of the oaks of North America, published by Mr. Michaux, the botanist employed by that monarch. Since that work on the Quercus family was published, the great performance of Mr. Michaux on the vegetables of that extensive country generally, has made its bles of that extensive country generally, has made its

appearance."
"The industrious author of this work had spent six years in Persia before his mission to America. He years in Persia before his mission to America. He afterward passed twelve years in exploring the regions between Hudson's Bay and Carolina. In the course of the numerous excursions he made during that time through the diversified states, provinces, and territories, he collected the materials of this new and more complete synopsis of North American plants. This, he hopes, will be found to be the case, notwithstanding the prior descriptions of the plants of Canada by Cornutics of Virginia by Clayton, aided by Gronovius; of Canada

the prior descriptions of the plants of Canada by Cornuti; of Virginia by Clayton, aided by Gronovius; of Carolina by Catesby, with plates, as well as by Walther and Bartram; and of the more northern parts, by Marshall and Forster.

"This work is published by the author's son, the father having left it in his hands rather unfinished, when he set off on his voyage of discovery to the Islands lying in the Great South Sea. We mention with concern the death of this indefatigable naturalist in 1802. He fell a victim to the zeal with which he in 1802. He fell a victim to the zeal with which he urged his physical inquiries on the coast of Mada-

"The author follows the Linnæan or sexual system. In addition to the vegetables, which are indigenous in America, he has also noted the European plants growing there. The generic characters are chiefly taken from Murray's last edition of the system chiefly taken from Murray's last edition of the system of vegetables. Mr. Michaux seems to have confirmed of vegetables. Mr. Michaux seems to have confirmed as many of the Linnman species as he could; though, for the sake of perspicuity, he has described some of them over again. It is affirmed that the work contains no species that have not either been seen or gathered by Michaux himself. This must give to this Flora great value, and render it peculiarly interesting to the lovers of botany in the United States. Genuine descriptions recently made of the plants of the country by an actual observer, possessing remarkable skill and discernment in the practical as well as the theoretical parts of the science, cannot fail to increase the facility of its ac-quirement among our studious youth. To them, in particular, it will shorten the way to knowledge, and at the same time, render it much more easy and de-

"Particular labour has been bestowed upon the Cyperacea and Gramineae; and all the Cryptogamia have been sedulously attended to, except the fungi. As respects the Filices, he adopts the arrangement of J. E. Smith; on the Musci, the system of Hedwig; and he follows the method of Acharius on the Lichens. Care has been taken that the genera of the same order should be assembled under the banner of affinities, and thrown into sections as far as the laws of the system would permit; so that they may be found by the in-quirer and student with the greater readiness and

"We consider this Flora boreali Americana as a most desirable addition to the natural history of our country. With this work in his hand, the botanist will be enabled to pursue his studies on the vegetables of Fredon (U.S.) and the adjoining regions, with additional ease and success. Though we cannot dismiss it from our notice, without expressing our regret that the author had not enriched his book with some that the author had not enriched his book with some of the synonyms from other writers, with some of the popular and trivial names, and with some little sketch of the dietetic, medicinal, and economical uses of the more distinguished species."—Med. Repos. vol. 8. A.]

FLORES BENZOES. See Benzoic acid.

FLORES MARTIALES. See Ferrum ammoniatum.

FLORES SALIS AMMONIACI. See Ammonia sub-

FLORES SULPHURIS. See Sulphur.
FLORES SULPHURIS LOTI. See Sulphur lotum.
FLORESCENTIA. (From floresco, to flourish or bloom.) The act of flowering, which Linnæus compares to the act of generation in animals.
FLORET. A hule flower.

FLOS. (Flos, ris. f.; a flower.) 1. A flower. That part of a plant, for the most part beautifully coloured, and protecting the internal organs.

Every flower has parts, which are
1. Essential, constituting properly the flower; as the

- pistil, stamen, and receptacle.

 2. Less essential, without which the flower is in some instances formed; as the calyx, corolla, and pedunculus.
- Accidental, noticed in a few only; as the bractea and nectarium.

A flower is said to be,

Complete, when furnished with calyx and corolla; as Nicotiana tabacum.

2. Incomplete, when the calyx or corolla is wanting.
3. Naked, devoid of the calyx; as in Lilium candidum, and Tulipa gesneriana.
4. Apetaloid, without the corolla; as in Galena Africana, and Saurarus cernuus.

When the decomposition of the late usual in

When the stamens and pistils are both, as usual, in one flower, that flower is called perfect, or united; when they are situated in different flowers of the same species, they are called separated flowers; that which has the stamens being named the barren flower, as producing no fruit in itself, and that with the pistils the fertile one, as bearing the seed.

The flower contains the internal or genital parts of

The stamen or male genital organ.
 The pistillum or female genital organ.
 From their diversity, flowers are called,
 Male, which have the stamina only.
 Female, in which are the pistils only.

3. Hermaphrodite, which contain both stamens and pistils.

4. Neuter, naturally deficient of stamens and pistils as the marginal flowers of the Centaurea cyanus, and Jacobea.

 Castrate, when the anthers or the pistils are naturally wanting. The pistils, for example, are wanting in the Calendula officinalis, and in the Viola mirabilis, there are no anthers.

Abortive, the fecundated germens of which wither

before the maturity of the fruit; as happens to the florets in the radius of the Helianthus annuus.

7. Monstrous, when the internal organs become petals, as is the case with full or double flowers.

Besides these distinctions, Linnæus's favourite division is into,

1. Aggregate. 2. Compound. 3. Amentaceous

Glumose, or chaffy, peculiar to the grasses.
 The sheathed flower, the common receptacle of which springs from a sheath; as in Arum.

6. The Umbellate.

7. The Cymose. See also Inflorescence.

II. A term used by former chemists to whatever had a flower-like appearance, especially if obtained by sub-limation, as flowers of sulphur, benjamin, zinc, &c.

FLOS FERRI. A radiated variety of carbonate of

FLOSCULUS. A little flower. A term applied in botany to the small and numerous florets of a compound flower, which are all sessile on a common undi vided receptacle, and enclosed in one contiguous calyx, or perianth.

FLOUR. The powder of the gramineous seeds.

FLOWER. See Flos.

FLOWER-DE-LUCE. See Iris germanica.

Flowers of benjamin. See Benzoic acid. FLOYER, Sir John, was born at Hinters, in Staffordshire, about the year 1649, and graduated at Ox-ford. He then settled at Litchfield, where his atten-tion and skill procured him extensive reputation, insomuch that he was honoured with knighthood, as a reward for his talents. He strongly advocated the use of cold bathing, particularly in chronic rheumatism, and nervous disorders: and he ascribed the increasing prevalence of consumption to the discontinuance of the practice of baptizing children by immersion. He published several works on this and other subjects; particularly an excellent treatise on the asthma, un-der which he himself laboured from the time of puberty, notwithstanding which he lived to be an old man. He is said to have been one of the first who reckoned the number of pulsations by a time-piece.

FLUATE. Fluas. A compound of the fluoric acid with salifiable bases: thus, fluate of lime, &c.

FLUCTUA'TION. Fluctuatio. A term used by surgeons, to express the undulation of a fluid; thus when pus is formed in an abscess, or when water accumulates in the abdomen, if the abscess or abdomen be lightly pressed with the fingers, the motion of fluctuation may be distinctly felt.

FLUELLIN. See Antirrhinum elatine.

FLUID. Fluidus. A fluid is that, the particles of

FLUID. Fluidus. A fluid is that, the particles of which so little attract each other, that when poured

which so little attract each other, that when poured out, it drops guttatim, and adapts itself in every respect to the form of the vessel containing it.

The fluids of animal bodies, and particularly those of the human body, are something very considerable in proportion to the solids; the ratio in the adult being as nine to one. Chaussier put a dead ody of 120 pounds into an oven, and found it, after many days' successive desiccation, reduced to 12 pounds. Bodies found, after being buried for a long time in the burning sands of the Arabian deserts, present an extraordinary diminution of weight.

The animal fluids are sometimes contained in vessels, wherein they move with more or less rapidity; sometimes in little areolæ or spaces, where they seem to be kept in reserve; and at other times they are placed in the great cavities where they make only a temporary stay of longer or shorter duration.

The fluids of the human body are,

The blood.
 The lymph.

3. The perspiratory or perspirable fluids, which comprise the liquids of cutaneous transpiration: the transpiration or exhalation of mucous membranes, as also of the synovial, serous, and cellular; of the adipose cells, the medullary membranes, the thyroid and thymus glands, &c.

thymus glands, &c.

4. The follicular fluid; the sebaceous secretion of the skin, the cerumen, the ropy matter from the eyelids, the mucus from the glands and follicles of that name from the tonsils, the cardiac glands, the prostate, the vicinity of the anus, and some other parts.

5. The glandular fluids; the tears, the saliva, the pancreatic fluid, the bile, the urine, the secretion from Cowper's glands, the semen, the milk, the liquid contained in the supra-renal capsules, that of the testicles, and of the mammæ of new-born infants.

6. The chyme and the chyle.

The chyme and the chyle.

The properties of fluids, both chemical and physical, are exceedingly various. Many have some analogy to each other under these two relations; but none exhibit a perfect resemblance. The writers of all ages have attached a considerable degree of importance to their methodical arrangement; and according to the doctrine then flourishing in the schools, they have created different systems of classification. Thus, the ancients, who attributed much importance to the four elements, said that there were four principal humours, the blood, the lymph, or pituita, the yellow bile, the black bile, or atra bilis; and these four humours correspond to the four elements, to the four seasons of the year, to the four elements, to the four seasons of the year, to the four divisions of the day, and to the four temperaments. Afterward, at different periods, other divisions have been substituted to this classification of the ancients. Thus, some have made three classes of liquids:—I. the chyme and chyle; 2. the blood; 3. the humours emanating from the blood. Some authors have been content with forming two classes. have been content with forming two classes:—1. primary, alimentary, or useless fluids; 2. secondary, or
useful. Consequently, they distinguished them into—
1. Recrementitious, or humours destined from their
formation to the nourishment of the body.

Excrementitious, or fluids destined to be thrown off from the system;

3. Humours, which at times participate in the characters of the two former classes, and are therefore

named excremento-recrementitious.

In later times, chemists have endeavoured to class the humours according to their intimate or component nature, and thus they have established albuminous, fibrinous, saponaeccus, watery, &c. fluids.

FLUOBORATE. A compound of the fluoboric conduction a salifable basis.

FLUOBORATE. A compound of the huoboric acid with a salifiable basis.

FLUOBORIC ACID. Acidum fluoboricum. Probably a compound of fluorine with boron. It is a gaseous acid, and may be obtained by heating in a glass retort twelve parts of sulphuric acid with a mix-

ture of one part of fused boracle acid, and two of fluorspar, reduced to a very fine powder. It must be received over mercury. It combines with salifiable bases, and forms salts called fluoborites.

FLU'OR. Octobedral fluor of Jameson. It is discontinuous foliated.

FLU'OR. Octohedral fluor of Jameson. It is divided into three sub-species, compact fluor, foliated fluor, and earthy fluor. This genus of mineral abounds in nature, formed by the combination of the fluoric acid with lime. It is called spar, because it has the sparry form and fracture: fluor, because it melts very readily; and vitreous, because it has the appearance of glass, and may be fused into glass of no contemptible appearance. ble appearance.

ble appearance.

FLUO RIC ACID. (Acidum fluoricum, because obtained from the fluor-spar.) Hydro-fluoric acid.

"The fusible spar which is generally distinguished by the name of Derbyshire spar, consists of calcareous earth in combination with this acid. If the pure fluor, or spar, be placed in a retort of lead or silver, with a receiver of the same metal adapted, and its weight of sulphuric acid be then poured upon it, the fluoric acid will be disengaged by the application of a moderate heat. This acid gas readily combines with water; for which purpose it is necessary that the receiver should previously be half filled with that fluid.

previously be half filled with that fluid.

If the receiver be cooled with ice, and no water put in it, then the condensed acid is an intensely active liquid. It has the appearance of sulphuric acid, but is much more volatile, and sends off white fumes when exposed to air. Its specific gravity is only 1.0609. It must be examined with great caution, for when applied to the skin it instantly disorganizes it, and produces very painful wounds. When potassium is intended into it it acts with intense energy and produced into it it acts with intense energy and protroduced into it, it acts with intense energy, and produces hydrogen gas and a neutral salt; when lime is made to act upon it, there is a violent heat excited, water is formed, and the same substance as fluor-spar is produced. With water in a certain proportion, its density increases to 1.25. When it is dropped into water, a hissing noise is produced, with much heat, and an early fluid not discoverable to the tasts. and an acid fluid not disagreeable to the taste is formed if the water be in sufficient quantity. corrodes and dissolves glass

It appears extremely probable, from all the facts known respecting the fluoric combinations, that fluorspar contains a peculiar acid matter; and that this acid matter is united to lime in the spar, seems evident from the circumstance, that gypsum or sulphate of lime is the residuum of the distillation of fluor-spar and sulphuric acid. The results of experiments on fluor-spar have been differently stated by chemists.

Some have considered fluoric acid as a compound of fluorics with budgeren but it seems on the whole to be

fluorine with hydrogen, but it seems on the whole to be the analogy of chlorine. But the analogy is incom-plete. Certainly it is consonant to the true logic of chemical science to regard chlorine as a simple body, since every attempt to resolve it into simpler forms of matter has failed. But fluorine has not been exhibited in an insulated state like chlorine; and here therefore the analogy does not hold.

The marvellous activity of fluoric acid may be in-ferred from the following remarks of Sir II. Davy, from which also may be estimated in some measure the prodigious difficulty attending refined investigations

on this extraordinary substance

I undertook the experiment of electrising pure liquid I undertook the experiment of electrising pure inquidifluoric acid with considerable interest, as it seemed to offer the most probable method of ascertaining its real nature; but considerable difficulties occurred in executing the process. The liquid fluoric acid immediately destroys glass, and all animal and vegetable substances; it acts on all bodies containing metallic oxides; and I know of no substances which are not rapidly dissolved or decomposed by it, except metals, charcoal, bhosphoor decomposed by it, except metals, charcoal, phosphorus, sulphur, and certain combinations of chlorine. I attempted to make tubes of sulphur, of muriates of lead, and of copper containing metallic wires, by which it might be electrised, but without success. I succeeded, however, in boring a piece of horn silver in such a manner that I was able to cement a platina wire into it by means of a spirit lamp; and by inverting this in a tray of platina, filled with liquid fluoric acid, I contrived to submit the fluid to the agency of electricity in such a manner, that, in saccessive experiments, it was possible to collect any elastic fluid that might be produced. Operating in this way with a very

weak voltaic power, and keeping the apparatus cool by a freezing mixture, I ascertained that the platina wire at the positive pole rapidly corroded, and became covered with a chocolate powder; gaseous matter sepa-rated at the negative pole, which I could never obtain in sufficient quantities to analyze with accuracy, but it

rated at the negative pole, which I could never obtain in sufficient quantities to analyze with accuracy, but it inflamed like hydrogen. No other inflammable matter was produced when the acid was pure.'

If instead of being distilled in metallic vessels, the mixture of fluor-spar and oil of vitriol be distilled in glass vessels, little of the corrosive liquid will be obtained; but the glass will be acted upon, and a peculiar gaseous substance will be produced, which must be collected over mercury. The best mode of procuring this gaseous body is to mix the fluor-spar with pounded glass or quartz; and in this case the glass retort may be preserved from corrosion, and the gas obtained in greater quantities. This gas, which is called silicated fluoric gas, is possessed of very extraordinary properties.

It is very heavy; about 48 times denser than hydrogen. When brought into contact with water, it instantly deposites a white gelatinous substance, which is hydrate of silica; it produces white fumes when suffered to pass into the atmosphere. It is not affected by any of the common combustible bodies; but when potassium is strongly heated in it, it takes fire and burns potassium is strongly neated in h, it takes are and burns with a deep red light; the gas is absorbed, and a fawn-coloured substance is formed, which yields alkali to water with slight effervescence, and contains a combustible body. The washings afford potassa, and a salt, from which the strong acid fluid previously described, may be separated by sulphuric acid.

If, instead of glass or silica, the fluor spar be mixed with dry vitreous boracic acid, and distilled in a glass vessel with sulphuric acid, the proportions being one

vessel with sulphuric acid, the proportions being one part boracic acid, two fluor-spar, and twelve oil of vitriol, the gaseous substance formed is of a different kind, and is called the *fluoboric gas*. It is colourless; its smell is pangent, and resembles that of muriatic acid; it cannot be breathed without suffocation; it extinguishes combustion; and reddens strongly the tinc-ture of turnsol. It has no manner of action on glass, but a very powerful one on vegetable and animal matter. It attacks them with as much force as conmatter. It attacks them with as much force as con-centrated sulphuric acid, and appears to operate on these bodies by the production of water; for while it car-bonizes them, or evolves carbon, they may be touched without any risk of burning. Exposed to a high tem-perature, it is not decomposed; it is condensed by cold without changing its form. When it is put in contact with oxygen, or air, either at a high or low temperature, it experiences no change, except seizing, at ordinary it experiences no change, except seizing, at ordinary temperatures, the moisture which these gases contain It becomes in consequence a liquid which emits extremely dense vapours. It operates in the same way with all the gases which contain hygrometric water. However little they may contain, it occasions in them very perceptible vapours. It may hence be employed with advantage to show whether or not a gas contains

No combustible body, simple or compound, attacks fluoboric gas, if we except the alkaline metals. Potassium and sodium, with the aid of heat, burn in this gas, almost as brilliantly as in oxygen. fluate of potassa are the products of this decomposinuate of potassa are the products of this decomposition. It might hence be inferred, that the metal seizes
the oxygen of the boracic acid, sets the boron at liberty,
and is itself oxidized and combined with the fluoric
acid. According to Sir H. Davy's views, the fluoboric
gas being a compound of fluorine and boron, the potassium unites to the former, giving rise to the fluoride of
potassium, while the boron remains disengaged.

Fluoboric gas is very soluble in water. Dr. John

Fluoboric gas is very soluble in water. Dr. John Davy says, water can combine with 700 times its own Davy says, water can combine with 700 times its own volume, or twice its weight, at the ordinary temperature and pressure of the air. The liquid has a specific gravity of 1.770. If a bottle containing this gas be uncorked under water, the liquid will rush in and fill it with explosive violence. Water saturated with this gas is limpid, fuming, and very caustic. By heat about one-fifth of the absorbed gas may be expelled; but it is impossible to abstract more. It then resembles concentrated sulphuric acid, and boils at a temperature considerably above 2129. It afterward condenses, altogether, in striæ, although it contains still a very large quantity of gas. It unites with the bases forming salts,

called fluoborates, none of which has been applied to any use.

The 2d part of the Phil. Transactions, for 1812, contains an excellent paper by Dr. John Davy on fluosilicic and fluoboric gases, and the combinations of the latter with ammoniacal gas. When united in equal volumes, a pulverulent salt is formed; a second volume of ammonia, however, gives a liquid compound; and a third of ammonia, which is the limit of combination, affords still a liquid; both of them curious on many accounts. 'They are,' says he, 'the first salts that have been observed liquid at the common temperature of the atmosphere. And they are additional facts in support of the doctrine of definite proportions, and of the relation of volumes.' The fluosilicic acid also unites to bases forming fluosilicates.

From the remarkable property fluoric acid possesses of corroding glass, it has been employed for etching on it, both in the gaseous state, and combined with water; and an ingenious apparatus for this purpose is given by Mr. Richard Knight. in the Philosophical Magazine, vol. xvii. p. 357.

Of the combinations of this acid with most of the bases, little is known.

Beside the fluor spar and cryolite, in which it is abundant, fluoric acid has been detected in the topaz; in wavelite, in which, however, it is not rendered sensible by sulphuric acid; and in fossil teeth and fossil ivory, though it is not found in either of these in their natural state."—Ure's Chem. Dict.

Fluoric acid, silicated. See Fluoric acid.

FLUORIDE. A combination of fluorine with a salifiable basis.

FLUORINE. The imaginary radical of fluoric

FLUORINE. The imaginary radical of fluoric

FLUOSILICIC ACID. See Fluoric acid. FLUX. 1. This word is often employed for dysen-

teria.

2. A general term made use of to denote any substance or mixture added to assist the fusion of metals.

FLUXION. Fluxio. A term mostly applied by chemists, to signify the change of metals, or other bodies, from the solid into the fluid state, by the application of heat. See Fusion.

FLY. Musca.
Fly. Spanish. See Cantharis.
FO'CILE. The ulna and the radius are occasionally denominated by the barbarous appellations of focile majus and minus; the tibia and fibula in the leg are also so called.

Fo'cus. A lobe of the liver.

Fodi'na. (From fodio, to dig.) A quarry. The

FORTULA (From Jouro, Education of the ear.

FORNICULA TUM LIGNUM. A name for sassafras.

FORNICULUM. (Quasi fanum oculorum, the hay or herb good for the sight; so called because it is thought good for the eyes.) Fennel. See Anethum.

FENICULUM ORIENTALE. See Cuminum.
FENICULUM PORCINUM. See Peucedanum officinale.
FENICULUM-BINENSEE. Aniseed.

Feniculum sylvestre. Seseli montanum, of Linnæus. Bastard spignel. See

FENICULUM TORTUOSUM. French hartwort. See Seseli tortuosum.

FŒNUM CAMELORUM. See Anethum fæniculum. FŒNUM. (Fænum, i. n. hay.) Hay. FŒNUM CAMELORUM. See Juncus odoratus. FŒNUM GRÆCUM. See Trigonella fænum græcum. FŒNUM SYLVESTRE. Wild fenugreek.

POESIUS, Anortius, was born at Mentz, in 1528, and received his education at Paris, where he imbibed a strong predilection for the Greek language, and particularly the works of Hippocrates. Returning to his native place about the age of 28, his talents soon procured him such extensive reputation, that several princes endeavoured to allure him to their respective courts, but without success. The practice of his profession, instead of weakening his attachment to Him. fession, instead of weakening his attachment to Hip-

called fluoborates, none of which has been applied to any use.

The 2d part of the Phil. Transactions, for 1812, contains an excellent paper by Dr. John Davy on fluosilicic and fluoboric gases, and the combinations of the latter with ammoniacal gas. When united in equal volumes, a pulverulent salt is formed; a second volume of ammonia, however, gives a liquid compound; and a third of ammonia, which is the limit of combination, affords still a liquid; both of them curious on many accounts. 'They are,' says he, 'the first salts that have been observed liquid at the common temperature of the atmosphere. And they are additional facts in support of the doctrine of definite proportions, was also author of a Pharmacopæia for his native city; and died in 1595.

FETA'BULUM. (From fateo, to become putrid.) 1.

An encysted abscess.

2. A foul ulcer.

FE'TUS. (From fee, to bring forth, according to Vossius.) Epicyema; Epigonion. The child enclosed in the uterus of its mother, is called a fœtus from the fifth month after pregnancy until the time of its birth. See Ovum.

FOLIATA TERRA. 1. Sulphur.
2. An old name of the acetate of potassa.
FOLIATIO. (From folium, a leaf.) The manner in which leaves are folded up in their buds. See Ver-

FOLIA'TUS. (From its resemblance to folium, a leaf.) Foliate, leafy. *
FOLICULUS. (Diminutive of follis, a leather

FOLIOLUS. (Diffinition of Jours, a teamer bag.) A small follicle.
FOLIOLUM. A leaflet or little leaf.
FO'LIUM. (Folium, i. n.; from φυλλον, the leaf of a tree.) See Leaf.

FOLIUM ORIENTALE. See Cassia senna. FOLLICLE. (Folliculus; diminutive of follis, a bag.) A small bag; applied to glands. See Folliculose.

FOLLICULOSE. (Folliculosus; from folliculus, a little bag.) A term applied to a simple gland or follicle. One of the most simple species of gland, consisting merely of a hollow vascular membrane or fol-

sisting merely of a nonlow vascular membrane or follicle, and an excretory duct; such are the muciparous
glands, the sebaceous, &c.

FOLLI'CULUS. (Diminutive of follis, a bag.)

1. A little bag. See Folliculose.

2. In botany, a follicle is a one-valved pericarp, or
seed-vessel. It has one cell, and bursts lengthwise,
and bears the seeds on or near its edges, or on a receptacle parallel therewith.

From the adhesion of the seeds it is distinguished.

From the adhesion of the seeds it is distinguished

1. Follicle, with a partition, when the seeds adhere to an intermediate dissepiment.

2. Follicle, without a partition, when the seeds adhere to the internal sides only.

From the number of seeds,

1. Monosperm follicle; as in Orontium.

2. Polysperm; as in Asclepias syriaca.

From the direction into,

1. Erret: as in Vinca and Nerium.

1. Erect; as in Vinca and Nerium.
2. Reflected; as in Plumeria.
3. Horizontal; as in Cameraria.
FOLLICULIS PELLIS. The gall-bladder.
FOMENTA'TION. Fomentatio. A sort of partial bathing, by applying hot flannels to any part, dipped in medicated decoctions, whereby steams are communicated to the parts, their vessels are relayed and their

in medicated decoctions, whereby steams are communicated to the parts, their vessels are relaxed, and their morbid action sometimes removed.

FOMES VENTRICULL. Hypochondriacism.

FO'MITES. A term mostly applied to substances imbued with contagion.

FONS. A fountain.

FONS PULSATILIS. See Fontanella.

FONTANE'LLA. (Diminutive of fons, a fountain.) Fons pulsatilis. The parietal bones and the frontal do not coalesce until the third year after birth, so that, before this period, there is an obvious interstice, commonly called mould, and scientifically the fontanel, or fons pulsatilis. There is also a less space, occasionally, between the occipital and parietal bones, termed the posterior fontanel. These spaces between the bones are filled up by the dura mater, perieranium, and external integuments, so that, during birth, the size of the head may be lessened; for, at that time, the bones of the head, upon the superior that time, the bones of the head, upon the superior

part, are not only pressed nearer to each other, but they frequently lap over one another, in order to diminish the size during the passage of the head through Digestion, was read originally as the Gulstonian Lec-

FONTI'CULUS. (Diminutive of fons.) An artificial ulcer formed in any part, and kept dis-charging, by introducing daily a pea, covered with any digestive cintroductors. digestive ointment.

FORA'MEN. (From fore, to pierce.) A little

opening.

FORAMEN CŒCUM. 1. A single opening in the basis of the cranium between the ethmoid and the frontal

bone, that gives exit to a small vein.

2. The name of a hole in the middle of the tongue. Foramen Lacerum in Basi cranii. A foramina in the basis of the cranium, through which the internal jugular vein, and the eighth pair and accessary nerves

FORAMEN LACERUM ORBITALE SUPERIUS. opening between the greater and less wing of the sphenoid bone on each side, through which the third, fourth, first branch of the fifth, and the sixth pair of

nerves, and the ophthalmic artery pass.

FORAMEN OPTICUM. The hole transmitting the

optic nerve.

FORAMEN OVALE. The opening between the two auricles of the heart of the fætus. See also Innomina-

Foramen of Winslow. An opening in the omentum. See Omentum.

The ethmoid bone. FORAMI'NULUM OS.

FORAMI'NULUM OS. The ethmoid bone.

Force, vital. See Vis vita.

FO'RCEPS. (Forceps, cipis. f.; quasi ferriceps, as being the iron with which we seize any thing hot, from ferrum, iron, and capio, to take.) Pincers. A surgical instrument with which extraneous bodies, or other substances, are extracted. Also an instrument occasionally used by men midwives to bring the head of the ferror through the polyis.

of the fætus through the pelvis.

FORDYCE, GEORGE, was born at Aberdeen, in 1736, after the death of his father, and his mother having married again, he was sent to Fouran, when about two years old, where he received his school edu-cation; and thence returned to Aberdeen, where he was made master of arts, when only fourteen. Having evinced an inclination to medicine, he was soon after sent to his uncle, Dr. John Fordyce, who practised at Uppingham, with whom he remained several years. He then studied at Edinburgh, where he graduated in 1758, having defended a thesis on catarrh: after which he went to Leyden, principally to improve himself in anatomy under Albinus. The following year he settled in London, and began to give lectures on chemistry; and, in 1764, he undertook also to teach the practice of physic, and the materia medica: these subjects occupied him nearly three hours every morning, except on Sunday, for about thirty years successively. In 1770, he was chosen physician to St. Thomas's hospital, and, six years after, a Fellow of the Royal Society: also, in 1787, he was admitted a Fellow of the College of Physicians; having been a licentiate for twenty-two years before. In 1793, he assisted in forming a small Society for the improvement of Medical and Chirurgical Knowledge, which has since pub-1758, baving defended a thesis on catarrh: after which forming a small Society for the improvement of Medical and Chirurgical Knowledge, which has since published three volumes of their Transactions. He died in 1802. The countenance of Dr. Fordyce was by no means expressive of his powers of mind: he was rather negligent of his dress, and not sufficiently pleasing in his manners, to enable him to get into very extensive practice: besides, he was too fond of the pleasures of society, to which he often sacrificed the hours that should have been dedicated to sleep. The vigour of his constitution long resisted these irregularities: of his constitution long resisted these irregularities; but at length they brought on the gout, which was followed by dropsy, and this terminated his existence. He possessed a remarkably strong memory, which enabled him to lecture without any notes, and to compose bled him to lecture without any notes, and to compose his works for publication without referring to authors, which he had before read; and his having relied too much on this faculty may help to explain the want of method and elegance, and the many inaccuracies, which appear in his writings. He was author of several publications on medical and philosophical subjects; many of which are to be found in the transactions of the societies to which he belonged. The most esteemed, and that on which he employed most labour, was a series of "Dissertations on Fever;" four of them ap-

script, which has since been printed. His Treatise on Digestion, was read originally as the Gulstonian Lecture before the College of Physicians. He was the projector of the Experiments in heated rooms, of which Sir Charles Blagden gave an account.

FORDYCE, Sir William, was born at Aberdeen in 1724. At the age of eighteen, having acquired a competent knowledge of physic and surgery, he went into the army. The support of the friends, whom he there procured, together with his own merit, soon brought him into great practice, when he afterward settled in procured, together with his own merit, soon brought him into great practice, when he afterward settled in London. The wealth, which he thus acquired, was liberally employed in acts of friendship, and in supporting useful projects; though he had some very severe losses. He wrote a Treatise on Fevers, and on the Ulcerated Sore Throat; on his entering into practice, he likewise published on the Venereal Disease. He died after a long illness in 1792.

FORENSIC. Forensis. Belonging to the forum, or courts of law: hence forensic medicine is that which is connected with a legal inquiry as to the cause of de-

is connected with a legal inquiry as to the cause of de-

FORESKIN. See Prepuce
FORESTUS, or VAN FOREST, PETER, was born at Alcmaer, in 1522. He was sent to Louvain to study the law, but soon showed a strong inclination to medicine. He therefore cultivated this science at different cine. He therefore cultivated this science at different universities in Italy, and afterward at Paris; but he graduated at Bologna. After being twelve years settled in his native town, he was invited to Delft, which was ravaged by a contagious epidemic; and being extremely successful in the treatment of this, he received a considerable pension, and was retained as the public physician for nearly thirty years. In 1575, he was pre-vailed upon to give the first lecture on Medicine at the opening of the University of Leyden. He spent the latter part of his life in his native city, where he died in 1597. He was a very diligent observer of diseases, and showed often great judgment in anticipating the result, or in treating them successfully. He published at different periods six volumes of Medical and Surgical Cases; to one of which was added a Dissertation, exposing the fallacy and absurdity of pretending to judge of every thing by the urine. Boerhaave has highly commended his writings, which have been often reprinted

(FORMATIONS, MINERAL. "The word Formation may signify a single mass of one kind of rock, more or less extensive, or a collection of mineral substances, formed by the same agent, under the same or similar circumstances; or it may convey the idea, that certain masses or collections of minerals were formed not only by the same agent, but also at the same time. In this latter sense, indeed, the term is almost always employed. The agent and time are to be determined by a careful examination of the external and internal relations of the whole formation."-Cleav. Min.

FO'RMIATE. Formias. A compound produced by the union of the formic acid with a salifiable basis:

thus, formiate of ammonia, &c.

FORMIC ACID. See Formica rufa.

FORMI'CA. (Formica, a. f.; quod ferat micas, because of his diligence in collecting small particles of provision together.)

1. The name of a genus of insects. The ant or pis-

mire. See Formica rufa.

2. The name of a black wart with a broad base, and cleft superficies, because the pain attending it resem-bles the biting of an ant.

3. A varicose tumour on the anus and glans penis.

FORMICA RUFA. The ant or pismire. This industrious little insect contains an acid juice, and gross oil, which were supposed to possess aphrodisiac virtues. The chrysalides of this animal are said to be diuretic and earninglive, and by some recommended in the and carminative, and by some recommended in the

Cure of dropsy.

The ant also furnishes an acid called the formic, which it has been long known to contain, and occasionally to emit. It may be obtained, either by simple distillation, or by infusion of them in boiling water, and subsequent distillation of as much of the water as can be brought over without burning the residue. After this it may be purified by repeated rectifications, or by boiling to separate the impurities; or after rectification it may be concentrated by frost.

This acid has a very sour taste, and continues liquid even at very low temperatures. Its specific gravity is 1.1168 at 68°, which is much denser than acetic acid

ever is.

Dobereiner has recently succeeded in forming this acid artificially. When a mixture of tartaric acid, or of cream of tartar, black oxide of magnesia and water is heated, a turnultness action ensues, carbonic acid is evolved, and a liquid acid distils over, which, on superficial examination, was mistaken for acetic acid, but which now proves to be formic acid. This acid, mixed with concentrated sulphuric acid, is at common temperatures converted into water and carbonic oxide; temperatures converted into water and carbonic oxide; nitrate of silver or of mercury converts it, when gently heated, into carbonic acid, the oxides being at the same time reduced to the metallic state. With barytes, oxide of lead, and oxide of copper, it produces compounds, having all the properties of the genuine formiates of these metals. If a portion of sulphuric acid be employed in the above process, the tartaric acid is resolved entirely into carbonic acid, water, and formic acid; and the product of the latter is much increased. The

best proportions are, two parts tartaric acid, five per-oxide of manganese, and five sulphuric acid diluted with about twice its weight in water. Fo'rmix. See Herpes exedens. FO'RMULA. (Diminutive of forma, a form.) A little form of prescriptions, such as physicians direct in extemporaneous practice, in distinction from the greater forms in pharmacongias &c.

FORNAX. A furnace.
FORNICIFORMIS. Vaulted. Applied to the nectary of some plants; as the Symphytum officinale, &c. See Nectarium.

FO'RNIX. (Fornix, an arch or vault.) A part of the corpus callosum in the brain is so called, because, if viewed in a particular direction, it has some resemblance to the arch of an ancient vault. It is the medullary body, composed of two anterior and two pos-terior crura, situated at the bottom and inside of the lateral ventricle over the third ventricle, and below the septum lucidum.

(From fodio, to dig.) Forea. FO'SSA. A little depression or sinus.

FOSSA AMYNTÆ. A double-headed roller for the

Fossa Magna. 1. The great groove of the ear.
2. The pudendum mulicbre.
Fossa Navicularis. 1. The cavity at the bottom of the entrance of the pudendum muliebre.

2. The great groove of the ear.
Fossa ovalis. The depression in the right auricle of the human heart, which in the fætus opened into the other auricle, forming the foramen ovale.

Fossa PITUITARIA. The depression in the sella turcica of the sphenoid bone.

FO'SSIL. (Fossilis; from fodio, to dig.) Any thing dug out of the earth.

Fossit coral. Highgate resin. A semi-transpa-rent, brittle, resinous substance, of a yellowish-brown colour; found in the bed of blue clay at Highgate, near London.

London.

Fo'ssilus. The bone of the leg.
FOTHERGILL, John, was born in Yorkshire, in 1712, of a respectable Quaker family. After passing through an apprenticeship to an apothecary, he went to Edinburgh, where he graduated at the age of twenty-four, taking for his inaugural thesis the use of emetics. He then studied for two years at St. Thomas's Hospital, and after an excursion to the continent, settled in London in 1740, and six years after became a licentiate. His practice was for some time chiefly gratuitous; but his "Account of the Putrid Sore Throat," published in 1748, brought him speedily into reputation. He was successively elected a Fellow of the College of Physicians at Edinburgh, of the Royal Society of London, and of some other societies abroad. College of Physicians at Edinburgh, of the Royal Society of London, and of some other societies abroad. His early partiality to botany induced him, as his practice increased, to purchase a large piece of ground for the cultivation of rare and valuable plants, in which he spared no expense; neither did he neglect other departments of natural history. He was also an active and liberal promoter of many successful schemes for the public benefit; and particularly in instituting the school at Ackworth in Yorkshire. He was of a rather delicate constitution, but a steady temperance preserved his health, till in 1778 he had an attack of a Rhamnus frangula.

suppression of urine, occasioned by a disease of the prostate gland; which, returning two years after, soon put a period to his existence. He had a quick and comprehensive understanding; and his pleasing address procured him general confidence, which his discretion was not apt to forfeit afterward. Besides the works already noticed, several papers of Dr. Fothergill were printed in the Philosophical Transactions, and in the Medical Observations and Inquiries: he also sent several communications to the Gentleman's Magasent several communications to the Gentleman's Maga-

zine, and other periodical publications.
FO'TUS. (Fotus, ús. m.) See Fomentation
FO'VEA. (From fodio, to dig.) I. A litt (From fodio, to dig.) 1. A little de-

pression.

2. The pudendum muliebre.

3. A partial sweating-bath.

FOVEATUS. Having a little depression, or pit.

Applied to the nectary of plants. See Nectarium.

FOX-GLOVE. See Digitalis.

Fox-glove, Eastern. See Sesamum orientale.

FRACASTORIUS, HIERONYMUS, was born at Version in 1482.

FRACASTORIUS, HIERONYMUS, was born at Verona, in 1483. He made a rapid progress in his studies, and attained early considerable excellence as a poet, philosopher, and astronomer. He was also much valued as a physician, particularly by the general of the Venetian army, whom he attended during several campaigns: but on his dying, in 1515, Fracastorius returned to his native place. He corresponded with most of the great men of his age, especially with Cardinal Bembo, to whom he dedicated his poem, "Syphilis;" which was thought worthy of comparison with the Georgics of Virgil by some of the best judges. He died in 1553; and a statue was erected to him by the town of Verona. He published also on Contagious Diseases, and several other Medical and Philosophical Subjects.

FRA'CTURE. (Fractura; from frango, to break.)
Catagma; Clasis; Clasma; Agme. A solution of a bone into two or more fragments. A simple fracture is when the bone only is divided. A compound fracture is a division of the bone, with a laceration of the integuments, the bone mostly protruding. A fracture is also termed transverse, oblique, &c. according to its

FRÆ NULUM. (Diminutive of frænum, a bridle.) The cutaneous fold under the apex of the tongue, that connects the tongue to the infralingual cavity. It is sometimes, in infancy, so short as to prevent the child from sucking, when it is necessary to cut it, in order to give more room for the notion of the tongue. FRÆNUM. The membraneous fold which con-

sects the prepuce to the inferior part of the glans

FRA'GARIA. (From fragro, to smell sweet.) The strawberry. 1. The name of a genus of plants in the Linnæan system. Class, Icosandria; Order, Poly-

gynia. 2. The pharmacopæial name of the strawberry. See

Fragaria vesca.
Fragaria sterilis. Barren strawberry. Astrin

gent, seldom used.

Fragaria Vesca. The systematic name of the strawberry plant. Fragaria. The mature fruit of the Fragaria, fragellis reptantibus of Linnaus, was formerly recommended in gouty and calculous affections, in consequence, it would appear, of its efficacy in removing tartar from the teeth, which it is said to the removing tartar from the teeth of the removing tartar from the removing tar do very effectually

FRAGILE VITREUM. An obsolete name for the fra

FRAGILE VITREUM. An obsolete name for the fra gilitas ossium.

FRAGILIS. Brittle.

FRAGILITAS. Brittleness.

FRAGILITAS OSSIUM. Brittleness of the bones.

FRA'GMEN. Fragmentum. A splinter of a bone.

FRA'GUM. (From fragro, to smell sweet.) The strawberry. See Fragaria.

FRAMBŒ'SIA. (From framboise, Fr. for a raspberry.) The yaws. A genus of disease, arranged by Cullen in the class Cachexia, and order Impetigines, It is somewhat similar in its nature to the lues venerea, and is endemial to the Antilles islands, as well as Africa. It appears with excrescences like mulberries growing out of the skin in various parts of the body, which discharge an ichorous fluid.

FRA'NGULA. (From frango, to break: so called because of the brittleness of its branches.) See Rhamnus frangula.

FRANKINCENSE. See Juniperus lycie, and Pinus |

FRANCE WALTERI. See American Columbo. A.]
FRAXINE LLA. (From frazinus, the ash: so called because its leaves resemble those of the ash.) See Dictamnus albus.

Fraxinclla, white. See Dictamnus albus.

FRA'XINUS. (A fragore, from the noise its seeds make when shaken by the wind; or from φραξις, a hedge, because of its use in forming hedges.) The

1. The name of a genus of plants in the Linnman system. Class, Polygamia; Order, Diacoia.

2. The pharmacopeial name of the ash-tree. See

Frazinus excelsior.

Fraxinus excelsior.

Fraxinus excelsior. The systematic name of the ash-tree. Frazinus. Called also brumelli and bumelia. The bark of this tree, Frazinus—foliis serratis floribus apetalis of Linnæus, when fresh, has a moderately strong bitterish taste. It possesses resolvent and diuretic qualities, and has been successfully exhibited in the cure of intermittents. The seeds are occasionally exhibited medicinally as diuretics, in the dose of a drachm. In warm climates, a sort of manna exudes drachm. In warm climates, a sort of manna exudes

from this species of fraxinus.

Fraxinus ornus. The systematic name of the tree from which manna flows. This substance is also termed Manna Calabrina; Ros calabrinus; Acromeli; Alusar; Drysomeli. That species which is of a rosy colour, is called nuba. Mel aërium, from the supposition that it descended from heaven. Manna is the condensed juice of the flowering ash, or Fraxinus ornus faliis and a changis servatis neticlatis. floribus nus-foliis ovato oblongis serratis petiolatis, floribus corollatis, Hort. Kew. which is a native of the southern parts of Europe, particularly Sicily and Calabria. Many other trees and shrubs have likewise been ob-Many other trees and shrubs have likewise been observed to emit a sweet juice, which concretes upon exposure to the air, and may be considered of the manna kind, especially the Fraxinus rotundifolia, and excelsior. In Sicily these three species of fraxinus are regularly cultivated for the purpose of procuring manna, and with this view are planted on the declivity of a hill with an eastern aspect. After ten years' growth, the trees first begin to yield the manna, but they require to be much older before they afford it in any considerable quantity. Although the manna exudes spontaneously upon the trees, yet, in order to obtain it more copiously, incisions are made through the bark, by means of a sharp crooked instrument; and the season thought to be most favourable for instituting this process, is a little before the dog days commence, when thought to be most favourable for instituting this pro-cess, is a little before the dog days commence, when the weather is dry and serene. Manna is generally dis-tinguished into different kinds, viz. the manna in tear, the canulated and flaky manna, and the common brown or fat manna. All these varieties seem rather to depend upon their respective purity, and the manner in which they are obtained from the plant, than upon any essential difference of the drug. The best manna any essential difference of the drug. The best manna is in oblong pieces or flakes, moderately dry, friable, very light, of a whitish or pale yellow colour, and in some degree transparent: the inferior kinds are moist, unctuous, and brown. Manna is well known as a gentle purgative, so mild in its operation, that it may be given with safety to children and pregnant women. to the delicacy of whose frames and situations it is particularly adapted. It is esteemed a good and pleasant auxiliary to the purgative neutral salts. It sheathes acrimony, and is useful in coughs, disorders of the breast, and such as are attended with fever and inflammation, as in pleasities for it is particularly inflammation, as in pleuritis, &c. It is particularly efficacious in bilious complaints, and helps the disefficacious in bilious complaints, and helps the discharge of mineral waters, when they are not of themselves sufficiently active. It is apt, in large doses, to create flatulencies and gripes; both of which are prevented by a small addition of some warm carminatives. It purges in doses of from \$\frac{7}{3}\$ to \$\frac{7}{3}\$ ij; but its purgative quality is much increased, and its flatulent effects prevented, by a small addition of cassia. The dose for children is from one scruple to three. It is hest discolved in where best dissolved in whey.

FRAXINUS ROTUNDIFOLIA. The systematic name of a tree which affords manna. See Fraxinus ornus. FREIND, John, was born in 1675, at Croton, in Northamptonshire, of which his father was rector. After being educated at Westminster he went to Oxford, where he distinguished himself greatly by his classical attainments. Having for some time studied

medicine, he communicated to the Royal Society some singular cases: but a work, which he published in 1703, entitled "Emmenologia," explaining the phenomena of menstruation, both natural and morbid, on mechanical principles, first brought him into notice as mechanical principles, first brought him into notice as a physiologist and physician. In the following year, he was appointed professor of Chemistry at Oxford, but soon after went to Spain as physician to the English forces; and he took this opportunity of visiting Italy. On his return, in 1707, he was created a Doctor by diploma, and published his Chemical Lectures in Latin. In 1712, he was chosen a Fellow of the Royal Society: but soon went abroad again with the traces. Society; but soon went abroad again with the troops Society; but soon went abroad again with the troops into Flanders. On the conclusion of the peace in the following year he settled in London, and rose to high professional reputation. In 1716, he was received as Fellow of the College of Physicians, and published the first and third books of Hippocrates on Epidemics, with a Commentary on Fevers, in nine parts; a work of great erudition and judgment. Some of his optnions having been severely attacked, he was led to defend them in a letter to Dr. Mead, entitled "De purgantibus in secundo Variolarum confluentium February fend them in a letter to Dr. Mead, entitled "De purgantibus in secundo Variolarum confluentium Febre adhibendis," 1719. A few years after this he got into parliament, and having warmly sided with the opposition, he was, in common with several persons of consequence, imprisoned on suspicion of high treason: but the minister, Sir Robert Walpole, having fallen sick, Dr. Mead refused to attend him till his friend was liberated; when he made over to him 5000 guineas, which he had received from his patients during his confinement of a few months only. While in the Tower, Dr. Freind formed the plan of his great work, "The History of Physic from Galen to the beginning of the Sixteenth Century, chiefly with regard to Practice;" which came out in two volumes within three years after. This was intended as a continuation of Le Clerc, and met with a very favourable reception; tice;" Which came to yours after. This was intended as a continuation of Le Clerc, and met with a very favourable reception; indeed it still continues to be a standard book. On the accession of George II. he was appointed physician to the Queen; and having died in July 1728, his widow and son experienced the royal protection.

FRE'NA. The sockets of the teeth.

FRE'NA. The sockets of the teeth.
FRIGERA'NA. A putrid fever.
FRIGIDA'RIUM. (From frigidus, cold.)

FRINGE. See Fimbria.

Fringed leaf. See Leaf. FRONS. (Frons, tis. f. or m.) 1. The forehead.

FRONS. (Frons, tis. 1. or m.) 1. The forehead. The part between the eyebrows and the hairy scalp.

2. (Frons, dis, f.) The frond, or leaf; a tree: now used by botanists to the cryptogamious plants only.

FRONTAL. (Frontalis; from frons, the forehead.) Belonging to the forehead.

Frontal bone. See Frontis os.

Frontal sinus. See Frontis os.

Frontal sinus. See Frontis os. FRONTA'LIS. See Occipito frontalis.

FRONTALIS VERUS. See Corrugator supercilii.
FRO'NTIS OS. The frontal bone. Os coronale;
Os inverecundula; Metopon. The external surface of
this bone is smooth at its upper convex part, but below several cavities and processes are observed. At each angle of the orbits the bone juts out to from two interand and two external processes; and the ridge under the eyebrow on each side is called the superciliary process; from which the orbitar processes extend backwards, forming the upper part of the orbits; and between these the ethmoid bone is received. The nasal process is situated between the two internal angular processes. At the internal angular processes. processes. At the internal angular process is a cavity for the caruncula lachrymalis; and at the external, another for the pulley of the major oblique muscle. The foramina are three on each side; one in each superciliary ridge, through which a nerve, artery, and vein, pass to the integuments of the forehead; a second near the middle of the internal side of the orbit, called internal orbitar; the third is smaller, and lies about an inch deeper in the orbit. On the inside of the os inch deeper in the orbit. On the inside of the os frontis there is a ridge which is hardly perceptible at the upper part, but grows more prominent at the bottom, where the foramen cocum appears; to this ridge the falx is attached. The frontal sinus is placed over the orbit on each side, except at this part the frontal bone is of mean thickness between the parietal and occipital; but the orbitar process is so thin as to be almost transparent.

most transparent.
FRUCTIFICATION. (Fructificatio; from fructus,

fruit, and facio, to make.) Under this term are comprehended the flowers and the fruit of a plant. It is a temporary part of plants appropriated to generation, terminating the old vegetable and beginning the new. By the parts of fructification, Sir James Smith observes, each species is perpetually renewed without limits, while all other modes of propagation are but the extension of an individual, and sooner or later terminate in its total extinction. minate in its total extinction. The fructification is therefore essential to vegetables. A plant may be destitute of stem, leaves, or even roots, because if one of these parts be wanting, the others may perform its functions, but it can never be destitute of those organs

by which its species is propagated.

Linnaus distinguishes seven parts of fructification, some of which are essential to the very nature of a flower or fruit; others not so indispensably necessary,

and therefore are not universal.

The calyx, or flower-cup, not essential and often absent. See Calyx.

2. The corolla, or petals, likewise not essential. See

3. The stamen or stamina. These are essential. See Stamen.

4. The pistillum, or pistilla, in the centre of the flower, consisting of the radiments of the fruit, with one or more organs attached to them, and therefore essential. See Pistillum.

5. The pericarpium, or seed-vessel, wanting in many ants. See Pericarpium.
6. The semen, or seed, the perfecting of which is

the sole end of all the other parts.

7. The receptaculum, which must necessarily be present in some form or other. See Receptaculum.

FRU'CTUS. (Fructus, tûs. m.; à fruor.) The fruit of a tree or plant. By this term is understood in botany, the produce of the germen, consisting of the

seed-vessel and seed.

FRUCTUS HOREI. Summer fruits. Under this term are comprehended strawberries, cherries, currants, mul-berries, raspberries, and the like. They possess a berries, raspberries, and the like. They possess a sweet subacid taste, and are exhibited as dietetic auxisweet subacid taste, and are exhibited as dietetic auxiliaries, as refrigerants, antiseptics, attenuants, and aperients. Formerly they were exhibited medicinally in the cure of putrid affections, and to promote the alvine and urinary excretions. The acid which they contain is either the tartaric, oxalic, citric, or mallic, or a mixture of two or more of them with sugar and gluten, starch, and a gelatinous substance. Considering them as an acticle of diet, they afford little powers. them as an article of diet, they afford little nourishment, and are liable to produce flatulencies. To persons of a bilious constitution and rigid fibres, and where the habit is disposed naturally, or from extrinsic causes, to an inflammatory or putrescent state, their moderate and even plentiful use, is salubrious; by those of a cold inactive disposition, where the vessels are lax, the circulation languid, and the digestion weak, they should be used very sparingly. The juices extracted from these fruits by expression, contain their active qualities freed from their grosser indigestible matter. On standing, the juice ferments and changes to a vinous or acetous state. By proper addition of sugar, and by boiling, their fermentative power is suppressed, and their medicinal qualities preserved. The juices of these fruits, when purified from their freculencies by settling and straining, may be made into syrups, with a due proportion of sugar in the usual way.

FRUIT. See Fructus.

Fruits, summer. See Fructus horai.
[Fruits affording spirit. "I shall class only the several productions which afford ardent spirits, and which may be worked to advantage at this day in the form of results of late experiments in some, and a slight knowledge of others, for the benefit of future improve-

ment and research, beginning with
"The Apple. The juice of this fruit (which is
called cider, when expressed and fermented,) affords,
by distillation, one-tenth of its weight of spirit of the
first proof on Dica's hydrometer.

"The Pear. This fruit, when expressed as the apple, affords nearly the same result; the qualities differing, as the quality of the fruit differs, in the same ratio
as the apple. Process, the same as the apple.

as the apple. Process, the same as the apple.

The Peach. This fruit is cultivated in abundance throughout the United States, though in greater abundance to the southward of Pennsylvania. It affords, by distillation, about one-eighth by clear expression. Although this is seldom done, it is nevertheless the best method to procure a fine flavour, which fixes the

principal value

" Peaches intended for distilling are thrown into bins; when the ripest should be assorted out, and thrown into a trough or vat, into which persons enter and mash them with their feet. In the southern states, wooden stampers are used, as they cannot conveniently be ground in a mill, owing to the danger of the stone. This is a practice which might well be remedied, by supplying their mills with stones after the manner of a tanner's bark-mill. It would also be attended with the advantage of breaking the peachstones, which would impart that rich aromatic bitter which its kernel possesses, and which is so highly prized in that celebrated cordial called noyeau. After being well macerated, it is thrown into vats or casks, and diluted with water, so as to prevent an empy-reuma. In this state it is called mobby, and, after a thorough fermentation, it is in that state committed to the still, together with the mass. Others press it in

cider-presses.
"The Plum. This is a fruit which is more used in "The Plam. This is a fruit which is more used in culinary purposes, and for the table. But there is a kind of plum which grows plentifully in most parts of the United States, called the red plum. It is of a beautiful saffron colour, inclining to red. This fruit affords nearly the same product as the peach, and should be treated in the same manner.

"The Charry. There is a variety of this fruit; that which affords the greatest quantity of spirit is the

"The Cherry. There is a variety of this fruit: that which affords the greatest quantity of spirit is the black-heart cherry, which should be treated precisely as the peach. This fruit is more valued for the aromatic flavour which it imparts to spirit, and from which is made the exhilarating water called cherry-

bounce.

"The Papaw is a fruit resembling seed cucumber. Its pulp is of a saffron colour, nearly of the consistence of a melon, and its flavour much like custard. It is too luscious, when ripe, to be agreeable to the palate, but when boiled, green, is pleasant. It ripens about the middle of September; is a native of Kentucky, Maryland, and Pennsylvania. The tree grows from twelve to twenty-six feet high. The fruit affords, by distillation, a societ by some highly prized, and in condistillation, a spirit by some highly prized, and in considerable quantities. The process is well known to the inhabitants where the fruit grows in abundance.

"The Blackberry, Whortleberry, &c. afford spirit in tolerable quantities, by expression, fermentation,

and distillation.

"The Sugar-maple is a tree which abounds in the northern and western parts of the United States: it grows from forty to sixty feet in height. The sap is drawn in February and March: of this sap the inhabitants make large quantities of sugar. This sap, duly fermented and distilled, produces a spirit of a very superior quality, and highly esteemed. The process is simply a fermentation of the sap, and distillation in

simply a termentation of the sap, and distinstical in the common way.

"The Persimmon is a fruit so well known throughout the United States, that a description is unnecessary. This fruit is fit for distillation only after a severe frost, which instantly ripens it, when it is gathered and thrown into a cistern or cask, in which state it is easily crushed and diluted with warm water, formented and the whole mass committed to the still fermented, and the whole mass committed to the still. Some strain the mass through a coarse catgut, which

Some strain the mass through a coarse catgut, which takes out the seeds, that are of a powerful astringent quality. This spirit is not highly esteemed.

"The Potato. There are two kinds of the potato; one of which is commonly called the Irish potato, and the other the sweet potato; the latter of which affords the greatest quantity by distillation. The process is the same in both, yet the sweet potato works more kindly. After being well boiled in water, (steam is the best,) they are macerated by various means (a heavy roller is the best): they are then diluted with a sufficient quantity of water, and strained through a coarse canvass, to separate the skins (this is a process, however, which may be dispensed with); they are then thrown into casks, fermented, and committed to the still. The distillation of potatoes may, in a short time, become a matter worthy of attention. At present, the negroes of Georgia and the Carolinas are the only manufacturers. The spirit is of an inferior quality, and is used by the poorer class of inhabitants but a vast field for improvement lies open. but a vast field for improvement lies open.

"Turnips, Parsnips, Carrots, Pumpions, Cashaws, &c. afford spirit of an inferior quality, and in tolerable quantities. They are to be treated similar to the

potato.
"Grain, of every description, affords spirits of different qualities, according to weight.
Wheat, weighing 60lbs. per bush affords 8 to 12 quarts. Indian corn, 60 10 - 14do. Buckwheat, do. 6-5- 7 do. Barley, do. Speltz, do.

Rice, 70 do.
"The spirit afforded by the distillation of rice is This article is imported chiefly from Bengal, and is distilled from rice, although the real and genuine arrack is distilled in the island of Goa, from the sap of a tree, drawn in

in the island of Goa, from the sap of a tree, drawn in the same manner as our sugar-maple.

"The Grape. In the United States, the cultivation of the domestic grape has but just commenced: the numerous species, however, of our wild grape, with which our forests abound, make it a matter of consideration. These being collected in sufficient quantities, when ripe, they may be treated with success, after the process of the apple, and afford a beautiful spirit, not unlike cogniac.

"Indian Corn (the stalk). The young stalk of the Indian corn, (which should be used about the time of earing,) like the sugar-cane of the West Indies, affords a large quantity of juice or sap by expression, which,

a large quantity of juice or sap by expression, which, when fermented and distilled, yields abundantly of spirit of a very superior quality. This should be broken and worked in the same manner as the sugar-cane, which is by nut-mills of iron, after the manner of our cider mills. **Example Amer. Distiller.** A large provider mills.

which is by nut-mills of iron, after the manner of our cider-mills.—Krafft's Amer. Distiller. A.]

FRUMENTA CEOUS. A term applied to all such plants as have a conformity with wheat, either with respect to their fruit, leaves, or cars.

FRUTESCENTIA. (From fructus, fruit.) The time at which the fruit arrives at maturity.

FRUTEX. A shrub or plant, which rises with a weed durable stem but never arrives at the height or

woody durable stem, but never arrives at the height, or has the appearance of an arbor, or tree.

FUCUS. The name of a genus of plants in the Linnaan system. Class, Cryptogamia; Order, Alga.

Fucus digitatus. This fucus grows upon stones and rocks in the sea near the shore. It has several plain, long leaves or sinuses springing from a round stalk, in the manner of fingers when extended. It affords soda.

Fucus recommendations are recommended to the sea of th

FUCUS ESCULENTUS. Edible fucus. Hudson has made this a distinct species, but Linnaus included it under his saccharinus. It grows plentifully in the sea near the shores of Scotland, and also those of Cumberland. It has a broad, plain, simple, sword-shaped leaf, springing from a pinnated stalk.

FUCUS HELMINTHOCORTON. See Corallina corsicana.
FUCUS PALMATUS. Handed fucus. This grows in
the sea, and consists of a thin-lobed leaf like a hand.

Fucus saccharinus. Sea-belts; so called from the supposed resemblance of its leaves to a belt or girdle. It grows upon rocks and stones by the sea-shore. The leaves are very sweet, and when washed and hung up to dry, will exude a substance like sugar, from whence it was named.

It was named.

FUCUS VESICULOSUS. The systematic name of the sea-oak. Sea wreck. Quercus marina. This seaweed, the Fucus—fronde plana dichotoma costata integerrima, vesiculis axillaribus geminis, terminalibus tuberculatis, of Linnæus, is said to be a useful assistant to sea-water, in the cure of disorder of the glands. Burnt in the open air, and reduced to a black powder, it forms the æthiops vegetabilis, which, as an integral medicine is similar to burnt sponge. internal medicine, is similar to burnt sponge.

But CRIM A prop or support. This term is ap-

FULCRUM. A prop or support. This term is applied by Linnæus, not only to those organs of vegetables correctly so denominated, such as tendrils, but also to various other appendages to the herbage of a plant, none of which are universal or essential, nor is there any one plant furnished with them all. Sir James Smith prefers the English term appendage, for these organs in general, to props, because the latter applies only to one of them. only to one of them.

The greater props, or fulcra of vegetables, are the roots, trunks, and branches.

A 2 '

To the less are referred,

1. The petiolus, or petiole, which is the fulcrum of the leaf.

2. Cirrus, the tendril. See Cirrus.
3. The stolo, or sucker; a filament, or underground bud, protruded from the root, and sending off radicles into the earth, pushes up a stem resembling the parent plant; as in the strawberry, and Syringa vulgaris.

4. Sarmentum, the runner, which gives off from the stem, and radicates on that which is nearest to it; as does the Hedera helix, or ivy.

The fulcra of a flower are the peduncle, scape, and

receptacle.

FULI'GO. (Quasi fumiligo; from fumus, smoke.)
Araxos; Asoper; Asuoli. Soot. Wood-soot, fuligo
ligni, or the condensed smoke from burning wood, has
a pungent, bitter, and nauseous taste, and is resolved
by chemical analysis into a volatile alkaline salt, an
empyreumatic oil, a fixed alkali, and an insipid earth.
The tincture prepared from this substance, finctura
fuliginis, is recommended as a powerful antispasmodic
in hysterical affections.

[FULLER, Dr. Samuel, one of the memorable
planters of Plymouth, who came over with the first
settlers, in 1620. He was the first regularly-educated
physician that visited New-England. He did not confine his benevolent offices to the inhabitants of NewPlymouth, and to the aboriginals of the country, but

Plymouth, and to the aboriginals of the country, but readily gave his assistance to the people of Naumkeak (Salem) and Charlestown, after Mr. Endicott came to that part of Massachusetts Bay. Several of the people died of the 'scurvy, and other distempers,' and many were subjected to diseases arising from unwholesome diet, and want of proper accommodations. Having no physician among themselves, it was for-tunate for those planters that Plymouth could supply them with one so well qualified as Dr. Fuller, who visited them at the request of Governor Endicott, and met with great success in his practice. He visited Salem first in 1628, and again in 1629, on account of the sickness introduced there by the newly-arrived ships. When he arrived at Plymouth, from Salem, Governor Endicott wrote to Governor Bradford a letter of thanks, speaking highly in praise of the physician, and also expressing his hearty concurrence with their church at Plymouth, its form and discipline; from which it is evident that the conversation of Dr. Fuller

which it is evident that the conversation of Dr. Fuller had some effect upon his religious opinions, for there was a difference of sentiment before this interview, and a jealousy, lest the Plymouth church should exercise a jurisdiction over the church in Salem.

In his medical character, and for his Christian virtues and unfeigned piety, Dr. Fuller was held in the highest estimation, and was resorted to as a father and wise counsellor during the perils of his day. He was fiver, which prevailed in Plymouth in the summer of 1633, and was most deeply lamented by all the colo-

fover, which prevailed in Plymouth in the summer of 1633, and was most deeply lamented by all the colonists."—Thatch. Med. Biog. A.]

FULLERS' EARTH. An earth found in large beds in Buckinghamshire and Surrey, composed of silica, alumine, magnesia, lime, muriate of soda, a trace of potassa, and oxide of iron. See Earth, Fuller's.

["FULTON, ROBERT. Notwithstanding the various unsuccessful projects of propelling boats by means of steam-enginery. Mr. Robert Fulton has had the courage to undertake and construct one at New-York, when a plan of his own, and his success is undoubted. rage to undertake and construct one at New-Lork, upon a plan of his own, and his success is undoubted. His hoat is upwards of 140 feet long, and about 15 feet wide, resembling a batteau of large dimensions. The engine is upon the plan of Wait & Boulton's latest improvement, and is a most complete piece of machinery. The power is applied to the water in which the heat moves by means of wheels, with only eight the boat moves, by means of wheels, with only eight arms, revolving on their axis. When the piston makes 20 strokes in a minute, these are turned with a motion brisk enough to stem the currents both of the East and brisk enough to stem the currents both of the East and North rivers, at the rate of four miles and more in an hour. She draws but a few inches of water. She actually made a voyage to Albany and back again in 100 hours, or a little more than four days, and she pro-mises to be of the greatest service in working her way against the streams of rivers, such as the Mississippi, and others that have no tides."—Med. Repos. vol. xi.

The preceding notice of Fulton's first experiment

with his rough-constructed steamboat, was published

in the summer of 1807, in the New-York Medical Re-pository. The writer of this article was on board pository. The writer of this article was on board during the first trial, and observed the anxiety and joy of Mr. Fulton at the prospect before him. The vessel moved from the dock in the eastern part of the city of New-York, and was steered into the North or Hudson where she was anchored, river, opposite Hoboken, where she was anchored, and after remaining there a while, returned to the place of starting. On the next day, Mr. Fulton proceeded to ascend the Hudson river, and, as stated above, was 100 hours in going to Albany and returning thence to New-York, a distance of 300 miles, or nearly that being on a average less than formula. that, being on an average less than four miles an hour. This boat was afterward fitted up as a packet-boat for passengers, and called the Car of Neptune. The next summer (1808) another boat was constructed upon a better model, and her speed surpassed the first. Some alteration or improvement was made in every sub-sequent boat constructed under the direction of Mr. Fulton, until the time of his death, (in Feb. 1815), when his boats went from New-York to Albany in about 20 hours, making an average of more than seven miles an hour. Since his death further improvements have been made in the construction of steamboats and their machinery, so that some of them make the trip from New-York to Albany by daylight, and some have made the passage down the river from Albany to New-York, in the extremely short period of twelve hours, making an average speed of more than twelve miles an hour. It is the opinion of some that further improvements will take place, and that the same distance will be run in nine or ten hours.

Mr. Fulton has the merit of being the first engineer

who made a practical and successful application of steam-power to the propulsion of vessels through the water. He claimed no more. He used Watt & Boulton's steam engine, and modified it to suit his wishes, and the object he had in view; and having succeeded beyond his own most sanguine expectations, and to the astonishment of all his countrymen, he has died and left a legacy of incalculable value to his country and the whole civilized world. Others had indeed engaged in similar experiments, but without success. He was the master spirit who pointed out the true method, and succeeding engineers have profited by his experience; and steamboats now navigate the rivers, bays, and lakes of the United States, in greater numbers than in

any other country.

Robert Fulton was a native of Pennsylvania, and by profession a portrait painter. He became acquaint-ed with Robert Livingston in Paris, while residing there as Minister of the United States near the French government. Their views corresponding on the feasi-bility of constructing a steamboat, Mr. Fulton was patronized by the minister, whose wealth enabled him to make all the necessary advances towards accom-plishing this object. He was so far successful as to put a boat in rapid motion on the river Seine; and after this prelude to his future success, he returned to his native country, and constructed his first boat in 1807, as above stated, from which has emanated all the steamboats now in use in this country and Eu-

FULMINA'TION. Fulminatio. Detonation. quick and lively explosion of bodies, such as takes place with fulminating gold, fulminating powder, and in the combustion of a mixture of inflammable gas and

vital air.

FUMA'RIA. (From fumus, smoke, from its juice, when dropped into the eye, producing the same sensations as smoke.)

1. The name of a genus of plants in the Linnean system. Class, Diadelphia; Order, Decandria. Fu-

mitory.

2. The pharmacopæial name of the common fumi-

See Fumaria officinalis.

FUMARIA BULBOSA. Aristolochia fabacea. The root of this plant, Fumaria—caule simplici, bracteis longitudine florum, of Linnæus, was formerly given to restore suppressed menses, and as an anthelmintic.

FUMARIA OFFICINALIS. The systematic name of the

funitory. Fumaria; Fumus terræ; Capnos; Herba melancholifuga. The leaves of this indigenous plant, Fumaria—pericarpiis monospermis racemosis, caule diffuse, of Linneus, are directed for medicinal use by the Edinburgh college; they are extremely succulent, and have no remarkable smell, but a bitter, somewhat 372

saline taste. The infusion of the dried leaves, or the expressed juice of the fresh plant, is esteemed for its property of clearing the skin of many disorders of the

leprous kind.

FUMIGATION. (Fumigatio; from fumus, smoke.)
The application of fumes, to destroy contagious miasmata or effluvia. The most efficacious substance for mata or effluvia. The most efficacious substance for this purpose is chlorine; next to it the vapour of nitric acid; and, lastly, that of the muriatic. The fumes of heated vinegar, burning sulphur, or the smoke of exploded gunpowder, deserve little confidence as antiloimics. The air of dissecting rooms should be nightly fumigated with chlorine, whereby their atmosphere would be more wholesome and agreeable during the

day. FUMITORY. See Fumaria.

FUMUS. Smoke.

FUNCTION. See Action.

An order of the FUNGI. (The plural of fungus.) class Cryptog amia of Linnæus's system. They cannot probably be said to have any herbage; their substance is fleshy; their parts of fructification are in form of very small capsules buried in their fleshy substance. These seminiferous capsules are on the surface, or in plates and are called lamella, or gills, pores, or prickles, and they burst, as in the algæ.

A fungus or mushroom affords the following parts. Pileus, the hat, which is the round upper part, or

2. The Umbo, the knob, or boss, or more prominent part in the centre of the hat.

3. Lamella, the gills, or membraneous parts on the under side. These are peculiar to the Agarici.

4. The pores, or small punctures on the under surface, observed only in the genus Boletus.

Echini, or Aculei, elevated points on the upper surface of the pileus, noticed in the genus Hydra only.

Verrucæ, warts, observed on the inferior surface.
 Stipes, the stem supporting the hat.

8. Volva, the wrapper, or covering, of a membra-neous texture, surrounding the stem, and concealing the parts of fructification, and in due time bursting all around, forming a ring upon the stalk; as in Agaricus campestris. Linnæus also uses this term for the more fleshy external covering of some other fungi, which is scarcely raised out of the ground, and enfolds the whole plant when young

9. Annulus, the ring, or slender membrane surrounding the stem.

The varieties of the pileus, or hat, are,

1. Planus, flat.

Convexus; as in Boletus bovinus. Concavus; as in Octospora.

4. Umbonatus, umbo or navel-like; as in Agaricue conspurcatus.

Campanulatus; as in Agaricus fimitarius
 Viscidus, viscid.

Dimidiatus, half round; as in Agaricus niveus.
 Squamosus, covered with coloured scales; as in

Agaricus procerus.
9. Squarrosus, having stiff elevated scales; as in

Agaricus conspurcatus.
The varieties of the lamella are,

Equal; as in Agaricus crinitus. Unequal.

3. Branched, when several run into one; as in Merulius cantharellus.

- Decurrent, proceeding down the stem.
 Venous, so small that they appear like elevated
- 6. Dimidiate, half round; as in Agaricus musea-
 - 7. Labyrinth-like; as in Agaricus quercinus The varieties of the volva are,

1. Simple.

2. Double.

3. Stellate, cut several times: as in Lycopodium stellatum.

The varieties of the annulus are,
1. Erect, loose above, and fixed below; as in Agari-

cus conspurcatus.

2. Inverse, fixed above, free, and bell-like below; as in Agaricus Mappa.

3. Sessile, fixed only laterally.

4. Mobile; as in Agaricus antiquatus.

Persistent, remaining after the perfect formation

6. Evanescent, disappearing after the complete evolution of the fungus.

Arachnoid, resembling a slender white web.
 The varieties of the stipes or stem.

The varieties of the stipes or stem.

1. Annulate, having a ring.
2. Naked, without any.
3. Squamose, scaly.
4. Bulbous; as in Agaricus separatus.
5. Filiform; as in Agaricus crinitus.
FUNGIC ACID. Acidum fungicum. The expressed juice of the boletus juglandis, boletus pseudotigniarius, the phallus impudicus, merulius cantharele lus, or the peziza nigra, being boiled to coagulate the albumen, then filtered evaporated to the consistence of bumen, then filtered, evaporated to the consistence of an extract, and acted on by pure alkohol, leaves a sub-

stance which is called Fungic acid.

It is a colourless, uncrystallizable, and deliquescent mass, of a very sour taste. The fungates of potassa and soda are uncrystallizable; that of ammonia forms regular six-sided prisms; that of lime is moderately soluble, and is not affected by the air; that of barytes is soluble in fifteen times its weight of water, and crystallizes with difficulty; that of magnesia appears in soluble granular crystals. This acid precipitates from the acetate of lead a white flocculent fungate, which is soluble in distilled vinegar. When insolated, it does not affect solution of nitrate of silver; but the it does not affect solution of nitrate of silver; but the

fungates decompose this salt.

FUNGIN. The fleshy part of mushrooms deprived by alkohol and water of every thing soluble.

FU'NGUS. 1. Proud-flesh. A term in surgery to express any luxuriant formation of flesh on an ulcer.

2. In morbid anatomy it is applied to a disease of the structure of a part which enlarges, is soft, and excressingly.

3. The name of an order of plants in the Linnman

system, belonging to the Cryptogamia class.

FUNGUS HEMATODES. See Hamatoma.

FUNGUS IGNIARIUS. See Boletus igniarius.

FUNGUS LARICIS. See Boletus laricis.

FUNGUS MELITENSIS. See Cynomorium.

FUNGUS ROSACEUS. See Bedeguar.

FUNGUS SALICIS. The willow fungus. See Boletus suaveoleus.

FUNGUS SAMBUCINUS. See Peziza auricula. FUNGUS VINOSUS. The dark cobweb-like fungus, which vegetates in dry cellars, where wine, ale, and

FUNICULUS. (Funiculus; diminutive of funis,

a cord.) A little cord.

FUNICULUS UMBILICALIS. See Umbilical cord.
The funiculus of a seed is a little filament by which
the immature seed adheres to the receptacle, seen in
Pisum sativum and Lunaria annua.
FU'NIS. A rope or cord.

FUNNEL'SHAPED. See Infundibuliformis.
FURCA. A fork or species of armature of plants. See Aculeus.

FURCE'LLA INFERIOR. The ensiform cartilage.
FU'REULA. The clavicle.
FU'RFUR. 1. Bran.
2. A disease of the skin, in which the cuticle keeps

2. A disease of the skin, in which the cuticle keeps falling off in small scales like bran.

FURFURA'CEOUS. (Furfuraceus; from furfur, bran.) A term applied to the bran-like sediment occasionally deposited in the urine.

FURNACE. Furnus. The furnaces employed in chemical operations are of three kinds:

1. The evaporatory furnace, which has received its name from its use; it is employed to reduce substances into vapour by means of heat, in order to separate the more fixed principles from those which are more volatile.

The reverberatory furnace, which name it has re-ceived from its construction, the flame being prevented

from rising; it is appropriated to distillation.

3. The forge furnace, in which the current of air is determined by bellows.

FUROR. Fury, rage.

FUROR UTERINUS. (From furo, to be mad, and uterus, the womb.) See Nymphomenia.
FURU'NCULUS. (From furo, to rage: so named from its heat and inflammation before it suppurates.) Dothern of Paracelsus. Chiadus; Chioli. A bile. An inflammation of a subcutaneous gland, known by an inflammatory tumour that does not exceed the size of a pigeon's egg.

Fusible metal. A combination of three parts of lead, with two of tin, and five of bismuth. It melts at 197° Fahr.

FUSIBILITY. The property by which metals and minerals assume the fluid state.
FUSIFORMIS. Fusiform. Spindleshaped or ta

pering. Applied to parts of plants, as roots, &c. which penetrate perpendicularly into the earth; as the carrot,

parsnip, radish, &c.

FUSION. (Fusio; from fundo, to pour out.) A chemical process, by which bodies are made to pass from the solid to the fluid state, in consequence of the application of heat. The chief objects susceptible of this operation are salts, sulphur, and metals. Salts are liable to two kinds of fusion; the one, which is peculiar to saline matters, is owing to water contained in them, and is called aqueous fusion; the other, which arises from the heat alone, is known by the name of igneous

FUSUS. (From fundo, to pour out.) Poured out. Applied by Dr. Good to a species of purging, diarrhaa fusa, in which the faces are loose, copious, and of a

bright yellow colour.

GABIA'NUM OLEUM. See Petroleum rubrum. GABI'REA. A fatty kind of myrrh, mentioned

GADOLINATE. A hard black-coloured semitransparent mineral from Sweden, composed of silica, yttria, oxide of cerum, and oxide of iron.

GADUS. The name of a genus of fishes, of the jugular tribe. The following species are brought to the European markets for the use of the table.

GADUS CILIARIS. The Baltic torsk. The Iceland-

Gadus ciliaris. The Baltic torsk. The Icelanders prepare it by salting and drying, when it becomes an article of commerce, under the name of Tetteling. Its flesh is white, tender, and well flavoured.

Gadus morhua. The cod-fish. This well-known fish in our markets, abounds in the northern seas. Its flesh is white, tender, and delicious. When salted, it is also well flavoured, and in general esteem.

Gadus relevinus. The haddock. An inhabitant of the northern seas of Europe. The larger ones are much esteemed during the winter; the smaller ones for summer use. They are of easy digestion. Salted and dried they are eaten at breakfast as a delicacy.

Gadus minutus. Very small, never exceeding six

or seven inches in length. It is found in the Mediterranean in great abundance, where it is called a capelau, or officier.

GADUS MERLANGUS. The whiting. A delicate white fish in great abundance in the Irish seas and German Ocean.

GADUS POLLACIUS. The whiting pollack, found on the rocky coasts of Britain, and other parts of Europe, and is in great esteem for the table.

GADUS CARBONARIUS. The coal-fish. Very abundant on the rocky coasts of the northern parts of this island, about the Orkneys, and the coast of Yorkshire, where they become two and these feet love. where they become two and three feet long, and con-

where they become two and three leet long, and constitute the chief support of the poor.

Gadus Merluccius. The hake. A native of the North and Mediterranean seas, not much eaten, except by the poor when dried, when it is called poor John, or stock-fish.

Gadus Molva. The ling. This grows to the length of five or six feet. It is not so good as the morhua, when fresh; but dried and saited, is much esteemed, and is the common food of the poor in Cornwall, where and is the common food of the poor in Cornwall, where it is prepared for exportation.

GADUS LOTA. The burbot. The flesh of this is

considered delicious and of easy digestion.

GADUS BROSME. The torsk. This swarms in the seas about the Shetland islands, and forms a considerable article of commerce, either dried, or salted, or

[Most of the fishes belonging to the genus Gadus, are edible. Of the preceding enumerated species three of them are common to the waters of the United States, of them are common to the waters of the United States, as the Gadus morhua, Gadus æglefinus, and Gadus merluccius. Besides these, there are found on the stalls of the fishermen in the markets of New-York the following species, viz. Gadus callarias, Gadus tomodus, Gadus blennoides, Gadus purpureus, Gadus tenuis, Gadus longipes, and Gadus punctatus. Of these different species, all of which are used as food, the Gadus morhua, or bank cod, and the Gadus callarias, are the most abundant, and most esteemed. The Gadus merluccius, or hake, is remarkable for its large sound, or swimming-bladder, which is prepared and dried for sale, and forms excellent icthyocolla; (which see.) A.] (which see.) A.]

GALA'CTIA. (From γαλα, lac, milk; or γαλακτινος, lacteus, milky.) Galactirrhaa. 1. An excess or overflowing of the milk.

2. The name of a genus of diseases, Class Genetica; Order, Cenotica, of Good's Nosology. Mislactation. It comprehends five species, viz. Galactia præmatura; defectura; depravata; crrotica; virorum.
GALACTINA. (From γαλα, milk.) Aliment pre-

pared of milk.

GALACTIRRHŒ'A. (From γαλα, milk, and ρεω, to flow.) See Galactia.

GALACTO'DES. (From γαλα, milk.) In Hippocrates it signifies both milk-warm and a milky colour.

GALACTO'PHOPLIS. (From γαλα, milk. and

It signifies both milk-warm and a milky colour. GALACTOPHORUS. (From $\gamma a \lambda a$, milk, and $\phi \epsilon \rho \omega$, to bring or carry.) 1. That which has the property of increasing the secretion of the milk.

2. The excretory ducts of the glands of the breasts of women, which terminate in the papilla, or nipple, are so called, because they bring the milk to the nipple. GALACTOPOIETIC. (Galactopoieticus; from γαλα, milk, and ποιτω, to make.) Milk-making, the faculty of making milk: applied to particular foods, plants &c.

GALACTOPO'SIA. (From $\gamma a \lambda a$, milk, and $\pi \iota \nu \omega$, to drink.) The method of curing diseases by a milk

GALA'NGA. (Perhaps its Indian name.)

Maranta and Kempferia.

Maranta and Kempferia.

Galanga Major. See Kempferia galanga.

Galanga Minor. See Maranta Galanga.

GALANGAL. See Maranta Galanga.

Galangal, English. See Cyperas longus.

GALBANUM. (From chalbanah, Heb.) See Bu-

GA'LBRUM. A medical bracelet worn by the Romans.
GA'LBULUS. (The name of the nut, or little GA'LBULUS. (The name of the nut, or little round ball of the cypress-tree.) Gærtner applies this term, the classical name of the cypress fruit, which is a true strobilus, to a globular spurious berry with three or more seeds formed by the coalescing of a few scales, of a fertile catkin become succulent, which happens in the Juniper.—Smith.

happens in the Juniper.—Smith.

GALBULUS. (From galbus, yellow.) When the skin of the body is naturally yellow.

GA'LDA. A gum-resin, mentioned by old writers, but totally forgot in the present day, and not to be obtained. Externally, it is of a brown colour, but white within, of a hard lamellated structure, and smells and tastes somewhat like elemi. When burnt it gives out an agreeable odour. It was formerly used as a warm stimulating medicine, and applied in plasters as a strengthener.

GA'LEA. (From γαλη, a cai, of the skin of which it was formerly made.) A helmet. 1. In anatomy, the amnios is so called, because it surrounds the fœtus

like a helmet.

In surgery; a bandage for the head.
 A species of headache is so called, when it surrounds the head like a helmet.

4. In botany it is applied to upper arched lip of ringent and personate corols. See Corolla.

GALEANTHRO'PIA. (This term seems to be from $\gamma a \lambda \eta$, a cat, and $\alpha \nu \theta \rho \omega \pi \sigma \varsigma_1$ a man.) It is a species of madness, in which a person imagines himself to be a cat, and imitates its manners.

GA'LEGA. (From yaλa, milk: so named because it increases the milk of animals which eat it.) 1. The name of a genus of plants in the Linnman system. Class, Diadelphia; Order, Decandria.

2. The pharmacopeial name of the Ruta capraria.

See Galega officinalis.

The systematic name of the GALEGA OFFICINALIS. The systematic name of the goat's rue. Galega. Ruta capraria. From the little smell and taste of this plant, Galega leguminibus strictis, erectis; foliolis lanceolatis, striatis, nudis, of Linnæus, it may be supposed to possess little virtues. In Italy, the leaves are eaten among salads.

GALEGE. A species of senna from the East Indies. The cassia tora of Linnæus.

GALE'NA. (From yakiv, to shine.) The name of an ore formed by the combination of lead with sulphur. A native sulphuret of lead ore. GALEGA OFFICINALIS.

hur. A native sulphuret of lead ore.
GALE'NIC. That practice of medicine which con-GALE'NIC. That practice of medicine which conforms to the rules of Galen, and runs much upon multiplying herbs and roots in the same composition, was long called Galenical medicine, after the manner of Galen. It is opposed to chemical medicine, which, by the force of fire, and a great deal of art, fetches out the virtues of bodies, chiefly mineral, into a small

Gale'nium. (From γαληνη, galena.) A cataplasm; in the composition of which was the galena. In Paulus Ægineta it is considered as anodyne.

lus Ægineta it is considered as anodyne.

GALENUS, CLAUDIUS, was born at Pergamus, in Asia Minor, in 131. His father, Nicon, having instructed him in the rudiments of knowledge, sent him to attend the best schools of philosophy. Galen soon displayed his judgment by selecting what appeared most rational from the different sects; but he totally rejected the Epicurean system, which was then in fashion. About the age of 17, he began his attachment to the science of medicine, over which he was destined to preside for many centuries with oracular authority. During his youth, he travelled much, that he might converse with the most intelligent physicians of the age, and inform himself concerning the drugs brought from other countries. He resided several years at Alexandria, which was then the great resort years at Alexandria, which was then the great resort of men of science, and the best school of medicine in the world. At the age of 28, returning to his native place, he met with distinguished success in practice; but four years after he attempted to establish himself at Rome. Here he encountered much because it is at Rome. Here he encountered much opposition from his professional brethren, who stigmatized him as a theorist, and even as a dealer in magic; and though he gained the esteem of several men of learning and rank, yet wanting temper and experience sufficient to maintain a successful contest with a numerous and popular party, he was obliged to return to Pergamus within five years, under the pretence of avoiding the plague, which then raged at Rome. He was, however, soon after sent for to attend the emperors Marcus Aurelius and Lucius Verus, of whom the latter died; and the former conceived so high an opinion of Galen, that subsequently, during his German expedition, he com mitted his two sons to the care of that physician. These princes were seized with fevers, in which Galen having prognosticated a favourable issue, contrary to the opinion of all his colleagues, and having accordingly restored them to health, he attained an eminence of reputation, which enabled him to defy the power, and finally to ruin the credit, of his former opponents. It is not certain whether he continued at Rome till his death, nor at what precise period this occurred; popular party, he was obliged to return to Pergamus It is not certain whether he continued at Rome till his death, nor at what precise period this occurred; but Fabricius asserts that he attained the age of 70, which corresponds to the 7th year of Severus; and his writings appear to indicate, that he was still in that city in the early part of this emperor's reign. The greatest part of Galen's life was spent in the zealous pursuit of knowledge, and especially of every thing which might have the least connexion with medicine; and he is said to have composed about 750 different and he is said to have composed about 750 different essays on such subjects. He appears, however, to have been too much elated with the consciousness of his superior endowments, and to have behaved rather contemptuously towards his brethren; which may have inflamed their opposition to him. The chief object in his writing appears to be to illustrate there are ject in his writing appears to be to illustrate those of Hippocrates, which he thought succeeding physicians had misunderstood or misrepresented: in this he has displayed great acuteness and learning, though he has not much increased the stock of practical information.

His example, too, had the unfortunate effect of introducing a taste for minute distinctions and abstract speculations; while the diligent observation of nature, which distinguished the father of medicine, fell into neglect. We must therefore regret that the splendour of Galen's talents so completely dazzled his successors, that, until about the middle of the 17th century, his opinion bore almost undivided sway. Numerous editions of his works, in the original Greek, or translated into Latin, have been printed in modern times.

GALEO'BDOLON. (From $\gamma a\lambda c_{ij}$, felis, and $\beta \delta c_{ij}$) and δc_{ij} and δc_{ij} and δc_{ij} and a good lodging, do not suffer so much during the sickly season as the poor people: however, these discases are not infectious, and seldom prove mortal to the natives.

Sir John Pringle observes, that the prevailing epidemic of autumn, in all marshy countries, is a fever of an intermitting nature, commonly of a tertian form, but of a bad kind; which, in the dampest places and

lon. See Lamium album.
GALERI'CULUM APONEUROTICUM. GALERI'CULUM APONEUROTICUM. A name in old writings for the tendinous expansion which lies over

the pericranium.

Galipot. See Barras.
GA'LIUM. (From γaλa, milk; some species having the property of coagulating milk.) 1. The name of a genus of plants in the Linnæan system. Class, Tetrandria; Order, Monogynia.
2. The pharmacopæial name of the herb cheeserennet, or ladies' bedstraw. See Galium verum.

3. A name for madder.

GALIUM ALBUM. The greater ladies' bedstraw. See

Galium mollugo.

Galium aparine. The systematic name of the goose-grass, and cleavers' bees. Cleavers; Goose-share; Hayriff. Aparine; Philanthropus; Ampelocarpus; Omphalocarpus; Ixus; Asparine; Asperula. This plant is common in our hedges and ditches: Galium—foliis octonis lanceolatis carinatis scabris retrorsum aculeatis, geniculis venosis, fructu hispido, of Linnæus. The expressed juice has been given with advantage as an aperient and diuretic in incipient dropsies; but the character in which it has of late been chiefly noticed, is that of a remedy against cancer. A tea-cupful, internally, gradually increased to half a pint, two or three times a day, and the herb applied, in cataplasm, externally, has been said to cure cancers. Such beneficial results are not confirmed by the experience of others.

Galium mollugo. The systematic name of the greater ladies' bedstraw. Galium album. Galiumfoliis octonis, ovato-linearibus, subserratis, paten-tissimis, mucronatis; caule flaccido, ramis patentibus of Linnzus. This herb, with its flowers, is used meof Linnzus. This herb, with its flowers, is used me-dicinally. Five ounces or more of the expressed juice, taken every evening upon an empty stomach, is said to

cure epilepsy.

GALIUM VERUM. The systematic name of the true ladies' bed-straw, or cheese-rennet. Galium of the pharmacopæias. The tops of this plant, Galium foliis octonis, linearibus, sulcatis; ramis floriferis, brevibus, of Linnæus, were long used as an efficacious medicine in the cure of epilepsy; but, in the practice of the present day, they are abandoned. Indeed, from the sensible qualities of the plant, little can be expected. The leaves and flowers possess the property of curdling milk; it is on that account styled cheeserennet.

GALL. See Bile. GALL SICKNESS. (See Febris remittens.) popular name for the remitting fever occasioned by marsh miasmata, in the Netherlands, and which proved so fatal to thousands of the English soldiers after the capture of Walcheren in the year 1809. Dr. Lind in-forms us, that at Middleburg, the capital of Walcheren, forms us, that at Middleburg, the capital of Walcheren, a sickness generally reigns towards the latter end of August or the beginning of September, which is always most violent after hot summers. It commences after the rains which fall in the end of July; the sooner it begins the longer it continues, and it is only checked by the coldness of the weather. Towards the end of August and the beginning of September, it is a continual burning fever, attended with a vomiting of bile, which is the gall-sickness. This fever, after continuing three or four days, intermits and assumes the form of a double tertian; leaving the patient in a fortnight or perhaps sooner. Strangers, that have been accustomed to breathe a dry, pure air, do not recover so quickly. Foreigners in indigent circumstances, such as the Scots and German soldiers, who were garrisoned quickly. Foreigners in indigent circumstances, as the Scots and German soldiers, who were garrisoned

many died.

These diseases are the same with the double tertians common within the tropics. Such as are seized with the gall sickness, have at first some flushes of heat over the body, a loss of appetite, a white, foul tongue, a yellow tinge in the eyes, and a pale colour of the lips. Such as live well, drink wine, and have warm clothes and a good lodging, do not suffer so much during the sickly season as the poor people; however, these diseases are not infectious, and seldom prove mortal to the natives.

the natives.

Sir John Pringle observes, that the prevailing epidemic of autumn, in all marshy countries, is a fever of an intermitting nature, commonly of a tertian form, but of a bad kind; which, in the dampest places and worst seasons, appears as a double tertian, a remitting, or even an ardent fever. But, however these may vary in their appearance, according to the constitution of the patient and other circumstances, they are all of a similar nature. For though, in the beginning of the epidemic, when the heat, or rather the putrefaction in the air, is the greatest, they assume a continued or a remitting form; yet, by the end of autumn, they usually terminate in regular intermittents.

terminate in regular intermittents.

But although in the gall sickness there is both a redundance and a depravation of the bile, still the dis-ease cannot, with justice, be said to originate wholly from that cause. It is certain, however, that the dis-ease may be continued, and the symptoms aggravated by an increased secretion and putrefaction of the bile, occasioned by the fever. In proportion to the coolness of the season, or the height and dryness of the ground, this disease is milder, remits and intermits more freely, and removes further from the nature of a continued fever. The higher ranks of people in general are the least liable to the diseases of the marshes; for such countries require dry houses, apartments raised above the ground, moderate exercise, without labour, in the sun, or evening damps; a just quantity of fermented fiquors, plenty of vegetables and fresh meats. Without such helps, not only strangers but the natives themselves are sickly, especially after hot and close summers. The hardiest constitutions are very little expectations.

selves are sickly, especially after hot and close summers. The hardiest constitutions are very little excepted more than others; and hence the British in the Netherlands have always been subject to this fever.

By this disease, the British troops were harassed throughout the war, from 1743 to 1747. It appeared in the month of August, 1743: the paroxysms came on in the evening, with great heat, thirst, a violent headache, and often a delirium. These symptoms lasted most of the night, but abated in the morning, with an imperfect sweat; sometimes with an hamorrhage of the nose, or looseness. The stomach, from the beginning, was disordered with a nausea and sense of oppression; frequently with a bilious and offensive vomiting. If evacuations were either neglected or too vomiting. If evacuations were either neglected or too sparingly used, the patient fell into a continued fever, and sometimes grew yellow, as in jaundice. When the season was further advanced, this fever was at-tended with a cough, rheumatic pains, and sizy blood. The officers, being better accommodated than the com-The officers, being better accommodated than the common men, and the cavalry, who had cloaks to keep them warm, were not so subject to it; and others, who belonged to the army, but lay in quarters, were least of all affected; and the less in proportion to their being exposed to heats, night damps, and the other fatigues of the service. In this manner did the remitting fever infest the army for the remaining years of the war and that exactly in proportion to their distance. war: and that exactly in proportion to their distance

from the marshy places, of which we have several notable instances in Pringle's observations.

GALL-BLADDER. Vesicula fellis. An oblong membraneous receptacle, situated under the liver, to which it is attached in the right hypochondrium. It is composed of three pembranes a common fibreus. which it is attached in the right hypochondrium. It is composed of three membranes, a common, fibrous, and villous. Its use is to retain the bile which regurgitates from the hepatic duct, there to become thicker, more acrid, and bitter, and to send it through the cystic duct, which proceeds from its neck into the ductos communis choledochus, to be sent on to the

duodenum.

GALL-STONE. Calculus biliosus. Biliary concretion. Hard concrete bodies, formed in the gall-bladder of animals. Of these there are four different

GAL GAL

1. The first has a white colour, and when broken presents crystalline plates, or strize, brilliant and white like mica, and having a soft, greasy feel. Sometimes its colour is yellow or greenish; and it has constantly a nucleus of inspissated bile. Its specific gravity is inferior to that of water: Gren found the specific gravity of one 0.803. When exposed to a heat considerably greater than that of boiling water, this crystallized calculus softens and melts, and crystallizes again when the temperature is lowered. It is altogether insoluble in water; but hot alkohol dissolves it with facility. Alkohol, of the temperature of 1670, dissolves one-twentieth of its weight of this substance; but alkohol, at the temperature of 600, scarcely dissolves any of it. As the alkohol cools, the matter is deposited in brilliant plates, resembling tale or boracic acid. It is soluble in oil of turpentine. When melted, it has the appearance of oil, and exhales the smell of melted wax; when suddenly heated, it evaporates altogether in a thick smoke. It is soluble in pure alkalies, and the solution has all the properties of a soap. Nitric acid also dissolves it; but it is precipitated unaltered by water.

This matter, which is evidently the same with the

acid also dissolves it; but it is precipitated unaltered by water.

This matter, which is evidently the same with the crystals Cadet obtained from bile, and which he considered as analogous to sugar of milk, has a strong resemblance to spermaceti. Like that substance, it is of an oily nature, and inflammable; but it differs from it in a variety of particulars. Since it is contained in bile, it is not difficult to see how it may crystallize in the gall-bladder if it happen to be more abundant than usual; and the consequence must be a gall-stone of this species. Fourcroy found a quantity of the same substance in the dried human liver. He called it adipocere.

2. The second species of biliary calculus is of a 2. The second species of bihary calculus is of a round or polygonal shape, often of a gray colour externally, and brown within. It is formed of concentric layers of a matter, which seems to be inspissated bile; and there is usually a nucleus of the white crystalline matter at the centre. For the most part, there are many of this species of calculus in the gall-bladder together; indeed, it is frequently filled with them. The calculi belonging to this species are often light and calculi belonging to this species are often light and friable, and of a brownish-red colour. The gall-stones of oxen, used by painters, belong to this species. These

are also adipocere.

3. The third species of calculi are most numerous of all. Their colour is often deep brown or green; and when broken, a number of crystals of the substance resembling spermaceti are observable, mixed with in-spissated bile. The calculi belonging to these three species are soluble in alkalies, in soap ley, in alkohol,

4. Concerning the fourth species of gall-stone, very little is known with accuracy. Dr. Saunders tells us, that he has met with some gall-stones insoluble both in alkohol and oil of turpentine; some of which do not flame, but become red, and consume to ashes like charcoal. Haller quotes several examples of similar exleuti. Gall-stones often occur in the inferior ani-

denote the same twith some gall-stones insoluble both in alkohol and oil of turpentine; some of which do not flame, but become red, and consume to askes like charcoal. Haller quotes several examples of similar calculi. Gall-stones often occur in the inferior animals, particularly in cows and hogs; but the biliary concretions of these animals have not hitherto been examined with much attention.

Gall-stones often lie quiet; so that until dissection after death, some are never known to exist; but when they are prevented from passing through the gall-ducts, they obstruct the passage of the bile into the intestines, and produce also many inconvenient symptoms, particularly the jaundice.

The diagnostics of this disorder are generally very obscure and uncertain: for other causes produce the same kind of symptoms as those which occur in this disease. The usual symptoms are a loss of appetite, a sense of fulness in the stomach, sickness, and vomiting, languor, inactivity, sleepiness; and, if the obstruction continues for a time, there is wasting of the flesh; yellowness of the eyes, skin, and urine; whitish stools; a pain in the pit of the stomach; while the pulse remains in its natural state. The pain excited by an obstruction of the gall-ducts, in consequence of gall-stones passing through them, and this not affecting the pulse, is considered as the leading pathognomonic symptom. This pain, in some, is extremely acute, in others there is only a slight uneasiness felt about the region of the liver; but its particular seat is the gall-ducting it to the decoction, frequently stirring the mixture and after edulcorating it completely by repeated ablutions, and after edulcorating it completely by repeated ablutions, and fer edulcorating it completely by repeated ablutions, and strain. Dissolve two ounces of alum in water, precipitate the alumina by carbonate of potassa; and after edulcorating it completely by repeated ablutions, and strain. Dissolve two ounces of alum in water, precipitate the alumina by carbonate of pota

duct, just where it enters the duodenum. In some pa-

duct, just where it enters the duodenum. In some patients there is no yellowness of the skin; in others it exists for several months. There is no disease more painful than this, in some instances; it is as frequent as any other affection of the liver; it admits of much relief from medicine, and is not immediately dangerous to the patient. See Icterus.

GA'LLA. (From Gallus, a river in Bithynia.) A gall. See Quercus cerris.

GALLA TURCICA. See Quercus cerris.

["GAL'LÆ. Galls. Most species of the oak, when stimulated by the puncture of an insect, and the deposition of its egg, produce a kind of spherical excrescence, which serves as the habitation and food of the young larva when hatched. These excrescences are known by the general name of galls, and are produced on various parts of the trees by different insects of the genera Cynips, and Diplolepsis. The best galls, and those which predominate in commerce, are brought from Smyrna, Aleppo, and the neighbouring countries. The Edinburgh College considers them as produced on the Quercus Cerris, a tree growing in the south of Europe. The French traveller, Olivier, informs us, that the Asiatic galls are the product of a species of oak, which he names Quercus infectoria, and that the puncturing insect is the Diplolepsis gallaw tinctoriae of Geoffroy. Both the insect and the gall have been observed in France.

Good galls are round, of a dark colour, and studded with tubercles. They are of various sizes, under that of a cherry. They are hard, brittle, and exhibit an irregular and partly resinous fracture. Their taste is highly astringent, and somewhat bitter and acrid. Those which have been perforated by the insect are of an inferior quality, their central portion being consumed.

highly astringent, and somewhat bitter and acrid. Those which have been perforated by the insect are of an inferior quality, their central portion being consumed. The chemical constituents, which give to galls their chief value, are tannin and gallic acid. Besides these, they contain, according to Davy, extractive mucilage; according to Bronchi, a concrete, volatile oil; and according to Braconnot, another acid, which he calls ellagic acid. Chemists, however, are not agreed as to their entire composition. It is obvious, that the presence or absence of the larva, as well as its stage of growth, must materially affect the analysis.

Most metallic salts produce precipitates with infu-

Most metallic salts produce precipitates with infusion of galls, consisting of the metallic oxides, tannin, and gallic acid. It is questionable how far the astringency of the galls is affected by such combinations. The sulphuric and muriation acids, lime water, and the alkaline carbonates also occasion precipitates. Gelaalkaline carbonates, also, occasion precipitates. Gela-tin and starch combine immediately with the tannin

of the galls.

Galls are among the most powerful vegetable astringents. They are sometimes given internally, in doses of a scruple; but their chief medical use is as a local

with a glass rod. The next day filter the mixture, wash the precipitate with warm water, till this will no longer blacken sulphate of iron; mix the washings with the filtered liquor, evaporate, and the gallic acid will be obtained in fine needled crystals.

These crystals obtained in any of these ways, however, are contaminated with a small portion of ex-tractive matter; and to purify them they may be placed in a glass capsule in a sand-heat, and sub-limed into another capsule inverted over this, and kept

The gallic acid placed on a red-hot iron, burns with flame, and emits an aromatic smell, not unlike that of benzoic acid. It is soluble in 20 parts of cold water, and in three parts at a boiling heat. It is more soluble in alkohol, which takes up an equal weight if heated, and one-fourth of its weight cold.

It has an acido-astringent taste, and reddens tincture of litmus. It does not attract humidity from the

This acid, in its combinations with the salifiable bases, presents some remarkable phenomena. If we pour its aqueous solution by slow degrees into lime, pour its aqueous solution by slow degrees into lime, barytes, or strontites water, there will first be formed a greenish-white precipitate. As the quantity of acid is increased, the precipitate changes to a violet hue, and eventually disappears. The liquid has then acquired a reddish tint. Among the salts, those only of black oxide and red oxide of iron, are decomposed by the pure gallic acid. It forms a blue precipitate with the first, and a brown with the second. But when this acid is united with tannin, it decomposes aimost all the salts of the permanent metals.

Concentrated sulphuric acid decomposes and carbo-nizes it; and the nitric acid converts it into malic and oxalic acids.

United with barytes, strontian, lime, and magnesia, it forms salts of a dull yellow colour, which are little soluble, but more so if their base be in excess. With alkalies it forms salts that are not very soluble in

Its most distinguishing characteristic is its great affinity for metallic oxides, so as, when combined with tannin, to take them from powerful acids. The more readily the metallic oxides part with their oxygen, the more they are alterable by the gallic acid. To a solution of gold, it imparts a green hue; and a brown precipitate is formed, which readily passes to the metallic state, and covers the solution with a shining golden pellicle. With nitric solution of silver, it produces a similar effect. Mercury it precipitates of an orange-yellow; copper, brown; bismuth, of a lemon colour; lead, white; iron, black. Platina, zinc, tin, cobalt, and manganese, are not precipitated by it.

The gallic acid is of extensive use in the art of dying, as it constitutes one of the principal ingredients in all the shades of black, and is employed to fix or im-Its most distinguishing characteristic is its great

GA'LVANISM. A professor of anatomy, in the university of Bologna, named Galvani, was one day making experiments on electricity in his elaboratory: near the machine were some frogs that had been flayed, the limbs of which became convulsed every time a spark was drawn from the apparatus. Galvani, surprised at this phenomenon, made it a subject of investigation, and discovered that metals, applied to the nerves and muscles of these animals, occasioned powerful and sudden contractions, when disposed in a cer-tain manner. He gave the name of animal electricity to this order of new phenomena, from the analogy that he considered existing between these effects and those produced by electricity.

The name animal electricity has been superseded,

notwithstanding the great analogy that exists between the effects of electricity and those of Galvanism, in favour of the latter term; which is not only more cold blood, on the contrary, it is more durable.

applicable to the generality of the phenomena, but likewise serves to perpetuate the memory of the dis-

In order to give rise to Galvanic effects in animal bodies, it is necessary to establish a communication between two points of one series of nervous and muscular organs. In this manner a circle is formed, one arch of which consists of the animal parts, rendered the subject of experiment, while the other arch is composed of excitatory instruments, which generally consist of several pieces, some placed under the animal parts called supporters, others destined to establish a communication between the latter, are called conductors. To form a complete Galvanic circle, take the thigh of a frog, deprived of its skin; detach the crural nerve, as far as the knee; put it on a piece of zinc; put the muscles of the leg on a piece of silver; then finish the excitatory arch, and complete the Gal-vanic circle by establishing a communication by means of the two supporters; by means of iron or copper-wire, pewter or lead. The instant that the communi-cators touch the two supporters, a part of the animal arch formed by the two supporters will be convulsed. Although this disposition of the animal parts, and of Galvanic instruments, be most favourable to the deve-In the composition of the animal and excitatory arch may be much varied. Thus contractions are obtained, by placing the two supporters under the nerve, and leaving the muscle out of the circle, which proves that nerves essentially constitute the animal arch. stitute the animal arch.

It is not necessary for nerves to be entire in order to produce contractions. They take place whether the organs be tied or cut through, provided there exists a simple contiguity between the divided ends. This proves that we cannot strictly conclude what happens in muscular action. Computer which takes placed in in muscular action, from that which takes place in Galvanic phenomena; since, if a nerve be tied or di-vided, the muscles on which this is distributed lose the

power of action.

The cuticle is an obstacle to Galvanic effects; they are always feebly manifested in parts covered by it.
When it is moist, fine, and delicate, the effect is not entirely interrupted. Humboldt, after having detached the cuticle from the posterior part of the neck and back, by means of two blisters, applied plates of metal to the bare cutis, and, at the moment of establishing a communication, he experienced sharp prickings, accompanied with a sero-sanguineous discharge.

Ings, accompanied with a sero-sanguineous discharge.

If a plate of zinc be placed under the tongue, and a flat piece of silver on its superior surface, on making them touch each other, an acerb taste will be perceived, accompanied with a slight trembling.

The excitatory arch may be constructed with three, two, or even one metal only, with alloys, amalgams, or other metallic or mineral combinations, carbonated substances for all is observed that metals which are substances, &c. It is observed that metals which are in general the most powerful excitors, induce contractions so much the more as they have an extent of surface. Metals are all more or less excitants; and it is observed that zinc, gold, silver, pewter, are of the highest rank; then copper, lead, nickel, anti-

Galvanic susceptibility, like muscular irritability, is exhausted by too long continued exercise, and is recruited by repose. Immersion of nerves and muscles in alkohol and opiate solutions diminishes, and even destroys. destroys, this susceptibility, in the same manner, doubtless, as the immoderate use of these substances in the living man blunts, and induces paralysis in mus-cular action. Immersion in oxymuriatic acid restores the fatigued parts, to be again acted on by the stimulus. Animals killed by the repeated discharge of an electric battery, acquire an increase of Galvanic susceptibility; and this property subsists unchanged in animals destroyed by submersion in mercury, pure hydrogen gas, azote, and ammonia; and finally, it is totally annibilated in animals suffocated by the vapour of charcoal.

Galvanic susceptibility is extinct in the muscles of Galvanic susceptionty is extinct in the muscles of animals of warm blood, in proportion as vital heat is dissipated; sometimes even when life is terminated in convulsions, contractility cannot be put into action, although warmth be not completely gone, as though the vital property were consumed by the convulsion, amidst which the animals had expired. In those of

thighe of frogs, long after being separated from every thing, and even to the instant of incipient putrefaction, are influenced by Galvanic stimuli; doubtless, because irritability, in these animals, is less intimately connected with respiration, and life more divided among the different organs, which have less occasion to act on each other for the execution of its phenomena. The Galvanic chain does not produce sensible persons the content of th each other for the execution of its phenomena. The Galvanic chain does not produce sensible actions (that is, contractions,) until the moment it is completed, by establishing a communication with the parts constituting it. During the time it is complete, that is, throughout the whole space of time that the communication remains established, every thing remains tranquil; nevertheless, Galvanic influence is not suspended: in fact, excitability is evidently increased, or diminished, in muscles that have been long continued in the Galvanic chain, according to the difference of

alminished, in muscles that have been long continued in the Galvanic chain, according to the difference of the reciprocal situation of the connecting metals.

If silver has been applied to nerves, and zinc to muscles, the irritability of the latter increases in proportion to the time they have remained in the chain. By this method, the thighs of frogs have been revivified in some degree, and afterward become sensible to stimuli, that before had ceased to act on them. By distributing the metals in an inverse manner applying tributing the metals in an inverse manner, applying zinc to nerves and silver to muscles, an effect absolutely contrary is observed; and the muscles that pos-sess the most lively irritability when placed in the chain, seem to be rendered entirely paralytic if they remain long in this situation.

This difference evidently depends on the direction of the Galvanic fluid, determined towards the muscles or nerves, according to the manner in which these metals are disposed, and this is of some importance to be known for the application of Galvanic means to the

cure of diseases.

cure of diseases.

Galvanic Pile.—Volta's apparatus is as follows:—
Raise a pile, by placing a plate of zinc, a flat piece of wet card, and a plate of silver, successively; then a second piece of zinc, &c. until the elevation is several feet high; for the effects are greater in proportion to its height; then touch both extremities of the pile, at the same instant, with one piece of iron wire; at the moment of contact, a spark is excited from the extremities of the pile, and luminous points are often perceived at different heights, where the zinc and silver come into mutual contact. The zinc end of this pile appears to be negatively electrified; that formed by the silver, on the contrary, indicates marks of positive electricity. on the contrary, indicates marks of positive electricity.

If we touch both extremities of the pile, after having

dipped our hands into water, or, what is better, a sa-line solution, a commotion, followed by a disagreeable prickling in the fingers and elbow, is felt.

If we place in a tube filled with water, and herme-tically closed by two corks, the extremities of two wires of the same metal which are in contact at the wires of the same metal which are in contact at the other extremity, one with the summit, the other with the base of the pile; these ends, even when separated only by the space of a few lines, experience evident changes at the instant the extremities of the pile are touched; the wire in contact with that part of the pile composed of silver becomes covered with bulke of hydrogen gas; that which touches the extremity formed by give becomes oxidized, or gives off oxygen gas. by zinc, becomes oxidized, or gives off oxygen gas. Fourcroy attributes this phenomenon to the decomposition of water by the Galvanic fluid, which abandons the oxygen to the metal that touches the positive ex-tremity of the pile; then conducts the other gas invisi-bly to the end of the other wire there to be disen-

gaged.

Galvanic Trough.—This is a much more convenient apparatus. Plates of two metals, commonly zinc and copper, are fastened together, and cemented into a wooden trough, so as to form a number of cells; or earthenware troughs with partitions being procured, the metals connected by a slip, are suspended over these, so that in each cell, except at the ends, there is a plate of each metal; then a diluted acid, (usually the sulphuric, nitric, or muriatic mixed with from twelve to twenty parts of water,) is poured into the trough. It is necessary that the metals be placed in the same order throughout, or one series will counteract another. The zinc end becomes negative, the copper positive; and the power is in proportion to the number of the series: and several such troughs may be connected together, so as to form a most powerful apparatus.

From the number of experiments of Davy, many

new and important facts have been established, and Galvanism has been found one of the most powerful Galvanism has been found one of the most powerful agents in chemistry: by its influence, platina wire has been melted; gold, silver, copper, and most of the metals, have easily been burnt; the fixed alkalies, and many of the earths, have been made to appear as consisting of a metallic base, and oxygen; compound substances, which were before extremely difficult to decompose, are now, by the aid of Galvanism, easily resolved into their constituents.

The Galvanic influence has been considered by some

The Galvanic influence has been considered by some practitioners as likely to increase the nervous influence in paralyzed and debilitated states of the muscular sysin paralyzed and debilitated states of the muscular sys-tem, and many ingenious ways of applying it have been resorted to; but it does not seem to have been useful. Dr. Ure's observations and experiments on this subject and on Galvanism are highly interesting. The following account of them is extracted from his Chemical Dictionary. "Many experiments," he ob-serves, "have oeen performed, in this country and abroad, on the bodies of criminals, soon after their execution. Vassali, Julio, and Rossi, made an ample set, on several bodies decapitated at Turin. They paid particular attention to the effect of Galvanic electricity on the heart, and other involuntary muscles: paid particular attention to the cast particular attention to the a subject of much previous controversy. Volta asserted, that these muscles are not at all sensible to this electric power. Fowler maintained, that they were affected; but with difficulty and in a slight degree. This opinion was confirmed by Vassali; who further showed, that the muscles of the stomach and intestines might thus also be excited. Aldini, on the contrast declared that he could not affect the heart by his trary, declared, that he could not affect the heart by his most powerful Galvanic arrangements.

Most of the above experiments were however made, either without a voltaic battery, or with piles, feeble in comparison with those now employed. Those indeed performed on the body of a criminal, at Newgate, in which the limbs were violently agitated; the eyes opened and shut; the mouth and jaws worked about, and the whole face thrown into frightful convulsions, were made by Aldini with I believe a considerable were made by Aldini, with, I believe, a considerable series of voltaic plates.

A circumstance of the first moment, in my opinion A circumstance of the first moment, in my opinion, has been too much overlooked in experiments of this kind,—that a muscular mass through which the Galvanic energy is directly transmitted, exhibits very weak contractile movements, in comparison with those which can be excited by passing the influence along the principal nerve of the muscle. Inattention to this important distinction, I conceive to be the principal source of the slender effects hitherto produced in such experiments on the heart, and other muscles, independent.

important distinction, I conceive to be the principal source of the slender effects hitherto produced in such experiments on the heart, and other muscles, independent of the will. It ought also to be observed, that too little distinction has been made between the positive and negative poles of the battery; though there are good reasons for supposing, that their powers on muscular contraction are by no means the same.

According to Ritter, the electricity of the positive pole augments, while the negative diminishes, the actions of life. Tumefaction of parts is produced by the former; depression by the latter. The pulse of the hand, he says, held a few minutes in contact with the positive pole, is strengthened; that of the one in contact with the negative is enfeebled: the former is accompanied with a sense of heat; the latter with a feeling of coldness. Objects appear to a positively electrified eye, larger, brighter, and red; while to one negatively electrified, they seem smaller, less distinct, and blunsh,—colours indicating opposite extremities of the prismatic spectrum. The acid and alkalines tastes, when the tongue is acted on in succession by the two electricities, are well known, and have been ingeniously accounted for by Sir H. Davy, in his admirable Bakerian lectures. The smell of oxymuriatic acid, and of ammonia, are said by Ritter to be the opposite odours, excited by the two opposite poles; as a full body of sound and a sharp tone are the corresponding effects on the ears. These experiments require verification.

Consonant in some respects, though not in all, with

Consonant in some respects, though not in all, with these statements, are the doctrines taught by a London practitioner, experienced in the administration of medical electricity. He affirms, that the influence of the electrical fluid of our common machines, in the cure of diseases, may be referred to three distinct heads; first, the form of radii, when projected from a point

positively electrified; secondly, that of a star, or the negative fire, concentrated on a brass ball; thirdly, the Leyden explosion. To each of these forms he assigns Leyden explosion. To each of these forms he assigns a specific action. The first acts as a sedative, allaying morbid activity; the second as a stimulant; and the last has a deobstruent operation, in dispersing chronic tumours. An ample narrative of cases is given in confirmation of these general propositions. My own experience leads me to suppose, that the negative pole of a Voltaic battery gives more poignant sensations than the recitive. than the positive.

The most precise and interesting researches on the relation between Voltaic electricity and the phenomena of life, are those contained in Dr. Wilson Philip's Dis-sertations in the Philosophical Transactions, as well as in his experimental Inquiry into the Laws of the

as in his experimental inquiry into the Laws of the Vital Functions, more recently published.

In his earlier researches he endeavoured to prove, that the circulation of the blood, and the action of the involuntary muscles, were independent of the nervous influence. In a late paper, read in January, 1816, he showed the immediate dependence of the secretory functions on the nervous influence.

The eighth pair of nerves distributed to the stomach, and subserviant to direction, were divided by incisions.

and subservient to digestion, were divided by incisions in the necks of several living rabbits. After the operation, the parsley which they are remained without alteration in their stomachs; and the animals, after evincing much difficulty of breathing, seemed to die of evincing much difficulty of breathing, seemed to die of suffocation. But when in other rabbits, similarly treated, the Galvanic power was transmitted along the nerve, below its section, to a disc of silver, placed closely in contact with the skin of the animal, opposite to its stomach, no difficulty of breathing occurred. The Voltaic action being kept up for twenty-six hours, the rabbits were then killed, and the parsley was found in as perfectly digested a state, as that in healthy rabbits fed at the same time; and their stomachs evolved the smell peculiar to that of a rabbit during digestion. These experiments were several times repeated with These experiments were several times repeated with similar results.

Hence it appears that the Galvanic energy is capable of supplying the place of the nervous influence, so that, while under it, the stomach, otherwise inactive, digests food as usual. I am not, however, wining to adopt the conclusion drawn by its ingenious author, that the identity of Galvanic electricity and nervous influence is established by these experiments.' They clearly show a remarkable analogy between these two however, since the one may serve as a substitute for the powers, since the one may serve as a substitute for the other. It might possibly be urged by the anatomist, that as the stomach is supplied by twigs of other nerves, which communicate under the place of Dr. Philip's section of the par vagum, the Galvanic fluid may operate merely as a powerful stimulus, exciting those slender twigs to perform such an increase of action, as may compensate for the want of the principal nerve. The above experiments were remeated on dozen The above experiments were repeated on dogs, with like results; the battery never being so strong as to occasion painful shocks.

The removal of dyspnæa, as stated above, led him to try Galvanism as a remedy in asthma. By transmitting its influence from the nape of the neck to the pit of the stomach, he gave decided relief in every one of twenty-two cases, of which four were in private practice, and eighteen in the Worcester Infirmary. The power employed varied from ten to twenty-five pairs.

The general inferences deduced by him from his multiplied experiments, are, that Voltaic electricity is capable of effecting the formation of the secreted fluids, when applied to the blood in the same way in which

capable of effecting the formation of the secreted fluids, when applied to the blood in the same way in which the nervous influence is applied to it; and that it is capable of occasioning an evolution of caloric from arterial blood. When the lungs are deprived of the nervous influence, by which their function is impeded, and even destroyed, when digestion is interrupted, by withdrawing this influence from the stomach, these two vital functions are renewed by exposing them to the influence of a Galvanic trough. 'Hence,' says he, 'Galvanism seems capable of performing all the functions fo the nervous influence in the animal economy; but obviously it cannot excite the functions of animal life, unless when acting on parts endowed with the living principle.'

These results of Dr. Philip have been recently confirmed by Dr. Clarke Abel, of Brighton, who employed, in one of the repetitions of the experiments, a com-

paratively weak, and in the other a considerable power of Galvanism. In the former, although the Galvanism was not of sufficient power to occasion evivanism was not of sufficient power to oceasion evident digestion of the food, yet the efforts to vomit, and the difficulty of breathing, constant effects of dividing the eighth pair of nerves, were prevented by it. These symptoms recurred when it was discontinued, and vanished on its reapplication. 'The respiration of the animal,' he observes, 'continued quite free during the experiment, except when the disengagement of the nerves from the tin-foil rendered a short suspension of the Galvanism necessary during their readjustment.' The nongalvanized rabbit breathed with difficulty, wheezed audibly, and made frequent attempts to vomit.' In the latter experiment, in which the greater power of Galvanism was employed, digestion went on as in Dr. Philip's experiments.—Jour. Sc. ix.

Gallois, an eminent French physiologist, had endeavoured to prove, that the motion of the heart depends entirely upon the spinal marrow, and immediately ceases when the spinal marrow is removed or destroyed. Dr. Philip appears to have refuted this notion by the following experiments. Rabbits were rendered insensible by a blow on the occiput; the spinal marrow and brain were then removed, and the respiration kept up by artificial means; the motion of the heart, and the circulation, were carried on as usual. When spirit of wine or opium was applied to the spinal marrow or brain, the rate of the circulation was accelerated. dent digestion of the food, yet the efforts to vomit, and

nal marrow or brain, the rate of the circulation was

the professor.

A middle-sized, athletic, and extremely muscular man, about thirty years of age, was the subject of the following highly interesting experiments. He was suspended from the gallows nearly an hour, and made no convulsive struggle after he dropped; while a thief, executed along with him, was violently agitated for a considerable time. He was brought to the

tated for a considerable time. He was brought to the anatomical theatre of our university in about ten minutes after he was cut down. His face had a perfectly natural aspect, being neither livid nor tumefied; and there was no dislocation of his neck.

Dr. Jeffray, the distinguished professor of anatomy, having on the preceding day requested me (says Dr. Ure) to perform the Galvanic experiments, I sent to his theatre, with this view, next morning, my minor Voltaic battery, consisting of 270 pairs of four-inch plates, with wires of communication, and pointed metallic rods with insulating handles, for the more commodious application of the electric power. About five tailic rods with insulating handles, for the more commodious application of the electric power. About five minutes before the police officers arrived with the body, the battery was charged with a dilute nitro-sulphuric acid, which speedily brought it into a state of intense action. The dissections were skilfully executed by Mr. Marshal, under the superintendence of the professor.

Exp. 1. A large incision was made into the nape of the neck, close below the occiput. The posterior half of the atlas vertebra was then removed by bone forof the atlas vertebra was then removed by bone forceps, when the spinal marrow was brought into view. A profuse flow of liquid blood gushed from the wound, inundating the floor. A considerable incision was at the same time made in the left hip, through the great gluteal muscle, so as to bring the sciatic nerve into sight; and a small cut was made in the heel. From neither of these did any blood flow. The pointed rod connected with one end of the battery, was now placed in contact with the spinal marrow, while the other rod was applied to the sciatic nerve. Every muscle of the body was immediately agitated with convulsive movements, resembling a violent shuddering from cold. The left side was most powerfully convulsed at each renewal of the electric contact. On convulsed at each renewal of the electric contact. On moving the second rod from the hip to the heel, the knee being previously bent, the leg was thrown out with such violence as nearly to overturn one of the assistants, who in vain attempted to prevent its ex-

tension.

Exp. 2. The left phrenic nerve was now laid bare at the outer edge of the sterno-thyroideus muscle, from three to four inches above the clavicle; the cutaneous incision having been made by the side of the sterno-cleido mastoideus. Since this nerve is distributed to the disphragm, and since it communicates. buted to the diaphragm, and since it communicates with the heart through the eighth pair, it was expected, by transmitting the Galvanic power along with it, that the respiratory process would be renewed. Accordingly, a small incision having been made under the

cartilage of the seventh rib, the point of the one insu- | plans of administering Voltaic electricity, hitherto pur lating rod was brought into contact with the great head of the diaphragm, while the other point was ap-plied to the phrenic nerve in the neck. This muscle, the main agent of respiration, was instantly contracted. but with less force than was expected. Satisfied, from ample experience on the living body, that more power-ful effects can be produced in Galvanic excitation, by leaving the extreme communicating rods in close conleaving the extreme communicating rods in close contact with the parts to be operated on, while the electric chain or circuit is completed by running the end of the wires along the top of the plates in the last trough of either pole, the other wire being steadily immersed in the last cell of the opposite pole, I had immediate recourse to this method. The success of it was truly wonderful. Full, nay, laborious breathing, instantly commenced. The chest heaved, and fell; the belly was protruded, and again collapsed, with the relaxing and retiring diaphragm. This process was continued, without interruption, as long as I continued the electric discharges.

without interruption, as long as I continued the erectric discharges.

In the judgment of many scientific gentlemen who witnessed the scene, this respiratory experiment was perhaps the most striking ever made with a philosophical apparatus. Let it also be remembered, that for full half an hour before this period, the body had been well nigh drained of its blood, and the spinal marrow severely lacerated. No pulsation could be perceived meanwhile at the heart or wrist; but it may be supposed, that but for the evacuation of the blood,—the essential stimulus of that organ,—this phenomenon might also have occurred.

might also have occurred.

Exp. 3. The supra-orbital nerve was laid bare in the forehead, as it issues through the supra-ciliary fora-men, in the eyebrow: the one conducting rod being applied to it, and the other to the heel, most extraor-dinary grimaces were exhibited every time that the electric discharges were exhibited every time that the electric discharges were made, by running the wire in my hand along the edges of the last trough, from the 220th to the 270th pair of plates: thus fifty shocks, each greater than the preceding one, were given in two seconds. Every muscle in his countenance was simultaneously thrown into fearful action; rage, horror, despair, anguish, and ghastly smiles, united their hideous expression in the murderer's face, surpassing far the wildest representations of a Fuseli or a Kean. At this period several of the spectators were forced to leave the apartment from terror or sickness, and one

leave the apartment from terror or sickness, and one gentleman fainted.

Ezp. 4. The last Galvanic experiment consisted in transmitting the electric power from the spinal marrow to the ulnar nerve, as it passes by the internal condyle at the elbow: the fingers now moved nimbly, like those of a violin performer; an assistant, who tried to close the fist, found the hand to open forcibly, in spite of his efforts. When the one rod was applied to a slight incision in the tip of the forefinger, the fist being previously clenched, that finger extended instantly; and from the convulsive agitation of the arm, he seemed to point to the different spectators, some of whom thought he had come to life.

About an hour was spent in these operations.

About an hour was spent in these operations.

In deliberating on the above Galvanic phenomena, we are almost willing to imagine, that if, without cutting into and wounding the spinal marrow and bloodvessels in the neck, the pulmonary organs had been set a-playing at first, (as I proposed,) by electrifying the phrenic nerve, (which may be done without any dangerous incision,) there is a probability that life might have been restored. This event, however little desirable with a murderer, and perhaps contrary to law, would yet have been pardonable in one instance, as it would have been highly honourable and useful to science. From the accurate experiments of Dr. Philip it appears, that the action of the diaphragm and lungs is indispensable towards restoring the suspended action of the heart and great vessels, subservient to the circulation of the blood.

It is known, that cases of deathlike lethargy, or suspended animation, from disease and accidents, have occurred, where life has returned, after longer interruption of its functions than in the subject of the preceding experiments. It is probable, when apparent death supervenes from suffocation with noxious gases, &c. and when there is no organic læsion, that a judiciously directed Galvanic experiment will, if any thing will, restore the activity of the vital functions. The

plans of administering Voltaic electricity, hitherto pur sued in such cases, are, in my humble apprehension, very defective. No advantage, we perceive, is likely to accrue from passing electric discharges across the chest, directly through the heart and lungs. On the principles so well developed by Dr. Philip, and now illustrated on Clydesdale's body, we should transmit along the channel of the nerves, that substitute for nervous influence, or that power which may perchance awaken its dormant faculties. Then, indeed, fair hopes may be formed of deriving extensive benefit from Galmay be formed of deriving extensive benefit from Gal-vanism; and of raising this wonderful agent to its expected rank among the ministers of health and life to man.

I would, however, beg leave to suggest another nervous channel, which I conceive to be a still readier nervous channel, which I conceive to be a still readier and more powerful one, to the action of the heart and lungs, than the phrenic nerve. If a longitudinal incision be made, as is frequently done for aneurism, through the integuments of the neck at the outer edge of the sterno-mastoideus muscle, about half way between the clavicle and angle of the lower jaw; then, on turning over the edge of this muscle, we bring into view the throbbing carotid, on the outside of which, the par vagum, and great sympathetic nerve, lie together in one sheath. Here, therefore, they may both be directly touched and pressed by a blunt metallic conductor. These nerves communicate directly, or indirectly, with the phrenic; and the superficial nerve of the heart is sent off from the sympathetic.

Should, however, the phrenic nerve be taken, that of the left side is the preferable of the two. From the position of the heart, the left phrenic differs a little in its course from the right. It passes over the pericar dium, covering the apex of the heart.

While the point of one metallic conductor is applied to the nervous cords above described, the other knob ought to be firmly pressed against the side of the person, immediately under the cartilage of the seventh

ought to be firmly pressed against the side of the person, immediately under the cartilage of the seventh rib. The skin should be moistened with a solution of common salt, or, what is better, a hot saturated solution of sal-ammoniac, by which means, the electric energy will be more effectually conveyed through the cuticle so as to complete the Voltaic chain.

To lay have the peryon above described, requires an

To lay hare the nerves above described, requires, as I have stated, no formidable incision, nor does it demand more anatomical skill, or surgical dexterity, than every practitioner of the hearing art ought to possess. We should always bear in mind, that the subject of experiment is at least insensible to pain; and that life is at stake, perhaps irrecoverably gone. And assuredis at stake, perhaps irrecoverably gone. And assured-ly, if we place the risk and difficulty of the operations in competition with the blessings and glory consequent on success, they will weigh as nothing, with the intelligent and humane. It is possible, indeed, that two small brass knobs, covered with cloth moistened with solution of sal ammoniae, pressed above and below, on the place of the nerve, and the diaphragmatic region, may suffice, without any surgical operation: it may first be tried.

Immersion of the body in cold water accelerates greatly the extinction of life arising from suffocation; and hence less hopes need be entertained of recovering drowned persons after a considerable interval, than when the vital heat has been suffered to continue with little abatement. None of the ordinary practices judiciously enjoined by the Humane Society, should ever on such occasions be neglected. For it is surely culpable to spare any pains which may contribute, in the slightest degree, to recall the fleeting breath of man to its cherished manision.

My attention has been again particularly directed to

My attention has been again particularly directed to this interesting subject, by a very flattering letter which I lately received from the learned Secretary of the Royal Humane Society.

In the preceding account, I had accidentally omitted to state a very essential circumstance relative to the electrization of Clydesdale. The paper indeed was very rapidly written, at the busiest period of my public prefections, to be presented to the society, as a substitute for the essay of an absent friend, and was sent off to London the morning after it was read to London the morning after it was read.

The positive pole or wire connected with the zinc end of the battery, was that which I applied to the nerve; and the negative, or that connected with the copper end, was that which I applied to the muscles. This is a matter of primary importance, as the following experiments will prove.

Prepare the posterior limbs of a frog for Voltaic electrization, leaving the crural nerves connected, as usual, to a detached portion of the spine. When the excitability has become nearly exhausted, plunge the limbs into the water of one wine-glass, and the crural nerves with their pendent portion of spine, into that of the other. The edges of the two glasses should be almost in contact. Then taking a rod of zinc in one hand, and a rod of silver (or a silver tea-spoon) in the other, plunge the former into the water of the limbs' glass, and the latter into that of the nerves' glass, without touching the frog itself, and gently strike the dry parts of the bright metals together. Feeble convulsive movements, or mere twitching of the fibres, will be perceived at every contact. Reverse now the position of the metallic rods, that is, plunge the zinc into the nerves' glass, and the silver into the other. On renewing the contact of the dry surfaces of the metal now, Prepare the posterior limbs of a frog for Voltaic elecing the contact of the dry surfaces of the metal now, very lively convulsions will take place; and if the limbs are skilfully disposed in a narrowish conical glass, they will probably spring out to some distance. This interesting experiment may be agreeably varied in the following way, with an assistant operator: let that person seize, in the moist fingers of his left hand, that person seize, in the moist fingers of his left hand, the spine and nervous cords of the prepared frog; and in those of the right hand, a silver rod; and let the other person lay hold of one of the limbs with his right hand, while he holds a zinc rod in the moist fingers of the left. On making the metallic contact, feeble convulsive twitchings will be perceived as before. Holding still the frog as above, let them merely exchange the pieces of metal. On renewing the contacts now, lively movements will take place, which become very conspicuous, if one limb be held nearly horizontal, while the other hangs freely down. At each touch of the Voltaic pair, the drooping limb will start up, and strike the hand of the experimenter.

It is evident, therefore, that for the purposes of re-

It is evident, therefore, that for the purposes of re-suscitating dormant irritability of nerves, or contrac-tility of their subordinate muscles, the positive pole must be applied to the former, and the negative to the

latter." - Ure's Chemical Dictionary.

GA'MMA. (From the letter I, gamma, which it resembles.) A surgical instrument for cauterizing a

GAMPHE'LE. (From yautos, crooked:) The cheek.

GA'NOAMON. (From γαγγαμη, a fishing-net, which it was said to resemble.) 1. A name of the omentum.
2. Some call the contexture of nerves about the

navel by this name.

GA'NGLION. (Γαγγλιον, a knot.) A knot. 1.
In anatomy it is applied to a natural knot-like enlarge-

ment in the course of a nerve. 2. In surgery it is an encysted tumour, formed in the sheath of a tendon, and containing a fluid like the white of an egg. It most frequently occurs on the back of the hand or foot.

GA'NGRENE. (Γαγγραινα; from γραω, to feed upon: so named from its eating away the flesh.) Gargan. See Mortification.
Garas. An Arabic name for the disorder of the

eyes. See Ægylops.
GARCI'NIA. (So called in honour of Dr. Garcin, who accurately described it.) The name of a genus of plants in the Linnæan system. Class Dodecandria;

Order, Monogynia.

GARCINIA MANGOSTANA. The systematic name of the mangosteen tree. The mangosteen is a fruit about the size of an orange, which grows in great abundance on this tree in Java and the Molucca islands. According to the concurring testimonies of all travellers, it is the most exquisitely flavoured, and the most salubrious of all fruits, it being such a delicious mixture of the tart and sweet. The flesh is juicy, white, almost transparent, and of a more delicate and agreeable flavoured, the state of the s vour than the richest grape. It is eaten in almost every disorder, and the dried bark is used medicinally in dysenteries and tenesmus, and a strong decoction of it is much esteemed as a gargle in ulcerated sore throats.

GA'RGALE. Γαργαλη. Irritation, or stimulation. Gargalos; Gargalismos.

GARGARISM. See Gargarisma.
GARGARISMA. (Gargarisma, atis. n.; and Gargarismus, i. m.; from γαργαριζω, to gargle.) A gargle, or wash for the throat.

GARGARISMUM. See Gargarisma.
GA'RGATHUM. A bed on which lunatics, &c. were formerly confined.
GARGLE. See Gargarisma.
GARLIC. See Allium.
GARNET. Professor Jameson divides this mineral containing the species the paramidal garnet, dode-

genus into three species: the pyramidal garnet, dode-cahedral garnet, and prismatic garnet.

1. The Pyramidal contains three sub-species; Vesu-vian, Egeran, Gehlenite.

2. The Dodccahedral contains nine sub-species; Pyreneite, Grossulare, Melanite, Pyrope, Garnet, Allochroite, Colophonite, Cinnamon-stone, Helvin.

3. The Prismatic; the grenatite. Of the garnet

3. The Prismatic; the grenatite. Of the garnet proper, there are two species:

1. The precious or noble garnet.

2. The common garnet.

GARNET, Thomas, was born in 1766, at Casterton in Westmoreland. After serving his time to a surgeon and apothecary, he went to study at Edinburgh, where he took his degree at twenty-two, and then attended the London hospitals for two years. In 1790 he settled at Bradford, and began to give private lectures on Philosophy and Chemistry; and here he wrote his Treatise on the Horley Green Spa. But in the following year he removed to Knaresborough, and soon after ing year he removed to Knaresborough, and soon after published an Analysis of the different Waters of Harpublished an Analysis of the different Waters of Harrowgate, which place he visited during the summer
season. About this period he formed the design of
going to America; but while waiting to take his passage at Liverpool, he was solicited to deliver some lectures there, which were so favourably received, that he
was induced to repeat his course at various other
places; and at length the professorship at Anderson's
Institution in Glasgow was offered him, where he
began lecturing in 1796. Two years after he made a
tour to the Highlands, of which he subsequently published an account. On the formation of the Royal Institution in London, he was invited by Count Rumford stitution in London, he was invited by Count Rumford to become the lecturer there; he accepted the appointment, and the room was crowded with persons of the first distinction and fashion. He then turned his thoughts more seriously to the practice of his profession, as likely to afford the most permanent support; but his prospects were cut short by death about the middle of the year 1802. A posthumous volume, entitled "Zoonomia," was published for the benefit of his family.

family.

GA'RON. Papor. A kind of pickle prepared of fish; at first it was made from a fish, which the Greeks call Garos; but the best was made from mackarel. Among the moderns, garum signifies the liquor in which fish is pickled.

GAROU. See Daphne gnidium.

GARROTI'LUS. See Eugenia caryophyllata.

GARROTI'LUS. (From garottar, to bind closely. Spanish.) A name of the cynanche maligna, from its sense of strangulation, as if the throat were bound with a cord.

GAS. (From Gascht, German, an eruption of wind.)
Gaz. Elastic fluid; Aériform fluid. This term is applied to all permanently elastic fluids, simple or compound, except the atmosphere, to which the term air is appropriated.

Some of the gases exist in nature without the aid of art, and may therefore be collected; others, on the contrary, are only producible by artificial means.

All gases are combinations of certain substances, reduced to the gaseous form by the addition of caloric. It is, therefore, necessary to distinguish in every gas, the matter of heat which acted the part of a solvent, and the substance which forms the basis of the gas.

Gases are not contained in those substances from

Gases are not contained in those substances from which we obtain them in the state of gas, but owe

their formation to the expansive property of caloric.

Formation of Gases.—The different forms under which bodies appear, depend upon a certain quantity of caloric, chemically combined with them. The very 381

formation of gases corroborates this truth. Their production totally depends upon the combination of the particular substances with caloric; and though called permanently elastic, they are only so because we can-not so far reduce their temperature, as to dispose them to part with it; otherwise they would undoubtedly become fluid or solid.

come fluid or solid.

Water, for instance, is a solid substance in all degrees below 32° of Fahrenheit's scale; above this temperature it combines with caloric, and becomes a fluid. It retains its liquid state under the ordinary pressure of the atmosphere, till its temperature is augmented to 212°. It then combines with a larger portion of caloric, and is converted, apparently, into gas, or at least into elastic vapour; in which state it would continue, if the temperature of our atmosphere was above 212°. Gases are therefore solid substances, between the particles of which a repulsion is established by the quantity of caloric.

quantity of caloric.

quantity of caloric.

But as in the gaseous water or steam, the caloric is retained with but little force, on account of its quitting the water when the vapour is merely exposed to a lower temperature, we do not admit steam among the class of gases, or permanently elastic aeriform fluids. In gases, caloric united by a very forcible affinity, and no diminution of temperature, or increase of pressure, that has ever yet been effected, can separate it from them. Thus the air of our atmosphere, in the most intense cold, or when very strongly compressed, still remains in the aeriform state; and hence is derived the essential character of gases, namely, that they shall remain aeriform, under all variations of pressure and temperature.

In the modern nomenclature, the name of every substance existing in the aëriform state, is derived from its supposed solid base; and the term gas is used to denote its existence in this state.

In order to illustrate the formation of gases, or to show in what manner caloric is combined with them, show in what manner caloric is combined with them, the following experiment may serve. Put into a retort, capable of holding half a pint of water, two ounces of muriate of soda (common salt): pour on it half its weight of sulphuric acid, and apply the heat of a lamp; a great quantity of gas is produced, which might be collected and retained over mercury. But to serve the purpose of this experiment, let it pass through a glass receiver, having two openings, into one of which the neck of the retort passes, while, from the other, a bent tube proceeds, which ends in a vessel of water. Before closing the apparatus, let a thermometer be included in the receiver, to show the temperature of the gas. It will be found that the mercury in the thermometer will rise only a few degrees: whereas the wamometer will rise only a few degrees: whereas the water in the vessel which receives the bent tube, will soon become boiling hot.

become boiling not.

Explanation.—Common salt consists of muriatic acid, united to soda; on presenting sulphuric acid to this union, a decomposition takes place, especially when assisted by heat. The sulphuric acid unites by virtue of its greater affinity to the soda, and forms sulphate of soda, or Giauber's salt; the muriatic acid becomes therefore disengaged, and takes the gaseous form in which it is capable of existing at the common temperature. To trace the caloric during this experi form in which it is capable of existing at the common temperature. To trace the caloric during this experiment, as was our object, we must remark, that it first flows from the lamp to the disengaged muriatic acid, and converts it into gas; but the heat thus expended is chemically united, and therefore not appreciable by the thermometer. The caloric, however, is again evolved, when the muriatic acid gas is condensed by the water, with which it forms liquid muriatic acid

In this experiment we therefore trace caloric in a chemical combination producing gas; and from this union we again trace it in the condensation of the gas,

producing sensible heat.

Such, in general, is the cause of the formation and fixation of gases. It may be further observed, that each of these fluids loses or suffers the disengagement of different quantities of heat, as it becomes more or less solid in its new combination, or as that combination is capable of retaining more or less spe-

The discovery of aeriform gaseous fluids has occasioned the necessity of some peculiar instruments, by means of which those substances may be conveniently collected and submitted to examination. The prin- the receiving vessel were large,

cipal ones for that purpose are styled the pneumatic

GAS

cipal ones for that purpose apparatus.

The pneumatic trough is made either of wood or strong sheet iron, tinned, japanned, or painted. A trough of about two feet long, sixteen inches wide, and fifteen high, has been found to be sufficient for most experiments. Two or three inches below its brim, a horizontal shelf is fastened, in dimension about half or one-third part of the width of the trough. In this shelf are several holes: these holes must be made in the centre of a small excavation, shaped like a in the centre of a small excavation, shaped like a funnel, which is formed in the lower part of the shelf. This trough is filled with water sufficient to cover

This trough is filled with water sufficient to cover the shelf to the height of an inch.

The use of this shelf is to support receivers, jars, or bell-glasses, which, being previously filled with water, are placed invertedly, their open end turned down upon the above-mentioned holes, through which the gases, conveyed there and directed by means of the funnel-shaped excavations, rise in the form of air-bubbles into the receiver. bubbles into the receiver.

bubbles into the receiver.

When the gaseous fluids are capable of being absorbed by water, as is the case with some of them, the trough must be filled with mercury. The price and gravity of this fluid make it an object of convenience and economy, that the trough should be smaller than when water is used.

A mercurial trough is best cut in marble, free-stone, or a solid block of wood. A trought bout twelve inches long, three inches wide, and four deep, is sufficient for all private experiments.

Method of collecting gases, and transferring them from one vessel to another.—If we are desirous of transmitting air from one vessel to another, it is necessary that the vessel destined to receive it be full of

sary that the vessel destined to receive it be full of water, or some fluid heavier than air. For that pur-pose, take a wide-mouthed bell-glass, or receiver; plunge it under the water in the trough, in order to fill it; then raise it with the mouth downwards, and place it on the shelf of the trough, so as to cover one or more of the holes in it.

It will now be full of water, and continue so as long as the mouth remains below the surface of the fluid in the cistern; for, in this case, the water is sustained in the vessel by the pressure of the atmosphere, in the same manner as the mercury is sustained in the barometer. It may without difficulty be imagined, that if common air (or any other fluid resembling common air in lightness and elasticity) be suffered to enter the inverted vessel filled with water, it will rise to the upper part, on account of its levity, and the surface of the water will subside. To exemplify this, take a glass, or any other vessel, in that state which is usually called amala, and plunge it into the water with its mouth. or any other vessel, in that state which is usually called empty, and plunge it into the water with its mouth downwards: scarce any of it will enter the glass, because its entrance is opposed by the elasticity of the included air; but if the vessel be turned with its mouth upwards, it immediately fills, and the air rises in bubbles to the surface. Suppose this operation be performed under one of the jars or receivers, which are filled with water, and placed upon the perforated shelf, the air will ascend in bubbles as before, but, instead of escaping, it will be caught in the upper part of the

of escaping, it will be caught in the upper part of the jar, and expel part of the water it contains.

In this manner we see that air may be emptied out of one vessel into another by a kind of inverted pouring, by which means it is made to ascend from the lower to the upper vessel. When the receiving vessel has a narrow neck, the air may be poured, in a similar manner, through an inverted funnel, inserted in its mouth.

month.

If the air is to be transferred from a vessel that is stopped like a bottle, the bottle must be unstopped, with its orifice downwards in the water; and then inclined in such a manner that its neck may come under the perforated excavation of the shelf. The gas will escape from the bottle, and passing into the vessel destined to receive it, will ascend in it in the form of bubbles.

In whatever manner this operation is performed.

In whatever manner this operation is performed, the necessity of the excavation in the lower part of the shelf may be readily conceived. It is, as mentioned before, destined to collect the gas which escapes from the vessel, and direct it in its passage towards the vessel adapted to receive it. Without this excavation, the gas, instead of proceeding to the place of its destination, would be dispersed and lost, unless the mouth of the receiving vessel were large.

The vessels, or receivers, for collecting the disengaged gases, should be glass cylinders, jars, or bell-glasses of various sizes; some of them should be open at both ends, others should be fitted with necks at the top, ground perfectly level, in order that they may be stopped by ground flat pieces of metal, glass, slate, &c.; others should be furnished with ground stoppers. Some should be graduated into cubic inches, and subdivided into decimal or other equidistant parts. Besides these, common glass-bottles, tumblers, &c. may be used. be used.

Classification of Gases.—All the elastic aeriform fluids with which we are hitherto acquainted, are generally divided, by systematic writers, into two classes, namely: those that are respirable and capable of maintaining combustion, and those that are not respirable and incapable of maintaining combustion. This division, indeed, has its advantage, but the term respirable, in its physiological application, has been very differently employed by different writers. Sometimes by the respirability of a gas has been meant its power of supporting life, when repeatedly applied to the blood in the lungs. At other times all gases have been considered respirable which were capable of introduction into the lungs by voluntary efforts, without any relation to their vitality. In the last case, the word respirable seems to us most properly employed,

Non-respirable gases are those which, when applied to the external organs of respiration, stimulate the muscles of the epiglottic such a manner as to keep it perfectly close on the gloris; thus preventing the smallest particle of gas from entering into the bronchia, in process of the external content of the smallest particle of gas from entering into the bronchia,

in spite of voluntary exertions.

Of respirable gases, or those which are capable of being taken into the lungs by voluntary efforts, only one has the power of uniformly supporting life, namely, atmospheric air; other gases, when respired, sooner or later impair the health of the human constitution, or perhaps occasion death; but in different modes

Some gases effect no positive change in the blood; animals immersed in it die of a disease produced by the privation of atmospheric air, analogous to that occasioned by their submersion in water.

Others again produce some positive change in the blood, as appears from the experiments of Dr. Beddoes and Sir Humphrey Davy. They seem to render it incapable of supplying the nervous and muscular fibres with principles essential to sensibility and irrita-These gases, therefore, destroy animal life on a different principle.

It is obvious, therefore, that the above classification is not very precise, but capable of misleading the student without proper explanation.

GASTRITUM. Potassa.

GASTRITIS. (From γαςηρ, the stomach.) Inflammation of the stomach. A genus of disease in the class Pyrexiæ, and order Phlegmasiæ of Cullen. It is known by pyrexia, anxiety, heat, and pain in the epigastrium, increased when any thing is taken into the stomach, vomiting, hiccup, pulse small and hard, and prostration of strength. There are two species: and prostration of strength.

Gastritis phlegmonodea, with acute pain and se-

vere fever.

in the fauces.

Gastritis erythematica, when the pain and fever are slighter, with an erysipelatous redness appearing

Gastritis is produced by acrid substances of various kinds, such as arsenic, corrosive sublimate, &c. taken into the stomach, as likewise by food of an improper parietes. See Hernia ventriculi.

nature; by taking large draughts of any cold liquor when the body is much heated by exercise, or dancing; and by repelled exanthemata and gout. Besides these, it may arise from an inflammation of some of the neighbouring parts being communicated to the stomach.

The erysipolatous gastritis arises chiefly towards the close of other diseases, marking the certain approach to dissolution, and being unaccompanied with any marks of general inflammation, or by any burning pain in the stomach.

The symptoms of phlegmonous gastritis, as observed above, are a violent burning pain in the stomach, with great soreness, distention, and flatulency; a severe vomiting, especially after any thing is swallowed, whether it be liquid or solid; most distressing thirst; restlessness, anxiety, and a continual tossing of the body, with great debility, constant watching, and a frequent, hard, and contracted pulse. In some cases, severe purging attends severe purging attends.

If the disease increases in violence, symptoms of irritation then ensue; there is a great loss of strength, with faintings; a short and interrupted respiration; cold, clammy sweats, hiccups, coldness of the extremities, an intermittent pulse, and the patient is soon cut

The event of gastritis is seldom favourable, as the person is usually either suddenly destroyed by the violence of the inflammation, or else it terminates in suppuration, ulceration, or gangrene.

If the symptoms are very mild, and proper remedies have been employed at an early period of the disease, it may, however, terminate in resolution, and that in the course of the first, or, at farthest, the second week. Its termination in suppuration may be known by the symptoms, although moderate, exceeding the con-

tinuance of this period, and a remission of pain occurring, while a sense of weight and anxiety still re-main; and on the formation of an abscess, cold shi-verings ensue, with marked exacerbations in the eve-ning, which are followed by night sweats, and other symptoms of hectic fever; and the eart length prove ked exacerbations in the evefatal, unless the pus is thrown the ulcer heals. comiting, and

Its tendency to gangrene may be dreaded, from the violence of its symptoms not yielding to proper remedies early in the disease; and, when begun, it may be known by the sudden cessation of the pain; by the pulse continuing its frequency, but becoming weaker; and by delirium, with other marks of increasing debi-

lity ensuing.

Fatal cases of this disease show, on dissection, a considerable redness of the inner coat of the stomach, having a layer of coagulable lymph lining its surface. They likewise show a partial thickening of the substance of the organ, at the inflamed part, the inflammation seldom extending over the whole of it. Where ulceration has taken place, the ulcers sometimes are found to penetrate through all its coats, and sometimes only through one or two of them.

The cure is to be attempted by copious and repeated bleedings, employed at an early period of the disease, not regarding the smallness of the pulse, as it usually becomes softer and fuller after the operation: also several leeches should be applied to the epigastrium, followed by fomentations, or the hot bath; after which a large blister will be proper. The large intestines may be in some measure evacuated by a laxative clyster; but scarcely any internal medicine can be borne by the stomach, till the violence of the disease is much abated; we may then try magnesia, or other mild cathartic, to clear out the canal effectually. Where acrid substances have been taken, mucilaginous drinks may be freely exhibited, to assist their evacuation and sheathe the stomach; otherwise only in small quan city: and, in the former case, according to the nature of the poison, other chemical remedies may come in aid, but ought never to be too much relied upon. Should suppuration occur, little can be done beyond avoiding irritation, and supporting strength by a mild farinaceous diet, and giving opium occasionally to relieve pain. GASTRO.

GASTROCE LE. (From γαςηρ, the stomach, and κηλη, a tumour.) A hernia of the stomach, occasioned by a protrusion of that viscus through the abdominal

GASTROCNE'MIUS. (From γαςηρ, the stomach, and κνημη, the leg.) The calf or belly of the leg.

GASTROCNEMIUS EXTERNUS. Gemellus. An extensor muscle of the foot, situated immediately under the integuments at the back part of the leg; sometimes called gemellus: this latter name is adopted by Albinus. Winslow describes it as two muscles; which he calls gastrocnemii; and Douglas considers this and the following as a quadriceps, or muscle with four heads, to which he gives the name of extensor tarsi suralis. It is called bi femoro calcanien by Dumas. The gastrocnemius externus arises by two distinct heads. The first, which is the thickest and longest of heads. The first, which is the thickest and longest of heads. The first, which is the thickest and longest of the two, springs by a strong thick tendon from the upper and back part of the inner condyle of the os femoris, adhering strongly to the capsular ligament of the joint, between which and the tendon is a considerable bursa mucosa. The second head arises by a thinner and shorter tendon from the back part of the outer condyle of the os femoris. A little below the joint, their fleshy bellies unite in a middle tendon, and below the middle of the tibia they cease to be fleshy, and low the middle of the tibia they cease to be fleshy, and terminate in a broad tendon, which, a little above the lower extremity of the tibia, unite with that of the gastrocnemius internus, to form one round tendon, sometimes called chorda magna, but commonly tendo Achillis.

Gastrochemius internus. Tibio peronei calcanien of Dumas. This, which is situated immediately under the last described muscle, is sometimes named solcas, on account of its shape, which resembles that of the sole-fish. It arises by two heads. The first springs by tendinous and fleshy fibres from the posterior part of the head of the fibula, and for some way below it. The second arises from an oblique ridge at the upper and posterior part of the tibia, which affords origin to the inferior edge of the popliteus, continuing to receive fleshy fibres from the inner edge of the tibia or some way down. This muscle, which is narrow at its origin, spreads wider, as it descent as far as its middle; after which it becomes narrower again, and begins to grow tendings. gin, spreads wider, as it descent, as far as its middle; after which it become narrower again, and begins to grow tendinon that as fleshy fibres do not entirely disappear till it has almost reached the extremity of the tibia, a little above which it unites with the last described muscle, to form the tendo Achillis. This thick round chord is inserted into the lower and posterior part of the os calcis, after sliding over a cartila-ginous surface on that bone, to which it is connected by a tendinous sheath that is furnished with a large bursa mucosa.

Both the gastrocnemii bave the same use, viz. that of extending the foot, by drawing it backwards and

downwards.

GASTROCO'LIC. (Gastrocolicus; from γαςηρ, the stomach, and κωλον, the colon.) A term applied to a vein which proceeds from the stomach to the colon.

GASTRODY'NIA. (From γαςηρ, the stomach, and οδυνη, pain.) Pain in the stomach.

GASTRO-EPIPLOIC ARTERY. Arteria gastrico-epiploica. The branch of the greater gastric artery that runs to the epiploon.

GASTRORAPHY. (Gastroraphe; from γαςυρ, the stomach, and order, a suture.) The service of

GASTRORAPHY. (Gastroraphe; from yasyp, the stomach, and $\rho \alpha \phi \eta$, a suture.) The sewing of wounds of the abdomen.

GASTROTO'MIA. (From $\gamma \alpha \varsigma \eta \rho$, the belly, and $\tau \epsilon \mu \nu \omega$, to cut.) The operation of cutting open the

τεμνω, to cut.) belly.

GAU'BIUS, JEROME DAVID, a celebrated Dutch physician, was a pupil of the illustrious Boerhaave at Leyden, where he graduated in 1725, and about ten years after he became professor there, and taught with great applause for a period of forty years. His repupreat appeause for a period of forty years. His reputation was extended all over Europe by several valuable publications, particularly by his "Institutiones Pathologiæ Medicinalis," and his "Adversaria;" which contributed not a little to the improvement both of the theory and practice of medicine. In another work, he treated ably of the majoral regulation of the mind. treated ably of the medical regulation of the mind:

medical properties of this plant are not unlike those of cinnamon, being a warm, aromatic, astringent, particularly useful in the secondary stage of diarrhea. It is popularly considered an emmenagogue. The dose may be one or two scruples, but a fincture and infusion are more convenient forms. The volatile oil of this article is officinal."—Bigel. Mat. Med. A.]

["GAYLUSSACITE. This name has recently been already a new metal obtained from a species of partites."

given to a new metal obtained from a species of pyrites found in South America, of which the following ac-count has been received by Dr. Mitchill, together with

a specimen of the substance in a crystalline form.

"The pyrites is obtained from a small lake in the province of Merida de Columbia, being the upper coat of a substratum of strong mineral alkali, called uras, much used by the lower class of the natives of Columbia. bia, mixed with an extract of tobacco, and then called chimoo. The alkali produces to the government a rental of from 50,000 to 60,000 dollars per annum. The mineral is at the bottom of the lake, about three fathoms under water. Several Indians are employed by the government to dive and extract it, which they do by government to dive and extract it, which they do by means of small crowbars. They are paid about two reales per pound for it, and the government afterward sell it at one dollar. The situation of the lake is about ten leagues west of the city of Merida, called Lagunillas. The pyrites are there called espejuelas, and have been analyzed in Paris, and found to contain a metal hitherto unknown, and now called Garassacite, from the celebrated French chemic of that name."—A.]

GAZ. (From gascht, a terman word which means an eruption of wind.) See Gas.

GEHLENITE. A mineral substance allied to Vesuvian, found along with calcareous spar in the Tyrol.

GEISO'MA. (From yesov, the eaves of the house)

Geiso'MA. (From γεισον, the caves of the house.)
Geison. The prominent parts of the eyebrows, which hang over the eyes like the eaves of a house.

GEI son. See Geisoma.

GELA'SINOS. (From γελαω, to laugh.) An epithet for the middle fore-teeth, because they are shown in laughter.

Gela'smus. (From γελαω, to laugh.) The Sardonic laugh. See Sardonic laugh.

GE'LATIN. Gelly, or jelly. An animal substance soluble in water, but not in alkohol: capable of assuming a well-known elastic or tremulous consistence, by cooling when the water is not too shundart and by cooling, when the water is not too abundant, and liquifiable again, by increasing its temperature. This liquifiable again, by increasing its temperature. This last property remarkably distinguishes it from albumen, which becomes consistent by heat. It is precipitated in an insoluble form by tannin, and it is this action of tannin on gelatin that is the foundation of the art of tanning leather.

Jellies are very common in our kitchens; they may be extracted from all the parts of animals, by boiling them in water. Hot water dissolves a large quantity of this substance. Acids likewise dissolve them, as do like-wise more particularly the alkalies. Jelly, which has been extracted without long decoction, possesses most of the characters of vegetable mucilage; but it is sel-

of the characters of vegetable mucilage; but it is seldom obtained without a mixture of albumen.

Jellies, in a pure state, have scarcely any smell or remarkable taste. By distillation, they afford an insipid and inodorous phlegm, which easily putrefies. A stronger heat causes them to swell up, become black, and emit a fætid odour, accompanied with white acrid fumes. An impure volatile alkali, together with empyreumatic oil, then passes over, leaving a spongy coal, not easily burned, and containing common salt and phosphate of lime.

phosphate of lime.

The jelly of various animal substances is prepared for the use of seafaring persons under the name of portable soup. The whole art of performing this operation consists in boiling the meat, and taking the scum off, as usual, until the soup possesses the requisite flavour. It is then suffered to cool, in order that the fat may be separated. In the next place, it is mixed with five or six whites of eggs, and slightly boiled. This operation serves to clarify the liquid, by the removal of opaque particles, which unite with the white of egg at treated ably of the medical regulation of the mind: and he printed also a very elegant little book "De Methodo concinnandi formulas Medicamentorum." He died in 1780, in the seventy-sixth year of his age.

GAULE. See Myrica gale.

["GAULTHERIA. Partridge berry. The gaultheria procumbens is a well known creeping evergreen, found m woody and mountainous tracts throughout the United States. Its taste is astrigent and aromatic, and bas been compared to that of orange flowers. It exactly 384

antil it becomes brittle. These cakes may be kept four or five years, if defended from moisture. When in-tended to be used, nothing more is required to be done than to dissolve a sufficient quantity in boiling water, which by that means becomes converted into soup.

Jelly is also wound in vegetables, as ripe currants, and other berries mixed with an acid.

GELA'TIO. (From gelo, to freeze.) 1. Freezing.

That rigidity of the body which happens in a

catalepsy, as if the person were frozen.

GEM. This word is used to denote a stone which is considered as precious; as the diamond, ruby, sapphire, topaz, chrysolite, beryl, emerald, &c

GEME'LLUS. (From geminus, double, having a fellow.) See Gastrocnemius and Gemini.

GEMINI. Gemelli of Winslow. Part of the marsupialis of Cowper. Ischio spini trochanterien of Dumas. A muscle of the thigh, which has been a subject of dispute among anatomists since the days of Vesatius. Some describe it as two distinct muscles; and hence the name it has gotten of gemini. Others contend that it ought to be considered as a single muscle. The truth is, that it consists of two portions, which are united together by a tendinous and fleshy membrane, and afford a passage between them to the tendon of the obdurator internets, which they enclose as it were in a purse. These two portions are placed under the glutaus maximus, between the ischium and the great trochanter.

The superior portion, which is the shortest and thickest of the two, rises fleshy from the external surface of the spine of the ischium; and the inferior, from the tuberosity of that bone, and likewise from the posterior sacro-ischiatic ligament. They are inserted, tendinous and fleshy, into the cavity at the foot of the great trochanter. Between the two portions of this muscle, and the termination of the obturator internus, there is a small bursa mucosa, connected to both, and there is a small bursa mucosa, connected to both, and to that part of the capsular ligament of the joint which

lies under the gemini.

This muscle assists in rolling the os fenoris out-wards, and prevents the tendon of the obturator inter-nus from slipping out of its place while that muscle is

GEMMA. 1. A precious stone or gem.
2. In botany this term is now applied exclusively to
the buds on the stems of plants. The ancients used
the terms germen and oculus to denote those buds
which contain the rudiments of branches and leaves, and gemma those in which flowers only are contained; but by the moderus, germen has been applied to denote the rudiment of the fruit, or as a generic term for all

buds.-Thompson.
A gemma or bud contains the rudiments of a plant, or of part of a plant, for a while in a latent state, till the time of the year, and other circumstances, favour their evolution. In the bud, therefore, the vital principle is dormant. Buds of trees or shrubs, destined for cold countries, are formed in the course of the summer in the bosoms of their leaves, and are generally solitary; but in the Lonicera carulea, or blue-berried honey-suckle, they grow one under another for three successive seasons.

The buds of the plane-tree, Platanus, are concealed in the footstalk, which must be removed before they can be seen, and which they force off by their in-crease; so that no plant can have more truly and

necessarily deciduous leaves.

Shrubs in general have no buds, neither have the

rees of hot climates.

Buds are various in their forms, but very uniform in the same species, or even genus. They consist of scales closely enveloping each other, and enfolding the embryo plant or branch. Externally they have often an additional guard of gum, resin, or woolliness, against wet or cold. The horse-chesnut affords a fine example of large and well-formed buds.

The contents of buds are different, even in different species of the same genus, as willows. The buds of some produce leaves only, others flowers, while in other species the same bud bears both leaves and flow-Different causes, depending on the soil or situation, seem in one case to generate leaf-buds, in another flower-buds. In general, whatever checks the luxu-riant production of leaf-buds, favours the formation of flowers and seeds .- Smith.

Gems are found in all trees and shrubs in temperate climates. In the majority of instances they are visible from the first, in which case they are axillary, that is, seated in the axilla of the leaves, or the angle which the upper part of the footstalk of the leaf makes with the surface of the stem; but in some instances, as the sumachs and planes, they are latent, being hid within the base of the footstalk, and never seen until the fall of the leaf. Gems are however sometimes protruded from the trunk, long after it has ceased to produce leaves, as in the case of adventitious buds; they are also situated on roots, and on tubers, but in these cases they are usually denominated oculi, or eyes.

Annual plants are supposed to be furnished with gems; but although they are devoid of covered gems,

yet their lateral shoots proceed from naked buds which

immediately spread into foliage.

The relative position of axillary gems is necessarily regulated by that of the leaf, and therefore we find them, Opposite, or placed exactly on the same line on opposite sides of the stem or the branch.

2. Alternate, or placed alternately, although on op-

posite sides; and,
3. Spiral, that is, placed round the stem or branch in 3. Spiral, that is, placed round the stem or branch in such a manner that a cord wound in a spiral manner round it would touch each gem. They are said to be simple or solitary, when one gem only is seen in the axilla of each leaf, as in the greater number of instances; and aggregate, when, as in some plants, two, three, or even more are protruded at the same time: thus we find two in the Sambucus nigra, or common elder; three in the Aristolochia sipho, or broad-leaved birth-wort; and many in the Zanthozylum frazine-um, or toothache tree. um, or toothache tree.

Du Hamel first noticed the fact, that stems and

branches furnished with alternate axillary gems have generally one terminal gemonly; and those with opposite have generally three terminal gems.

The gems on most trees and shrubs rise with a broad base from the surface where they are protruded, and consequently being in close contact with it, are said to be sessile; but they are distant or stalked on some, as the common alder, on which they are supported on a short footstalk, and are termed pedicillate, or stalked.

Genis differ very considerably in the number and characters of the enclosing scales, their contents, the folding up of the leaves within them, and the manner

in which they are evolved in the spring.

a. The scales differ in size and texture, even in the same gem: in the gems of different plants, they differ also in number and in the nature of their coverings; some gems are entirely destitute of scales; as those of annual plants, and many perennials of tropical cli-mates. The scales in some instances are besmeared with a resinous matter; in others they are entirely free from any moist exudation, but are smooth and polished, being covered with a dry gummy varnish; or they are externally hairy or enveloped in a velvety

Gems are arranged into three species:

Gemme foliifere, leaf gems

Gemma florifera, flower gems.

Gemma mixta, mixed gens.

The Amygdalus persica, or peach-tree, the Daphne metereum, and many other plants, afford examples of distinct leaf and flower gems; the Syringa vulgaris and Æsculus hippocastanum, of mixed gems; and the pear and apple trees of both leaf and mixed gems.

pear and apple trees of both leaf and mixed gems.

The leaves, as has already been mentioned, are variously folded up so as to occupy the smallest possible space in the gem. This regulates the expansion of the leaves when the gem opens in spring, and it is invariably the same in individual plants of the same species. This process is termed foliation, and the figures which the leaves assume at the time have received different appellations—Thempson.

ceived different appellations.—Thompson.

1. Foliatio involuta, involute, in which each internal margin of the leaf is rolled inwards; as in Humu-

lus lupulus and Nymphæa lutea.

2. F. revoluta, revolute, in which the lateral margins are rolled outwards; as in willows, and Rumez patientia.

3. F. obvoluta, obvolute, in which one leaf, doubled lengthways, embraces within its doubling one half of the other leaf, folded in the same manner; as in Sulvia officinalis, and Dipsacus communis.

lengthwise in a spiral manner, one margin forming the air round which the other turns; as in Prunus domestica, and Prunus armeniaca, the cabbage, grasses, &c. 5. F. equitans, equitant, in which the leaf is so folded that the two sides deeply embrace the opposite leaf, which in its turn encloses the one opposed to it, and so on to the centre of the bud; this is beautifully examplified in the Hermannian. exemplified in the Hemarocallis, or day-lily, and Syringa vulgaris.

6. F. conduplicate, in which the two sides of the leaf lie parallel to each other; as in Fagus sylvatica

and Quercus robur.

7. P. plicata, plaited, the leaf being folded up like a fan; as in Betula alba, and Alchemilla vulgaris.

8. F. reclinata, reclinate, turned down, the leaf hanging down and wrapped round the footstalk; as in Aconitum and Arum.

Aconitum and Arum.

9. F. circinata, circinal, in which the leaf is rolled from the apex to the base; as in all ferns.

As the gems open, the leaves gradually unfold themselves, and assume their natural forms; but the opening of the bud does not, in every instance, immediately set free the leaves, for in some gems each leaf is separately enclosed in a membraneous cover.

GEMMACEUS. A term used by botanists to a flower-stalk which grows out of a leaf-bud, as is seen in the Berberis pulgaris.

in the Berberis vulgaris.

GEMMATIO. (From gemma, a bud.) A term used by Linnaus expressive of the origin, form, &c. of

GEMU'RSA. (From gema, to groan: so called from the pain it was said to occasion in walking.) The name of an excrescence between the toes.

GENEI'AS. (From γενυς, the cheek.)

1. The downy hairs which first cover the cheek.

2. The name of a bandage mentioned by Galen,

which covers the cheek, and comes under the chin.

GENERATION. (Generatio; from yetvopat, to beget.) Many ingenious hypotheses have been instituted by physiologists to explain the mystery of generative description. ration; but the whole of our knowledge concerning it appears to be built upon the phenomena it affords, and may be seen in the works of Haller, Buffon, Cruickshanks, and Haighton. It is a sexual action, performed in different ways in most animals; many of them have different sexes and require conjunction: such are the human species, quadrupeds, and others. The females human species, quadrupeds, and others. The females of quadrupeds have a matrix, separated into two cavities, uterus bicornis, and a considerable number of teats; they have no menstrual flux; most of them bear teats; they have no menstrual flux; most of them bear several young at a time, and the period of their gestation is generally short. The generation of birds is very different. The males have a strong genital organ, which is often double. The vulva in the females is placed behind the anus; the ovaries have no matrices, and there is a duct for the purpose of conveying the egg from the ovarium into the intestines; this passage is called the oviduct. The eggs of pullets have exhibited unexpected facts to physiologists, who examined the phenomena of incubation. The most important discoveries are those of the immortal Haller, who found the chicken perfectly formed in eggs which were not fecundated. There is no determinate conjunction between fishes; the female deposites her eggs on the sands, over which the male passes, and emits its seminal fluid, doubtless for the purpose of fecundatiis them; these eggs are hatched after a certain time. The males of several oviparous quadrupeds have a double or forked organ. Insects exhibit all the variedouble or forked organ. Insects exhibit all the varieties which are observed in other animals; there are some, indeed the greater number, which have the sexes in two separate individuals; among others, the reproduction is made either with or without conjunctions. tion, as in the vine-fretter; one of these insects, confined alone beneath a glass, produces a great number of others. The organ of the male in insects is usually of others. The organ of the male in insects is usually armed with two hooks to seize the female: the place of these organs is greatly varied; with some, it is at the upper part of the belly, near the chest, as in the female dragon-fly; in others, it is at the extremity of the antenna, as in the male spider. Most worms are hermaphrotite; each individual has both sexes. Polypi, with respect to congretion, are signaler animals. lypi, with respect to generation, are singular animals, they are reproduced by buds or offsets: a bud is separated from each vigorous polypus, which is fixed to some neighbouring body, and grows: polypi are like

4. F. convoluta, convolute, in which the leaf is rolled lengthwise in a spiral manner, one margin forming the axis round which the other turns; as in Prunus domestica, and Prunus armeniaca, the cabbage, grasses, &c. which engages our attention more particularly, the phenomena are as follow

The part of the male, in the act of reproduction, is to deposite the semen in the vagina, at a greater of less distance from the orifice of the uterus.

The function which the female discharges is much

more obscure; some feel, at this moment, very strong voluptuous sensations; others appear entirely insensible; while others, again, experience a sensation which is very painful. Some of them pour out a mucous substance in considerable abundance, at the instant of the most vivid pleasure: while, in the greater part, this phenomenon is entirely wanting. In all-these respects, there is, perhaps, no exact resemblance between any two females.

These different phenomena are common to the most frequent acts of copulation, that is, to those which do not produce impregnation, as well as those which are

effective.

The most recent opinion is, that the uterus during impregnation opens a little, draws in the semen by aspiration, and directs it to the ovarium by means of the Fallopian tubes, the fimbriated extremity of which closely embraces that organ.

The contact of the semen determines the rupture of one of the vesicles, and the fluid that passes from it, or the vesicle itself, passes into the uterus, where the new individual is to be developed.

However satisfactory this explanation may appear, it is purely hypothetical, and even contrary to the ex-

periments of the most exact observers.

In the numerous attempts made upon animals, by Harvey, DeGraaf, Valisneri, &c. the semen has never been perceived in the cavity of the uterus; much less has it been seen in the Fallopian tube at the surface of the ovarium. It is quite the same with the motion which the Fallopian tube is supposed to have in embracing the circumference of the ovarium: it has never been proved by experiment. Even if one should suppose that the semen penetrates into the uterus at suppose that the semen penetrates into the uterus at the moment of coition, which is not impossible, though it has not been observed, it would still be very difficult to comprehend how the fluid could pass into the Fallopian tubes, and arrive at the ovarium. The uterus in the empty state is not contractible; the uterine orifice of the Fallopian tubes is extremely narrow, and these

canals have no known sensible motion.

On account of the difficulty of conceiving the passage of the semen to the ovarium, some authors have imagined that this matter is not carried there, but only the vapour which exhales from it, or the aura seminalis. Others think that the semen is absorbed in the vagina, passes into the venous system, and arrives at the ova-ria by the arteries. The phenomena which accompany the fecundation of women are, then, nearly unknown. An equal obscurity rests on the fecundation of other mammiferous females. Nevertheless, it would be more easy to conceive a passage of the semen to the ovaria in these, since the uterus and the Fallopian tubes possess a peristaltic motion like that of the intestines. Fecundation, however, taking place by the contact of the semen with the ova, in fishes, reptiles, and birds, it is not very likely that nature employs any other mode for the mammifera; it is necessary, then, to consider it as very probable, that, either at the instant of coition, or at a greater or a less time afterward, the semen arrives at the ovarium, where it exerts more especially its action upon the vessels most developed.

But, even should it be out of doubt that the semen arrives at the vesicles of the ovarium, it would still remain to be known how its contact animates the germ contained in it. Now, this phenomenon is one of those on which our senses, and even our mind, have o hold: it is one of those impenetrable mysteries of which we are, and, perhaps, shall ever remain ig-

We have, however, on this subject, some very ingenious experiments of Spallanzani, which have removed the difficulty as far as it seems possible.

This philosopher has proved, by a great number of trials, 1st, that three grains of semen, dissolved in two pounds of water, are sufficient to give to it the fecun tating virtue; 2d, that the spermatic animalcula are

thors have thought; 3d, that the aura seminalis, or seminal vapour, has no secundating property; 4th, that a bitch can be impregnated by the mechanical injec-

tion of semen into her vagina, &c. &c.

It is thus necessary to consider as conjectural what authors say about the general signs of fecundation. At the instance of conception, the woman feels, it is said, a universal tremor, continued for some time, accompanied by a voluptuous sensation; the features are discomposed, the eyes lose their brilliancy, the pupils are dilated, the visage pale, &c. No doubt, impregnation is sometimes accompanied by these signs but many mothers have never felt them, and reach

but many mothers have never felt them, and reach even the third month of their pregnancy without suspecting their situation."—Magendie's Physiology.

Fecundation having thus taken place, a motion is induced in the vivified ovum, which ruptures the tender vesicle that contains it; the fimbriæ of the Fallopian tube then grasp and convey it into the tube, which, by its peristaltic motion, conducts it into the cavity of the uterus, there to be evolved and brought to maturity, and, at the expiration of nine months, to be sent into the world.

be sent into the world.

GENERATION, ORGANS OF. The parts subservient to generation in a woman are divided into external and internal. The external parts are the mone veneris, the labia, the perinaum, the clitoris, and the nympha. To these may be added the meatus urinarius, or orifice of the prethra. The hymen may be esteemed the barrier between the external and internal parts. The internal parts of generation are the vagina and uterus, and its appendages.

The parts which constitute the organs of generation in men, are the penis, testes, and vesicula semi-

nales.
GENICULATUS. Geniculate; bent like the knee: applied to the culm or straw of grasses; as in Alopecu-

ris geniculatus.

GENIO. (From γενείον, the chin.) Names compounded of this word belong to muscles which are

attached to the chin.

Genio-nyo-glossus. (From γενείον, the chin, νοτίδες, the os byoides, and γλωσσα, the tongue; so called from its origin and insertion.) Genio glossus of some authors. The muscle which forms the fourth layer between the lower jaw and os hyoides. It arises from a rough protuberance in the inside of the middle of the lower jaw; its fibres run like a fan, forwards, upwards, and backwards, and are inserted into the tip, middle, and root of the tongue, and base of the os hyoides, near its corner. Its use is to draw the tip of the tongue backwards into the mouth, the middle downwards, and to render its back concave. It also draws its root and the os hyoides forwards, and thrusts the tongue out of the mouth.

GENIO-HYOIDEUS. (From yevelow, the chin, and vocaces, the os hyoides; so called from its origin in the chin, and its insertion in the os hyoides.) The muscle which contitutes the third layer between the lower jaw and os hyoides. It is a long, thin, and fleshy muscle, arising tendinous from a rough protuberance at the inside of the chin, and growing somewhat broader and thicker as it descends backward to be inserted by very short tendinous fibres into both the edges of the base of the os byoides. It draws the os

hyoides forwards to the chin.

See Constrictor pharyngis GENIOPHARYNGE'US.

GENIPI ALBUM. See Artemisia rupestris.

GENIPI VERUM. The plant directed for medicinal purposes under this title, is the Achillea—foliis pinnatis, pinnis simplicibus, glabris, punctatis, of Haller. It has a very grateful smell, and a very bitter taste, and is exhibited in Switzerland, in epilepsy, diarrhœa, and

debility of the stomach.

GENTSTA. (From genu, a knee; so called from the inflection and angularity of its twigs.) 1. The name of a genus of plants in the Linnaan system. Class, Diadelphia; Order, Decandria.

2. The pharmacopeial name of the common broom.

See Spartium scoparium. Genista canariensis. This tree was supposed to afford the lignum Rhodium, which is now known to be an aspalathus. See Aspalathus canariensis.

GENISTA SPINOSA INDICA. Babel schulli. An In-

dian tree, a decoction of the roots of which is diuretic.

not necessary to fecundation, as Buffon and other au- i The leaves, boiled and sprinkled in vinegar, have the The leaves, ponco and same effect, according to Ray.

The systematic name of

GEN

Chameparteam, or Dyer's broom.

GENITA LE. (From gigno, to beget.) The membrum virile See Penis.

GENITA'LUM. (From genitale, the membrum virile.)

A disease of the genital parts.

GENITICA. (From yttvopat, gignor.) The name of a class of diseases, in Good's Nosology, embracing diseases of the sexual function. It has three orders, viz. Cenotica, Orgastica; Carpotica.
GENITU'RA (From gigno.) 1. The male seed.

2. The membrum virile.

GENON. (From yow, the knee.) A moveable articulation like that of the knee.

["GENESEE OIL. This is a variety of petroleum found in various parts of the United States, sometimes abundantly, as in Kentucky, Ohio, the western parts of Pennsylvania, and in New York, at Seneca lake, &c. It usually floats on the surface of springs, which, in many cases, are known to be in the vicinity of coal. It is sometimes called Seneca or Genesee oil."-Cleav. Min. A. GENSING.

GENSING. See Panaz.
GENTIA'NA. (From Gentius, king of Illyria, who first used it.) 1. The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Digyaia. Gentian.
2. The pharmacopæial name of the gentian root.

See Gentiana lutea.

GENTIANA ALBA. See Laserpitium latifolium.
GENTIANA CENTAURIUM. Less centaury was so called in the Linnman system; but it is now Chironia

GENTIANA LUTEA. The systematic name of the officinal gentian. Gentiana rubra. Felwort. The gentian met with in the shops is the root of the gentiana—corollis subquinquefidis rotatis verticillatis, calycibus spathaccis, of Linnæus; and is imported from Switzerland and Germany. It is the only medicinal part of the plant, has little or no smell, but to the taste manifests great bitterness, on which account it is in general use as a tonic, stomachic, anthelmintic, antiseptic, emmenagogue, and febrifuge. The officinal preparations of this root are the infusum gentiana compositum, and tinctura gentianæ composita, of the London Pharmacopeia; and the infusum amarum, vinust amarum, tinctura amara, of the Edinburgh Pharmacopeia; and the extractum gentianæ is ordered by both.

GENTIANA RUBRA. See Gentiana lutea.

GENTIANA RUBRA. See Gentiana lufea.

["GENTIANA CATESBEI. Blue gentian. Of various native species of gentian, which our country affords; this approaches most nearly to the officinal plant in bitterness. Its virtue appears to reside chiefly in an extractive principle, soluble in water and alkohol. It has also a little resin. Like the imported gentian, it is an active tonic, invigorating the stomach, and giving relief in complaints arising from indigestion. It and relief in complaints arising from indigestion. pears to possess much reputation in the Southern States, to which its growth is principally confined."-Bigel. Mat. Med. A.]

Continuing. The bitter principle of the Gentian

[" The discovery of this immediate principle, presents a circumstance so singular as to merit being re-

"M. Henry, chief of central pharmacy, and M. Caventou, were occupied at the same time, and without the knowledge of each other, on the analysis of gentian. They arrived at results so much alike, that having communicated their labours to each other, they perceived that they seemed to have acted in concert, and resolved to publish them in common.

and resolved to publish them in common.

"Preparation of gentianine. The powder of gentian is treated with cold ether. After forty-eight hours, a tincture is obtained of a greenish yellow;—this tincture filtered, poured into an open vase, and exposed to heat, will become, by cooling, if the liquor is sufficiently concentrated, a yellow crystalline mass, with a very perceptible taste and smell of gentian.

"This mass is treated with alkohol until it ceases taking a citron tinge. The washings are reunited and exposed to a mild heat; the yellow crystalline mass reappears, which, upon evaporation, becomes concentrated, and of a very strong bitterness.

a Resumed by feeble alkohol, it is redissolved in part, with the exception of a certain quantity of oily matter.

This last alkoholic solution begins to be a sum and a sum anthelminitic.

This last alkoholic solution begins to be a sum and a sum anthelminitic. matter.
"This last alkoholic solution, besides the bitter prin-

ciple of the gentian, contains an acid substance, and

the odorous matter of gentian.
"By evaporating this liquor to dryness, soaking the matter in water, adding a little washed and calcined magnesia, boiling and evaporating with a vapour bath, the greatest part of the odorous matter of the gentian the greatest part of the odorous matter of the gentian is expelled; the acidity disappears by means of the magnesia, and the yellow bitter principle remains in part free and in part combined with the magnesia, to which it communicates a beautiful yellow colour. Then by boiling this magnesia with ether, the greater part of this bitter principle is taken up, which is obtained pure and alone by evaporation. If it be wished to separate the greatest part of the bitter principle, which remains fixed in the magnesia, and which the ether could not take up, it must be treated with oxalic which remains fixed in the magnesia, and either could not take up, it must be treated with oxalic ether could not take up, it must be acaduse acidity. This acid, in a quantity sufficient to produce acidity. acid unites with the magnesia, and sets free the bit-ter principle, which is retaken by the means already pointed out.

"Properties of gentianine. The gentianine is yellow, inodorous, with the aromatic bitterness of the gentian very strong, and which is increased very much when it is dissolved in an acid.

"It is very soluble in ether and alkohol, and is separated by spontaneous evaporation, in the form of very small yellow crystalline needles. It is much less soluble in cold water, which it renders, however, very bitter; boiling water dissolves more.

"The dilute alkalies deepen very much its colour,

and dissolve it a little more than water alone.

" Acids lighten its yellow colour in a very evident Its solutions are almost colourless with sulphuric and phosphoric acid, and yellowish with acids more feeble, such as the acetic acid. Concentrated sulphuric acid carbonizes it and destroys its bitterness.

"Gentianine, exposed in a glass tube to the heat of boiling mercury, is sublimed in the form of small yellow crystalline needles. One part is decomposed.

"Action of gentianine on man and other animals. Some which I made, taught me that gentianine has no poisonous qualities. Several grains of this substance injected into the veins, produce no apparent effect. I myself swallowed two grains dissolved in alkohel, and myself swallowed two grains dissolved in alkohol, and only experienced an extreme bitterness, and a slight feeling of warmth at the stomach

"Mode of employing gentianine. The tincture is the preparation which should be most frequently used. It may be prepared from the following formula:

Tincture of gentianine. R. Alkohol at 24°, 1 ounce.

Gentianine, 5 grains.

"This tincture replaces with success the clixir of gentian, and is employed in the same circumstances:

Syrup of gentianine R. syrup of sugar, 1 pound.

Gentianine, 16 grains. Gentianine, 16 grains.

"This is one of the best bitters which can be used in scrofulous affections."—Magendie's Formulary. A.] GE'NU. The knee.

GENU'GRA. (From yere, the knee, and aypa, a seizure.) A name in Paracelsus for the gout in the

GENUS. (From γενος, a family.) By this term is understood, in natural history, a certain analogy of a number of species, making them agree together in the number of species, making them agree together in the number, figure, and situation of their parts; in such a manner, that they are easily distinguished from the species of any other genus, at least by some one article. This is the proper and determinate sense of the word genus, whereby it forms a subdivision of any class, or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common and distinct characters.

mal, vegetable, or mineral kinguous, an agreeing in certain common and distinct characters.

GEODES. A kind of ætites, the hollow of which contains only loose earth, instead of a nodule.

GEOFFRÆ'A. (Named in honour of Dr. Geoffroy.)

Geoffroya. 1. The name of a genus of plants in the Linnæau system. Class, Diadelphia; Order, Decan-

dria.

2. The pharmacopæial name of the cabbage bark-

cc. See Geoffrea mermis.

GEOFFREA INERMIS. The systematic name of the cabbage bark-tree, or worm bark-tree. Geoffraafoliis lanceolatis of Swartz. It has a mucilaginous

GEOFFREA JAMAICENSIS. The systematic name of the bastard cabbage-tree, or bulgewater-tree. Geoffroya -inermis foliolis lanceolatis, of Swartz. The bark is principally used in Jamaica, and with great success, as a vermifuge.

GEOFFREA SURINAMENSIS. The systematic name of a tree, the bark of which is esteemed as an anthel-

GEOFFROY, STEPHEN FRANCIS, was born at aris, in 1672. After giving him an excellent general Paris, in 1672. education, his father, who was an apothecary, sent him to study his own profession at Montpelier; where he attended the several lectures. On his return to Paris, having already acquired considerable reputation, he was appointed to attend the Duke de Tallard, on his embassy to England, in 1698. Here he was very favour-ably received, and elected a member of the Royal Society: and he afterward visited Holland and Italy. His attention was chiefly directed to natural history and the materia medica, his father wishing him to succeed to his establishment at Paris: however, he became ambitious of the higher branch of the profession, and at length graduated in 1704. His reputation rapidly in-creased; and he was called in consultation even by the most distinguished practitioners. In 1705 he was appointed to the professorship of medicine on the death of Tournefort. He then undertook to deliver to his pupils a complete History of the Materia Medica, divided into mineral, vegetable, and animal substances; the first part of which he finished, and about half of the second: this was afterward published from his papers, in Latin, in three octave volumes. his papers, in Laun, in times octave, the king's gar-he was made professor of chemistry in the king's garhe was made professor of chemistry in the king's garden; and 14 years after, dean of the faculty. In this office he was led into some active disputes; whence his health, naturally delicate, began to decline; and fied ied in the beginning of 1731. Nothwithstanding his illness, however, he completed a work, which had been deemed necessary by preceding deans, but never accomplished; namely, a Pharmacopeia, which was published under the name of "Code Medicamentaire de la Faculté de Paris."

GEOGNOSY. The same as geology.

GEOLOGY. (Geologia; from yn, the earth, and $\lambda oyos$, a discourse.) A description of the structure of the earth. This study may be divided, like most others, into two parts; observation and theory. By the first we learn the relative positions of the great

the first we learn the relative positions of the great rocky or inineral aggregates that compose the crust of our globe; through the second, we endeavour to pene-trate into the causes of these collocations. A valuable work was some time since published, comprehending a view of both parts of the subject, by Mr. Greenough, to which the reader is referred for much instruction, communicated in a very lively manner.

Very recently the world has been favoured with the first part of an excellent view of this science by Messrs.

Conyheare and Phillips, in their "Outlines of the Geology of England and Wales;" from which work, the following brief sketch of the subject is taken: The Traité de Geognosie of D'Aubuisson bears a high character on the continent.

Werner's Table of the different Mountain Rocks, from Jameson.

Class I.—Primitive rocks.

8. Porphyry. Granite. 9. Syenite. 10. Topaz-rock. Mica-slate.

 Quartz-rock.
 Primitive flinty-slate.
 Primitive gypsum. Clay-slate. Primitive limestone. Primitive trap.

14. White stone Serpentine.

CLASS II.—Transition rocks.
ion lime-stone.

4. Transition flinty-slate. 1. Transition lime-stone. 2. Transition trap. 5. Transition gypsum.

3. Greywacke

CLASS III .- Flortz rocks. Old red sandstone, or first sandstone formation.

First or oldest floetz limestone. First or oldest floetz gypsum.

Second or variegated sandstone formation.

Second floetz gypsum. Second floetz limestone. Third floetz limestone.

- 8. Rocksalt formation.
- Chalk formation.
- 10. Floetz-trap formation.
- Independent coal formation. 12. Newest floetz-trap formation.

CLASS IV.—Alluvial rocks.
5. Nagelfluh.
d gravel.
6. Calc-tuff.

- 2. Sand and gravel. Loam.
- 7. Calc-sinter.
- 4. Bog-iron ore.

CLASS V.—Volcanic rocks.
Pseudo-volcanic rocks.

- 1. Burnt clay.
- Porcelain jasper.
- 3. Earth slag.
- 4. Columnar clay ironstone.
 5. Polier, or polishing state.

 True volcanic rocks.
- Ejected stones and ashes. Different kinds of lava.
- The matter of muddy eruptions.

chemical structure of the primitive, than the mechantcal of the secondary rocks. As these transition rocks were taken by Werner from among those which, in were taken by Werner from among those which, in his general arrangement, were called secondary, the formation of that class made it necessary to abandon the latter term. To denote the mineral masses reposing in his transition series, he accordingly employed the term fluetz rocks, from the idea that they were generally stratified in planes nearly horizontal, while those of the older strata were inclined to the horizon at considerable angles. But this holds good with regard to the structure of those countries which are comparatively low; in the Jura chain, and on the borders of the Alps and Pyrenees, Werner's floetz formations are highly inclined. Should we therefore persist in the use of this term, says Mr. Conybeare, we must prepare ourselves to speak of vertical beds of floetz, (i. c. horizontal), limestone, &c. As the inquiries of geologists extended the knowledge of the various formations, Werner, or his disciples, found it necessary to subdivide the bulky class of floetz rocks into floetz and newest floetz, thus completing a fourfold into floetz and newest floetz, thus completing a fourfold The primitive rocks lie undermost, and never contain any traces of organized beings imbedded in them.

The transition rocks contain comparatively few organic remains, and approach more nearly to the is given by the Rev. Mr. Conybeare.

CHARACTER.	Proposed Names.	WERNERIAN NAMES	OTHER WRITERS.
1. Formations (chiefly of sand and clay) above the chalk.	Superior order.	Newest floetz class.	Tertiary class.
2. Comprising, a. Chalk. b. Sands and clay, beneath the chalk. c. Calcareous freestones (oolites) and argillaceous beds. d. New red sandstone, conglomerate, and magnesian limestone.	Supermedial order.	Floetz class.	Secondary class.
3. Carboniferous rocks, comprising, a. Coal measures. b. Carboniferous limestone. c. Old red sandstone.	Medial order.	Sometimes referred to the preceding, some- times to the succeeding class, by writers of these schools; very often the coal measures are refer- red to the former, the subjacent limestone and sandstone to the latter.	
4. Roofing slate, &c. &c.	Submedial order.	Transition class.	Intermediate class.
5. Mica slate, gness, granite, &c.	Inferior order.	Primitive class.	Primitive class.

In all these formations, from the lowest to the highest, we find a repetition of rocks and beds of similar chemical composition; i.e. siliceous, argillaceous, and calcareous, but with a considerable difference in texture; those in the lowest formations being compact and often crystalline, while those in the highest and most recent are loose and earthy. These repetitions form what the Wernerians call formation suites. We may mention

1st. The limestone suite. This exhibits, in the in-ferior or primitive order, crystalline marbles; in the two next, or transition and carboniferous orders, compact and subcrystalline limestones (Derbyshire limestone); in the supermedial or floetz order, less compact limestone (lias), calcareous freestone (Portland and Bath stone), and chalk; in the superior or newest floetz order, loose earthy limestones.

2d. The argillaceous suite presents the following gradations; clay slate, shale of the coal-measures, shale of the lias, clays alternating in the oolite series, and that of the sand beneath the chalk; and, lastly, clays above the chalk.

3d. The siliceous suite may (since many of the sand-stones of which it consists present evident traces of felspar and abundance of mica, as well as grains of quartz, and since mica is more or less present in every bed of sand) perhaps deserves to have granite placed at its head, as its several members may possibly have been derived from the detritus of that rock: it may be continued thus; quartz rock and transition sandstone, old red sandstone, millstone-grit, and coal-grits, new red sandstone, sand and sandstone beneath the chalk, and above the chalk. In all these instances a regular diminution in the degree of consolidation may be perceived in ascending the series.

["A Geological Nomenclature for North America, founded upon Geological Surveys, by Amos Eaton, Professor in the Rensellaer School at Troy, N. Y.

Classes of Rocks.

Classes of Rocks.

Classes 1. Primitive Rocks; being those which contain no organic relics nor coal See Fig. 1, 2, 3, 4, 5, and 6.

Class 2. Transition Rocks; being those which contain no animal remains, but radiated and molluscous—

tain no animal remains, but radiated and molluscous—
the latter more than one valved, or one valved and
chambered. See Fig. 7, 8, 9, 10, 11, and 12.

Class 3: Secondary Rocks; being those which contain in some localities, one valved molluscous animal
remains, not chambered. They embrace most of those
remains found in transition rocks also; and the upper
secondary rocks contain oviparous vertebral remains.
See Fig. 13, 14, 15, 16, 17, 18, and 19.

Class 4: Superincumbent Rocks; being those hornblende rocks, which overlay others without any regular
order of superposition, supposed to be of volcanic

order of superposition, supposed to be of volcanic origin. See Fig. 20.

Classes of Detritus.

Classes 5. Allavial Detritus; being those masses of detritus, which have been washed into their present situation. See Fig. 21, 22, 23, and 24.

Class 6. Anallavial Detritus; being those masses of detritus, which have not been washed from places where they were first formed by the disintegration of rocks. See Fig. 25 and 26.

^{*} No. 21. (Anteditavion) is the genuine fertiary infrantion in New Jersey, along the toy of Amony.

Frofestor Eaton has recently reviewed most of the territory upon which his synopsis was founded. He now Frofestor Eaton has recently reviewed most of the territory upon which his synopsis was founded. He now from that all strata may be arranged under five series, each comprising three formations: the first series according says that all strata may be arranged under five series, each comprising three formations: the first series according with the primitive class, the second with the transition, the third with the lower secondary, the fourth with the upper secondary, and the fifth with the territary: that the lower formation of every series is carboniferous, the middle upper secondary, and the fifth with the territary: that the lower formation of every series is carboniferous, the middle upper secondary, the upper one calcarcous. In the course of a year, this view of the series will appear in Silliman's Hustrated by a geological map of the State of New York. A prodeomus of these series will appear in Silliman's Journal.

392

DEFINITIONS* OF NAMES ARRANGED IN THE SYNOPSIS.

Names under the Primitive Class.

1. Granite, is an aggregate of angular masses of quartz, felspar, and mica. Subdivisions.—It is called chrystalline (granite proper) when the felspar and quartz present a crystalline, not a slaty, form. It is called slaty (gneiss) when the mica is so interposed in layers as to present a slaty form. Varieties.—It is graphic when the felspar is in a large proportion, and the quartz is arranged in oblong coasses, so as to present an appearance resembling Chinese letters. It is porphyritic when spotted with cuboid blocks of felspar. This variety is peculiar to the slaty division.

2. Mica-Slate, is an aggregate of grains of quartz and scales of mica. Subdivisions.—Compact, when the slaty laminæ are so closely united, that it will present a uniform smooth face when cut transversely. Fissile, when the laminæ separate readily by a blow 1. Granite, is an aggregate of angular masses of

Fissile, when the laming separate readily by a blow

upon its surface.

3. Hornblende Rock, is an aggregate, not basaltic, consisting wholly, or in part, of hornblende and felspar. Subdivisions.—Granitic, when it presents the appearance of crystalline granite with hornblende substituted for mica. Slaty, when of a rifty or tabular structure. Varieties.—Gneisscoid, when it resembles slaty granite (gneiss) with scales of hornblende substituted for mica. Greenstone, when of a pretty uniform green colour, and containing but a small proportion of felspar, generally of a slaty structure. Porphyritic, when spotted with cuboid blocks of felspar. when speckled with small irregular masses of felspar.

when speckled with small irregular masses of felspar.

4. Talcose Slate, is an aggregate of grains of quartz and scales of mica and talc.‡ Subdivisions.—

Compact, having the laminæ so closely united that a transverse section may be wrought into a smooth face. When the quartzose particles are very minute and in a large proportion, it is manufactured into scythe-whetstones, called Quinnebog stones. Fissile, when the laminæ separate readily by a blow upon the surface. Varieties.—Chloritic, when coloured green by chlorite. In some localities the chlorite seems to form beds; or rather the mek passes into an aggregate consisting of rather the rock passes into an aggregate consisting of quartz, mica, tale, and a large proportion of chlorite. Vast beds of pure chlorite are embraced in this rock on

Deerfield river, in Florida, Mass.

5. GRANULAR QUARTZ, consists of grains of quartz 5. Granular Quartz, consists of grains of quartz united without cement. Subdivisions.—Compact, when it consists of fine grains, so as to appear almost homogeneous; generally in large rhomboidal blocks. Sandy, when the grains are so slightly attached as to be somewhat friable. Varieties.—Translucent, when it is so compact and homogeneous as to transmit light. Yellow, when slightly tinged with iron (probably a carbonate). Ferruginous, when an aggregate of minute crystals, strongly coloured yellow or red with the carbonate or peroxyde of iron. There is a remarkable bonate or peroxyde of iron. There is a remarkable locality two miles north of Bennington village, in Vermont. Large masses may be found consisting of six-sided crystals, with six-sided pyramids on both ends.

6. Granular Limestone, consists of glimmering grains of carbonate of lime united without cement. Subdivisions.—Compact, when it consists of grains of nearly pure carbonate of lime, so closely united that it will take a polish. Sandy, when grains of quartz are aggregated with the grains of carbonate of lime, but so loosely as to be somewhat friable. Varieties.—Dodomite, when it consists in part of magnesia, and is friable. Verd-antique, when it is variegated in colour by the presence of serpentine, giving it more or less of

a clouded green.

Names under the Transition Class.
7. Argillite, is a slate rock of an aluminous

* Every rock consists, essentially, of one, two, or three, of the following nine homogeneous minerals. These are called the geological sphalet; and every student must procure and familiarize himself rith a specimen of each, before he commences the study of geology—unry, felspar, mics, take, horshleade, argillite, limestone, gypsum, hlorite. He should pracure also a specimen of iron pyrites, horshose, cale spar, reddle-ore, bog-ore, glance coal, hituminous coal.

1 I berieve McClure first applied this general name, to all the arbeites of primitive horableade rock.

2 That a small proportion of tale scales should serve to distinguish his rock from micasalate, would scarcely satisfy a mere cabine tudent. But the travelling geologist will acknowledge its importance of Taphocomo and Saddle mountains, and the same range along the vest side of the Green mountains to Canada.

character and nearly homogeneous, always consisting of tables or laminæ whose direction forms a large angle with the general direction of the rock. Subdivisions. Clay Slate, when the argillite is nearly destitute of all Clay State, when the argillite is nearly destitute of all griftliness, and contains no scales of mica or talc. Wacke State, when it is somewhat gritty and contains glimmering scales of mica or talc. Varieties.—Roof State, when the state is susceptible of division into pieces suitable for roofing houses and for ciphering state. Glazed State, when the natural cleavages are lined with a black glazing. This variety contains anthracite coal and marine organic relics.

8. First Graywaces is an aggregate of angular

8. First Graywacee, is an aggregate of angular grains of quartzose sand, united by an argillaceous cement, apparently disintegrated clay slate, and is never above the calciferous sandrock. Subdivisions.—Compact, when the grains are so fine and united so compactly, as to be suitable for quarrying. Rubble, when the grains, or a part of them, are too large for quarrying. This division is often very hard, and sometimes contains felspar, and has the appearance of coarse granite; though some of the largest pebbles are generally rounded. It is often coloured green with coarse grainte; though some of the largest penhies are generally rounded. It is often coloured green with chlorite. Every kind of first graywacke is almost horizontal—being a little elevated at the edge next to the primitive rocks only.

9. Sparry Limerock, consists of carbonate of lime intermediate in texture between granular and compact; and is traversed by veins of calcareous spar. Subdivisions.—Compact, when the masses or blocks, between the veins of spar, are sufficiently homogeneous and

the veins of spar, are sufficiently homogeneous and uniform to receive a polish. Slaty, when the rock is in slaty tables or laminæ, with transverse veins of calcareous spar. This rock is often cut into very small irregular blocks by the spar, which gives it the name of checkered rock.

of checkered rock.

of checkered rock.

10. CALCIFEROUS SANDROCK, consists of fine grains of quartzose sand and of carbonate of lime, united without cement, or with an exceeding small proportion. Subdivisions.—Compact, when the rock is uniform, or nearly so, without cells or cavities. Geodiferous, when it contains numerous geodes, or curvilinear cavities; which are empty or filled with calc spar, quartzerouslas harvess anthrocite or other mineral substances. crystals, barytes, anthracite, or other mineral substances different from the rock. Varieties.—Oditic, when it consists in part of colite, of a dark colour, and harder than the kind which is common in the lias or colitic formation of Europe.

11. METALLIFEROUS LIMEROCK, consists of carbonate of lime in a homogeneous state, or in a state of petrifactions. Subdivisions.—Compact, when it contains but few petrifactions, and is susceptible of a polish. Shelly, when it consists of petrifactions, mostly of bivalve molluscous animals. Variety.—Birdseye mar ble, when the natural layers are pierced transversely with cylindrical petrifactions, so as to give the birds-

eye appearance when polished.

12. Second Graywacke, scarcely distinguished from first graywacke, excepting by its relative position, being always above calciferous sandrock. visions .- Compact, when in blocks or slaty, consisting of fine grains. Rubble, when it consists of, or contains large rounded pebbles. The rubble of second graywacke is in a much smaller proportion than in first gray-wacke. Varieties.—Red sandy, when it passes into red sandstone, which formation occurs in a few locali-ties. Hone-slate, when soft, and suitable for setting a fine edge. Grind-stone, when the quartzose particles are sharp-angular.

Names under the Secondary Class.

13. MILLSTONE GRIT, is a coarse, hard aggregate of sharp angular quartzone sand or pebbles; mostly without any coment, always gray or rusty gray. Subdivisions.—Sandy, when it contains few or no pebbles. Conglomerate, when it consists chiefly of rounded

peobles.

14. Saliferous Rock, consists of red, or bluishgray, sand or clay-marle, or both. The grains of sand are mostly somewhat rounded, and all the varieties of this rock, in some localitics, form the floor of salt mines and salt springs. Subdivisions.—Marle-slate, when the rock is soft, slaty, and contains thinute grains of carbonate of lime. Sandy, when it is in solid blocks or layers, consisting of red or bluish grains. of carbonate of lime. Sanay, when it is in some blocks or layers, consisting of red or bluish-gray quartzose sand. Varieties.—Gray-band, the uppermost layers of bluish-gray sandrock. Conglomerate, (breccia) consisting chiefly of rounded pebbles, red. gray, or 393

Sandy, consists of a gray, or rusty-gray, aggregate of quartzose sandrock, in compact blocks or layers, overlaying or embracing red argillaceous iron ore. Variety. Conglomerate, consists of rounded pebbles, comented together by carbonate or oxide of iron, or adhering

without cement.

16. Lias, consists of rounded grains of quartzose sand, clay-slate, and sometimes partly of other aluminous compounds, of a dark or light-gray colour, aggregated with fine grains of carbonate of lime. Subdivisions .- Calciferous state, when it is of a slaty texture, and the argillaceous and calcareous constituents predominate. Calciferous grit, when it is in blocks or thick layers, and the quartzose sand, or sharp grit, predominates. Varieties.—Conchoidal, when the slaty kind is separated into small divisions, somewhat of a lenticular form, by natural conchoidal cleavages. Shell grit, when the gritty variety consists, in part, of petrifactions of quartzose sand.

17. Geodiferous Limerock, (lowest of the oolitic formation of Europe,) consists of carbonate of lime, combined with a small proportion of argillite or quartz, in a compact state, mostly fætid, and always containing numerous geodes. Subdivisions.—Swinestone, when it contains very little or no quartzose sand, is irregular in structure, fætid and abounds in geodes.

Sandy, when it contains quartzose sand, is stratified, scarcely fetid, and contains but few geodes.

18. Corntiferous Limerock, (included in the colitic formation of Europe,) consists of carbonate of lime, embracing hornstone. Subdivisions.—Compact, when the rock is close-grained; and it generally contains hornstone in layers. Shelly, when it consists of shells, and contains hornstone in nodules or irregular

mas 19. THERD GRAYWACKE, (well-known to be embraced in the oolitic formation of Europe; but contains no oolite,) having the character of first and second tains no colite,) having the character of first and second graywacke in general; but differing in containing much iron pyrites, fine grains of carbonate of lime, in larger or smaller proportion, and in having the quartzose grains mostly rounded.—Subdivisions.—Pyritiferous slate, when the rock has a slaty structure, and is in thin laminæ or in blocks or thick layers. Pyritiis in thin laming or in blocks of thick layers. Pyritferous grit, when the rock has a siliceous or gritty
structure, containing a large proportion of quartzose
sand or pebbles. Varieties.—Red sandstone, and red
wacke, when the gray rock passes into a dirty orange,
and thence into a red siliceous sandrock. This has
been called old red sandstone; but I do not believe that
week a green latest up is admissible. Conglowerate. such a general stratum is admissible. Conglomerate.

such a general stratum is admissible. Conglomerate, (breccia) when the rock consists chiefly of rounded pebbles, of a light-red, grayish red, or rust colour.

Names under the Superincumbent Class.

20. Basalt, is a hornblende rock, not primitive, probably of volcanic origin. Subdivisions.—Amygdaloid, when amorphous, of a compact texture, but containing cellules, empty or filled. Greenstone trap, when of a columnar structure, or in angular blocks, often coarsegrained. Variety.—Toadstone, when the amygdaloid has a warty appearance, and resembles slag.

Names under the Alluvial Class.

21. Antedluvion, or upper Tertians, when the

21. Antedituvion, or upper Tertians, when the detritus is in layers, so situated that it must have been deposited from water, while standing over it at a great depth, in nearly a quiescent state. As we have no chaik in North America, and as no tertiary rocks have As we have no hitherto been ascertained, this grand division may all be referred to detritus. Subdivisions.—Plastic clay, when it will not effervesce with acids; being destitute of carbonate of lime. Marly clay, when the clay contains fine grains of carbonate of lime, sufficient to effervesce strongly with acids. Marine, or Bagshot, sand and crag, when it consists of quartzose sand, nearly pure, or combined with a little loam, it is called nearly pure, or combined with a little main, it is called marine sand; when it passes into a gravelly formation, often containing pudding-stone, beds of clay, &c., it is called crag. Variety.—Hard-pan, when the crag consists of gravel, strongly cemented by clay.

22. DILUVION, consists of a confused mixture of

rust-colour, as under the superincumbent rocks at Mount Holyoke, the Pälisades, on the Hudson river, &c. 15. Ferrererors Rock, is a soft, slaty, argillaceous, or a hard, sandy, siliceous rock, embracing red argillaceous iron ore. Subdivisions.—Slaty, consists of green, or bluish-green, smooth soft slate, generally immediately under the layer of red argillaceous iron ore. Sandy, consists of a gray, or rusty-gray aggregate of 23. Littmate Dilivion, a thin deposite of yellow-

23. ULTIMATE DILUVION, a thin deposite of yellow-ish-gray loam, reposing on crag or some other sub-stance in ancient uncultivated forest grounds. It is so situated, that it could not have been produced by the disintegration of any stratum in the vicinity, nor by water when running with much velocity. It appears to have usen deposited from waters greatly elevated, and which had been rendered turbid by violent action, but had become almost quiescent. It may be consi-

dered as the last settlings of a deluge.

24. Post-pilluvion, when the detritus is so arranged that coarse pebbles appear towards the source of the waters which deposited them, and fine sediment more

remote.

Names under the Analluvial Class.

25. STRATIFIED ANALLUVION, is the detritus formed by the disintegration of rock strata, which remains in the situation formerly occupied by the rocks, retaining the same order of superposition. Subdivisions.— These take the names, and retain the essential characters, of the original rocks; as saliferous, ferriferous,

lias, &c.
26. Superficial Analluvion, is the detritus formed by the disintegration of the exposed surfaces of all rocks, and remains on or near the place of disintegration. Subdivisions.—Clay-loam, when the detritus is fine and adhesive. Granulated, when in coarse grains, or friable. The character of the soil depends on the character of the rock disintegrated.

Remarks.

1. The upper part of every general rock-stratum, is either more fissile or more loose and siliceous, than the under part. This affords a natural character for making the two-fold divisions adopted in this nomenclature.

2. The upper surface of every general rock-stratum in our district, is destitute of a superimposed rocky covering, for a great distance. This affords a very natural guide for the limit of general strata-

3. By general strata is meant, those deposites of rocks and detritus, which constitute the exterior visible rind of the earth, of nearly equal importance. They may be distinguished from each other by essential characters. The most conclusive is relative position -the next in importance is the contents-the last is the constituents. For example, we know the third gray-wacke as the uppermost rock in the regular series of superposition—we know the ferriferous rock from its embracing the argillaceous peroxyde of iron—we know the granite from its consisting of quartz, feldspar, and mica.

4. The words upper and lower are applied, without reference to degree of elevation. A stratum is said to be geologically the lowest, or oldest, when it is nearest to the centre of the range of granite towards which it

inclines.

5. General strata may be very naturally subdivided, are subject to variations in character, and contain beds. Numerous minerals not essential to their respective characters, are found in them in the state of veins and of dissemination. They appear to have become hard, while the strata containing them were in a soft state; for their forms are always impressed in them.

6. All strata have their peculiar associates and con-tents. Therefore a knowledge of strata enables us to foretell the probable discovery of useful minerals. Geology, then, embraces the "Science of Mining."

7. The bassetting, or out-cropping sides of transition and secondary rocks, at and near the edges approaching primitive rocks, present more of a primitive aspect, and contain fewer petrifactions, than other parts of the same rocks. A.)

GERA'NIS. (From yepavos, a crant: so called from its supposed resemblance to an extended crane.) A

bandage for a fractured clavicle.

GERA'NIUM. (From ycpavos, a crane: so called because its pistil is long like the bill of a crane.) Class, Monadelphia; Order, Decandria. The name of a genus of plants in the Linnman system. Geranium or crane's-bill.

appear to be considerable.

["Geranium Maculatum. Crane's-bill. The Geranium maculatum is a native (American) plant, common about woods and fences, and conspicuous for its large purple flowers in May and June.

"The root is horizontal, nearly as large as the little finger, tortuous, and full of knobs. To the taste it is a pure and powerful astringent. It abounds with tannin, which is imparted in great quantities both to the tincture and watery solution, and appears to be the basis of its medicinal efficacy.

"It is applicable to all the purposes of vegetable

"It is applicable to all the purposes of vegetable astringents, being surpassed by very few articles of that class. In various debilitating discharges, particularly from the bowels, it has afforded relief, when the disease has been of a nature to require astringent medicines. In apthous eruptions, and ulcerations of the mouth and throat, a strong decoction has been found beneficial as a gargle. A dose of the powder is twenty or thirty grains, and of a saturated tincture from one to two fluid drachms. The extract of this root is a very powerful astringent, and may be substituted for kino and catechu."—Big. Mat. Med. A.}

It is of great moment, for botanical distinctions, to observe whether it be superior, above the bases of the

at Strasburg. His master allowed him to devoce some time to study, in which he made great progress; and having acquired a little money, he went to Paris, where he improved rapidly in the classics and rheto-ric, and then turned his attention to philosophy and medicine. But he was soon compelled to return to his native country, and teach the languages, &c. for a livelihood. This enabled him afterward to resume his medical studies at Montrelier, and he graduated at livelihood. This enabled him afterward to resume his medical studies at Moutpelier, and he graduated at Basil in 1540. He then settled in his native city, where he was appointed professor of philosophy, which office he discharged with great reputation for twenty-four years. He had an early predilection for botany, which led him to cultivate other parts of natural history; he was the first collector of a museum, and acquired the character of being the greatest naturalist since Aristotle. He also founded and supported a botanic garden, had numerous drawings and wood engravings made of plants, and appears to have wood engravings made of plants, and appears to have meditated a general work on that subject. He likewise discovered the only true principles of botanical arrangement in the flower and fruit. Though of a feeble and sickly constitution, he traversed the Alps, and even sometimes plunged into the waters in search of plants: he also carefully studied their medical properties, and frequently hazarded his life by experiments on himself; indeed he was at one time reported to have been killed by the root of doronicum. His other occupations prevented his entering very extensively included in the control of the con sively into practice, but his enlarged views rendered him successful; and the profits of his profession ena-bled him to support the great expense of his favourite pursuits. He gave also many proofs of liberal and active friendship. He died of the plague, in 1565. His chief works are his "Historiæ Animalium," in three folio volumes, with wood cuts; and a pharma-copœia, entitled "De Secretis Remediis Thesaurus," which passed through many editions.

Gestation, uterine. See Pregnancy.
GE'UM. 1. The name of a genus of plants in the
Linnwan system. Class, Icosanaria; Order, Poly-

gynia.

2. The pharmacopæiai name of the two following species of this genus.

GEUM RIVALE. The root is the part directed for medicinal uses. It is inodorous, and imparts an austere taste. In America it is in high estimation in the constitution of intermittents, and is said to be more efficacious cure of intermittents, and is said to be more efficacious

cure of intermittents, and is said to be more efficacious than the Peruvian bark. Diarrhoeas and hæmorrhages are also stopped by its exhibition.

Geum urbanum. The systematic name of the herb bunnet, or avens. Caryophyllata; Herba bunedicta; Caryophyllus vulgaris; Garyophylla; Janamunda; Geum-floribus erectis, fructibus globosis villosis, aristis uncinatis nudis, foliis lyratis, of Linnæus. The root of this plant has been employed as a gentle styptic, corroborant, and stomachic. It has a mildly austere, somewhat aromatic taste, and a very pleasant styptic, corroborant, and stomachic. It has a mildly austere, somewhat aromatic taste, and a very pleasant smell, of the clove kind. It is also esteemed on the Continent as a febrifuge.

GIBBUS. Gibbous; swelled; applied to leaves when swelled on one side or both, from excessive abundance of pulp; as in the Aloe retusa.

GIDDINESS. See Vertigo.

GILBERT, WILLIAM, was born at Colchester, in 1540. After studying at Cambridge, he went abroad for improvement, and graduated at some foreign universal.

improvement, and graduated at some foreign univerobserve whether it be superior, above the bases of the calyx, or below.

GERMINATION. Germinatio. The vital developement of a seed, when it first begins to grow.

GEROCO'MIA. (From γερων, an aged person, and κομεω, to be concerned about.) That part of medicine which regards the regimen and treatment of old age. Gerontopo Gon. (From γερων, an old man, and aged man.) The herb old man's beard, a species of tragopogon.

Geronto'xon. (From γερων, an old person, and τοξον, a dart.) 1. A small ulcer, like the head of a dart, appearing sometimes in the cornea of old persons.

2. The socket of a tooth.

Geron' Gon. See Gerontopogon.

The root is much branched and knobby. It conwhich, when dry, is bittle, and very bitter to the taste, which, when dry, is bittle, and very bitter to the taste. The predominant soluble ingredients appear to be, a bitter extractive matter and resin. When boiled in water, it imparts to it a beautiful red wine-colour, and an intensely bitter taste. The tincture deposites an abundant regions, presimilate on the addition of abundant resinous precipitate on the addition of

"This article is one of the most prominent indigenous emetics, resembling ipecacuanha in its operation, but requiring a large dose. It sometimes fails to produce vomiting, especially if the portion used has become old. Thirty grains of the bark of the root, recently dried and powdered, are a suitable dose for an emetic. In doses so small as not to excite nausea, it has been thought useful as a tonic. The Gillenia stinulacea, of the western states, possesses properties pulacea, of the western states, possesses properties similar to those of this species."—Bigelow's Mat. Med.

GIN. Spiritus Juniperi. Geneva. Hollands. name of a spirit distilled from malt or rye, which afterward undergoes the same process, a second time, with juniper-berries. This is the original and most whole-some state of the spirit; but it is now prepared without juniper-berries, and is distilled from turpentine, which gives it something of a similar flavour. The consumption of this article, especially in the metropolis, is im-

mense, and the consequences are pernicious to the health of the inhabitants.

GINGER. See Zingiber.

GINGIBER. See Zingiber.

GINGIBERA'CHIUM. (From gingivæ, the gums, and brachium, the arm.) A name for the scurvy, because the gums, arms, and legs, are affected with it.

the gums, arms, and legs, are affected with it.

Ginoi'dium. A species of Daucus.

G'noihil. See Zingiber.

Ginoge dium. (From gingivæ, the gums, and pes, the foot.) A name for the scurvy, because the gums, arms, and legs are affected.

GINGI'VÆ. (From gigno, to beget; because the teeth are, as it were, born in them.) The gums. See

GINGLYMUS. (Γιγγλυμος, a hinge.) The hinge-ke joint. A species of diarthrosis or moveable connexion of bones, which admits of flexion and extension, as the knee-joint, &c.

GINSENG. An Indian word. See Panax quinque-

GIR. Quick-lime.
GI'RMIR. Tartar.
GITHAGO. A name used by Pliny, for the Lolium,

or darnet-grass.

GIZZARD. The stomach of poultry. Those from white flesh, have long been considered in France as medicinal. They have been recommended in obstructions of the urinary passages, complaints of the blad-der, and nephritic pains; but particularly as a febri-fuge. Bouillon Lagrange considers its principal sub-stance as oxygenated gelatine, with a small quantity of extractive matter.

of extractive matter.

Glabe'lla. (From glaber, smooth; because it is without hair.) The space between the eyebrows.

Glaber. Glabrous; Smooth; applied to stems, leaves, seeds, &c. of plants, and opposed to all kinds of hairiness and pubescence; as in the stem of the Euphorbia peplus, and the seeds of Galium montanum.

Glacies. Ice.

Gladi'olus. (Diminutive of gladius, a sword; so named from the sword-like shape of its leaf.) The name of a genus of plants in the Linnaan system.

Class, Triandria; Order, Monogynia.

Gladiolus luteus. See Iris pseudacorus.

Gla'ma. Thama. The sordes of the eye.

Gland. Glams. Glandula. I. In anatomy, an organic part of the body, composed of blood-vessels, nerves, and absorbents, and destined for the secretion or alteration of some peculiar fluid. The glands of nerves, and absorbents, and destined for the secretion or alteration of some peculiar fluid. The glands of the human body are divided, by anatomists, into different classes, either according to their structure, or the fluid they contain. According to their fabric, they are distinguished into four classes:

1. Simple glands.
2. Compounds of simple glands.
3. Conglobate glands.

3. Conglobate glands.

4. Conglomerate glands.

According to their fluid contents, they are more properly divided into, 1. Mucons glands.

Sebaceous glands.

Lymphatic glands.

Salival glands.

Lachrymal glands. Simple glands are small hollow follicles, covered with a peculiar membrane, and having a proper ex-cretory duct, through which they evacuate the liquor contained in their cavity. Such are the mucous glands of the nose, tongue, fauces, trachea, stomach, Such are the mucous intestine, and urinary bladder, the sebaceous glands about the anus, and those of the ear. These simple glands are either dispersed here and there, or are configuous to one another, forming a heap in such a man-ner that they are not covered by a common mem-brane, but each hath its own excretory duct, which is never joined to the excretory duct of another gland. The former are termed solitary simple glands, the lat-

The former are termed solidary simple glands, the latter aggregate or congregate simple glands.

2. The compound glands consist of many simple glands, the excretory ducts of which are joined in one common excretory duct; as the sebaceous glands of the face, lips, palate, and various parts of the skin, especially about the pubes.

3. Conglobate, or, as they are also called, lymphatic glands, are those into which lymphatic vessels enter, and from which they go out again; as the mescenteric

and from which they go out again: as the mesenteric, lumbar, &c. They have no excretory duct, but are composed of a texture of lymphatic vessels connected together by cellular membrane: they are the largest in the fœtus.

4. Conglomerate glands are composed of a congeries of many simple glands, the excretory ducts of which open into one common trunk: as the parotid gland, thyroid gland, pancreas, and all the salival glands. Conglomerate glands differ but little from the composed of more simple. pound glands, yet they are composed of more simple

glands than the compound.

glands than the compound.

The excretory duct of a gland is the duct through which the fluid of the gland is excreted. The vessels and nerves of glands always come from the neighbouring parts, and the arteries appear to possess a high degree of irritability. The use of the glands is to separate a peculiar liquor, or to change it. The use of the conglobate glands is unknown.

If the botany, Linnaus defines it, a little tumour discharging a fluid.

From their situation they are said to be

From their situation they are said to be, 1. Foliares, when on the surface of the leaf; as in the Gossypium religiosum, which has one gland on the leaf; and Gossypium barbadense, the leaves of which have three.

2. Petiolares, when in the footstalk; as in Prunus

3. Corollares. The claw of the corolla of the Berberis vulgaris has two glands.

4. Filamentares, in the filaments; as in Dictamnus albus.

From their adhesion,

1. Glandula sessilis, without any peduncle; as in Prunus cerasus.

2. Glandula pedicillata, furnished with a peduncle;

Glands are abundant on the stalk and calyx of the

Glands are abundant on the stalk and calyx of the moss-rose, and between the serratures of the leaf of the Salix pentandria; on the footstalks of the Viburnum opulus, and various species of passion-flower. The liquor discharged is resinous and fragrant.

GLANDORP, MATTRIAS LOUIS, was born at Cologne, in 1595. Soon after commencing his medical pursuits, he went to Padua, which had at that time great reputation. He improved so much in anatomy under Spigelius, that he was deemed competent to give public demonstrations: and he took his degree in 1618. He settled in Bromen, whence his family originated; and he was so successful in practice, that he was raised to the most honourable offices. He was physician to the archbishop, and to the republic, when he raised to the most honograble offices. He was physician to the archbishop, and to the republic, when he died in 1640. He left several works, with plates, containing many important observations on anatomy, &c. The principal are his "Speculum Chirurgorum," and The principal are his "Speculum Chirurgorum," and a Treatise on Issues and Setons. He was very partial to the use of the actual cautery, even in the most comGLA'NDULA. (A diminutive of glans, a gland.)
A small gland. See Gland.

GLANDULA LACHRYMALIS. See Lachrymal gland. GLANDULÆ MYRTIFORMES. See Carunculæ myr-

tiformes.

GLANDULÆ PACCHIONIÆ. A number of small, oval, fatty substances, not yet ascertained to be glandular, situated under the dura mater, about the sides of the longitudinal sinus. Their use is not known.

GLANDULOSOCA RNEUS. An epithet given by Ruysch to some excrescences, which he observed in the bladder.

bladder.

GLANDULOSUS. Glandular. 1. In anatomy, having the appearance, structure, or function of a

2. In botany, applied to leaves which have little glandiform elevations; as the bay-leaved willow, and Hypericum montanum.

GLANS. A gland, or nut. See Gland.
GLANS PENIS. The very vascular body that forms the apex of the penis. The posterior circle is termed the corona glandis. See Corpus spongiosum urethræ.
GLANS UNGUENTARIA. See Guilandina moringa.
GLASS. This substance was formerly employed

by surgeons, when roughly powdered, to destroy opacities of the cornea.

Glass of antimony. See Antimony.
Glass-wort, snail-seeded. See Salsola kali.
GLA'STUM. (Quasi callastum; from Callia, who first used it.) The herb woad. See Isatis tinctoria.
Glauber's salt. A sulphate of soda. It is found native in Bohemia, and is the produce of art. See

GLAUBERITE. A native crystallized salt, composed of dry sulphate of lime, and dry sulphate of soda, found in rock salt at Villarubra in Spain.

GLAUCEDO. (From γλαυκος, bluish, or greenish

GLAUCEDO. (From γλαυκος, bluish, or greenish tint.) See Glaucoma.

GLAUCIUM. (So named from its glaucous or seagreen colour. The name of a genus of plants in the Linnxan system. Class, Polyandria; Order, Monogynia.) The horned poppy.

GLAUCOMA. (From γλαυκος, blue; because of the eye becoming of a blue, or sea-green colour.) Glaucedo; Glaucosis; Apoglaucosis. 1. An opacity of the vitreous humour. It is difficult to ascertain, and is only to be known by a very attentive examination of is only to be known by a very attentive examination of

the eye.

2. A species of cataract. See Cataract.
GLAUCO'SIS. See Glaucoma.
GLAUCUS. (Γλαυκος, sea-green.) Stems are called glaucous which are clothed with a fine sea-green mealiness, which easily rubs off; as in Chlora per-

GLECO'MA. (From γληχων, the name of a plant in Dioscorides.) Class, Didynamia; Order, Gymnospermia. The name of a genus of plants in the Linnæan system. Ground-ivy.

GLECOMA HEDERACKA. The systematic name of the

ground-ivy, or gill. Hedera terrestris. Glecoma-foliis-reniformibus crenatis, of Linnæus. This indi-genous plant has a peculiar strong smell, and a bitterish somewhat aromatic taste. It is one of those plants which was formerly much esteemed for possessing virtues that, in the present age, cannot be detected. In obstinate coughs, it is a favourite remedy with the

Gle'chon. (Γληχων.) Pennyroyal, Glechon'tes. (From γληχων, pennyroyal.) Wine

GLECHONI TES. (From γληχων, pennyroyal.) Wine impregnated with pennyroyal.

GLEET. In consequence of the repeated attacks of gonorrhæa, and the debility of the part occasioned thereby, it not unfrequently happens, that a gleet, or constant small discharge takes place, or remains behind, after all danger of infection is removed. Mr. Hunter remarks, that it differs from gonorrhæa in being uninfections, and in the discharge consisting of ing uninfectious, and in the discharge consisting of globular particles, contained in a slimy mucus, instead of serum. It is unattended with pain, scalding in

of serum. It is unattended with pain, scalding in making of water, &c.

GLE'NE. Γληνη. Strictly signifies the cavity or socket of the eye; but by some anatomists is also used for that cavity of a bone which receives another with-

GLE'NOID. (Glenoides; from γληνη, a cavity, and ειδος, resemblance.) The name of articulate cavities of bones.

GLEU'CINUM. (From γλευκος, must.) An ointement, in the preparation of which was must.

GLEU'XIS. (From γλευκυς, sweet.) A sweet wine.

GLIADINE. Ser Gluten.

GLI SCERE. To increase gradually, properly as fire does; but, by physical writers, is sometimes applied to the natural heat and increase of spirits; and by others to the exacerbation of fevers which return performs the exacerbation of the exacerbation of fevers which return performs the exacerbation of the exacerbation of fevers which return performs the exacerbation of the ex others to the exacerbation of fevers which return periodically

GLISCHRO CHOLOS. (From γλισχρος, viscid, and χολη, the bile.) Viscid bilious excrement.
GLISCRA'SMA. (From γλισχραινώ, to become glutinous.) Viscidity.
GLISCON, Francis and born in Dorsetshire, 1597.

GLISSON, FRANCIS, was born in Dorsetshire, 1597.
He studied at both the English universities; but took
his degree of doctor in Cambridge, where he was
made Regius professor of Physic, which office he
held about forty years. He settled, however, to practise in London, and became a Fellow of the College in 1635; four years after which he was chosen reader of Anatomy, and distinguished himself much by his lectures "De Morbis Partium," which he was requested to publish. During the civil wars he retired to Colchester, where he practised with great credit; and was there during the siege of that town by the Parliamentary forces. He was one of the members of the society, which, about the year 1645, held weekly meetings in London to promote Natural Philosophy; and which having removed to Oxford during the troubles, was augmented after the Restoration, and became ultimately the present Royal Society. He was afterward several years president of the College of Physicians, and died at the advanced age of eighty. He left the following valuable works: 1. A Treatise on the Rickets. 2. The Anatomy of the Liver, which he described much more accurately than any one before, and particularly the capsule of the Vena Portarum, which has since been named after him. 3. A large metaphysical treatise "De Nata a Substantiæ Energetica," after the manner of Aristotle. 4. A Treatise on the Stomach, Intestines, &c., a well-arranged and comprehensive work, with various new observations, which came out the year before his death.

Glisson's Cansule. See Cansule of Glisson's Cansule. 1635; four years after which he was chosen reader of the year before his death.

Glisson's Capsule. See Capsule of Glisson.
GLOBATE. See Gland.
GLOBOSUS. Globose. A root is so called which is rounded, and gives off radicles in every direction; as that of the Cyclamen curopeum. The receptacle of the Cephalanthus and Nauclea, are so called from their form.

GLOBULA'RIA. (From globus, a globe: so called from the shape of its flower.) The French

GLOBULA'RIA ALYPUM. The leaves of this plant are used in some parts of Spain in the cure of the venereal disease. It is said to act also as a powerful but safe cathartic.

GLO'BUS. A ball.

GLOBUS HYSTERICUS. The air rising in the œso-phagus, and prevented by spasm from reaching the mouth, is so called by authors, because it mostly attends hysteria, and gives the sensation of a ball ascending in the throat.

GLOCHIS. (Γλωχις, cuspis teli.) A pointed hair. A sharp point: used in botany to a bristle-like pubescence, which is turned backwards at its point into

many straight teeth.
GLO'MER. A clue of thread. A term mostly ap-

plied to glands GLOMERATE. A gland is so called which is formed of a glomer of sanguineous vessels, having no cavity, but furnished with an excretory duct; as the

lachrymal and mammary glands
GLOMERULUS. In botany, a small tuft, or capitulum, mostly in the axilla of the peduncle.

GLOSSA GRA. (From γλωσσα, the tongue, and aγρα, a seizure.) A violent pain in the tongue.

GLOSSO. (From γλωσσα, the tongue.) Names compounded with this word belong to muscles, nerves, or vessels, from their being attached, or going to the

GLOSSO-PHARYNGEAL NERVES. The ninth pair of nerves. They arise from the processes of the cerebellum, which run to the medulla spinalis, and terminate by numerous branches in the muscles of the tongue and pharynx.

GLOSSO-PHARYNGEUS. See Constrictor pharyngeus

superior. GLOSSO-STAPHYLINUS. See Constrictor isthmi fau-

Glossoca Tochos. (From γλοσσα, tongue, and κα-τεχω, to hold.) An instrument in P. Ægineta for de-pressing the tongue. A spatula linguæ. The ancient glossocatochus was a sort of forceps, one of the blades

glossocatochus was a sort of forceps, one of the blades of which served to depress the tongue, while the other was applied under the chin.

GLOSSOCE LE. (From γλωσσα, the tongue, and κηλη, a tumour.) An extrusion of the tongue.

GLOSSOCOMA. A retraction of the tongue.

GLOSSOCOMA. By this was formerly meant a case for the tongue, for a hautboy; but the old surgeons, by metaphor, use it to signify an instrument, or case, for containing a fractured limb.

GLOTTA. (Γλωτ/α, the tongue.) The tongue.

GLOTTIS. (From γλωτ/α, the tongue.) The superior opening of the larynx at the bottom of the tongue.

tongue.

GLUCINA. (From ylukus, which signifies sweet, because it gives that taste to the salts in forms.) The name of an earth, for the discovery of which we are indebted to Vauquelin, who found it, in 1795, in the Aigue-marine or beryl, a transparent stone, of a green colour, and in the emerald of Peru. It exists combined with silex, alumine, lime, and oxide of iron, in the one; and with the same carths, and oxide of chrome, in the other. It has lately been discovered in the gadelinite by Mr. Ekeberg.

Glucina is white, light, and soft to the touch. It is insipid, and adheres to the tongue; and is intusible by itself in the fire. Its specific gravity is 2.967. It is so-

itself in the fire. Its specific gravity is 2.967. luble in alkalies and their carbonates, and in all the acids except the carbonic and phosphoric, and forms with them saccharine and slightly astringent salts. It is exceedingly soluble in sulphuric acid used to excess. It is fusible with borax, and forms with it a transparent glass. It absorbs one-fourth of its weight of carbonic acid. It decomposes sulphate of alumine. It is not precipitated by the hydro-sulphurets nor by prus-siate of potassa, but by all the succinates. Its affinity for the acids is intermediate between magnesia and alumine.

To obtain this earth, reduce some beryl to an impal-pable powder, fuse it with three times its weight of potassa, and dissolve the mass in muriatic acid. Separate the silex by evaporation and filtration, and de-compose the remaining fluid by adding carbonate of potassa; redissolve the deposite when washed in sul-pharic acid, and by mingling this solution with sul-phate of potassa, alum will be obtained, which crys-

Then mix the fluid with a solution of carbonate of ammonia, which must be used in excess; filter and boil it, and a white powder will gradually fall down,

boil it, and a white powder will gradually fall down, which is glucine.

GLUE. An inspissated jelly made from the parings of hides and other offals, by boiling them in water, straining through a wicker basket, suffering the impurities to subside, and then boiling it a second time. The articles should first be digested in lime water, to cleanse them from grease and dirt; then steeped in water, stirring them well from time to time; and, lastly, laid in a heap, to have the water pressed out, before they are put into the boiler. Some recommend, that the water should be kept as nearly as possible to a boiling heat, without suffering it to enter into ebullition. In this state it is poured into flat frames or moulds, then cut into square pieces when congealed, and afterward dried in a coarse net. It is said to improve by age; and that glue is reckoned the best, which swells considerably without dissolving by three or four days' infusion in cold water, and recovers its or four days' infusion in cold water, and recovers its former dimensions and properties by drying. Shreds or parings of vellum, parchment, or white leather, make a clear and almost colourless glue.

GLUMA. (Gluma, à glubendo, a husk of corn.)
The husk. The peculiar calyx of grasses and grasslike plants, of a chaffy texture, formed of little concave leaflets which are called valves. To the husk
belongs the arista, the beard or awn. See Arista.

The duma is

The gluma is,

1. Univalve, in Loilum perenne.

2. Bivalve, in most grasses.

398

Trivalved in Panicum miliaceum.

Many-valved, in Uniola paniculata:
Coloured, otherwise than green; as in Holcus

From the number of flowers the husk contains, it is

1. Gluma uniflora, one-flowered; as in Panicum.
2. G. biflora, with two; as in Aira.
3. G. multiflora, having many; as in Poa and

From the external appearance, the gluma is termed,
1. Glabrous, smooth; as in Holcus laxus.
2. Hispid, briskly; as in Secale orientale.
3. Striate; as in Holcus striatus.
4. Villose; as in Holcus sorgham, Holcus saccharatus, and Bromus purgans.
5. Ciliate, fringed; as in Bromus ciliatus.
6. Beardless; as in Briza and Poa.
7. Awned; as in Hordeum.
GLUMOSUS. A flower is so called, which is aggregate, and has a glumous or husky calyx.

gregate, and has a glumous or husky calyx.
GLUTEAL. Belonging to the buttocks.
GLUTEAL ARTERY. A branch of the internal iliac

GLU'TEN. (Quasigeluten; from gelo, to congeal.) See Gluc.

GLUTEN, ANIMAL. This substance constitutes the basis of the fibres of all the solid parts. It resembles in its properties the gluten of vegetables.

GLUTEN, VEGETABLE. If wheat-flower be made into a paste, and washed in a large quantity of water, it is separated into three distinct substances: a mucilaginous saccharine matter, which is readily dissolved in the liquor, and may be separated from it by evaporation; starch, which is suspended in the fluid, and subsides to the bottom by repose; and gluten, which remains in the hand, and is tenacious, very ductile, somewhat elastic, and of a brown-gray colour. The somewhat elastic, and of a brown-gray colour. The first of these substances does not essentially differ from other saccharine mucilages. The second, namely, the starch, forms a gluey fluid by boiling in water, though it is scarcely, if at all, acted upon by that fluid when cold. Its habitudes and products with the fire, or with nitric acid, are nearly the same as those of gum and of sugar. It appears to be as much more remote from the saline state than gum, as gum is more remote from the saline state than gum, as gum is more remote from that state than sugar.

The vegetable gluten, though it existed before the washing in the pulverulent form, and has acquired its tenacity and adhesive qualities from the water it has imbibed, is nevertheless totally insoluble in this fluid. It has scarcely any taste. When dry, it is semitransparent, and resembles glue in its colour and appearance. If it be drawn out thin, when first obtained, it may be dried by exposure to the air: but if it be exposed to warmth and moisture white wet, it putrefies like an animal substance. The dried gluten applied to the flame of a candle, crackles, swells, and burns, exactly like a feather, or piece of horn. It affords the same products by destructive distillation as animal matters do; is not soluble in alkohol, oils, or ather; and is acted upon by acids and alkalies, when heated. According to Rouelle, it is the same with the caseous substance of milk. tenacity and adhesive qualities from the water it has

According to Rouelle, it is the same with the caseous substance of milk.

Gluten of Wheat.—Taddey, an Italian chemist, has lately ascertained that the gluten of wheat may be decomposed into two principles, which he has distinguished by the names, gliadine (from $\gamma \lambda \iota a$, gluten,) and zimome (from $\zeta \iota \mu \eta$, ferment.) They are obtained in a separate state by kneading the fresh gluten in successive portions of alkohol, as long as that liquid continues to become milky, when diluted with water The alkohol solutions being set aside, gradually deposite a whitish matter, consisting of small filaments of gluten, and become perfectly transparent. Being now site a whitish matter, consisting of small filaments of gluten, and become perfectly transparent. Being now left to slow evaporation, the gliadine remains behind, of the consistence of honey, and mixed with a little yellow resinous matter, from which it may be freed by digestion in sulphuric æther, in which gliadine is not sensibly soluble. The portion of the gluten not dissolved by the alkohol is the zimome.

Properties of Gliadine.—When dry, it has a strawyellow colour, slightly transparent, and in thin plates, brittle, having a slight smell, similar to that of honeycomb, and, when slightly heated, giving out an odour similar to that of boiled apples. In the mouth, it becomes adhesive, and has a sweetish and balsamic

taste. It is pretty soluble in boiling aixohol, which loses its transparency in proportion as it cools, and then retains only a small quantity in solution. It forms a kind of varnish in those bodies to which it is applied. It softens, but does not dissolve in cold distilled water. At a boiling heat it is converted into froth, and the liquid remains slightly milky. It is specifically heavier than water.

The alkoholic solution of gliadine becomes milky when mixed with water, and is precipitated in white flocks by the alkaline carbonates. It is scarcely affected by the mineral and vegetable acids. Dry gliadine dissolves in caustic alkalies and in acids. swells upon red-hot coals, and then contracts in the manner of animal substances. It burns with a pretty lively flame, and leaves behind it a light spongy charcoal, difficult to incinerate. Gliadine, in some respects, approaches the properties of resins; but differs from them in being insoluble in sulphuric either. It is very sensibly affected by the infusion of nut-galls. It is capable of itself of undergoing a slow fermentation, and produces fermentation, and produces fermentation in saccharine substances. and produces fermentation in saccharine substances.

From the flour of barley, rye, or oats, no gluten can be extracted as from that of wheat, probably because

they contain too small a quantity.

The residue of wheat which is not dissolved in alkohol, is called zimome. If this be boiled repeatedly in

alkohol, it is obtained pure.

Zimome thus purified has the form of small globules, or constitutes a shapeless mass, which is hard, tough, destitute of cohesion, and of an ash-white colour. When washed in water, it recovers part of its visco-sity, and becomes quickly brown, when left in contact with the air. It is specifically heavier than water. Its mode of fermenting is no longer that of gluten; for when it purifies it exhales a fætid urinous odour. It dissolves completely in vinegar, and in the mineral acids at a boiling temperature. With caustic potassa, it combines and forms a kind of soap. When put into lime water, or into the solutions of the alkaline carbonates, it becomes harder, and assumes a new appearance without dissolving. When thrown upon red-hot coals, it exhales an odour similar to that of burning hair or hoofs, and burns with flame.

Zimome is to be found in several parts of vegetables. It produces various kinds of fermentation, according to the nature of the substance with which it comes in

GLUTE'US. (From γλουτος, the buttocks.) The name of some muscles of the buttocks.

GLUTEUS MAXIMUS. Gluteus magnus of Albinus. Glutaus major of Cowper; and Ilio sacro femeral of Dumas. A broad radiated muscle, on which we sit, is divided into a number of strong fasciculi, is covered by a pretty thick aponeurosis derived from the fascia lata, and is situated immediately under the integuments. It arises fleshy from the outer lip of somewhat more than the posterior half of the spine of the ilium, from the ligaments that cover the two posterior spinous processes; from the posterior sacro-ischiatic ligament; processes; and from the outer sides of the os sacrum and os coccygis. From these origins the fibres of the muscle run towards the great trochanter of the os femoris, where they form a broad and thick tendon, between which and the trochanter there is a considerable bursa mu cosa. This tendon is inserted into the upper part of the linea aspera, for the space of two or three inches downwards; and sends off fibres to the fascia lata, and to the upper extremity of the vastus externus. This muscle serves to extend the thigh, by pulling it directly backwards; at the same time it draws it a little outwards, and thus assists in its rotatory motion. Its origin from the coccyx seems to prevent that bone from being forced too far backwards.

GLUTEUS MEDIUS. Ilie trochanterien of Dumas. The posterior half of this muscle is covered by the gluteus maximus, which it greatly resembles in shape; but the anterior and upper part of it is covered only by the integuments, and by a tendinous membrane which belongs to the fascia lata. It arises fleshy from the outer lip of the anterior part of the spine of the ilium, from part of the posterior surface of that bone, and likewise from the fascia that covers it. From these origins its fibres run towards the great trochanter, into the outer and posterior part of which it is inserted by a broad tendon. Between this tendon and the trochanter there is a small thin bursa mucosa. The uses of

this muscle are nearly the same as those of the gide teus maximus; but it is not confined, like that muscle, to rolling the os femoris outwards, its anterior portion being capable of turning that bone a little inwards. As it has no origin from the coccyx, it can have no effect on that bone.

GLUTEUS MINIMUS. Glutæus minor of Albinus and Cowper; and Ilio ischii trochanterien of Dumas. A radiated muscle, is situated under the gluteus me-dius. In adults, and especially in old subjects, its outer surface is usually tendinous. It arises fleshy between the two semicircular ridges we observe on the outer surface of the ilium, and likewise from the edge of its great niche. Its fibres run, in different direc-tions, towards a thick flat tendon, which adheres to a capsular ligament of the joint, and is inserted into the fore and upper part of the great trochanter. A small bursa mucosa may be observed between the tendon of this muscle and the trochanter. This muscle assists the two former in drawing the thigh backwards and outwards, and in rolling it. It may likewise serve to prevent the capsular ligament from being pinched in the motions of the joint.
GLU'TIA. (From ylouros, the buttocks.) The

buttocks. See Nates
GLUTTU'PATENS. (From gluttus, the throat, and
GLUTTU'PATENS.) The stomach, which is an extension of the throat.
GLU'TUS. (Γλουτος; from γλοιος, filthy.) The

buttock. See Nates.
GLYCA'SMA. (From yhukus, sweet.) A sweet medicated wine.

GLYCYPI'CROS. (From γλυκυς, sweet, and πικρος, bitter: so called from its bitterish-sweet taste.) See

Solanum dulcamara.

GLYCYRRHIZA. (From γλυκυς, sweet, and ριζα, a root.) 1. The name of a genus of plants in the Linnæan system. Class, Diadelphia; Order, Decandria.

2. The pharmacopæial name of liquorice.

Glycyrrhiza glabra.
GLYCYRRHIZA ECHINATA. This species of liquorice

GLYCYRRHIZA ECHINATA. This species of liquorice is substituted in some places for the root of the glabra. GLYCYRRHIZA GLABRA. The systematic name of the officinal liquorice. Glycyrrhiza; leguminibus glabris, stipulis nullis, foliolo impari petiolato. A native of the south of Europe, but cultivated in Britain. The root contains a great quantity of saccharine matter, joined with some proportion of mucilage, and hence it has a viscid sweet taste. It is in common use as a postoral or empliient in catarrhal defluxions. use as a pectoral or emollient, in catarrhal defluxions on the breast, coughs, hoarsenesses, &c. Infusions, or the extract made from it, which is called Spanish liquorice, afford likewise very commodious vehicles for the exhibition of other medicines; the liquorice taste concealing that of unpalatable drugs more effectually than syrups or any of the sweets of the saccharine kind.

GLYCYSA'NCON. (From yluxus, sweet, and ayxwy, the elbow: so called from its sweetish taste, and its inflections, or elbows at the joints.) A species of south-

GNAPHA'LIUM. (From γνηφαλον, cotton: so named from its soft downy surface.) 1. The name of a genus of plants in the Linnaan system. Class, Syngenesia; Order, Polygamia superflua.

2. The pharmacopæial name of the herb cotton weed. See Gnaphalium dioicum.

GNAPHALIUM ARENARIUM. The flowers of this plant, as well as those of the gnaphalium stochas, are called, in the pharmacopoias, fores elichrysi. See Gnaphalium stachas.

GNAPHALIUM DIOICUM. The systematic name of The pes cati. Gnaphalium albinum. Cotton weed. The flores gnaphalii of the pharmacopæias, called also flores hispidulæ, seu pedis cati, are the produce of this plant. They are now quite obsolete, but were for merly used as astringents, and recommended in the cure of hooping-cough, phthisis pulmoralis, and hæ-

moptysis.

GNAPHALIUM STECHAS. The systematic name of Goldilocks. Elichrysum; Stachas citrina. The flowers of this small downy plant are warm, pungent, and bitter, and said to possess aperient and corroborant

GNA THUS. (From γναπ7ω, to bend; so called from their curvature.) 1. The jaw, or jaw-bones.

A compound rock, consisting of felspar, quartz, and mica, disposed in states, from the prepon-

derance of the mica scales,
GNI DIUS. A term applied by Hippocrates, and
others since, to some medicinal precepts wrote in the island of Gnidos.

Goat's-rue. See Galega.

Goat's-rue. See Galega.
Goat's-thorn. See Astragalus verus.
GOAT-WEED. See Egopodium.
GOUT WEED. See Egopodium podagraria.
GODDARD, Jonathan, was born at Greenwich, in
1617. After studying at Oxford, and travelling for improvement, he graduated at Cambridge, and settled to
practise in London. He was elected a Fellow of the
College of Physicians in 1646, and, the following year,
appointed Lecturer on Anatomy. He formed a Society for Experimental Inquiry, which met at his
house; and he was very assiduous in promoting its
objects. Having gained considerable reputation, and
sided with the popular party, he was appointed by
Cromwell chief physician to the army, and attended
him in some of his expeditions. Cromwell then made
him warden of Merton College, Oxford, afterward sole
representative of that university in the short partiahim warden of Merton College, Oxford, afterward sole representative of that university in the short parliament, in 1653, and in the same year one of the Council of State. On the Restoration, being driven from Oxford, he removed to Gresham College, where he had been chosen Professor of Physic. Here he continued to frequent those meetings, which gave birth to the Royal Society, and he was nominated one of the first council of that institution. He was an able and conscientious practitioner; and was induced, partly from the love of experimental chemistry, but principally from doubting the competency of apothecaries, to prepare his own medicines: in which, however, finding from doubting the competency of apothecaries, to prepare his own medicines: in which, however, finding numerous obstacles, he published "A Discourse, setting forth the unhappy Condition of the Practice of Physic in London;" but this was of no avail. Two papers of his appeared in the Philosophical Transactions, and many others in Birch's History of the Royal Society. He died in 1674, of an apoplectic stroke.

GOELICKE, Andrew Offon, a German physician, acquired considerable reputation in the beginning of the eighteenth century, as a medical professor.

ning of the eighteenth century, as a medical professor, and especially as an advocate of the doctrines of Stahl. and especially as an advocate of the doctrines of Stahl. He left several works which relate principally to the History of Anatomy, &c., particularly the "Historia Medicinæ Universalis," which was published in six different portions, between the years 1717 and 1720.

Goitre. See Bronchocele.

GOLD. Aurum. A metal found in nature only in a metallic state; most commonly in grains, ramifications, leaves, or crystals, rhomboidal, octahedral, or

a metallic state; most commonly in grains, ramincations, leaves, or crystals, rhomboidal, octahedral, or
pyramidal. Its matrix is generally quartz, sandstone,
siliceous schistus, &c. It is found also in the sands
of many rivers, particularly in Africa, Hungary, and
France, in minute irregular grains, called gold dust.
Native gold, found in compact musses, is never completely pure; it is alloyed with silver, or copper, and
sometimes with iron and tellurium. The largest piece
of native gold that has been hitherto discovered in of native gold that has been hitherto discovered in Europe, was found in the county of Wicklow, in Ireland. Its weight was said to be twenty-two ounces, and the quantity of alloy it contained was very small.

and the quantity of alloy it contained was very small. Several other pieces, exceeding one ounce, have also been discovered at the same place, in sand, covered with turf, and adjacent to a rivulet.

Gold is also met with in a particular sort of argentiferous copper pyrites, called, in Hungary, Gelf. This ore is found either massive, or crystallized in rhomboids, or other irregular quadrangular or polygonal masses. It exists likewise in the sulphurated area of masses. It exists likewise in the sulphurated ores of Nigaya in Transylvania. These all contain the metal called tellurium. Berthollet, and other French chemists, have obtained gold out of the ashes of vege-

cause they are as nails driven into their sockets.) The

dentes molares, or grinding teeth.

Go arno Ma. See Gomphosis.

GoMPHO'SIS. (From γομφοω, to drive in a nail.)

Gomphoma. A species of inmoveable connexion of bones, in which one bone is fixed in another, like a nail in a board, as the leath in the giveoli of the laws.

GONA'LGIA. See Gonyalgia.

GONA'GRA. (From yore, the knee, and αγρα, a seizure.) The gout in the knee.

GO'NE. (γονη.) 1. The seed.

GO'NE. (γονη.) 1. The seed.
2. In Hippocrates it is the uterus.

GONG. Tam-tam. A species of cymbal which produces a very loud sound when struck. It is an alloy of about eighty parts of copper with twenty of

GONGRO'NA. (From yoyyoos, a hard knot.) 1.

The cramp.

2. A knot in the trunk of a tree.

3. A hard round tumour of the nervous parts; but particularly a bronchocele, or other hard tumour of the

GONGY LION. (From γογγυλος, round.) A pill.
GONIOMETER. An instrument for measuring the
angles of crystals.
GONOI DES. (From γονη, seed, and ειδος, form.)

GONOI DES. (From γονη, seed, and stoos, torin.)
Resembling seed. Hippocrates often uses it as an epithet for the excrements of the belly, and for the contents of the urine, when there is something in them which resembles the seminal matter.

GONORRHŒ'A. (From γονη, the semen, and ρεω, to flow; from a supposition of the ancients, that it was a seminal flux.) A genus of disease in the class Locales, and order Apocenoses, of Dr. Cullen's arrangement, who defines it a preternatural flux of fluid rangement, who defines it a preternatural flux of fluid from the urethra in males, with or without fibidinous desires. Females, however, are subject to the same complaint in some forms. He makes four species, viz.

1. Generala pura of benigna; a puriform discharge from the urethra, without dysuria, or lascivious inclination, and not following an impure connexion.

inclination, and not following an impure connexion.

2. Gonorrhea impure, maligna, syphilitica, virulenta; a discharge resembling pus, from the urethra, with heat of urine, &c., after impure coition, to which often succeeds a discharge of mucus from the urethra, with little or no dysury, called a gleet. This disease is also called Finor albus malignus. Blennorrhagia, by Swediaur. In English, a clap, from the old French word clapises, which were public shops, kept and inhabited by single prostitutes, and generally confined to a particular quarter of the town, as is even now the case in several of the great towns in Italy. In Gercase in several of the great towns in Italy. In Germany, the disorder is named tripper, from dripping; and in French, chaudpisse, from the heat and scalding in making water.

No certain rule can be laid down with regard to the time that a clap will take before it makes its appear-ance, after infection has been conveyed. With some persons it will show itself in the course of three or four days, while, with others, there will not be the least appearance of it before the expiration of some weeks. appearance of it before the expiration of some weeks. It most usually is perceptible, however, in the space of from six to fourteen days, and in a male, begins with an uneasiness about the parts of generation, such as an itching in the glans penis, and a soreness and tingling sensation along the whole course of the ure-thra; soon after which, the person perceives an appearance of whitish matter at its orifice, and also some

degree of pungency upon making water.

In the course of a few days, the discharge of matter will increase considerably; will assume, most proba-bly, a greenish or yellowish hue, and will become thinbly, a greensh or yellowish me, and will become thin-ner, and lose its adhesiveness; the parts will also be occupied with some degree of redness and inflamma-tion, in consequence of which the glans will put on the appearance of a ripe cherry, the stream of urine will be smaller than usual, owing to the canal being made narrower by the inflamed state of its internal membrane, and a considerable degree of pain, and scalding heat will be experienced on every attempt to make

GOMPHI'ASIS. (From γομφος, a nail.) Gomphiassmus. A disease of the teetli, when they are loosened from the sockets, like nails drawn out of the wood.

Gomphia'smus. See Gomphiasis.

erected, particularly when the patient is warm in bed, and so deprives him of sleep, producing, in some cases, an involuntary emission of semen.

In consequence of the inflammation, it sometimes happens that, at the time of making water, owing to the rupture of some small blood-vessel, a slight hæmorrhage ensues, and a small quantity of blood is voided. In consequence of inflammation, the prepuce likewise becomes often so swelled at the end, that it cannot be drawn back, which symptom is called a phimosis; or, that being drawn behind the glans, it cannot be returned, which is known by the name of paraphimosis. Now and then, from the same cause, little hard swellings arise on the lower surface of the penis, along the course of the urethra, and these perhaps suppurate and form into fistulous sores. form into fistulous sores

The adjacent parts sympathizing with those already affected, the bladder becomes irritable, and incapable of retaining the urine for any length of time, which gives the patient a frequent inclination to make water, and he feels an uneasiness about the scrotum, perinaum, and fundament. Moreover, the glands of the groins grow indurated and enlarged, or perhaps the testicles become swelled and inflamed, in consequence of which he experiences excruciating pains, extending from the seat of the complaint up into the small of the back; he gets hot and restless, and a small sympto-

matic fever arises.

Where the parts are not occupied by much inflammation, few or none of the last-mentioned symptoms will arise, and only a discharge with a slight heat or

If a gonorrhea be neither irritated by any irregularity of the patient, nor prolonged by the want of timely and proper assistance, then, in the course of about a fortnight, or three weeks, the discharge, from having been thin and discoloured at first, will become thick, white, and of a ropy consistence; and from having gradually begun to diminish in quantity, will at last cease entirely, together with every inflammatory symptom whatever; whereas, on the contrary, if the patient has led a life of intemperance and sensuality, has partaken freely of the bottle and high-seasoned meats, and has, at the same time, neglected to pursue the necessary means, it may then continue for many weeks or mouths; and, on going off, may leave a weakness or gleet behind it, besides being accompanied with the risk of giving rise, at some distant period. nied with the risk of giving rise, at some distant period, to a constitutional affection, especially if there has been a neglect of proper cleanliness; for where vene-real matter has been suffered to lodge between the prepuce and glans penis for any time, so as to have oc-casioned either excoriation or ulceration, there will always be danger of its having been absorbed.

Another risk, arising from the long continuance of gonorrhoa, especially if it has been attended with inflammatory symptoms, or has been of frequent re-currence, is the taking place of one or more strictures in the urethra. These are sure to occasion a consider-able degree of difficulty, as well as pain, in making water, and, instead of its being discharged in a free and uninterrupted stream, it splits into two, or perhaps is voided drop by drop. Such affections become, from neglect, of a most serious and dangerous nature, as they not unfrequently block up the urethra, so as to

induce a total suppression of urine.

Where the gonorrhea has been of long standing, warty excrescences are likewise apt to arise about the parts of generation, owing to the matter falling and lodging thereon; and they not unfrequently prove both

numerous and troublesome.

Having noticed every symptom which usually at-tends on gonorrhæa, in the male sex, it will only be necessary to observe, that the same heat and soreness in making water, and the same discharge of discoloured mucus, together with a slight pain in walking, and an uneasiness in sitting, take place in females as in the former; but as the parts in women, which are most apt to be affected by the venereal poison, are less complex in their nature, and fewer in number, than in men, so of course the former are not liable to many of the symptoms which the latter are; and, from the urinary canal being much shorter, and of a more simple form, in them than in men, they are seldom, if ever, incommoded by the taking place of strictures.

With women, it indeed often happens, that all the

symptoms of a gonorrheea are so very slight, they ex-

perience no other inconvenience than the discharge, except perhaps immediately after menstruation, at which period, it is no uncommon occurrence for them to perceive some degree of aggravation in the symp-

Women of a relaxed habit, and such as have had frequent miscarriages, are apt to be afflicted with a disease known by the name of fluor albus, which it is often difficult to distinguish from gonorrhea virulenta, as the matter discharged in both is, in many cases, of the same colour and consistence. The surest way of forming a just conclusion, in instances of this nature, will be to draw it from an accurate investigation, both of the symptoms which are present and those which have preceded the discharge; as likewise from the concurring circumstances, such as the character and mode of life of the person, and the probability there may be of her having had venereal infection conveyed to her by any connexion in which she may be engaged.

Not long ago, it was generally supposed that gonor-rhea depended always upon ulcers in the urethra, producing a discharge of purulent matter; and such ulcers do, indeed, occur in consequence of a high degree of inflammation and suppuration; but many dissections of persons, who have died while labouring under a gonorrhœa, have clearly shown that the disease may, and often does, exist without any ulceration in the urethra, so that the discharge which appears is usually of a vitiated mucus, thrown out from the mucous folli-cles of the urethra. On opening this canal, in recent cases, it usually appears red and inflamed; its mucous glands are somewhat enlarged, and its cavity is filled with matter to within a small distance from its extremity. Where the disease has been of long continuance, its surface all along, even to the bladder, is generally found pale and relaxed, without any crosion.

3. Gonorrhaa laxorum, libidinosa; a pellucid dis-charge from the urethra, without erection of the penis,

but with venereal thoughts while awake.

4. Gonorrhæa dormientium. Oncirogonos. When during sleep, but dreaming of venergal engagements there is an erection of the penis, and a seminal dis-

A species of gonorrhæa af-GONORRHŒA BALANI.

GORGONIA. The name of a genus of corals.

Gorgonia nobilis. The red coral.

GOSSY PIUM. (From gotne, whence gottipium, Egyptian.) 1. The name of a genus of plants in the Linnæan system. Class, Monadelphia; Order, Polymerical

2. The pharmacopæial name of the cotton-tree. See

Gossypium herbaccum:

Gossypium Herbaceum. The systematic name of the cotton-plant. Gossypium; Bombaz. Gossypium—foliis quinquelobis subtus eglandulosis, caula herbaceo, of Linnæus. The seeds are directed for medicinal use in some foreign pharmacopæias; and are administered in coughs, on account of the mucilage they contain. The cotton, the produce of this tree, is well known for domestic purposes.

[Besides the Gossypium herbaceum, there are other species, producing cotton-wool, some of which is of a fawn-colour, found in Peru, and used by the natives of the country. Which of the following species it is, we have not been able to ascertain. Persoon, in his Synopsis Plantarum, gives the ten following species of Gossypium, viz. GOSSYPIUM HERBACEUM. The systematic name

of Gossypium, viz.

1. Gossypium herbaceum. indicum. micranthum.

> arboreum. vitifolium.

6. Gossypium hirsutum! religiosum. latifolium. barbadense.

peruvianum.

Goulard's Extract. A saturated solution of acetate of lead. See Plumbi acetatis liquor.
GOULSTON, THEODORE, was born in Northamptonshire. After studying medicine at Oxford, he practically active to the control of the tonsaire. After studying medicine at Oxford, he practised for a time with considerable reputation at Wymondham, of which his father was rector. Having taken his doctor's degree in 1610, he removed to London, and became a fellow of the College of Physicians. He was much esteemed for classical and theological learning, as well as in his profession. He died in 1632, and bequeathed £200 to purchase a rent-charge for maintaining an annual Pathological Lecture, to be read at the college by one of the tour innior doctors. He at the college by one of the four junior doctors. He translated and wrote learned notes on some of the works of Aristotle and Galen; of which the latter were not published till after his death.

GOURD. See Cucurbita.

Gourd, bitter. See Cucumis colocynthis.

GOUT. See Arthritis, and Podagra.

Gout stone. See Chalk stone.

GRAAF, REINIER DE, was born at Schoonhove, in Holland, 1641. He studied physic at Leyden, where he made great progress, and at the age of twenty-two published his treatise "De Succo Pancreatico," which gained him considerable reputation. Two years after he went to France, and graduated at Angers; he then returned to his native country, and settled at Delft, where he was very successful in practice; but he died at the early age of thirty-two. He published three dissertations relative to the organs of generation in both sexes; upon which he had a controversy with Swammerdam.

GRACULIS. (So named from its smallness.) Rec-

GRA'CILIS. (So named from its smallness GRA'CILIS. (So named from its smallness.) Rectus interior femoris, sive gracilis interior of Winslow. Sous pubio cretitibial of Dumas. A long, straight, and tender muscle, situated immediately under the integuments, at the inner part of the thigh. It arises by a broad and thin tendon, from the anterior part of the ischium and pubis, and soon becoming fleshy, descends nearly in a straight direction along the inside of the thigh. A little above the knee, it terminates in a slender and roundish tendon, which afterward becomes flatter, and is juserted into the middle ward becomes flatter, and is inserted into the middle of the tibia, behind and under the sartorius. Under the tendons of this and the rectus, there is a considerable bursa mucosa, which on one side adheres to them and to the tendon of the semitendinosus, and on the other to the capsular ligament of the knee. This musle assists in bending the thigh and leg inwards.

GRÆCUS. The trivial name of some herbs found

in or brought from Greece.

GRAFTING. Budding and inoculating is the process of uniting the branches or buds of two or more separate trees. The bud or branch of one tree, accompanied by a portion of its bark, is inserted into the bark of another, and the tree which is thus engrafted upon is called the stock. By this mode different kinds of fruits, pears, apples, plums, &c., each of which is only a variety accidentally raised from seed, but no further perpetuated in the same manner, are multiplied; buds of the kind wanted to be propagated, being engrated on so many stalks of a wild nature.

GRA'MEN. (Gramen, inis. n.) Grass. Any kind of grass-like herb.

of grass-like herb.
Gramen arundinaceum. See Calamagrostis.
Gramen cannum. See Triticum repens.
Gramen crucis cyperioldis. Gramen agyptiacum. Egyptian cock's-foot grass, or grass of the cross. The roots and plants possess the same virtues as the dog's grass, and are serviceable in the earlier stages of dropsy. They are supposed to correct the bad smell of the breath, and to relieve nephritic disorders, colics, &c., although now neglected.
Gramia. The sordes of the eyes.
GrammaTite. See Tremolite.

GRAMMATITE. See Tremolite.

GRAMMATITE. See Tremotte.

GRAMME. (From youngn, a line: so called from its linear appearance.) The iris of the eye.

GRAMADI'LLA. (Diminutive of granado, a pomegranate, Spanish: so called because at the top of the flower there are points, like the grains of the pomegranate.) The passion-flower, the fruit of which is said to possess refrigerating qualities. to possess refrigerating qualities.

GRANATITE. See Grenatite.
GRANATRI'STUM. A bile or carbuncle.
GRANATUM. (From granum, a grain, because if is full of seed.) The pomegranate. See Punica gra-

GRANDE'BALE. (Quod in grandioribus atate nas-cantur, because they appear in those who are advanced in years.) The hairs under the arm-pits. GRANDINOSUM OS. The os cuboides. GRA'NDO. (Grando, inis.f. Quod similitudinsm granorum habeat, because it is in shape and size like

a grain of seed.)

1. Hail.

A moveable tumour on the margin of the eyelid is so called, from its likeness to a hail-stone.
 GRANITE. A compound rock consisting of quartz,

GRANITE. A compound rock consisting of quartz, felspar, and mica, each crystallized, and cohering by mutual affinity without any basis or cement.

GRANULATION. (Granulatie; from granum, a grain.) '1. In surgery: The little grainlike fleshy bodies which form on the surfaces of ulcers and suppose the surfaces of ulcers. purating wounds, and serve both for filling up the cavities, and bringing nearer together and uniting their sides, are called granulations.

Nature is supposed to be active in bringing parts as nearly as possible to their original state, whose disposition, action, and structure, have been altered by accident, or disease; and after having, in her operations for this purpose, formed pus, she immediately sets about forming a new matter upon surfaces, in which there have been a breach of continuity. This there has been a breach of continuity. This process is called granulating or incarnation; and the substance formed is called granulations. The colour of healthy granulations is a deep florid red. When livid, they are unhealthy, and have only a languid circulation. Healthy granulations, on an exposed or flat surface, rise nearly even with the surface of the surrounding skin, and often a little higher; but when they exceed this, and take on a growing disposition, they are unhealthy, become soft, spongy, and without any disposition to form skin. Healthy granulations are

always prone to unite to each other, so as to be the means of uniting parts.

2. In chemistry: The method of dividing metallic substances into grains or small particles, in order to facilitate their combination with other substances, and sometimes for the purpose of readily subdividing them

GRANULATUS. Granulated. Applied to ulcers and to parts of plants. A root is so called which is jointed; as that of the Oxalis acetocella.

GRA'NUM. (Granum, i. n.) A grain or kernel. GRANUM CRIDIUM. See Daphne mezereum. GRANUM INFECTORIUM. Kermes berries.

GRANUM MERMES. Kermes berries.

GRANUM MOSCHI. See Hibiscus abelmoschus GRANUM PARADISI. See Amomum.

GRANUM REGIUM. The castor-oil seed. GRANUM TIGLII. See Croton tiglium.

GRANUM TIGLII. See Croton tiglium. GRANULATUS. Granulated. Applied to ulcers

GRAPHIC ORE. An ore of tellurium.
GRAPHIOTDES. (From γραφις, a pencil, and ειδος, a form.) 1. The styliform process of the os

2. A process of the ulna.
3. The digastricus was formerly so called from its

supposed origin from the above-mentioned process of the temporal bone
GRAPHITE. Rhomboidal graphite of Jameson, or plumbago, or black-lead, of which he gives two sub-species, the scaly and compact.

GRA'SSA. Borax.
GRATFOLA. (Diminutive of gratia, so named from its supposed admirable qualities.) Hyssop.

1. The name of a genus of plants in the Linnman system. Class, Diandria: Order, Monogynia.

2. The pharmacopæial name of the hedge-hyssop.

See Gratiola officinalis.

See Gratiola officinalis.

Gratiola officinalis.

Gratiola officinalis.

The systematic name of the hedge-hyssop. Digitalis minima; Gratia dei; Gratiola centauriodes. This exotic plant, the Gratiola;—foliis lanceolatis, serratis, floribus pedunculatis, of Linnœus, is a native of the south of Europe; but is raised in our gardens. The leaves have a nauscous bitter taste, but no remarkable smell; they purge and vomit briskly in the dose of half a drachm of the dry helb, or of a drachm infused in wine or water dry herb, or of a drachm infused in wine or water

This plant, in small doses, has been commonly employed as a cathartic and diuretic in hydropical diseases; and instances of its good effects in ascites and anasarca are recorded by many respectable practitioners. Gesner and Bergius found a scruple of the powder a sufficient dose, as in this quantity it frequently excited nausea or vomiting; others have given it to half a drachm, two scruples, a drachm, and even more.

An extract of the root of this plant is said to be more efficacious than the plant itself, and exhibited in the dose of half a drachm, or drachm, in dysenteries, produces the best effect. We are also told by Kostrzewski that in the hospitals at Vienna, three maniacal patients were perfectly recovered by its use; and in the most confirmed cases of lues venerea, it effected a complete cure; it usually acted by increasing the uri-

complete cure; it usually acted by increasing the urinary, cutaneous, or salivary discharges.

GRAVE'DO. (From gravis, heavy.) A catarrh, or cold, with a sense of heaviness in the head.

GRAVEL. See Calculus.

[GRAVEL ROOT. See Eupatorium purpureum. A.].

GRAVITY. A term used by physical writers to denote the cause by which all bodies move toward each other, unless prevented by some other force or obstacle.

GRAVITY, SPECIFIC. The density of the matter of which any body is composed, compared to the destiny of another body, assumed as the standard. This standard is pure distilled water, at the temperature of 60° F. To determine the specific gravity of a solid, we weigh it, first in air, and then in water. In the latter weigh it, first in air, and then in water. In the latter case, it loses of its weight a quantity precisely equal to the weight of its own bulk of water; and hence, by comparing this weight, with its total weight, we find its specific gravity. The rule, therefore, is, Divide the total weight by the loss of weight in water, the quotient is the specific gravity. If it be a liquid or a gas, we weigh it in a glass or other vessel of known capacity; and dividing that weight by the weight of the same bulk of water, the quotient is, as before, the specific gravity.

cific gravity.

["GREEN, THOMAS. The family of Green has made itself remarkable, in the medical profession, by its humble and singular origin. The subject of this notice, the medical ancestor of the family, was born in Maiden, and was one of the first settlers of Leicester, county of Worcester, Massachusetts. He received his first medical impressions, and impulse, from a book, given him by a surgeon of a British ship, who resided a few months at his father's, and took an interest in his vigorous and opening intellect. His outfit, for the wilderness, consisted of his gun, his axe, his book, his sack, and his cow. His first habitation was built by nature, its roof composed of a shelving rock. Here he passed the night in sound repose, after the labour of the day, in felling and clearing the forest. Soon after he began his settlement, he was attacked by a fever. Foreseeing the difficulties which must attend his situation, without a friendly hand to admiattend his situation, without a friendly hand to administer even the scanty necessaries of life, he had the precaution to tie a young calf to his cabin, formed under the rock. By this stratagem he was enabled to obtain sustenance from the cow, as often as she returned to give nourishment to her young. In this manner he derived his support for some weeks. By the aid of his book, and the knowledge of simples, a proficiency is provided by a consider of the programment of the provided by a proficiency is provided by a proficiency is provided by a profice of the provided by a profit of the provided by the ciency in which he early acquired by an intercourse with the Indians, he was soon enabled to prescribe successfully for the simple maladies of his fellow-settlers. By practice, from the necessity of the case, as

Green has attained its present eminence in the medical profession "—Thach. Med. Biog. A.]

["GREEN, Dr. John, (senior,) son of the above mentioned, was born at Leicester, in the year 1736. By the aid of his father, he early became a physician, and settled at Worcester. He married a daughter of Brigadier Ruggles, of Hardwick, and became the father of a large family. Not satisfied, as too many are, with the limited means of knowledge which necessarily fell to his lot, he afforded his children the best education in his lot, he afforded his children the best education. cation in his power. He was extensively employed, and distinguished himself for his tenderness and fidelity. He inherited a taste and skill in botany, with

well as from choice, he acquired theory and skill, and soon rose to great reputation. Thus, from fortuitous circumstances, and an humble beginning, the name of

his profession, from his father. In his garden were to be found the useful plant, the healing berb, and the grateful fruit; which either his humanity bestowed on the sick, or his hospitality on his friends. He died, November 29th, 1799, aged 63 years.—Thach. Med. Riog., A.1

November 29th, 1799, aged 63 years.—Thack. Med. Biog. A.]

["GREEN, Dr. John, (junior,) son of the preceding, was born A. D. 1763. Descended from ancestors who made the art of healing their study, Dr. Green was easily initiated in the school of physic; and, from his childhood, the natural bias of his mind led him to that profession, which, through life, was the sole object of his ardent pursuit. To be distinguished as a physician, was not his chief incentive. To assuage the sufferings of humanity, by his skill, was a higher motive of his benevolent mind. Every duty was performed with delicacy and tenderness. With these propensities, aided by a strong, inquisitive, and these propensities, aided by a strong, inquisitive, and discriminating mind, he altained to a pre-eminent rank among the physicians and surgeons of our country. To this sentiment of his worth, correctly derived from witnessing his practice on others, a more feeling tribute is added by those who have experienced his skill; for so mild was his deportment, so soothing were his manners, and so indefatigable was his attention, that he gained the unbounded confidence of his patients, and the cure was in a good measure performed before medicine was administered. To those who were acquainted with Dr. Green, the idea, that "some men are born physicians," was not absurd; for he not only possessed an innate mental fitness for the profession but was constitutionally formed to hear its fasion, but was constitutionally formed to bear its fatigues and privations. Few men, of his age, have had such extensive practice, or endured a greater va riety of fatigue, or have been so often deprived of stated rest and refreshment. It is worthy of remark, that in all the variety of duty, incident to his calling, he was never known to yield to the well-intended proffer of that kind of momentary refreshment, so ready at command, and so often successfully pressed upon the weary, exhausted, and incautious physician.
"The firmness and equanimity of his mind, which

were conspicuous in all the exigencies of life, forsook him not in death. With Christian resignation, he "set his house in order," knowing he "must die and not live." In perfect possession of his intellectual faculties, with a mind callm and collected, he spent the last moments of life performing its lest during with the moments of life performing its last duties, with the sublime feelings of a philosopher and Christian. And when, by an examination of his pulse, he found the cold hand of death pressing hard upon him, he bade a calm adieu to his attending physicians, whom he wished should be the sole witnesses of nature's last conflict. Placing himself in the most favourable posture for an easy exit, he expressed a hope that his for-titude would save his afflicted family and friends from the distress of hearing a dying groan. His hope was accomplished! He died, August 11th, 1808, aged 45 years. At his request, his body was examined. The cause of death was found in the enlargement, and consequent flaccidity, of the aorta."—Thacher's Med.

Biog. A.]

GREEN EARTH. Mountain green. A mineral of a celandine green colour, found in Saxony, Verona, and Hungary.

GREEN SICKNESS. See Chlorosis.

GREEN SICKNESS. See Chlorosis.

Green vitriol. Sulphate of iron.

GREENSTONE. A rock of the trap formation, consisting of a hornblend, and felspar, both in the state of grains or small crystals. See Diabase.

GREGORY, John, was born in 1725, his father being professor of medicine at King's College, Aberdeen: after studying under whom, he went to Edinburgh, Leyden, and Paris. At the age of 20, he was elected professor of philosophy at Aberdeen, and was made doctor of medicine. In the year 1756 he was chosen professor of medicine on the death of his brother James, who had succeeded his father in that chair. But about nine years after he went to Edinburgh; and But about nine years after he went to Edinburgh; and was appointed professor of the practice of medicine there, Dr. Rutherford having resigned in his favour. The year following, on the death of Dr. White, he was nominated first physician to the king for Scotland. He also enjoyed very extensive practice, prior to his death in 1773. He published, in 1765, "A Comparative View of the State and Faculties of Man with those of the Animal World," which contains many just and originate the state and the state But about nine years after he went to Edinburgh; and

nal remarks, and was very favourably received. Five years after his "Observations on the Duties and Offices of a Physician, &c.," given in his introductory lectures, were made public surreptitiously; which induced him to print them in a more correct form. The work has been greatly admired. His last publication, "Elements of the Practice of Physic" was intended as a syllabus to his lectures; but he did not live to

GRENATITE. Prismatoidal garnet.

GRESSURA. (From gradier, to proceed.) The perincum which goes from the pudendum to the anus.
GREW, NEHEMIAH, was born at Coventry; where, after graduating at some foreign university, he settled after graduating at some foreign university, he settled in practice. He there formed the idea of studying the anatomy of plants. His first essay on this subject was communicated to the Royal Society in 1670, and met with great approbation: whence he was induced to settle in London, and two years after became a fellow of that society; of which he was also at one period secretary. In 1680 he was made an honorary fellow of the College of Physicians. He is said to have atsecretary. In 1680 he was made an honorary fellow of the College of Physicians. He is said to have attained considerable practice, and died in 1711. His "Anatomy of Vegetable Roots and Trunks," is a large collection of original and useful facts; though his theories have been invalidated by subsequent discoveries. He had no correct ideas of the propulsion or direction of the sap; but he was one of the first who adopted the doctrine of the sexes of plants; nor did even the principles of methodical arrangement entirely escape his notice. In 1681, he published a descriptive catalogue of the Museum of the Royal Society; to which were added some lectures on the comciety; to which were added some lectures on the comparative anatomy of the stomach and intestines. Another publication was entitled "Cosmographia Sacra, or a Discourse of the Universe; as it is the Creature and Kingdom of God." His works were soon translated into French and Latin; but the latter very

GREYWACKE. A mountain formation, consist-ing of two similar rocks, which alternate with, and pass into each other, called greywacke, and greywacke-

GRIAS. (A name mentioned by Apuleius.) The name of a genus of plants. Class, Polyandria; Order,

Monogynia.

GRIAS CAULIFLORA. The systematic name of the tree, the fruit of which is the anchovy pear. The inhabitants of Jamaica esteem it as a pleasant and cool-

GRIE'LUM. A name formerly applied to parsley and

smallage.

GRIPHO'MENOS. (From γριφος, a net; because it surrounds the body as with a net.) Applied to pains which surround the body at the loins.

GROMWELL. See Lithospermum. GROSSULARE. A mineral of an asparagus-green

GROSSULARE. A mineral of an asparagus-green colour, of the garnet genus.
GROSSULA'RIA. (Diminutive of grossus, an unripe fig; so named because its fruit resembles an unripe fig.) The gooseberry, or gooseberry-bush. See Ribes.
GROTTO DEL CANE. (The Italian for the dogs' grotto.) A grotto near Naples, in which dogs are suffocated. The carbonic acid gas rises about eighteen inches. A man therefore is not affected, but a dog forcibly held in, or that cannot rise above it, is soon killed, unless taken out. He is recovered by plunging him in an adjoining lake. him in an adjoining lake.

Ground ivy. See Glecoma hederacea, Ground liverwort. See Lichen caninus. Ground nut. See Bunium bulbocastanum. See Teuerium chamæpitys.

Ground-pine. See Teuerium chamæpitys.
GROUNDSEL. See Senecio vulgaris.
GRUINALES. (From grus, a crane.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of geranium, or crane's-

bill genus principally.
GRU TUM. A hard, white tubercle of the skin, re-

sembling in size and appearance a millet-seed.

GRYLLUS. The name of an extensive genus of insects, including the grasshoppers, and the locust of the Scriptures.

GRYLLUS VERRUCIVORUS. The wart-cating grass-hopper. It has green wings, spotted with brown, and is caught by the common people in Sweden to destroy warts, which they do, by biting off the excrescence and discharging a corrosive liquor on the wound.

GRYPHO'SIS. (From γρυποω, to incurvate.) A disease of the nails, which turn inwards, and irritate

GUAI ACUM. GUAI ACUM. (From the Spanish Guayacan, which is formed from the Indian Hoazacum.) 1. The name of a genus of plants in the Linnman system.
Class, Decandria; Order, Monogynia.
2. The pharmacopeial name of the officinal guara-

cum. See Guaiacum officinale.

GUAIACUM OFFICINALE. This tree, Guaiacumfoliss bijugis, obtusis of Linnæus, is a native of the
West Indian islands. The wood, gum, bark, fruit,
and even the flowers, have been found to possess medicinal qualities. The wood, which is called Guaiacum Americanum; Lignum vitæ; Lignum sanctum; Lignum benedictum; Palus sanctus, is brought principally from Jamaica, in large pieces of four or five hundred weight each, and from its hardness and beauty is used The wood, which is called Guaiacum for various articles of turnery-ware. It scarcely dis-covers any smell, unless heated, or while rasping, in covers any smell, unless heated, or while rasping, in which circumstances it yields a light aromatic one; chewed, it impresses a slight acrimony, biting the palate and fauces. The gum, or rather resin, is obtained by wounding the bark in different parts of the body of the tree, or by what has been called jagging. It exudes copiously from the wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered and packed up in small kegs for exportation: it is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste, but little or no smell, unless heated. The bark contains less resinous matter than the wood, and is consequently a less powerful medicine, wood, and is consequently a less powerful medicine, though in a recent state it is strongly cathartic. "The though in a recent state it is strongly cathartic. "The fruit," says a late author, "is purgative, and, for medicinal use, far excels the bark. A decoction of it has been known to cure the venereal disease, and even the yaws in its advanced stage, without the use of mercury." The flowers, or blossoms, are laxative, and in Jamaica are commonly given to the children in the form of syrup. It is only the wood and resin of guaiacum which are now in general medicinal use in Europe; and as the efficacy of the former is supposed to be derived merely from the quantity of resinous to be derived merely from the quantity of resinous matter which it contains, they may be considered in-discriminately as the same medicine. Guafacum was first introduced into the materia medica soon after the discovery of America; and previous to the use of mercury in the lues venerea, it was the principal reme-dy employed in the cure of that disease: its great success brought it into such repute, that it is said to have been sold for seven gold crowns a pound: but notwithstanding the very numerous testimonies in its favour, it often failed in curing the patient, and was at length entirely superseded by mercury; and though it be still occasionally employed in syphilis, it is rather with a occasionally employed in syphilis, it is rather with a view to correct other diseases in the habit, than for its effects as an anti-venereal. It is now more generally employed for its virtues in curing gouty and rheumatic pains, and some cutaneous diseases. Dr. Woodville and others frequently conjoined it with mercury and soap, and in some cases with bark or steel, and found it eminently useful as an alterative. In the pharmacopoia it is directed in the form of mixture and tincture: the latter is ordered to be prepared in two ways. copæia it is directed in the form of mixture and tinc-ture: the latter is ordered to be prepared in two ways, viz. with rectified spirit, and the aromatic spirit of ammonia. Of these latter compounds, the dose may be from two scruples to two drachms; the gum is gene-rally given from six grains to twenty, or even more, for a dose, either in pills or in a fluid form, by means of mucilage or the yelk of an egg. The decoctum ligno-rum (Pharm. Edinb.) of which guaiacum is the chief ingredient, is commonly taken in the quantity of a pint a day. As many writers of the sixteenth century contended

that guaiacum was a true specific for the venereal dis-ease, and the celebrated Boerhaave maintained the ease, and the celebrated boernaave maintained the same opinion, the following observations are inserted: Mr. Pearson mentions, that when he was first intrusted with the care of the Lock Hospital, 1781, Mr. Bromfield and Mr. Williams were in the labit of reposing great confidence in the efficacy of a decoction of guaia-cum wood. This was administered to such patients as had already employed the usual quantity of mer-cury; but who complained of nocturnal pains, or had gummata, nodes, ozana, and other effects of the vene-

real virus, connected with secondary symptoms, as did not yield to a course of mercurial frictions. The diet consisted of raisins, and hard biscuit; from two to four pints of the decoction were taken every day; the hot bath was used twice a week; and a dose of anti-monial wine and laudanum, or Dover's powder, was commonly taken every evening. Constant confine-ment to bed was not deemed necessary; neither was exposure to the vapour of burning spirit, with a view of exciting perspiration, often practised; as only a moist state of the skin was desired. This treatment was sometimes of singular advantage to those whose health had sustained injury from the disease, long confinement, and mercury. The strength increased; bad ulcers healed; exfoliations were completed; and these anomalous symptoms which would have been exastered. perated by mercury, soon yielded to guaiacam.

Besides such cases, in which the good effects of

guaiacum made it be erroneously regarded as a specific for the lues venerea, the medicine was also formerly given, by some, on the first attack of the venereal dis-case. The disorder being thus benefited, a radical cure was considered to be accomplished: and though frequent relapses followed, yet, as these partly yielded to the same remedy, its reputation was still kept up. Many diseases also, which got well, were probably not venereal cases. Pearson seems to allow, that in syphilitic affections, it may indeed operate like a true antidote, suspending, for a time, the progress of certain venereal symptoms, and removing other appearances altogether; but he observes that experience has evinced, the content of the that the unsubdued virus yet remains active in the

constitution.

Pearson has found guaiacum of little use in pains of the bones, except when it proved sudorifie; but that it was then inferior to antimony or volatile alkali. When the constitution has been impaired by mercury and long confinement, and there is a thickened state of the ligaments, or periosteum, or foul ulcers still re-maining, Pearson says, these effects will often subside during the exhibition of the decoction; and it will often suspend, for a short time, the progress of certain often suspend, for a short time, the progress of certain secondary symptoms of the lues venera; for instance, ulcers of the tonsils, venereal eruptions, and even nodes. Pearson, however, never knew one instance in which guaiacum eradicated the virus; and he contends, that its being conjoined with mercury neither increases the virtue of this mineral, lessens its bad effects, nor diminishes the necessity of giving a certain quantity of it. Pearson remarks that he has seen guaiacum produce good effects in many patients, having cutaneous diseases, the ozena, and scrofulous affections of the membranes and ligaments.

GUILA'NDINA. (Named after Guilandus, a Prussian, who travelled in Palestine, Egypt, Africa, and Greece, and succeeded Faliopius in the botanical chair at Padua. He died in 1589.) The name of a genus of plants. Class, Decanaria; Order, Monogynia.

GUILANDINA BONDUC. The systematic name of the plant, the fruit of which is called Bonduch indorum. Molucca or bezoar nut. It possesses warm, bitter, and

Molucca or bezoar nut. It possesses warm, bitter, and carminative virtues.

GUILANDINA MORINGA. This plant, Guilandina-inermis, foliis subpinnatis, foliolis inferioribus terna-tis of Linnæus, affords the ben-nut and the lignum

nephriticum.

1. Ben nux; Glans unguentaria; Balanus myrepsica; Coatis. The oily acom, or ben-nut. A whitish nut, about the size of a small filberd, of a roundish triangular shape, including a kernel of the same figure, covered with a white skin. They were formerly employed to remove obstructions of the prime viæ. The oil afforded by simple pressure, is remarkable for its not growing rancid in Keeping, or, at least, not until it has stood for a number of years; and on this account, it is used in extricating the aromatic principles of such odoriforous flowers as yield little or no essenof such odoriferous flowers as yield little or no essential oil in distillation. The unalterability of this oil would render it the most valuable substance for cerates, or liniments, were it sufficiently common. It is actually employed for this purpose in many parts of

2. Lignum nephriticum. Nephritic wood. It is brought from America in large, compact, ponderous pieces, without knots, the outer part of a whitish, or pale yellowish colour, the inner of a dark brown or red. When rasped, it gives out a faint aromatic smell.

It is never used medicinally in this country, but stands high in reputation abroad, against difficulties of making urine, nephritic complaints, and most disorders of the kidneys and urinary passages.
GUINEA PEPPER. See Capsicum annuum.

Guinea-worm. See Medinensis vena. GUINTERIUS, Jonn, was born in 1487, at Anderreal name was said to have been Winther. He showed very early a great zeal for knowledge, and at the age of 12 went to Utrecht to study; but he had to struggle with great hardships, supported partly by his own in dustry, partly by the bounty of those who commiserated dustry, partly by the bounty of those who commiscrated his situation. At length, having given striking proofs of his talents, he was appointed professor of Greek at Louvain. But his inclination being to medicine, he went to Paris in 1525; where he was made doctor five years after. He was appointed physician to the king, and practised there during several years; giving also lectures on anatomy. His reputation had reached the north of Europe; and he received the most advantageous offers to repair to the court of Denmark. But geous offers to repair to the court of Denmark. But in 1537 he was compelled by the religious disturbances to retire into Germany. At Strasburgh he was received with honour by the magistrates, and had a chair as-lived, however, only twelve years to enjoy these honours, having died in 1574. His works are numerous, consisting partly of translations of the best ancient physicians, but principally of commentaries and illustrations of them.

GLIM I Grami. The publicate of regulations.

and illustrations of them.

GUM. I. Gummi. The mucilage of vegetables. It is usually transparent, more or less brittle when dry, though difficultly pulverable; of an insipid, or slightly saccharine taste; soluble in, or capable of combining with, water in all proportions, to which it gives a gluey adhesive consistence, in proportion as its quantity is greater. It is separable, or congulates by the action of weak acids; it is insoluble in alkohol, and in oil; and capable of the acid fermentation, when diluted with water. The destructive action of fire causes it to emit much carbonic acid, and converts it into coal without exhibiting any flame. Distillation affords water, acid, a small quantity of oil, a small quantity of ammonia, and much coal.

of ammonia, and much coal.

These are the leading properties of gums, rightly so called; but the inaccurate custom of former times applied the term gum to all concrete vegetable juices, so that in common we hear of gum copal, gum sandarach, and other gums, which are either pure resms, or mix-

tures of resins with the vegetable mucilage.

The principal gams are, 1. The common gams, obtained from the plum, the peach, the cherry-tree, &c. 2. Gum Arabic, which flows naturally from the acacia in Egypt, Arabia, and elsewhere. This forms a clear transparent mucilage with water. 3. Gum Seneca, or Sunegal. It does not greatly differ. Senegal. It does not greatly differ from gum Arabic: the pieces are larger and clearer; and it seems to com-municate a higher degree of the adhesive quality to water. It is much used by calico-printers and others. The first sort of gums are frequently sold by this name, but may be known by their darker colour. 4. Gum adragant, or tragacanth. It is obtained from a small plant, a species of astragalus, growing in Syria, and other eastern parts. It comes to us in small white con-torted pieces, resembling worms. It is usually dearer than other gums, and forms a thicker jelly with water.

Willis has found, that the root of the common blue-bell, Hyacinthus non scriptus, dried and powdered, affords a mucilage possessing all the qualities of that from gum Arabic. The roots of the vernal squill, white lily, and orchis, equally yield mucilage. Lord Dun-donald has extracted a mucilage also from lichens.

Gums treated with nitric acid afford the saclactic,

malic, and oxalic acids.

II. Gingiva. The very vascular and elastic substance that covers the alveolar arches of the upper and under jaws, and embraces the necks of the teeth.

See Acaria vera. Gum acacia. See Acacia vera. Gum arabic. See Acacia vera.

Gum, elastic. See Caoutchouc. GUM-BILE. See Parulis. GU'MMA. A strumous tumour on the periosteum of a bone

GUMMI. (Gummi, n. indeclin.) See Gum

GUMMI ACACLE. See Acacia vera. GUMMI ACANTHINUM. See Acacia vera. GUMMI ARABICUM. See Acacia vera. GUMMI CARANNE. See Caranna.

GUMMI CERASORUM. The juices which exude from the bark of cherry-trees. It is very similar to gum Arabic, for which it may be substituted.

GUMMI CHIBOU. A spurious kind of gum elemi, but little used.

GUMMI COURBARIL. An epithet sometimes applied to the juice of the Hymenaa courbaril. See Anime. Gummi Euphorbii. See Euphorbia.

GUMMI GALDA. See Galda. GUMMI GAMBIENSE. See Kino. GUMMI GUTTÆ. See Stalagmitis. GUMMI HEDERÆ. See Hedera heliz.

GUMMI JUNIPERINUM. See Juniperus communis.

GUMMI SENEGALENSE. See Mimosa Senegal.
GUMMI SENICA. See Acacia vera.
GUMMI THEBAICUM. See Acacia vera.
GUMMI TRAGACANTHE. See Astragalus.
GUM-RE'SIN. Gummi resina. Gum-resins are

the juices of plants that are mixed with resin, and an extractive matter, which has been taken for a gummy substance. They seldom flow naturally from plants, but are mostly extracted by incision in the form of white, yellow, or red fluids, which dry more or less quickly. Water, spirit of wine, wine, or vinegar, dissolve them only in part according to the proportion they contain of resin or extract. Gum-resins may also be formed by art, by digesting the parts of vegetables containing the gum-resin in diluted alkohol, and then evaporating the solution. For this reason most tinc-tures contain gum-resin. The principal gum-resins employed medicinally are aloes, ammoniacum, assafœti-da, galbanum, cambogia, guaiacum, myrrha, olibanum, opoponax, sagapenum, sarcocolla, scammonium, and

GUNDELIA. GUNDELIA. (The name given by Tournefort in honour of his companion and friend, Andrew Gundelscheimer, its discoverer, in the mountains of Armenia.) A genus of plants. Class, Syngenesia; Order, Poly-

gamia segregata.

GUNDELIA TOURNIFORTH. The young shoots of this plant are eaten by the Indians but the roots are

GUTTA. (Gutta, c. f.) 1. A drop. Drops are uncertain forms of administering medicines, and should never be trusted to. The shape of the bottle or of its mouth, from whence the drops fall, as well as the consistence of the fluid, occasion a considerable difference in the quantity administered. See Minimum.

A name of apoplexy, from a supposition that its cause was a drop of blood falling from the brain upon

the heart.

the heart.

GUTTA GAMBA. See Stalagmitis.

GUTTA NIGRA. The black drop, occasionally called the Lancashire, or the Cheshire drop. A secret preparation of opium said to be more active than the common tincture, and supposed to be less injurious, as seldom followed by headache.

GUTTA OPACA. A name for the cataract.

GUTTA SERENA. (So called by the Arabians.) See

Amaurosis.

GUTTE ROSACEE. Red spots upon the fice and

GUTTURAL. Belonging to the throat.

GUTTURAL ARTERY. The superior thyroideal artery. The first branch of the external carotid.

GYMNA'STIC. (Gymnasticus; from γυμνος, naked, performed by naked men in the public games.) This term is applied to a method of curing diseases by exercise, or that part of physic which treats of the rules that are to be observed in all sorts of exercises, for the preservation of health. This is said to have been invented by one Herodicus, born at Salymbra, a city of Thrace; or, as some say, at Leutini, in Sicily. He was first master of an academy where young gentlemen came to learn warlike and manly exercises; and observing them to be very healthful on that account, he made exercise become an art in reference to and observing them to be very healthful on that account, he made exercise become an art in reference to the recovering of men out of diseases, as well as preserving them from them, and called it Gymnastic, which he made a great part of his practice. But Hippocrates, who was his scholar, blames him sometimes for his excesses with this view. And Plato exclaims against him with some warmth, for enjoining his patients to walk from Athens to Megara, which is about 25 miles, and to come home on foot as they went, as soon as ever they had but touched the walls of the as soon as ever they had but touched the walls of the

GYMNOCARPI. The second division in Persoon's arrangement of mushrooms, such as bear seeds em-bedded in an appropriate, dilated, exposed membrane, denominated hymenium, like helvella, in which that part is smooth and even; boletus, in which it is porous; and the vast genus agaricus, in which it consists of

GYMNOSPERMIA. (From γυμνος, naked, and σπερμα, a seed.) The name of an order of the class Didynamia, of the sexual system of plants, embracing such as have added to the didynamial character, four naked seeds.

GYNÆ'CIA. (From γυνη, a woman.) The and also the lochia.

GYNÆ'CIUM. (From γυνη, a woman.) (From γυνη, a woman.) The menses,

1. A seraglio.
2. The pudendum muliebre.
3. A name for antimony.
GYNÆCOMA'NIA. (From γυνη, a woman, and μανια, madness.) That species of insanity that arises

GYNECOMY STAX. (From γυνη, a woman, and μυςταξ, a beard.) The hairs on the female pudendum. GYNECOMA STON. (From γυνη, a woman, and μαςος, a breast.) An enormous increase of the breasts

GYNANDRIA. (From yern, a woman, and grup, a man, or husband.) The name of a class in the sexual system of plants. It contains those hermaphrodite flowers, the stamina of which grow upon the pistil,

Gite flowers, the stamina of which grow upon the pistil, so that the male and female organs are united, and do not stand separate as in other hermaphrodite flowers.

GYPSATA. (From gypsum, a saline body consisting of sulphuric acid and lime.) Dr. Good denominates a species of purging diarrhaa gypsata, in which the digestions are liquid, serous, and compounded of earth of lime.

GYPSUM. A genus of minerals, composed of lime and sulphuric acid, containing, according to Jameson, two species: the prismatic and the axifrangible.

1. Prismatic gypsum, or anhydrite, has five sub-species: sparry anhydrite, scaly anhydrite, fibrous anhydrite, convoluted anhydrite, compact anhydrite. See Anhydrite.

Azifrangible gypsum contains six sub-species: sparry gypsum, foliated, compact, fibrous, scaly foliated, and earthy gypsum.

hæmorrhoidal discharges.

HÆMALO PIA. (From αιμα, blood, and οπ ζομαι, to see.) A disease of the eyes, in which all things appear of a red colour. A variety of the Pseudoblepsis

HÆ MALOPS. (From αμα, blood, and ωψ, the

11. MALOPS. (From αμα, blood, and ωψ, the face.) 1. A red or livid mark in the face or eye.

2. A blood-shot eye.

1. HEMA'NTHUS. (From αιμα, blood, and ανθος, a flower, so called from its colour.) The blood-flower.

1. HEMATE MESIS. (From αιμα, blood, and εμεω, to vomit.) Vomitus cruentus. A vomiting of blood is to vomit.) Vomitus cruentus. A vomiting of blood is readily to be distinguished from a discharge from the lungs, by its being usually preceded by sense of weight, pain, or anxiety in the region of the stomach; by its being unaccompanied by any cough; by the blood being discharged in a very considerable quantity; by its being of a dark colour, and somewhat grumous; and by its being mixed with the other contents of the

The disease may be occasioned by any thing re-ceived into the stomach, which stimulates it violently or wounds it; or may proceed from blows, bruises, or any other cause capable of exciting inflammation in this organ, or of determining too great a flow of blood to it; but it arises more usually as a symptom of some other disease (such as a suppression of the menstrual, or hæmorrhoidal flux, or obstructions in the liver, spleen, and other viscera) than as a primary affection. It is seldom, so profuse as to destroy the patient suddenly. seldom so profuse as to destroy the patient suddenly, and the principal danger seems to arise, either from the great debility which repeated attacks of the complaint induce, or from the lodgment of blood in the intestines,

which by becoming putrid might occasion some other disagreeable disorder.

This hamorrhage, being usually rather of a passive character, does not admit of large evacuations. Where it arises, on the suppression of the menses, in young persons, and returns periodically, it may be useful to anticipate this by taking away a few ounces of blood; not neglecting proper means to help the function of the uterus. In moderate attacks, particularly where the bowels have been confined, the infusion of roses and sulphate of magnesia may be employed: if this should not check the bleeding, the sulphuric acid may be exhibited more largely, or some of the more powerful astringents and tonics, as alum, tincture of muriate of iron, decoction of bark, or superacetate of lead. Where pain attends, opium should be given freely, taking care that the bowels be not constipated; and a blister to the epigastrium may be useful. If depending on scirrhous tumours, these must be attacked by mercury, hemlock, &c. In all cases the food should be light, and easy of digestion; but more nourishing as the patient is more exhausted.

HÆMATICA. The name of a class of diseases in HÆMATICA. The name of a class of diseases in Good's Nosology, of the sanguineous system. Its orders are, Pyretica, Phlegotica, Exanthematica, Dysthetica.

HÆMATIN. The colouring matter of logwood, and according to Chevreuil, a distinct vegetable substance. See Hæmatoxylon.

HÆMATITES. (From atµa, blood: so named from its property of stopping blood, or from its colour.)

Lapis hamatites. An elegant iron ore called blood Finely levigated, and freed from the grosser parts by frequent washings with water, it has been long recommended in hæmorrhages, fluxes, uterine obstructions, &c. in doses of from one scruple to three

Hæmati'tinus. (From αιμαζίζης, the bloodstone.) n epithet of a collyrium, in which was the bloodstone. Hæmatoce'le. (From αιμα, blood, and κηλη,

HARKIES. Werner's name for the capillary pyrites of Jameson, and the Nickel natif of Haüy. Native nickel. A.]

HABE'NA. A bridle. A bandage for keeping the lips of wounds together, made in the form of a bridle. HACUB. See Gundelia tournefortii.

HEMAGO'GA. (From aμα, blood, and αγω, to bring off.) Medicines which promote the menstrual and hamorrhoidal discharges. properly called hæmatoceic, is of four kinds; two of which have their seat within the tunica vaginalis testis; one within the albuginea; and the fourth in the tunica communis or common cellular membrane, investing the spermatic vessels.

In the passing an instrument, in order to let out the water from a hydrocele of the vaginal coat, a vessel is sometimes wounded, which is of such size, as to tinge the fluid pretty deeply at the time of its running out: the orifice becoming close, when the water is all discharged, and a plaster being applied, the blood ceases to flow from thence, but insinuates itself partly into the cavity of the vaginal coat, and partly into the cells of the scrotum; making in the space of a few hours, a tumour nearly equal in size to the original hydrocele.

This is one species.

This is one species.

It sometimes happens in tapping a hydrocele, that although the fluid discharged by that operation be perfectly clear and limpid, yet in a very short space of time (sometimes in a few hours,) the scrotum becomes as large as it was before, and palpably as fuil of a fluid. If a new puncture be now made, the discharge, instead of being limpid (as before,) is either pure blood or very bloody. This is another species; and, like the preceding, confined to the tunica vaginalis.

The whole vascular compages of the testicle is

The whole vascular compages of the testicle is sometimes very much enlarged, and at the same time rendered so lax and loose, that the tumour produced thereby has, to the fingers of an examiner, very much the appearance of a swelling composed of a mere fluid, supposed to be somewhat thick, or viscid. This is in supposed to be somewhat thick, or viscid. This is in some measure a deception; but not totally so: the greater part of the tumefaction is caused by the loosened texture of the testes; but there is very frequently a quantity of extravasated blood also. If this be supposed to be a hydrocele, and pierced, the discharge will be mere blood. This is a third kind of hæmatocele; and very different, in all its circumstances, from the two preceding: the fluid is shed from the vessels of the glandular part of the testicle, and contained within the glandular part of the testicle, and contained within the tunica albuginea.

The fourth consists in a rupture of, and an effusion of blood, from a branch of the spermatic vein, in its pas sage from the groin to the testicles. In which case, the extravasation is made into the tunica communis, or cellular membrane, investing the spermatic vessels.

Each of these species, Pott says, he has seen so dis-tinctly, and perfectly, that he has not the smallest doubt concerning their existence, and of their difference from each other.

HÆMATO'CHYSIS. (From arua, blood, and xew,

to pour out.) A hæmorrhage or flux of blood.

HÆMATO'DES. (From auµa, blood, and stöos, appearance: so called from the red colour.) 1. An old name for the bloody, crane's-bill. See Geranium sanguineum.

2. A fungus, which has somewhat the appearance of

blood.

blood. See Hamatoma.

HÆMATO'LOGY. (Hamatologia; from αιμα, blood, and λονος, a discourse.) The doctrine of the

HEMATOMA. (From αιμα, blood.) Fungus hamatodes. The bleeding fungus. Spongoid inflammation of Burns. This disease has been described also under the names of soft cancer and medullary sarcoma. It assumes a variety of forms, and attacks most parts of the body, but particularly the testicle, eye, breast, and the extremities. It begins with a soft enlargement or tumour of the part, which is extremely elastic, and in some cases very painful; as it increases, it often has the feel of an encysted tumour, and at length becomes irregular, bulging out here and there, and insinuates itself between the neighbouring parts, and forms a large mass, if under an aponeurotic expansion. When it ulcerates it bleeds, shoots up a mass of a bloody fungus, and then shows its decided character if unknown Most of the medicines which have been employed against cancerous diseases have been unprofitably exhibited against hæmatoma; as alteratives, both vegetable and mineral; tonics and narcotics. Extirpa-tion, when practicable, is the only cure.

Η ΕΜΑΤΟΜΡΗΛΙΟCΕ LE. (From αιμα, blood, ομφαλος, the navel, and κηλη, a tumour.) A tumour about the navel, from an extravasation of blood. A species of

ecchymosis.

H.EMATOPEDE'sis. (From αιμα, blood, and πεδαω, a ap.) The leaping of the blood from a wounded leap.)

HÆMATO'SIS. (From atua, blood.) A hæmorrhage or flux of blood.

HÆMATO'XYLON. (From atua, blood, and ξυλον, wood: so called from the red colour of its wood.) The name of a genus of plants in the Linnman system. Class,

Decandria; Order, Monogynia.

Hæmatoxylon campechlanum. The systematic name of the logwood-tree. Acacia Zeylonica. The part ordered in the Pharmacopæia, is the wood, called Hæmatoxyli lignum; Lignum campechense; Lignum Hamatoxyli lignum; Lignum campechense; Lignum campechianum; Lignum campescanum; Lignum indicum; Lignum sappan. Logwood. It is of a solid texture and of a dark red colour. It is imported principally as a substance for dying, cut into junks and logs of about three feet in length; of these pieces the largest and thickest are preserved, as being of the deepest colour. Logwood has a sweetish sub-adstringent taste, and no remarkable smell; it gives a purplish red tincture both to watery and spirituous infusions, and tinges the stools, and sometimes the urine, of the same colour. the stools, and sometimes the urine, of the same colour. It is employed medicinally as an adstringent and corroborant. In diarrheas it has been found peculiarly efficacious, and has the recommendation of some of the first medical authorities; also in the latter stages of dysentery, when the obstructing causes are removed; dysentery, when the obstructing causes are removed; to obviate the extreme laxity of the intestines usually superinduced by the repeated dejections. In the form of a decoction the proportion is two ounces to 2th. of fluid, reduced by boiling to one. An extract is ordered in the pharmacopæias. The dose from ten to forty grains. The colouring principle of this root is called hemetin. On the watery extract of logwood, digest alkohol for a day, filter the solution, evaporate, add a little water, evaporate greatly again, and then leave the little water, evaporate gently again, and then leave the liquid at rest. Hematin is deposited in small crystals, which, after washing with alkohol, are brilliant, and of a reddish-white colour. Their taste is bitter, acrid, and slightly astringent.

Hematin forms an orange-red solution with boiling water, becoming yellow as it cools, but recovering, with increase of licat, its former hue. Excess of alkali converts it first to purple, then to violet, and, lastly, to brown: in which state the hematin seems to be decomposed. Metallic oxides unite with hematin, forming a blue-coloured compound. Gelatin throws down reddish flocculi. Peroxide of tin, and acid, merely redden it.

down reddish floccult. Peroxide of tin, and acid, merely redden it.

HÆMATO'XYLUM. See Hæmatozylon.

HÆMATU'RIA. (From aima, blood, and ovoov, urine.) The voiding of blood with urine. This disease is sometimes occasioned by falls, blows, bruises, as hard riding and or some violent exertion, such as hard riding and jumping; but it more usually arises, from a small stone lodged either in the kidney or ureter, which by its size or irregularity wounds the inner surface of the part it comes in contact with; in which case the blood discharged is most usually somewhat coagulated, and the urine deposites a sediment of a dark brown colour, resembling the grounds of coffee.

A discharge of blood by urine, when proceeding

from the kidney or dreter, is commonly attended with an acute pain in the back, and some difficulty of mak-ing water, the urine which comes away first, being muddy and high coloured, but towards the close of its flowing, becoming transparent and of a natural ap-pearance. When the blood comes immediately from the bladder, it is usually accompanied with a sense of

matter 408

nant disease, it shows a highly putrid state of the blood, and always indicates a fatal termination. The appearances to be observed on dissection will

accord with those usually met with in the disease which

has given rise to the complaint.

When the disease has resulted from a mechanical injury in a plethoric habit, it may be proper to take blood, and pursue the general antiphlogistic plan, opening the bowels occasionally with castor oil, &c. When owing to calculi, which cannot be removed, we must be chiefly content with palliative measures, giving al-kalies or acids according to the quality of the urine; likewise mucilaginous drinks and clysters; and opium, fomentations, &c. to relieve pain; uva ursi also has been found useful under these circumstances; but more decidedly where the hæmorrhage is purely passive; in which case also some of the terebinthate remedies may be cautiously tried; and means of strengthening the constitution must not be neglected.

Η εμο' DIA. (From αιμωδεω, to stupefy.) A painful stupor of the teeth, caused by acrid substances touch-

ing them.

ing them.

HÆMO'PTOE. (From αιμα, blood, and π/νω, to spit up.) The spitting of blood. See Hæmoptysis.

HÆMO'PTYSIS. (From αιμα, blood, and π/νω, to spit.) Hæmoptoe. A spitting of blood. A genus of disease arranged by Cullen in the class Pyrexiæ, and order Hæmoprhagiæ. It is characterized by coughing up florid or frothy blood, preceded usually by heat or pain in the chest, irritation in the larynx, and a saltish taste in the mouth. There are five species of this disease.

Hamoptysis.plethorica, from fulness of the vessels. 2. Hamoptysis violenta from some external violence.
3. Hamoptysis phthisica, from ulcers corroding the Hamoptysis phthisica, from ulcers corroding the small vessels.

4. Hamoptysis calculosa, from calculous matter in

the lungs.

5. Hamoptysis vicaria, from the suppression of

some customary evacuation.

It is readily to be distinguished from hæmatemesis, as in this last, the blood is usually thrown out in considerable quantities; and is, moreover, of a darker con-lour, more grumous, and mixed with the other con-tents of the stomach; whereas blood proceeding from the lungs is usually in small quantity, of a florid co-lour, and mixed with a little frothy mucus only.

A spitting of blood arises most usually between the

ages of sixteen and twenty-five, and may be occasioned by any violent exertion either in running, jumping, wrestling, singing loud, or blowing wind-instruments; as likewise by wounds, plethora, weak vessels, hectic fever, coughs, irregular living, excessive drinking, or a suppression of some accustomed discharge, such as the menstrual or hæmorrhoidal. It may likewise be occa-sioned by breathing air which is too much rarefied to be able properly to expand the lungs.

Persons in whom there is a faulty proportion, either in the vessels of the lungs, or in the capacity of the chest, being distinguished by a narrow thorax and prominent shoulders, or who are of a delicate make and minent shoulders, or who are of a delicate make and sanguine temperament, seem much predisposed to this hamorrhage; but in these, the complaint is often brought on by the concurrence of the various occasional and exciting causes before mentioned.

A spitting of blood is not, however, always to be considered as a primary disease. It is often only a symptom, and in some disorders, such as pleurisies, peripneumonies, and many fevers, often arises, and is

peripneumonies, and many fevers, often arises, and is the presage of a favourable termination.

Sometimes it is preceded, as has already been observed, by a sense of weight and oppression at the chest, a dry tickling cough, and some slight difficulty of breathing. Sometimes it is ushered in with shiverings, coldness at the extremities, pains in the back and loins, flatulency, costiveness, and lassitude. The blood which is spit up is generally thin, and of a florid red colour; but sometimes it is thick, and of a dark or blackish cast; nothing, however, can be inferred from this circumstance, but that the blood has lain a longer or shorter time in the breast, before it was discharged. An hæmoptoe is not attended with danger, where no

symptoms of phthisis pulmonalis have preceded or accompanied the hæmorrhage, or where it leaves beheat and pain at the bottom of the belly.

The voiding of bloody urine is always attended with some danger, particularly when mixed with purulent that when it arises in the course of any malignal of a sound constitution; but when it attacks persons hind no cough, dyspnæa, or other affection of the lungs; nor is it dangerous in a strong healthy person, of a weak lax fibre, and delicate habit, it may be difficult to remove it.

It seldom takes place to such a degree as to prove fatal at once; but when it does, the effusion is from some large vessel. The danger, therefore, will be in proportion as the discharge of blood comes from a

large vessel, or a small one.

When the disease proves fatal, in consequence of the rupture of some large vessels, there is found, on dissection, a considerable quantity of clotted blood in the lungs, and there is usually more or less of an in-flammatory appearance at the ruptured part. Where the disease terminates in pulmonary consumption, the same morbid appearances are to be met with as de-scribed under that particular head.

In this hæmorrhage, which is mostly of the active kind, the antiphlogistic regimen must be strictly observed; particularly avoiding heat, muscular exer-tion, and agitation of the mind; and restricting the patient to a light, cooling, vegetable diet. Acidulated drink will be useful to quench the thirst, without so drink will be useful to quench the thirst, without so much liquid being taken. Where the blood is discharged copiously, but no great quantity has been lost already, it will be proper to attempt to check it by bleeding freely, if the habit will allow and sometimes, where there is pain in the chest, local evacuations and blisters may be useful. The bowels should be well cleared with some cooling saline cathartic, which may be given in the infusion of roses. Digitalis is also a proper remedy, particularly where the pulse is very quick, from its sedative influence on the heart and arteries. Antimonials in nauseating doses have some Antimonials in nauseating doses have sometimes an excellent effect, as well by checking the force of the circulation, as by promoting diaphoresis; calo-mel also might be added with advantage; and opium, or other narcotic, to relieve pain and quiet cough, which may perhaps keep up the bleeding. Emetics have, on some occasions, been successful; but they are not altogether free from danger. In protracted cases, internal astringents are given, as alum, kino, &c. but their effects are very precarious: the superacetate of lead, however, is perhaps the most powerful medicine, especially combined with opium, and should always be resorted to in alarming or obstinate cases, though as it is liable to occasion colic and paralysis, its use should not be indiscriminate; but it acts probably rather as a sedative than astringent. Sometimes the application of cold water to some sensible part of the body, producing a general refrigeration, will check the bleeding. When the discharge is stopped, great attention to regimen is still required, to obviate its return, with occasional evacuations: the exercise of swinging, riding in an easy carriage, or on a gentle horse, or especially sailing, may keep up a salutary determination of the blood to other parts: an occasional blister may be applied, where there are marks of local disease, or an issue or seton perhaps answer better. Should hæmoptysis occasionally exhibit rather the passive character, evacuations must be sparingly used, and tonic medicines will be proper, with a more nutritious diet.

nutritious diet.

HÆMORRHAGIA. (From aiµa, blood, and pyyvoµi, to break out.) A hæmorrhage, or flow of blood.

HÆMORRHA'GIÆ. Hæmorrhages, or fluxes of blood. The name of an order in the class Pyreziæ of Cullen's Nosology is so called. It is characterized by pyrexia with a discharge of blood, without any external injury; the blood on venæsection exhibiting the buffy coat. The order Hæmorrhagiæ contains the following genera of diseases, viz. epistaxis, hæmoptysis, (of which phthisis is represented as a sequel,) hæmorrhois, and menorrhagia.

rhois, and menorrhagia.

HÆMORRHOI DAL. (Hamorrhoidalis; the name of the vessels which are the seat of the hæmorrhoids or piles.) 1. Of or belonging to the hæmorrhoidal vessels.

2. The trivial name of some plants which were supposed to be efficacious against piles; as Carduus ha-

morrhoidales, &c.

HEMORRHOIDAL ARTERIES. Arteriæ hæmorrhoi-dales. The arteries of the rectum are so called: they are sometimes two, and at other times three in number. The upper hamorrhoidal artery, which is the great branch of the lower mesenteric continued into the petvis 2 The middle hamorrhoidal, which somepelvis 2 The middle harmorrhoidal, which some-times comes off from the hypogastric artery, and very often from the pudical artery. It is sometimes want-ing. 3 The lower or external harmorrhoidal is almost

always a branch of the pudical artery, or that artery which goes to the penis.

HEMORRHOIDAL VEINS. Venæ Hemorrhoidales. These are two. 1. The external, which evacuates it self into the vena iliaca interna.

2. The internal, which conveys its blood into the

HÆMO'RRHOIS. (From atμa, blood, and ρεω, to flow.) Aimarrhois. The piles. A genus of disease in the class pyrexiæ, and order Hæmarrhagiæ of Cullen. They are certain excrescences or tumours arising about the verge of the anus, or the inferior part of the intestinum rectum; when they discharge blood, partiknown by the name of bleeding piles; but when there is no discharge, it is called blind piles. The rectum as well as the colon, is composed of several membranes connected to each other by an intervening cellular substance; and as the muscular fibres of this intestine always tend, by their contraction, to lessen its cavity, the internal membrane, which is very lax, forms itself into several rugæ, or folds. In this construction nature respects the use of the part, which occasionally gives passage to, or allows the retention of, the excrements, the hardness and bulk of which might produce considerable lacerations, if this intestine were not capable of dilatation. of dilatation. The arteries and veins subservient to this part are called hæmorrhoidal, and the blood that returns from hence is carried to the meseraic veins. The intestinum rectum is particularly subject to the hemorrhoids, from its situation, structure, and use; for while the course of the blood is assisted in almost all the other veins of the body, by the distention of the adjacent muscles, and the pressure of the neigh-bouring parts, the blood in the hæmorrhoidal veins, which is to ascend against the natural tendency of its own weight, is not only destitute of these assistances, but is impeded in its passage: for, first, the large ex-crements which lodge in this intestine dilate its sides, and the different resistances which they form there are so many impediments obstructing the return of the blood; not in the large veins, for they are placed along the external surface of the intestine, but in all the capillaries which enter into its composition. as often as these large excrements, protruded by others, approached near the anus, their successive pressure upon the internal coats of the intestine, which they dilate, drives back the blood into the veins, and for so dilate, drives back the blood into the veins, and for so long suspends its course; the necessary consequence of which is, a distention of the veins in proportion to the quantity of blood that fills them. Thirdly, in every effort we make, either in going to stool, or upon any other occasion, the contraction of the abdominal muscles, and the diaphragm pressing the contents of the abdomen downwards, and these pressing upon the parts contained in the pelvis, another obstruction is thereby opposed, to the return of the blood, not only in the large veins, but also in the canillaries, which in the large veins, but also in the capillaries, which, being of too weak a texture to resist the impulse of the blood that always tends to dilate them, may hereby become varicose.

The dilatation of all these vessels is the primary cause of the hamorrhoids; for the internal coat of the intestine, and the cellular membrane which connects that to the muscular coat, are enlarged in proportion to the distention of the vessels of which they are composed. This distention, not being equal in every part, produces separate tumours in the gut, or at the verge of the anus, which increases according as the venal blood is obstructed in them, or circulates there

more slowly.

Whatever, then, is capable of retarding the course of the blood in the hemorrhoidal veins, may occasion of the blood in the hæmorrhoidal veins, may occasion this disease. Thus, persons that are generally costive, who are accustomed to sit long at stool, and strain hard; pregnant women, or such as have had difficult labours: and likewise persons who have an obstruction in their liver, are for the most part afflicted with the piles; yet every one has not the hæmorrhoids, the different causes which are mentioned above being not common to all, or at least not having in all the same effects. When the hæmorrhoids are once formed, they seldom disappear entirely, and we may judge of those within the rectum by those which, being at the verge of the anus, are plainly to be seen. A small pile, that has been painful for some days, may cease to be so, and dry up; but the skin does not afterward

etain its former firmness, being more lax and wrin-ded, like the empty skin of a grape. If this external dile swells and sinks again several times, we may pereive, after each return, the remains of each hough shrivelled and decayed, yet still left larger than before. The case is the same with those that are situated within the rectum; they may happen indeed hever to return again, if the cause that produced them is removed; but it is probable that the excrements in passing out occasion a return of the swelling, to which the external ones are less liable: for the internal piles make a sort of knots or tumours in the intestine, which straightening the passage, the excrements in passing out, occasion irritations there that are more or less out, occasion irritations there that are more or less painful in proportion to the efforts which the person makes in going to stool; and it is thus these tumours become gradually larger. The hemorrhoids are subject to many variations; they may become inflained from the above irritations to which they are exposed, and this inflammation cannot always be removed by art. In some, the inflammation terminates in an abscess, which arises in the middle of the tumour, and degenerates into a fistula. These piles are very painful till the abscess is formed. In others, the inflammation terminates by induration of the hemorrhoid, which re-mains in a manner scirrhous. These never lessen, but often grow larger. This scirrhus sometimes ulcerates, often grow larger. This scirrhus sometimes ulcerates, and continually discharges a sanies, which the patient perceives by stains on his shirt, and by its occasioning a very troublesome itching about the verge of the anus. These kinds of hæmorrhoids sometimes turn cancerous. There are some hæmorrhoids, and those of different sizes, which are covered with so fine a skin as frequently to admit blood to pass through. This fine skin is only the internal coat of the rectum, greatly attenuated by the varicose distention of its vessels. The hæmorrhage may proceed from two causes, namely, either from an excoriation produced by the hardness of the excrements, or from the rupture of the tumefied vessels, which break by their too great distention. In some of these, the patient voids blood almost every time he goes to stool; in others not so constantly. We sometimes meet with men who have a periodical bleeding by the piles, not unlike the menses in women; and as this evacuation, if moderate, does not weaken the constitution, we may infer that it supplies some other evacuation which nature either ceases to carry on, or does not furnish in due quantity; and hence also we may explain why the suppression of this discharge, to which nature had been accustomed, is frequently at-tended with dangerous diseases. The hæmorrhoids tended with dangerous diseases. The hæmorrhoids are sometimes distended to that degree as to fill the rectum, so that if the excrements are at all hard they cannot pass. In this case the excrements force the hamorrhoids out of the anus to procure a free passage, consequently the internal coat of the rectum, to which they are connected, yields to extension, and upon examining these patients immediately after having been at stool, a part of the internal coat of that gut is perceived. A difficulty will occur in the return of these, in proportion to their size, and as the verge of the anus is more or less contracted. If the bleeding piles come out in the same manner upon going to stool, it is then they void most blood, because the verge of the anus forms a kind of ligature above them. The treatment of this complaint will vary much, according to circumstances. When the loss of blood is considerable, we should endeavour to stop it by applying cold water, or ice; or some astringent, as a solution of alum, or sulphate of zinc: but a more certain way is making continued pressure on the part. At the same time interamining these patients immediately after having been phate of zinc; but a more terrain way is making con-tinued pressure on the part. At the same time inter-nal astringents may be given; joined with opium, if much pain or irritation attend. Care must be taken, aowever, to avoid constipation: and in all cases pa-ients find benefit from the steady use of some mild cathartic, procuring regular loose motions. Sulphur is nostly resorted to for this purpose; and especially in combination with supertartrate of potassa, tamarinds, &c. in the form of electuary, usually answers very well; likewise castor oil is an excellent remedy in these well; likewise castor oil is an excellent remedy in these cases. Should the parts be much inflamed, leeches may be applied near the anus, and cold saturnine lotions used; sometimes, however, fomenting with the decocion of poppy will give more relief; where symptomatic fever attends, the antiphlogistic regimen must be wrictly observed, and besides clearing the bowels, antiphlogistic may be given to promote diaphoresis. Where

the tumours are considerable and flaccid, without inflammation, powerful astringent or even stimulant applications will be proper, together with similar internal medicines; and the part should be supported by a compress kept on by a proper bandage. An ointment of galls is often very useful, with opium, to rement of galls is often very useful, with opium, to re-lieve pain; and some of the liquor plumbi subacetatis may be farther added, if there be a tendency to inflam-mation. In these cases of relaxed piles of some stand-ing, the copaiba frequently does much good, both ap-plied locally and taken internally, usually keeping the bowels regular; also the celebrated Ward's paste, a medicine of which the active ingredient is black pepper. Sometimes where a large tumour has been formed by extravasated blood, subsequently become organized, permanent relief can only be obtained by extir-

HÆMOSTA'SIA. (From αιμα, blood, and ισημι, to stand.) A stagnation of blood.

HÆMOSTA'TICA. (From αιμα, blood, and ςαω, to stop.) Medicines which stop hæmorrhages. See

NATHONY DE, was born in Leyden, in 1704, and became one of the distinguished pupils of the celebrated Boerhaave. After graduating at his native place, he settled at the Hague, where he practised with considerable reputation for nearly 20 years. Baron Van Swieten, being acquainted with the extent of his talents, invited him to Vienna, to assist in the plan of reform, which the empress had consented to support in the medical faculty of that capital. De Haen accordingly repaired thither in 1754, was made professor of the practice of medicine, and fully answered the expectation which had been formed of him. He undertook a system of clinical education, as the best method of forming good physicians: the result of this was the collection of a great number of valuable observations, which were published in successive volumes of a work, entitled, "Ratio Medendi in Nosocomio Practico," amounting ultimately to 16. He left also several other works, as On the Division of Fevers, &c., and died at the age of 72. He was generally an enemy to new opinions and innovations in practice, which led him into several controversies; particularly against variolous inoculation, and the use of poisonous plants him into several controversies; particularly against variolous inoculation, and the use of poisonous plants in medicine: but he exhibited much learning and practical knowledge.

tical knowledge.

Hagiospe'rmum. (From αγιος, holy, and σπερμα, seed: so called from its reputed virtues.) Wormseed.

Hagio'xylum. (From αγιος, holy, and ξυλον, wood: so named because of its medical virtues.) Guaiacum.

HAIR. See Capillus.

[Hair salt. The Haar salz, (or hair salt,) of Werner, formerly supposed to be a variety of alum, is, according to Klaproth, a mixture of the sulphates of magnesia and iron.—Cleav. Min. A.]

HALA'TIUM. (From αλς, salt.) A clyster, composed chiefly of salt.

chiefly of salt.

Halberd-shaped leaf. See Leaf.
[Halberd-shaped leaf. See Leaf.
[Halb-opal. This is the Semi-opal of Jameson, and Cleaveland. The other synonymes are La demi-opale of Brochant; Silex résinite of Brogniart; Quartz résinite commune of Haûy: all these being the same as the Halb-opal of Werner. "This variety is a little harder than the precious opal, and is easily broken. list fracture is imperfectly conchoidal with large cavities, or nearly even, usually more or less glistening and a little resinous, but sometimes nearly dull. The edges of the conchoidal fracture, and those of the fragments, are usually very sharp. It is more or less translucent, sometimes only in a slight degree at the edges, and some specimens are semitransparent."-

Cleav. Min. A.] HALCHE'MIA. CHE'MIA. (From aλς. salt, and χεω, to pour The art of fusing salts

Halele 'υм. (From αλς, salt. and ελαιον. oil.) Λ medicine composed of salt and oil.

Halica'cabum. (From αλς, the sea, and κακαδος, night-shade: so called because it grows upon the banks of the sea.) See Physalis alkekengi.

Ha'limus. (From αλιμος, belonging to the sea.)
The Atriplex halimus of Linnæus. or sea-purslain, said to be antispasmodic.

HALINI'TRUM. (From als, the sea, and vi7pov. niire.) Nitre, or rather rock salt.

HA'LITUS. (From halito, to breathe out.) A

vapour.

HALLER, ALBERT, was born at Berne, where his father was an advocate, in 1709. He displayed, at a very early age, extraordinary marks of industry and talents. He was intended for the church, but having there is an excellent chalybeate water, not inferior to lost his father when only thirteen, he soon after determined upon the medical profession. Having studied a short time at Tubingen, he was attracted to Leyden by the reputation of Boerhaave, to whom he has expressed his obligations in the most affectionate terms; but he took his degree at the former place, when about seventeen years of age. He soon after visited England and France; then returning to his native country, land and France; then returning to his native country, first acquired a taste for botany, which he pursued with great zeal, making frequent excursions to the neighbouring mountains. He also composed a "Poem on the Alps," and other pieces, which were received with much applause. Having settled in his native city, about 1730, he began to give lectures on anatomy, but with indifferent success; and some detached pieces on anatomy and botany having gained him considerable reputation abroad, he was invited by George II. in 1736. to become professor in the university. II., in 1736, to become professor in the university, which he had recently founded at Gottingen. He accepted this advantageous offer, and, though his arrival was rendered melancholy by the loss of a beloved wife, from some accident which occurred in the journey, he commenced at once the duties of his office with great zeal; he encouraged the most industrious of his pupils to institute an experimental investigation on some part of the animal economy, affording them his assistance therein. He was likewise himself indefatigable in similar researches, during the seventeen years which he spent there, having in view a grand reform in physiology, which his writings ultimately effected, dissipating the metaphysical and chemical jargon, whereby it was before obscured. He procured the establishment of a botanic garden, an anatomical theatre, a school for surgery and for midwifery, with a lying in hospital, and other useful institutions at that university. He received also many honourable testimonies of his fame, being chosen a member of the Royal Societies of Stockholm and London, made physician and counsellor to George II., and the emperor conferred on him the title of Baron; which, however, he declined, as it would not have been esteemed in his native country. To this he returned in 1753, and during the to institute an experimental investigation on some part country. To this he returned in 1753, and during the remainder of his life discharged various important public offices there. He ultimately received testimony of the general estimation in which he was held; the learned societies of Europe, as well as seveheld; the learned societies of Europe, as well as several sovereigns, vying with each other in conferring honours upon him. His constitution was delicate, and impatiente of pain, or interruption to his studies, led him to use violent remedies when ill; however, by temperance and activity, he reached an advanced age, having died towards the end of 1777. He was one of the most universally informed men in modern times. He spoke with equal facility the German, French, and Latin languages; and read all the other tongues of Europe, except the Sclavonic; and there was scarcely any book of reputation, with which he was not acquainted. His own works were extremely numerous, quanted. His own works were extremely numerous, on anatomy, physiology, pathology, surgery, botany, &c., besides his poems and political and religious publications. The principal are, 1. His large work on the Botany of Switzerland, in 3 vols. folio, with many plates; 2. Commentaries on Boerhaave's Lectures, 7 vols. octavo; 3. Elements of Physiology, 8 vols. quarto, a work of the greatest merit; 4. His "Bibliotheca," or Chronological Histories of Authors, with theca," or Chronological Histories of Authors, with brief Analyses; 2 vols. quarto on Botany, two on Sur-gery, two on Anatomy, and four on the Practice of Medicine, displaying an immense body of research. HALLUCINA'TIO. (From hallucinor, to err.)

An erroneous imagination.

HALMYRO'DES. (From αλμυρος, salted.) A term applied to the humours; it means acrimonious. It is also applied to fevers which communicate such an itching sensation as is perceived from handling salt

HA'LO. (From αλος, an area or circle.) The red circle surrounding the nipple, which becomes somewhat brown in old people, and is beset with many sebaceous glands.

HAMA'LGAMA. See Amalgam.
HAMOSUS. Hooked. Applied to the bristly pubescence of seeds and plants; as the pericarpe of the

that of Tunbridge-wells in any respect, except being

nearer to the metropolis.

HA'MULUS. (Diminutive of hamus, a hook.) A term in anatomy, applied to any hook-like process, as the hamulus of the pterygoid process of the sphenoid

HA'MUS. A hook. A species of pubescence of plants formed of bristles, bent at their point into a hook; as in Rumez tuberosus, Caucalis daucoides, and HA'MUS.

Galium aparine, &c.

HAND. Manus. The hand is composed of the carpus or wrist, metacarpus, and fingers. The arteries of the hand are the palmary arch, and the digital arteries. The veins are the digital, the cephalic of the thumb, and the salvatella. The nerves are the cuta-

thumb, and the salvatella. The nerves are the cutaneous, externus, and internus.

HARDE SIA. See Lapis Hibernicus.

HARE. See Lepus timidus.

HARE-LIP. Lagocheilus; Lagostoma; Labium
leporinum. A fissure or longitudinal division of one
or both lips. Children are frequently born with this or both lips. Children are frequently born with this kind of malformation, particularly of the upper lip. Sometimes the portions of the lip which ought be united, have a considerable space between them; in other instances they are not much apart. The cleft is occasionally double, there being a little lobe, or small portion of the lip, situated between the two fissures. Every species of the deformity has the same appellation of hare-lip, in consequence of the imagined resemblance which the part has to the upper lip of a bare.

The fissure commonly affects only the lip itself. In many cases, however, it extends along the bones of the palate, even as far as the uvula. Sometimes these bones are totally wanting: sometimes they are only

divided by a fissure.

Such a malformation is always peculiarly afflicting. In its least degree, it constantly occasions considerable deformity; and when it is more marked, it frequently hinders infants from sucking, and makes it indispensable to nourish them by other means. When the lower lip alone is affected, which is more rarely the case, the child can neither retain its saliva, nor learn to speak, except with the greatest impediment. But when the fissure pervades the palate, the patient

not only never articulates perfectly, but cannot masticate nor swallow, except with great difficulty, on account of the food readily getting up into the nose.

HARMO'NIA. (From αρω, to fit together.) Harmony. A species of synarthrosis, or immoveable connexion of bones, in which bones are connected together by means of rough margins, not dentiform: in this manner most of the bones of the face are connected together.

HARMOTOME. See Cross-stone.

HARRIS, WALTER, was born at Gloucester about the year 1651. He took the degree of bachelor of physic at Oxford, but, having embraced the Roman Catholic religion, he was made doctor at some French university. He settled in London in 1676, and two years after, to evade the order that all Catholics should years after, to evade the order that all Catholics should quit the metropolis, he publicly adopted the Protestant Faith. His practice rapidly augmented, and on the accession of William III. he was appointed his physician in ordinary. He died in 1725. His principal work, "De Morbis Acutis Infantum," is said to have been published at the suggestion of the celebrated Sydenham: it passed through several editions. He left also a Treatise on the Plague, and a collection of medical and surgical papers, which had been read before the College of Physicians.

dical and surgical papers, which had been read before the College of Physicians.

HARROGATE. The villages of High and Low Harrogate are situate in the centre of the county of York, adjoining the town of Knaresborough. The whole of Harrogate, in particular, has long enjoyed considerable reputation, by possessing two kinds of very valuable springs: and, some years ago, the chalybeate was the only one that was used internally, while the sulphureous water was confined to external use. At present, however, the latter is employed largely as an internal medicine.

The sulphureous springs of Harrogate are four in number, of the same quality, though different in the

number, of the same quality, though different in the

degree of their powers. This water, when first taken appears perfectly clear and transparent, and sends forth a few air bubbles, but not in any quantity. It possesses a very strong sulphureous and fætid smell, precisely like that of a damp rusty gun barrel, or bilgewater. To the taste it is bitter, nauseous, and strongly saline, which is soon borne without any disgust. In a few hours of exposure this water losses its transparency, and becomes somewhat nearly and stronger. cy, and becomes somewhat pearly, and rather greenish to the eye; its sulphureous smeil abates, and at last the sulphur is deposited in the form of a thin film, on the bottom and sides of the vessel in which it is kept. The volatile productions of this water show carbonic

acid, sulphuretted hydrogen, and azotic gas.

The sensible effects which this water excites, are often a headache and giddiness on being first drunk, followed by a purgative operation, which is speedy and mild, without any attendant gripes; and this is the only apparent effect the exhibition of this water dis-

The diseases in which this water is used are namerous, particularly of the alimentary canal, and irregularity of the bilious secretions. Under this water the health, appetite, and spirits improve; and, from its opening effects, it cannot fail to be useful in the costive opening effects, it cannot fail to be useful in the costive habit of hypochondriasis. But the highest recommendation of this water has been in cutaneous discases, and for this purpose it is universally employed, both as an internal medicine, and an external application: in this united form, it is of particular service in the most obstinate and complicated forms of cutaneous affections; nor is it less so in states and symptoms supposed connected with worms, especially with the round worm and ascarides, when taken in such a dose as to prove a brisk purgative; and in the latter case also, when used as a clyster, the ascarides being also, when used as a clyster, the ascarides being chiefly confined to the rectum, and, therefore, within the reach of this form of medicine. From the union of the sulphureous and saline ingredients, the benefit of its use has been long established in hæmorrhoidal affections.

A course of Harrogate waters should be conducted so as to produce sensible effects on the bowels; half a pint taken in the morning, and repeated three or four times, will produce it, and its nauseating taste may be corrected by taking a dry biscuit, or a bit of coarse bread after it. The course must be continued, in obstinate cases, a period of some months, before a cure

can be expected.

can be expected.

HARTFELL. The name of a place near Moffat, in Scotland. It has a mineral water which contains iron dissolved by the sulphuric acid, and is much celebrated in scrofulous affections, and cutaneous diseases: It is used no less as an external application, than drank internally. The effects of this water, at first, are some degree of drowsiness, vertigo, and pain in the head, which soon go off, and this may be hastened by a slight purge. It produces generally a flow of urine, and an increase of appetite. It has acquired much reputation also in old and languid ulcers, where the texture of the diseased part is very lax, and the discharge profuse and ill conditioned.

The dose of this water is more limited than that of most of the mineral springs which are used medicinally. It is of importance in all cases, and especially in delicate and irritable habits, to begin with a very small quantity, for an over-dose is apt to be very soon rejected by the stomach, or to occasion griping and dis-

quantity, for an over-dose is apt to be very soon rejected by the stomach, or to occasion griping and disturbance in the intestinal canal; and it is never as a
direct purgative that this water is intended to be employed. Few patients will bear more that an English
pint in the course of the day; but this quantity may
be long continued. It is often advisable to warm the
water for delicate stomachs, and this may be done
without occasioning any material change in its prowithout occasioning any material change in its pro-

HARTLEY, DAVID, was born in 1705, son of a clergyman in Yorkshire. He studied at Cambridge, and was intended for the church, but scruples about subscribing to the 39 Articles ied him to change to the medical profession; for which his talents and benevolent disposition well qualified him. After practising in different parts of the country, he settled for some time in London, but finally went to Bath, where he died in 1757. He published some tracts concerning the stone. 1757. He published some tracts concerning the stone, especially in commendation of Mrs. Stephens's medicine, and appears to have been chiefly instrumental in 412

procuring her a reward from Parliament; yet he is said to have died of the disease after taking about two hundred pounds of soap, the principal ingredient in that nostrum. Some other papers were also written by him; but the principal work, upon which his fame securely rests, is a metaphysical treatise, entitled "Observations on Man, his Frame, his Duty, and his Expectations." The doctrine of vibration, indeed, on which he explained sensation, is merely gratuitous; but his Disquisitions on the Power of Association, and other mental Phenomena, evince great subtlety and other mental Phenomena, evince great subtlety and

HARVEY, WILLIAM, the illustrious discoverer of the circulation of the blood, was born at Folkstone, in Kent, in 1578. After studying four years at Cambridge, he went abroad at the age of 19, visited France and Germany, and then fixed himself at Padua, which was the most calculated was the most calculated was the most calculated as the control of the contr Germany, and then fixed himself at Padua, which was the most celebrated medical school in Europe, where he was created Doctor in 1602. On returning to England he repeated his graduation at Cambridge, and settled in London: he became a Fellow of the College of Physicians in 1603, and soon after physician to St. Bartholomew's hospital. In 1615 he was appointed Lecturer on Anatomy and Surgery to the College, which was probably the more immediate cause of the publication of his grand discovery. He appears to have was probably the more immediate cause of the publication of his grand discovery. He appears to have withheld his opinions from the world, until reiterated experiment had confirmed them, and enabled him to prove the whole in detail, with every evidence of which the subject will admit. The promulgation of this important doctrine brought on him the most unjust experiment and improvation. opposition, some condemning it as an innovation, others pretending that it was known before; and he complained that his practice materially declined afterward: however, he had the satisfaction of living to see the truth fully established. He likewise received considerable marks of royal favour from James and Charles L, to whom he was appointed physician; and the latter particularly assisted his inquiries concerning generation, by the opportunity of dissecting numerous females of the deer kind in different stages of pregnancy. During the civil war, when he retired to Oxford, his house in London was pillaged, and many valuable nis douse in Loudon was piliaged, and many valuable papers, the result of several years labour, destroyed. He published his first work on the circulation in 1628, at Frankfort, as the best means of circulating his opinions throughout Europe; after which he found it necessary to write two "Exercitations" in refutation of his opponents. In 1651 he allowed his other great work, "De Generatione Animalium," to be made public, leading to the inference of the universal prevapublic, leading to the inference of the universal prevalence of oval generation. In the year following he had the gratification of seeing his bust in marble, with a suitable inscription recording his discoveries, placed in suitable inscription recording his discoveries, placed in the hall of the College of Physicians, by a vote of that body, and he was soon after chosen President, but declined the office on account of his age and infirmities. In return he presented to the College an elegantly furnished convocation room, and a museum filled with choice books and surgical instruments. He also gave up his paternal estate of 56 pounds per annum for the institution of an annual feast, at which a Latin oration should be spoken in commemoration of the benefactors of the College, &c. He died in 1658. A splendid edition of his works was printed in 1766, by the College, in quarto, to which a Latin life of the author was prefixed, written by Dr. Laurence.

fixed, written by Dr. Laurence.

HASTATUS. Spear, or halberd-shaped. Applied to a triangular leaf, hollowed out at the base and sides, but with spreading lobes; as in Rumez acetocella and

Solanum dulcamara.

Hatchet-shaped. See Dolabriformis.

HAUYNE. A blue-coloured mineral found imbedded in the basalt rock of Albaco and Frescate, which Jameson thinks is allied to the azure stone. So named Jameson thinks is affect to the azure stone. So hained after Hauy, the celebrated French mineralogist.

Hoy, camel's. See Juncus odoratus.

HEAD. See Caput.

HEARING. Auditus. "The hearing is a function

intending to-make known to us the vibratory motion

HEA HEA

Sound is to the hearing what light is to the sight.

Sound is the result of an impression produced upon the arrow the vibratory motion impressed upon the atoms of the body by percussion, or any other cause. This ord signifies also the vibratory motion itself. When the animals, it may be removed without any inconvenience beyond a few days.

The Means and it the sound in the sound Sound is the result of an impression produced upon the ear by the vibratory motion impressed upon the atoms of the body by percussion, or any other cause. This word signifies also the vibratory motion itself. When the atoms of a body have been thus put in motion, they communicate it to the surrounding elastic bodies: these communicate it in the same manner, and so the vibratory motion is often continued to a great distance. In general, only elastic bodies are capable of producing and propagating sound; but for the most part solid bodies produce it, and the air is generally the medium by which it reaches the ear.

There are three things distinguished in sound, intensity, tone, and timbre, or expression. The intensity

of sound depends on the extent of the vibrations.

The tone depends on the number of vibrations which are produced in a given time, and, in this respect, sound is distinguished into acute and grave.

The grave sound arises from a small number of vi-

brations, the acute from a great number.

The gravest sound which the air is capable of perceiving, is formed of thirty-two vibrations in a second. The most acute sound is formed of twelve thousand vibrations in a second. Between these two limits are contained all the distinguishable sounds; that is those sounds of which the ear can count the vibration. differs from distinguishable sound in so much as the ear cannot distinguish the number of vibrations of

which it is composed.

A distinguishable sound, composed of double the number of vibrations of another sound, is said to be its octave. There are intermediate sounds, between these two, which are seven in number, and which constitute the diatonic scale, or gamut: they are distinguished

by the names, ut, re, mi, fa, sol, la, si.

When the sonorous body is put in motion by percussion, there is at first heard a sound very distinct, more or less intense, more or less acute, &c., according as it may happen; this is the fundamental sound; but with a little attention other sounds can be perceived. are called harmonic sounds. This can be easily perceived in touching the strings of an instrument.

The timbre, or expression of sound, depends on the

nature of the sonorous body.

Sound is propagated through all elastic bodies. rapidity is variable according to the body which propagates it. The rapidity of sound in the air is a thousand one hundred and thirty English feet. It is still more rapidly transmitted by water, stone, wood, &c. Sound loses its force in a direct proportion to the square of the distance; this happens at least in the air. It may also become more intense as it proceeds; as happens when it passes through very elastic bodies, such as metals, wood, condensed air, &c. All sorts of sounds are propagated with the same rapidity, without being confounded one with another.

It is generally supposed that sound is propagated in right lines, forming cones, analogous to those of light, with this essential difference, however, that, in sonorous cones, the atoms have only a motion of oscillation, while those of the cones of light have a real transitive

motion.

When sound meets a body that prevents its passage it is reflected in the same manner as light, its angle of reflection being equal to the angle of incidence. form of the body which reflects sound, has similar in-fluence upon it. The slowness with which sound is propagated, produces certain phenomena, for which we can easily account. Such is the phenomenon of echo, of the mysterious chamber, &c.

Apparatus of Hearing.—There are in the appara-tus of hearing a number of organs, which appear to concur in that function by their physical properties; and behind them, a nerve for the purpose of receiving

and transmitting impressions.

The apparatus of hearing is composed of the outer, middle, and internal ear; and of the acoustic nerve.

The auricle collects the sonorous radiations, and di-

The auricle collects the sonorous radiations, and directed them towards the meatus externus; in proportion as it is large, elastic, prominent from the head, and directed forward. Boe:haave supposed he had proved by calculation, that all the sonorous radiations (or pulsations) which fall upon the external face of the pinna, are, ultimately, directed to the auditory passage. This assertion is evidently erroneous, at least for those pinnae and the best for the series of the prinae and the province of the pinnae and the in which the antihelix is more projecting than the helix.

The Meatus auditorius transmits the sound in the same manner as any other conduit, partly by the air it contains, and partly by its parietes, until it arrives at the membrane of the tympanum. The hairs, and the cerumen with which it is provided at the entrance, are intended to prevent the introduction of sand, dust,

insects, &c.

The Membrane of the Tympanum receives the sound which has been transmitted by the meatus auditorius. In what circumstances is it stretched by the internal muscle of the malleus? Or when is it relaxed by the contraction of the anterior muscle of the mal-lens?—All our knowledge on this subject is merely conjectural. An opening made in this membrane does not much impair the faculty of hearing. As this membrane is dry and elastic, it ought to transmit the sound very well, both to the air contained in the tympanum, and to the chain of little bones. The chorda tympani cannot fail to participate in the vibrations of the membrane, and transmit impressions to the brain. The contact of any foreign body upon the membrane is very painful, and a violent noise also gives great pain. The membrane of the tympanum may be torn, or even totally destroyed, without deranging the hearing in any sensible degree.

The Cavity of the Tympanum transmits the sounds from the external to the internal ear. The transmission of sound by the tympanum happens—lst, By the chain of bones which has a particular action upon the chain of bones which has a particular action upon the membrane of the fenestra ovalis. 2d, By the air which fills it, and which acts upon the whole petrous portion, but particularly upon the membranum of the fenestra ovalis. 3d, By its sides.

The Eustachian Tube renews the air in the tympanum; being destroyed, it is said to cause deafness.

The notion of its being capable of carrying sound to the internal ear is erroneous; there is nothing to support this assection; it permits the air to pass in cases.

port this assertion: it permits the air to pass in case when the tympanum is struck by violent sounds, and it permits the renewal of that which fills the tympa-num, and the mastoid cells. The air in the tympanum being much rarefied, is very suitable for diminishing the intensity of the sounds it transmits.

The use of the mastoid cells is not well known; it

is supposed that they help to augment the intensity of the sound that arises in the cavity. If they produce this effect it ought to be rather from the vibrations of the partitions which separate the cells than from the air which they contain. Sound may arrive in the tympanum by another way than the external meatus; the shocks received by the bones of the head are directed towards the temples, and perceived by the ear. It is well known that the movement of a watch is heard distinctly when it is placed in contact with the

We know little of the functions of the internal ear; we can only imagine that the sonorous vibrations are propagated in different modes, but principally by the membrane of the femestra ovalis, by that of the fenestra rotunda, and by the internal partition of the tympanum; that the liquor of Cotunnius ought to suffer vibrations which are transmitted to the acoustic nerve It may be conceived how necessary it is that this liquid should give way to those vibrations which are too in-tense, and which might injure this nerve. Possibly, in his case, it flows into the aqueducts of the cochlea and of the vestibule, which, in this respect, would

have a great deal of analogy with the Eustachian.

The internal gyri of the cochlea ought to receive the vibrations principally by the membrane of the fenestra ovalis; the vestibule, by the chain of bones; the semicircular canals, by the sides of the tympanum, and perhaps by the mastoid cells, which frequently extend beyond the canals. But the aid which is given to the hearing by each separate part of the internal ear is totally unknown.

The osseo-membraneous partition, which separates

The osseo-membraneous partition, which separates the cochlea into two parts, has given rise to an hypothesis which no one now admits.

The impressions are received and transmitted to the brain by the acoustic nerve; the brain perceives

ticularly appreciable sounds, combined, and succeeding each other in a certain manner, are a source of agreeable sensations. It is in such combinations, for the production of this effect, that music is employed. the production of this effect, that music is employed. On the contrary, certain combinations of sound produce a disagreeable impression; the ear is hurt by very acute sounds. Sounds which are very intense and very grave, hurt excessively the membrane of the tympanum. By the absence of the liquor of Cotunnius, the hearing is destroyed. When a sound has been of long duration, we still think we hear it, though it may have been some time discontinued.

We receive two impressions, though we perceive

We receive two impressions, though we perceive only one. It has been said that we use only one car at once, but this notion is erroneous.

When the sound comes more directly to the one ear, it is in reality distinguished with more facility by that when the sound comes more directly to the one ear, it is in reality distinguished with more facility by that one, than by the other: therefore in this case we employ only one ear; and when we listen with attention to a sound which we do not hear exactly, we place ourselves so that the rays may enter directly into the concha; but when it is necessary to determine the direction of the sound, that is, the point whence it proceeds, we are obliged to employ both ears, for it is only by comparing the intensity of the two impressions, that we are capable of deciding from whence the sound proceeds. Should we shut one ear perfectly close, and cause a slight noise to be made, in a dark place, at a short distance, it would be utterly impossible to determine its direction; in using both ears this could be determined. In these cases the eye is of great use, for even in using both ears it is frequently impossible to tell in the dark from whence a sound comes. By the sound we may also estimate the distance of the body from which it proceeds: but in order to judge exactly in this respect we ought to be perfectly acquainted with the nature of the sound, for without this condition the estimation is always erroneous. The this condition the estimation is always erroneous. The this condition the estimation is always erroneous. The principle upon which we judge is, that an intense sound proceeds from a body which is near, while a feeble sound proceeds from a body at a distance: if it happen that an intense sound comes from a distant body while a feeble sound proceeds from a body which is near, we fall into acoustic errors. We are generally very subject to deception with regard to the point whence a sound comes: sight and reason are of great use in assisting our judgment.

subject to deception with regard to the point whence a sound comes: sight and reason are of great use in assisting our judgment.

The different degree of convergence, and divergence, of the sonorous rays, do not seem to have any influence on the hearing, neither are they modified in their course, except for the purpose of making them enter into the ear in greater quantity: it is to produce this effect that speaking trumpets are used for those who do not hear well. Sometimes it is necessary to diminish the intensity of sounds: in this case a soft and searcely elastic body is placed in the external meatus."

—Magendie's Physiology.

HEART. Cor. A hollow muscular viscus, situated in the cavity of the pericardium for the circulation of the blood. It is divided externally into a base, or its broad part; a superior and an inferior surface, and an anterior and posterior margin. Internally, it is divided into a right and left ventricle. The situation of the heart is oblique, not transverse; its base being placed on the right of the bodies of the vertebre, and its apex obliquely to the sixth rib on the left side; so that the left ventricle is almost posterior, and the right anterior. Its inferior surface lies upon the diaphragm. There are two cavities adhering to the base of the heart, from their resemblance called auricles. The right auricle is a muscular sac, in which are four of the heart, from their resemblance called auricles. The right auricle is a muscular sac, in which are four The right auricle is a inuscular sac, in which are four apertures, two of the venæ cavæ, an opening into the right ventricle, and the opening of the coronary vein. The left is a similar sac, in which there are five apertures, viz. those of the four pulmonary veins, and an opening into the left ventricle. The cavities in the heart are called tentricles: these are divided by a

them with more or less facility and exactness in different individuals. Many people have a false ear, which means that they do not distinguish sounds perfectly.

There is no explanation given of the action of the acoustic nerve and of the brain in hearing.

In order to be heard, sounds must be within certain limits of intensity. Too strong a sound hurts us, while one too weak produces no sensation. We can perceive a great number of sounds at once. Sounds, particularly appreciable sounds, combined, and succeeding each other in a certain manner, are a source of agreeable sensations. It is in such combinations, for the production of this effect, that music is employed. transverse, and its interior oblique. The internal superfices of the ventricles and auricles of the heart are invested with a strong and smooth membrane, which is extremely irritable. The vessels of the heart are divided into common and proper. The common are, I. The aorta, which arises from the left ventricle. 2. The pulmonary artery, which originates from the right ventricle. 3. The four pulmonary veins, which terminate in the left auricle. 4. The two vena cava, which evacuate themselves into the right auricle. The proper vessels are, 1. The coronary arteries, which arise from the aorta, and are distributed on the heart. 2. The coronary veins, which return the blood into the right auricle. The merces of the heart are branches of the eight and great intercostal pairs. The heart of the fetus differs from that of the adult, in having a foramen ovale, through which the blood passes from the right auricle to the left.

HEART'S EASE. See Viola tricolor.

HEART. See Calorie.

HEART. See Calorie.

HEAT, ABSOLUTE. This term is applied to the whole quantity of caloric existing in a body in chemical union. perfices of the ventricles and auricles of the heart are

HEAT, ABSOLUTE. This term is applied to the whole quantity of caloric existing in a body in chemical

HEAT, ANIMAL. "An inert body which does not change its position, being placed among other bodies, very soon assumes the same temperature, on account of the tendency of caloric to an equilibrium. The body of man is very different: surrounded by bodies hotter than itself, it preserves its inferior temperature as long as life continues; being surrounded with bodies of a lower temperature, it maintains its temperature more elevated. There are, then, in the animal economy, two different and distinct properties, the one of producing heat, the other of producing cold. We will examine these two properties. Let us first see how heat is produced.

The respiration appears to be the principal, or at least the most evident source of animal heat. In fact, experience demonstrates that the heat of the blood increases nearly a degree in traversing the lungs; and as it is distributed to all parts of the body from the lungs, it carries the heat every where into the organs; for we have also seen that the heat of the veins is less

than that of the arteries

than that of the arteries.

This developement of heat in the respiration appears, as we have already said, to proceed from the formation of carbonic acid, whether it takes place directly in the lungs, or happens afterward in the arteries, or in the parenchyma of the organs. Some very good experiments of Lavoisier, and De Laplace, lead to this conclusion: they placed animals in a calorimeter, and compared the quantity of acid formed by the respiration, with the quantity of heat produced in a given time: except a very small proportion, the heat produced was that which would have been occasioned by the quantity of carbonic acid which was formed. formed.

It has also been proved by the experiments of Bro-die, Thillage, and Legallois, that if the respiration of an animal is incommoded, either by putting it in a fatiguing position, or in making it respire artificially, its temperature lowers, and the quantity of carbonic acid that it forms becomes less. In diseases when the respiration is accelerated, the heat increases, except in particular circumstances. The respiration is then a focus in which caloric is developed.

In considering for an instant only this source of beautiful to the considering for an instant only this source of beautiful to the considering for an instant only this source of beautiful to the considering for an instant only this source of beautiful to the considering for an instant only this source of beautiful to the considering for an instant only this source of beautiful to the considering for an instant only this source of beautiful to the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only this source of the considering for an instant only the consider

In considering for an instant only this source of heat in the economy, we see that the caloric must be dis-tributed to the different parts of the body in an unequal manner; those farthest from the heart, those that re-ceive least blood, or which cool more rapidly, must generally be colder than those that are differently dis-

This difference partly exists. The extremities are

solder than the trunk; sometimes they present only 890 or 910 F., and often much less, while the cavity of the thorax is about 1040 F.: but the extremities have a considerable surface relative to their mass; they are farther from the heart, and receive less blood than most of the organs of the trunk.

On account of the extent of their surface and distance from the heart, the feet and hands would probably have a temperature still lower than that which is peculiar to them, if these parts did not receive a greater proportional quantity of blood. The same disposition exists for all the exterior organs that have a very large surface, as the nose, the pavilion of the ear, &c.: their temperature is also higher than their surface and distance from the heart would seem to indicate.

Notwithstanding the providence of nature, parts that have large surfaces lose their caloric with greater facility; and they are not only habitually colder than the others, but their temperature often becomes very low: the temperature of the feet and hands in winter is often nearly as low as 320 F. It is on this account we expose them so willingly to the heat of our fires.

Among other means that we instinctively employ to remedy or prevent coldness, are motion, walking, run-ning, leaping, which accelerate the circulation; pressure, shocks upon the skin, which attract a great quantity of blood into the tissue of this membrane. ther equally effective means consists in diminishing the surface in contact with the bodies that deprive us of caloric. Thus we bend the different parts of the limbs upon each other, we apply them forcibly to the trunk when the exterior temperature is very low. Children and weak persons often take this position when in bed. In this respect it would be very proper that young children should not be confined too much in their swathing clothes to prevent them from thus bending themselves. Our clothes preserve the heat of our bodies; for the substance of which they are formed being bad conductors of caloric, they prevent that of the

body from passing off.

According to what has been said, the combination of the oxygen of the air with the carbon of the blood is sufficient for the explanation of most of the pheno-mena presented by the production of animal heat; but there are several which, if real, could not be explained by this means. Authors worthy of credit have remarked, that, in certain local diseases, the temperature of the diseased place rises several degrees above that of the blood, taken at the left auricle. If this is so, the continual renewal of the arterial blood is not sufficient

to account for this increase of heat.

This second source of heat must belong to the nutritive phenomena which take place in the diseased part. There is nothing forced in this supposition; for most

of the chemical combinations produce elevations of temperature, and it cannot be doubted that both in the secretions and in the nutrition, combinations of this sort take place in the organs.

By means of these two sources of heat, life can be maintained though the external temperature is very low, as that of winter in countries near the pole, which descends sometimes to — 42° F. Generally such an excessive cold is not supported without great difficulty, and it often happens that the parts most easily cooled are mortified: many of the military suffered these accidents in the wars of Russia. Nevertheless, as we easily resist a temperature much lower than our own, it is evident that we are possessed of the faculty of producing heat to a great degree.

The faculty of producing cold, or, in more exact terms, of resisting foreign heat, which has a tendency to enter our organs, is more confined. In the torrid zone, it has happened that men have died suddenly, when the temperature has approached 122° F.

But this property is not less real, though limited.

Banks, Blagden, and Fordyce, having exposed them-selves to a heat of nearly 260°, they found that their bodies had preserved nearly their own temperature. More recent experiments of Berger and Delaroche have shown that by this cause the heat of the body may rise several degrees; for this to take place it is only necessary that the surrounding temperature should be a little elevated. Having both placed themselves in a stove of 120°, their temperature rose nearly 6.8° F. Delaroche having remained sixteen minutes in a dry gtove at 176°, his temperature rose 9° F.

Franklin, to whom the physical and moral sciences are indebted for many important discoveries, and a great many ingenious views, was the first who discovered the reason why the body thus resists such a strong heat. He showed that this effect was due to the evaporation of the cutaneous and pulmonary transpiration, and that in this respect the bodies of animals re-semble the porous vases called alcarrazas. These vessels, which are used in hot countries, allow the water that they contain to sweat through them; their surface is always humid, and a rapid evaporation takes place, which cools the liquid they contain.

In order to prove this important result, Delaroche placed animals in a hot atmosphere that was so saturated with humidity that no evaporation could take These animals could not support a heat but a hitle greater than their own without perishing, and they became heated, because they had no longer the means of cooling themselves. Thus, there is no doubt that the cutaneous and pulmonary evaporation are the causes which enable man and animals to resist a strong heat. This explanation is also confirmed by the considerable loss of weight that the body suffers

after having been exposed to a great heat.

According to these facts it is evident that the authors who have represented animal heat as fixed, have

been very far from the truth. To judge exactly of it, it would be necessary to take into account the surrounding temperature and humidity; the degree of heat of different parts ought to be considered, and the

temperature of one part ought not to be determined by that of another.

We have few correct observations upon the temperature proper to the body of man; the latest are due to Edwards and Gentil. These authors observed that the most suitable place for judging of the heat of the body is the armpit. They noticed nearly 2½ degrees of difference between the heat of a young man and that of a young girl: the heat of her hand was a little less than 974°, that of the young man was 98.4°. The same person observed great differences of heat in the different temperaments. There are also diurnal variations; the temperature may change about two or three degrees from proving to evening. degrees from morning to evening.—Ure's Chem. Dict.
HEAT, FREE. If the heat which exists in any sub-

stance be from any cause forced in some degree to quit that substance, and to combine with those that surround it, then such heat is said to be free, or sensible,

until the equilibrium is restored.

HEAT, LATENT. When any body is in equilibrium with the bodies which surround it with respect to its heat, that quantity which it contains is not perceptible by any external sign, or organ of sense, and is termed combined caloric, or latent heat.

Heat, sensible. See Heat, free.

Heavy carbonated hydrogen. See Carburetted hy-

HEAVY SPAR. Baryte. A genus of minerals, divided by Professor Jameson into four species.

1. Rhomboidal baryte, or Witherite. This is a carbonate of barytes; and is found in Cumberland and Durham.

2. Prismatic baryte, or heavy spar, a sulphate; found also in Cumberland and Durham.

3. Diprismatic baryte, or strontianite. A coof barytes; found in Strontian, in Argyleshire. A carbonate

4. Axifrangible baryte, or Celestine. A sulphate of strontites, with about two per cent. of sulphate of barytes: found near Edinburgh, in Inverness-shire, and Bristol.

Heavy inflammable air. See Carburetted hydrogen

HEBERDEN, WILLIAM, was born in London in 1710, and graduated at Cambridge, where he afterward 1710, and graduated at Cambridge, where he afterward practised during ten years, and gave lectures on the Materia Medica. During this period he published a little Tract, entitled "Antitheriaca," condemning the complication of certain ancient Formulæ of Medicines. In 1748, he removed to London, having previously been elected a fellow of the College of Physicians; and he was shortly after admitted into the Royal Society. He soon rose to considerable reputation and practice in his profession. At his suggestion "the Medical Transactions of the College of Physicians" first appeared in 1768; and four other volumes." cians," first appeared in 1768; and four other volumes have since been published at different periods. Dr. Heberden contributed some valuable papers to this

wibrk, especially on the Angina Pectoris, a disease not before described; and on Chicken Pox, which he first accurately distinguished from Small Pox. Some other papers of his appeared in the Philosophical Transactions. As he advanced in years he began to relax from the fatigue of practice: and in 1782 he drew up the result of his experience in a volume of "Commentaries," written in Latin, the great excellence of which is ries," written in Latin, the great excellence of which is its style. He reserved it for publication, however, till after his death, which did not happen till 1801.

HECTIC. (Hecticus; from zics, habit.) See Febris

Hetlea.

HE DERA. (From hareo, to stick, because it attaches itself to trees and old walls.) The name of a genus of plants in the Linnaan system. Class, Pentandria; Order, Monogynia. The ivy.

HEDERA ARBOREA. See Hedera Helix.

HEDERA HELIX. Hedera arborea. The ivy. The layers of this tree have little or no smell, but a very hauseous taste. Haller informs us that they are re-

leaves of this tree have little or no smell, but a very nauseous taste. Haller informs us, that they are recommended in Germany against the atrophy of children. By the common people of this country they are sometimes applied to running sores, and to keep issues open. The berries were supposed by the ancients to have a purgative and emetic quality; and an extract was made from them by water, called by Quercetanus extractum purgans. Later writers have recommended them in small doses as alexipharmic and sudorific; It is said, that in the plague at London, the powder of them was given in vinegar, or white wine, with good success. It is from the stalk of this tree that a resinous juice, called Gummi hedera, exudes very plentifully in juice, called Gummi heders, exudes very plentifully in warm climates. It is imported from the East Indies, though it may be collected from trees in this country. It is brought over in hard compact masses, externally of a reddish brown colour, internally of a bright brownish yellow, with reddish specks or veins. It has a strong, resinous, agreeable smell, and an adstringent taste. Though never used in the practice of the present day, it possesses corroborant, astringent, and antispasmodic virtues.

HEDERACEÆ. (From hedera, the tvy.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of the ivy and a few other genera which in their form and appearance resem-

Hedge hyssop. See Gratiola officinalis. Hedge mustard. See Erysimum officinale. Hedge mustard, stinking. See Erysimum Alliaria. He'dra. 1. The anus.

HEDYO'SMOS. Mint.
HEISTER, LAURENCE, was born at Frankfort on the Maine in 1683. Afterstudying in different German iniversities, and serving sometime as an army-surgeon, he graduated at Leyden: and in 1709 was appointed physician general to the Dutch Military Hospital. The hext year he became professor of anatomy and surgery at Altorf: and having distinguished himself greatly by his lectures and writings, he received in 1720 a more advantageous appointment at Helmstadt, under the Duke of Brunswick, as physician, Aulic counsellor, and professor of medicine; in which he continued, notwithstanding an invitation to Russia from the Czar Peter, till the period of his death in 1758. He was author HEDYO'SMOS. Mint. Peter, till the period of his death in 1758. He was author of several esteemed works, particularly a Compendium of several esteemed works, particularly a Compendium of Anatomy, which became very popular, being remarkable for its conciseness and clearness. "His Institutions of Surgery," also gained him great credit; being translated into Latin, and most of the modern languages of Europe. Another valuable practical work was entitled "Medical, Surgical, and Anatomical Cases and Observations." He had some taste for botany also, which he taught at Helmstadt, and considerably enriched the garden there; but he unfortunately became an antagonist of the celebrated Linnacus, not properly appreciating the excellence of the system not properly appreciating the excellence of the system of that eminent naturalist.

HELCO'MA. Ulceration.

HELCONIA. (From κλκος, an ulcer.) An ulcer in the external or internal superficies of the cornea, known by an excavation and oozing of purulent matter from the

HELCY'DRION. (From ελκος, an ulcer, and υδωο, water.) Helcydrium. A moist ulcerous pustule.

HELCY'STER. (From ελκω, to draw.) An instru-

ment for extracting the feetus.

Hele'sium. (From Helene, the island where it grew.) See Inula helenium.

HELIANTHUS. (From ηλιος, the sun; and ανθος, a flower. This name originated from the resemblance which its broad golden disk and ray bear to the sun, and is rendered further appropriate by its having the and is rendered further appropriate by its having the power of constantly presenting its flowers to that luminary.) The name of a genus of plants. Class, Syngenesia; Order, Polygamia frustranea. The sun-flower.

Helianthus annuus. The systematic name of the Corona solis, and chimalatus. The seeds have been made into a nutritious bread. The whole plant when

young is boiled and eaten in some countries, as being

aphrodisiac.

Helianthus tuberosus. Jerusalem artichoke. Although formerly in estimation for the table, this root is now neglected, it being apt to produce flatulency and dyspepsia.

Helica'lis major. See Helicis major.
Helica'lis minor. See Helicis minor.
HE'LICIS MAJOR. A proper muscle of the ear, which depresses the part of the cartilage of the ear into which it is inserted; it lies upon the upper or sharp point of the helix, or outward ring, arising from the upper and acute part of the helix anteriorly, and passing to be inserted into its cartilage a little above the tragus. tragus.

Helicis minor. A proper muscle of the ear, which contracts the fissure of the ear; it is situated below the helicis major, upon part of the helix. It arises from the inferior and anterior part of the helix, and is inserted into the crus of the helix, near the fissure in the

cartilage opposite to the concha.

HELIOTROPE. A sub-species of rhomboidal

HELIOTROPIUM. (Ἡλιοτροπιον τω μεγα, of Dioscorides; from ηλιος, the sun, and τροπη, a turning or inclination: because, says that ancient writer, it turns its leaves round with the declining sun.) The name of a genus of plants. Class, Pentandria; Order, Monogynia.

HELIOTRO'FH SUCCUS. See Croton tinctorium. HE'LIX. (Ελιξ, from ειλω, to turn about.) The external circle or border of the outer ear, that curls in-

Helix hortensis. The garden snail. HELLEBORA'STER. (From ελλεδορος, hellebore.)

Helleboras fatidus.

Helleboras fatidus.

Helleboras fatidus.

Hellebore, solack. See Helleborus niger.

Hellebore, white. See Veratrum album.

Hellebore, white. See Veratrum album.

Helleboras it destroys, if eaten.) The name of a genus of plants in the Linnean system. Class Polyandria; Order, Polygynia. Hellebore.

Helleboras fætidus. See Veratrum album.

Helleboras fætidus. See Veratrum album.

Helleboras fætidus. See Veratrum album.

Helleboraster. Helleborus—caule multifloro folieso, foliis pedatis, of Linnæus. The leaves of this indigenous plant are recommended by many as possessing extraordinary anthelmintic powers. The smell of the recent plant is extremely fætid, and the taste is bitter and remarkably acrid, insomuch that, when chewed, it excoriates the mouth and fauces. It commonly operates as a cathartic, sometimes as an emetic, and in large doses proves highly deleterious.

Helleborus niger. Black hellebore, or Christmas rose. Melampodium. Helleborus—scapo subbiflore submudo, foliis pedatis, of Linnæus. The root of this exotic plant is the part employed medicinally: its taste, when fresh, is bitterish, and somewhat acrid: it also comits a nauseous scrid smell: but, being long kent.

exotic plant is the part employed medicinally: its taste, when fresh, is bitterish, and somewhat acrid: it also emits a nauseous acrid smell: but, being long kept, both its sensible qualities and medicinal activity suffer very considerable diminution. The ancients esteemed it as a powerful remedy in maniscal cases. At present it is exhibited principally as an alterative, or, when given in a large dose, as a purgative. It often proves a very powerful emmenagogue in plethoric habits, where steel is ineffectual, or improper. It is also recommended in dropsies, and some cutaneous diseases.

HELMET-FLOWER. See Anthora, HELMI'NTHAGOGUE. (Helminthagogus, from ελριγς, a worm, and αγω, to drive out.) Whatever destroys and expels worms. See Anthelmintic.

HELMINTHIA. The name of a genus of diseases.

Class, Celiaca; Order, Enterica, in Good's Nosology. Invermination, worms. It has three species, viz. Helmintkia alvi, podicis, erratica.

HELMINTHI'ASIS. (Ελμινθιασις; from ελμινς, which signifies any species of worm.) A disease in which worms, at the larvæ of worms, are bred under the skin, or some external part of the body. It is endemial to Martinique, Westphalia, Transylvania, and some other places.

HELMINTHOCO'RTON. See Corallina corsicana. HELMINTHOCO'RTON. See Corallina corsicana-HELMONT, John Baptist Van, was born of a noble family at Brussels in 1577. He exhibited very early proofs of superior abilities, and soon became convinced how much hypothesis was ranked under the name of science and philosophy in books; he seems to have perceived the necessity of experiment and induc-tion in the discovery of real knowledge; but did not methodize his ideas sufficiently, to pursue that plan methodize his ideas sufficiently, to pursue that plan with its full advantage. After taking his degree at Louvain he travelled during ten years, and in this period acquired some practical knowledge of chemistry. On his return in 1609 he married a noble lady of large fortune, which enabled him to pursue his re-searches into the three kingdoms of nature with little interruption. He declined visiting patients, but gave gratuitous advice to those who went to consult him; and he boasts of having cured several thousands and and he boasts of having cured several thousands au-nually. He continued his investigations with astonish-ing diligence during thirty years, and made several dis-coveries in chemistry; among which were certain articles possessed of considerable activity on the human body. This confirmed his opposition to the Galenical school, the absurd hypotheses, and inert practice of which he attacked with great warmth and ability. Indeed he contributed greatly to overturn their influence; but from a desire to explain every thing on chemical principles, he substituted doctrines equally gratuitous or unintelligible. He published various works from time to time, which brought him considerable reputation, and he was repeatedly invited to Vienna; but he preferred continuing in his laboratory. He died in 1644.

HELO'DES. (From ελος, a marsh.)

plied to fevers generated from marsh miasma. HELO'SIS. (From ειλω, to turn.) An ev (From ειλω, to turn.) An eversion or

HELVINE. (From ελκω, to draw: so called because it sticks to whatever it touches.) Pellitory of the wall.

HEMALO'PIA. Corruptly written for hæmalopia.
HEMATIN. The colouring principle of logwood.
See Hæmatozylon campechianum.
HEMATU'RIA. See Hæmaturia.
HEMERALO'PIA. (From ημερα, the day, and ωψ, the eye.) A defect in the sight, which consists in being able to see in the daytime, but not in the evening. The following is Scarpa's description of this curious disorder. Hemeralopia. or nocturnal blindness, is prodisorder. Hemeralopia, or nocturnal blindness, is pro-perly nothing but a kind of imperfect periodical amaurosis, most commonly sympathetic with the stomach. Its paroxysms come on towards the evening, and disappear in the morning. The disease is endemic in some countries, and epidemic, at certain seasons of the year, in others. At sunset, objects appear to persons affected with this complaint as if covered with an ashcoloured veil, which gradually changes into a dense cloud, which intervenes between the eyes and surrounding objects. Patients with hemeralopia, have the pupil, both in the day and nighttime, more dilated, and less moveable than it usually is in healthy eyes. The majority of them, however, have the pupil more or less moveable in the daytime, and always expanded and motionless at night. When brought into a roem faintly lighted by a candle, where all the bystanders can see tolerably well, they cannot discern at all, or in a very feeble manner, scarcely any one object; or they only find themselves able to distinguish light from darkness, and at moonlight their sight is still worse. At daybreak they recover their sight, which continues perfect all the rest of the day till sunset.

["According to M. Dujardin, this term is derived from hutpa, the day, $\partial \lambda aos$, blind, and $\omega \psi$, the eye; and in its right signification is therefore inferred to be diurna excitudo, or day blindness. In the same sense, Dr. Hillary and Dr. Heberden, have employed the

"Hemeralopia then, which is of very rare occurrence, stands in opposition to the nyctalopia of the ancients, or night-blindness. Numerous modern writers, however, have used these terms in the contrary sense considering the hemeralopia, as denoting sight during the day, and blindness in the night; and nyctalopia as expressing night-seeing, (owl-sight, as the French call it,) and blindness during the daytime."—Cooper's

Sur. Dic. A.]

HEMERALOPS. (From ημερα, the day, and ωψ, the eye.) One who can see but in the daytime.

Hemickrau'nios. (From ημισυς, half, and κειρω, to cut: so called because it was cut half way down.) A bandage for the back and breast.

HEMICRA'NIA. (From $\eta\mu\sigma\sigma\nu_5$, half, and $\kappa\rho\sigma\nu\nu_e\nu$, the head.) A pain that affects only one side of the head. It is generally nervous or hysterical, sometimes bilious; and in both cases sometimes comes at a regular period, like an ague. When it is accompanied by a strong pulsation like that of a nail piercing the part, it is depositionally assets.

a strong paisation like that of a nail piercing the part, it is denominated clavus.

HEMIO'PSIA. (From ημισυς, half, and ωψ, an eye.) A defect of vision, in which the person sees the half, but not the whole of an object.

HEMIPA'GIA. (From ημισυς, half, and παγιος, fixed.) A fixed pain on one side of the head. See

HEMIPLE GIA. (From ημισυς, half, and πλησσω, to strike.) A paralytic affection of one side of the body. See Paralysis.

HEMLOCK. See Conium maculatum.

HEMLOCK-DROPWORT. See Enantho crocata.

Hemlock, water. See Cicuta virosa.

Hemorrhage from the lungs. See Hamoptysis. Hemorrhage from the nose. See Epistazis. Hemorrhage from the stomach. See Hamatemesis.

Hemorrhage from the urinary organs. See Hama-

Hemorrhage from the uterus. See Menorrhagia. HEMP. See Cannabis. HEMP-AGRIMONY. See Eupatorium canniba-

Hemp, water. See Eupatorium. HENBANE. See Hyoscyamus. HE'PAR. (Hepar, atis. n. Ηπαρ, the liver.) See

HEPAR SULPHURIS. Liver of sulphur. A sulphurert made either with potassa or soda. See Sulphuretum potassæ.

HEPAR UTERINUM. The placenta.
HEPATA'LGIA. (From ηπαρ, the liver, and αλγος,

pain.) Pain in the liver.

HEPATIC. (Hepaticus; from ηπαρ, the liver.) Belonging to the liver.

Hepatic air. See Hydrogen sulphuretted.
HEPATIC ARTERY. Arteria hepatica. The artery which nourishes the substance of the liver. It arises from the cœliac, where it almost touches the point of the lobulus Spigelii. Its root is covered by the pan-creas; it then turns a little forwards, and passes under the pylorus to the porta of the liver, and runs between the biliary ducts and the vena porta, where it divides into two large branches, one of which enters the right, and the other the left lobe of the liver. In this place it is enclosed along with all the other vessels in the capsule of Glisson.

HEPATIC DUCT. Ductus hepaticus. The trunk of the biliary pores. It runs from the sinus of the liver towards the duodenum, and is joined by the cystic duct, to form the ductus communis choledochus. Biliary duct.

HEPATIC VEINS. See Vein, and Vena ports. HEPATICA. (From $\eta\pi a\rho$, the liver: so called because it was thought to be useful in diseases of the

liver.) See Marchantia polymorpha.
HEPATICA NOBILIS. See Anemone hepatica.

are voided.

HEPATICA TERRESTRIS. See Marchantia poly-

HEPATIRRHÆ'A. (From μπαρ, the liver, and ρεω, to flow.)
 1. A purging with bilious evacuations.
 2. A diarrhæa, in which portions of flesh, like liver,

HEPATITE. Fortid, straight, lamellar, heavy spar. A variety of lamellar barytes, containing a small quantity of sulphur, in consequence of which, when it is heated or rubbed, it emits a fætld sulphureous

HER HEP

HEPATITIS. (From $\eta\pi a\rho$, the liver.) Inflammation hepatis. An inflammation of the liver. A genus to hepatis. An inflammation of the liver. A genus of disease in the class Pyrexiw, and order Phlegmasiw of Cullen, who defines it "febrile affection, attended with tension and pain of the right hypochondrium, often pungent, like that of a pleurisy, but more frequently dull, or obtuse, a pain at the clavicle and at the top of the shoulder of the right side; much uneasiness in lying down on the left side; difficulty of breathing; a dry cough, younting, and hierar."

a dry cough, vomiting, and hiccup."

Besides the causes producing other inflammations, such as the application of cold, external injuries from contusions, blows, &c. this disease may be occasioned by certain passions of the mind, by violent exercise, by intense summer heats, by long-continued intermit-tent and remittent fevers, and by various solid concre-tions in the substance of the liver. In warm climates this viscus is more apt to be affected with inflammation than perhaps any other part of the body, proba-bly from the increased secretion of bile which takes place when the blood is thrown on the internal parts, by an exposure to cold; or from the bile becoming acrid, and thereby exciting an irritation in the part. Hepatitis has generally been considered of two kinds; one the acute, the other chronic.

The acute species of hepatitis comes on with a pain in the right hypochondrium, extending up to the clavicle and shoulder; which is much increased by pressing upon the part, and is accompanied with a cough, oppression of breathing, and difficulty of lying on the left side; together with nausea and sickness, and often with a vomiting of bilious matter. The urine is of a deep saffron colour, and small in quantity; there is loss of appetite, great thirst, and costiveness, with a strong, hard, and frequent pulse; and when the disease has continued for some days, the skin and eyes become tinged of a deep yellow. When the inflammation is in the cellular structure or substance of the liver, it is called by some hepatitis parenchymatosa, and when the gall-bladder which is attached to this organ, is the seat of the inflammation, it has been called hepatitis cystica.

The chronic species is usually accompanied with a morbid complexion, loss of appetite and flesh, costiveness, indigestion, flatulency, pains in the stomach, a yellow tinge of the skin and eyes, clay-coloured stools, high-coloured urine, depositing a red sediment and ropy mucus; an obtuse pain in the region of the liver, extending to the shoulder, and not unfrequently with a considerable degree of asthma.

These symptoms are, however, often so mild and insignificant as to pass almost unnoticed; as large abscesses have been found in the liver upon dissection, which in the person's lifetime had created little or no

inconvenience, and which we may presume to have been occasioned by some previous inflammation.

Hepatitis, like other inflammations, may end in resolution, suppuration, gangrene, or scirrhus, but its termination in gangrene is a rare occurrence.

The disease is seldom attended with fatal conse-

quences of an immediate nature, and is often carried off by hæmorrhage from the nose, or hæmorrhoidal vessels, and likewise by sweating, by a diarrhæa, or by an evacuation of urine, depositing a copious sedi-ment. In a few instances, it has been observed to cease on the appearance of erysipelas, in some external

when suppuration takes place, as it generally does, before this forms an adhesion with some neighbouring part, the pus is usually discharged by the different outlets with which this part is connected, as by coughing, vomiting, purging, or by an abscess breaking outwardly; but, in some instances, the pus has been discharged into the cavity of the abdomen, where no such charged into the cavity of the abdomen, where no such

adhesion had been formed.

On dissection, the liver is often found much enlarged, and hard to the touch; its colour is more of a deep purple than what is natural, and its membranes are more or less affected by inflammation. Dissections likewise show that adhesions to the neighbouring parts often take place, and large abscesses, containing a considerable quantity of pus, are often found in its sub-

The treatment of this disease must be distinguished, as it is of the acute, or of the chronic form. In acute hepatitis, where the symptoms run high, and the constitution will admit, we should, in the beginning, bleed

freely from the arm; which it will seldom be necessary to repeat, if carried to the proper extent at first in milder cases, or where there is less power in the system, the local abstraction of blood, by copping or leeching, may be sufficient. We should next give calomel alone, or combined with opium, and followed up by infusion of senna with neutral salts, jalap, or other cathartic, to evacuate bile, and thoroughly clear out by infusion of senna with neutral salts, jalap, or other cathartic, to evacuate bile, and thoroughly clear out the intestines. When, by these means, the inflammation is materially abated, we should endeavour to promote diaphoresis by suitable medicines, assisted by the warm bath; a blister may be applied; and the antiphlogistic regimen is to be duly enforced. But the discharge of bile, by occasional doses of calomel, must not be neglected: and where the alvine evacuations are deficient in that secretion, it will be proper to push are deficient in that secretion, it will be proper to push this, or other mercurial preparation, till the mouth is in some measure affected. In India this is the re-medy chiefly relied upon, and exhibited often in much medy chiefly relied upon, and exhibited often in much larger doses than appear advisable in more temperate climates. Should the disease proceed to suppuration, means must be used to support the strength; a nutritious diet, with a moderate quantity of wine, and decoction of bark, or other tonic medicine: fomentations or poultices will also be proper to promote the discharge externally; but when any fluctuation is perceptible, it is better to make an opening, lest it should burst inwardly. In the chronic form of the disease, mercury is the remedy chiefly to be relied upon; but due can is the remedy chiefly to be relied upon; but due caution must be observed in its use, especially in scrofulous subjects. It appears more effectual in restoring the healthy action of the liver, when taken internally: but if the mildest forms, though guarded by opium, or rather sedative, cannot so be borne, the ointment may be rubbed in. In the measuring calumba, or other be rubbed in. In the meantime, calumba, or other tonic, with antacids, and mild aperients, as rhubarb, to regulate the state of the primæ viæ, will be proper. Where the system will not admit the adequate use of mercury, the pitric acid is the most recognition. mercury, the nitric acid is the most promising substi-tute. An occasional blister may be required to relieve unusual pain; or where this is very limited and continued, an issue, or seton may answer better. strength must be supported by a light nutritious diet; and gentle exercise with warm clothing, to maintain the perspiration steadily, is important, in the convalescent state: more especially a sea voyage in persons long resident in India has often appeared the only means of restoring perfect health.

HEPATITIS PARENCHYMATOSA. the substance of the liver. Inflammation of

HEPATITIS PERITONÆALIS. Inflammation in the

peritonæum covering the liver.

HEPATOCE'LE. (From ηπαρ, the liver, and κηλη, a tumour.) A hernia, in which a portion of the liver protrudes through the abdominal parietes.

HEPATO'RIUM. The same as Eupatorium.

HEPHÆ'STIAS. (From Ηφαιςος, Vulcan, or fire.)

A drying plaster of burnt tiles.

HEPI'ALUS. (From ηπιος, gentle.) A mild quoti-

HEPTA'NDRIA. (From επτα, seven, and ανηρ, a man, or husband.) The name of a class in the sexual system of plants, consisting of such hermaphrodite flowers as have seven stamens.

ПЕРТАРНА RMACUM. (From επ/a, seven, and φαρμα-κον, medicine.) A medicine composed of seven in gredients, the principal of which were cerusse, litharge,

HEPTAPHY'LLUM. (From επ]a, seven, and φυλλον, a leaf: so named because it consists of seven leaves.) See Tormentilla erecta. HEPTAPHY'LLUM.

HEPTAPLE'URUM. (From επ/a, seven, and πλευρα, a rib: so named from its having seven ribs upon the leaf.) The herb plantain. See Plantago major.

HERA'CLEA. 1. Water hoarhound.

2. The common wild marjoram received a trivial

name from its growing in abundance in Heraclea. See

HERA CLEUM. (From Heraclea, the city near which it grows; or from 'Ηρακλης, Hercules, being the plant sacred to him.) The name of a genus of plants in the Linngan system. Class, Pentandria; Order, Digunia.

HERACLEUM GUMMIFERUM. This species is supposed by Wildenow to afford the gum ammoniacum.

See Ammoniacu:n.

HERACLEUM SPONDYLIUM. Branca ursina Germa-

HER

uica; Spondylium. Cow-parsnip. All-heal. Hera-cleum-foliolis pinnatifidis, lævibus; floribus unifor-mibus of Linnæus. The plant which is directed by the name of Branca ursina in foreign pharmacopæias. In Siberia it grows extremely high, and appears to have virtues in the cure of dysentery which the plants of

this country do not possess.

["The Heracleum Lanatum is one of our largest native umbellate plants, growing frequently to the height of a man, with a stalk more than an inch in thickness. Its taste is strong and acrid. The bruised root or leaves, externally applied, excite rubefaction. Internally used, this article has been recommended in It appears to me to possess a virose character, and should be used with caution, especially when gathered, from a watery or damp situation."—Big.

Mat. Med. A.]

HERB-BENNET. See Geum urbanum.

HERB-OF-GRACE. See Gratiola.

HERB-MASTICH. See Thymus mastichina.

HERB MASTICH. See Trymus masticaina.

Herb-trinity. See Anomone hepatica.

HERBA. An herb. A plant is properly so called which bears its flower and fruit once only, and then with its root wholly perishes. There are two kinds:

annuals, which perish the same year; and biennials, which have their leaves the first year, and their flowers and fruit the second, and then die away

By the term herba, Linnaus denominates that portion of every vegetable which arises from the root,

and is terminated by the fructification.

HERBA BRITANNICA. See Rumex hydrolapathum.
HERBA MILITARIS. See Achillaa millefolium.
HERBA SACRA. See Verbena trifoliata.
HERBA TRINITATIS. See Anemone hepatica.
HERBACEUS. Herbaceous. Plants are so con-

sidered which have succulent stems or stalks, and die

down to the root every year.

HERBARIUM. A collection of dried or preserved plants: called also Hortus siccus.

See Laserpitium HERCULES'S ALL-HEAL. chironium.

HERCULES BOVII. Gold and mercury dissolved in a distillation of copperas, nitre, and sea-salt.

HERE DITARY. (From hares, an heir.) A disease, or predisposition to a disease, which is transferred from parents to their children.

HERMA PHRODITE. (Hermaphroditus; from

Ερμης, Mercury, and $\Lambda \phi \rho o \delta i / \eta$, Venus, i. e. partaking of both sexes.) 1. The true hermaphrodite of the ancients was, the man with male organs of generation, and the female stature of body, that is, narrow chest and large pelvis; or the woman with female organs of generation, and the male stature of body, that is, broad chest and narrow pelvis. The term is now, however, used to express any lusus natura wherein the parts of generation appear to be a mixture of both

2. In botany, an hermaphrodite flower is one which contains both the male and female organs, for the production of the fruit, within the same calyx and

HERME TIC. (From Ερμης, Mercury.) In the language of the ancient chemists, Hermes was the father of chemistry, and the hermetic seal was the closing the end of a glass vessel while in a state of

closing the end of a glass vessel while in a state of fusion, according to the usage of chemists.

HERMODACTYL. See Hermodactylus.

HERMODA'CTYLUS. ('Ερμοδακγυλος. Etymologists have always derived this word from 'Ερμης, Mercury, and δακγυλος, a finger. It is, however, probably named from Hermus, a river in Asia, upon whose banks it grows, and δακγυλος, a date, which it is like.) Anima articulorum. The root of a species of colchicum, not yet ascertained, but supposed to be the Colchicum illyricum of Linnæus, of the shape of a heart, flattened on one side, with a furrow on the other, of a white colour, compact and solid, yet easy to cut of a white colour, compact and solid, yet easy to cut or powder. This root, which has a viscous, sweetish, farinaceous taste, and no remarkable smell, is imported from Turkey. Its use is totally laid aside in the practice of the present day. Formerly the roots were esteemed as cathartics, which power is wanting in those that reach this country.

protrusion of some of the viscera of the abdomen out Dd2

of that cavity into a kind of sac, composed of the portion of peritoneum, which is pushed before them. However, there are certainly some cases which will not be comprehended in this definition; either because the parts are not protruded at all, or have no hernial sac. The places in which these swellings most frequently make their appearance, are the groin, the navel, the labia pudendi, and the upper and forepart of the thigh; they do also occur at every point of the anterior part of the abdomen; and there are several less common instances, in which hernial tumours present themseives at the foramen ovale, in the peringum, in the vagiña, at the ischiatic notch, &c. The parts which, by being thrust forth from the cavity, in which they ought naturally to remain, mostly produce herniæ, are either a portion of the omentum, or a part of the in-testinal canal, or both together. But the stomach, the liver, the spleen, uterus, ovaries, bladder, &c. have been known to form the contents of some hernial tubeen known to form the contents or some hermal tumours. From these two circumstances of situations
and contents, are derived all the different appellations
by which hernix are distinguished. If a portion of
intestine only forms the contents of the tumour, it is
called enterocele; if a piece of omentum only, epiplocele; and if both intestine and omentum contribute to the formation of a tumour, it is called entero-epiplo-cele. When the contents of a hernia are protruded at the abdominal ring, but only pass as low as the groin, or labium pudendi, the case receives the name of bubonocele, or inguinal hernia; when the parts descend into the scroum, it is called an oscheocele or scrotal hernia. The crural, or femoral hernia, is the name given to that which takes place below Poupart's ligament. When the bowels protrude at the navel, the case is named an exomphalos, or umbilical hernial and ventral is the epithet given to the swelling, when it occurs at any other promiscuous part of the front of the abdomen. The congenital rupture is a very parti-cular case, in which the protruded viscera are not covered with a common hernial sac of peritoneum, but are lodged in the cavity of the tunica vaginalis, in contact with the testicle; and, as must be obvious, it is not named, like hernia in general, from its situation, or contents, but from the circumstances of its existing from the time of birth.

When the hernial contents lie quietly in the sac, and admit of being readily put back into the abdomen, it is admit of being readily put back into the abdomen, it is termed a reducible hernia: and when they suffer no constriction, yet cannot be put back, owing to adhesions, or their large size in relation to the aperture, through which they have to pass, the hernia is termed irreducible. An incarcerated, or strangulated hernia, signifies one which not only cannot be reduced, but suffers constriction: so that, if a piece of intestine be protruded, the pressure to which it is subjected stops the passage of its contents onward towards the anus, makes the bowel inflame, and brings on a train of most makes the bowel inflame, and brings on a train of most alarming and often fatal consequences.

alarming and often fatal consequences.

The general symptoms of a hernia, which is reducible and free from strangulation, are—an indolent tumour at some point of the parietes of the abdomen; most frequently descending out of the abdominal ring, or from just below Poupart's ligament, or else out of the navel; but occasionally from various other situations. The swelling mostly originates suddenly, except in the circumstances above related; and it is subject to a change of size, being smaller when the patient lies down upon his back, and larger when he stands up, or draws in his breath. The tumour frequently diminishes when pressed, and grows large again when diminishes when pressed, and grows large again when the pressure is removed. Its size and tension often increase after a meal, or when the patient is flatulent. Patients with hernia, are apt to be troubled with colic, constipation, and vomiting in consequence of the un-natural situation of the bowels. Very often, however, the functions of the viscera seem to suffer little or no interruption.

Interruption.

If the case be an enterocele, and the portion of the intestine be small, the tumour is small in proportion; but though small, yet, if the gut be distended with wind, inflamed, or have any degree of stricture made on it, it will be tense, resist the impression of the finger, and give pain upon being handled. On the contrary, if there be no stricture, and the intestine suffers no degree of inflammation, let the prolapsed piece be of gree of inflammation, let the prolapsed piece be of what length it may, and the tumour of whatever size, yet the tension will be little, and no pain will attend

HER HER

feel as if it was blown into; and, in general, it will be found very easily returnable. A guggling noise is often made when the bowel is ascending.

If the hernia be an epiplocele, or one of the omental kind, the tumour has a more flabby and a more unequal feel; it is in general perfectly indolent, is more compressible, and (if in the scrotum) is more oblong and less round than the swelling occasioned in the and less found than the swelling occasioned in the same situation by an intestinal hernia; and, if the quantity be large, and the patient an adult, it is, in some measure, distinguishable by its greater weight.

If the case be an entero-epiplocele, that is, one consisting of both intestine and omentum, the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the same stream of the characteristic marks will be less clear than in either of the similar than the same stream of the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the same stream of the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than in either of the similar than the characteristic marks will be less clear than th

ple cases; but the disease may easily be distinguished from every other one, by any body in the habit of

making the examination.

HERNIA CEREBRI. Fungus cerebri. This name is given to a tumour which every now and then rises from the brain, through an ulcerated opening in the dura mater, and protrudes through a perforation in the cranium, made by the previous application of the

Hernia congenita. (So called because it is, as it were, born with the person.) This species of hernia consists in the adhesion of a protruded portion of intestine or omentum to the testicle, after its descent into the scrotum. This adhesion takes place while the testicle is yet in the abdomen. Upon its leaving the abdomen, it draws the adhering intestine, or omentum, along with it into the scrotum, where it forms the

hernia congenita.

From the term congenital, we might suppose that this hernia always existed at the time of birth. The protrusion, however, seldom occurs till after this period, on the operation of the usual exciting causes of hernia in general. The congenital hernia does not usually happen till some months after birth; in some instances not till a late period. Hey relates a case, in which a hernia congenita was first formed in a young man, aged sixteen, whose right testis had, a little while before the attack of the disease, descended into the scrotum. It seems probable that, in cases of hernia congenita, which actually take place when the testicle descends into the scrotum before birth, the event may commonly be referred, as observed above, to the testi-cle having contracted an adhesion to a piece of intes-tine, or of the omentum, in its passage to the ring. Wrisberg found one testicle which had not passed the ring, adhering, by means of a few slender filaments, to the omentum, just above this aperture, in an infant that died a few days after birth.

Excepting the impossibility of feeling the testicle in hernia congenita, as we can in most cases of bubonocele, (which criterion Mr. Samuel Cooper, in his Sur-gical Dictionary, observes Mr. Pott should have mentioned,) the following account is very excellent. "The appearance of a hernia, in very early infancy, will always make it probable that it is of this kind; but in an adult, there is no reason for supposing his rupture to be of this sort, but his having been afflicted with it from his infancy; there is no external mark, or cha-racter, whereby it can be certainly distinguished from the one contained in a common hernial sac; neither would it be of any material use in practice, if there

HERNIA CRURALIS. Femoral hernia. The parts composing this kind of hernia are always protruded under Poupart's ligament, and the swelling is situated towards the inner part of the bend of the thigh. The rupture descends on the side of the femoral artery and vein, between these vessels and the os pubis. Fe-males are particularly subject to this kind of rupture in consequence of the great breadth of their pelvis, while in them the inguinal heruia is rare. It has been computed, that nineteen out of twenty married women, afflicted with hernia, have this kind; but that not one out of a hundred unmarried females, or out of the same number of men, have this form of the disease. The situation of the tumour makes it liable to be mistaken for an enlarged inguinal gland; and many fatal events are recorded to have happened from the sur-geon's ignorance of the existence of the disease. A gland can only become enlarged by the gradual effects of inflammation; the swelling of a crural hernia comes

the handling of it; upon the patient's coughing, it will | strangulated, occasions the train of symptoms described in the account of the bernia incarcerata, which symptoms an enlarged gland could never occasion. circumstances seem to be sufficiently discriminative: though the feel of the two kinds of swelling is often not in itself enough to make the surgeon decided in his opinion. A femoral hernia may be mistaken for a bubonocele, when the expanded part of the swelling lies over Poupart's ligament. As the taxis and opera-tion for the first case ought to be done differently from those for the latter, the error may lead to very bad consequences. The femoral hernia, however, may always be discriminated, by the neck of the tumour having Poupart's ligament above it. In the bubonocele, the angle of the pubes is behind and below this part of the see; but in the femoral hernia, it is on the part of the sac; but in the femoral hernia, it is on the same horizontal level, a little on the inside of it.

Until very lately, the stricture, in cases of femoral hernia, was always supposed to be produced by the lower border of the external oblique muscle, or as it is termed, Poupart's ligament. A total change of surgical opinion on this subject has, however, latterly taken place, in consequence of the accurate observations first made in 1768, by Gimbernat, surgeon to the king of Spain. In the crural hernia, (says he,) the aperture through which the parts issue is not formed by two-bands, (as in the inguinal hernia,) but it is a foramen, almost round, proceeding from the internal margin of the crural arch, (Poupart's ligament,) near its insertion into the branch of the os pubis, between the bone and the iliac vein, so that, in this hernia, the branch of the os pubis is situated more internally than the intestine, and a little behind: the vein externally, and behind: place, in consequence of the accurate observations first and a little behind; the vein externally, and behind; and the internal border of the arch before. Now it is this border which always forms the strangulation.

HERNIA FLATULENTA. A swelling of the side, caused by air that has escaped through the pleura: an

obsolete term.

HERNIA GUTTURIS. Bronchocele, or tumour of the bronchial gland.

HERNIA HUMORALIS. See Orchitis. HERNIA INCARCERATA. Incarcerated hernia. Strangulated hernia, or a hernia with stricture. The symptoms are a swelling in the groin, &c. resisting the im-pression of the fingers. If the hernia be of the intestinal kind, it is generally painful to the touch, and the pain is increased by coughing, sneezing, or standing upright. These are the very first symptoms, and, if they are not relieved, are soon followed by others; viz. a sickness at the stomach, a frequent retching, or inclination to vomit, a stoppage of all discharge per anum, attended with frequent hard pulse, and some degree of fever. These are the first symptoms; and if they are not appeased by the return of the intestine, that is, if the attempts made for this purpose do not succeed, the sickness becomes more troublesome, the vomiting more frequent, the pain more intense, the tension of the belly greater, the fever higher, and a general restlessness comes on, which is very terrible to bear. When this is the state of the patient, no to bear. When this is the state of the patient, no time is to be lost; a very little delay is now of the ntmost consequence; and if the one single remedy, which the disease is now capable of, be not administered immediately, it will generally baffle every other attempt. This remedy is the operation whereby the parts engaged in the stricture may be set free. If this be not now performed, the vomiting is soon exchanged for a convulsive hiccup, and a frequent gulp-ing up of bilious matter: the tension of the belly, the restlessness and fever, having been considerably increased for a few hours, the patient suddenly becomes perfectly easy, the belly subsides, the pulse, from having been hard, full, and frequent, becomes low, languid, and generally interrupted; and the skin, especially that of the limbs, cold and moist; the eyes have now a languor and glassiness, a lack lustre not easy to be described: the tumour of the part disappears, and the skin covering it sometimes changes its natural colour for a livid hue; but whether it keeps or loses its colour, it has an emphysematous feel, a crepitus to the touch, which will easily be conceived by all who have attended to it, but is not easy to convey an idea of by words. This crepitus is the too sure indicator of gangrenous mischief within. In this state, the gut either goes up spontaneously or is returned with the smallest degree of pressure; a discharge is made on in a momentary and sudden manner; and, when by stool, and the patient is generally much pleased at

the case he finds; but this pleasure is of short duration, for the hiccup and the cold sweats continuing and increasing, with the addition of spasmodic rigours

and subtultus tendinum, the tragedy soon finishes.

Hernia inguinalis. Bubonocele. Inguinal hernia.

The hernia inguinalis is so called because it appears in both sexes at the groin. It is one of the divisions of hernia, and includes all those herniæ in which the parts displaced pass out of the abdomen through the ring, that is, the arch formed by the aponeurosis of the musculus obliquus externus in the groin, for the passage of the spermatic vessels in men, and the round ligament in women. The parts displaced that form the bernia, the part into which they fall, the manner of the hernia being produced, and the time it has continued, occasion great differences in this disorder. There are three different parts that may produce a hernia in the groin, viz., one or more of the intestines, the epiploon, and the bladder. That which is formed by one or more of the intestines, was called, by the ancients, enterocele. The intestine which most frequently produces the hernia, is the ilium: because, being placed in the iliac region, it is nearer the groin than the rest: but notwithstanding the situation of the other intestines, which seems not to allow of their coming near the groin, we often find the jejunum, and frequently also a portion of the colon and cæcum, included in the hernia. It must be remembered, that the mesentery and mesocolon are membranous substances, capable of extension, which, by little and little, are sometimes so far stretched by the weight of the intes-tines, as to escape with the ilium, in this species of hernia. The hernia made by the epiploon, is called epiplocele; as that caused by the epiploon and any of the intestines together, is called entero epiplocele. The hernia of the bladder is called crytocele. the bladder is uncommon, and has seldom been known to happen but in conjunction with some of the other When the parts, having passed through the abdominal rings, descend no lower than the groin, it is called an incomplete hernia; when they fail into the scrotum in men, or into the labia pudendi in women, it is then termed complete.

The marks of discrimination between some other

diseases and inguinal hernia are these

The disorders in which a mistake may possibly be made, are the circocele, bubo, hydrocele, and hernia humoralis, or inflamed testicle.

For an account of the manner of distinguishing cir-

cocele from a bubonocele, see Circocele.

The circumscribed incompressible hardness, the situation of the tumour, and its being free from all connexion with the spermatic process, will sufficiently point out its being a bubo, at least while it is in a recent state; and when it is in any degree suppurated, he must have a very small share of the tactus cruditus who cannot feel the difference between matter, and

either a piece of intestine or omentum. The perfect equality of the whole tumour, and free-dom and smallness of the spermatic process above it, the power of feeling the spermatic vessels, and the vas deferens in that process; its being void of pain upon being handled, the fluctuation of the water, the gra-dual formation of the swelling, its having begun below and proceeded upwards, its not being affected by any posture or action of the patient, nor increased by his coughing or sneezing, together with the absolute im-possibility of feeling the testicle at the bottom of the scrotum, will always, to an intelligent person, prove

the disease to be hydrocele.

Pott, however, allows that there are some exceptions in which the testicle cannot be felt at the bottom of the in which the testicle cannot be felt at the bottom of the scrotum, in cases of hernia. In recent bubonoceles, while the hernial sac is thin, has not been long, or very much distended, and the scrotum still preserves a regularity of figure, the testicle may almost always be easily felt at the inferior and posterior part of the tumour. But in old ruptures, which have been long, down, in which the quantity of contents is large, the sac considerably thickened, and the scrotum of an irregular figure, the testicle frequently cannot be felt; neither is it in general easily felt in the congenital herneither is it in general easily felt in the congenital hernia, for obvious reasons.

In the hernia humoralis, the pain in the testicle, its enlargement, the hardened state of the epididymus, and the exemption of the spermatic cord from all unnatural fulness, are such marks as cannot easily be in men, its existence can only be distinguished by ex-

mistaken; not to mention the generally preceding go-norrhœa. But if any doubt still remains of the true nature of the disease, the progress of it from above downwards, its different state and size in different postures, particularly lying and standing, together with its descent and ascent, will, if duly attended to, put it out of all doubt that the tumour is a true hernia.

When an inguinal hernia does not descend through the abdominal ring, but only into the canal for the spermatic cord, it is covered by the aponeurosis of the external oblique muscle, and the swelling is small and

Now and then, the testicle does not descend into the scrotum till a late period. The first appearance of this body at the ring, in order to get into its natural situation, might be mistaken for that of a hernia, were the surgeon not to pay attention to the absence of the testicle from the scrotum, and the peculiar sensation occasioned by pressing the swelling.

HERNIA INTESTINALIS. A rupture caused by the protrusion of a portion of the intestine. See Hernia

inguinalis.

HERNIA ISCHIATICA. A rupture at the ischiatic notch. This is very rare. A case, however, which was strangulated, and undiscovered till after death, is related in Sir A. Cooper's second part of his work on The disease happened in a young man aged hernia. The disease happened in a young man aged 27. On opening the abdomen, the ilium was found to have descended on the right side of the rectum into the pelvis; and a fold of it was protruded into a small sac, which passed out of the pelvis at the ischiatic notch. The intestine was adherent to the sac at two points; the strangulated part, and about three inches on each side, were very black. The intestines towards the stemach was a strangulated with air and on each side, were very black. The intestines towards the stomach, were very much distended with air, and here and there had a livid spot on them. A dark spot was even found on the stomach itself, just above the pylorus. The colon was exceedingly contracted, as far as its sigmoid flexure. A small orifice was found in the side of the pelvis, in front of, but a little above the sciatic nerve, and on the forepart of the pyriformis muscle. The sac lay under the glutaus maximus muscle, and its orifice was before the internal iliac

artery, below the obturator artery, but above the vein.
HERNIA LACHRYMALIS. When the tears pass through
the puncta lachrymalia, but stagnate in the succulus lachrymalis, the tumour is styled hernia lachrymalis with little propriety or precision. It is with equal impropriety called, by Anel, a dropsy of the lachrymal sac. If the inner angle of the eye is pressed, and an aqueous humour flows out, the disease is the fistula

lachrymalis.

HERNIA MESENTERICA. Mesenteric hernia. If one of the layers of the mesentery be torn by a blow, while the other remains in its natural state, the intestines may insinuate themselves into the aperture and form a kind of hernia. The same consequences may result from a natural deficiency in one of these layers. Sir A. Cooper relates a case, in which all the small intestines, except the duodenum, were thus circumstanced. The symptoms during life were unknown.

HERNIA MESOCOLICA. Mesocolic hernia. So named by Sir A. Cooper, when the bowels glide between the

layers of the mesocolon. Every surgeon should be aware that the intestines may be strangulated from the aware that the intestines may be strangulated from the following causes: 1. Apertures in the omentum, mesentery, or mesocolon, through which the intestine protrudes. 2. Adhesions, leaving an aperture, in which a piece of intestine becomes confined. 3. Membranous bands at the mouth of hernial sacs, which becoming elongated by the frequent protrusion and return of the viscera, surround the intestine, so as to strangulate them within the abdomen when returned from the sac.

HERNIA OMENTALIS. Epiplocele. A rupture of the omentum; or a protrusion of the omentum through apertures in the integuments of the belly. Sometimes, according to Sharpe, so large a quantity of the omentum hath fallen into the scrotum, that its weight, drawing the stomach and bowels downwards, hath excited inflammation and symmetry similar to the scrotum. vomiting, inflammation, and symptoms similar to those of the incarcerated hernia.

HERNIA PERINEALIS. Perineal hernia. In men, the parts protrude between the bladder and rectum; in hervien between the rectum and vagina. The hernia women, between the rectum and vagina. does not project so as to form an external tumour; and,

The abdominal viscera are occasionally protruded through the diaphragm, either through some of the natural apertures in this muscle, or deficiencies, or wounds, and lacerations in it. The second kind of case is the most frequent. Morgagni furnishes an instance of the first. frequent. Morgagni furnishes an instance of the first. Two cases related by Dr. Macauley, and two others published by Sir A. Cooper, are instances of the second sort. And another case has been lately recorded by the latter gentleman, affording an example of the third kind. Hildanus, Parè, Petit, Schenck, &c. also mention cases of phrenic hernia.

HERNIA PUDENDALIS. Pudendal hernia. This is the name assigned by Sir A. Cooper, to that which descends between the vagina and ramus ischii, and forms an oblong tumour in the labium, traceable within

forms an oblong tumour in the labium, traceable within the pelvis, as far as the os uteri. Sir A. C. thinks this case has sometimes been mistaken for a hernia of the

foramen ovale.

foramen ovale.

Hernia Scrotalis. Hernia Oscheolis. Oscheocle.

Paracelsus calls it Crepatura. When the omentum, the intestine, or both, descend into the scrotum, it has these appellations; when the omentum only, it is called epiploscheocele. It is styled a perfect rupture in contradistinction to a bubonocele, which is the same disorder; but the descent is not so great. The hernia scrotalis is distinguished into the true and false; in the former, the omentum or intestine, or both, fall into the scrotum; in the latter, an inflammation, or a fluid, causes a tumour in this part, as in hernia humoralis, or hydrocele. Sometimes sebaceous matter is collected in the scrotum; and this hernia is called steatocele.

Hernia Thyroidealis. Hernia foraminis ovalis.

HERNIA THYROIDEALIS. Hernia foraminis ovalis. Thyroideal hernia. In the anterior and upper part of the obturator ligament there is an opening, through which the obturator artery, vein, and nerve proceed, and through which occasionally a piece of omentum or intestine is protruded, covered with a part of the peritonaum, which constitutes the hernial sac.

HERNIA UMBILICALIS. Epiploomphalion; Omphalocele; Exomphalos; Omphalos; and when owing to flatulency, Pneumatomphalos. The exomphalos, or umbilical rupture, is so called from its situation, and has, like other herniæ, for its general contents, a porhas, like other herniz, for its general contents, a por-tion of intestine, or omentum, or both. In old umbi-lical ruptures, the quantity of omentum is sometimes very great. Mr. Ramby says, that he found two ells and a half of intestine in one of these, with about a third part of the stomach, all adhering together. Gay and Nourse found the liver in the sac of an umbilical hernia; and Bohnius says that he did also. But whatever are the contents, they are originally contained in the sac, formed by the protrusion of the peritoneum.

formed by the protrusion of the peritoneum.

In recent and small ruptures, this sac is very visible; but in old and large ones, it is broken through at the

but in old and large ones, it is broken through at the knot of the navel, by the pressure and weight of the contents, and is not always to be distinguished; which is the reason why it has by some been doubted whether this kind of rupture has a hernial sac or not.

Infants are very subject to this disease, in a small degree, from the separation of the funiculus; but in general they either get rid of it as they gather strength, or are easily cured by wearing a proper bandage. It is of still more consequence to get this disorder cured in females, than in males; that its return, when they are become adult and premant, may be prevented as much as possible; for at this than it often happens, from the too great distention of the belly, or from unguarded motion when the parts are upon the stretch.

Dr. Hamilton has met with about two cases annually for the space of seventeen years, of unbilical hernia, which strictly deserve the name of congenical umbilical hernia. The funis ends in a sort of bag, containing some of the viscera, which pass out of the abdonant

some of the viscera, which pass out of the abdomen through an aperture in the situation of the navel. The swelling is not covered with skin, so that the contents of the hernia can be seen through the then distended covering of the cord. The disease is owing to a pre-ternatural deficiency in the abdominal muscles, and the hope of cure must be regulated by the size of the

malformation and quantity of viscera protruded.

HERNIA UTERI. Hysterocele. Instances have occurred of the uterus being thrust through the rings of the muscles; but this is scarcely to be discovered, unless in a pregnant state, when the strugglings of a child

amining in the rectum. In women, it may be detected both from this part and the vagina.

Hernia Phrenica. Phrenic hernia. The abdomi-

Hernia Vaginalis. Elytrocele. Vaginal hernia. A tumour occurs within the os externum of the vagina. It is clastic, but not painful. When compressed, it readily recedes, but is reproduced by coughing, or even without this, when the pressure is removed. The inconveniences produced are an inability to undergo much exercise or exertion; for every effort of this sort brings on a sense of bearing down. The vaginal hernia pro-trudes in the space left between the uterus and rectum. This space is bounded below by the peritoneum, which membrane is forced downwards, towards the perinaum; but being unable to protrude further in that direction, is pushed towards the back part of the vagina. These cases probably are always intestinal. Some hernise

cases probably are always intestinal. Some herniae protrude at the anterfor part of the vagina.

Hernia varicosa. See Circocile.

Hernia ventosa. See Pneumatocile.

Hernia wentraatis. Hypogastrocile. The ventral hernia may appear at almost any point of the anterior part of the belly, but is most frequently found between the recti muscles. The portion of intestine, &c. &c. is always contained in a sac made by the protrusion of the peritongum. Sir A. Cooper inputtes its causes to the peritonæum. Sir A. Cooper imputes its causes to the dilatation of the natural foramina, for the transmission of vessels, to congenital deficiencies, lacerations, and wounds of the abdominal muscles, or their tendons In small ventral hernig, a second fascia is found be neath the superficial one; but in large ones the latter is neath the superficial one; but in large ones the latter is the only one covering the sac.

HERNIA VENTRICULI. Gastrocele. A ventral rup-ture caused by the stomach protruding through some part of the abdominal parietes. It rarely occurs, but it

does it generally at or near the navel.

HERNIA VESICALIS. Hernia cystica; Cystocele. The urinary bladder is liable to be thrust forth, from its proper situation, either through the openings in the oblique muscle, like the inguinal hernia, or under Pou-part's ligament, in the same manner as the femoral.

This is not a very frequent species of hernia, but does happen, and has as plain and determined a character

HERNIA'RIA. (From hernia, a rupture: so called from its supposed efficacy in curing ruptures.) The name of a genus of plants in the Linnscan system.

name of a genus of plants in the Linnean system. Class, Pentandria; Order, Digynia. Rupture-wort. Hernia Glabra. The systematic name of the rupture-wort. Herniaria. This plant, though formerly esteemed as efficacious in the cure of hernias, appears to be destitute, not only of such virtues, but of any other. It has no smell nor taste.

HERNIO TOMY. (Herniotomia; from hernia, and τεμνω, to cut.) The operation to remove the strangulated part in cases of incarcerated hernias.

HERPES. From herno, to refere the sause it creeks.

HE RPES. From loπω, to creep; because it creeps and spreads about the skin.) Tetter. A genus of disease in the class Locales, and order Dialyses of Cullen, distinguished by an assemblage of numerous little

creeping ulcers, in clusters, itching very much, and difficult to heal, but terminating in furfuraceous scales. Bell, in his Treatise on Ulcers, arranges the herpes among the cutaneous ulcers, and says, that all the varieties of importance may be comprehended in the

four following species:

1. Herpes farinosus, or what may be termed the dry tetter, is the most simple of all the species. It appears indiscriminately in different parts of the body, but most commonly on the face, neck, arms and wrists, in pretty broad spots and small pimples. These are generally very itchy, though not otherwise troublesome; and, after continuous account time there there are after continuing a certain time, they at last fall off in the form of a white powder, similar to fine bran, leav-ing the skin below perfectly sound; and again return-ing in the form of a red efflorescence, they fall off, and are renewed as before.

2. Herpes pustulosus. This species appears in the form of pustules, which originally are separate and distinct, but which afterward run together in clusters. At first, they seemed to contain nothing but a thin wa-At hist, they seemed to contain nothing out a tinn watery serum, which afterward turns yellow, and, exuding over the whole surface of the part affected, it at last dries into a thick crust, or scab; when this falls off, the skin below frequently appears entire, with only a slightdegree of redness on its surface; but on some occasions, when the matter has probably been more acrid,

out maiscrimmately over the whole body; but more frequently about the loins, breast, perinaum, scrotum, and inguina, than in other parts. It generally appears in clusters, though sometimes in distinct rings, or circles, of very minute pimples, the resemblance of which to the millet-seed has given rise to the denomination of the species. The pimples are at first, though small, perfectly separate, and contain nothing but a clear perfectly separate, and contain nothing but a clear lymph, which, in the course of this disease, is excreted lymph, which, in the course of this disease, is excreted upon the surface, and there forms into small distinct scales; these, at last, fall off, and leave a considerable degree of inflammation below, and still continues to exude fresh matter, which likewise forms into cakes, and so falls off as before. The itching, in this species of complaint, is always very troublesome; and the matter discharged from the pimples is so tough and viscid, that every thing applied to the part adheres, so as to occasion much trouble and uneasiness on its being removed. removed.

4. Herpes exedens, the eating and corroding tetter (so called from its destroying or corroding the parts which it attacks,) appears commonly, at first, in the form of several small painful ulcerations, all collected into larger spots, of different sizes and of various figures, with always more or less of an erysipelatous inflammation. These ulcers discharge large quantities of a thin, sharp, serous matter, which sometimes forms into small crusts, that in a short time fall off; but most frequently the discharge is so thin and acrid as to spread along the neighbouring parts, where it soon produces the same kind of sores. Though these ulcers do not, in general, proceed farther than the cutis vera, yet sometimes the discharge is so very penetrating and corrosive as to destroy the skin, cellular substance, and, on some occasions, even the muscles themselves. It is this species that should be termed the depascent, or phagedenic ulcer, from the great destruction of parts which it frequently occasions. See Phagedana.

Herres ambulativa. A species of erysipelas which moves from one part to another.

Herres depascens. The same as herpes exedens.

See Herpes.
Herpes estimomenos. Herpes destroying the skin

by ulceration. HERPES FARINOSUS. See Herpes.

HERPES FERUS. An erysteelas. HERPES INDICA. A fiery, itchy herpes, peculiar to

HERPES MILIARIS. See Herpes. HERPES PERISCELIS. The shingles. See Erysipe-

las phlyctonodes.

Herres pustulosus. See Herres.

Herres serrigo. The ring-worm.

Herres siccus. The dry, mealy tetter.

HERPES ZOSTER. Shingles encircling the body. See Erysipelas. HERPETIC.

Relating to Herpes.

HE RPETON. (From έσπεω, to creep.) A creeping

HESPERIDEÆ. (From Hesperides, whose orchards, according to the poets, produced golden apples.) Golden or precious fruit. The name of an order of plants in Linnæus's Fragments of a Natural Method Method, consisting of plants which have rigid evergreen leaves; odorous and polyandrous flowers; as the myrtle, clove, &c.

["The Heuchera Cortusa of Michaux, is a native

["The Heuchera Cortusa of Michaux, is a native plant, growing in woods, from New-England to Carolina. The root is one of the strongest vegetable astringents. As such, it has been employed in various complaints, to which astringents are adapted, and favourable reports are made of its operation. Hitherto it has been more known as an external application than as an internal remedy."—Big. Mat. Med. A.]

HEWSON, WILLIAM, was born at Hexham, in 1739. After serving an apprenticeship to his father, he came to London at the age of twenty, and resided with Mr. John Hunter, attending also the lectures of Dr. Hunter. His assiduity and skill were so conspicuous, that he was appointed to superintend the dissecting room, when the former went abroad with the army in 1760. He then studied a year at Edinburgh,

upon the scab falling off, the skin is found slightly excoriated. Eruptions of this kind appear most frequently on the face, behind the ears, and on other parts of the head; and they occur most commonly in children.

3. Herpes miliaris. The miliary tetter. This breaks out indiscriminately over the whole body; but more out indiscriminately over the whole body; but more of which he published an account in 1771. He also of which he published an account in 1771. He also of which he published an account in 1771. He asso-communicated to the Royal Society several papers concerning the lymphatic system in birds and fishes, for which he received the Copleyan medal, and was soon after elected a fellow of that body. He began a course of lectures alone in 1772, having quitted Dr. Hunter two years before, and soon became very popu-lar. In 1774, he published his work on the Lymphatic System. But not long after, his life was terminated System. But not long after, his life was terminated by a fever, occasioned by a wound received in dis-secting a morbid body, in the thirty-fifth year of his

HEXAGY'NIA. (From & six, and youn, a woman, or wife.) The name of an order of plants in the sexual system, which, besides the classic character, have

six females or pistils.

HEXA NDRIA. (From εξ, six, and ανηρ, a man, or husband.) The name of a class of plants in the sexual system, consisting of plants with hermaphrodite flowers that are furnished with six stamens of an equal

HEXAPHA'RMACUM. (From & six, and papuakov, a medicine.) Any medicine in the composition of which are six ingredients.

Which are six ingredients.

Hibe'renicus Lapis. See Lapis hibernicus.

Hibe'renicus (From ιβις, a stork, who is said to chew it, and inject it as a clyster.) The name of a genus of plants in the Linnæan system. Class, Monadelphia; Order, Polyandria.

Hibiscus abelmoschus. The systematic name of

the plant, the seeds of which are called musk-seed; Abelmoschus; Granum moschi; Moschus Arabum; Abetmoschus; Granum moschi; Moschus Arabum; Ægyptia moschata; Bamia moschata; Alcea; Alcea Indica; Mcea Ægyptiaca villosa; Abrette; Abelmosch; Abetmusk. The plant is indigenous in Egypt, and in many parts of both the Indies. These seeds have the flavour of musk. The best comes from Martinico. By the Arabians, they are esteemed cordial, and are mixed with their coffee, to which they impart their fragrance. In this country they are used by the

HICCUP. Singultus. A spasmodic affection of the diaphragm, generally arising from irritation produced by acidity in the stomach, error of diet, &c.

HIDRO'A. (From ιδρως, sweat.) A pustular disease, produced by sweating in hot weather.

HIDRO'CRISIS. (From ιδρως, sweat, and κρινω, to judge.) A judgment formed from the sweat of the patient

HIDRO'NOSOS. (From ιδρως, sweat, and roσος, disease.) The sweating sickness.
HIDROPY'RETUS. (From ιδρως, sweat, and

a disease.) The sweatin

ος 7ος, a fever.) Sweating fever. HIDRO TICA. (From ιδρως, (From ιδρως, sweat.) Medicines

HIDRO TICA. (From ιδρως, sweat.) Medicines which cause perspiration.

HIDRO TOPOLE TICA. (From ιδρως, sweat, and ποιεω, to make.) Sudorifics.

HI ERA. (From ιερος, holy; and from ιεραξ, a hawk.) Holy: Also applied to some plants which hawks are said to be fond of.

HIERA PICRA. (From ιερος, holy, and πικρος, bitter. Holy bitter.) Pulvis alpeticus, formerly called kiera logadii, made in the form of an electuary with honey. It is now kept in the form of dry powder, prepared by mixing Socotorine aloes, one pound, with three ounces of white canella. of white canella.

HIERABO'TANE. (From ιερος, holy, and βο aνη, an herb: so called from its supposed virtues.) See Verbena trifoliata.

hieraca'ntha. (From upat, a hawk, and aphos, a flower: so named because it seizes passengers as a hawk does its prey.) A sort of thistle.

HIERA'CIUM. (From upat, a hawk: so called because hawks feed upon it, or because it was said that hawks applied the juice of it to cleanse their eyes.) The name of a genus of plants in the Linnean system. Class, Syngenesia; Order, Polygamia equals. Hawk-weed.

Hieracium plosella. The systematic name of

HIERACIUM PILOSELLA. The systematic name of the mouse-ear, Auricula muris; Pilosella; Myosotis; Hieraculum. This common plant contains a bitter lactescent juice, which has a slight degree of astrin-

tues.

Highgate resia. See Fossil copal.

HIGHMORE, NATHANIEL, was born at Fording-bridge, in Hampshire, in 1618. After graduating at Oxford, he settled at Sherborne, where he obtained considerable reputation in practice, and died in 1684. He pursued the study of anatomy with zeal, though with limited opportunities of dissection; and his name has been attached to a part, though not originally discovered by him, namely, the Antrum Maxillare, which had been before mentioned by Casserius. His principal work is "Corporis humani Disquisitio anatomica," printed at the Hague in 1651, with figures, chiefly from Vesalius. He also published two dissertations on Hysteria and Hypochondriasis; and a history of Generation. tory of Generation.

Highmore's antrum. See Antrum of Highmore. Higur'so. The calabash-tree, the fruit of which is

Higur'ro. The calabash-tree, the fruit of which is said to be febrifuge.

HILDA'NUS. See Fabricius, William.

HILUM. The scar, or point by which the seed is attached to its seed-vessel or receptacle, and through which alone life and nourishment are conveyed for the perfecting of its internal parts. Consequently all those parts must be intimately connected with the inner surface of this scar, and they are all found to meet there, and to divide or divaricate from that point, more or less immediately. In describing the form or various external portions of any seed, the hilum is always to be considered as the base. When the seed is quite ripe, the communication through this channel is interrupted, it separates from the parent plant without injury, a scar being formed on each. Yet the hilum is so far capable of resuming its former nature, that the moisture of the earth is imbibed through it, previous to germination .- Smith.

HIMANTO'SIS. (From thas, a thong of leather.) A relaxation of the uvula, when it hangs down like a

HI'MAS. A relaxation of the uvula

HIN. Hindisch. Hing. Assafætida. HIP. The ripe fruit of the dog-rose.

HIP. The ripe fruit of the dog-rose. They are chiefly used as a sweetmeat, or in a preserved state.

chiefly used as a sweetmeat, or in a preserved state. See Confectio rosw caninw.

HIPPOCAMPUS. (Ιπποκαμπος, the name of a sea insect which has a head like that of the horse, and tail like the καμπη, or cruca.) 1. The sea-horse.

2. Some parts are so called from their supposed resemblance. See Cerebrum.

HIPPOCA'STANUM. (From ιππος, a horse, and καςαιον, a chesnut: so called from its size.) See Æsculus hippocastanum.

HIPPOCRATES, usually called the father of physic, was born in the island of Cos, about 460 years before Christ. He is reckoned the 18th lineal descendant from Æsculapius, the profession of medicine having from Æsculapius, the profession of medicine having been hereditarily followed in that family, under whose direction the Coan school attained its high degree of eminence, and by the mother's side he is said to have descended from Hercules. Born with these advantages, and stimulated by the fame of his ancestors, he devoted himself zealously to the cultivation of the healing art. Not content with the empirical prac-tice, which was derived from his predecessors, he studied under Herodicus, who had invented the gymnastic medicine, as well as some other philosophers. But he appears to have judged carefully for himself, and to have adopted only those principles, which seemed founded in sound reason. He was thus enabled to throw light on the deductions of experience, and clear away the false theories with which medicine had been loaded by those who had no practical knowledge clear away the false theories with which medicine had been loaded by those who had no practical knowledge of diseases, and bring it into the true path of observation, under the guidance of reason. Hence the physicians of the rational or degmatic sect always acknowledged him as their leader. The events of his life are involved in much obscurity and fable. But he appears the latter that the second places for to have travelled much, residing at different places for

They are very seldom used in this country.

HIERA'NOSOS. (From tepos, holy, and vocos, a disease: so called because it was supposed to be that disorder which our Saviour cured in those who were said to be possessed of devils.) The epilepsy.

HIERA'TICUM. (From tepos, holy.) A poultice for the stomach, so named from its supposed divine virtues. respected as oracles, not only in the schools of medi-cine, but even in the courts of law. He has shared with Plato the title of divine: statues and temples have been erected to his memory, and his altars co-vered with incense, like those of Æsculapius himself. Indeed, the qualifications and duties required in a physician, were never more fully exemplified than in his conduct, and more eloquently described than by his pen. He is said to have admitted no one to his instructions without the solemnity of an oath, in which the chief obligations are, the most religions atten-tion to the advantages of the sick, the strictest chastity, and inviolable secrecy concerning matters which ought not to be divulged. Besides these characteristics, he displayed great simplicity, candour, and benevolence, with unwearied zeal, in investigating the progress and nature of disease, and in administering to their cure. The books attributed to him amount to 22, of which benevore many accountered continued. their cure. The books attributed to him amount to 72; of which, however, many are considered spurious, and others have been much corrupted. The most esteemed, and generally admitted genuine, are the essay "On Air, Water, and Situation," the first and third books of "Epidemics," that on "Prognostics," the "Aphorisms," the treatise "On the Diet in acute Diseases," and that "On Wounds of the Head." He wrote in the Ionic dialect, in a pure but remarkably concise style. He was necessarily deficient in the concise style. He was necessarily deficient in the knowledge of anatomy, as the dissection of human bodies was not then allowed; whence his Physiology bodies was not then allowed; whence his rhyslology also is, in many respects, erroneous: but he, in a great measure, compensated this by unceasing observation of diseases, whereby he attained so much skill in pathology and therapeutics, that he has been regarded as the founder of medical science: and his opinions still influence the healing art in a considerable degree. He diligently investigated the several causes of eases, but especially their symptoms, which enabled him readily to distinguish them from each other: and very few of those noticed by him are now unknown, mostly retaining even the same names. But he is more remarkably distinguished by his Prognostics, which have been comparatively little improved since. which have been comparatively little improved since, founded upon various appearances in the state of the patient, but especially upon the excretions. His at tention seems to have been directed chiefly to these in consequence of a particular theory. He supposed that there are four humours in the body, blood, phlegm, yellow and black bile, having different degrees of heat or coldness, moisture or dryness, and that to certain changes in the quantity or quality of these all diseases might be referred; and farther, that that to certain changes in the quantity or quality of these, all diseases might be referred; and farther, that in acute disorders a concoction of the morbid humours took place, followed by a critical discharge, which he believed to happen, especially on certain days. But he seems to have paid little, if any, attention to the state of the pulse. He advanced another opinion, which has since very generally prevailed, that there is a principle, or power in the system, which he called Nature, tending to the preservation of health, and the removal of disease. He, therefore, advised practitioners carefully to observe and promote the efforts of nature, at the same time correcting morbid states by their opposites, and endeavouring to bring back the fluids into their proper channels. The chief part of his treatment at first was a great restriction of the diet; in very acute diseases merely allowing the mouth to be ins treatment at first was a great restriction of the diet; in very acute diseases merely allowing the mouth to be moistened occasionally for three or four days, and only a more plentiful dilution during a fortnight, provided the strength would bear it; afterward a more substantial diet was directed, but hardly any medicines, except gentle emetics, and iaxatives, or clysters. Where these means failed, very active purgatives were employed, as hellebore, elaterium, &c., or sometimes the sudorific regimen, or garlic and other direction. sudorific regimen, or garlic and other diuretics. He seems cautious in the use of narcotics, but occasionally had recourse to some of the preparations of lead, copper, silver, and irou. He bled freely in cases of extreme pain or inflammation, sometimes opening two veins at

HOD HOL

once, so as to produce fainting; and also took blood often by cupping, but preferably from a remote part, with a view of producing a revulsion. Where medicines fan, he recommends the knife, or even fire, as a last resource, and he advises trepanning, in cases of violent headache. But he wishes the more difficult operations of surgery to be performed only by particular persons, who might thereby acquire more expertness.

HIPPOCRATIC. Relating to Hippocrates. See

Facies hippocratica.

HIPPOLA PATHUM. (From lππος, a horse, and λαπα-θον, the lapathum.) Λ species of lapathum; so named from its size. See Rumex patientia. HIPPOMA'RATHRUM. (From lππος, a horse, and μαραθρον, fennel: so named from its size.) See Peuce-

danum silaus.

HIPPOSELI'NUM. (From iππος, a horse, and σελινον, purslane; so named because it resembles a large kind of pursiane.) See Smyrnaum olasafrum.
HIPPU'RIS. (From ππος, a horse, and ονρα, a tail.)

1. Some herbs are thus named because they resemble

a horse's tail.

2, The name of a genus of plants in the Linnman system. Class, Monanaria; Order, Monagynia. Mare's tail

HIPPURUS VULGARIS. The systematic name of the horse's or mare's tail. Equisction; Cauda equina. It possesses astringent qualities, and is frequently used by the common people as tea in diarrheas and harmorrhages. The same virtues are also attributed to the Equisetum arvense, fluviatile, limosum, and other species, which are directed indiscriminately by the

term Equisctum. HIPPUS. (From $\{\pi\pi\sigma\varsigma$, a horse; because the eyes of those who labour under this affliction are continually twinkling and trembling, as is usual with those who ride on horseback.) A repeated dilatation and alternate constriction of the pupil, arising from spasm, or

convulsion of the iris.

Hir. (From χειο, the hand.) The palm of the

(From hir, the palm of the hand; because HIRA.

it is usually found empty.) The intestinum jejunum. HIRCUS. Tragus. The goat.
HIRCUS BEZOARTICUS. (Quasi kirtus; from his shaggy hair.) The goat which affords the oriental

bezoar.

H'raguus. (From ερκος, a hedge; because it is hedged in by the eyelash.) The angle of the eye.

HIRSUTIES. A trivial name in Good's Nosology for a species of disease in which hair grows in extraneous parts, or superfluously in parts where it naturally grows. Trichosis hirsuties.

HIRSUTUS. Hairy: applied to leaves, petals, seeds, &c. of plants; as the petals of the Menyanthes trifoliata and Asclepias crispa: the seeds of the Scandiz trichosnerma.

diz trickosperma.

HI'RTUS. (A contraction of hirsutus.) Hairy: applied to stems of plants, as that of the Cirastium al-

HIRU'DO. (Quasi haurudo; from haurio, to draw out: so named from its greediness to suck blood.) See Leech.

HIRUDO MEDICINALIS. See Leech. HIRUNDINA'RIA. (From hirundo, the swallow: so called from the resemblance of its pods to a swallow.) Swallowwort, or asclepias. See Lysimachia numularia and Asclepias vincetoxicum.

Hiru'ndo. (Ab hærendo; from its sticking its nest to the eaves of houses.)

The swallow.

The cavity in the bend of the arm.

HISPI'DULA. (From hispidus, rough: so named from the rough, woolly surface of its stalks.) See

HISPIDUS. Bristly; applied to stems, seeds, &c. of plants. The Borago officinalis is a good example of the Caulus hispidus: the seeds of the Daucus carota,

and Galium boreals.
HOARHOUND. See Marrubium.
HODGES, NATHANIEL, son of the Dean of Hereford,
was born at Kensington, and graduated at Oxford in
1659. He then settled in London, and continued there during the plague, when most other physicians deserted their post. He was twice taken ill, but by timely reme-dies recovered. He afterward published an authentic account of the disease, which appears to have de-

stroyed 68,596 persons in the year 1665. It is to be regretted, that a person who had performed such an important and dangerous service to his fellow-citizens,

HOFFMANN, FREDERIC, was born at Halle, in Saxony, 1660. Having lost his parents from an epidemic disease, he went to study medicine at Jena, where he graduated in 1681. The year following he published an excellent tract, "De Cinnabari Antimonic "which sained him." monii," which gained him great applause, and nume-rous pupils to attend a course of chemical lectures, rous pupils to attend a course of chemical lectures, which he delivered there. He then practised his profession for two years at Minden with very good success; and after travelling to Holland and England, where he received many marks of distinction, he was appointed, on his return in 1685, physician to the garrison, and subsequently to Frederic William, Elector of Brandenburgh, and the whole principality of Minden. He was, however, induced to settle, in 1688, as public physician at Halberstadt; where he published a treatise, "De Insufficiencia Acidi et Viscidi." A university being founded at Halle, by Frederic III, afterward first King of Prussia, Hoffman was appointed, in 1693, primary Professor of Medicine, and composed the Statutes of that institution, and recommended Stahl as his colleague. He was most active mended Stahl as his colleague. He was most active in his professional duties; and by the eloquence and learning displayed in his lectures and publications, he extended his own reputation, and that of the new university. He was admitted into the scientific societies at Berlin, Petersburgh, and London; and had the honour of attending many of the German courts as physician. Haller asserts that he acquired great wealth by the sale of various chemical nostrums. examined many of the mineral waters in Germany, particularly those of Seidlitz, which he first introduced to public notice in 1717. The year after he commenced the publication of his "Medicina Rationalia Systematica," which was received with great applause by the faculty in various parts of Europe, and is said to have occupied him nearly twenty years. He also to have occupied him nearly twenty years. He also published two volumes of "Consultations," and three books of select chemical observations. In 1727, he was created Count Palatine, by the Prince of Swart-zenburgh, whom he carried through a dangerous disease. About seven years after, he attended Frederic William, King of Prussia, and is said by dignified remonstrance to have secured himself against the brutal ruedness shown by that monarch to those about him; he was ultimately distinguished with great honours, and invited strongly to settle at Berlin, but declined it on account of his advanced age. He con-tinued to perform his duties at Halle till 1742, in which year he died. Hoffman was a very voluminous writer. His works have been collected in six folio volumes, printed at Geneva. They contain a great mass of valuable practical matter, partly original, but detailed in a prolix manner, and intermixed with much hypothesis. He has the merit, however, of first turning the thesis. He has the merit, however, of first turning the attention of practitioners to the morbid affections of the nervous system, instead of framing mere mechanical or chemical theories: but he did not earry the doctrine to its fullest extent, and retained some of the errors of the humoral pathology. He pursued the study of chemistry and pharmacy with considerable ardour; but his practice was cautious, particularly in advanced age, trusting much to vegetable simples.

[HOFFMAN'S ANODYNE LIQUOR. Formerly so called; now known by the name of compound spirit of Sulprow known by the name of compound spirit of Sulprow known by the name of compound spirit of Sulprow known by the name of compound spirit of Sulprow known by the name of compound spirit of Sulprow has the support of th

Hog's fennel. See Peucedanum.

[Hog-tooth spar. A variety of calcareous spar. A.]

Ho'LCIMOS. (From ελκω, to draw.) It sometimes means a tumour of the liver.

HO'LCUS. 1. The name of a genus of plants in the Linnaan system. Class, Polygamia; Order, Mo-

nacia.

2. The Indian millet-seed, which is said to be nutri tive.

Holeus sorgum. Guinea corn.

HOLERACEUS. See Oleraceous.
[HOLYOKE, Dr. EDWARD. This beloved and venerated man was born at Marblehead, Mass. in 1728. The house in which he was born is still standing. He was graduated at Harvard University in 1746, and settled in this place in 1749, where he has ever since, for a period of 80 years, resided, useful, beloved,

and honoured. He was married, the first time in 1755, and a second time in 1759. He had by the second marriage 12 children, of whom only two survive. His only child by his first wife died in infancy He has lived in his mansion-house, in Essex-street, for the last 66 years, and at one period of his practice, he has stated that there was not a dwelling-house in Salem which he had not visited professionally. For a long period he nearly engrossed the medical practice of the period he hearly engrossed the medical practice of the place, and is known to have made a hundred professional visits in a day. This was in May or June of 1783, at which time the measles prevailed epidemically. He passed his long life in almost uninterrupted health, without any of those accidents and dangers which his skill was exerted to remedy and remove in others, and his old age has been almost without judice. others, and his old age has been almost without infirmity, and literally without decreptude. Who that saw him does not recollect his firm and elastic step and his cheerful looks on the day of his hundredth anniversary? To much exercise and great temperance be was disposed to attribute his health and advanced age. And when to these causes we add those of pious opinions, virtuous practices, and a calm, cheerful, and contented spirit, we shall have disclosed much of the secret of his corporeal advantages. Of his temperance we are induced to make one remark, that it was not a system of rules in diet and regimen, but a temperance of motor than the corporate of the corp derate desires. He enjoyed all the bounties of Provi-dence with remarkable appetency, but his well-regu-lated mind always saved him from excessive indulgence. Of his exercise some idea may be formed by a computation which he made a short time before his decease, that he had walked in the course of his practice, a distance which would reach three times round theglobe. He died in 1829. A.]

Hollow leaf. See Concavus. HOLLY. See Ilex. Holly, knee. See Ruscus. Holly, sea. See Eryngium.

Holmi'scus. (Dim. of ολμος, a mortar.)

A small mortar.
 The cavity of the large teeth, because they pound

the food as in a mortar.

HOLMITE. A new mineral composed of lime, carbonic acid, alumina, silica, oxide of iron, and

HOLOPHLY CTIDES. (From ολος, whole, and φλυκζις, a pustule.) Little pimples all over the body.

HOLO STES. See Holosteus.

Holo'sTEUM. See Holosteus. Holo'sTEUS. (From olos, whole, and ogcov, a bone.) Glue-bone. See Osteocolla.

HOLOTO'NICUS. (From ολος, whole, and τεινω, to stretch.) A term formerly applied to diseases accom-

panied with universal convulsion, or rigour.

HOLY THISTLE. See Centaurea benedicta.

HOLYWELL. There is a mineral water at this place arranged under the class of simple cold waters, remarkable for its purity. It possesses similar virtues to that of Malvern. See Malvern water.

Ho'MA. An anasarcous swelling.

Homberg's phosphorus. Ignited muriate of lime.

Homberg's salt. See Boracic acid.

HOMOGENEOUS. (Homogeneus; from opos, like, and yeros, a kind.) Uniform, of a like kind or species, of the same quality. A term used in contradistinction to be the same when the parts of the body are of to heterogeneous, when the parts of the body are of different qualities.

HOMOPLA'TA. (From whos, the shoulder, and

πλα/α, the blade.) See Scapula.

HONEY. See Mel.

HONEY-STONE. Mellite. Crystalhartz of Mohs. HONEY-STONE. Mellite. Crystalhartz of Mohs. Pyramidal honey-stone of Jameson. This is of a honey colour, distinctly crystallized, and occurs on bituminous wood and earth coal, and is usually accompanied with sulphur at Artern, in Thuringta.

HONEY-SUCKLE. See Lonicera periclymenum. Hooded leaf. Cucullatus.

HOOPING-COUGH. See Pertussis.

HOP. See Humulus lupulus.

HOPLOCHRI'SMA. (From oπλον, a weapon, and χοισμα, a salve.) A salve which was ridiculously said to cure wounds by consent; that is, by anointing the instrument with which the wound was made.

HORDE'OLUM. (Diminutive of hordeum, barley.)

HORDE'OLUM. (Diminutive of hordeum, barley.) A little tumour on the eyelids, resembling a barley-corn. A stye. Scarpa remarks, the stye is strictly 426

only a little bile, which projects from the edge of the eyelids, mostly near the great angle of the eye. This little tumour, like the furunculus, is of a dark red colour, much inflamed, and a great deal more painful than might be expected, considering its small size. The latter circumstance is partly owing to the vehemence of the inflammation producing the stye, and partly to the exquisite sensibility and tension of the skin, which covers the edge of the eyelids. On this account, the hordcolum very often excites fever and restlessness in delicate, uritable constitutions; it suppurates slowly and imperfectly; and, when suppurated, has no tendency to burst.

The stye, like other furunculous inflammations, forms an exception to the general rule, that the best mode in which inflammatory swellings can end, is resolution; for whenever a furunculous inflammation extends so deeply as to destroy any of the cellular substance, the little tumour can never be resolved, or only imperfectly This event, indeed, would rather be hurtful, since there would still remain behind a greater or smaller portion of dead cellular membrane; which, sooner or later, might bring on a renewal of the stye in the same place as before, or else become converted into a hard indolent body, deforming the edge of the cyclid.

HORDEUM. (Ab horrore arista; from the unpleasantness of its beard to the touch.) 1. The name of a senus of plants in the Linnaan system. Class

of a genus of plants in the Linnaan system. Class, Triandria; Order, Digynia. Barley.

2. The pharmacopeial name of the common barley

See Hordeum vulgare.

See Hordeum vulgare.
HORDEUM CAUSTICUM. See Cevadilla.
HORDEUM DISTICUON. This plant affords the barley in common use. See Hordeum vulgare.
HORDEUM PERLATUM. See Hordeum vulgare.
HORDEUM VULGARE. The systematic name of the common barley. The seed called barley, is obtained from several species of hordeum, but principally from the vulgare, or common of Scotch barley, and the distichon, or hordeum gallicum vel mundatum, or French barley, of Linnæus. It is extremely nutritious and mucilarinous, and in common use as a drink. and mucilaginous, and in common use as a drink, when boiled, in all inflammatory diseases and affections of the chest, especially where there is cough or irritation about the fauces. A decoction of barley with gum, is considered a useful diluent and demulcent in dysury and strangury; the gum mixing with the urine, sheaths the urinary canal from the acrimony of the urine. Among the ancients, decoctions of barley, κριθη, were the principal medicine, as well as aliment, in acute diseases. Barley is freed from its shells in mills, and in this state called Scotch and French barley. In Holland, they rub barley into small round grains, somewhat like pearls, which is therefore called pearls barley, or hordeum perlatum.

HORIZONTALIS. Horizontal: applied to leaves,

roots, &c. which spread in the greatest possible degree; as the leaves of Gentiana campestris, and roots of the

Loserpitium prutenicum.

HO'RMINUM. (From oppaw, to incite: named from its supposed qualities of provoking venery.) See

HORN. An animal substance chiefly membraneous, composed of coagulated albumen, with a fittle gelatin, and about a half per cent. of phosphate of lime. The horns of the buck and hart are of a different nature, being intermediate between bone and horn. See Cornu.

See Cornu.

Horn silver. A chloride of silver.
HORNBLENDE. A sub-species of straight-edged augite. There are three varieties of it:
1. Common hornblende, which is of a greenish black colour: is an essential ingredient of the mountain rocks, syenite and green-stone, and occurs frequently in granite, gneiss, &c. It is found abundantly in the British isles, and on the Continent.
2. Hornblende slate, of a colour intermediate between green and black. It occurs in beds of gneiss in many parts of Scotland, England, and the Continent.

3. Basaltic hornblende, of a velvet black colour. It is found imbedded in basalt, along with olivine and augite, at Arthur's Seat, near Edinburgh, and in basaltic rocks of England, Ireland, and the Continent.

HORNSTONE. Professor Jameson's ninth sub-

cies of rhomboidal quartz

HORRIPILA'TIO. Horripilation. (From horror,

and pilus, a hair.) A shuddering or a sense of creeping in different parts of the body. A symptom of the approach of fever.

Horse-chesnut. See Æsculus hippocastanum.

Horse-radish. See Cochlearia armoracia.
HORSE-TAIL. See Hippurus vulgaris.
HORSTIUS, Gregory, was born at Torgau, in
1578. After studying in different parts of Germany
and Switzerland, he graduated at Basil in 1606, and was soon after appointed to a medical professorship at Wittenburg. But two years after he received a similar appointment at Giessen, and was made chief physician of Hesse; where he attained considerable reputation in his profession. In 1722 he went to Ulm, on an invitation from the magistracy as public physician and president of the college; where his learning, skill, and humanity, procured him general esteem. He died in 1636. His works were collected by his sons in three folio volumes.

HO'RTUS. (From orior, to rise, as being the place where vegetables grow up.) 1. A garden.

2. The genitals of a woman, which is the repository of the human semen.

HORTUS SICCUS. A collection of dried plants

HOUNDS-TONGUE. See Cynoglossum.
HOUNE-LEEK. See Sempervivum tectorum.
HUBER, John James, was born at Basle in 1707,
and graduated there at the age of 26, after studying under the celebrated Haller and other able teachers. Two years after he was appointed physician to the Court of Baden Dourlach. He materially assisted Haller in his work on the Botany of Switzerland, and was consequently invited by him in 1738 to be dissector at Gottingen.

He speedily rose to considerable reputation there, and received different public appointments. He had likewise the honour of being elected into the most celebrated of the learned societies in Europe. He died in 1778. The chief objects of his research were the spinal marrow, and the nerves originating from it: he also inquired into the supposed influence of the imagination of the mother on the fœtus, and into the cause

of miscarriages.
[HULL, Dr. Amos G. This gentleman is a living practitioner of physic and surgery in the city of New-York. He has paid particular attention to the cure of Reducible Hernia, and has succeeded beyond all other surgeons in the cure of this frequent complaint. Practitioners have most usually directed their patients to apply a truss. Dr. Hull, however, in attending more particularly and personally to the adaptation of trusses to different kinds of Reducible Hernia, found that they were all made upon erroneous principles. He has ac-cordingly invented a truss differing from all preceding trusses, and it has the general approbation of practitioners in this country, for its simplicity and superior utility. He has improved upon those he first made, and he now calls it his improved kinge and pivot Truss, for an account of which see article, Tauss. A.]

HULME, NATHANIEL, was born at Halifax, in York-shire, 1732, and bred to the profession of a surgeon-After serving some time in the navy, he graduated at Edinburgh in 1765. He then settled in London, and was soon after appointed physician to the General Dispensary, the first institution of that kind established in the metropolis. About the year 1775 he was elected physician to the Charter-house. In 1807 he died, in consequence of a severe bruise by a fall. He was author of several dissertations on scurvy, puerperal fever, &c. He also made a series of experiments on the light spontaneously emitted from various bodies, published in the Philosophical Transacture. tions: and he was one of the editors of the London

Practice of Physic.

HUMECTA'NTIA. (From humceto, to make moist.)

Medicines which are supposed capable of softening by making the solids of the body moist.

HUMERAL. Humeralis. Belonging to the hume-

HUMERAL ARTERY. Arteria humeralis. HUMERAL ARTERY. Arteria humeralis. Brachial artery. The axillary artery, having passed the tendon of the great pectoral muscle, changes its name to the brachial or humeral artery, which name it retains in its course down the arm to the bend, where it divides into the radial and ulnar arteries. In this course it gives off several muscular branches, three of which only deserve attention: 1. The arteria profunda supe-

rior, which goes round the back of the arm to the exrior, which goes round the back of the arm to be ex-terior muscle, and is often named the upper muscular artery. 2. Another like it, called arteria profunda in-ferior, or the lower muscular artery. 3. Ramus anas-tomoticus major, which anastomoses round the elbow with the branches of the ulnar artery.

HUMERALIS MUSCULUS. See Deltoides. HU'MERUS. (From ωμος, the shoulder.) 1. The arm, as composed of hard and soft parts, from the shoulder to the forearm,

2. The shoulder.

3. The bone of the arm, or os humeri, os brackii. A long cylindrical bone, situated between the scapula and forearm. Its upper extremity is formed somewhat laterally and internally, into a large, round, and smooth head, which is admitted into the glenoid cavity of the scapula. Around the basis of this head is observed a circular fossa, deepest anteriorly and externally, which forms what is called the neck of the bone, and from the edge of which arises the capsular ligament, which is further strengthened by a strong membraneous expansion, extending to the upper edge of the glenoid cavity, and to the coracoid process of the scapula; and likewise by the tendinous expansions of the muscles, inserted into the head of the humerus. This capsular ligament is sometimes torn in Auxation, and becomes an obstacle to the easy reduction of the bone. The articulating surface of the head is covered by a cartilage, which is thick in its middle part, and thin towards its edges; by which means it is more convex in the recent subject than in the skeleton. This upper extremity, besides the round smooth head, affords two other smaller protuberances. One of these, which is the largest of the two, is of an irregular oblong shape, and is placed at the back of the head of the bone, from and is placed at the back of the head of the bone, from which it is separated by a kind of groove, that makes a part of the neck. This tuberosity is divided, at its upper part, into three surfaces; the first of these, which is the smallest and uppermost, serves for the insertion of the supraspinatus muscle; the second or middle-most, for the insertion of the infraspinatus; and the third, which is the lowest and hindmost, for the inser-tion of the teres minor. The other smaller tuberosity is situated anteriorly, between the larger one and the head of the humerus, and serves for the insertion of the subscapularis muscle. Between these two tuberosities there is a deep groove for lodging the tendinous head of the biceps brachii; the capsular ligament of the joint affording here a prolongation, thinner than the capsule itself, which covers and accompanies this muscle to its fieshy portion, where it gradually disap-pears in the adjacent cellular membrane. Immediately below its neck, the os humeri begins to assume a cylindrical shape, so that here the body of the bone may be said to commence. At its upper part is observed a continuation of the groove for the biceps, which extends downward, about the fourth part of the length of the bone in an oblique direction. The edges of this groove are continuations of the greater and smaller tuberosities, and serve for the attachment of the pectoralis, latissimus dorsi, and teres major mus-cles. The groove itself is lined with a glistening substance like cartilage, but which seems to be nothing more than the remains of tendinous fibres. lower down, towards the external and anterior side of the middle of the bone, it is seen rising into a rough ridge for the insertion of the deltoid muscle. On each side of this ridge the bone is smooth and flat, for the lodgment of the brachialis internus muscle; and behind the middle part of the outermost side of the ridge is a channel, for the transmission of vessels into the substance of the bone. A little lower down, and near the inner side of the ridge, there is sometimes seen such another channel, which is intended for the same purpose. The os humeri, at its lower extremity, becomes gradually broader and flatter, so as to have this end nearly of a triangular shape. The bone, thus expanded, affords two surfaces, of which the anterior one is the broadest, and somewhat convex; and the posterior one narrower and smoother. The bone terminates in four large processes, the two outermost of which are called condyles, though not designed for the articulation of the bone. These condyles, which are placed at some distance from each other, on each side hind the middle part of the outermost side of the ridge placed at some distance from each other, on each side of the bone, are rough and irregular protuberances, formed for the insertion of muscles and ligaments, and differ from each other in size and shape. The external

HUN HUN

head is placed hear the external control which it has been sometimes described. The other, and larger process, is composed of two lateral protuberances and a middle cavity, all of which are smooth and covered with cartilage. From the manner in and covered with cartiage. From the manner in which the ulna moves upon this process, it has gotten the name of trecklea, or pulley. The sides of this pulley are unequal; that which is towards the little head, is the highest of the two; the other, which is contiguous to the external condyle, is more slanting, being situated obliquely from within outwards, so that when the forearm is fully extended, it does not form a straight line with the os humeri, and, for the same reason, when line with the os humeri, and, for the same reason, when we bend the elbow, the hand comes not to the shoulder, as it might be expected to do, but to the forepart of the breast. There is a tavity at the root of these processes, on each of the two surfaces of the bone. The cavity on the anterior surface is divided by a ridge into two, the external of which receives the end of the radius, and the internal one lodges the coronoid pro-cess of the ulna in the flexions of the forearm. The cavity on the posterior surface, at the basis of the pul-ley, is much larger, and lodges the olecranon when the arm is extended. The internal structure of the os humeri is similar to that of other long bones. In newcorn infants, both the ends of the bone are cartilaginous, and the large head, with the two tubercles above, and the condyles, with the two articulating processes below, become epiphyses before they are entirely united to the rest of the bone.

HI'MILIS (From the bone)

HU'MILIS. (From humi, on the ground: so named because it turns the eye downwards, and is expressive

of humility.) See Rectus inferior oculi.

HUMITE. A mineral of a reddish brown colour found near Naples, and named by Count Bournon in honour of Sir Abraham Hume, a distinguished culti-

nonour of Sir Abraham Hume, a distinguished cultivator of mineralogy.

HU'MOR. (Ab hume, from the ground; because moisture springs from the earth.) Humour, a general name for any fluid of the body except the blood.

HUMOR VITREUS. The vitreous humour of the eye, which takes its name from the resemblance to melted

glass, is less dense than the crystalline but more than the aqueous humour; it is very considerable in the human eye, and seems to be formed by the small arteries that are distributed in cells of the hyaloid membrane; it is heavier than common water, slightly albu-

Humour, aqueous. See Humor vitreus.

Humour, vitreous. See Humor vitreus.

Humours of the Eye. See Eye.

Humulin. The narcotic principle of the fruit of

the hop. See Humulus.

HU'MULUS. (From humus, the ground: so named because, without factitious support, it creeps along the ground.) The name of a genus of plants in the Linnaan system. Class, Diacia; Order, Pentandria. The hop.

HUMULUS LUPULUS. The systematic name of the hop-plant. Lupulus; Convolvulus perennis. The hop is the floral leaf or bractea of this plant: it is dried and used in various kinds of strong heer. Hops have a bitter taste, less ungrateful than most of the other strong bitters, accompanied with some degree of warmth and aromatic flavour, and are highly intoxicating. The hop-flower also exhales a considerable currently of its reasons.

condyle, when the arm is in the most natural position, is found to be placed somewhat forwarder than the other. The internal condyle is longer, and more protesses a ridge is continued upwards, at the side of the bone. In the interval between the two condyles are placed the two articulating processes, contiguous to each other, and covered with cartilage. One of these, which is the smallest, is formed into a small, obtuse, smooth head, on which the radius plays. This little head is placed near the external condyle, as a part of which it has been sometimes described. The other, and larger process, is composed of two lateral protuberances and a middle cavity, all of which are smooth it increases, and may become a severe pain: the same takes place with the sensation of weakness and general fatigue, which is felt, and which may increase, so as to render the motions difficult, or even im-

Authors distinguish in hunger, local phenomena, and

general phenomena.

This distinction is good in itself, and may be useful for study; but have not mere gratuitous suppositions been described as local or general phenomena of hunger, the existence of which was rendered probable by this theory? This point of physiology is one of those in which the want of direct experiment is the most strongly felt.—The pressure and contraction of the stomach are considered among the local phenomena of hunger: 'the sides of that viscus,' it is said, 'become thicker: it changes its form and situation, and come thicker; it changes its form and situation, and draws the duodenum a little towards it; its cavity contains saliva mixed with air, mucosities, bile, which has regurgitated in consequence of the dragging of the duodenum; the quantity of these humours increases in the stomach in proportion as hunger is of longer continuation. The cystic bile does not flow into the duodenum; it collects in the gall-bladder, and the beauty to the conit becomes abundant and black according to the continuance of abstinence. A change takes place in the order of the circulation of the digestive organs; the stomach receives less blood, perhaps on account of the flexion of these vessels, which is then greater; perhaps by the compression of the nerves, in consequence of this confinement, the influence of which upon the cir-culation will then be diminished. On the other hand, culation will then be diminished. On the other hand, the liver, the spleen, the epiploon, receive more, and perform the office of diverticula: the liver and the spleen, because they are less supported when the stomach is empty, and then present a more easy access to the blood; and the epiploon, because the vessels are then less flexious; &c. The most of these data are mere conjectures, and nearly devoid of proof. After twenty-four, forty-eight, and even sixty hours of complete abstinence, Dr. Magendie says he never saw the contraction and pressure of the stomach of which some authors speak: this organ has always presented to him very considerable dimensions, particularly in its splenic extremity; it was only after the fourth and fifth day that it appeared to icturn upon itself, to diminish much in size, and slightly in position; even these effects are not strongly marked unless fasting has been very strictly observed.

Bichát thinks that the pressure sustained by the

Bichat thinks that the pressure sustained by the empty stomach is equal to that which it supports when distended by aliments, since, says he, the sides of the abdomen are compressed in proportion as the volume of the stomach diminishes. The contrary of this may be easily proved by putting one or two fingers into the abdominal cavity, after having made an incision in its sides; it will then be easily seen that the pressure sustained by the vicera in a cavity in a ca sides; it will then be easily seen that the pressure sustained by the viscera, is, in a certain degree, in direct proportion to the distention of the stomach; if the stomach is full, the finger will be stronger pressed, and the viscera will press outward to escape through the opening; if it is empty, the pressure will be very trifling, and the viscera will have little tendency to pass out from the abdominal cavity. It must be in cating. The hop-flower also exhales a considerable quantity of its narcotic power in drying; hence those who sleep in the hop-houses are with difficulty roused from their slumber. A pillow stuffed with these flowers is said to have laid our late monarch to sleep when other remedies had failed. The young sprouts, called hop-tops, if plucked when only a foot above the ground, and boiled, are eaten, like asparagus, and are a wholesome delicacy. The active or narcotic principle of the hop, is called humulin.

HUNGER. Fames. The want of solid aliments HUN HUN

hunger, ruless in certain sickly cases bile does not enter it, though it continues to flow into the small in-

The quantity of mucus that the cavity of the stomach presents is so much greater in proportion to the prolongation of abstinence.

Relatively to the quantity of blood which goes to the stomach when empty, in proportion to the volume of its vessels, and the mode of circulation which then exists, the general opinion is that it receives less of this fluid than when it is full of aliments; but, far from being in this respect in opposition with the other abdominal organs, this disposition appears to be com-

mon to all the organs contained in the abdomen.

To the general phenomena of hunger is ascribed a weakness and diminution of the action of all the organs; the circulation and the respiration become slow, the heat of the body lowers, the secretions diminish, the whole of the functions are exerted with more The absorption alone is said to become more active, but nothing is strictly demonstrated in this respect.

Hunger, appetite itself, which is only its first degree, ought to be distinguished from that feeling which induces us to prefer one sort of food to another, from that which causes us, during a repast, to choose one dish

rather than another, &c.

These feelings are very different from real hunger, which expresses the true wants of the economy; they which expresses the true wants of the economy; they in a great measure depend on civilization, on habits, and certain ideas relative to the properties of aliments. Some of them are in unison with the season, the climate, and then they are equally legitimate as hunger itself; such is that which inclines us to a vegetable regimen in hot countries, or during the heats of

Certain circumstances render hunger more intense, and cause it to return at nearer intervals; such as a and cause it to return at nearer intervals; such as a cold and dry air, winter, spring, cold baths, dry frictions upon the skin, exercise on horseback, walking, bodily fatigue, and generally all the causes that put the action of the organs in.play, and accelerate the nutritive process with which hunger is essentially connected. Some substances, being introduced into the stomach, excite a feeling like hunger, but which ought not to be confounded with it.

There are causes which diminish the intensity of

There are causes which diminish the intensity of hunger, and which prolong the periods at which it habitually manifests itself; among this number are the inhabiting of hot countries, and humid places, rest of inhabiting of hot countries, and humid places, rest of
the body and mind, depressing passions, and indeed
all the circumstances that interrupt the action of the
organs, and diminish the activity of nutrition. There
are also substances which, being brought into the digestive canals, prevent hunger, or cause it to cease, as
opium, hot drinks, &c.

With respect to the cause of hunger, it has been, by
truns, attributed to the providence of the vital princiture, the frictions of the sides of the stomach against

ple, to the frictions of the sides of the stomach against each other, to the dragging of the liver upon the dia-phragm, to the action of bile upon the stomach, to the acrimony and acidity of the gastric juice, to fatigue of the contracted fibres of the stomach, to compression of

the nerves of this viscus, &c. &c. Hunger arises, like all other internal sensations, from the action of the nervous system; it has no other seat than this system itself, and no other causes than the general laws of organization. What very well proves the truth of this assertion is, that it sometimes conti-nues though the stomach is filled with food; that it cannot be produced though the stomach has been some time empty; lastly, that it is so subject to habit as to cease spontaneously after the habitual hour of repast is over. This is true not only of the feeling which takes place in the region of the stomach, but also of the general weakness that accompanies it, and which, consequently, cannot be considered as real, at least in the first instant in which it is manifested."

HUNTER, WILLIAM, was born in 1718, at Kilbride in Scotland. He was educated for the church at Glas-

gow; but feeling scruples against subscription, and having become acquainted with the celebrated Cullen, he determined to pursue the medical profession. After living three years with that able teacher, who then practised as a surgeon-apothecary at Hamilton, he went to Edinburgh in November, 1740; and in the following summer came to London with a recommenda-

tion to Dr. James Douglas, who engaged him to assist in his dissections, and superintend the education of his son. He was also enabled by that physician's libe-rality to attend St. George's Hospital, and other teach-ers; but death deprived him of so valuable a friend within a year. However, he remained in the family within a year. However, he remained in the family, and prosecuted his studies with great zeal. In 1743, he communicated to the Royal Society a paper on the ne communicated to the Royal Society a paper on the structure and diseases of articulating cartilages, which was much admired. He now formed the design of teaching anatomy; and, after encountering some difficulties, commenced by giving a course on the operations of surgery to a society of navy surgeons in lieu of Mr. Samuel Sharpe. At first he felt considerable solicitude in speaking in public; but gradually this wore off, and he evinced a remarkable facility in expressing himself with perspicitiv and elegance. He pressing himself with perspicuity and elegance. He gave so much satisfaction, that he was requested to extend the plan to anatomy, which he began accordingly in 1746. His success was considerable, but having somewhat embarrassed himself at first by assisting his friends, he was obliged to adopt proper caution in lending money; which, with his talents, industry, and economy, enabled him to acquire an ample fortune. In 1748, he accompanied his pupil, young Douglas, on a tour, and having seen the admirable injections of Albinus at Leyden, he was inspired with a strong emulation to excel in that branch. On his return, he emulation to excel in that branch. On his return, he relinquished the profession of surgery, and devoted himself to midwifery, to which his person and manners well adapted him; and having been appointed to the Middlesex and British lying-in hospitals, as well as favoured by other circumstances, he made a rapid advance in practice. In 1750 he obtained a doctor's degree from Glasgow, and was afterward often consulted as a physician, in cases which required peculiar anatomical skill. Six years after he was admitted as sulted as a physician, in cases which required peculiar anatomical skill. Six years after, he was admitted a licentiate of the College in London; and also a member of the society, by which the "Medical Observations and Inquiries" were published. He enriched that work with many valuable communications; particularly an account of the disease, since called Aneurismal Varix, a case of emphysema, with practical remarks, wherein he showed the fat to be deposited in distinct vesicles; and some observations on the retrodistinct vesicles; and some observations on the retro-version of the uterus: and, on the death of Dr. Fothergill, he was chosen president of that society. In 1762 he published his "Medical Commentaries," in which he laid claim, with much asperity, to several anatomical discoveries, especially relative to the absorbent system, in opposition to the second Monro, of Edinburgh. He was extremely tenacious of his rights in this respect, and would not allow them to be infringed, even by his own brother. It must be very difficult, and of little importance, to decide such controversies; especially as the principal points concerning the absorbent system had been stated as early as 1726, in a work printed at Paris by M. Noguez. About the same period, the queen being pregnant, Dr. Hunter was consulted; and, two years after, he was appointed her physician extraordinary. In 1767 he was chosen a Fellow of the Royal Society, to which he communicated some papers; and, in the year following, he was appointed, by the king, Professor of Anatomy to the Royal Academy, on its first institution; he was also elected into the Society of Antiquaries, and some respectable foreign associations. In 1775 he published a splendid work, which had occupied him for 24 years previously, "The Anatomy of the Gravid Uterus," illustrated by plates, admirable for their accuracy, as well as elegance; among other improvements, the well as elegance; among other improvements, the membrana decidua reflexa, discovered by himself, was membrana decidua reflexa, discovered by himself, was here first delineated. He drew up a detailed description of the figures; which was published after his death by his nephew, Dr. Baillie. Another posthumous publication, deservedly much admired, was the "Two Introductory Lectures" to his anatomical course. As his wealth increased, he formed the noble design of establishing an anatomical school; and proposed to government, on the grant of a piece of ground, to build a proper edifice and endow a perpetual professorship: but this not being acceded to, he set about the establishment in Great Windmill-street, where he collected a most valuable museum of anatomical precollected a most valuable museum of anatomical pre-parations, subjects of natural history, scarce books, coins, &c. to which an easy access was always given. He continued to lecture and practise till near the pe-

HUNTER, John, was born ten years after his brother William. His early education was much neglected, and his temper injured, through his mother's glected, and his temper injured, through his mother's tidulgence. At a proper age he was put under a relation, a carpenter and cabinet-maker, who failed in his business. Hearing, at this period, of his brother's success, he applied to become his assistant, and accordingly came to London in the autumn of 1748. He made such proficiency in dissection, that he was capable of undertaking the demonstrations in the following season. During the suprince he attended the surgical ble of undertaking the demonstrations in the following season. During the summer he attended the surgical practice at different hospitals; and, in 1756, he was appointed house-surgeon at St. George's. He had been admitted by his brother to a partnership in the lectures the year before. After labouring about ten years with unexampled ardour in the study of human anatomy, he turned his attention to that of other animals, with a view to elucidate physiology. His health was so much impaired by these pursuits, that, in 1760, he went abroad as surgeon on the staff, and thus acquired a knowledge of gun-shot wounds. On his required a knowledge of gun-shot wounds. On his re-turn, after three years, he settled in London as a sur-geon, and gave instructions in dissection and the per-formance of operations; and he continued, with great zeal, his researches into comparative anatomy and zeal, his researches into comparative anatomy and natural history. Several papers were communicated by him to the Royal Society, of which he was elected a member in 1767. About this time, by his brother's interest, he was appointed one of the surgeons at St. George's Hospital; and his professional reputation was rapidly increasing. In 1771 he published the first part of his work on the teeth, displaying great accuracy of research: and, two years after, he began a course of lectures on the principles of surgery. He fell short of his brother in methodical arrangement, and facility of his brother in methodical arrangement, and facility of expressing his ideas, and indeed adopted a peculiar language, perhaps in part from the deficiency of his education; but he certainly brought forward many ingenious speculations in physiology and pathology, and suggested some important practical improvements, particularly the operation for popliteal aneurism. In 1776 he was appointed surgeon-extraordinary to the king; and soon after received marks of distinction from several foreign societies. His emoluments in-creasing, he took a large house in Leicester-square, and built a spacious museum, which he continued to store with subjects in comparative anatomy, at a very great expense. The post of Deputy-Surgeon General to the Army was conferred upon him in 1786; and, in the same year, his great work on the venereal disease appeared, which will ever remain a monument of his extraordinary sagacity and talent for observation. He also published, at this period, "Observations on the Animal Economy," chiefly composed of papers already printed in the Philosophical Transactions. In 1790 he was appointed Inspector-General of Hospitals, and Surgeon-General to the Army; when he resigned his lectures to Mr. Home, whose sister he had married. He had been for two years before labouring under symptoms of organic disease about the heart, which were aggravated by any sudden exertion or agiwhich were aggravated by any sudden exertion or agitation of his mind; these increased progressively, and, in October 1793, while at the hospital, being vexed by some untoward circumstance, he suddenly expired. He left a valuable treatise on the blood, inflammation, and gun-shot wounds, which was published soon after, with a life prefixed, by his brother-in-law. His museum was directed to be offered to the purchase of government: it was bought for 15,000l. and presented to the College of Surgeons, on condition of their opening it to public inspection, and giving a set of lectures ing it to public inspection, and giving a set of lectures annually, explanatory of its contents. The prepara-tions are arranged so as to exhibit all the gradations of nature, from the simplest state of animated existence up to man, according to the different functions. It comprehends also a large series of entire animals, skeletons of almost every genus, and other subjects of na-

HURTSICKLE. (So called because it is troublesome to cut down, and sometimes notches the sickle.)

See Centaurca cyanus.

HUSK. See Gluma.

HUXHAM, John, was born about the end of the 17th century, and practised as a physician, with consider430

riod of his death, in 1783. He bequeathed the use of his museum, for thirty years, to Dr. Baillie; after which it was to belong to the University of Glasgow. servation. He kept a register of the weather and prevailing diseases for nearly thirty years, which was published in Latin, in three volumes. He was early elected into the Royal Society, and communicated several papers on pathology and morbid anatomy. But his fame rests chiefly upon his "Essay on Fevers," which went through several editions; a dissertation being afterward added on the malignant sore throat.

HVACINTH I A sub-species of pyramidal zircon.

HYACINTH. I. A sub-species of pyramidal zircon. It comes from Ceylon, and is much esteemed as a gem.

See Hyacinthus.

2. See Hyacinthus.

HYACINTHUS. (Said by the poets to be named from the friend of Apollo, who was turned into this flower.) The name of a genus of plants. Class, Hexandria; Order, Monogynia.

Hyacinthus muscari. Muscari. The systematic name of the musk-grape flower, which, according to Ray, possesses emetic and diuretic qualities.

Hyacinthus non scriptus. Hare-bells. The systematic name of the blue-bells, so common in our hedges in spring. The roots are bulbous; the flowers agreeably scented. Galen considered the root as a remedy in jaundice. It is ranked among the astringents, but of very inferior power.

HYALITE. A transparent siliceous stone, which is often cut into ring-stones, found near Frankfort on the Maine.

HYALO'IDES. (Membrana hyaloides; from baλos, glass, and ειδος, likeness.) Membrana arachnoidea. Capsule of the vitreous humour. The transparent membrane enclosing the vitreous humour of the eye.

HYBERNACULUM. This is defined by Linnæus to be a part of the plant which protects the embryo herb from external injuries.

An extensic body which sprouts from the surface of

An organic body which sprouts from the surface of different parts of a plant, enclosing the rudiments of the new shoot, and which is capable of evolving a new in-

new shoot, and which is capable of evolving a new individual perfectly similar to the parent. This is a modification of the definition of Gærtner.—Thompson. Hyboma. A gibbosity of the spine.

Hybrida, from νόρις, an injury; because its nature is tainted.) A monstrous production of two different species of animals or plants. In the former it is called mongrel, or mule. Neither the animal nor the seeds of hybrid plants propagate their species.

Hydarthrol. (From νόωρ, water, and αρθρον, a joint.) Hydarthron. Hydarthros. Spina ventosa of the Arabian writers, Rhazes and Avicenna. White swelling. The white-swelling, in this country, is a peculiarly common and exceedingly terrible disease. The varieties of white-swelling are very numerous, and The varieties of white-swelling are very numerous, and might usefully receive particular appellations. Systematic writers have generally been content with a dis tinction into two kinds, viz. rheumatic and scrofnlous The last species of the disease they also distinguish into such tumours as primarily affect the bones, and then the ligaments and soft parts; and into other cases,

then the ligaments and soft parts; and into other cases, in which the ligaments and soft parts become diseased before there is any morbid affection of the bones.

These divisions, Mr. Samuel Cooper, in his Treatise on the Diseases of the Joints, proves to be not sufficiently comprehensive; and the propriety of using the term rheumatic he thinks to be very questionable.

The knee, ankle, wrist, and elbow, are the joints most subject to white-swellings. As the name of the disease implies, the skin is not at all altered in colour. In some instances, the swelling yields, in a certain degree, to pressure; but it never pits, and is almost always sufficiently firm to make an uninformed examiner believe that the bones contribute to the tumour. aminer believe that the bones contribute to the tumour. The pain is sometimes vehement from the very first in other instances, there is bardly the least pain in the beginning of the disease. In the majority of scrofulous white-swellings, let the pain be trivial or violent it is particularly situated in one part of the joint, viz cither the centre of the articulation, or the head of the tibia, supposing the knee affected. Sometimes the pain continues without interruption; sometimes there are intermissions; and in other instances the pain recurs at regular times, so as to have been called by some writers, periodical. Almost all authors describe the patient as suffering more uneasiness in the diseased part, when he is warm, and particularly when he is in this condition in bed.

At the commencement of the disease in the majority

HYD

of instances, the swelling is very inconsiderable, or there is even no visible enlargement whatever. In the little depressions, naturally situated on each side of the patella, a fulness first shows itself, and gradually

the patella, a fulness first shows itself, and gradually spreads all over the affected joint.

The patient, unable to bear the weight of his body on the disordered joint, in consequence of the great increase of pain thus created, gets into the habit of only touching the ground with his toes: and the knee being generally kept a little bent in this manner, soon loses the capacity of becoming extended again. When whiteswellings have fasted a while, the knee is almost always the capacity of becoming extended again. When whiteswellings have lasted a while, the knee is almost always
found in a permanent state of flexion. In scrofulous
cases of this kind, pain constantly precedes any appearance of swelling; but the interval between the two
symptoms differs very much in different subjects.

The morbid joint, in the course of time, acquires a
vast magnitude. Still the integuments retain their
natural colour, and remain unaffected. The enlargement of the articulation, however, always seems
greater than it really is, in consequence of the emacia-

greater than it really is, in consequence of the emaciation of the limb both above and below the disease

An appearance of blue distended veins, and a shining smoothness, are the only alterations to be noticed in the skin covering the enlarged joint. The shining smoothness seems attributable to the distention, which obliterates the natural furrows and wrinkles of the cutis. When the joint is thus swollen, the integuments cannot be pinched up into a fold, as they could in the state of health, and even in the beginning of the disease.

As the distemper of the articulation advances, collections of matter form about the part, and at length The ulcerated openings sometimes heal up; but such abscesses are generally followed by other collections, which pursue the same course. In some cases, these abscesses form a few months after the first affection of the joint; on other occasions, several years elapse, and no suppuration of this kind makes its ap-

pearance.

Such terrible local mischief must necessarily produce constitutional disturbance. The patient's health be-comes gradually impaired; he loses both his appetite and natural rest and sleep; his pulse is small and frequent; and obstinate debilitating diarrhoa and profuse nocturnal sweats ensue. Such complaints are sooner or later followed by dissolution, unless the constitution be relieved in time, either by the amendment or remo-val of the diseased part. In different patients, how-ever, the course of the disease, and its effects upon the system, vary very much in relation to the rapidity with which they occur.

Rheumatic white-swellings are very distinct diseases from the scrofulous distemper of large joints. In the first, the pain is said never to occur without being attended with swelling. Scrofulous white-swellings, on the other hand, are always preceded by a pain, which is particularly confined to one point of the articulation.

In rheumatic cases, the pain is more general, and diffused over the whole joint.

With respect to the particular causes of all such white-swellings as come within the class of rheumatic ones, little is known. External irritation, either by exposure to damp or cold, or by the application of violence, is often concerned in bringing on the disease; but very frequently no cause of this kind can be assigned for the complaint. As for scrofulous white-swellings, there can be no doubt that they are under the influence of a particular kind of constitution, termed a scrofulous or strumous habit. In this sort of temperament, every cause capable of exciting inflammation, or any morbid and irritable state of a large joint, may bring such disorder as may end in the severe disease of which we are now speaking.

In a man of a sound constitution, an irritation of the kind alluded to might only induce common healthy

inflammation of the affected joint.

In scrofulous habits, it also seems probable that the irritation of a joint is much more easily produced than in the other constitutions; and no one can doubt that, when once excited in scrofulous habits, it is much more dangerous and difficult of removal than in other

HYDATID. (Hydatis; from νδωρ, water. 1. A very singular animal, formed like a bladder, and distended with an aqueous fluid. These animals are sometimes formed in the natural cavities of the body,

frequently in the liver, kidney, and lungs, where they produce diseased actions of those viscera. Cullen arranges these affections in the class *Locales*, and order *Tumores*. If the vires natura medicatrices are not sufficient to effect the context of the cont not sufficient to effect a cure, the patient mostly falls a sacrifice to their ravages. Dr. Baillie gives the following interesting account of the hydatids, as they are sometimes found in the liver:—'There is no gland in the human body in which hydatids are so frequently found as the liver, except the kidneys, where they are still more common. Hydatids of the liver are usually found in a cyst, which is frequently of considerable size, and is formed of very firm materials, so as to give to the touch almost the feeling of cartilage. This cyst, when cut into, is obviously laminated, and is much thicker in one liver than another. In some liver than thicker in one liver than another. In some livers it is not thicker than a shilling, and in others it is near a quarter of an inch in thickness. The laminæ which compose it are formed of a white matter, and on the compose it are formed of a white matter, and on the inside there is a lining of a pulpy substance, like the coagulable lymph. The cavity of the cyst, I have seen, in one instance, subdivided by a partition of this pulpy substance. In a cyst may be found one hydatid, or a greater number of them. They lie loose in the cavity, swimming in a fluid; or some of them are attached to the side of the cyst. They consist of a round hag, which is composed of a white, semi-opaque, pulpy matter, and contain a fluid capable of coagulation. Although the common colour of hydatids be white yet I have occasionally seen some of a light white, yet I have occasionally seen some of a light amber colour. The bag of the hydatid consists of two lamina, and possesses a good deal of contractile power laminæ, and possesses a good deal of contractile power In one hydatid this coat, or bag, is much thicker and more opaque than in another; and even in the same hydatid, different parts of it will often differ in thick ness. On the inside of a hydatid, smaller ones are sometimes found, which are commonly not larger than the heads of pins, but sometimes they are even larger in their size than a gooseberry. These are attached to the larger hydatid, either at scattered irregular distances, or so as to form small clusters; and they are also found finating loose in the liquor of the larger also found floating loose in the liquor of the larger hydatids. Hydatids of the liver are often found unconnected with each other; but sometimes they have been said to enclose each other in a series, like pill-boxes. The most common situation of hydatids of the liver is in its substance, and enclosed in a cyst; but they are occasionally attached to the outer surface of the liver, hanging from it, and occupying more or less of the general cavity of the abdomen. The origin and real nature of these hydatids are not fully ascertained; it is extremely probable, however, that they are a sort of imperfect animalcules. There is no doubt at all, that the hydatids in the livers of sheep are aniat all, that the hydatids in the livers of sheep are animalcules; they have been often seen to move when taken out of the liver and put into warm water; and they retain this power of motion for a good many hours after a sheep has been killed. The analogy is great between hydatids in the liver of a sheep and those of the human subject. In both, they are contained in strong cysts, and in both they consist of the same white pulpy matter. There is undoubtedly some difference between them in simplicity of organization; the hydatid in the human liver being a simple uniform the hydatid in the human liver being a simple uniform bag, and the hydatid in that of a sheep having a neck need be no considerable objection to the opinion above stated. Life may be conceived to be attached to the most simple form of organization. In proof of this, hydatids have been found in the brains of sheep, re sembling almost exactly those in the human liver, and which have been seen to move and therefore are certainly known to be animalcules. The hydatids of the human liver, indeed, have not, as far as I know, been found to move when taken out of the body and put found to move when taken out of the body and put into warm water; were this to have happened, no uncertainty would remain. It is not difficult to see a good reason why there will hardly occur any proper opportunity of making this experiment. Hydatids are not very often found in the liver, because it is not a very frequent disease there; and the body is allowed to remain for so long a time after death before it is examined, that the hydatids must have lost their living principle, even if they were animalcules, and it are principle, even if they were animalcules, and it appears even more difficult to account for their producsometimes formed in the natural cavities of the body, as the abdomen and ventricles of the brain, but more than for that of intestinal words. We do not get rid

HYD

of the difficulty by asserting, that the hydatids in the human liver are not living animals, because in sheep they are certainly such, where the difficulty of accounting for their production is precisely the same."

2. The name of a tumour, the contents of which is a tenter like fluid.

2. The name of a tumour, the contents of which is a water-like fluid.

HYDERUS. (From νδιρος, ley-drops; from νδωρ, water.) An increased flow of urine.

HYDRAGOGUE. (Hydragogus; from νδωρ, water, and αγω, to drive out.) Medicines are so termed which possess the property of increasing the secretions of excretions of the body so as to cause the removal of water from any of its cavities, such as cameral of water from any of its cavities, such as camoval of water from any of its cavities, such as ca-

HYDRARGYRATUS. Of or belonging to mer-

HYDRA'RGYRUM. ('Υδραργυρος; from υδωρ, water, and αργυρος, silver: so named from its having a resemblance to fluid silver.) Hydrargyrus. The name in the London Pharmacopæia, and other works,

for mercury. See Mercury.

HYDRARGYRUM PRÆCIPITATUM ALBUM. White pre cipitated mercury. Calx hydrargyri alba. Take of oxymuriate of mercury, half a pound; muriate of ammonia, four ounces; solution of subcarbonate of potassa, half a pint; distilled water, four pints. First of mercury, in the distilled water, and add thereto the of mercury, in the distilled water, and add thereto the solution of subcarbonate of potassa. Wash the precipitated powder until it becomes tasteless; then dry it. It is only used externally, in the form of ointment,

As an application in some cutaneous affections.

Hydrargyrum purificatum. Purified mercury.

Argentum vivum purificatum. Take of mercury, by weight, six pounds; iron filings, a pound. Rub them together, and distil the mercury from an iron retort, by the application of heat to it. Purified quicksilver is sometimes administered in its metallic state, in doses of an ounce or more, in constipation of the

Hydrargyrus acetatus. Mercurius acetatus; Pilula Keyseri. By this preparation of mercury, the celebrated Keyser acquired an immense fortune in curing the venereal disease. It is an acetate of mercury, and therefore termed hydrargyri acetas in the new chemical nomenclature. The dose is from three to five grains. Notwithstanding the encomium given to it hy same, it does not annear to be so efficacious as

to five grains. Notwithstanding the encomium given to it by some, it does not appear to be so efficacious as some other preparations of inercury.

Hydrargyrum cum creta. Mercury with chalk.

Mercurius alkalizatus. Take of purified mercury, by weight, three ounces; prepared chalk, five ounces. Rub them together, until the metallic globules disappear. This preparation is milder than any other mercurial, except the subhuret, and does not so easily act pear. This preparation is milder than any other mercurial, except the sulphuret, and does not so easily act
upon the bowels; it is therefore used largely by many
practitioners, and possesses alterative properties in
cutaneous and venereal complaints, in obstructions of
the viscera, or of the prostate gland, given in the dose
of 988 to 388, two or three times a day.

Hydrargyrus prosphoratus. This remedy has
been observed to heal inveterate venereal ulcers in a
seem short time, may in the course of a very few days.

been observed to heal inveterate venereal ulcers in a very short time, nay, in the course of a very few days, particularly those about the pudenda. In venereal inflammations of the eyes, chancres, rheumatisms, and chronic eruptions, it has proved of eminent service. Upon the whole, if used with necessary precaution, and in the hands of a judicious practitioner, it is a medicine mild and gentle in its operation. The cases in which it deserves the preference over other mercurial preparations, are these: in an inveterate stage of syphilis, particularly in persons of torpid insensible fibres; in cases of exostosis, as well as obstructions in the lymphatic system; in chronic complaints of the skin. The following is the formula. R. Hydrargyri phosphorati, gr. iv. Corticis cinnannomi' in pulverem triti, gr. xiv. Sacchari purif. 3 ss. Misce. The whole to be divided into eight equal parts, one of which is to be taken every morning and evening, unless salivation be taken every morning and evening, unless salivation takes place, when it ought to be discontinued. Some patients, however, will bear from one to two grains of the phosphate of quicksilver, without inconvenience.

HYDRARGYRUS PRECIPITATUS CINEREUS. This preparation is an oxide of mercury, and nearly the same with the hydrargyri oxydum cincreum of the London pharmacopæia. It is used as an alterative in cases of pains arising from an admixture of rheumatism with

syphilis. It may be substituted for the hydrargyrus sniphuratus ruber, in fumigating ozena, and venoreal ulcerated sore throat, on account of its not yielding

any vapour offensive to the patient.

HYDRARGYRUS VITRIOLATUS. Turpethum minerale; Mercurius emcticus flavus; Sulphas hydrargyri. Formerly this medicine was in more general use than in the present day. It is a very powerful and active alterative when given in small doses. Two grains act on the stomach so as to produce violent vomitings. It is recommended as an errhine in cases of amaurosis. In combination with antimony it acts powerfully on

the skin.

Hydrargyri; Hydrargyrus nitratus ruber; Mercurius corrosious ruber; Mercurius pracipitatus corrosious. Nitric oxide of mercury. Red precipitate. Take of purified mercury, by weight, three pounds of nitric acid, by weight, a pound and a half: of distilled water two pints. Mix in a glass vessel, and boil the mixture in a sand-bath, until the mercury be dissolved, the water also evaporated, and a white mass remain. Rub this into powder, and put it into another shallow vessel, then apply a moderate heat, and raise the fire gradually, until red vapour shall cease to rise. This preparation is very extensively employed by surgeons as a stimulant and escharotic, but its extraordinary activity does not allow of its being given internally. Finely levigated and mixed with common cerates, it is an excellent application to indolent ulcers, especially those which remain after burns and cers, especially those which remain after burns and scalds, and those in which the granulations are indo-lent and flabby. It is also an excellent caustic application to chancres.

cation to chancres.

Hydrargyri oxydum cinereum. Oxydum hydrargyri nigrum. The gray or black oxide of mercury. It has received several names; Æthiops per se; Pulvis mercurialis cinereus; Mercurius cinereus; Turpethum nigrum; Mercurius præcipitalus niger. Take of submuriate of mercury, an ounce; limewater, a gallon. Boil the submuriate of mercury in the limewater, constantly stirring, until a gray oxide of mercury is separated. Wash this with distilled water, and then dry it. The dose from gr. ii. to x. There are four other preparations of this oxide in high estimation:

One made by rubbing mercury with mucilage of gum-arabic. Plenk, of Vienna, has written a treatise on the superior efficacy of this medicine. It is very troublesome to make; and does not appear to posses more virtues than some other mercurial preparations. more virtues than some other mercurial preparations. Another made by triturating equal parts of sugar and mercury together. The third, composed of honey or liquorice and purified mercury. The fourth is the blue mercurial ointment. All these preparations possess anthelmintic, antisyphilitic, alterative, sialagogue, and deobstruent virtues, and are exhibited in the cure of worms, syphilis, amenorrhora, diseases of the skin, chronic diseases, obstructions of the viscera, &c.

Hydrargyri

oxydum cinereum.

oxydum cincreum.

Hydrargyrii oxydum rubrum. Oxydum hydrargyri rubrum; Hydrargyris calcinatus. Red oxide of mercury. Take of purified mercury by weight a pound. Pour the mercury into a glass matrass, with a very narrow mouth and broad bottom. Apply a heat of 600° to this vessel, without stopping it, until the mercury has changed into red scales: then reduce these to a very fine powder. The whole process may probably require an exposure of six weeks. This preparation of mercury is given with great advantage in the cure of syphilis. Its action, however, is such, when given alone, on the bowels, as to require the addition of opium, which totally prevents it. It is also given in conjunction with opium and camphire, as a diaphoretic, in chronic pains and diseases of long continuance. It is given as an alterative and diaphoretic from gr. ss. to ii. every night, joined with camphor and opium, each gr. one-fourth or one-balf. It is violently emetic and cathartic in the dose of gr. iv. to gr. v. HYDRARGYRI OXYDUM RUBRUM. Oxydum hydrar

HYDRARGYRI OXYMURIAS. Oxymurias hydrargyri; Hydrargyrus muriatus. Oxymuriate of mercury. Take of purified mercury by weight two pounds, sulphuric acid by weight thirty ounces, dried muriate of soda four pounds. Boil the mercury with the sulphuric acid in a glass vessel until the sulphate of mercury

shall be left dry. Rub this, when it is cold, with the muriate of soda in an earthen-ware mortar; then sublime it in a glass cucurbit, increasing the heat gradually. An extremely acrid and violently poisonous

preparation.

Given internally in small doses properly diluted, and never in the form of pill, it possesses antisyphilitic and alterative virtues. Externally, applied in form of lotion, it facilitates the healing of venereal sores, and cures the itch. In gargles for venereal ulcers in the throat the constraint of managers, it is a large whereas the oxymuriate of mercury gr. iii. or iv. barley decoc tion lbj., honey of roses 3 ij., proves very serviceable; also in cases of tetters, from gr. v. to gr. x. in water bj.; and for films and ulcerations of the cornea, gr. i.

to water 3 iv.

Mr. Pearson remarks, that " when the sublimate is given to cure the primary symptoms of syphilis, it will sometimes succeed; more especially, when it produces a considerable degree of soreness of the gums, and the common specific effects of mercury in the animal system. But it will often fail of removing even a recent chancre; and where that symptom has vanished dur-ing the administration of corrosive sublimate, I have known, says he, a three months' course of that medicine fail of securing the patient from a constitutional affection. The result of my observation is, that simple affection. The result of my observation is, that simple mercury, calomel or calcined mercury, are preparations more to be confided in for the cure of primary symptoms, than corrosive sublimate. The latter will often check the progress of secondary symptoms very conveniently, and I think it is peculiarly efficacious in relieving venereal pains, in healing ulcers of the throat, and in promoting the desquamation of eruptions. Yet even in these cases it never confers permanent benefit; for new symptoms will appear during the use of it; and on many occasions it will fail of affording the least advantage to the patient from first to last. I do, sometimes, indeed, employ this preparation in venereal least advantage to the patient from first to last. I do, sometimes, indeed, employ this preparation in venereal cases; but it is either at the beginning of a mercurial course, to bring the constitution under the influence of mercury at an early period, or during a course of inunction, with the intention of increasing the action of simple mercury. I sometimes also prescribe it after the conclusion of a course of friction, to support the mercurial influence in the habit, in order to guard against the danger of a relapse. But on no occasion whatever do I think it safe to confide in this preparation sizely and uncombined for the cure of any truly tion singly and uncombined for the cure of any truly venereal symptoms."

A solution of it is ordered in the pharmacopæia termed Liquor kydrargyri ozymuriatis. Solution of oxymuriate of mercury. Take of oxymuriate of mercury, eight grains; distilled water, fifteen fluid ounces; rectified spirit, a fluid ounce. Dissolve the oxymuriate of mercury in the water, and add the spirit.

This solution is directed in order to facilitate the administration of divisions of the grain of this active medicing. Half an owner of it contains one fourth of

medicine. Half an ounce of it contains one-fourth of a grain of the salt. The dose is from one drachm to

half an ounce.

Hydrargyri submurias, Submurias hydrargyri. Submuriate of mercury. Calometas. Calomel. Take of oxymuriate of mercury, a pound; purified mercury, by weight nine ounces. Rub them together until the metallic globules disappear, then sublime; take out the sublimed mass, and reduce it to powder, and sublime it the lime it in the same manner twice more successively. Lastly, bring it into the state of very fine powder by the same process which has been directed for the preparation of chalk. Submuriate, or mild muriate of mercury, is one of the most useful preparations of mercury. As an anti-venereal it is given in the dose of a grain pight and mercury. of a grain night and morning, its usual determination to the intestines being prevented, if necessary, by opium. It is the preparation which is perhaps most usually given in the other diseases in which mercury is employed, as in affections of the liver, or neighbour-ing organs, in cutaneous diseases, chronic rheumatism, ing organs, in cutaneous diseases, chronic rheumatism, tetanus, hydrophobia, hydrocephalus, and febrile affections, especially those of warm climates. It is employed as a cathartic alone, in doses from v. to xii. grains, or to promote the operation of other purgatives. Its anthelminuc power is justly celebrated; and it is perhaps superior to the other mercurials in assisting the operation of diuretics in dropsy. From its specific gravity it ought always to be given in the form of a bolus or pill.

Hydrargy-rus cum sulphure. Æthiop's mineral. Take of puri-fied mercury, sublimed sulphur, each a pound, by weight. Rub them together, till the metallic globules disappear. Some suppose that the mercury is oxidized in this process but that is not confirmed by the best in this process, but that is not confirmed by the best experiments. The mercury, by this admixture of the sulphur, is deprived of its salivating power, and may be administered with safety to all ages and constitutions, as an anthelmintic and alterative.

HYDRARGYRI SULPHURETUM RUBRUM. Red sul-HYDRARGYRI SULPHURETUM RUBRUM. Red sulphuret of mercury. Hydrargyrus sulphuratus ruber; Minium purum; Minium Gracorum; Magnes epilepsia; Atzemafor; Amnion; Azamar. Vitruvius calls it anthrax. A red mineral substance composed of mercury combined with sulphur. It is either native or factitious. The native is an ore of quicksilver moderately compact, and of an elegant striated red colour. It is found in the dutchy of Deuxponts, in the Palatinate, in Spain, South America, &c. It is called native vermilion, and cinnabar in flowers. The factitious is thus prepared: "Take of purified mercury, by weight forty ounces; sublimed sulphur, eight ounces. Having melted the sulphur over the fire, mix in the mercury, melted the sulphur over the fire, mix in the mercury, and as soon as the mass begins to swell, remove the vessel from the fire, and cover it with considerable vessel from the fire, and cover it with considerable force to prevent inflammation; then rub the mass into powder, and sublime." This preparation is esteemed a mild mercurial alterative, and given to children in small doses. Hoffman greatly recommends it as a sedative and antispasmodic. Others deny that cinnabar, taken internally, has any medicinal quality; and their opinion is grounded on the insolubility of it in any mentions. menstruum. In surgery its chief and almost only use is in the administration of quicksilver by fumigation. Thus employed it has proved extremely serviceable in venereal cases. Ulcers and excrescences about the venereal cases. Ulcers and excrescences about the pudendum and anus in women, are particularly benefited by it; and in these cases it is most conveniently applied by placing a red hot heater at the bottom of a night stool-pan, and after sprinkling on it a few grains of the red sulphuret of quicksilver, placing the patient on the stool. To fumigate ulcers in the throat, it is necessary to receive the fumes on the part affected, the same is the tube of a funnel. By enclosing the patient through the tube of a funnel. By enclosing the patient naked in a box, it has on some occasions been contrived to fumigate the whole body at once, and in this way the specific powers of the quicksilver have been very rapidly excited.

rapidly excited.

This mode of curing the lues venerea is spoken of as confirmed; and the subject has of late years been revived in a treatise by Sabonette, and by trials made in Bartholomew's hospital.

Mr. Pearson, from his experiments on mercurial fumigation, concludes, that where checking the progress of the disease suddenly is an object of great moment, and where the hody is covered with places or large and where the body is covered with ulcers or large and where the body is covered with ulcers or large and numerous eruptions, and in general to ulcers, fungi, and excrescences, the vapour of mercury is an application of great efficacy and utility; but that it is apt to induce a ptyalism rapidly, and great consequent debility, and that for the purpose of securing the constitution against a relapse, as great a quantity of mercury must be introduced into the system, by inunction, as if no fumigation had been employed.

HYDRATE. Hydroxure. Hydro-oxide. A compound of oxygen, in a definite proportion, with water. HYDRELÆ'UM. (From νόωρ, water, and ελαιον, oil.) A mixture of oil and water.

HYDRENTEROCE'LE. (From νόωρ, water, εν-

HYDRENTEROCE'LE. (From $v\delta\omega\rho$, water, $\varepsilon\nu$ - $\gamma_{\varepsilon\rho\sigma\nu}$, an intestine, and $\kappa\eta\lambda\eta$, a tumour.) A hydrocele, or dropsy of the scrotum, attended with a rup-

cele, or dropsy of the sciously accele, or dropsy of the sciously acid, combined in a definite proportion with an oxide.

HYDRIODIC ACID. Acidum hydriodicum. A gaseous acid in its insulated state. "If four parts of iodine be mixed with one of phosphorus, in a small glass retort, applying a gentle heat, and adding a few drops of water from time to time, a gas comes over, which must be received in the mercurial bath. Its specific gravity is 44; 100 cubic inches, therefore, weigh 134.2 grs. It is elastic and invisible, but has a smell somewhat similar to that of muriatic acid. Mercury after some time decomposes it, seizing its iodine, and leaving its hydrogen, equal to one-half the original bulk, at liberty. Chlorine, on the other hand,

unites to its hydrogen, and precipitates the iodine. From these experiments, it evidently consists of vapour of iodine and hydrogen, which combine in equal volumes, without change of their primitive bulk. Hydriodic acid is partly decomposed at a red-heat, and the decomposition is complete if it be mixed with oxygen. Water is formed, and iodine separated.

We can easily obtain an aqueous hydriodic acid very economically, by passing sulphuretted hydrogen gas through a mixture of water and iodine in a Woolfe's bottle. On heating the liquid obtained, the excess of sulphur flies off, and leaves liquid hydriodic acid. At temperatures below 262°, it parts with its water; and becomes of a density = 1.7. At 262° the acid distils over. When exposed to the air, it is speed-ily decomposed, and iodine is evolved. Concentrated sulphuric and nitric acids also decompose it. When

ily decomposed, and iodine is evolved. Concentrated sulphuric and nitric acids also decompose it. When poured into a saline solution of lead, it throws down a fine orange precipitate. With solution of peroxide of mercury, it gives a red precipitate; and with that of silver, a white precipitate insoluble in ammonia. Hydriodic acid may also be formed, by passing hydrogen over iodine at an elevated temperature.

The compounds of hydriodic acid with the salifiable bases may be easily formed, either by direct combination, or by acting on the basis in water, with iodine. The latter mode is most economical. Upon a determinate quantity of iodine, pour solution of potassa or soda, till the liquor ceases to be coloured. Evaporate to dryness, and digest the dry salt in alkohol of the specific gravity 0.810, or 0.820. As the iodate is not soluble in this liquid, while the hydriodate is very soluble, the two salts easily separate from each other. After the two salts easily separate from each other. having washed the iodate two or three times with alkohol, dissolve it in water, and neutralize it with acetic acid. Evaporate to dryness, and digest the dry salt in alkohol, to remove the acetate. After two or three washings, the iodate is pure. As for the alkohol containing the hydriodate, distill it off, and then complete the neutralization of the potassa, by means of a little hydriodic acid separately obtained. Sulphurous and muriatic acids, as well as sulphuretted hydrogen, produce no change on the hydriodates, at the usual temperature of the air. perature of the air.

Chlorine, nitric acid, and concentrated sulphuric, in-

Chlorine, nitric acid, and concentrated sulphuric, instantly decompose them, and separate the iodine.

With solution of silver, they give a white precipitate insoluble in ammonia; with the pernitrate of mercury, a greenish-yellow precipitate; with corrosive sublimate, a precipitate of a fine orange-red, very soluble in an excess of bydriodate; and with nitrate of lead, a precipitate of an orange-yellow colour. They dissolve iodine, and acquire a deep reddish-brown colour.

Hydriodate of potassa, or in the dry state, iodide of potassium, yields crystals like sea-salt, which melt and sublime at a red-heat. This salt is not changed by being heated in contact with air. 100 parts of water at 64°, dissolve 143 of it. It consists of 15.5 iodine, and 5 potassium.

Hydriodate of soda, called in the dry state iodide of sodium, may be obtained in pretty large flat rhomboidal prisms. It consists, when dry, of 15.5 iodine boidal prisms.

Hydriodate of barytes crystallizes in fine prisms, similar to muriate of strontites. In its dry state, it con-

similar to muriate of strontites. In its dry state, it consists of 15.5 iodine + 8.75 barium.

The hydriodates of lime and strontites are very soluble; and the first exceedingly deliquescent.

Hydriodate of ammonia results from the combination of equal volumes of ammoniacal and hydriodic gases; though it is usually prepared by saturating the liquid acid with ammonia. It is nearly as volatile as sal ammoniac; but it is more soluble and more deligence of the revestallizes in cubes.

quescent. It crystallizes in cubes.

Hydriodate of magnesia is formed by uniting its constituents together; it is deliquescent, and crystallizes with difficulty.—It is decomposed by a strong

Hydriodate of zinc is easily obtained, by putting iodine into water with an excess of zinc, and favouring their action by heat. When dried it becomes an

All the nydriodates nave the property of dissolving abundance of iodine; and thence they acquire a deep reddish-brown colour. They part with it on boiling, or when exposed to the air after being dried."

HYDRO-CHLORIC ACID. Muriatic acid; a com-

HYDRO-CHLORIC ACID. Muriatic acid; a compound of chlorine and hydrogen. See Muriatic acid. HYDRO-CYANIC ACID. See Prussic acid. HYDRO-FLUORIC ACID. Acidum hydrofluoricum. This is procured by distilling, in lead or silver, a mixture of one part of the purest fluor spar, in fine powder, with two of sulphuric acid. The heat required is not considerable; sulphate of lime remains in the retort, and a highly acrid and corrosive liquid passes over, which requires the assistance of ice for its condensation.

HYDRO-SULPHURIC ACID. The aqueous solution of sulphuretted hydrogen, is so called by Gay

HYDRO-SULPHUROUS ACID. When three vo-lumes of sulphuretted hydrogen gas and two of sulphurous acid gas, both dry, are mixed together over mercury, they are condensed into a solid orange-yellow body, which Dr. Thompson calls hydro-sulphurous

HYDRO'A. (From υδωρ, water.) A watery pus-

HYDROCARBONATE. See Carburetted hydro-

gen gas.

HYDROCA'RDIA. (From νδωρ, water, and καρδια, the heart.) Hydrocordis. Hydrops pericardia.

Dropsy of the heart. Dropsy of the pericardium. A
collection of fluid in the pericardium, which may be
either coagulable lymph, serum, or a puriform fluid.

It produces symptoms similar to those of hydrotherax, with violent palpitation of the heart, and mostly an

with violent palpitation of the heart, and mostly an intermittent pulse. It is incurable.

HYDROCE'LE. (From $v \delta \omega \rho$, water, and $\kappa \eta \lambda \eta$, a tumout.) The term kydrocele, used in a literal sense, means any tumour produced by water; but surgeons have always confined it to those which possess either the membranes of the scrotum, or the coats of the testicle and its vessels. The first of these, viz. that which has its seat in the membranes of the scrotum, anasarca integumentorum, is common to the whole bag, and to all the cellular substance which loosely envelopes both the testes. It is, strictly speaking, only a symptom of a disease, in which the whole habit is most frequently more or less concerned, and very selmost frequently more or less concerned, and very sel-dom affects the part only. The latter, or that which occupies the coats immediately investing the testicle and its vessels, hydrocele tunica vaginalis, is absolutely local, very seldom affects the common membrane of the scrotum, generally attacks one side only; and is frequently found in persons who are perfectly free from all other complaints.

The anasarca integumentorum retains the impression of the finger. The vaginal hydrocele has an un-

dulating feel.

The hydrocele of the tunica vaginalis testis is a morbid accumulation of the water separated on the internal surface of the tunica vaginalis, to moisten or lubri-

cate the testicle.

From its first appearance, it seldom disappears or diminishes, but generally continues to increase, sometimes rapidly, at others more slowly. In some it grows to a painful degree of distention in a few months; in others, it continues many years with little disturbance.

others, it continues many years with little disturbance. As it enlarges, it becomes more tense, and is sometimes transparent; so that if a candle is held on the opposite side, a degree of light is perceived through the whole tumour; but the only certain distinction is the fluctuation, which is not found when the disease is a hernia of the omentum, or intestines, or an inflammatory or scirrhous tumour of the testicle.

Hydrocele cystata. Encysted hydrocele of the spermatic cord, resembles the common hydrocele; but the tumour does not extend to the testicle, which may be felt below or behind it, while, in the hydrocele of the vaginal coat, when large, the testicle cannot be discovered. In this disease, also, the penis is not buried in the tumour. Sometimes the fluid is contained in two distinct cells; and this is discovered by little contractions in it. It is distinguished from the anasarcous hydrocele by a sensible fluctuation, and the want of the inelastic pitting; from hernia, by its beginning below, from its not receding in a horizontal position, and not enlarging by coughing and sneezing. and not enlarging by coughing and sneezing

HYDROCELE FUNICULI SPERMATICI, or hydrocele of the spermatic cord. Anasarcous hydrocele of the spermatic cord sometimes accompanies ascites, and, at other times, it is found to be confined to the cellular

HYD HYD

substance, in or about the spermatic cord. The causes | kind of dropsy is the same; viz. such a state of the of this disease may be obstructions in the lymphatics, | parts as makes the exhalent arteries throw out a greater leading from the part, in consequence of scirrhous affections of the abdominal viscera, or the pressure of a truss applied for the cure of hernia.

When the affection is connected with anasarca in other parts, it is then so evident as to require no par-ticular description. When it is local it is attended with a colourless tumour in the course of the spermatic cord, soft and inelastic to the touch, and unaccompanied with fluctuation. In an erect position of the body, it is of an oblong figure; but when the body is recumbent, it is flatter, and somewhat round. Generally it is no longer than the part of the cord which lies in the groin; though sometimes it extends as far as the testicle, and even stretches the scrotum to an uncommon size. By pressure a great part of the swelling can always be made to recede into the abdomen. It instantly, however, returns to its former situation, on the pressure being withdrawn.

HYDROCELE PERITONÆI. The common dropsy of

the belly

HYDROCELE SPINALIS. A watery swelling on the

HYDROCE'PHALUS. (From νόωρ, water, and κεφάλη, the head.) Hydrocephalum; Hydrencephalus. Dropsy of the head. A genus of disease arranged by Cullen in the class Cachexice, and order Intumescentias. It is distinguished by authors into external and internal:

Hydrocephalus externus, is a collection of water between the membranes of the brain.

2. Hydrocephalus internus, is when a fluid is collected in the ventricles of the brain, producing dilatation of the pupils, apoplexy, &c. See Apoplexia. It is sometimes of a chronic nature, when the water has been known to increase to an enormous quantity, effecting a diastasis of the bones of the head, and an absorption of the brain.

Pain in the head, particularly across the brow, stupor, dilatation of the pupils, nausea, vomiting, preternatural slowness of the puise, and convulsions, are the pathognomonic symptoms of this disease, which have

pathognomonic symptoms of this disease, which have been laid down by the generality of writers.

Hydrocephalus is almost peculiar to children, being rarely known to extend beyond the age of twelve or fourteen; and it seems more frequently to arise in those of a scrofulous and rickety habit than in others. It is an affection which has been observed to pervade families, affecting all or the greater part of the children at a certain period of their life; which seems to show that, in many cases, it depends more on the general habit, than on any local affection or accidental cause.

The disease has generally been supposed to arise in

The disease has generally been supposed to arise in consequence either of injuries done to the brain itself, by blows, falls, &c. from scirrhous tumours or excrescences within the skull, from original laxity or weak-ness in the brain, or from general debility and an impoverished state of the blood.

With respect to its proximate cause, very opposite opinions are still entertained by medical writers, which, in conjunction with the equivocal nature of its symptoms, prove a source of considerable embarrassment to the young practitioner. Some believe it to be inflam-

matory, and bleed largely.

Dr. Withering observes, that in a great many cases, if not in all, congestion, or slight inflammation, are the

precursors to the aqueous accumulation.

Dr. Rush thinks that, instead of its being considered an idiopathic dropsy, it should be considered only as an effect of a primary inflammation or congestion of blood in the brain. It appears, says he, that the dis-ease, in its first stage, is the effect of causes which proease, in its first stage, is the effect of causes which produce a less degree of that inflammation which constitutes phrenitis; and that its second stage is a less degree of that effusion which produces serous apoplexy in adults. The former partakes of the nature of the chronic inflammation of Dr. Cullen, and the asthenic inflammation of Dr. Brown.—There are others, again, who view the subject in a very different light. Dr. Darwin supposes inactivity, or torpor of the absorbent vessels of the brain, to be the cause of hydrocephalus internus; but he confesses, in another part of his work, that the torpor of the absorbent vessels may often exist as a secondary effect.

Dr. Whytt, who has published an ingenious treatise on the disease, observes, the immediate cause of every

on the disease, observes, the immediate cause of every | E e 2

From what he afterward mentions, he evidently con-siders this state as consisting in debility.

As many cases are accompanied with an increased or inflammatory action of the vessels of the brain, and others again are observed to prevail along with general anasarca, it seems rational to allow, that hydrocepha-lus is, in some instances, the consequence of congestion, or slight inflammation of the brain; and that, in others, it arises either from general debility or topical laxity. In admitting these as incontrovertible facts, Dr. Thomas is, at the same time, induced to suppose, that the cases of it occurring from mere debility are by no means frequent.

The great analogy subsisting between the symptoms which are characteristic of inflammation, and those which form the first stage of the acute species of hydrocephalus, (for the disease, as already observed, has cephalus, (for the disease, as already observed, has been divided into the chronic and acute by some writers,) together with the good effects often consequent on blood-letting, and the inflammatory appearance which the blood frequently exhibits, seems to point out strong proof of the disease being, in most instances, an active inflammation, and that it rarely occurs from mere debility, as a primary cause.

The progress of the disorder-has, by some, been divided into three stages.

When it is accommanied by an increased or inflam-

When it is accompanied by an increased or inflammatory action of the brain, as not uncommonly hap-pens, its first stage is marked with many of the symptoms of pyrexia, such as languor, inactivity, loss of appetite, nausea, vomiting, parched tongue, hot, dry skin, flushing of the face, headache, throbbing of the temporal arteries, and quickened pulse; which symptoms always suffer an exacerbation in the evening, but towards morning become milder.

When it is unaccompanied by any inflammatory action of the brain, many of these appearances are not to be observed. In these cases, it is marked by a dejection of countenance, loss of appetite, pains over the eyes, soreness of the integuments of the cranium to the touch, propensity to the bed, aversion to being moved, nausea, and costiveness. The disease, at length, makes a remarkable transition, which denotes the commencement of its second stage. The child screams commencement of its second stage. The child screams out, without being able to assign any cause; its sleep is much disturbed; there is a considerable dilatation of the pupils of the eyes, without any contraction on their being exposed to light; lethargic torpor, with strabismus, or perhaps double vision ensues, and the pulse becomes slow and unequal.

In the third stage, the pulse returns again to the

In the third stage, the pulse returns again to the febrile state, becoming uncommonly quick and variable; and coma, with convulsions, ensue. When the accumulation of water is very great, and the child young, the sutures recede a considerable way from each other, and the head, towards the end, becomes

much enlarged.

When recoveries have actually taken place in hydrocephalus, we ought probably to attribute more to the efforts of nature than to the interference of art. It

is always to be regarded as of difficult cure.

An accumulation of water in the ventricles of the brain, is one of the most common appearances to be observed on dissection. In different cases this is accumulated in greater or less quantities. It sometimes amounts only to a few ounces, and occasionally to some pints. When the quantity of water is considersome pints. When the quantity of water is considerable, the fornix is raised at its anterior extremity, in consequence of its accumulation, and an immediate opening of communication is thereby formed between the lateral ventricles. The water is of a purer colour and more limpid than what is found in the dropsy of the thorax, or abdomen. It appears, however, to be generally of the same nature with the water that is accumulated in these cavities. In some instances, the water in hydrocephalus contains a very small proportion of coagulable matter, and in others it is entirely free form it. free from it.

When the water is accumulated to a very large quantity in the ventricles, the substance of the brain appears to be a sort of pulpy bag, containing a fluid. The skull, upon such occasions, is very much enlarged in its size, and altered in its shape; and it appears exceedingly large in proportion to the face. On re-

moving the scalp, the bones are found to be very thin, and there are frequently broad spots of membrane in the bone. These appearances are, however, only to be observed where the disease has been of some years' continuance.

In some cases, where the quantity of water collected is not great, the substance of the brain has appeared to be indurated, and in others softened. At times, the organ has been found gorged with blood: collections also of a viscid tenacious matter have been discovered in cysts, upon its external surface, and tumours have

been found attached to its substance

The treatment must be prompt and active to give a tolerable chance of success. The general indications are, in the first stage, to lessen the inflammatory action, are, in the first stage, to lessen the inflammatory action, afterward to promote absorption. Should the patient be about the age of puberty, of a plethoric habit, and the symptoms run high at the beginning, it will be proper to take some blood, especially from the temporal artery, or the jugular vein; but, if younger, or the disease more advanced, a sufficient quantity may be withdrawn by leeches, applied to the temples, or in the direction of the sutures. The bowels must then be thoroughly evacuated by some active cathartic, as they are usually very torpid, calomel with scammony, or are usually very torpid, calomel, with scammony, or jalap, for example; and, in the progress of the com-plaint, this function must be kept up with some degree of activity. For this purpose, calomel may be given in divided doses, or some other mercurial preparation, which may not run off too rapidly, producing mere watery stools, but regularly clear out the bowels, as well as the liver, and promote the other secretions. Besides, mercury is the most powerful remedy in rousing the absorbents, and some of the most remarkable cures of this disease, even at an advanced excited. rousing the absorbents, and some of the most remarkable cures of this disease, even at an advanced period, have been affected by it: whence it would be advisable, where the disease was proceeding rapidly, and particularly if the bowels were irritable, to use mercurial frictions, that the system might be sooner affected. Another very important step, after clearing the bowels, is to apply some evaporating lotion assiduously to the scalp, previously shaved; and the antiphlogistic regimen should be steadily observed. Diaphoretics will generally be proper, assisted by the phoretics will generally be proper, assisted by the warm bath; and diuretics on some occasions may be useful; but digitalis, which has been recommended on this ground, seems more likely to avail by lessening arterial action. Blisters may be applied to the temples, behind the ears, or to the nape of the neck, each perhaps successively: and dressed with savine cerate occasionally, to increase the discharge, and irritation externally: issues appear not so likely to prove beneficial. Errhines may farther contribute to obviate internal efficiency. Electricity has been proposed to internal effusion. Electricity has been proposed to rouse the absorbents to the second stage; but its efficacy, and even propriety, is very doubtful. Should the progress of the complaint be fortunately arrested, the strength must be established by a nutritious diet, and tonic medicines; taking care to keep the bowels in good order, and the head cool: an issue, under these circumstances, may be a very useful remedy.

Circumstances, may be a very useful remedy.

Hydrocephalus acutus. See Hydrocephalus.

Hydrocephalus externus. Water between the brain and its membranes.

HYDROCEPHALUS INTERNUS, Water in the ventri-

cles of the brain.

HYDROCO TYLE. (From υδωρ, water, and κογυλη, the cotula.) 1. The name of a genus of plants in the Linnwan system. Class, Pentandria; Order,

Digunia.
2. The name, in some pharmacopæias, for the common marsh or water cotula, or pennywort, which is

said to possess acrid qualities.

Hyprocy'sris. (From υδωρ, water, and κυςις, a vesicle.) An encysted dropsy.

HYDROGEN. (Hydrogenium; from υδωρ, water, and γινομαι, to become, or γενναω, to produce, because withoxygen it produces water.) Base of inflammable air. Hydrogen is a substance not perceptible to our sensations in a separate state; but its existence is not at all the less certain. Though we cannot exhibit it experimentally uncombined, we can pursue it while it passes out of one combination into another; we cannot, indeed arrest it on its passage, but we never fail not, indeed, arrest it on its passage, but we never fail to discover it, at least if we use the proper chemical means, when it presents itself to our notice in a new compound.

Hydrogen, as its name expresses, is one of the constituent elements of water, from which it can alone be procured. Its existence was unknown till lately. It is plentifully distributed in nature, and acts a very considerable part in the process of the animal and vegetable economy. It is one of the ingredients in the varieties of bitumen, oils fat argent spring ather and in ties of bitumen, oils, fat, ardent spirits, ather, and, in fact, all the proximate, component parts of animal and vegetable bodies. It forms a constituent part of all animal and vegetable acids. It is one of the constituents of ammonia and of various other compound gases.

It possesses so great an affinity for caloric, that it can only exist separately in the state of gas; it is consequently impossible to procure it in the concrete or liquid state, independent of combination.

Solid hydrogen, therefore, united to caloric and light, forms hydrogen gas.

Properties of Hydrogen Gas.

This gas, which was commonly called inflammable air, was discovered by Cavendish in the year 1768, or rather he first obtained it in a state of purity, and ascertained its more important properties, though it had been noticed long before. The famous philosophical candle attests the antiquity of this discovery.

Hydrogen gas, like oxygen gas, is a triple compound, consisting of the ponderable base of hydrogen, caloric, and light. It possesses all the mechanical properties of atmospheric air. It is the lightest substance whose weight we are able to estimate: when in its purest that and free from periture it is about four terms. state, and free from moisture, it is about fourteen times lighter than atmospheric air. It is not fitted for respi-ration; animals, when obliged to breathe in it, die alration; animals, when obliged to breathe in it, die almost instantaneously. It is decomposed by living vegetables, and its basis becomes one of the constituents of oil, resin, &c. It is inflammable, and burns rapidly when kindled, in contact with atmospheric air or oxygen-gas, by means of the electric spark, or by an inflamed body; and burns, when pure, with a yellowish lambent flame: but all burning substances are immediately extinguished when immersed in it. It is therefore, incapable of supporting combustion. It is not injurious to growing vegetables. It is unabsorbable by most substances; water absorbs it very sparingly. ble by most substances; water absorbs it very sparingly. It is capable of dissolving carbon, sulphur, phosphorus, arsenic, and many other bodies. When its basis combines with that of oxygen gas, water is formed; with nitrogen it forms ammonia. It does not act on earthy substances.

Method of obtaining Hydrogen Gas.—A ready method of obtaining hydrogen gas consists in subjecting water to the action of a substance which is capa-

ble of decomposing this fluid.

1. For this purpose, let sulphuric acid, previously diluted with four or five times its weight of water, be poured on iron filings, or bits of zinc, in a small retort, or gas-bottle, called a pneumatic flask, or proof; as soon as the diluted acid comes in contact with the metal, a violent effervescence takes place, and hydrogen gas escapes without external heat being applied. It may be collected in the usual manner over water, taking care to let a certain portion escape on account of the atmospheric air contained in the disengaging vessels.

The production of hydrogen gas in the above way is owing to the decomposition of water. The iron, or zinc, when in contact with this fluid, in conjunction with sulphuric acid, has a greater affinity to oxygen than the hydrogen has; the oxygen, therefore, unites to it, and forms an oxide of that metal which is in-stantly attacked and dissolved by the acid; the other constituent part of the water, the hydrogen, is set free, which, by uniting with caloric, assumes the form of hydrogen gas. The oxygen is, therefore, the bond of union between the metal and the acid.

The hissing noise, or effervescence, observable during the process, is owing to the rapid motion excited in the mixture by means of the great number of air-bubbles quickly disengaged and breaking at the surface of the

We see, also, in this case, that two substances exert we see, also, in this case, that two substances exert an attraction, and are even capable of decomposing jointly a third, which neither of them is able to do singly; vir. if we present sulphuric acid alone, or iron or zinc alone, to water, they cannot detach the oxygen from the hydrogen of that fluid; but, if both are applied, a decomposition is instantly effected. This experiment, therefore, proves that the agency of chemical affinity between two or more bodies may lie dormant, until it is called into action by the interposition of another body, which frequently exerts no energy upon any of them in a separate state. Instances of this kind fire of a candle, taper, or pipe.

of them in a separate state. Instances of this kind were formerly called predisposing affinities.

2. Iron, in a red heat, has also the property of decomposing water, by dislodging the oxygen from its combination with hydrogen, in the following manner:

Let a gun-barrel, having its touch-hole screwed up, pass through a furnace, or large crucible perforated for that purpose, taking care to incline the barrel at the parawest part; adjust to its upper extremity a retort narrowest part; adjust to its upper extremity a retort charged with water, and let the other extremity termi-nate in a tube introduced under a receiver in the pneumatic trough. When the apparatus is thus disposed, and well luted, bring the gun-barrel to a red heat, and, when thoroughly red-hot, make the water in the retort boil; the vapour, when passing through the red-hot tube, will yield hydrogen gas abundantly. In this ex-periment, the oxygen of the water combines with the the caloric applied combines with the hydrogen of the water, and forms hydrogen gas. It is, therefore, the result of a double affinity, that of the oxygen of the water for the metal, and that of its hydrogen for caloric.

The more caloric is employed in the experiment of decomposing water by means of iron, &c. the sooner is

the water decomposed

Hydrogen gas, combined with carbon, is frequently found in great abundance in mines and coal-pits, where it is sometimes generated suddenly, and becomes mixed with the atmospheric air of these subterraneous cavi-ties. If a lighted candle be brought in, this mixture often explodes, and produces the most dreadful effects. It is called by miners, fire damp. It generally forms a cloud in the upper part of the mine, on account of its levity, but does not mix there with atmospheric air, unless some agitation takes place. The miners freunless some agitation takes place. The miners fre-quently set fire to it with a candle, lying at the same time flat on their faces to escape the violence of the shock. An easier and more safe method of clearing the mine, is by leading a long tube through the shaft of it, to the ash-pit of a furnace; by this means the gas will be conducted to feed the fire.

Sir Humphrey Davy has invented a valuable instrument called a safety lamp, which will enable the miners to convey a light into such impure air without risk. This is founded on the important discovery, made by him that flame is increable of the same in the same is increased. made by him, that flame is incapable of passing through minute apertures in a metallic substance, which yet are pervious to air; the reason of which appears to be, that the ignited gas, or vapour, is so much cooled by the metal in its passage as to cease being luminous.

Hydrogen gas, in whatever manner produced, always originates from water, either in consequence of a pre-ceding decomposition, by which it had been combined in the state of solid or fixed hydrogen, with one of the

substances employed, or from a decomposition of water actually taking place during the experiment.

There are instances recorded of a vapour issuing from the stomach of dead persons which took fire on the approach of a candle. We even find accounts, in several works, of the combustion of living human beings, which appeared to be spontaneous. Dr. Swediaur has related some instances of porters at Warsaw, who having drunk abundantly of spirit, fell down in the street, with the smoke issuing out of their mouths; and people came to their assistance, saying they would take fire; to prevent which, they made them drink a great quantity of milk, or used a more singular expedient, by caus-ing them to swallow the urine of the bystanders, immediately on its evacuation.

However difficult it may be to give credit to such narratives, it is equally difficult to reject them entirely, without refusing to admit the numerous testimonies of men, who were, for the most part, worthy of credit. Citizen Lair has collected all the circumstances of this Citizen Lair has collected all the circumstances of this nature which he found dispersed in different books, and has rejected those which did not appear to be supported by respectable testimony, to which he has added some others related by persons still living. These narratives are nine in number; they were communicated to the Philomathic Society, at Paris, and inserted in the bulletin Thermidor, An. 5, No. 29. The cause of this pnenomenon has been attributed to a developement of hydrogen gas taking place in the stomachs of these individuals.

Lair believes that the bodies of these people were

HYDROGEN GAS, SELENIURETTED. This gas is co-lourless. It reddens litmus. Its density has not been determined by experiment. Its smell resembles, at first, that of sulphuretted hydrogen gas; but the sensation soon changes, and another succeeds, which is at once pungent, astringent, and painful. The eyes become almost instantly red and inflamed, and the sense of amelling entirely disappears. A bubble of the size of a little pea is sufficient to produce these effects. Of all the bodies derived from the morganic kingdom, seleniuretted hydrogen is that which exercises the strongest action on the animal economy. Water dissolves this gas; but in what proportions is not known.
This solution disturbs almost all the metallic solutions, producing black or brown precipitates, which assume, on rubbing with polished hæmatites, a metallic lustre. Zinc, manganese, and cerium, form exceptions. They yield flesh-coloured precipitates, which appear to be hydro-seleniurets of the oxides, while the others, for the most part, are merely metallic seleniurets.

HYDROGEN, SULPHURETTED. Sulphuretted hydrogen gas possesses the properties of an acid; for, when absorbed by water, its solution reddens vegetable blues; it combines also with alkalies, earths, and with seve ral metallic oxides. Sulphuretted hydrogen, combined ral metallic oxides. Sulphuretted hydrogen, combined with any base, forms a hydro-sulphuret, which may be also called an hepatule, to distinguish it from an hepar, which is the union of sulphur singly with a base. Sulphuretted hydrogen gas possesses an extremely offensive odour, resembling that of putrid eggs. It kills animals, and extinguishes burning bodies. When in contact with oxygen gas, or atmospheric air, it is inflammable. Mingled with nitrous gas, it burns with a yellowish green flame. It is decomposed by ammonia, by oxymuriatic acid gas, and by sulphurous acid gas. It has a strong action on the greater number of metallic oxides. Its specific gravity is about 1.18 acid gas. It has a strong action on the greater number of metallic oxides. Its specific gravity is about 1.18 when pure. It is composed, according to Thomson, of sixteen parts of sulphur, and one of hydrogen. It has the property of dissolving a small quantity of

phosphorus. Sulphuretted hydrogen gas may be obtained in seve-

ral ways:—

1. Take dry sulphuret of potassa, put it into a tubulated retort, lodged in a sand-bath, or supported over a lamp; direct the neck of the retort under a receiver placed in the pneumatic trough; then pour gradually upon the sulphuret diluted sulphuric or muriatic acid; a violent effervescence will take place, and sulphuretted hydrogen gas will be liberated. When no more gas is produced spontaneously, urge the mixture with heat, by degrees, till it boils, and gas will again be liberated abundantly.

The water made use of for receiving it, should be heated to about 80° or 90°; at this temperature it dissolves little of the gas; whereas, if cold water be made

use of, a much greater quantity of it is absorbed.

Explanation.—Though sulphur makes no alteration. on water, which proves that sulphur has less attraction for oxygen than hydrogen has, yet if sulphur be united to an alkali, this combination decomposes water whenever it comes in contact with it, though the alkali itself has no attraction either for oxygen or hydrogen.

Itself has no attraction either for oxygen or hydrogen. The formation of this gas explains this truth. On adding the sulphuret of potassa to the water, this fluid becomes decomposed, part of the sulphur robs it of its oxygen; and forms with it sulphuric acid; this generated acid unites to part of the alkali, and forms sulphate of potassa. The liberated hydrogen dissolves another part of the sulphur, and forms with it sulphuretted hydrogen, the basis of this gas, which is retained by the separated portion of the alkali. The sulphuric or muriatic acid, added now, extricates it from the

by the separated portion of the alkali. The sulphuric or muriatic acid, added now, extricates it from the alkali, and makes it fly off in the form of gas.

Diluted muriatic acid seems best adapted for the production of sulphuretted hydrogen gas from alkaline sulphurets. If nitric acid be made use of, it must be much diluted. Sulphuric acid yields little gas, unless assisted by heat. When the proportion of sulphur the sulphuret exceeds that of the alkali, the dense sulphuric acid, poured upon it, emits sulphurous acid. sulphuric acid, poured upon it, emits sulphurous acid gas. All the rest of the acids may be made use of for decomposing the sulphurets.

2. When iron and sulphur are united together, they

afford a large quantity of sulphuretted hydrogen gas, on submitting them to the action of heat, in contact with diluted muriatic acid.

Melt together, in a crucible, equal parts of iron filings and sulphur; the product is a black brittle mass, called sulphuret of iron. Reduce this to powder, and put it, with a little water, into a tubulated retort; add diluted muriatic acid, and apply a gentle heat, till no more gas is disengaged. The philosophy of this experiment is analogous to the former. Part of the oxygen of the water unites to part of the sulphur, and forms of the water unites to part of the sulphur, and forms sulphuric acid; another part oxidizes the iron, which, dissolved by the acid, forms sulphate of iron: the hydrogen of the water unites to another part of the sulphur, and forms sulphuretted hydrogen, which becomes gaseous by the addition of caloric.

3. Sulphuretted hydrogen gas may also be obtained by heating an alkaline sulphuret, with the addition of water, without the aid of an acid. In this case, the water is also decomposed: its hydrogen unites with

water is also decomposed; its hydrogen unites with part of the sulphur, and forms sulphuretted hydrogen; the oxygen of the water unites with another part of the sulphur, and produces sulphuric acid, which joins to the alkali and forms a sulphate. The sulphuretted bydrogen becomes disengaged by heat in the gaseous

form.

4. Sulphuretted hydrogen gas may be obtained by passing hydrogen gas through sulphur, in a state of

For this purpose, put sulphur into a gun-barrel, or Wedgewood's tube, and place it across a furnace; fit to the lower extremity a bent glass tube, which goes under a receiver placed in the pneumatic trough, and adapt to the upper extremity a tubulated retort, or other apparatus proper for producing hydrogen gas. The sulphur must then be heated, and, when melted the hydrogen gas evolved must be made to pass over it, which, in this manner, will dissolve part of the sulphur, and become converted into sulphuretted bysulphur, and become converted into sulphuretted hy-

5. It may likewise be procured in the following direct manner: let a smail quantity of sulphur be en-closed in a jar full of hydrogen gas, and melt it by means of a burning-glass. This method does not suc-ceed except the hydrogen gas be as dry as possible, for its affinity to sulphur is weakened in proportion to its

moisture.

6. The method, however, which affords it purest, is by treating sulphuret of antimony with diluted muri-atic acid. The explanation is similar to the preceding

HYDROLA PATHUM. (From υδωρ, water, and

λαπαθον, the dock.) See Rumex hydrolapathum.

HYDRO MELL. (From νδωρ, water, and μελι, honey.) Mulsum; Aqua Mulsa; Melicratum; Braggat; Hydromel. Water impregnated with honey.

After it is fermented, it is called vinous hydromel, or meed.

HYDROTHIONIC ACID. See Sulphuretted hy-

drogen. HYDROMETER. (Hydrometer; from υδωρ, water, or fluid, and μετρον, a measure.) The best method of weighing equal quantities of corrosive volatile fluids, to determine their specific gravities, appears to consist in enclosing them in a bottle with a conical stopper, in the side of which stopper a fine mark is cut with a file. The fluid being poured into the bottle, it is easy to put in the stopper, because the redundant is easy to put in the stopper, because the redundant fluid escapes through the notch, or mark, and may be carefully wiped off. Equal bulks of water, and other fluids, are by this means weighed to a great degree of accuracy, care being taken to keep the temperature as walks slowly, as if half asleep, and then runs suddenly,

equal as possible, by avoiding any contact of the bot the with the hand, or otherwise. The bottle itself shows with much precision, by a rise or fall of the liquid in the notch of the stopper, whether any such

change have taken place.

The hydrometer of Fahrenheit consists of a hollow ball, with a counterpoise below, and a very stender stem above, terminating in a small dish. The middle, or half length of the stem, is distinguished by a fine line across. In this instrument every division of the line across. In this instrument every division of the stem is rejected, and it is immersed in all experiments to the middle of the stem, by placing proper weights in the little dish above. Then, as the part immersed is constantly of the same magnitude, and the whole weight of the hydrometer is known, this last weight, added to the weights in the dish, will be equal to the weight of fluid displaced by the instrument, as all writers on hydrostatics prove. And, accordingly, the sparvities for the common form of the tables will be had by the proportion: by the proportion

As the whole weight of the hydrometer and its had, when adjusted in distilled water, Is to the number 1000, &c.

So is the whole weight when adjusted in any

other fluid

To the number expressing its specific gravity. The hydrometers, or pese-liqueurs, of Baumé, though in reality comparable with each other, are subect in part to the defect, that their results, having no

independent numerical measure, require explanation to those who do not know the instruments.

HYDROME TRA. (From νόωρ, water, and μητοα, the wornb.) Hydrops uteri. Dropsy of the womb. A genus of disease in the class Cacaccia, and order Intumescentia, of Cullen. It produces a swelling of the hypogastric region, slowly and gradually increasing, resembling the figure of the uterus, yielding to or discussing on pressure. Without ischury or were to, or fluctuating on pressure; without ischury or preg-nancy. Sauvages enumerates seven species. It must be considered as a very rare disease, and one that can with difficulty be ascertained.

HYDRO MPHALUM. (From νδωρ, water, and ομφαλος, the navel.) A tumour of the navel, contain-

ing water. Hydro'nosos. Hydro'sosos. (From υδωρ, water, and νοσος, a disease.) The sweating sickness. See Ephidrosis. Hydro-OXIDE. See Hydrate. HydroPEDE'SIS. (From υδωρ, water, and πηδαω,

to break out.) A breaking out into a violent sweat.

HYDROPHANE. Oculus mundi. A variety of

opal, which has the property of becoming transparent

on immersion in water. HYDROPHO BIA. (From υδωρ, water, and φοδεω, to fear.) Rabies canina; Cynanthropia; Cynolesia. Canine madness. This disease arises in consequence Canne madness. This disease arises in consequence of the bite of a rabid animal, as a dog or cat, and sometimes spontaneously. It is termed hydrophobia, because persons that are thus bitten dread the sight or the falling of water when first seized. Cullen has arranged it under the class Neuroses, and order Spasmi, and defines it a loathing and great dread of drinking any liquids, from their creating a painful convul-sion of the pharynx, occasioned most commonly by the bite of a mad animal.

There are two species of hydrophobia.

1. Hydrophobia rabiosa, when there is a desire of biting

Hydrophobia simplex, when there is not a desire

of bitting.

Dr. James observes, that this peculiar affection properly belongs to the canine genus, viz. dogs, foxes, and wolves; in which animals only it seems to be innate and natural, scarcely ever appearing in-any others, except when communicated from these. When a dog is affected with madness, he becomes dull, solitary, and endeavours to hide himself, seldom barking, but making a murmuring noise, and refusing all kinds of meat and drink. He flies at strangers; but, in this stage, he remembers and respects his master; his head and tail hang down; he wells as if each first stage. stage, he remembers and respects his master; his head and tail hang down; he walks as if overpowered by sleep; and a bite, at this period, though dangerous, is not so apt to bring on the disease in the animal bitten as one inflicted at a later period. The dog at length begins to pant; he breathes quickly and heavily; his tongue hangs out; his mouth is continually open, and discharges a large quantity of froth. Sometimes he walks slowly, as if half addent and then was sufficient and the presentation.

but not always directly forward. At last he forgets his master; his eyes have a dull, watery, red appearance; he grows thin and weak, often falls down, gets up and attempts to fly at every thing, becoming very soon quite furious. The animal seldom lives in this latter

quite furious. The animal seldom lives in this latter state longer than thirty hours; and it is said, that his bites toward the end of his existence, are the most dangerous. The throat of a person suffering hydrophobia is always much affected; and, it is asserted, the nearer the bite to this part the more perilous.

Hydrophobia may be communicated to the human subject from the bites of cats, cows, and other animals, not of the canine species, to which the affection has been previously communicated. However, it is from the bites of those domestic ones, the dog and cat, that most cases of hydrophobia originate. It does not appear that the bite of a person affected can communicate the disease to another; at least the records of medicine furnish no proof of this circumstance.

In the human species, the general symptoms attend-

diciae furnish no proof of this circumstance.

In the human species, the general symptoms attendant upon the bite of a mad dog, or other rabid animal, are, at some indefinite period, and occasionally long after the bitten part seems quite well; a slight pain begins to be felt in it, now and then attended with itching, but generally resembling a rheumatic pain. Then come on wandering pains, with an uneasiness and heaviness, disturbed sleep, and frightful dreams, accompanied with great restlessness, sudden startings, and spasms, sighing, anxiety, and a love for solitude. These symptoms continuing to increase daily, pains begin to shoot from the place which was wounded, all along up to the throat with a straitness and sensation of choking, and a horror and dread at the sight of water, and other liquids, together with a loss of appetite and tremor. The person is, however, capable of swallowing any solid substance with tolerable ease; but the moment that any thing in a fluid form is

swallowing any solid substance with tolerable ease; but the moment that any thing in a fluid form is brought in contact with his lips, it occasions him to start back with much dread and horror, although he labours perhaps under great thirst at the time.

A vomiting of bilious matter soon comes on, in the course of the disease, and an intense hot fever ensues, attended with continual watching, great thirst, dryness and roughness of the tongue, hoarseness of the voice, and the discharge of a viscid saliva from the mouth, which the patient is constantly spitting out: forether which the patient is constantly spitting out; together with spasms of the genital and urinary organs, in consequence of which the evacuations are forcibly thrown out. His respiration is laborious and uneasy, but his judgment is unaffected; and, as long as he retains the power of speech, his answers are distinct.

In some few instances, a severe delirium arises, and closes the tragic scene; but it more frequently happens, that the pulse becomes tremulous and irregular, that

convulsions arise, and that nature being at length ex-hausted, sinks under the pressure of misery.

The appearances to be observed, on dissection in hydrophobia, are unusual aridity of the viscera and other parts; marks of inflammation in the fauces, gula, and larynx; inflammatory appearances in the stomach, and an accumulation or effusion of blood in the lunes. Some marks of inflammation are likewise to the lungs. Some marks of inflammation are likewise to be observed in the brain, consisting in a serous effusion on its surface, or in a redness of the pia mater; which appearances have also presented themselves in the dog.
In some cases of dissection, not the least morbid ap-

pearance has been observed, either in the fauces, diaphragm, stomach, or intestines. The poison has, therefore, been conceived by some physicians to act upon the nervous system, and to be so wholly confined to it, as to make it a matter of doubt whether the qualities of the blood are altered or not. There is no known cure for this terrible disease: and the only preventive to be relied upon is the complete excision of the bitten part, which should be performed as soon as possible; though it may perhaps not be too late any time before

the symptoms appear.

HYDROPHOSPHOROUS ACID. See Phosphorous

HYDROPHTHA'LMIA. From υδωρ, water, and oφθαλμος, the eye.) Hydrophthalmium. There are two diseases, different in their nature and consequence, thus termed. The one is a mere anasarcous or ædematous swelling of the eyelid. The other, the true hydrophthalmia, is a swelling of the bulb of the eye, from too great a collection of vitreous or aqueous humoura. HYDROPHTHA'LMIUM. (From υδωρ, water, and

φθαλμος, the eye.) See Hydrophthalmia. HYDROPHTORIC ACID. Acidum hydrophtori-

AT DROPHTORIC ACID. Actum hydropatercum. (From νόωρ, water, and φθοριος, destructive.)
Ampére's name for the base of the fluoric acid, called
by Davy, fluorine. See Hydro-fluoric acid.
HYDROPHYSOCE'LE. (From νόωρ, water, φνση,
flatulence, and κηλη, a tumour.) A swelling formed
of water and air. It was applied to a hernia, in the
sac of which was a fluid and air.
HYDRO'PICA. (From νόρωψ, the dropsy.) Medi
cines which relieve or cure dropsy

cines which relieve or cure dropsy.

HYDRO'PIPER. (From υδωρ, water, and πεπερι, pepper: so called from its biting the tongue like pepper, and growing in marshy places.) See Polygonum hydro-

HYDROPNEUMOSA'RCA. (From υδωρ, water, πνευμα, wind, and σαρξ, flesh.) A tumour of air, water, and solid substances.

HYDROPOLDES. (From υδρωψ, a dropsy, and

HYDROPOLDES. (From υδρωψ, a dropsy, and ειδος, likeness.) Serous or watery, formerly applied to liquid and watery excrements.

HY'DROPS. (Hydrops, pis. m.; from υδωρ, water.) Dropsy. A preternatural collection of serous or watery fluid in the cellular substance, or different cavities of the body. It receives different appellations, according to the particular situation of the fluid.

When it is diffused through the cellular membrane, either generally or partially, it is called anasarca. When it is deposited in the cavity of the cranium, it is called hydrocephalus; when in the chest, hydrothorax, or hydrops pectoris; when in the abdomen, ascites. In the uterus, hydrometra, and within the scrotum,

hydrocele.

The causes of these diseases are a family disposition The causes of these diseases are a family disposition thereto, frequent salivations, excessive and long-continued evacuations, a free use of spirituous liquors, (which never fail to destroy the digestive powers,) scirrhosities of the liver, spleen, pancreas, mesentery, and other abdominal viscera; preceding diseases, as the jaundice, diarrhœa, dysentery, phthisis, asthma, gout, intermittents of long duration, scarlet fever, and some of the exanthemata; a suppression of accustomed evacuations, the sudden striking in of eruptive humours, ossification of the valves of the heart, polyping the right vertricle ancurrism in the arteries, tumours in the right ventricle, aneurism in the arteries, tumours making a considerable pressure on the neighbouring parts, permanent obstruction in the lungs, rupture of the thoracic duct, exposure for a length of time to a moist atmosphere, laxity of the exhalants, defect in the absorbents, topical weakness, and general debility.

Hydrops articuli. A white swelling of a joint is

sometimes so called.

Hydrops cysticus. A dropsy enclosed in a bag,

Hydrops genu. An accumulation of synovia, or serum, within the capsular ligament of the knee.
Hydrops ad Matulam. Diabetes.

Hyprops Medulle spinalis. and Spina bifida. See Hydrorachitis

HYDROPS OVARII. A dropsy of the ovarium. See Ascites.

HYDROPS PECTORIS. See Hydrothorax.
HYDROPS PERICARDII. See Hydrocardia.
HYDROPS PULMONUM. Water in the cellular inter-

stices of the lungs.

HYDROPS SCROTT. See Hydrocele. HYDROPS UTERL. See Hydrometra.

HYDROPY TERIL. See Hydrometra.

HYDROPY TETUS. (From νόωρ, water, and πυρεγος, fever.) A sweating fever.

HYDRORACHI TIS. (From νόωρ, water, and ραχις, the spine.) A fluctuating tumour, mostly situated on the lumbar vertebræ of new-born children. It is a genus of disease in the class Cachexia, and order Intumescentia, of Cullen, and is always incurable. See Spina bifida.

A drink made of water, honey, HYDRORO SATUM:

and the juice of roses.

HYDROSA'CCHARUM. (From υδωρ, water, and σακχαρου, sugar.) A drink made of sugar and water.

HYDROSA'RCA. (From υδωρ, water, and σαρξ,

HYDROSA RCOLE LE. (From υξωρ, water, σαρξ, the flesh, and κηλη, a tumour.) Sarcocele, with an effusion of water into the cellular membrane.

HYDROSELENIC ACID. The best process which

we can employ for procuring this acid, consists in treating the seleniuret of iron with the liquid muriatic quantity of water deposited in the chest. In some cases, the event is suddenly fatal; but in others, it is cases, the event is suddenly fatal; but in others, it is treating the seleniuret of iron with the liquid muriatic acid. The acid gas evolved must be collected over mercury. As in this case a little of another gas, condensible neither by water nor alkaline solutions, ap-pears, the best substance for obtaining absolutely pure hydroselenic acid would be seleniuret of potas-

HYDROSELI'NUM. (From υδωρ, water, and σελεινον, pursiane.) A species of pursiane growing in

marshy places.
HYDROSULPHURET. HYDROSULPHURET. Hydrosulphuretum. A compound of sulphuretted hydrogen with a salifiable

Hydrosulphure'tum stiell luteum. See Anti-

monii sulphuretum præcipitatum.

HYDROSULPHURETUM STIBIL RUBRUM. Kermes mineralis. A hydro-sulphuret of antimony formerly in high estimation as an expectorant, sudorific, and antispasmodic, in difficult respiration, rheumatism, diseases of the skin and glands.

HYDROTHIONIC ACID. Some German chemists distinguish surpuretted hydrogen by this name on account of its properties resembling these of an acid.

distinguish sulphuretted hydrogen by this name on account of its properties resembling those of an acid. HYDROTHO'RAX. (From $v \bar{w} \omega_{\rho}$, water, and $\theta \omega_{\rho} a \xi$, the chest.) Hydrops thoracis; Hydrops pectoris. Dropsy of the chest. A genus of disease in the class Cacheziæ, and order Intumescentiæ, of Cullen. Difficulty of breathing, particularly when in a horizontal posture; sudden startings from sleep, with anxiety, and palpitations of the heart; cough, paleness of the visage, anasarcous swellings of the lower extremities, thirst, and a scarcity of urine, are the characteristic symptoms of hydrothorax; but the one which is more decisive than all the rest is a flucwhich is more decisive than all the rest is a fluctuation of water being perceived in the chest, either by the patient himself or his medical attendant, on certain motions of the body.

The causes which give rise to the disease, are pretty much the same with those which are productive of the other species of dropsy. In some cases, it exists without any other kind of dropsical affection being present; but it prevails very often as a part of more

universal dropsy.

It frequently takes place to a considerable degree before it becomes very perceptible; and its presence is not readily known, the symptoms, like those of hydrocephalus, not being always very distinct. In some in-stances, the water is collected in both sacs of the pleura; but, at other times, it is only in one. Sometimes it is lodged in the pericardium alone; but, for the most part, it only appears there when, at the same time, a collection is present in one or both cavities of the thorax. Sometimes the water is effused in the cellular texture of the lungs, without any being deposited in the cavity of the thorax. In a few cases, the water that is collected is enveloped in small cysts, of a membraneous patters, known by the name of of a membraneous nature, known by the name of hydatides, which seem to float in the cavity; but more frequently they are connected with, and attached to, particular parts of the internal surface of the

pleura.

Hydrothorax often comes on with a sense of uneasiness at the lower end of the sternum, accompanied by a difficulty of breathing which is much increased by any exertion, and which is always most considerable during night, when the body is in a horizontal posture. during night, when the body is in a horizontal posture. Along with these symptoms there is a cough, that is at first dry, but which, after a time, is attended with an expectoration of thin mucus. There is likewise a paleness of the complexion, and an anasarcous swelling of the feet and legs, together with a considerable degree of thirst and a diminished flow of urine. Under these appearances, we have just grounds to suspect that there is a collection of water in the chest; but if the fluctuation can be perceived, there can then reif the fluctuation can be perceived, there can then re-main no doubt as to the reality of its presence.

During the progress of the disease, it is no uncommon thing for the patient to feel a numbness, or degree of palsy, in one or both arms, and to be more than ordinarily sensible to cold. With regard to the pulse, it is usually quick at first, but, towards the end, becomes irregular and intermitting.

Our prognostic in bydrotherax must, in seneral, be

Our prognostic in hydrothorax must, in general, be unfavourable, as it has seldom been cured, and, in many cases, will hardly admit even of alleviation, the difficulty of breathing continuing to increase, until the

preceded, for a few days previous to death, by a spitting of blood.

Dissections of this disease show that, in some cases, the water is either collected in one side of the thorax, or that there are hydatides formed in some particular part of it; but they more frequently discover water in both sides of the chest, accompanied by a collection in the cellular texture and principal cavities of the body. The fluid is usually of a yellowish colour; possesses properties similar to serum, and, with respect to its quantity, varies very much, being from a few ounces to several quarts. According to the quantity, so are the lungs compressed by it; and, where it is very considerable, they are usually found much reduced in size. When universal anasarca has preceded the collection in the chest, it is no uncommon occurrence to find some of the abdominal viscera in a

The treatment of this disease must be conducted on the same general plan as that of enasarca. Emetics, however, are hazardous, and purgatives do not afford so much benefit; but the bowels must be kept regular, and other evacuating remedies may be employed in conjunction with tonics. Squill has been chiefly resorted to, as being expectorant as well as diuretic; but its power is usually not great, unless it be carried so far. as to cause nausea, which cannot usually be borne to any extent. Digitalis is more to be relied upon; but it

will be better to conjoin them, adding, perhaps, some form of mercury; and employing at the same time other diuretics, as the supertartrate or acetate of potassa, juniper berries, &c. Where febrile symptoms attend, diaphoretics will probably be especially serviceable, as the pulse incompanies according viceable, as the pulvis ipecacuanha compositus, or antimonials, in small doses; which last may also pro-mote expectoration. Blisters to the chest will be proper in many cases, particularly should there be any pain or other mark of inflammatory action. Myrrh seems to answer better than most other tonics, as more decidedly promoting expectoration; or the nitric acid may be given, increasing the secretion of urine, as well as supporting the strength. The inhalation of oxygen gas is stated to have been in some instances singularly Where the fluid is collected in either of the sacs of the pleura, the operation of paracentesis of

the thorax may afford relief under urgent symptoms, and, perhaps, contribute to the recovery of the patient.

HYDROXURE. See Hydrate.

HYDRURET A compound of hydrogen with a

Sec Uret. HYGEIA. Hygicia. The goddess of health. One of the four daughters of Esculapius. She often accompanies her father in the monuments of him now remaining, and appears like a young woman, com-monly holding a serpent in one hand, and a patera in the other. Sometimes the scrpent drinks out of the

the goddess.

HYGIE'NE. (From vytativo, to be well.) Hygicsis.

Modern physicians have applied this term to that division of therapeia which treats of the diet and non naturals of the sick.

Hyorg'sis. See Hygiene. Hy'ora. (From vyoos, humid.) An ancient term for liquid plasters.

for liquid plasters.

Hygrenpla's trum. (From υγρος, moist, and εμπλαςρον, a plaster.) A liquid plaster.

Hygroblepha'ricus. (From υγρος, humid, and δλεφαρον, the eyelid.) Applied to the emunctory ducts in the extreme edge, or inner part of the eyelid Hygrocites (From υγρος, moist, κιρσος, a varix, and κηλη, a tumour.) Dilated spermatic veins, or circocele, with dropsy of the scrotum.

Hygrocolly'rium. (From υγρος, liquid, and κολλυριον, a collyrium.) A collyrium composed of liquids Hygro'logy. (Hygrologia, from υγρος, a humour or fluid, and λογος, a discourse.) The goctrine of the fluids.

Of the huids.

HYGRO'MA. (Υγρωμα; from υγρος, a liquid.) An encysted tumour, the contents of which are either serum or a fluid-like lymph. It sometimes happens that these tumours are filled with hydatids. Hygromatous tumours require the removal of the cyst, or the destruction of its secreting surface.

HYGRO'METER. (Hygrometrum; from υγρος, moist, and μετρου, a measure.) Hygrometer. An instrument to measure the degrees of moisture in the

atmosphere. It also means an infirm part of the body, affected by moisture of the atmosphere.

Hygromy'rum. (From υγρος, moist, and μυρον, a liquid ointment.) A liquid ointment.

HYGROSCO'PIC. Substances which have the property of absorbing moisture from the atmosphere. See Atmosphere.

HYGROPHO'BIA. See Hydrophobia. HY'LE. ('Υλη, matter.) The materia medica, or matter of any kind that comes under the cognizance

matter of any kind that comes under the cognition of a medical person.

HY'MEN. (From Hymen, the god of marriage, because this membrane is supposed to be entire before marriage, or copulation.) The hymen is a thin membrane, of a semilunar or circular form, placed at the entrance of the vagina, which it partly closes. It has a very different appearance in different women, but it is generally, if not always, found in virgins, and is a very different appearance in ginerent women, out is generally, if not always, found in virgins, and is very properly esteemed the test of virginity, being ruptured in the first act of coition. The remnants of the hymen are called the carunculæ myrtiformes. The hymen is also neculiar to the human species. There are two circumstances relating to the hymen which require medical assistance. It is sometimes of such a strong ligamentous texture, that it cannot be ruptured, and prevents the connexion between the sexes. It is also sometimes imperforated, wholly closing the entrance into the vagina, and preventing any discharge from the uterus; but both these cases are extremely rare. If the hymen be of an unnaturally firm texture, but perforated though perhaps with a very ture, but perforated, though perhaps with a very small opening, the inconveniences thence arising will not be discovered before the time of marriage, when they may be removed by a crucial incision made through it, taking care not to injure the adjoin-

The imperforation of the hymen will produce its inconveniences when the person begins to menstruate. For the menstruous fluid, being secreted from the uterus at each period, and not evacuated, the patient suffers much pain from the distention of the parts, many strange symptoms and appearances are occasioned, and suspicions injurious to her reputation are often entertained. In a case of this kind, for which Dr. Denman was consulted, the young woman, who was twenty-two years of age, having many uterine complaints, with the abdomen enlarged, was suspected to be pregnant, though she persevered in asserting the contrary, and had never menstruated. When she was prevailed upon to submit to an examination, the circumscribed tumour of the uterus was found to reach as high as the navel, and the external parts were stretched by a round soft substance at the entrance of the vagina, in such a manner as to resemble that appearance which they have when the head of a child is passing through them; but there was no entrance into the vagina. On the following morning an incision was carefully made through the hymen, which had a fleshy appearance, and was thickened in proportion to its detention. Not less than four pounds of blood, of the colour and consistence of tar, were discharged; and the tumefaction of the abdomen was immediately removed. Several stellated incisions were afterward made through the divided edges, which is a very necessary part of the operation: and care was taken to prevent a reunion of the hymen till the next period of menstruation, after which she suffered no inconvenience. The blood discharged was not putrid or co-agulated, and seemed to have undergone no other change after its secretion, but what was occasioned by the absorption of its more fluid parts. Some caution is required when the hymen is closed in those who are in advanced age, unless the membrane be distended by the confined menses; as Dr. Denman once saw an instance of inflammation of the peritonæum being immediately produced after the operation, of which the patient died as in the true puerperal fever; and no other reason could be assigned for the disease.

The carunculæ myrtiformes, by their elongation and

enlargement, sometimes become very painful and troublesome.

HYMENÆA. (From Hymen, the god of marriage because, as Linnaus informs us, its younger leaves schere together in pairs, throughout the night.) The

name of a genus of plants. Class, Decandria; Order,

HYMENEA COURBARIL. The systematic name of the locust-tree which affords the resin called gum anime, which is now fallen into disuse, and is only to

be found in the collections of the curious.

HYMENIUM. (From $v\mu\eta\nu$, a membrane.) The dilated exposed membrane of gymnocarpous mushrooms, in which the seed is placed. See Gymnocarpit.

HYMENODES. (From $v\mu\eta\nu$, a membrane, and $u\delta o g$, likeness.) An old term for such urine as is found to be full of little films and pellicles. Hippocrates applies it also to the menstrual discharge when mixed with a touch viscid phlegm.

with a tough viscid phlegm.

HYO. Names compounded of this word belong to muscles which originate from, or are inserted into, or connected with, the os hyoides; as Hyo-glossus, Hyo-

connected with, the os hyoides; as Hyo-glossus, Hyo-pharyngcus, Genio-hyo-glossus, &c.

HYO-GLOSSUS. Cerato-glossus of Douglas and Cowper. Basio-cerato-chondro-glossus of Albinus. Hyo-chondro-glosse of Dumas. A muscle situated at the sides, between the os hyoides and the tongue. It arises from the basis, but chiefly from the corner of the os hyoides, running laterally and forwards to the tongue, which it rulls invasid and downwards.

which it pulls inward and downward.

HYOl'DES OS. (From the Greek letter v, and ecos, likeness: so named from its resemblance.) This bone, which is situated between the root of the tongue and the larynx, derives its name from its supposed resem-blance to the Greek letter v, and is, by some writers, described along with the parts contained in the mouth. Ruysch has seen the ligaments of the bone so com-pletely ossified, that the os hyoides was joined to the temporal bones by anchylosis. In describing this bone, it may be distinguished into its body, horns, and appendices. The body is the middle and broadest part of the bone, so placed that it may be easily felt with the finger in the forepart of the throat. Its forepart, which is placed toward the tongue, is irregularly convex, and its inner surface, which is turneds to wards the larynx, is unequally concave. The cornua, or horns, which are flat, and a little bent, are considerably longer than the body of the bone, and may be said to form the sides of the v. These horns are thickest near the body of the bone. At the extremity of each is observed a round tubercle, from which a ligament passes to the thyroid cartilage. The appendices, or smaller horns, cornua minora, as they are called by some writers, are two small processes, which, in their size and shape, are somewhat like a grain of wheat. They rise up from the articulations of the cornua, with the body of the bone, and are sometimes connected with the styloid process on each side, by means of a ligament. It is not unusual to find small portions of bone in these liga-ments; and Ruysch, as we have already observed, has seen them completely ossified. In the foctus, almost the whole of the bone is in a cartilaginous state, excepting a small point of a bone in the middle of its body, and in each of its horns. The appendices do not begin to appear till after birth, and usually remain cartilaginous many years. The os hyoides serves to support the tongue, and affords attachment to a variety of muscles, some of which perform the motions of the tongue,

while others act on the larynx and fauces.

HYOPHARYNGE'US. (From votedess) the hyoid bone, and φαρυγζ, the pharynx.) A muscle so called from its origin in the os hyoides, and its insertion in

the pharvnx

the pharynx.

HYOPHTHA'LMUS. (From v5, a swine, and φφθαλμως, an cye: so named from the supposed resemblance of its flower to a hog's eye.) Hogs-eye plant.

Most probably the Buphthalmum spinosum of Linnæus.

HYOSCIANIA. A new vegetable alkali extracted
by Dr. Brande from henbane. See Hyoscyamus niger.

HYOSCY'AMUS. (From v5, a swine, and κυαμφ5,
a bean: so named because hogs eat it as a medicine,
or it may be because the plant is hairy and bristly, like

1. The name of a genus of plants in the Linnman system. Class, Pentandria; Older, Monogynia.

2. The pharmacopælal name of the henbane. See

Hyoscyamus niger.

Hyoscyamus albus. This plant, a native of the south of Europe, possesses similar virtues to the hyoscyamus niger

HYOSCYAMUS LUTEUS. A species of tobacco, the Nicotiana rustica of Linngeus.

HYOSCYAMUS NIGER. The systematic name of common or black henbane, called also Faba suilla; Apollimonth that hemother, caned also Fada suita; Apollinaris altercum; Agone; Altercangenon; Hyoscyamus—folius amplexicaudibus sinuatis, floribus sessilibus of Linnæus. The leaves of this plant, when recent, have a slightly foetid smell, and a mucilaginous taste; when dried, they lose both taste and smell, and part also of their narcotic power. The root possesses the same qualities as the leaves, and even in a more eminent degree. Henbane resembles opium in its action, more than any other narcotic dose. In a moderate dose it increases at first the strength of the pulse, and occasions some sense of heat, which are followed by diminished sensibility and motion; in some cases, by thirst, sickness, stupor, and dimness of vision. In a larger quantity it occasions profound sleep, hard pulse, and sometimes fierce delirium, ending in coma, or conwhen dried, they lose both taste and smell, and part also and sometimes fierce delirium, ending in coma, or convulsions, with a remarkable dilatation of the pupil, distortion of the countenance, a weak tremulous pulse, and eruption of petechie. On dissection, gangrenous spots have been found on the internal surface of the stomach. Its baneful effects are best counteracted by a powerful emetic, and by drinking largely of the vege-

Henbane has been used in various spasmodic and rienbane has been used in various spasmonic and a painful diseases, as in epilepsy, hysteria, palpitation, headache; paralysis, mania, and scirrhus. It is given in the form of the inspissated juice of the fresh leaves, the dose of which is from one to two grains; which requires to be gradually increased. It is sometimes employed as a substitute for opium, where the latter, from idiosyncrasy, occasions any disagreeable symp-The henbane also is free from the constipating

quality of the opium. Dr. Brande has extracted a new alkali from this plant, which he calls hyosciania. It crystallizes in long prisms, and when neutralized by sulphuric or nitric acid, forms characteristic salts.

HYOTHYRO'DES. (From νοειδες, the hyoid bone, and θυροειδης, the thyroid cartilage.) A muscle named from its origin in the hyoid bone, and insertion in the thyroid cartilage. Ηγρα'οτικα. (From υπαγω, to subdue.) Medicines

which evacuate the faces.

Hypalet Firens. (From υπαλειφω, to spread upon.) A spatula for spreading ointments with. Hype Lata. (From υπελαω, to move.) Medicines

which purge.

HYPERÆTHE'SIS. (From υπιρ, and αισθανομαι, Error of appetite, whether by excess or deto feel.) ficienc

HYPERCATHA'RSIS. (From υπερ, supra, over or

above, and καθαιρω, to purge.) Hyperinesis; Hyperines. An excessive purging from medicines.

Hypercorypno'sis. (From υπερ, above, and κορυφη, the vertex.) A prominence or protuberance. Hippocrates calls the lobes of the liver and lungs Hyper-

HYPE RCRISIS. (Υπερκρισις; from υπερ, over or above, and κρινω, to separate.) A critical excretion above measure; as when a fever terminates in a looseness, the humours may flow off faster than the strength

can bear, and therefore it is to be checked.

HYPERE'MESIS. (From υπερ, in excess, and εμεω, to vomit.) An excessive evacuation by vomiting.

HYPEREPHIDRO'SIS. (From υπερ, excess, and

Immoderate sweating.

HYPE RICUM. (From υπορ, over, and εικων, an image or spectre: so named because it was thought to have powerover and to drive away evil spirits.) 1. The name of a genus of plants in the Linnæan system. Class, Polyadelphia; Order, Polyandria. St. John's

2. The pharmacopæial name of the common St.

John's wort. See Hypericum perfoliatum.

Hypericum Bacciferum. Caa-opia; Arbuncula gummifera Braziliensis. A juice exudes from the wounded bark of this plant, in the Brazils, which, in a dry state, resembles camboge, but is rather darker.

In a dry state, resembles camboge, but is father darker.

Hypericum coris. Coris lutea; Coris legitima cretica. Bastard St. John's wort. The seeds are diuretic, emmenagogue, and antispasmouic.

Hypericum perfoliatum. The systematic name of the St. John's wort, called also fuga damonum; and androsamum. Hypericum perforatum—floribus trigymis, caule ancipiti, foliis obtusis pellucido-punctatis, of Linnaus. This indigenous plant was greatly ex-

teemed by the ancients, internally in a great variety of diseases, and externally as an anodyne and discutient, but is now very rarely used. The flowers were formerly used in our pharmacopæia, on account of the great proportion of resinous oily matter, in which the medical efficacy of the plant is supposed to reside, but are your omitted. but are now omitted.

HYPERICUM SAXATILE. Hypericoides. are said to be diuretic and antispasmodic.

HYPERI'NA. (From wπερ, in excess, and ωνω, to evacuate.) Medicines which purge excessively.

HYPERI'NOS. See Hypercatharsis.

HYPERO'A. (From wπερ, above, and ωον, the top of a house.) The palate.

Hyperopharyson'us. (From wπερ, above, and

HYPEROPHARYNGE'US. (From υπερ, above, and φαρυγξ, the pharynx.) A muscle named from its situation above the pharynx.

HYPEROSTO'SIS. (From υπερ, upon, and ωον, a

See Exostosis.

Hypero'um. (From υπερ, above, and ωον, the roof or palate.) A foramen in the upper part of the palate. Hyperoxymuriate of potassa. See Murias potassa Hyperoxymuriate of potassa.

Oxygenatus
Hyperoxymuriatic acid. See Chlorine.
HYPEROXYMURIATE. A salt now called a chlo-

rate.

HYPERSARCO'MA. (From υπερ, in excess, and σαρξ, flesh.) Hypersarcosis. A fleshy excrescence. A polypus.

HYPERSARCO'SIS. See Hypersarcoma.

HYPERSTENE. Labrador schiller spar. Found in Labrador, Greenland, and Isle of Skye. It has a heavitid sever solver when ever and proliphed into

beautiful copper colour when cut and polished into

rings, brooches, &c.

Hyperydro's is. (From υπερ, in excess, and υδωρ, water.) A great distention of any part, from water collected in it.

Hype xodos. (From υπο, under, and εξοδος, passing out.) A flux of the belly.
 HYPNO BATES. (From υπνος, sleep, and βαενω, to go.) Hypnobatasis. One who walks in his sleep.

HYPNOLO'GIA. (From υπνος, sleep, and λογος, a discourse.) A dissertation, or directions for the due regulation of sleeping and waking.

HYPNOPOIE'TICA. (From υπνος, sleep, and ποιεω, to cause.) Medicines which procure sleep. See

HYPNO'TIC. (Hipnoticus; from υπνος, sleep.)

See Anodyne.
HYPO-SULPHITE. A sulphuretted sulphite.

HYPOÆMA. (From υπο, under, and αιμα, blood; because the blood is under the cornea.) An effusion of red blood into the chambers of the eye.

Hypocarothis. (From vno, and kapos, a carus.) of carus.

Hypocatha'rsis. (From υπω, under, and καθαίου, to purge.) It is when a medicine does not work so

much as expected, or but very little. Or a slight purging, when it is a disorder.

HYPOCAU'STRUM. (From υπο, under, and καιώ, to burn.) A stove, hot house, or any such like con-

trivance, to preserve plants from cold air.

Hypocerchna'leon. (From υπο, and κερχνος, an asperity of the fauces.) A stridulous kind of asperity of the fauces

Hypocheo'Menos. (From υπο, under, and χεω, to pour.) One who labours under a cataract.

Hypochloro'sis. (From υπο, and χλωρωσις, the green-sickness.) A slight degree of chlorosis.

HYPOCHO'NDRIAC. (From υπο, under, and χονδρος, a cartilage.) 1. Belonging to the hypochon-

2. A person affected with lowness of spirits. See

Hypochondriasis
Hypochondria. The spaces in the abdomen that are under the cartilages of the spurious ribs on each side of the epigastrium.

side of the epigastrum.

HYPOCHONDRI'ASIS. (From υποχονδριακος, one who is hipped.) Hypochondriacus morbus; Affectio hypochondriaca; Passio hypochondriaca. The hypochondriac affection, vapours, spleen, &c. A genus of chondriac affection, vapours, spleen, &c. A genus of disease in the class Neuroses, and order Adynamia, of Cullen, characterized by dyspepsia, languor, and want

of energy; sadness and fear from uncertain causes, with a melancholic temperament.

The state of mind peculiar to hypochondriacs is thus described by Cullen:—"A langour, listlessness, or want of resolution and activity, with respect to all undertakings; a disposition to seriousness, sadness, and timidity, as to all future events, and apprehension of the worst or most unhappy state of them; and, therefore, often upon slight grounds, and apprehension of great evil. Such persons are particularly attentive to the state of their own health, to every the smallest change of feeling in their bodies: and from any unusual sensation, perhaps of the slightest kind, they apprehend great danger, and even death itself. In respect to these of resolution and activity, with respect to all undertakings; a disposition to seriousness, sadness, and timidity, as to all future events, and apprehension of the worst or most unhappy state of them; and, therefore, often upon slight grounds, and apprehension of great evil. Such persons are particularly attentive to the state of their own health, to every the smallest change of feeling in their bodies: and from any unusual sensation, perhaps of the slightest kind, they apprehend great danger, and even death itself. In respect to these feelings and fears, there is commonly the most obstinate belief and persuasion." He adds, "that it is only when the state of mind just described is joined with indigestion, in either sex, somewhat in years, of a melancholic temperament, and a firm and rigid habit, that the disease takes the name of Hypochondriacism."

The scat of the hypochondriac passions is in the stomach and bowels; for, first these parts are disordered, then the others suffer from the connexion. The causes are, sorrow, fear, or excesses of any of the passions is the stomach and bowels; for, first these parts are disordered, then the others suffer from the connexion.

causes are, sorrow, fear, or excesses of any of the passions; too long continued watching; irregular diet. Those habitually disposed to it (and these causes have little effect in other constitutions,) have generally a sal-low or brown complexion, and a downcast look; a rigidity of the solids, and torpor of the nervous system. Whatever may occasion nervous disorders in general,

may also be the cause of this.

The signs of this complaint are so various, that to describe them is to describe almost every other disease; but, in general, there is an insurmountable indolence, dejected spirits, dread of death, costiveness, a slow and somewhat difficult inspiration, flatulencies in the prima viæ, and various spasmodic affections. It is seldom fatal; but if neglected, or improperly treated, may bring on incurable melancholy, jaundice, madness, or

or incurate heranchofy, jaundice, madness, or vertigo, palsy, and apoplexy.

On dissections of hypochondriacal persons, some of the abdominal viscera (particularly the liver and spleen) are usually found considerably enlarged. In some few instances, effusion and a turgescence of the

vessels have been observed in the brain.

This being a disease of a mixed description, the treatment must be partly corporeal, partly mental; but it has been too often neglected, as merely imaginary, and their complaints met by argument or raillery, which, however, can only weaken their confidence in the practitioner. It may be very proper to luform them, that their disorder is not so dangerous as they suppose, and may be removed by suitable remedies; but to tell them they all nothing, is absurd. In reality, medicine is often of much service; and though others have been is often of much service; and though others have been cared chiefly by annusements, country air, and exercise, it by no means follows, that their disorder was only in the imagination. In so far as dyspeptic symptoms appear, these must be encountered by the renedies pointed out under that head; antacids, aperients, &c. Sometimes emetics, or drastic cathartics, have produced speedy relief; but they are too debilitating to be often employed. The bowels will be better regulated by milder remedies, as castor oil, senna, aloes, (unless they are subject to hæmorrhoids,) and the like; and magnesia may at the same time correct ascidity; but if the liver be torpid, some mercurial preparation will be the liver be torpid, some mercurial preparation will be of more avail. Flatulence and spasmodic pains may be relieved by aromatics, ether, the feeting gum resins, musk, valarian, &c. but severe and obstinate pain, or high irritation, will be best attacked by opium: it is important, however, to guard against the patient get-ting into the habitual use of this remedy. Occasionally, mild tonics appear useful, especially chalybeate waters; and tepid bathing, with friction, gentle exercise, and warm clothing, are important to keep up the function of the skin. The diet should be light, and sufficiently nutritious; but moderation must be en-joined to those who have been accustomed to indulge too much in the luxuries of the table: and, in all cases, those articles which are ascescent, flatulent, or difficult of digestion, must be avoided. Malt liquors do not usually agree so well as wine or spirits, considerably diluted; but these stimuli should never be allowed unnecessarily. The mental treatment required will be such as is calculated to restore the strength, and correct the aberrations of the judgment. When any

Hypocle Pricum. (From υπο, under, and κλεπτω, to steal.) A chemical vessel for separating liquors, particularly the essential oil of any vegetable from the HYPOCLE PTICUM. water; and named because it steals, as it were, the water from the oil.

water from the oil.

Hypocoelon. (From υπο, under, and κοιλον, a cavity.) The cavity under the lower eyelid.

Hypocopho'sis. A trifling degree of deafness.

Hypocra'nium. (From υπο, under, and κρανιον, the skull.) A kind of abscess, so called because scated under the cranium, between it and the dura mater.

HYPOCRATERIFORMIS. (From υπο, χρατηρ, a cup, goblet, or salver, and forma, likeness.) Hypocrateriform, salver-shaped; applied to leaves so shaped, as those of the Primula.

Hypoper'ris. In Rufus Ephesius, it is the extremity of the forepart of the neck.

of the forepart of the neck.

Hypode Rmis. (From υπο, under, and δερμα, the skin.) 1. The skin over the clitoris, which covers it like a prepuce.
2. The clitoris.

Hypo'dessus. (From υπο, under, and δεω to bind.)

Hypo'desmus. An underswathe, or bandage.

HYPO'GALA. (From υπο, under, and γαλα, milk; because it is a milk-like effusion under the cornea.) A collection of white humour, like milk, in the chambers of the eye. There are two species of this disease; the one takes place, it is said, from a deposition of the milk, as is sometimes observed in women who suckle, the other from a depression of the milky cataract.

HYPOGA'S'IRIC. (From vno, under, and γαςηρ, the stomach.) Belonging to the hypogastria. See

Hupogastrium.

Hypogastrium.

Hypogastrium. See Hiac arteries.

Hypogastrium. See Hiac arteries.

Hypogastrium. See Hypogastrium.

HyPOGA'STRIUM. (From νπο, under, and γαςηρ, the stomach.) Regio hypogastrica. The region of the abdomen that reaches from above the pubes to within three fingers' breadth of the navel.

HYPOGASTROCE'LE. (From νπογαςροιον, the

HYPOGASTROCE LE. (From υπογαςοιον, the hypogastrium, and κηλη, a tumour.) A hernia, in the

hypogastric region. HYPOGLO'SSIS. HYPOGLO'SSIS. (From υπο, under, and γλωσσα, the tongue.) The under part of the tongue, which adheres to the jaw.

HYPOGLO'SSUS. (From υπο, under, and γλωσσα, the tongue.) A nerve which goes to the under part of the tongue.

the tongue

HYPOGLO'TTIDES. (From υπο, under, and γλωτ7α, the tongue.) They are a kind of lozenge to be held under the tongue until they are dissolved.

HYPOGLU'TIS. (From υπο, under, and γλουτος, the nates.) It is the fleshy part under the nates towards the thigh. Some say it is the flexure of the coxa, under the nates.

Hypo'MIA. (From υπο, under, and ωμος, shoulder.) In Galen's Exegesis, it is the part subjacent to the

shoulder.

HYPONITRIC ACID. See Nitric acid.

HYPONITROUS ACID. Pernitrous acid. "It appears from the experiments of Gay Lussac, that there exists an acid, formed of 100 azote and 150 oxygen. When into a test tube filled with mercury, we pass up from 500 to 600 volumes of deutoxide of azote, a little alkaline water, and 100 parts of oxygen gas, we obtain an absorption of 500, proceeding from

the condensation of the 100 parts of oxygen with 400 ment, as that which is occasionally let down from of deutoxide of azote. Now these 400 parts are composed of 200 azote and 200 oxygen; consequently, the HYPOSULPHUREOUS ACID. "In order to obnew acid is composed of azote and oxygen, in the ratio of 100 to 150, as we have said above. acid, according to Gay Lussac, which is produced on leaving for a long time a strong solution of potassa in contact with deutoxide of azote. At the end of three months he found that 100 parts of deutoxide of azote were reduced to 25 of protoxide of azote, and that

crystals of hyponitrite (pernitrite) were formed.

Hyponitrous acid (called pernitrous by the French chemists) cannot be insulated. As soon as we lay hold, by an acid, of the potassa with which it is associated, it is transformed into deutoxide of azote, which is disengaged, and into nitrous or nitric acid, which remains in solution."

Hypo'nomos. (From υπονομος, a phagedenic ulcer.) A subterraneous place.

2. A deep phagedenic ulcer.

Hypope DIUM. (From vmo, under, and mov;, the foot.) A cataplasm for the sole of the foot.

Hypo'phora. (From υποφερομαι, to be carried or conveyed underneath.) A deep fistulous ulcer.
HYPOPHOSPHOROUS ACID. This acid was lately discovered by Dulong. Pour water on the phosphoreted. lately discovered by Dulong. Pour water on the phosphuret of barytes, and wait till all the phosphuretted hydrogen be disengaged. Add cautiously to the filtered liquid dilute sulphuric acid, till the barytes be all precipitated in the state of sulphate. The supernatant liquid is hypophosphorous acid, which should be passed through a filter. This liquid may be concentrated by evaporation, till it become viscid. It has a very sour taste, reddens vegetable blues, and does not crystallize. It is probably composed of 2 primes of phosphorus = 3+1 of oxygen. Dulong's analysis approaches to this proportion. He assigns, but from rather precarious data, 100 phosphorus to 37.44 oxygen. The hypophosphites have the remarkable property of being all soluble in water; while many of the phosphates and phosphites are insoluble.

HYPOPHTHA'LMION. (From vπo, under, and oφθαλμος, the eye.) The part under the eye which is subject to swell in a cachexy, or dropsy.

Hypo prysis. (From vπo, under, and φνω, to produce). A disease of the available when the balls are

subject to swell in a cachexy, or dropsy.

Hypo'physis. (From υπο, under, and φυω, to produce.) A disease of the eyelids, when the hairs grow so much as to irritate and offend the pupil.

HYPO'PYUM. (From υπο, under, and πυον, pus; because the pus is under the cornea.) Hypopion; Pyosis; Abscessus oculi. An accumulation of a glutinous yellow fluid, like pus, which takes place in the anterior chamber of the aqueous humour, and frequently also in the posterior one, in consequence of severe, acute ophthalmy, particularly the internal species. This viscid matter of the hypopyum, is commonly called pus; but Scarpa contends, that it is only monly called pus; but Scarpa contends, that it is only coagulating lymph. The symptoms portending an extravasation of coagulable lymph in the eye, or an hypopyum, are the same as those which occur in the highest stage of violent acute ophthalmy, viz. prodi-gious tumefaction of the eyelids; the same swelling and redness as in chemosis; burning heat and pain in the eye; pains in the eyebrow, and nape of the neck; fever, restlessness, aversion to the faintest light, and a contracted state of the pupil.

Hypori'nion. (From vno, under, and ou, the nose.)

A name for the parts of the upper lip below the

Hyrosa'RCA. (From v=0, under, and saot, flesh.) Hyposarcidios.

Hypospadiæ'os. (From υπο, under, and σπασ draw.) The urethra terminating under the glans. (From vno, under, and onaw, to

Hypospathi'smus. (From υπο, under, and σπαθη a spatula.) The name of an operation formerly used in surgery, for removing defluxions in the eyes. It was thus named from the instrument with which it was performed.

Hypospha' αMA. (From υπο, under, and σφαζω, to kill.) Aposphagma. An extravasation of blood in the tunica adnata of the eye, from external

Hyposple'nia. (From υπο, under, and σπλην, the spleen.) A tumour under the spleen. Hyposple'nia. (From υπο, and γαφυλη, the hyposple'nia.) Relaxation of the uvula. Hyposple'nia. (From υπος and γαφυλη, the hyposple'nia.) Relaxation of the uvula. Hypo'sple'nia. (From υπος γημι, to nubside.) A sedi-hypo'sple'nia. (From υπος γημι, to nubside.) A sedi-hypo'sple'nia.

HYPOSULPHUREOUS ACID. "In order to obtain hyposulphureous acid, Herschel mixed a dilute solution of hyposulphite of strontites with a slight excess of dilute sulphuric acid, and, after agitation, poured the mixture on three filters. The first was received into a solution of carbonate of potassa, from which it expelled carbonic acid gas. The second por tion being received successively into nitrates of silver and mercury, precipitated the metals copiously in the state of sulphurets, but produced no effect on solutions of copper, iron, or zinc. The third, being tasted, was acid, astringent, and bitter. When fresh filtered, it was clear; but it became milky on standing, depositing sulphur, and colouring sulphureous acid. A moderate experience to air or a greatle heat, caused its endeants. derate exposure to air, or a gentle heat, caused its en-

HYPOSULPHURIC ACID. "Gay Lussac and Welther have recently announced the discovery of a new acid combination of sulphur and oxygen, intermediate between sulphureous and sulphuric acids, to which they have given the name of hyposulphuric acid. It is obtained by passing a current of sulphureous acid gas over the black oxide of manganese. A combination takes place; the excess of the oxide of manganese is separated by dissolving the hyposulphate of managements in water. Caustic harving meanings in water. manganese is separated by dissolving the hyposulphate of manganese in water. Caustic barytes precipitates the manganese, and forms with the new acid a very soluble salt, which, freed from excess of barytes by a current of carbonic acid, crystallizes regularly, like the nitrate or muriate of barytes. Hyposulphate of barytes being thus obtained, sulphuric acid is cautiously added to the solution, which throws down the barytes, and leaves the hyposulphuric acid in the wa-This acid bears considerable concentration under the receiver of the air-pump. It consists of five parts of oxygen to four of sulphur. The greater number of the hyposulphates, both earthy and metallic, are solu-ble, and crystallize; those of barytes and lime are un-

alterable in the air. Hyposulphuric acid is distinguished by the following

properties:

1st, It is decomposed by heat into sulphurous and sulphuric acids. 2d, It forms soluble salts with barytes, strontites,

lime, lead, and silver

3d, The hyposulphates are all soluble.

4th, They yield sulphurous acid when their solutions are mixed with acids, only if the mixture becomes hot of itself, or be artificially heated.

5th, They disengage a great deal of sulphurous acid at a high temperature, and are converted into neutral

HYPO THENAR. (From υπο, under, and θεναρ, the palm of the hand.) 1. A muscle which runs on the inside of the hand.

That part of the hand which is opposite to the

HYPO'THESIS. An opinion, or a system of gene ral rules, founded partly on fact but principally on conjecture. A theory explains every fact, and every circumstance connected with it; an hypothesis explains only a certain number, leaving some unaccounted for, and others in opposition to it.

HYPO THETON. (From υπο, under, and τιθημι, to put.) A suppository, or medicine introduced into the rectum, to procure stools.

Hypo'xyLon. (From υπο, and ξυλου, wood. A species of clavaria, which grows under old wood.

Hypozo'ma. (From υπο and ζωννυμι, to bind round.) The diaphragm.

Hypsiglo'ssus. (From υψιλοτιδτς, the hyoid bone, and γλωσσα, the tongue.) A muscle named from its origin in the os hyoides, and its insertion in the

HYPSILOI'DES. 1. The Os hyoides.
2. The hyoglossus muscle.

HYPTIA's MOS. (From υπ Γιαζω, to lie with the face upwards.) A supine decubiture, or a nausea, with inclination to vomit.

Hypu'tus. (From υπο, under, and ουλη, a cicatrix.) An ulcer under a cicatrix.

HYSSOP. See Hyssopus.
Hyssop hedge. See Gratiola.
Hyssopitzs. (Hyssopitzs.) Wineim-

Hyssop.

2. The pharmacopæial name of the common hyssop. See Hyssopus efficinalis.

Hyssopus capitata. Wild thyme.

Hyssopus officinalis. The systematic name of the common hyssop. Hyssopus—spicis secundis, foliis lanceolatis of Linnæus. This exotic plant is esteemed as an aromatic and stimulant, but is chiefly employed as a pectoral, and has long been thought useful in humoral asthmas, coughs, and catarrhal affections: for this purpose, an infusion of the leaves, tions; for this purpose, an infusion of the leaves, sweetened with honey, or sugar, is recommended to

be drank as tea. HY'STERA. HY'STERA. (From uggos, behind: so called be-cause it is placed behind the other parts.) The womb.

HYSTERA'LGIA. (From υςτρα, the womb, and αλγος, pain.) A pain in the womb.

HYSTERIA. (From υςτρα, the womb, from which the disease was supposed to arise.) Passio hysterica. Hysterics. Dr. Cullen places this disease in the class Neuroses, and order Spasmi. There are four species:

1. Hysteria chlorotica, from a retention of the

Hysteria & leucorrhæa, from a fluor albus.

3. Hysteria à menorrhagia, from an immoderate flow of the menses.

Hysteria libidinosa, from sensual desires.

The complaint appears under such various shapes, imitates so many other diseases, and is attended with such a variety of symptoms, which denote the animal and vital functions to be considerably disordered, that it is difficult to give a just character or definition of it; and it is only by taking an assemblage of all its appearances, that we can convey a proper idea of it to others. The disease attacks in paravyrages or fits. These are The disease attacks in paroxysms, or fits. These are sometimes preceded by dejection of spirits, anxiety of mind, effusion of tears, difficulty of breathing, sickness at the stomach, and palpitations at the heart; but it more usually happens, that a pain is felt on the left side, about the flexure of the colon, with a sense of distention advancing upwards, till it gets into the stomach, and removing from thence into the throat, it occasions, by its pressure a sensation as if a ball, was casions, by its pressure, a sensation as if a ball was lodged there, which by authors has been called globus hystericus. The disease having arrived at this height, the patient appears to be threatened with suffocation, becomes faint, and is affected with supor and insensibility; while, at the same time, the trunk of the body is turned to and fro, the limbs are variously agitated; wild and irregular actions take place in alternate fits of laughter, crying, and screaming: incoherent expressions are uttered, a temporary delirium prevails, and a frothy saliva is discharged from the mouth. The spasms at length abating, a quantity of wind is evacuated upwards, with frequent signing and sobbing, and the woman recovers the exercise of sense and motion without any collection of what has taken and motion without any recollection of what has taken place dur-ing the fit; feeling, however, a severe pain in her head, and a soreness over her whole body. In some cases, there is little or no convulsive motion, and the person lies seemingly in a state of profound sleep, without either sense or motion. Hiccup is a symptom which likewise attends, in some instances, on hysteria; and now and then it happens, that a fit of hysteria consists of this alone. In some cases, of this nature, it has been known to continue for two or three days, during which it frequently seems as if it would suffocate the patient, and proceeds, gradually weakening her, till it either goes off or else occasions death by suffocation: but this last is extremely rare. Besides hiccup, other slight spasmodic affections sometimes wholly form a fit of hysteria, which perhaps continue for a day or two, and then either go off of themselves, or are re-moved by the aid of medicine. In some cases the pa-

HYSSO'PUS. (Υσσωπος; from Azob, Hebrew.)

1. The name of a genus of plants in the Linnæan system. Class, Didynamia; Order, Gymnospermia.

Hyssop.

2. The pharmacopæial name of the common hyssop. See Hyssopus efficinalis.

HYSSOPUS CAPITATA. Wild thyme.

HYSSOPUS OFFICINALIS. The systematic name of the common hyssop. Hussopus—spicis secundis, folimitation and sympathy.

imitation and sympathy.

Women of a delicate habit, and whose nervous sys-tem is extremely sensible, are those who are most sub-ject to hysteric affections; and the habit which predisposes to their attacks, is acquired by inactivity and a scdentary life, grief, anxiety of mind, a suppression or obstruction of the menstrual flux, excessive evacua-tions, and a constant use of a low diet, or of crude un-

wholesome food.

wholesome food.

Hysteria differs from hypochondriasis in the following particulars, and, by paying attention to them, may always readily be distinguished from it:—Hysteria attacks the sanguine and plethoric; comes on soon after the age of puberty; makes its onset suddenly and violently, so as to deprive the patient of all sense and voluntary motion: is accompanied with the sensation of a ball rising upwards in the throat, so as to threaten suffocation; is attended usually with much spasmodic affection; is more apt to terminate in epilepsy than in any other disease; and, on dissection, its morbid appearances are confined principally to the uterus and ovaria.

The reverse happens in hypochondriasis. It attacks the melancholic; seldom occurs till after the age of thirty-five; comes on gradually; is a tedious disease, and difficult to cure; exerts its pernicious effects on the membraneous canal of the intestines, as well by spasms as wind; is more apt to terminate in melancholy, or a low fever, than in any other disease; and, on dissection, exhibits its morbid effects principally on the liver, spleen, and pancreas, which are often found in a disease state.

Another very material difference might be pointed out between these two diseases, which is, that hysteria is much relieved by advancing in age, whereas hypo-

chondriasis usually becomes aggravated.

Is much relieved by advancing in age, whereas hypochondriasis usually becomes aggravated.

The two diseases have often been confounded together; but, from considering the foregoing circumstances, it appears that a proper line of distinction should be drawn between them.

The hysteric passion likewise differs from a syncope, as in this there is an entire cessation of the pulse, a contracted face, and a ghastly countenance; whereas, in the uterine disorder, there is often something of a colour, and the face is more expanded; there is likewise a pulse, though languid; and this state may continue some days, which never happens in a syncope.

It also differs from apoplexy, in which the abolition of sense and voluntary motion is attended with a sort of snoring, great difficulty of breathing, and a quick pulse; which do not take place in hysteria.

It differs from epilepsy, in that this is supposed to arise in consequence of a distention of the vessels of the brain: whereas, in hysteria, the spasmodic and convulsive motions arise from a turgescence of blood in the uterus, or in other parts of the genital system.

However dreadful and alarming any hysteric fit may appear, still it is seidom accompanied with danger, and the disease never terminates fatally, unless it changes into epilepsy, or that the national is in a yeary week re-

the disease never terminates fatally, unless it changes into epilepsy, or that the patient is in a very weak re-

duced state

duced state.

The indications in this disease are, 1. To lessen the violence of the fits. 2. To prevent their return by obviating the several causes. Where the attack is slight, it may be as well to leave it in a great measure to have its course. But where the paroxysm is severe, and the disease of no long standing, occurring in a young plethoric female, as is most frequent, and especially from suppression of the menses, a liberal abstraction of blood should be made, and will often afford speedy relief. If this step do not appear advisable, and the disorder be rather connected with the state of the primæ viæ, an emetic may check its progress, if the patient can be got to swallow during a remission of the convulsions. At other times the application of cold water to the skin more or less extensively; strong and disagreeable odours, as hartshorn, burnt feathers, &c.; moved by the aid of medicine. In some cases the patient is attacked with violent pain in the back, which extend from the spine to the sternum, and at length become fixed upon the region of the stomach, being evidently of a spasmodic nature, and often prevailing in so high a degree as to cause clammy sweats, a pale cadaverous look, coldness of the extremities, and a pulse hardly perceptible.

Hysteric affections occur more frequently in a single straction of blood should be made, and with other above speed relief. If this step do not appear advisable, and the disorder be rather connected with the state of the prime viæ, an emetic may check its progress, if the patient can be got to swallow during a remission of the convulsions. At other times the application of cold water to the skin more or less extensively; strong and disagreeable odours, as hartshorn, burnt feathers, &c.; rubbing the temples with æther; antispasmodics, particularly opium, by the mouth or in glyster: the pedition of blood should be made, and with other above speed of the stored with the state of the disorder be rather connected with the state of the prime viæ, an emetic may check its progress, if the patient can be got to swallow during a remission of the convulsions. At other times the application of cold water to the skin more or less extensively; strong and disagreeable odours, as hartshorn, burnt feathers, &c.; rubbing the temples with the state of the prime viæ, an emetic may check its progress, if the prime viæ, an emetic may check its progress, if the prime viæ, an emetic may check its progress, if the prime viæ, and as the prime viæ, and an emetic may check its progress, if the prime viæ, and the disorder be rather connected with the state of the disorder be rather connected with the state of the disorder be rather connected with the disorder be rat

luvium, &c. may be resorted to according to the state of the patient. During the intervals, we must endeavour to remove any observable predisposition; in the vour to remove any observable predisposition; in the plethoric, by a spare diet, exercise, and occasional purgatives; in those who are weakly, and rather deficient in blood, by proper nourishment, with chalybeates, or other tonic medicines. The state of the uterine functions are relieved to as well as that other tonic medicines. The state of the uterine runc-tion must be particularly attended to, as well as that of the primæ viæ; those catharties are to be preferred which are not apt to occasion flatulence, nor particuwhich are not apt to occasion flatulence, nor particularly irritate the rectum, unless where the menses are interrupted, when the aloetic preparations may claim a preference; and the perspiration should be maintained by warm clothing, particularly to the feet, with the prudent use of the cold bath. The mind ought also to be occupied by agreeable and useful pursuits, and regular hours will tend materially to the restoration of the general health. the general health.

HYSTERIA'LGES. (From vgcpa, the womb, and al-HYSTERIA'LGES.

pain in the uterus.

2. Hippocrates applies this word to vinegar.
3. The pains which resemble labour-pains, generally called false pains.

HYSTERITIS. (From v5c0a, the womb.) Me-HYSTERI'TIS. (From v5tpa, the womb.) Metritis. Inflammation of the womb. A genus of disease in the class Pyrexia, and order Phlegmasia, of Cullen; characterized by fever, heat, tension, tumour, and pain in the region of the womb; pain in the os uteri, when touched, and vomiting.

In natural labours, as well as those of a laborious sort, many causes of injury to the uterus, and the peri-

sort, many causes of injury to the uterus, and the per-tonaum which covers it, will be applied. The long continued action of the uterus on the body of the child, and the great pressure made by its head on the soft parts, will further add to the chance of injury. Besides these, an improper application of instruments, or an officiousness of the midwife in hurrying the labour, may have contributed to the violence. these causes may be added exposure to cold, by taking the woman too early out of bed after delivery, and thereby throwing the circulating fluids upon the internal parts, putting a stop to the secretion of milk, or occasioning a suppression of the lochia.

An inflammation of the womb is sometimes per-

An inflammation of the womb is sometimes per-fectly distinct, but is more frequently communicated to the peritoneum, Fallopian tubes, and ovaria; and having once begun, the natural functions of the organ become much disturbed, which greatly adds to the disease. It is oftener met with in women of a robust and plethoric habit than in those of lax fibres and a dehad pethoric habit than in those of fax fibres and a de-ficate constitution, particularly where they have in-dulged freely in food of a heating nature, and in the use of spirituous liquors. It never prevails as an epi-demic, like puerperal fever, for which it has probably often been mistaken; and to this we may, with some reason, ascribe the difference in the mode of treatment which has taken place among physicians.

which has taken place among physicians.

An inflammation of the uterus shows itself usually about the second or third day after delivery, with a painful sensation at the bottom of the belly, which gradually increases in violence, without any kind of gradually increases in violence, without any kind of intermission. On examining externally, the uterus appears much increased in size, is hard to the feel, and on making a pressure upon it, the patient experiences great soreness and pain. Soon afterward there ensues an increase in heat over the whole of the body, with pains in the head and back, extending into the groins, rigors, considerable thirst, nausea, and vomiting. The tongue is white and dry, the secretion of milk is usually much interrupted, the lochia are greatly diminished, the urine is high-coloured and scanty; the body is costive, and the pulse hard, full, and frequent.

These are the symptoms which usually present them-selves when the inflammation does not run very high, and is perfectly distinct; but when it is so extensive as to affect the peritoneum, those of irritation succeed, and soon destroy the patient.

Uterine inflammation is always attended with much

danger, particularly where the symptoms run high, and the proper means for removing them have not been timely adopted. In such cases, it may terminate in suppuration, scirrhus, or gangrene.

Suppuration, scirrhus, or gangrene.

Frequent rigors, succeeded by flushings of the face, quickness and weakness of the pulse, great depression of strength, delirium, and the sudden cessation of pain and soreness in the region of the abdomen, denote a fatal termination. On the contrary, the ensuing of a gentle diarrhea, the lochial discharge returning in due quantity and quality, the secretion of milk recommencing, and the uterus becoming gradually softer and less tender to the touch, with an abatement of heat and thirst, prognosticate a favourable issue.

When shiverings attack the patient, after several days' continuance of the symptoms, but little relief can be afforded by medicine, the event being generally fatal. In this case, the woman emaciates and loses her strength, becomes hectic, and sinks under colliquative

strength, becomes hectic, and sinks under colliquative

sweating, or purging.

Upon opening the bodies of women who have died of this disease, and where it existed in a simple state, little or no extravasated fluid is usually to be met with in the cavity of the abdomen. In some instances, the peritonwal surfaces have been discovered free from the peritonwal surfaces have been discovered free from the disease; while in others, that portion which covers the uterus and posterior part of the bladder, has been found partially inflamed. The inflammation has been observed, in some cases, to extend to the ovaria and Fallopian tubes, which, when cut open, are often loaded with blood. The uterus itself usually appears of a firm substance, but is larger than in its patternal state, and, when cut into, a quantity of pus natural state, and, when cut into, a quantity of pus is often found. Gaugrene is seldom, if ever, to be met with.

HYSTEROCE'LE. (From υςερα, the womb, and κηλη, a tumour.) A hernia of the womb. This is occasioned by violent muscular efforts, by blows on the abdomen at the time of gestation, and also by wounds and abscesses of the abdomen which permit the uterus to dilate the part. Ruysch relates the case of a woman, who, becoming pregnant after an ulcer had been healed descended into a dilated sac of the peritonaum in that weakened part, till it hung, with the included foctus, at her knees. Yet when her full time was come, the midwife reduced this wonderful hernia, and, in a natural sale of a sale of the sale o

ral way, she was safely delivered of a son.

Hy'STERON. (From ustoos, afterward; so named because it comes immediately after the feetus.) The

HYSTEROPHY'SA. (From v5epa, the womb, and φυσα, flatus.) A swelling, or distention of the womb, from a collection of air in its cavity.

HYSTERO TOMY. (Hysterotomia; from υς ερα,

the womb, and τεμνω, to cut.) See Casarian ope-

ration.

ration.

HYSTEROTOMATOCIA. See Casarian operation.
HYSTEROPTO'SIS. (From υςτοα, the womb, and πιπτω, to fall.) A bearing down of the womb.
HYSTRICI'ASIS. (From υςτοξ, a hedge-hog, or porcupine.) A disease of the hairs, in which they stand erect, like porcupine quills. An account of this rare disease is to be seen in the Philosophical Transactions, No. 424.
Hy'stricis lapis. See Bezoar hystricis.
HYSTRI'TIS See Hysteritis.

TATRALEI'PTES. (From ιατρος, a physician, and αλειφω, to anoint.) One who undertakes to cure distempers by external unction and friction: Galen makes mention of such in his time, particularly one Diotas; and Pliny informs us, that this practice was first introduced by Prodicus of Selymbria, who was a disciple of Æsculapius.

IATROCHY MICUS. (From tarpos, a physician,

and χυμια, chemistry.) Chymiater. A chemical physician, who cures by means of chemical medicines.

IATROLI'PTICE. (From ιατρος, a physician, and αλειφω, to anoint.) The method of curing diseases by unction and friction.

IATROPHY SICUS. (From tarpos, physician, and ovots, nature.) An epithet bestowed on some writings which treat of physical subjects with relation to

IBE'RIS. (So named from Iberia, the place of its natural growth.) 1. The name of a genus of plants in the Linnaan system. Class, Tetradynamia; Order, Siliculosa.

The pharmacopæial name of the Sciatica cresses. See Lepidium iberis.

IBIRA'CE. See Guaiacum.

TBIS. Iβις. A bird much like our kingfisher, taken notice of by the Egyptians, because, when it was sick, it used to inject with its long bill the water of the Nile into its fundament, whence Langius, lib. ii. ep. ii.

Nile into its fundament, whence Langius, lib. ii. ep. ii. says they learned the use of clysters.

IBI'SCUS. (From 1\beta_{\beta}, the stork, who was said to chew it and inject it as a clyster.) Marshmallow.

IBI'XUMA. (From 1\beta_{\beta \beta \beta}, the mallow, and 1\beta_{\beta}, glue: so named from its having a glutinous leaf, like the mallow.) Saponaria arbor. The soap tree, probably the Sapindus saponaria of Linneus.

ICE. Glacies. Water made solid by the application of cold. It is frequently applied by surgeons to resolve external inflammatory diseases, to stop homore.

resolve external inflammatory diseases, to stop hæmorrhages, and constringe relaxed parts.

Iceland spar. A calcareous spar.

I'CHOR. (Ιχωρ.) A thin, aqueous, and acrid dis-

Charge. PCTHYA. $(J\chi\theta\nu\alpha$, a fish-hook; from $(\chi\theta\nu\varsigma$, a fish.) The skin of the Squatina, or monkfish. 2. The name of an instrument like a fish-hook, for

extracting the fœtus.

See Ichthyosis.

ICHTHYOCO'LLA. (From 1χθυς, a fish, and κολλα, glue.) Colla piscium. Isinglass. Fish glue. This substance is almost wholly gelatin; 100 grains of good dry isinglass containing rather more than 98 of matter soluble in water.

Isinglass is made from certain fish found in the Danube, and the rivers of Muscovy. Willoughby and others inform us, that it is made of the sound of the Beluga; and Neumann, that it is made of the Huso Germanorum, and other fish, which he has frequently seen sold in the public markets of Vienna. Jackson remarks, that the sounds of cod, properly prepared, afford this substance; and that the lakes of America abound with fish from which the very finest sort may be obtained.

Isinglass receives its different shapes in the following manner: the parts of which it is composed, particularly the sounds, are taken from the fish while sweet and fresh, slit open, washed from their slimy sordes, divested of a very thin membrane which envelopes the sound, and then exposed to stiffen a little in the air. In this state, they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple: a thin membrane is generally selected for the centre of the roll, round which

the rest are folded alternately, and about half an inch of each extremity of the roll is turned inwards.

Isinglass is best made in the summer, as frost gives it a disagreeable colour, deprives it of weight, and im-

a disagreeasic tonormal and the pairs its gelatinous principles.

Isinglass boiled in milk forms a mild nutritious jelly,

This, when flavoured by the art of the cook, is the blancmanger of our tables A solution of isinglass in water, with a very small proportion of some balsam, spread on black silk, is the court-plaster of the shops.

[That variety of the codfish called the Hake, and

that variety of the coalish called the Hake, and known to naturalists as the Gadus Merluccius, has a very large sound or swimming bladder, which affords ichthyocolla in abundance. In 1824, a quantity was presented to the New-York Lyceum of Natural History for their inspection, and a committee of that learned body made the following report on the subject:

"The Isinglass, or Ichthyocolla, made by Mr. William Hall, at the Isle of Shoals, which was presented by him, for examination, at the last sitting of the Ly ceum, has been submitted to several experiments by the committee. It proved more pure than the Russian isinglass, with which it was compared, possesses greater solubility, and exhibits more tenacity; and its solution resists longer the process of putrefaction; but it retains to a peculiar degree the unpleasant flavour peculiar to fish.

The result of the experiment induces the committee to recommend the article as a valuable acquisition to our domestic manufactures. It is found excellent in clarifying liquors, and merits the particular attention of brewers; it is valuable in preparing leather, render-ing it soft and pliable, and deserves to be employed in cotton manufactories for glazing, and starching gene-In its present state, however, it would not be agreeable as an article in the preparation of food; it

might be, if deprived of the fishy smell.

The form of the ichthyocolla from the Isle of Shoals, is far preferable to that of foreign manufacture. The peculiar shape of the isingless from the Muscovy rivers was probably adopted to conceal and disguise the real substance, and to preserve the mono-poly; but now, as the subterfuge is no longer necessary, it is acknowledged to answer every purpose more effectually in its native state. In the rolled or curled form, it is more apt to retain oily particles and exuvia of insects between the membranes, that frequently contaminate the liquor for whose clarification it is em-ployed. The sounds of the Cod (gadus morhua) and Ling (gadus molva) have long been used by Newfoundland (gadus moiva) have long been used by Newloundland and Iceland fishermen, and bear a strong resemblance to those of the genus Accipenser; the Huso (or Beluga) which family has always supplied Muscovy (to which country we are originally indebted for it) with this article of commerce. Mr. Hall, alone, as far as we know, employs the Hake (gadus merluccius) and he offers his isinglass at \$4,000 a ton, nearly one quarter less than we pay for the foreign, of which 100 tons are every year imported. If the manufacture tons are every year imported. If the manufacture succeeds, of which (with capital and zeal) we little doubt, it will save yearly from 80 to \$100,000 to our citizens; at the same time it opens to them a field of enterprise which will yield annually from 4 to \$5,000, and

which must increase with the growth of our country.

In concluding, we may remark, that Mr. Hall employs the mode described in the 63d volume of the Transactions of the Royal Society of London, but

without previously salting the sounds.

J. VAN RENSSELAER. J. E. DE KAY. SAMUEL AKERLY.

Mr. Hall observes that the unpleasant smell of the isinglass can be entirely extracted by three weeks' exposure to the night-air, after finished."—From the Statesman, Jan. 9th, 1824.]
ICHTHYOPHTHAL'MITE. Fish eyestone. See

ICHTHYOPHTHAL MITE. Fish eyestone. See Apophyllite.

ICHTHYO'SIS. (From ιχθυα, the scale of a fish; from the resemblance of the scales to those of a fish.) Ichthyasis. A genus of diseases of the second order of Dr. Willan's disease of the skin. The characteristic of ichthyosis is a permanently harsh, dry, scaly, and in some cases, almost horny texture of the integuments of the body, unconnected with internal disorder. Psoriasis and Lepra differ from this affection, in being but partially diffused, and in having deciduous scales. but partially diffused, and in having deciduous scales.

The arrangement and distribution of the scales in ichthyosis are peculiar. Above and below the olecranon on the arm, says Dr. Willan, and in a similar situation with respect to the patella on the thigh and leg, they are small, rounded, prominent, or papillary, and of a black colour; some of the scaly papillae have a short, narrow neck, and broad irregular tops. On some part of the extremities, and on the trunk of the body, the scales are flat and large, often placed like tiling, or in the same order as scales on the back of a fish; but, in a few cases, they have appeared separate, being intersected by whitish furrows. There is usually in this complaint a dryness and roughness of the soles of the feet; sometimes a thickened and brittle state of the skin in the palms of the hands, with large painful fissures, and on the face an appearance of the scurf rather than of scales. The inner part of the wrist, the hams, the inside of the elbow, the furrow along the spine, the inner and upper part of the thigh, are perhaps the only portions of the skin always exempt from the scaliness. Patients affected with ichthyosis are occasionally much harased with infamed pustures or with large painful biles on different parts of tules, or with large painful biles on different parts of the body; it is also remarkable, that they never seem to have the least perspiration or moisture of the skin. This disease did not, in any case, appear to Dr. Willan to have been transmitted hereditarily; nor was more than one child from the same parents affected with it. Dr. Willan never met with an instance of the horny Dr. Willan never met with an instance of the horny rigidity of the integuments, Ichthyosis cornea, impeding the motion of the muscles or joints. It is, however, mentioned by authors as affecting the lips, prepuce, toes, fingers, &c. and sometimes as extending over nearly the whole body.

ICOSA'NDRIA. (From εκοσι, twenty, and ανηρ, a man, or husband.) The name of a class of plants in the sexual system of Linnæus, consisting of those which have hermaphrodite flowers furnished with twenty or more staming that are inserted into the inner

twenty or more stamina that are inserted into the inner side of the calyx, or petals, or both. By this last cir-cumstance is this class distinguished from Polyandria.

ICTERITIA. (From icterus, the jaundice.)
An eruption of yellowish spots.

2. A yellow discoloration of the skin.
I'CTERUS. (Named from its likeness to the plumage of the golden thrush, of which Pliny relates, that if a jaundiced person looks on one, the bird dies, and the patient recovers.) Morbus arcuatus, or arquatus; Aurigo; Morbus regius; Morbus lescoli. The jaundice. A genus of disease in the class Cachezia, and order Impetigines, of Cullen; characterized by yellowness of the skin and eyes; faces white, and urine of a high colour. There are six species:—

of a high colour. There are six species:—

1. Icterus calculosus, acute pain in the epigastric region, increasing after eating: gall-stones pass by

Icterus spasmodicus, without pain, after spasmo-

dic diseases and passions of the mind.

3. Icterus mucosus, without either pain, gall-stones, or spasm, and relieved by the discharge of tough phlegm by stool.

4. Icterus hepaticus, from an induration in the liver. Icterus gravidarum, from pregnancy, and disappearing after delivery.

6. Icterus infantum, of infants. It takes place most usually in consequence of an interrupted excretion of bile, from an obstruction in the ductus communis choledochus, which occasions its absorption into the blood-vessels. In some cases it may, however, be owing to a redundant secretion of the bile. The causes producing the first species are, the presence of biliary calculi in the gall-bladder and its ducts; spasmodic constriction of the ducts themselves; and, lastly, the pressure made by tumours in adjacent parts; hence jaundice is often an attendant symptom on a scirrhosity of the liver, pancreas, &c., and on

Chronic bilious affections are frequently brought on by drinking freely, but more particularly by spirituous. liquors: hence they are often to be observed in the debauchee and the drinker of drams. They are likewise frequently met with in those who lead a sedentary life; and who indulge much in anxious thoughts.

A slight degree of jaundice often proceeds from the redundant secretion of bile; and a bilious habit is therefore constitutional to some people, particularly to those who reside long in a warm climate.

By attending to the various circumstances and symp By attending to the various circumstances and symptoms which present themselves, we shall in general be able to ascertain, with much certainty, the real nature of the cause which has given rise to the disease.

We may be assured by the long continuance of the complaint, and by feeling the liver and other parts externally, whether or not it arises from disease of the liver, pancreas, or adjacent parts.

Where passions of the mind induce the disease, without any hardness or enlargement of the liver, or adjacent parts, and without any appearance of calculi

without any nardness or enlargement of the liver, or adjacent parts, and without any appearance of calculi in the faces, or on dissection after death, we are naturally induced to conclude that the disorder was owing to a spasmodic affection of the biliary ducts.

Where gall-stones are lodged in the ducts, acute lancinating pains will be felt in the region of the parts, which will cease for a time and then return acad.

which will cease for a time, and then return again; great irritation at the stomach and frequent vomiting will attend, and the patient will experience an aggra-vation of the pain after eating. Such calculi are of various sizes, from a pea to that of a walnut; and, in some cases, are voided in a considerable number, being, like the gall, of a yellowish, brownish, or green colour.

The jaundice comes on with languor, inactivity, loathing of food, flatulence, acidities in the stomach and bowels, and costiveness. As it advances in its progress, the skin and eyes become tinged of a deep yellow; there is a bitter taste in the mouth, with frequent nausea and vomiting; the urine is very high-coloured; the stools are of a gray or clayey appearance, and a dull obtuse pain is felt in the right hypochon-drium, which is much increased by pressure. Where drium, which is much increased by pressure.

the pain is very acute, the pulse is apt to become hard and full, and other febrile symptoms to attend.

The disease, when of long continuance, and proceeding from a chronic affection of the liver, or other neighbouring viscera, is often attended with anasarcous swellings, and sometimes with ascites: also scorbuite symptoms frequently supervene.

Where impudice is recent, and is occasioned by con-

Where jaundice is recent, and is occasioned by con-oretions obstructing the biliary ducts, it is probable that, by using proper means, we may be able to effect a cure; but where it is brought on by tumours of the neighbouring parts, or has arisen in consequence of other diseases attended with symptoms of obstructed viscera, our endeavours will most likely not be crowned with success. Arising during a state of pregcrowned with success. Arising during a state of preg-nancy, it is of little consequence, as it will cease on

On opening the bodies of those who die of jaundice, the yellow tinge appears to pervade even the most in-terior part of the body; it is diffused throughout the whole of the cellular membrane, in the cartilages and bones, and even the substance of the brain is coloured with it. A diseased state of the liver, gall-bladder, or

adjacent viscera, is usually to be met with.

The Icterus infantum, or yellow gum, is a species of jaundice which affects children, at or soon after their birth, and which usually continues for some their birth, and which usually continues for some days. It has generally been supposed to arise from the meconium, impacted in the intestines, preventing the flow of bile into them. The effects produced by it are languor, indolence, a yellow tinge of the skin, and a tendency to sleep, which is sometimes fatal, where the child is prevented from sucking.

The indications in this disease are 1. To passive

The indications in this disease are, 1. To palliate urgent symptoms. 2. To remove the cause of obstruction to the passage of the bile into the duodenum: this tion to the passage of the bile into the duodenum: this is the essential part of the treatment; but the means will vary according to circumstances. When there are appearances of inflammation, of which perhaps the jaundice is symptomatic, or both produced by a gall-stone, the means explained under the head of hepatitis will be proper. If there be severe spasmodic pain, as is usual when a gall-stone is passing, the liberal use of opium and the warm bath will probably relieve it. After which, in all instances, where there is lieve it. After which, in all instances, where there is reason for supposing an obstructing cause within the duct, a nauseating emetic, or brisk cathartic, would be the most likely to force it onward: emetics, however, are hardly advisable, except in recent cases without inflammation; and calomel, seeming to promote the discharge of bile more than other cathartics, may be given in a large dose with or after the opium. remedies have been recommended, on the idea that they may dissolve gall-stones; which, however, is hardly probable, unless they should have advanced to

the end of the common duct: the fixed alkalies, ether the end of the common duct: the fixed alkalies, guer-with oil of turpentine, raw eggs, &c. come under this head; though the alkalies may be certainly beneficial by correcting acidity, which usually results from a de-ficient supply of bile to the intestines; and possibly alter the secretion of the liver so much as to prevent the formation of more concretions. When the com-plaint arises from scirrhous tumours, mercury is the remedy most likely to afford relief particularly should remedy most likely to afford relief, particularly should the liver itself be diseased; but it must be used with proper caution, and hemlock, or other narcotic, may sometimes enable the system to bear it better. Where this remedy is precluded, nitric acid promises to be the this remedy is precluded, nitric acid promises to be the best substitute, the taraxacum appears by no means so much to be depended upon. In all tedious cases the strength must be supported by the vegetable bitters, or other tonics, and a nutritions diet, easy of digestion: there is often a dislike of animal food; and a craving for acids, which mostly may be indulged; indeed, when scorbutic symptoms attended, the native vegetable acids have been sometimes very serviceable. The bowels must be kept regular, and the other secretions bowels must be kept regular, and the other secretions promoted, to get rid of the bile diffused in the system; as well as to obviate febrile or inflammatory action. When accumulations of hardened faces induce the complaint, or in the icterus infantum, catharties may be alone sufficient to afford relief, and in that of present be alone sufficient to afford relief: and, in that of preg-nant females, we must chiefly look to the period of delivery.

ICTERUS ALBUS. The white jaundice. Chlorosis

is sometimes so called.
I'CTUS. 1. A stroke or blow. The pulsation of an artery.

 The phisation of an artery.
 The sting of a bee, or other insect.
 IDÆUS. (From κôη, a mountain in Phrygia, their ative place.) A name of the peony and blackberry.
 IDE. This terminal is affixed to oxygen, chlorine. native place.)
IDE. This

and iodine, when they enter into combination with each other, or with simple combustibles or metals in proportions not forming an acid, thus ox-ide of chlorine, ox-ide of nitrogen, chlor-ide of sulphur, iod-ide

IDE'OLOGY. (Ideologia; from ιδεα, a thought, and λογος, a discourse.) The doctrine or study of the understanding. "Whatever be the number and the diversity of the phenomena which belong to human intelligence, however different they appear from the other phenomena of life, though they evidently depend on the soul, it is absolutely necessary to consider them as the result of the action of the brain, and to mal no distinction between them and the other phenon na that depend on the actions of that organ. The functions of the brain are absolutely subject to the same laws as the other functions; they develope and go to decay in the progress of age; they are modified by habit, sex, temperament, and individual disposition; they become confused, weakened, or elevated in diseases; the physical injuries of the brain weaken or destroy them; in a word, they are not susceptible of any ex-planation more than the other actions of the organ; and setting aside all hypothetical ideas, they are capa-ble of being studied only by observation and experience.

We must also be cautious in imagining that the study of the functions of the brain is more difficult than that of the other organs, and that it appertains peculiarly to metaphysics. By keeping close to observation, and avoiding carefully any theory, or conjecture, this study becomes purely physiological, and perhaps it is easier than the most part of the other functions, on account of the facility with which the phenomena can be produced and observed. The innumerable phenomena which form the intellect of man, are only phenomena which form the intellect of man, are only modifications of the faculty of perception. If they are examined attentively, this truth, which is well illustrated by modern metaphysicians, will be found very

There are four principal modifications of the faculty

of perception.

1st. Sensibility, or the action of the brain, by which we receive impressions, either from within or from

without.
2d. The Memory, or the faculty of reproducing im-

pressions, or sensations formerly received.

3d. The faculty of perceiving the relations which sensations have to each other, or the Judgment.

4th. The Desires, or the Will.

The study of the understanding, from whatever cause, is not at present an essential part of physiology; the science which treats particularly of it is Ideology. Whoever may wish to acquire an extensive knowledge on this interesting subject, should consult the works of Bacon, Locke, Condillac, Cabanis, and especially the excellent book of Destutt Tracy, entitled "Elements

of Ideology."

IDIOCRA'SIA. See Idiosyncrasy.

IDIOPA'THIC. (Idiopathicus; from τότος, peculiar, and παθος, an affection.) A disease which does not depend on any other disease, in which respect it is opposed to a systematic disease, which is dependent

opposed to a systematic disease, which is dependent on another.

IDIOSY'NCRASY. (Idiosyncrasia; from totos, peculiar, gov., with, and soasts, a temperament.) A peculiarity of constitution, in which a person is affected by certain agents, which, if applied to a hundred other persons, would produce no effect: thus some people cannot see a finger bleed without fainting; and thus violent inflammation is indeed on the skin of some people in the substances that are perfectly innocent to persons, by substances that are perfectly innocent to

IDIOT'ROPIA. (From ιδιος, peculiar, and τρεπω, to turn.) The same as Idiosyncrasia.

IDOCRASE. See Vesuvian.

IGASURIC ACID. Acidum Igusaricum. Pelletier and Caventou, in their elegant researches in the faba Sancti Ignatii, et nux vomica, having observed that these substances contained a new vegetable base (strychnine) in combination with an acid, sought to separate the latter, in order to determine its nature. appeared to them to be new, and they called it ignsuric acid, from the Malay name by which the natives designate in the Indies the faba Sancti Ignatii. This bean, according to these chemists, is composed of igasurate of strychnine, a little wax, a concrete oil, a yellow colouring matter, gum, starch, bassorine, and vegetable fibre.

To extract the acid, the rasped bean must be heated To extract the acid, the rasped bean must be heated in ether, in a digester, with a valve of safety. Thus the concrete oil, and a little igasurate of strychnine, are dissolved out. When the powder is no longer acted on by the ether, they subject it, at several times, to the action of boiling alkohol, which carries off the oil which had escaped the ether, as also wax, which is deposited on cooling, some igasurate of strychnine, and colouring matter. All the alkoholic decoctions are united, filtered, and evaporated. The brownish-yellow residuum is diffused in water; magnesia is now added, and the whole is boiled together for some minutes. and the whole is boiled together for some minutes By this means, the igasurate is decomposed, and from this decomposition there results free strychnine, and a sub-igasurate of magnesia, very little soluble in water. Washing with cold water removes almost completely the colouring matter, and boiling alkohol then separates the strychnine, which falls down as the liquid cools. Finally, to procure igasuric acid from the sub-igasurate of magnesia, which remains united to a small quantity of colouring matter, we must dissolve the magnesian salt in a great body of boiling distilled water; concentrate the liquor, and add to it acetate of lead, which immediately throws down the acid in the state of an igasurate of lead. This compound is then decomposed, by transmitting a current of sulphuretted hydrogen through it, diffused in 8 or 10 times its weight of boiling

This acid, evaporated to the consistence of syrup, and left to itself, concretes in hard and granular crys tals. It is very soluble in water, and in alkohol. Its taste is acid and very styptic. It combines with the alkaline and earthy bases, forming salts soluble in water and alkohol. Its combination with barytes is very soluble, and crystallizes with difficulty, and mushroom-like. Its combination with ammonia, when perfectly neutral, does not form a precipitate with the salts of silver, mercury, and iron; but it comports itself with the salts of copper in a peculiar manner, and which seems to characterize the acid of strychnes (for the same acid is found in muz vomica, and in snake-wood, bois de couleurre): this effect consists in the decomposition of the salts of copper, by its ammoniacal compound. These salts pass immediately to a green colour, and gradually deposite a greenish-white salt, of very sparing solubility in water. The acid of strycknow seems thus to resemble meconic acid; but it differs essentially from it, by its action with saits of iron,

which immediately assume a very deep red colour with the meconic acid; an effect not produced by the acid of strycknos. The authors, after all, do not positively affirm this acid to be new and peculiar.

IGNA TIA (So passed by Linear Produced By Linear Produc

strychnos. The authors, after all, do not positively affirm this acid to be new and peculiar.

IGNA'TIA. (So named by Linnæus, because the seeds are known in the materia medica by the name of Saint Ignatius's beans.) The name of a genus of plants. Class, Pentandria; Order, Monogynua.

IGNATIA AMARA. The systematic name of the plant which affords St. Ignatius's bean; Faba indica; Faba Sancti Ignatii; Faba febrifuga. These beans are of a roundish figure, very irregular and uneven, about the size of a midding nutmeg, semi-transparent, and of a hard, horny texture. They have a very bitter taste, and no considerable smell. They are said to be used in the Philippine islands in all diseases, acting as a vomit and purgative. Infusions are given in the

a vomit and purgative. Infusions are given in the cure of intermittents, &c.

IGNATIUS'S BEAN. See Ignatia amara.

IGNS. Fire. 1. Van Helmont, Paracelsus, and other alchemists, applied this term to what they considered as universal substants. sidered as universal solvents.

2. In medicine, the older writers used it to express several diseases characterized by external redness and

IGNIS CALIDUS. A hot fire: a gangrene: also a violent inflammation, just about to degenerate into a gangrene, were formerly so called by some.

IGNIS FATUUS. A luminous appearance or flame, frequently seen in the night in different country places, and called in Factory for key beith a lantern or Kell with

and called in England Jack with a lantern, or Will with the wisp. It seems to be mostly occasioned by the extrication of phosphorus from rotting leaves and other vegetable matters. It is probable, that the motionless ignes fatui of Italy, which are seen nightly on the same spot, are produced by the slow combustion of sulphur, emitted through clefts and apertures in the soil of that volcanic country.

IGMS FRIGIDUS. A cold fire. A sphacelus was so called, because the parts that are so affected become

as cold as the surrounding air.

IGNIS PERSICUS. A name of the erysipelas, also of the carbuncle. See Anthraz.

IGNIS ROTA. Fire for fusion. It is when a vessel, which contains some matter for fusion, is surrounded with live, i. e. red-hot, coals.

IGNIS SACER. A name of crysipelas, and of a species

of herpes.

IONIS SAPIENTIUM. Heat of horse-dung. IGNIS SANCTI ANTONII. See Erysipelas. IONIS SYLVATICUS. See Impetigo. IONIS VOLAGRIUS. See Impetigo. IONIS VOLATICUS. See Erysipelas.

I'KAN RADIX. A somewhat oval, oblong, compressed root, brought from China. It is extremely rare, and would appear to be the root of some of the orchis

l'LAPHIS. A name in Myrepsus for the burdoch.

See Arctium lappa.

I'lech. By this word, Paracelsus seems to mean a

first principle.

Hippocrates describes it in lib. LEON CRUENTUM. Hippocrates describes it in lib. De Intern. Affect. In this disease, as well as in the scurvy, the breath is factid, the gums recede from the teeth, hemorrhages of the nose happen, and sometimes there are ulcers in the legs, but the patient can move

TLEUM. (From ειλεω, to turn about; from its convolutions.) Ileum intestinum. The last portion of the small intestines, about rifteen hands' breadth in length, which terminates at the valve of the cocum. See Intestine.

ILEUS. See Iliac passion.
I'LEX. (The name of a genus of plants in the
Linnman system. Class, Tetrandria; Order, Tetra-

gynia.) The holly.

ILEX AQUIFOLIUM. The systematic name of the common holly. Aquifolium. The leaves of this plant, Ilex—foliis ovatis acutis spinosis, of Linnaus, have been known to cure intermittent fevers; and an infusion of the leaves, drank as tea, is said to be a pre-

ventive against the gout.

ILEX CASSINE. Cassina; Apalachine gallis. This tree grows in Carolina; the leaves resemble those of senna, blackish when dried, with a bitter taste, and aromatic smell. They are considered as stomachic rewing it as it grows dry, with a view of heating, dry-

small intestines.

2. The small intestines.

2. The small intestines.
I'LIAC. (Iliacus; from ileum intestinum.) Belonging to the ilium; an intestine so called.

LIAC ARTERIES. Arteriæ iliacæ. The arteries so called are formed by the bifurcation of the aorta, near the last lumbar vertebra. They are divided into internal and external. The internal iliac, also called the hypograstic artery, is distributed in the fœtus into six, and in the adult into five branches, which are divided about the pelvis, viz. the little iliac, the gluteal, the ischiatic, the pudical, and the obturatory; and in the fœtus, the umbilical. The external iliac proceeds out of the pelvis through Poupart's ligament, to form the of the pelvis through Poupart's ligament, to form the femoral artery

ILIAC PASSION. (Ειλεος, ιλεος, ειλειος, is described as a kind of nervous colic, the seat of which is the ilium.) Passio iliaca; Volvulus; Miserere mei; Convolvulus; Chardapsus; Tormentum. A violent vomiting, in which the fæcal portion of the food is voided by the mouth. It is produced by many morbid conditions of the bowels, by inflammatory affections of the abdominal viscers, and by hernism.

nal viscera, and by hernize.

ILIAC REGION. The side of the abdomen, between

ILIAC REGION. The side of the abdomen, between the ribs and the hips. ILI'ACUS. The name of muscles, regions, or dis-eases, situated near to, or connected with, parts about the ilia or flanks.

ILIACUS INTERNUS. Iliacus of Winslow. Iliaco trachanten of Dumas. A thick, broad, and radiated muscle, which is situated in the peivis, upon the inner surface of the ilium. It arises fleshy from the inner lip of the ilium, from most of the hollow part, and likewise from the edge of that bone, between its anterior superior spinous process and the acetabulum. It joins with the pages magnus, where it begins to become tenwith the psoas magnus, where it begins to become ten-dinous, and passing under the ligamentum Fallopii, is inserted in common with that muscle. The tendon of this muscle has been seen distinct from that of psoas, and, in some subjects, it has been found divided into two portions. The iliacus internus serves to assist the psoas magnus in bending the thigh, and in bringing it directly forwards.

ILI'ADUM. Iliadus. The first matter of all things, consisting of mercury, salt, and sulphur. These are Paracelsus's three principles. His iliadus is also a mineral spirit, which is contained in every element,

and is the supposed cause of diseases.

LLA'STER. Paracelsus gives this name to the occult

virtue of nature, whence all things have their increase. ILI'NGOS. (From $t\lambda t\gamma \xi$, a vortex.) A giddiness, in which all things appear to turn round, and the eyes grow dim.

Lu'scus. Avicenna says, it is madness caused by

love.
I'LIUM OS. (From ilia, the small intestines; so named because it supports the ilia.) The haunch-bone. The superior portion of the os innominatum, which, in the superior portion of the os innominatum os. the fœtus, is a distinct bone. See Innominatum os. ILLA. See Ula.

ILLE/CEBRA. (From ειλεω, to turn; because its leaves resemble worms.) See Sedum acre.

ILLI'CIUM. (Rlicium, ab illiciendo; denoting an enticing plant, from its being very fragrant and aromatic.) The name of a genus of plants in the Linnman system. Class, Polyandria; Order, Polygynia.

ILLICIUM ANISATUM. The systematic name of the

yellow-flowered aniseed-tree: the seeds of which are stinense; Semen badian. They are used with the same views as those of the Pimpinella anisum. The same tree is supposed to furnish the aromatic bark, called cortex anisi stellati, or cortex lavola.

ILLO SIS. (From ιλλος, the eye.) A distortion of

the eyes.

ILLUTANE'NTUM. An ancient form of an external medicine, like the Ceroma, with which the limbs of wrestlers, and others delighting in like exercises, were rubbed, especially after bathing; an account of which may be met with in Bactius De Thermis.

ing, and discussing. It was chiefly done with the mud

found at the bottom of mineral springs.

LLYS. (From ιλλος, the eye.) A person who squints, or with distorted eyes.

TLYS. (From ιλυς, mud.) 1. The fæces of wine. An obsolete term.

2. The sediment in stools which resemble feces of

The sediments in urine, when it resembles the

IMBECI'LLITAS OCULORUM. Celsus speaks of the Nyctalopia by this name.

IMBIBI'TIO. (From imbibo, to receive into.) An obsolete term. In chemistry for a kind of cohobation, when the liquor ascends and descends upon a solid sub-

stance, till it is fixed therewith.

IMBRICATUS. Imbricated: like tiles upon a house.

A term applied to leaves as those of the Euphorbia

IMMERSUS. Immersed: plunged under water-folia immersa: leaves which are naturally under the water, and are different from those which naturally float. See Leaf

It is remarked by Linnæus, that aquatic plants have their lower, and mountainous ones their upper, leaves most divided, by which they better resist the action of

the stream in one case, and of the wind in the other.

IMME asus. A term given by Bartholine, and some other anatomists to the Subscapularis muscle, because

other anatomists to the Subscaputaris muscle, occause it was hidden, or, as it were, sunk.

IMPA'TIENS. (From in, not, and patier, to suffer; because its leaves recede from the hand with a cracking noise, as impatient of the touch, or from the great elasticity of the sutures of its seed vessel which is completely impatient of the touch, curling up with the greatest velocity, and scattering round the seeds, the instant any extraneous body comes in contact with it.)

The same of a genus of plants. Class, Pentandria. The name of a genus of plants. Class, Pentandria; Order, Monogynia. IMPERATO'RIA.

(From impero, to overcome: so named because its leaves extend and overwhelm the less herbs which grow near it.) 1. The name of a genus of plants in the Linnaan system. Class, Pentandria;

Order, Monogynia.
2. The pharmacopeial name of the master-wort.

See Imperatoria ostruthium.

IMPERATORIA OSTRUTHIUM. The systematic name of the master-wort. Imperatoria; Magistrantia. The roots of this plant are imported from the Alps and Pyrenees, notwithstanding it is indigenous to this island: they have a fragrant smell, and a bitterish pungent taste. The plant, as its name imports, was formerly thought to be of singular efficacy; and its great success, it is said, caused it to be distinguished by the name of divinium remedium. At present, it is consiname of divinium remedium. At present, it is considered merely as an aromatic, and consequently is superseded by many of that class which possess superior qualities

IMPETIGINES. (The plural of impetigo; from impeto, to infest.) An order in the class Cachexiae of Cullen, the genera of which are characterized by cachexia deforming the external parts of the body with

tumours, eruptions, &c.
IMPETI'GO. Ignis sylvaticus; Ignis volagrius.
A disease of the skin, variously described by authors, but mostly as one in which several red, hard, dry, prurient spots arise in the face and neck, and sometimes all over the body, and disappear by furfuraceous or tender scales.

IMPETUM FACIENS. See Vis vites.

IMPETUSA. Force or motion.
I'MPIA HERBA. (From in, not, and pius, good; because it grows only on barren ground.) A name given to cudweed. See Gnaphalium.
IMPLICATED. Celsus, Scribonius, and some others,

call those parts of physic so, which have a necessary dependence on one another; but the term has been more significantly applied, by Bellini, to fevers, where two at a time afflict a person, either of the same kind, as a double tertian; or, of different kinds, as an intermittent tertian, and a quotidian, called a Semitertian.

(From impluo, to shower upon.) 1. IMPLU'VIUM.

The shower-bath.

2. An embrocation.
IMPOSTHUMA. A term corrupted from impostem and apostem. An abscess.

IMPREGNA'TION. Impregnatio See Conception

and Generation.

INANI'TIO. (From inanio, to empty.) Inanition. Applied to the body or vessels, it means emptiness; applied to the mind, it means a defect of its powers.

INCANTA'TION. Incantatio; Incantamentum. A way of curing diseases by charms, defended by Paracelsus, Helmont, and some other chemical enthusiasts.

INCANUS. Hoary. Applied to stems which are covered with a kind of scaly mealiness, as that of the A-temisia absinthium, and Atriplex portulacoides.

INCE'NDIUM. (From incendo, to burn.) A burning fever, or heat.

fever, or heat.

Incz'nsto. 1. A burning fever. 2. A hot inflammatory tumour.

INCERNI'CULUM. (From incerno, to sift.)

1. A strainer, or sieve.

2. A name for the pelvis of the kidney, from its office as a strainer.

INCIDE'NTIA. (From incide, to cut.) Medicines which consist of pointed and sharp particles, as acids, and most salts, which are said to incide or cut the phlegm, when they break it, so as to occasion its dis-

INCINERA'TION. (From incinero, to reduce to ashes.) Incineratio. The combustion of vegetable and animal substances, for the purpose of obtaining their ashes or fixed residue.

INCISI'VUS. (From incide, to cut.) A name given

to some muscles, &c.

Incisivus inferior. See Levator labii inferioris. INCISIVUS LATERALIS. See Levator labii superioris alæque nasi.

INCISIVUS MEDIUS. See Depressor labii superioria

alwque nasi.
INCI'SOR. (Dentes incisores; from incido, to cut, from their use in cutting the food.) The four front teeth of both jaws are called incisors, because they cut

the food. See Teeth.

INCISO'RIUM. (From incide, to cut.) A table
whereon a patient is laid for an operation.

INCISORIUM FORAMEN. A name of the foramen,
which lies behind the dentes incisores of the upper

INCISUS. (From incido, to cut.) Cut. A term applied in botany, synonymously with dissectus, to leaves; as those of the Geranium dissectum.

INCONTINE'NTIA. (From in, and contineo, to contain.) Inability to retain the natural evacuations. Hence we say, incontinence of urine, &c.

INCRASSA'NTIA. (Incrassans; from incrasso, to make thick.) Medicines which thicken the fluids.
I'NCUBUS. (From incubo, to lie upon; because the patient fancies that something lies upon his chest.) See Oncirodynia.
INCURVUS. Curved inwards: applied to leaves;

as in Erica empetrifolia.

INCUS. (A smith's anvil: from incude, to smite upon: so named from its likeness in shape to an anvil) The largest and strongest of the bones of the ear in the tympanum. It is divided into a body and two crura. Its body is situated anteriorly, is rather broad and thick, and has two eminences and two depressions, both covered with cartilage, and intended for the reception of the head of the malleus. Its shorter crus extends no farther than the cells of the mastoid apophysis. Its longer crus, together with the manubrium of the malleus, to which it is connected by a ligament, is of the same extent as the shorter; but its extremity is curved inwards, to receive the os orbiculare, by the intervention of which it is united with the stapes

FNDEX. (From indico, to point out; because it is enerally used for such purposes.) The forefinger.

I'NDEX. (From indico, to point out; because it is generally used for such purposes.) The forefinger.

Indian arrow-root. See Maranta.

Indian cress. See Tropwolum majus.

Indian date-plum. See Diospyros lotus.

Indian leaf. See Laurus cassia.

Indian-pink. See Spigelia.

Indian-rubber. See Caoutchoue,

Indian wheat. See Zea mays.

"INDIAN TOBACCO. Lobelia. The Lobelia inflata is an annual American plant, found in a great variety of soils throughout the United States.

It is lactescent, like many others of its genus. When

It is lactescent, like many others of its genus. When chewed it communicates to the mouth a burning, pungent sensation, which remains long in the fauces, resembling the effect of green tobacco. The plant contains caoutchouc, extractive, and an acrid principle, which is present in the tincture, decoction, and distilled water.

The lobelia is a prompt emetic, attended with narcotic effects during its operation. If a leaf or capsule
be held in the mouth for a short time, it brings on giddiness, headache, a trembling agitation of the whole
body, sickness, and finally vomiting. These effects are
analogous to those which tobacco produces in the unaccustomed. If swallowed in substance, it excites
speedy vomiting, accompanied with distressing and
long-continued sickness, and even with dangerous
symptoms, if the dose be large. On account of the
violence of its operation, it is probable that this plant
will never come in use for the common purpose of an
emetic. It is, however, entitled to notice as a remedy
in asthma and some other pulmonary affections. It
produces relief in asthmatic cases, sometimes without vomiting, but more frequently after discharging
the contents of the stomach. On account of the
harshness of its operation, it is reluctantly resorted to
by patients, who expect relief from any milder means.
It, however, certainly relieves some cases, in, which
other emetic substances fail. In small doses the lobelia is found a good expectorant for pneumonia, in its
advanced stances and for catarry. In the marrison is The lobelia is a prompt emetic, attended with narthe circumstances (a). In small doses the lobe-lia is found a good expectorant for pneumonia, in its advanced stages, and for catarrh. In rheumatism it has also been found of service.

The strength of the lobelia varies with its age, and other circumstances. In some instances, a grain will produce vomiting. The tincture is most frequently

produce vomiting. The inclure is most frequently given in asthma, in doses of about a fluid drachm."—
Big. Mat. Med. A.]
[INDIAN TURNIP. Dragon root. Arum. "The Arum triphyllum is an American plant, growing in damp, shady situations, and sometimes called Indian Turnip, and Wake robin. The root is large and fleshy, consisting chiefly of focula, which it affords, without taste or smell, in the form of a white delicate powder. In its recent state, this root, and in fact every part of In its recent state, this root, and in fact every part of the plant, is violently acrid, and almost caustic. Ap-plied to the tongue, or to any secreting surface, it pro-duces an effect like that of Cayenne pepper, but far more powerful, so as to leave a permanent soreness for many hours. Its action does not readily extend through the cuticle, since the bruised root may be worn upon the skin till it becomes dry, without occasioning pain or rubefaction. The acrimony of this plant resides in a highly volatile principle, which is driven off by heat, and gradually disappears in drying. It is not communicated to water, alkohol, nor oil, but may be obtained in the form of an inflammable gas or vapour, obtained in the form of an inflammable gas or vapour, by boiling the plant under an inverted receiver, filled with water. Arum is too violently acrid to be a safe medicine in its recent state, though it has sometimes been given with impunity. The dried root, while it retains a slight portion of acrimony, is sometimes grated in milk, and given as a carminative and diaphoretic."—Big. Mat. Med. A.]

INDIA NA RADIX. Ipecacuanha.

INDICANT. (Indicans; from indico, to show.)

That from which the indication is drawn, which is in reality the proximate cause of a disease.

reality the proximate cause of a disease.

Indicating days Critical days.

INDICATION. (Indicatio; from indico, to show.)

An indication is that which demonstrates in a disease what ought to be done. It is three-fold: preservative, which preserves health; curative, which expels a present disease; and vital, which respects the powers and reasons of diet. The scope from which indications are taken, or determined, is comprehended in this dis-

Ars, atas, regio, complexio, virtus,
Mos et symptoma, repletio, tempus, et usus.
INDICATOR. (From indico, to point: so named from its office of extending the index, or forefinger)
An extensor muscle of the forefinger, situated chiefly on the lower and posterior part of the forearm. Ex-tensor indicis of Cowper. Extensor secundii inter-nodii indicis proprius, vulgo indicator of Douglas; and Cubitosus phalangettien de l'indix of Dumas. It arises, by an acute fleshy beginning, from the middle of the posterior part of the ulna; its tendon passes under the same ligament with the extensor digitorum communis, with part of which it is inserted into the posterior Part of the forefinger.
INDICUM LIGNUM. Logwood.

INDICUS MORBUS. The venereal disease.
INDIGENOUS. (Indigenus; indigena ab inda, i. e. in et geno, i. e. gigno, to beget.) Applied to diseases, plants, and other objects which are peculiar to

any country.

INDIGO. A blue colouring matter extracted from

the Indigofera tinctoria. Anil, or the Indigo plant. INDIGOFERA. (From indigo, and fero, to bear.) The name of a genus of plants. Class, Diadelphia; Order, Decandria.

INDIGOFERA TINCTORIA. The systematic name of the plant which affords indigo.

INDUCIUM. (From induce, to cover or draw over.)
A covering. 1. A shirt.

2. The name of the amnios from its covering the

fætus like a shirt. Wildenow and Swart's name for the involucrum, or thin membraneous covering of the fructification of

Its varieties are,

1. Inducium planum, flat; as in the genus Polypodium.

2. I. peltatum, connected with the seed by a filament or stalk; as in Aspidium filizmas.

3. I. corniculatum, round and hollow; as in Equi-

(From indure, to harden.) Medi-INDURA'NTIA.

cines which harden.

INEQUALIS. Unequal. Applied to a leaf when the two halves are unequal in dimensions and the base

end parallel; as in Eucalyptus resinifera.

INERMIS. (From in, priv. and arma.) Unarmed: opposed, in designating leaves, to such as are spinous. Unarmed:

INE'SIS. (From ιναω, to evacuate) Inethus. An

evacuation of the humours.

INFECTION. See Contagion.

INFERNAL. A name given to a caustic, lapis infernalis, from its strong burning property. See Argenti

INFIBULA'TIO. (From infibulo, to button together.) An impediment to the retraction of the prepuce.

INFLAMMABLE. Chemists distinguish by this term such bodies as burn with facility, and flame in an increased temperature.

Inflammable air. See Hydrogen gas. Inflammable qir, heavy. See Carburetted hydrogen

INFLAMMATION. (Inflammatio, onis. f.; from in-flammo, to burn.) Phlogosis; Phlogmasia. A dis-ease characterized by heat, pain, redness, attended with more or less of tumefaction and fever. Inflammation is divided into two species, viz. phlegmonous and erysipelatous.

Besides this division, inflammation is either acute or chronic, local or general, simple or complicated with

other diseases.

1. Phleamonous inflammation is known by its bright red colour, tension, heat, and a circumscribed, throbbing, painful tumefaction of the part; tending to suppuration. Phleamon is generally used to denote an inflammatory tumour, situated in the skin or cellular membrane. When the same disease affects the viscous colors is according to the state of the same disease. cera, it is usually called phlegmonous inflammation.

2. Erysipelatous inflammation is considered as an inflammation of a dull red colour, vanishing upon pressure, spreading unequally, with a burning pain, the tumour scarcely perceptible, ending in vesicles, or desquamation. This species of inflammation admits of a division into erythema, when there is merely an affection of the skin, with very little of the whole system; and erysipelas, when there is general affection of the system.

The fever attending erysipelatous inflammation is generally synochus or typhus, excepting when it affects very vigorous habits, and then it may be synocha. The fever attending phlegmonous inflammation is almost always synocha. Persons in the prime of life, and in full vigour with a plethoric habit of body, are most liable to the attacks of a phlegmonous inflammation; whereas those advanced in years, and those of a weak habit of body, irritable, and lean, are most apt to be attacked with crysipelatous inflammation.

Phlegmonous inflammation terminates in resolution,

suppuration, gangrene, and scirrhus, or induration. Resolution is known to be about to take place when the symptoms gradually abute; suppuration, when the inflammation does not readily yield to proper remedies,

the throbbing increases, the tumour points externally, the distended and hollow perlanths of the Cucubalus and rigors come on. Gangrene is about to take place, behen, and Physalis alkekengi in fruit. when the pain abates, the pulse sinks, and cold per-spirations come on. Schirrhus, or induration, is known by the inflammation continuing a longer time than usual; the tumeraction continues, and a considerable hardness remains. This kind of tumour gives little or no pain, and, when it takes place, it is usually the sequel of inflammation affecting glandular parts. It

pairs, lowever, is accompanied with lancinating pairs, ulcerates, and becomes cancerous.

Erythematous inflammation terminates in resolution, suppuration, or gangrene. The symptoms of inflammation are accounted for in the following way:

The reduces arises from the dilutation of the specific

The redness arises from the dilatation of the small vessels, which become sufficiently large to admit the red particles in large quantities; it appears also to occur, in some cases, from the generation of new vessels. The swelling is caused by the dilatation of the vessels, the plethoric state of the arteries and veins, the exudation of coagulable lymph into the cellular membrane, and the interruption of absorption.

In regard to the augmentation of heat, as the thermometer denotes very little increase of temperature, it appears to be accounted for from the increased sensito the sensorium. The pain is occasioned by a deviation from the natural state of the parts, and the unusual condition into which the nerves are thrown. The throbbing depends on the action of the arteries.

Blood taken from a person labouring under active inflammation, exhibits a yellowish white crust on the surface; this is denominated the buffy coriaceous, or inflammatory coat. This consists of a layer of coagulable lymph, almost destitute of red particles. Blood, in this state, is often termed sizy. The colouring part of the blood is its heaviest constituent; and, as the blood of a person labouring under inflammation is longer coagulating than healthy blood, it is supposed that the red particles have an opportunity to descend to a considerable depth from the surface before they become entangled. The buffy coat of blood is generally the best criterion of inflammation; there are a few anomalous constitutions in which this state of blood is always found; but these are rare.

The occasional and exciting causes of inflammation The occasional and exciting causes of inflammation are very numerous: they, however, may generally be classed under external violence, produced either by mechanical or chemical irritation, changes of temperature, and stimulating foods. Fever often seems to be a remote cause; the inflammation thus produced is generally considered as critical. Spontaneous inflammation sometimes occurs when no perceptible cause can be assigned for its production. Scrofula and syphilis may be considered as exciting causes of inflammation. flammation.

With regard to the proximate cause, it has been the subject of much dispute. Galen considered phlegmon to be produced by a superabundance of the humor sanguineus. Boerhaave referred the proximate cause to an obstruction in the small vessels, occasioned by a lenter of the blood. Cullen and others attributed it rather to an affection of the vessels than a change of the

The proximate cause, at the present period, is generally considered to be a morbid dilatation, and increased action of such arteries as lead and are distributed to the inflamed part.

Inflammation of the bladder. See Cystitis.
Inflammation of the brain. See Phrenitis.
Inflammation of thecyes. See Ophthalmia.
Inflammation of the intestines. See Enteritis.
Inflammation of the kidneys. See Nephritis.
Inflammation of the liver. See Hepatitis.
Inflammation of the liver. See Preumonia.
Inflammation of the peritonoum. See Peritonit Inflammation of the peritonaum. See Peritonitis. Inflammation of the pleura. See Pleuritis. Inflammation of the stomach. See Gastritis.
Inflammation of the testicle. See Orchitis.
Inflammation of the uterus. See Hysteritis.
INFLATIO. (From inflo, to pull up.) A windy

swelling. See Pnoumatosis.

INPLA'TIVA. (Inflativus; from inflo, to puff up with wind.) Medicines or food which cause flatulence.

INFLATUS. Inflated. In botany applied to vesiculated parts, which naturally contain only air; as legumen inflatum, seen in Astrogalus vesicarius, and | any required degree of temperature on such substances

behen, and Physalis alkekengi in fruit.
INFLEXUS. Curved inwards; synonymous to incurvus, as applied to leaves, petals, &c. See Incurvus. The petals of the Pimpinella, and Charophyllum, are

INFLORESCENCE. (Inflorescentia; from infloresco, to flower or blossom.) A term used by Linnaus to express the particular manner in which flowers are situated upon a plant, denominated by preceding

writers, modus florendi, or manner of flowering.
It is divided into simple, when solitary, and compound, when many flowers are placed together in one

The first affords the following distinctions.

1. Flos pedunculatus, furnished with a stalk; as in Gratiolus and Vinca.

2. F. sessilis, adhering to the plant without a flowerstalk; as in Daphne mezerium, and Zinia pauciflora.

3. F. caulinus, when on the stem.

F. rameus, when on the branch.

5. F. terminalis, when on the apex of the stem, or branch; as Paris quadrifolia, and Chrysanthemum leucanthemum.

6. F. azillaris, in the axilla; as in Convallaria multiflora

7. F. foliaris, on the surface of the leaf; as in Phyl-Lanthus

8. F. radicalis, on the root; as Carlina acaulis,

Crocus, and Colchicum.

9. F. latitans, concealed in a fleshy receptacle; as in Ficus carica.

Again, it is said to be,

1. Alternate; as in Polyanthes tuberosa.

Opposite; as in Passiflora hirsuta.

Unilateral, hanging all to one side; as Erica her-

bacea, and Silene amana.
4. Solitary; as in Campanula speculum, and Carduus tuberosus.

The second, or compound inflorescence, has the following kinds:

1. The verticillus, or whirl. 2. The capitulum, or tuit.

The spica, or spike.
 The racemus, or cluster.
 The corymbos, or corymb.
 The umbella, or umbel.

The cyma, or cyme.
The fasciculus, or fascicle.
The panicula, or panicle.

10. The thyrsus, or bunch.
11. The spadiz, or sheath.
12. The amentum, or catkin.
1NFLUE'NZA. (The Italian word for influence.)
The disease is so named because it was supposed to be produced by a possible rinfluence of the stars. See produced by a peculiar influence of the stars. See

Catarrhus à contagione.

INFRASCAPULA'RIS (From infra, beneath, and scapula, the shoulder-blade.) A muscle named from its position beneath the scapula. See Subscapularis.

INFRASPINA'TUS. (From infra, beneath, and spina, the spine.) A muscle of the humerus, situated

spina, the spine.) A muscle of the humerus, situated on the scapula. It arises fleshy, from all that part of the dorsum scapulae which is below its spine; and from the spine itself, as far as the cervix scapulæ. fibres run obliquely towards a tendon in the middle of a muscle, which runs forwards, and adheres to the capsular ligament. It is inserted by a flat, thick tendon, into the upper and outer part of the large protuberance on the head of the os humeri. Its use is to roll the os humeri outwards, to assist in raising and supporting humeri outwards, to assist in raising and supporting it when raised, and to pull the ligament from between the bones. This muscle and the supra spinatus are covered by an aponeurosis, which extends between the costæ, and edges of the spine of the scapula, and gives rise to many of the muscular fibres.

INFUNDIBULIFORMIS. Funnel-shaped. Applied to the corolla of plants; as in Pulmonaria.

INFUNDIBULUM. (From infundo, to pour in.)

1. A canal that proceeds from the vulva of the brain to the pituitary gland in the sella turcica.

2. The beginnings of the excretory duct of the kidney, or cavities into which the urine is first received, from the secretory cryptæ, are called infundibula.

from the secretory crypts, are called infundibula.

INFUSION. (Infusum; from infundo, to pour in.)
Infusio. A process that consists in pouring water of

as have a loose texture, as thin bark, wood in shavings, or small pieces, leaves, flowers, &c. and suffering it to stand a certain time. The liquor obtained by the above process is called an infusion. The following are among the most approved infusions.

INFU'SUM. See Infusion.

INFUSUM ANTHEMIDIS. Infusion of chamomile. Take of chamomile-flowers, two drachms; boiling-water, half a pint. Macerate for ten minutes in a covered vessel, and strain. For its virtues, see Anthemis nobilis.

INFUSUM ARMORACIÆ COMPOSITUM. Compound infusion of horse-radish. Take of fresh horse-radish root, sliced, mustard-seeds, bruised, of each one ounce; boiling water, a pint. Macerate for two hours, in a covered vessel, and strain; then add compound spirit of horse-radish, a fluid ounce. See Cochlearia armo-

INFUSUM AURANTH COMPOSITUM. Compound infusion of orange-peel. Take of orange-peel, dried, two drachms; lemon-peel, fresh, a drachm; cloves, bruised, half a drachm; boiling water, half a pint. Macerate for a quarter of an hour, in a covered vessel, and strain. See Citrus aurantum.

INFUSUM CALUMBE. Infusion of calumba. Take of calumba-root, sliced, a drachm; boiling water, half a pint. Macerate for two hours, in a covered vessel, and

strain. See Calumba.

INFUSUM CARYOPHYLLORUM. Infusion of cloves. Take of cloves, bruised, a drachm; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See Eugenia caryophyllata.

INFUSUM CASCARILLE. Infusion of cascarilla. Take

of cascarilla bark, bruised, half an ounce; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See Croton cascarilla.

INFUSUM CATECHU COMPOSITUM. Compound infusion of catechu. Take of extract of catechu, two drachms and a half; cinnamon bark, bruised, half a drachm; boiling water, half a pint. Macerate for an hour, in a covered vessel, and strain. See Acacia catechu.

INFUSUM CINCHONÆ. Infusion of cinchona. Take of lance-leaved cinchona bark, bruised, half an ounce; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See Cinchona.

INFUSUM CUSPARIA. Infusion of cusparia. Take of cusparia bark, bruised, two drachms; boiling water, half a pint. Macerate for two hours, in a covered ves-

half a pint. Macerate for two hours, in a covered vessel, and strain. See Cusparia febrifuga.

INFUSUM DIGITALIS. Infusion of fox-glove. Take of purple fox-glove leaves, dried, a drachm; boiling water, half a pint. Macerate for four hours, in a covered vessel, and strain; then add spirit of cinnamon, half a fluid ounce. See Digitalis purpurea.

INFUSUM GENTIANE COMPOSITUM. Compound infusion of gentian. Take of gentian-root, sliced, orangeneed dried of each a drachm; lemon-roed fresh, two

peel, dried, of each a drachm; lemon-peel, fresh, two drachms; boiling water, twelve fluid ounces. Macerate for an hour, in a covered vessel, and strain.

Gentiana lutea. INFUSUM LINI. Infusion of linseed. Take of linseed, bruised, an ounce; liquorice-root, sliced, half an ounce; boiling water, two pints. Macerate for two hours, near the fire, in a covered vessel, and strain.

See Linum usitatissimum. INFUSUM QUASSIÆ. Infusion of quassia. Take of quassia wood, a scruple; boiling water, half a pint. Macerate for two hours and strain. See Quassia

INVISUM RHEL Infusion of rhubarb. Take of rhubarb-root, sliced, a drachm; boiling water, half a pint. Macerate for two hours, and strain. See Rheum.

INFUSUM ROSE. Take of the petals of red rose, dried, half an ounce; boiling water, two pints and a half; dilute sulphuric acid, three fluid drachms; doublerefined sugar, an ounce and a half. Pour the water upon the petals of the rose in a glass vessel; then add the acid, and macerate for half an hour. Lastly, strain the infusion, and add the sugar to it. See Rosa Gallica.

INFUSUM SENNÆ. Infusion of senna. Take of senna-leaves, an ounce and a half; ginger-root, sliced, a drachm; boiling water, a pint. Macerate for an hour, in a covered vessel, and strain the liquor. See Cassia senna.

INFUSUM SIMAROUBE. Infusion of simarouba. Take of simarouba bark bruised, half a drachm; boiling water, half a pint. Macerate for two hours, in a co-

vered vessel, and strain. See Quassia simarouba.

INFUSUM TABACL. Infusion of tobacco. Take of tobacco-leaves, a drachm; boing water, a pint. Mace rate for an hour, in a covered vessel, and strain. See

INGENHOUZ, John, was born at Breda, in 1730 Little is known of his early life; but in 1767, he came to England to learn the Suttonian method of inocula-In the following year he went to Vienna, to tion. In the following year he went to Vienna, to inoculate some of the imperial family, for which service he received ample honours; and shortly after performed the same operation on the Grand Duke of Tuscany, when he returned to this country, and spent the remainder of his life in scientific pursuits. In 1779, he published "Experiments on Vegetables," discovering their great powering the sixty of the contraction of the service of the s vering their great power of purifying the air in sun-shine, but injuring it in the shade and night. He was also author of several papers in the Philosophical Transactions, being an active member of the Royat Society. He died in 1799.

INGLUVIES. 1. Gluttony.

2. The claw, crop, or gorge of a bird.

INGRASSIAS, John Philip, was born in Sicily, and graduated at Padua in 1537 with singular reputations whence he was invited to a professorable in

whence he was invited to a professorship in tion; whence he was invited to a professorant in several of the Italian schools; but he gave the prefer-ence to Naples, where he distinguished himself greatly by his learning and judgment. At length he returned to his native island, and settled in Palermo, where he was also highly esteemed; and in 1563 made first physi-cian to that country by Philip II. of Spain, to whom it then belonged. This office enabled him to introduce then belonged. This office enabled him to introduce excellent regulations into the medical practice of the island, and when the plague raged there in 1575, the judicious measures adopted by him arrested its progress; whence the magistrates decreed him a large gress; whence the magistrates decreed him a large reward, of which, however, he only accepted a part, and applied that to religious uses. He died in 1580, at the age of 70. He cultivated anatomy with great assiduity, and is reckoned one of the improvers of that art, especially in regard to the structure of the cranium, and the organ of hearing. He is said also to have discovered the seminal vesicles. He published several works, particularly an account of the plague, and a treatise, "De Tumoribus præter Naturam," which is chiefly a commentary on Avicenna, but is deserving

But his principal work was published by his nephew, in 1603, entitled, "Commentaries on Galen's Book concerning the Bones." INGRAVIDATION. (From ingravidor, to be great with child.) The same as impregnation, or going with child.

I'NGUEN. (Inguen, inis. n.) The groin. The lower and lateral part of the abdomen, above the thigh.

chiefly a commentary on Avicenna, but is deserving of notice, as containing the first modern description of

Scarlatina, under the name of Rossalia; and perhaps the first account of varicella, which he called crystalli.

INGUINAL. Inguinalis. Appertaining to the groin. Inguinal hernia. See Hernia.

Inguinal hernia. See Hernia.

Inguinal ligament. See Poupart's ligament.

INHUMATION. (From inhumo, to put into the ground.) The burying a patient in warm or medicated earth. Some chemists have fancied thus to call that kind of digestion which is performed by burying the materials in dung, or in the earth.

I'nion. (From 15, a nerve; as being the place where erves originate.) The occiput. Blancard says it is nerves originate.) The occiput. Blancard says it is the beginning of the spinal marrow; others say it is

the back part of the neck.

INJACULA'TIO. (From injaculor, to shoot into.) So Helmont calls a disorder which consists of a violent spasmodic pain in the stomach, and an immobility of

the body.

INJE CTION. (Injectio; from injicio, to cast into.)

A medicated liquor to throw into a natural or preternatural cavity of the body by means of a syringe.

INNOMINA TUS. (From in, priv., and nomen, a name.) Some parts of the body are so named: thus, the relivie hones, which in the young subject are three the pelvic bones, which in the young subject are three in number, to which names were given, become one in the adult, which was without a name; an artery from the arch of the aorta, and the fifth pair of nerves, because they appeared to have been forgotten by the older anatomists.

ENNOMINATA ARTERIA. The first branch given off by the arch of the aorta. It soon divides into the right

carotid and right subcla ian arteries.

INNOMINATUM OS. (So called because the three bones of which it originally was formed grew together, and formed one complete bone, which was then left name-less.) A large irregular bone, situated at the side of the pelvis. It is divided into three portions, viz. the iliac, ischiatic, and pubic, which are usually described as three distinct bones.

The os ilium, or haunch-bone, is of a very irregular shape. The lower part of it is thick and narrow; its superior portion is broad and thin, terminating in a ridge, called the spine of the ilium, and more commonly known by the name of the haunch. The spine rises up like an arch, being turned somewhat outward, and from this appearance, the upper part of the pelvis, when viewed together, has not been improperly compared to the wings of a phæton. This spine, in the recent subject, appears as if tipped with cartilage; but this appearance is nothing more than the tendinous fibres of the muscles that are inserted into it. Externally, this bone is unequally prominent, and hollowed for the attachment of muscles; and internally, at its broadest forepart, it is smooth and concave. At its lower part, there is a considerable ridge on its inner surface. This ridge, which extends from the os sacrum, and corresponds with a similar prominence, both on that bone and the ischium, forms, with the inner part of the ossa pubis, what is called the brim of the pelvis. The whole of the internal surface, behind this ridge, is very unequal. The os illium has likewise a smaller surface posteriols by which it is activated to the very unequal. The os mum has newlise a similar surface posteriorly, by which it is articulated to the sides of the os sacrum. This surface has, by some, been compared to the human ear, and, by others, to the head of a bird: but neither of these comparisons seem to convey any just idea of its form or appearance. Its upper part is rough and porous; lower down it is more solid. It is firmly united to the os sacrum by a cartilaginous substance, and likewise by very strong ligamentous fibres, which are extended to that bone from the whole circumference of this irregular surface. The spine of this bone, which is originally an epiphysis, has two considerable tuberosities, one anteriorly, and has two considerable fuberosities, one anteriorly, and the other posteriorly, which is the largest of the two. The ends of this spine too, from their projecting more than the parts of the bone below them, are called spinal processes. Before the anterior spinal process, the spine is hollowed, where part of the Sartorius muscle is placed; and below the posterior spinal process, there is a very large niche in the bone, which, in the recent subject, has a strong ligament stratched over the recent subject, has a strong ligament stretched over its lower part, from the os sacrum to the sharp-pointed process of the ischium; so that a great hole is formed, through which pass the great sciatic nerve and the posterior crural vessels under the pyriform muscle, part of which is likewise lodged in this hole. The lowest, thickest, and narrowest part of the ilium, in conjunction with the other two portions of each os innominatum, helps to form the acetabulum for the os femoris.

The os ischium, or hip-bone, which is the lowest of the three portions of each os innominatum, is of a very irregular figure, and usually divided into its body, tuberosity, and ramus. The body externally forms the inferior portion of the acetabulum, and sends a sharppointed process backward, called the spine of the schium. This is the process to which the ligament is attached, which was just now described as forming a great foramen for the passage of the sciatic nerve. The tuberosity is large and irregular, and is placed at the inferior part of the bone, giving origin to several muscles. In the recent subject, it seems covered with a cartilaginous crust; but this appearance, as in the spine of the ilium, is nothing more than the tendinous fibres of the muscles that are inserted into it. This tuberosity, which is the lowest portion of the trunk, supports us when we sit. Between the spine and the supports us when we sit. Between the spine and the tuberosity is observed a sinuosity, covered with a car-tilaginous crust, which serves as a pulley, on which the obturator muscle plays. From the tuberosity, the bone, becoming narrower and thinner, forms the ramus, or branch, which, passing forwards and upwards, makes, with the ramus of the os pubis, a large hole, of an oval shape, the foramen magnum ischu, which affords, through its whole circumference, attachment to muscles. This foramen is more particularly noticed In describing the os pubis.

The os pubis, or share-bone, which is the smallest

INNOMINATI NERVI. The fifth pair of nerves. See | of the three portions of the os innominatum, is placed at the upper and forepart of the pelvis, where the two ossa pubis meet, and are united to each other by means ossa pubis meet, and are united to each other by mean-of a very strong cartilage, which constitutes what is called the *symphysis pubis*. Each os pubis may be divided into its body, angle, and ramus. The body, which is the outer part, is joined to the os ilium. The angle comes forward to form the symphisis, and the angle comes forward to form the symphisis, and the ramus is a thin apophysis, which, uniting with the ramus of the ischium, forms the foramen magnum ischii, or thyroideum, as it has been sometimes called, from its resemblance to a door or shield. This foramen is somewhat wider above than below, and its greatest diameter is, from above downwards, and obliquely from within outwards. In the recent subject, it is almost completely closed by a strong fibrous membrane, called the abtractor ligament. Unwards and outwards. called the obturator ligament. Upwards and outwards, where we observe a niche in the bone, the fibres of this ligament are separated, to allow a passage to the posterior crural nerve, an artery and vein. The great uses of this foramen seem to be to lighten the bones of the pelvis, and to afford a convenient lodgment to the obturator muscles. The three bones now described as constituting the os innominatum on each side, all concur to form the great acetabulum, or cotyloid cavity, which receives the head of the thigh-bone; the os ilium and os ischium making each about two-fifths, and the os pubis one-fifth, of the cavity. This acetabulum, which is of considerable depth, is of a spherical shape. Which is of considerable depth, is of a spherical shape. Its brims are high, and, in the recent subject, it is tipped with cartilage. These brims, however, are higher above and externally, than they are internally and below, where we observe a niche in the bone (namely, the ischium), across which is stretched a ligament, forming a hole for the transmission of blood-vessels. and nerves to the cavity of the joint. The cartilage which lines the acetabulum, is thickest at its circumference, and thinner within, where a little hole is to be observed, in which is placed the apparatus that serves to lubricate the joint, and facilitate its motions. We are likewise able to discover the impression made by the internal ligament of the os femoris, which, by being attached both to this cavity and to the head of the os femoris, helps to secure the latter in the aceta-bulum. The bones of the pelvis serve to support the spine and upper parts of the body, to lodge the intes-tines, urinary bladder, and other viscera; and likewise to unite the trunk to the lower extremities. But, besides these uses, they are destined, in the female subject, for other important purposes; and the accoucheur finds, in the study of these bones, the foundation of all midwifery knowledge. Several eminent writers are of opinion, that in difficult parturition, all the bones of the pelvis undergo a certain degree of separation. It has been observed, likewise, that the cartilage uniting the ossa pubis is thicker, and of a more spongy texture, in women than in men; and therefore more likely to swell and enlarge during pregnancy. That many instances of a partial separation of these bones, during labour, have happened, there can be no doubt; such a separation, however, ought by no means to be considered as a uniform and salutary work of nature, as some writers seem to think, but as the effect of disease. But there is another circumstance in regard to this part of osteology, which is well worthy of attention; and this is, the different capacities of the pelvis in the male and female subject. It has been observed that the os sacrum is shorter and broader in women than in men; the ossa ilia are also found more expanded; whence it happens, that in women the centre of gravity does not fall so directly on the upper part of the thigh as in men, and this seems to be the reason why, in general, they step with less firmness, and move their hips forward in walking. From these circum-stances, also, the brim of the female pelvis is nearly of an oval shape, being considerably wider from side to of an oval shape, being considerably wider from side to side, than from the symphysis pubis to the os sacrum; whereas, in men, it is rounder, and everywhere of less diameter. The inferior opening of the pelvis is likewise proportionably larger in the female subject, the ossa ischia being more separated from each other, and the foramen ischii larger, so that, where the os ischium and os pubis are united together, they form a greater circle; the os sacrum is also more hollowed, though shorter, and the os coccygis more loosely connected, and, therefore, capable of a greater degree of motion than therefore, capable of a greater degree of motion than

INOCULATION. Inoculatio. The insertion of a | fresh matter can be procured, to give it the prefer-poison into any part of the body. It was mostly practice. tised with that of the small-pox, because we had learned, from experience, that by so doing, we generally pro-cured fewer pustules, and a much milder disease, than when the small-pox was taken in a natural way. Al-though the advantages were evident, yet objections were raised against inoculation, on the notion that it exposed the person to some risk, when he might have passed through life, without ever taking the disease naturally; but it is obvious that he was exposed to much greater danger, from the intercourse which he must have with his fellow-creatures, by taking the disorder in a natural way. It has also been adduced, that a person is liable to take the small-pox a second time, when produced at first by artificial means; but such instances are very rare, besides not being sufficiently authentic. We may conjecture that, in most of those cases, the matter used was not variolous, but that of some other eruptive disorder, such as the chicken-pox, which has often been mistaken for the small-pox. However, since the discovery of the preventive power of the cow-pox, small-pox inoculation has been rapidly falling into disuse. See Variola vaccina.

To illustrate the benefits arising from inoculation, it has been calculated that a third of the adults die who take the disease in a natural way, and about one-seventh of the children; whereas of those who are inoculated, and are properly treated afterward, the proportion is probably not greater than one in five or

Inoculation is generally thought to have been introduced into Britain from Turkey, by Lady Mary Wort-ley Montague, about the year 1721, whose son had been inoculated at Constantinople, during her resi-dence there, and whose infant daughter was the first that underwent the operation in this country. It appears, however, to have been well known before this period, both in the south of Wales and Highlands of Scotland. Mungo Park, in his travels into the interior of Africa, found that inoculation had been long practised by the Negroes on the Guinea coast; and nearly in the same manner, and at the same time of life, as in Europe. It is not clearly ascertained where inocu-lation really originated. It has been ascribed to the Circassians, who employed it as the means of preserving the beauty of their women. It appears more probable that accident first suggested the expedient among different nations, to whom the small-pox had long been known, independently of any intercourse with each other; and what adds to the probability of this conjecture is, that in most places where inoculation can be traced back, for a considerable length of time, it seems to have been practised chiefly by old women, before it was adopted by regular practitioners.

Many physicians held inoculation in the greatest

contempt at first, from its supposed origin; others again discredited the fact of its utility; while others, on the testimony of the success in distant countries, believed in the advantages it afforded, but still did not think themselves warranted to recommend it to the families they attended; and it was not until the experiment of it had been made on six criminals (all of whom recovered from the disease and regained their liberty), that it was practised, in the year 1726, on the royal family, and afterward adopted as a general thing.

To ensure success from inoculation, the following precautions should strictly be attended to.

1. That the person should be of a good habit of body, and free from any disease, apparent or latent, in order that he may not have the disease and a bad constitution, or perhaps another disorder, to struggle with at the same time.

2. To enjoin a temperate diet and proper regimen; and, where the body is plethoric, or gross, to make use of gentle purges, together with mercurial and antimo-

nial medicines.

3. That the age of the person be as little advanced as possible, but not younger if it can be avoided, than

four months.

4. To choose a cool season of the year, and to avoid external heat, either by exposure to the sun, sitting by fires, or in warm chambers, or by going too warmly clothed, or being too much in bed.

5. To take the matter from a young subject, who has the small-pox in a favourable way, and who is other-wise healthy, and free from disease; and, when

Where matter of a benign kind cannot be procured, and the patient is evidently in danger of the casual small-pox, we should not, however, hesitate a moment to inoculate from any kind of matter that can be procured; as what has been taken in malignant kinds of small-pox has been found to produce a very mild disease. The mildness or malignity of the disease appears, therefore, to depend little or not at all on the inoculating matter. Variolous matter, as well as the vaccine, by being kept for a length of time, particularly in a warm place, is apt, however, to undergo decompo-sition, by putrefaction; and then another kind of con-tagious material has been produced.

In inoculating, the operator is to make the slightest puncture or scratch imaginable in the arm of the person, rubbing that part of the lancet which is besmeared with matter repeatedly over it, by way of ensuring the absorption; and in order to prevent its being wiped off, the shirt sleeve ought not to be pulled down until the

part is dry.

A singular circumstance attending inoculation is, that when this fails in producing the disease, the in-oculated part nevertheless sometimes inflames and suppurates, as in cases where the complaint is about to follow; and the matter produced in those cases, is as fit for inoculation as that taken from a person actually labouring under the disease. The same happens very frequently in inoculation for the cow-

If, on the fourth or fifth day after the operation, no redness or inflammation is apparent on the edge of the wound, we ought then to inoculate in the other arm, in the same manner as before; or, for greater certain-

ty, we may do it in both.

Some constitutions are incapable of having the disease in any form. Others do not receive the disease at one time, however freely exposed to its contagion, even though repeatedly inoculated, and yet receive it afterward by merely approaching those labouring under it.

On the coming on of the febrile symptoms, which is On the coming on of the febrile symptoms, which is generally on the seventh day in the inoculated small-pox, the patient is not to be suffered to lie abed, but should be kept cool, and partake freely of antiseptic cooling drinks. See Variola.

INOSCULATION. (Inesculatio; from in, and osculum, a little mouth.) The running of the veins

and arteries into one another, or the interunion of the extremities of the arteries and veins.

INSA'NIA. (From in, not, and sanus, sound.) Insanity, or deranged intellect. A genus of disease in the class Neuroscs, and order Vesania, characterized by erroneous judgment, from imaginary perceptions or recollections, attended with agreeable emotions in per-

sons of a sanguine temperament. See Mania.

INSE'SSUS. (From insideo, to sit upon.) A hotbath, simple or medicated, over which the patient

(From in, and sapientia, wisdom.) INSIPIE'NTIA.

A delirium without fever.

INSOLATIO. (From in, upon, and sol, the sun.) disease which arises from a too great influence of the

sun's heat upon the head, a coup de soleil.
INSPIRA'TION. (Inspiratio; from in, and spira, to breathe.) The act of drawing the air into the lungs.

See Respiration.
INSTINCT. (Instinctus, ûs. m.) Animals are not abandoned by nature to themselves: they are all employed in a series of actions; whence results that marvellous whole that is seen among organized beings. To incline animals to the punctual execution of those actions which are necessary for them, nature has provided them with instinct; that is, propensities, inclinations, wants, by which they are constantly excited, and forced to fulfil the intentions of nature.

Instinct may excite in two different modes, with or without knowledge of the end. The first is enlight-ened instinct, the second is blind instinct; the one is particularly the gift of man, the other belongs to

animals.

In examining carefully the numerous phenomena which depend on instinct, we see that there is a double design in every animal:—1: The preservation of the individual. 2. The preservation of the species. Every animal fulfils this end in its own way, and according to

fis organization; there are therefore as many different instincts as there are different species; and as the organization varies in individuals, instinct presents individual differences sometimes strongly marked.

When the folium integrum respects the whole shape; and has nothing to do with the margin.

INTERCO'STAL. (Intercostatis; from inter, besents individual differences sometimes strongly marked.)

We recognise two sorts of instinct in man: the one depends more evidently on his organization, on his animal state; he presents it in whatever state he is found. This sort of instinct is nearly the same as that of animals. The other kind of instinct springs from the social state; and, without doubt, depends on orga-nization: what vital phenomenon does not depend on it? But it does not display itself except when man lives in civilized society, and when he enjoys all the

advantages of that state.

To the first, that may be called animal instinct, be-long hunger, thirst, the necessity of clothing, of a covering from the weather; the desire of agreeable sensations; the fear of pain and of death; the desire to injure others, if there is any danger to be feared from them, or any advantage to arise from hurting them; the venereal inclinations; the interest inspired by children; inclination to imitation; to live in society, which leads man to pass through the different degrees of civilization, &c. These different instinctive feelings incline him to concur in the established order of organized beings. Man is, of all the animals, the one whose natural wants are most numerous, and of the greatest variety; which is in proportion to the extent of his intelligence: if he had only these wants, he would have always a marked superiority over the animals.

When man, living in society, can easily provide for all the wants which we have mentioned, he has then time and powers of action more than his original wants require: then new wants arise, that may be called social wants: such is that of a lively perception of existence; a want which, the more it is satisfied, the more difficult it becomes, because the sensations

become blunted by habit.

This want of a vivid existence, added to the conti-nually increasing feebleness of the sensations, causes a mechanical restlessness, vague desires, excited by the remembrance of vivid sensations formerly felt: in order to escape from this state, man is continually forced to change his object, or to overstrain sensations of the same kind. Thence arises an inconstancy which never permits our desires to rest, and a progres sion of desires, which, always annihilated by enjoyment, and irritated by remembrance, proceed forward without end; thence arises ennui, by which the civilized idler is incessantly tormented.

The want of vivid sensations is balanced by the

love of repose and idleness in the opulent classes of society. These contradictory feelings modify each society. These contradictory feelings modify each other, and from their reciprocal reaction results the love of power, of consideration, of fortune, &c. which

gives us the means of satisfying both.

These two instinctive sensations are not the only ones which spring from the social state; a crowd of others arise from it, equally real, though less important; besides, the natural wants become so changed as no longer to be known; hunger is often replaced by a capricious taste; the venereal desires by a feeling of quite another nature, &c.

The natural wants have a considerable influence

upon those which arise from society; these, in their turn, modify the former; and if we add age, temperament, sex, &c. which tend to change every sort of want, we will have an idea of the difficulty which the study of the instinct of man presents. This part of physi-ology is also scarcely begun. We remark, however, that the social wants necessarily carry along with them the enlargement of the understanding; there is no comparison in regard to the capacity of the mind, between a man in the higher class of society, and a man whose physical powers are scarcely sufficient to provide for his natural wants.

INTEGER. When applied to leaves, perianths, petals, &c. folia integra, means undivided; and is said of the simple leaves as those of the orchises and grasses. The female flower of the oak affords an example of the perianthium integrum, and the petals of the Nigella arvensis and Silene quinquevulnera are described as petala integra.

INTEGERRIMUS. Most perfect or entire. Applied to leaves, the margin of which has no teeth, notches, or incisions. It regards solely the margin

INTERCO'STAL. (Intercostalis; from inter, between, and costa, a rib.) A name given to muscles, vessels, &c. which are between the ribs.

INTERCOSTAL ARTERIES. Arteriæ intercostales. The arteries which run between the ribs. The superior intercostal artery is a branch of the subclavian.

other intercostal arteries are given off from the aorta.

INTERCOSTAL MUSCLES. Intercostales externi et interni. Between the ribs on each side are eleven double rows of muscles. These are the intercostales externi, and interni. Galen has very properly observed, that they decussate each other like the strokes of the letter X. The intercostales externs arise from the lower edge of each superior rib, and, running obliquely downwards and forwards, are inserted into the upper edge of each inferior rib, so as to occupy the intervals of the ribs, from as far back as the spine to their cartilages; but from their cartilages to the sternum, there is only a thin aponeurosis covering the internal interceptables. costales. The intercostales interni arise and are in-serted in the same manner as the external. They begin at the sternum, and extend as far as the angles of the ribs, their fibres running obliquely backwards. These fibres are spread over a considerable part of the inner surface of the ribs, so as to be longer than those of the external intercostals. Some of the posterior portions of the internal intercostals. Some of the posterior portuous of the internal intercostals pass over one rib, and are inserted into the rib below. Verheyen first described these portions as separate muscles, under the name of infra costales. Winslow has adopted the same name. comper, and after him Douglas, call them costarum depressores proprii. These distinctions, however, are altogether superfluous, as they are evidently nothing more than appendages of the intercostals. The number of these portions varies in different subjects. Most commonly there are only four, the first of which runs from the second rib to the fourth, the second from the third rib to the fifth, the third from the fourth rib to the sixth, and the fourth from the fifth rib to the seventh. The internal intercostals of the two inferior false ribs are frequently so thin acto be with difficulty senarated. are frequently so thin, as to be with difficulty separated from the external; and, in some subjects, one or both of them seem to be altogether wanting. It was the opinion of the ancients, that the external intercostals serve to elevate, and the internal to depress the ribs. They were probably led to this opinion, by observing the different direction of their fibres; but it is now well known, that both have the same use, which is that of raising the ribs equally during inspiration. Fallopius was one of the first who ventured to call in question the opinion of Galen on this subject, by contending that both layers of the intercostals serve to elevate the ribs. In this opinion he was followed by Hierony mus Fabricius, our countryman Mayow, and Borelli, But, towards the close of the last century, Bayle, a writer of some eminence, and professor at Toulouse, revived the opinion of the ancients by the following arguments:—He observed, that the oblique direction of the fibres of the internal intercostals is such, that of the fibres of the internal intercostals is such, that in each inferior rib, these fibres are nearer to the vertebræ than they are at their superior extremities, or in the rib immediately above; and that, of course, they must serve to draw the rib downwards, as towards the most fixed point. This plausible doctrine was adopted by several eminent writers, and among others, by Nicholls, Hoadley, and Schreiber; but above all, by Hamberger, who went so far as to assert, that not only the ribs, but even the sternum, are pulled down wards by these muscles, and constructed a particular instrument to illustrate this doctrine. He pretended likewise that the intervals of the ribs are increased by their elevation, and diminished by their depression; but he allowed that, while those parts of the internal intercostals that are placed between the bony part of the ribs pull them downwards, the anterior portions of the ribs pull them downwards, the anterior portions of the muscle, which are situated between the cartilages, concur with the external intercostals in raising them upwards. These opinions gave rise to a warm and interesting controversy, in which Hamberger and Haller were the principal disputants. The former argued chiefly from theory, and the latter from experiments on living animals, which demonstrate the fallacy of Hamberger's arguments, and prove, beyond a doubt, that the internal intercostals perform the same functions as the external.

INT

INTERCOSTAL NERVE. Nervus intercostalis. Great | dicis, and Winslow semi-interosseus indicis. Albinus, intercostal nerve. Sympathetic nerve. The great in-tercostal nerve arises in the cavity of the cranium, from a branch of the sixth and one of the fifth pair, uniting into one trunk, which passes out of the cranium through the carotid canal, and descends by the sides of the bodies of the vertebræ of the neck, thorax, loins, of the bodies of the vertebræ of the peck, thorax, loins, and os sacrum: in its course, it receives the small accessory branches from all the thirty pair of spinal nerves. In the neck, it gives off three cervical ganglions, the upper, middle, and lower; from which the cardiac and pulmonary nerves arise. In the thorax, it gives off the splanchnic or anterior intercostal, which perforates the diaphragm, and forms the semilunar ganglions, from which nerves pass to all the abdominal viscera. They also form in the abdomen ten peculiar plexuses, distinguished by the name of the viscus, to which they belong, as the cœliac, splenic, hepatic, superior, middle, and lower mesenteric, two renal, and two spermatic plexuses. The posterior intercostal nerve gives accessory branches about the pelvis and ischiatic nerve, and at length terminates.

INTERCOSTAL VEINS. The intercostal veins empty their blood into the verse aggregate.

their blood into the vena azygos.

INTERCURRENT. Those fevers which happen in certain seasons only, are called stationary: others are called, by Sydenham, intercurrents.

INTERCUS. (From inter, between, and cutis, the skin.) A dropsy between the skin and the flesh. See

INTERDE'NTIUM. (From inter, between, and dens, a tooth.) The intervals between teeth of the

(From inter, between, and A corn between the toes, or INTERDIGITUM. digitus, a toe, or finger.) wart between the fingers.

INTERFÆMUNEUM. (From inter, between, and famen, the thigh.) The perinaum, or space between the anus and pudendum.

INTERLU'NIUS. (From inter, between, and luna, the moon; because it was supposed to affect those who were born in the wane of the moon.) The epi-

Intermediate affinity. See Affinity intermediate. INTERMITTENT. (Intermittens; from in

INTERMITTENT. (Intermittens; from inter, between, and mitto, to send away.) A disease is so called which does not continue until it finishes one way or the other, as most diseases do, but ceases and returns again at regular or uncertain periods; as agues, &c.

Intermittent fover. See Febris intermittens.
INTERNODIS. Applied to a flowerstalk or pedunculus, when it proceeds from the intermediate part of a branch between two leaves; as in Ehretia internodis.

INTERNU'NTII DIES. (From internuncio, to go between.) Applied to critical days, or such as stand between the increase of a disorder and its decrease.

INTERO'SSEI MANUS. (Interosseus; from inter, between, and os, the bone.) These are small muscles situated between the metacarpal bones, and extending from the bones of the carpus to the fingers. They are from the bones of the carpus to the fingers. They are divided into internal and external; the former are to be seen only on the palm of the hand, but the latter are conspicuous both on the palm and back of the hand. The interossei interni are three in number. The first, which Albinus names posterior indicis, arises tendinous and fleshy from the basis and inner part of the metacarpal bone of the forefinger, and likewise from the upper part of that which supports the middle finger. Its tendon passes over the articulation of this part of these bones with the forefinger. tion of this part of these bones with the forefinger, and, uniting with the tendinous expansion that is sent off from the extensor digitorum communis, is inserted into the posterior convex surface of the first phalanx of that finger. The second and third, to which Albinus gives the names of prior annularis, and interrosseus auricularis, arise, in the same manner, from the basis of the outsides of the metacarpal bones that sustain the ring-finger and the little finger, and are inserted into the outside of the tendinous expansion of the extensor digitorum communis that covers each of those These three muscles draw the fingers into which they are inserted, towards the thumb. The interossei externi are four in number; for among these is included the small muscle that is situated on the outside of the metacarpal bone that supports the forefinger. Douglas calls it extensor tertii internodii in-

who describes it among the interrossel, gives it the name of prior indicis. This first interosseus externus arises by two tendinous and fleshy portions. One of these springs from the upper half of the inner side of the first bone of the thumb, and the other from the ligaments that unite the os trapezoides to the metacar-pal bone of the forefinger, and likewise from all the outside of this latter bone. These two portions unite as they descend, and terminate in a tendon, which is inserted into the outside of the control of the inserted into the outside of that part of the tendinous expansion from the extensor digitorum communis that is spread over the posterior convex surface of the fore-The second, to which Albinus gives the name of prior medii, is not quite so thick as the last described muscle. It arises by two heads, one of which springs from the inner side of the metacarpal bone of the forefinger, chiefly towards its convex surface, and the other arises from the adjacent ligaments, and from the whole outer side of the metacarpal bone that sustains the middle finger. These two portions unite as they de-scend, and terminate in a tendon, which is inserted, scend, and terminate in a tendon, which is inserted, in the same manner, as the preceding muscle, into the outside of the tendinous expansion that covers the posterior part of the middle finger. The third belongs likewise to the middle finger, and is therefore named posterior medii by Albinus. It arises, like the last described muscle, by two origins, which spring from the roots of the metacarpal bones of the ring and middle fingers, and from the adjacent ligaments and is in fingers, and from the adjacent ligaments, and is in-serted into the inside of the same tendinous expansion as the preceding muscle. The fourth, to which Albinus gives the name of posterior annularis, differs from the last two only in its situation, which is between the metacarpai bones of the ring and little fingers. It is inserted into the inside of the tendinous expansion of the extensor digitorum communis, that covers the posterior part of the ring-finger. All these four muscles serve to extend the fingers into which they are inserted, and likewise to draw them inwards, towards the thumb, except the third, or posterii medii, which, from its situation and insertion, is calculated to pull the

ins situation and insertion, is calculated to pair the middle finger outwards.

INTEROSEI PEDIS. These small muscles, in their situation between the metatarsal bones, resemble the interosei of the hand, and, like them, are divided into internal and external. The interosei pedis internal are three in number. They arise tendinous and fleshy, from the basis and inside of the metatarsal bones of the middle, the third, and little toes, in the same manner as those of the hand, and they each terminate in a tendon that runs to the inside of the first joint of these toes, and from thence to their upper surface, where it loses itself in the tendinous expansion that is sent off from the extensors. Each of these three muscles serves to draw the toe into which it is inserted towards the great toe. The interossei externi are four in num-The first arises tendinous and fleshy from the outside of the root of the metatarsal bone of the great toe, from the os cuneiforme internum, and from the root of the inside of the metatarsal bone of the foretoe Its tendon is inserted into the inside of the tendinous expansion that covers the back part of the testamous expansion that covers the back part of the toes. The second is placed in a similar manner between the metatarsal bones of the fore and middle toes, and is inserted into the outside of the tendinous expansion on the back part of the foretoe. The third and fourth are placed between the two next metatarsal bones, and are inserted into the outside of the middle and third toes. The first of these muscles draws the foretoe inwards towards the great toe. The three others pull the toes, into which they are inserted, outwards. They

all assist in extending the toes.

INTEROSSEOUS. (Interosseus; from inter, between, and os, a bone.) A name given to muscles, ligaments, &c. which are between bones.

INTERPELLA'TUS. (From interpello, to interrupt.)
A name given by Paracelsus to a disease attended with irregular or uncertain paroxysms.

INTERPOLA'TUS DIES. (From interpolo, to renew.) In Paracelsus, these are the days interpolated between two paroxysms

intersection inter, between, and scapula, the shoulder-blade.) That part of the spine which lies between the shoulders.

INTERSE PTUM. (From inter, between, and sep-

tum, an enclosure.) The uvula and the septum narium.

INTERSPINA'LIS. (From inter, between, and spina, the spine.) Muscles, nerves, &c. are so named which are between the processes of the spine.

INTERSPINALES. The fleshy portions between the spinous processes of the neck, back, and loins, distinguished by the names of interspinales colli, darsi et lumborum. Those which connect processes of the back and loins, are rather small tendous than muscles: they draw these processes pearer to each other.

they draw these processes nearer to each other.
INTERTRANSVERSA'LES. Four distinct small bundles of flesh, which fill up the spaces between the

transverse processes of the vertebre of the loins, and serve to draw them towards each other.

INTERTRIGO. (From inter, between, and tero, to rub.) An excoriation about the anus, groins, axilla, or other parts of the body, attended with inflammation and moisture. It is most commonly produced by the irritation of the urine, from riding, or some acrimony

INTE'STINE. (Intestinum; from intus, within.) The convoluted membraneous tube that extends from the stomach to the anus, receives the ingested food, retains it a certain time, mixes with it the bile and pan-creatic juice, propels the chyle into the lacteals, and covers the faces with mucus, is so called. The intes-tines are situated in the cavity of the abdomen, and are divided into the small and large, which have, be-sides their size, other circumstances of distinction.

The small intestines are supplied internally with folds, called valvula conniventes, and have no bands on their external surface. The large intestines have no folds internally; are supplied externally with three strong muscular bands, which run parallel upon the surface, and give the intestines a succated appearance; they have also small fatty appendages, called appendi-

culæ epiploicæ.

The first portion of the intestinal tube, for about the extent of twelve fingers' breadth, is called the duode-num; it lies in the epigastric region; makes three turnings, and between the first and second flexure receives by a common opening, the pancreatic duct, and the ductus communis choledochus. It is in this portion of the intestines that chylification is chiefly per-formed. The remaining portion of the small intestines is distinguished by an imaginary division into the jejunum and ileum.

The jejunum, which commences where the duode-num ends, is situated in the umbilical region, and is

mostly found empty; hence its name: it is everywhere covered with red vessels, and, about an hour and a half after a meal, with destended lacteals.

The ileum occupies the hypogastric region and the pelvis, is of a more pallid colour than the former, and pelvis, is of a more pallid colour than the former, and terminates by a transverse opening into the large intes-tines, which is called the valve of the ileum, valve of the cæcum, or the valve of Tulpius.

The beginning of the large intestines is firmly tied

down in the right iliac region, and for the extent of about four fingers' breadth is called the cacum, having adhering to it a worm-like process, called the processus caci vermiformis, or appendicula eaci vermiformis. The great intestine then commences colon, ascends towards the liver, passes across the abdomen, under the stomach, to the left side, where it is contorted like the letter S, and descends to the pelvis: hence it is divided in this course into the ascending portion, the transverse arch, and the sigmoid flexure. When it has reached arch, and the sigmoid flexure. When it has reached the pelvis, it is called the rectum, from whence it proceeds in a straight line to the anus.

The intestinal canal is composed of three membranes, or coats; a common one from the peritoneum, a muscular coat, and a villous coat, the villi being formed of the fine terminations of arteries and nerves, and the origins of lacteals and lymphatics. The intestines are connected to the body by the mesentery; the duodenum has also a peculiar collecting cellular substance, as have likewise the colon and rectum, by whose means the former is firmly accreted to the back, the colon to the kidneys, and the latter to the os coccygis, and, in women, to the vagina. The remaining portion of the tube is loose in the cavity of the abdomen. The arterice is loose in the cavity of the abdomen. The arteries of this canal are branches of the superior and inferior mesenteric, and the duodenal. The veins evacuate their blood into the vena ports. The negves are branches of the eight pair and intercostals. The lacteal vessels, which originate principally from the jejunum, proceed to the glands in the mesentery.

INTRAFOLIACEUS. Applied to stipulæ, which are above the footstalk, and internal with respect to

the leaf; as in Ficus carica and Morus nigra.

INTRICA'TUS. (From intrico, to entangle; so called from its intricate folds.) A muscle of the ear.

INTRI'NSECUS. (From intra, within, and secus, towards.) A painful disorder of an internal part

wards.) A painful disorder of an internal part
INTROCE'ssio. (From introcedo, to go in.) Depressio. A depression or sinking of any part inwards.
INTUS-SUSCE'PTION. (Intus-susceptio, and intro-susceptio; from intus, within, and suscipio, to receive.) A disease of the intestinal tube, and most frequently of the small intestines; it consists in a portion of gut passing for some length within another portion.
INTYBUS. (From in, and tuba, a hollow instrument: so named from the hollowness of its stalk.) See

Cichorium endivia.

I'NULA. (Contracted or corrupted from helenium, ηλενιον, fabled to have sprung from the tears of Helen.)

1. The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Polygamia superflua.

2. The herb inula, or elecampane. See Inula kelenium.

Inula, common. See Inula helenium.

INULA CRITHMOIDES. Caaponga of the Brazilians.
Trifolia spica; Crithmum marinum non spinosum.
The leaves and young stalks of this plant are pickled for

The leaves and young stakes of this plant are pickled for the use of the table; they are gently diuretic.

INULA DYSENTERICA. The systematic name of the smaller inula, Conyza media. Arnica Suedensis, Arnica spurio, Conyza: Inula—amplexicaulibus, cordato oblongis; caule villoso, paniculato; squamis calycinis, setaccis, of Linnæus. This indigenous plant was once considered as possessing great antidysenteric virtues. The whole herb is to the taste acrid, and at the same time rather aromatic. It is now fallen into dissame time rather aromatic. It is now fallen into dis-

INULA HELENIUM. The systematic name of the common inula or elecampane. Enula campana: Helenium. Inula—foliis amplexicaulibus ovatis rugosis subtus tomentosis, calycum squamis ovatis, of Linnæus. This plant, though a native of Britain, is seldom met with in its wild state, but mostly cultivated. The root, which is the part employed medicinally, in its recent state, has a weaker and less grateful smell than when thoroughly dried, and kept for a length of time, by which it is greatly improved; its odour then approaching to that of Florentine orris-root. It was formerly in high estimation in dyspepsia, pulmonary affections, and uterine obstructions, but is now fallen into disuse. From the root of this plant, Rose first extracted the peculiar vegetable principle called *inulin*. Funke has since given the following as the analysis of elecampane root:—A crystallizable vokatile oil; inulin; extractive; essertic adversabilizable region along the property of the control of t acetic acid; a crystallizable resin; gluten; a fibrous See Inulin.

INULIN In examining the Inula helenium, or Elecampane, Rose imagined he discovered a new vegetable product, to which the name of Inulin has been given. It is white and pulverulent, like starch. When thrown on red-hot coals, it melts, diffusing a white smoke, with the smell of burning sugar. It yields, on distillation in a retort, all the products furnished by gum. It dissolves readily in hot water; and precipitates almost entirely on cooling, in the form of a white powder; but before falling down, it gives the liquid a mucilaginous consistence. It precipitates quickly on the addition of alkohol.

The above substance is obtained by boiling the root of this plant in four times its weight of water, and leaving the liquid in repose. Pelletier and Caventou have found the same starch-like matter in abundance in the root of colchicum; and Gautier in the root of

pellitory.

INUSTION. (From in, and uro, to burn.) It is sometimes used for hot and dry seasons; and formerly by surgeons for the operation of the cautery.

INVERECU'NDUM OS. (From in, not, and verecundus modest.) An obsolete name of the frontal bones, from its being regarded as the seat of impudence.

INVERSION. Inversio. Turned inside outward. INVOLUCELLUM. A partial involucrum. See

Involucrum. INVOLU'CRUM. (From in, and volvo, to wrap up; because parts are enclosed by it.) In anatomy.

1. A name of the pericardium.

2. A membrane which covers any part

In botany. A leafy calyx, remote from the flower, applied particularly to umbelliferous plants.

From the part of the umbel in which it is placed, it

is called.

1. Involucrum universaie, being at the base of the whole umbel; as in Coriandrum sativum, Scandiz cerefolium, and Cornus mascula.

2. I. partiale, called involucellum; at the bottom of each umbellula, or partial stalk of the umbel; as in

Daucus carota.

3. I. dimidiatum, surrounding the middle of the stalk at the base of the umbel; as in Ethusa cynapium.

From the number of the involucre leaves

4. Monophyllous; as in Coriander and Hermas.
5. Tryphillous; as in Bupleurum junceum.
6. Polyphillous; as in Bunium bulbocastanum, and

7. Pinnatifid; as in Daucus carota, and Sium an-

8. Reflex, turned back; as in Selinum monnieri. Solitary flowers rarely have an involucrum; yet it

is found in the anemones INVOLUTUS. Involute. Rolled inwards.

plied to leaves, petals, &c. when their margins are turned inward; as in the leaves of Pinguicula, and petals of Anethum, Pastinaca, and Bupleurum.

IODATE. A compound of iodine with oxygen, and a metallic basis. The oxiodes of Davy.

lones. (From 105, verdigris.) Green matter thrown

off by vomiting

IODIC ACID. Acidum iodicum. Oxiodic acid. When barytes water is made to act on iodine, a soluble hydriodate, and an insoluble iodate of barytes, are formed. On the latter, well washed, pour sulphuric acid, equivalent to the barytes present, diluted with twice its weight of water, and heat the mixture. The iodic acid quickly abandons a portion of its base, and combines with the water; but though even less than the equivalent proportion of sulphuric acid has been used, a little of it will be found mixed with the liquid acid. If we endeavour to separate this portion, by IODIC ACID. Acidum iodicum. Oxiodic acid. acid. If we endeavour to separate this portion, by adding barytes water, the two acids precipitate to-

adding barytes water, the two acids precipitate together.

The above economical process is that of Gay Lussac; but Sir H. Davy, who is the first discoverer of this acid, invented one more elegant, and which yields a purer acid. Into a long glass tube, bent like the letter L inverted, (7) shut at one end, put 100 grains of chlorate of potassa, and pour over it 400 grains of muriatic acid, specific gravity 1.105. Put 40 grains of iodine info athin long-necked receiver. Into the open end of the bent tube put some muriate of lime, and then connect it with the receiver. Apply a gentle heat to the sealed end of the former. Protoxide of chlorine is evolved, which, as it comes in contact with the iodine, produces combustion, and two new compounds, a compound of iodine and oxygen, and one of iodine and chlorine. The latter is easily separated by heat, while the former remains in a state of purity.

The iodic acid of Sir H. Davy is a white semitransparent solid. It has a strong acide-astringent taste,

parent solid. It has a strong acido-astringent taste, but no smell. Its density is considerably greater than that of sulphuric acid, in which it rapidly sinks. It melts, and is decomposed into iodine and oxygen, at a temperature of about 620°. A grain of iodic acid gives out 176.1, grain measure, of oxygen gas. It would appear from this, that iodic acid consists of 15.5 iodine,

to 5 oxygen

Iodic acid deliquesces in the air, and is, of course, very soluble in water. It first reddens and then destroys the blues of vegetable infusions. It blanches other vegetable colours. Between the acid prepared by Gay Lussac, and that of Sir H. Davy, there is one important difference. The latter, being dissolved, may, by evaporation of the water, pass not only to the inspissated syrup state, but can be made to assume a pasty consistence; and, finally, by a stronger heat, yields the solid substance unaltered. When a mixture of it, with charcoal, sulphur, resin, sugar, or the combustible metals, in a finely divided state, is heated, detonations are produced; and its solution rapidly corrodes all the metals to which Sir H. Davy exposed it, both gold and platinum, but much more intensely the both gold and platinum, but much more intensely the first of these metals.

phuric acid is dropped into a concentrated solution of it in hot water, a solid substance is precipitated, which consists of the acid and the compound; for, on evaporating the solution by a gentle heat, nothing rises but water. On increasing the heat in an experiment of this kind, the solid substance formed fused; and on cooling the mixture, rhomboidal crystals formed of a pale yellow colour, which were very fusible, and which did not change at the heat at which the com-

pale yellow colour, which were very fusible, and which did not change at the heat at which the compound of oxygen and iodine decomposes, but sublimed unaltered. When urged by a much stronger heat, it partially sublimed, and partially decomposed, affording oxygen, iodine, and sulphuric acid.

With hydro-phosphoric, the compound presents phenomena precisely similar, and they form together a solid, yellow, crystalline combination.

With hydro-nitric acid, it yields white crystals in rhomboidal plates, which, at a lower heat than the preceding acid compounds, are resolved into hydro-nitric acid, oxygen, and iodine. By liquid muriatic acid, the substance is immediately decomposed, and the compound of chlorine and iodine is formed. All these acid compounds redden vegetable blues, taste sour, and dissolve gold and platinum. From these curious researches Sir H. Davy infers, that Gay Lussac's iodic acid is a sulpho-iodic acid, and probably a definite compound. However minute the quantity of sulphuric acid made to act on the iodide of barium may be, a part of it is always employed to form the compound acid; and the residual fluid contains both the compound acid and a certain quantity of the original salt."—Ure.

IODIDE. Iode; Iodure. A compound of iodine with a metal; as Iodide of potassium.

IODINE. (Iodina; from widns, a violet colour, so termed from its beautiful colour.) A peculiar or un decompounded principle.

"Iodine was accidentally discovered, in 1812, by

decompounded principle.
"Iodine was accidentally discovered, in 1812, by De Courtois, a manufacturer of saltpetre at Paris. In his processes for procuring soda from the ashes of sea-weeds, he found the metallic vessels much corroded; and, in searching for the cause of the corrosion, he made this important discovery. But for this circum-stance, nearly accidental, one of the most curious of stance, nearly accidental, one of the most curious of substances might have remained for ages unknown, since nature has not distributed it, in either a simple or compound state, through her different kingdoms, but has confined it to what the Roman satirist considers as the most worthless of things, the vile seaweed.

Iodine derived its first illustration from Clement and

Iodine derived its first illustration from Clement and Desormes. In their memoir, read at a meeting of the Institute, these able chemists described its principal properties. They stated its sp. gr. to be about 4; that it becomes a violet-coloured gas at a temperature below that of boiling water,—whence its name; that it combines with the metals, and with phosphorus and sulphur, and likewise with the alkalies and metallic oxides; that it forms a detonating compound with ammonia; that it is soluble in alkohol, and still more soluble in ether; and that, by its action upon phosphorus and upon hydrogen, a substance having the characters of muriatic acid is formed. In this communication they offered no decided opinion respecting its cation they offered no decided opinion respecting its

In 1813, Sir H. Davy happened to be on a visit to Paris, receiving, amid the political convulsions of France, the tranquil homage due to his genius. 'When Clement showed iodine to me,' says Sir H. Davy, 'he believed that the hydriodic acid was muriatic acid; and Gay Lussac, after his early experiments, made originally with Clement, formed the same opinion, and maintained it, when I first stated to him my belief, that it was a new and peculiar acid, and that iodine was a substance analogous in its chemical relations to chlorine.'

Iodine has been found in the following seaweeds,

the Alga aquatica of Linnaus:-Fucus cartilagineus, Fucus Fucus palmatus, filum, membranaceus, filamentosus, digitatus, rubens, saccharinus, nodosus, Ulva umbilicalis, serratus, pavonia,

siliquosus, linza, and in sponge.

It is from the incinerated seaweed, or kelp, tha iodine in quantities is to be obtained. Dr. Wollaston It appears to form combinations with all the fluid or solid aeids which it does not decompose. When sulfirst communicated a precise formula for extractive it

Dissolve the soluble part of kelp in water. Concentrate the liquid by evaporation, and separate all the crystals that can be obtained. Pour the remaining liquid into a clean vessel, and mix with it an excess of pulphuric acid. Boil this liquid for some time. Sul-phur is precipitated, and muriatic acid driven off. Decant off the clear liquid, and strain it through wool. Put it into a small flask, and mix it with as much black oxide of manganese as we used before of sulphuric acid. Apply to the top of the flask a glass tube, shut at one end. Then heat the mixture in the flask. The iodine sublimes into the glass tube. None can be obtained from sea-water.

lodine is a solid, of a grayish-black colour and me-tallic lustre. It is often in scales similar to those of micaceous iron ore, sometimes in rhomboidal plates, very large and very brilliant. It has been obtained in elongated octohedrons, nearly half an inch in length; the axes of which were shown by Dr. Woliaston to be to each other, as the numbers 2, 3, and 4, at least so nearly, that in a body so volatile, it is scarcely possible nearly, that in a body so volatile, it is scarcely possible to detect an error in this estimate, by the reflective goaiometer. Its fracture is lamellated, and it is soft and friable to the touch. Its taste is very acrid, though it be very sparingly soluble in water. It is a deadly poison. It gives a deep brown stain to the skin, which soon vanishes by evaporation. In odour, and power of destroying vegetable colours, it resembles very diduce aqueous chlorine. The sp. gr. of iodine at 62½ is 4.948. It dissolves in 7000 parts of water. The solution is of an orange-vellow colour, and in small quantity tinges an orange-yellow colour, and in small quantity tinges raw starch of a purple hue.

It melts, according to Gay Lussac, at 227° F., and is volatilized under the common pressure of the atmosphere, at the temperature of 350°. It evaporates pretty quickly at ordinary temperatures. Boiling water aids its sublimation, as is shown in the above process of extraction. The sp. gr. of its violet vapour is 8.678. It is a non-conductor of electricity. When the voltaic chain is interrupted by a small fragment of it, the de-

composition of water instantly ceases.

Iodine is incombustible, but with azote it forms a curious detonating compound; and in combining with several bodies, the intensity of mutual action is such as to produce the phenomena of combustion. Its combi-nations with oxygen and chlorine are described, under iodic and chloriodic acids.

With a view of determining whether it was a simple or compound form of matter, Sir H. Davy exposed it to the action of the highly inflammable metals. When the action of the highly inflammable metals. When its vapour is passed over potassium heated in a glass tube, inflammation takes place, and the potassium burns slowly with a pale blue light. There was no gas disengaged when the experiment was repeated in a mercu ial apparatus. The iodide of potassium is white, fusible at a red heat, and soluble in water. It has a peculiar acrid taste. When acted on by sulphuric acid, it effervesces, and iodine appears. It is evident that in this experiment there had been no decoupons. that in this experiment there had been no decomposition; the result depending merely on the combination of iodine with potassium. By passing the vapour of iodide over dry red-hot potassa, formed from potassium, oxygen is expelled, and the above iodine results. Hence, we see, that at the temperature of ignition, the affinity between iodine and potassium is superior to that of the latter for oxygen. But iodine in its turn is displaced by chlorine, at a moderate heat, and if the latter be in ex-cess, chloricdic acid is formed. Gay Lussac passed vapour of iodine in a red heat over melted subcarbonate of potassa; and he obtained carbonic acid and oxygen gases, in the proportions of two in volume of the first, and one of the second, precisely those which exist in the salt.

The oxide of sodium, and the succarbonate of soda, are also completely decomposed by iodine. these experiments it would seem, that this substance ought to disengage oxygen from most of the oxides; but this happens only in a small number of cases. protoxides of lead and bismuth are the only oxides not reducible by mere heat, with which it exhibited that power. Barytes, strontian, and lime combine with lodine, without giving out oxygen gas, and the oxides of zine and iron undergo no alteration in this respect. From these facts we must conclude, that the decomposition of the oxides by iodine depends less on the condensed state of the oxygen, than upon the affinity of the metal for iodine. Except barytes, strontjan, and the metals which do not decompose water will give

lime, no oxide can remain in combination with loding at a red heat. For a more particular account of some iodides, see Hydriodic acid; the compounds of which, in the liquid or moist state, are hydriodates, but change, on drying, into iodides, in the same way as the muriates become chlorides.

From the proportion of the constituents in hydriodic acid, 15.5 has been deduced as the prime equivalent of

iodine.

Indine forms with sulphur a feeble compound, of a grayish-black colour, radiated like sulphuret of antimony. When it is distilled with water, iodine separates. Iodine and phosphorus combine with great rapidity

at common temperatures, producing heat without light. From the presence of a little moisture, small quantities

of hydriodic acid gas are exhaled.

Oxygen expels iodine from both sulphur and phos-

phorus.

Hydrogen, whether dry or moist, did not seem to have any action on iodine at the ordinary temperature; but if we expose a mixture of hydrogen and iodine to a red heat in a tube, they unite together, and hydriodic acid is produced, which gives a reddish brown colour to water. Sir H. Davy threw the violetcoloured gas upon the flame of hydrogen, when it seemed to support its combustion. He also formed a compound of iodine with hydrogen, by heating to redness the two bodies in a glass tube.

Charcoal has no action upon iodine, either at a high or low temperature. Several of the common metals, on the contrary, as zinc, iron, tin, mercury, attack it readily, even at a low temperature, provided they be in a divided state. Though these combinations take place rapidly, they produce but little heat, and but

rarely any light.

The compound of iodine and zinc, or iodide of zinc, is white. It melts readily, and is sublimed in the state of fine, acicular, four-sided prisms. It is very soluble in water, and rapidly deliquesces in the air. It dissolves in water without the evolution of any gas. The solution is slightly acid, and does not crystallize. The alkalies precipitate from it white oxide of zinc; while concentrated sulphuric acid disengages hydriodic acid and iodine, because sulphurous acid is produced. The solution is a hydriodate of oxide of zinc. When iodine and zinc are made to act on each other under water in vessels hermetically sealed, on the application of a slight heat, the water assumes a deep reddish-brown colour, because, as soon as hydriodic acid is produced, it dissolves iodine in abundance. But by degrees the zinc, supposed to be in excess, combines with the whole iodine, and the solution becomes colourless like

Iron is acted on by iodine in the same way as zinci and a brown iodide results, which is fusible at a red heat. It dissolves in water, forming a light green so-lution, like that of muriate of iron. When the dry iodide was heated, by Sir H. Davy, in a small retort containing pure ammoniacal gas, it combined with the ammonia and formed a compound which volatilized

without leaving any oxide.

without leaving any oxide.

The iodide of tin is very fusible. When in powder, its colour is a dirty orange-yellow, not unlike that of glass of antimony. When put into a considerable quantity of water, it is completely decomposed. Hydrodic acid is formed, which remains in solution in the water, and the oxide of tin precipitates in white flocanii. If the quantity of water be small, the acid, being more sonewheath, exterior a postion of oxide of being more concentrated, retains a portion of oxide of tin and forms a silky orange-coloured salt, which may be almost entirely decomposed by water. tin act very well on each other, in water of the temperature of 2129. By employing an excess of tin, we may obtain pure hydriodic acid, or at least an acid containing only traces of the metal. The tin must be in considerable quantity, because the oxide which precipitates on its surface, diminishes very much its action on loding. on lodine.

Antimony presents with iodine the same phenomena as tin; so that we might employ either for the prepara-tion of hydriodic acid, if we were not acquainted with

preferable methods.

The iodides of lead, copper, bismuth, silver, and mer-cury, are insoluble in water, while the iodides of the very oxidizable metals are soluble in that liquid. It we mix a hydriodate with the metallic solutions, all

precipitates, while those which decompose that liquid | mandy (in France) for the express purpose of examin-will give none. This is at least the case with the | ing upon the spot the different species of Fucus; and will give none. This above-mentioned metals

above-mentioned metals

There are two iodides of mercury; the one yellow, the other red; both are fusible and volatile. The yellow or prot-iodide, contains one half less iodine than the deut-iodide. The latter when crystallized is a bright crimson. In general, there ought to be for each metal as many iodides as there are oxides and chlorides. All as many footness as there are exides and chlorides. All the iodides are decomposed by concentrated sulphuric and nitric acids. The metal'is converted into an oxide, and iodine is disengaged. They are likewise decom-posed by oxygen at a red heat, if we except the iodides of potassium, sodium, lead, and bismuth. Chlorine likewise separates iodine from all the iodides; but iodine, on the other hand, decomposes most of the sulphurets and phosphurets.

phurets and phosphurets.

When iodine and oxides act upon each other in contact with water, very different results take place from those above described. The water is decomposed; its hydrogen unites with iodine, to form hydriodic acid; while its oxygen, on the other hand, produces with iodine, iodic acid. All the oxides, however, do not give the same results. We obtain them only with potassa, soda, barytes, strontian, lime, and magnesia. The oxide of zinc, precipitated by ammonia from its solution in sulphuric acid, and well washed, gives no trace of iodate and hydriodate.

From all the above-recited facts, we are warranted

From all the above-recited facts, we are warranted in concluding iodine to be an undecompounded body. In its specific gravity, lustre, and magnitude of its prime equivalent, it resembles the metals; but in all its chemical agencies, it is analagous to oxygen and chlorine. It is a non-conductor of electricity, and possesses, like these two bodies, the negative electrical energy with regard to metals, inflammable and alkaline substances; and hence, when combined with these substances in aqueous solution, and electrised in the voltaic stances in aqueous solution, and electrised in the voltaic circuit, it separates at the positive surface. But it has a positive energy with respect to chlorine: for when united to chlorine, in the chloriodic acid, it separates at the negative surface. This likewise corresponds with their relative attractive energy, since chlorine expels iodine from all its combinations. Iodine dissolves in carburet of sulphur, giving, in very minute quantities, a fine amethystine tint to the liquid.

Iodide of mercury has been proposed for a pigment.

Iodide of mercury has been proposed for a pigment. Orfila swallowed 6 grains of iodine; and was immediately affected with heat, constriction of the throat, nausea, eructation, salivation, and cardialgia. In ten nausea, cructation, salivation, and cardialgia. In ten-minutes he had copious bilious vomitings, and slight colic pains. His pulse rose from 70 to about 90 beats in a minute. By swallowing large quantities of muci-lage, and emollient clysters, he recovered, and felt nothing next day but slight fatlgue. About 70 or 80 grains proved a fatal dose to dogs. They usually died on the fourth or fifth day.

Dr. Coindet of Geneva has recommended the use of lodine in the form of tincture, and also hydriedita of

lodine in the form of tincture, and also hydriodate of potassa or soda, as an efficacious remedy for the cure of glandular swellings, of the goitrous and scrofulous kind. I have found an ointment composed of 1 oz. hog's lard, and I drachm of iodide of zinc, a powerful external application in such cases. About a drachm of this ointment should be used in friction on the swelling once or twice a-day."—Ure's Chem. Dict.

[This powerful remedy, which has recently been introduced into practice, is obtained from the plants affording soda, or the vegetables called "Varecks," by the French, or from other species of the algae or seaweeds. A species furnishing a more considerable portion of iodine than its congeners is the Fucus saccharinus, or Sugar-seaweed, belonging to the class lodine in the form of tincture, and also hydriodate of

charinus, or Sugar-seaweed, belonging to the class Cryptogamia, order Alga.

In the year 1815, Dr. Mitchill received from Mr. G. De Claubry, of Paris, his researches upon this subject. His particular objects were to find whether iodine ex-His particular objects were to find whether iodine existed in ocean-water, and the condition and manner of its evolution from the vegetables that furnished the soda or salt of Varecks. He ascribes the discovery of this substance to Messrs. Macquer and De La Salle, who, in their experiments upon the Varecks or seaweeds, discovered iodine in the mother-water of the soda they afforded. This fact he deemed sufficiently important to encourage chemists to look for it in the vegetables themselves, from which that kind of soda was obtained. He made a journey to the west of Nor-462 ing upon the spot the different species of Fucus; and he obtained from the able botanist of Caen, various kinds of these marine plants, which he submitted to experiment. His analyses were chiefly made upon the following sorts, viz.

I. Of the Family of the Ulvæ.

1. The Ulva saccharina.

digitata.

3. The Fucus saccharinus, of Linnaus.

II. Of the Family of the Varecks. 1. The Fucus vesiculosus.

siliquosus. III. Of the Family of the Ceramium,

1. The Ceramium filum, or the Fucus filum, of Linnæus.

Such and other seaweeds are gathered on the shores of the ocean, among other purposes, for that of being burned to ashes, for the preparation of the fixed alkali, called the soda or salt of Varecks by the French and Dutch, as distinguished from the soda or barilla, made by burning the maritime plant called salsola. The product of the above-mentioned scawceds is a compli-1. A small quantity of the subcarbonate of soda.

2. A good deal of the hydro-chlorate of soda.

3. . . . sulphate of soda.

Sulphate of magnesia.

Hydro-chlorate of potash and magnesia.

Subcarbonate of potash.

A little sulphuretted sulphate of soda, and

8. A minute portion of the hydro-iodate of potash.

The poverty of this sort of soda gives it but little value in commerce, its chief consumption being in the glass manufactures. It is called kelp, and contains much less soda than barilla.

It was in the mother waters of the leys or lixiviums kelp that iodine was first discovered, as is said by Mr. Courtois. All the foregoing products were consequent upon the preceding incineration of the fuci. As a number of these fuci are employed in their recent state as human food, (as is the fucus edulis) the several sorts acquired an interest corresponding to their usefulness, as applicable for manure, for making kelp or

iodine, or for food.

On burning the fucus saccharinus, one of the results of a most elaborate and complicated analysis of the residue, was that potash was associated with iodine in

the form of a hydro-todate, the hydro-todate of potash. As a general remark, he says, that the species of fuci which contain the most mucilage, contain more iodine than the others, by a large difference.

This analysis of ocean or sea-water, proved that it contained no iodine; therefore it may be fairly concluded, that the peculiar article under consideration, is prepared or stable and by the living oceanous of these prepared, or elaborated, by the living economy of these marine vegetables. Of the fuci he analyzed, the fucus saccharinus which contained more of it than the other saccharinus which contained more of it than the other species. This species, treated with sulphuric acid, yielded immediately the lodine it contained, without the process of burning to ushes. This saves the trouble of resorting to the cau mere, or mother water, to obtain it. The iodine has an affinity to oxygen, and under convenient circumstances, forms the hydro-iodic

Iodine is particularly acted upon by starch, and other

Iodine is particularly acted upon by starch, and other vegetable feculæ, whereby it acquires, in the cool and dry way by trituration, a violet colour, passing into blue and black, according to the relative proportions of the iodine and starch employed. The hue is reddish if the starch predominates; a superb blue, if the ingredients are duly apportioned; and black, if the iodine is in excess; as also violets of different shades, between the reds and blues. By a particular process, iodine may be obtained white. This is shown in the memoir of Messrs. Colin and Claubry, on the combination of iodine with vegetable and animal substances, as contained in the Annals of Chemistry for 1814.

It has lately been discovered, that iodine existed in small quantity, with a portion of carbon, and of the other muriate and carbonate of soda, in the officinal preparation called burnt sponge, or pulvis spongia

The sponges are in modern zoology, classed among

the zoophytes. They are marine productions, of a fibrous and tough constitution, covered with a slimy matter, in which it has not yet been possible to discover either polypes, or other moveable parts, nor any decided proofs of animality. It seems, nevertheless, that living sponges evince a kind of shrinking, or contraction, on being touched, and that there is a sort of palpitation in the pores, with which the body of the palpitation in the pores with which the body of the sponge is pierced.

From such feeble evidence of the animal nature of the sponge, it has been doubted by some naturalists, whether they ought to be referred to the animal kingdom. By others they have been roundly pronounced to be vegetables. Dr. Mitchill's opinion is, that from the analysis of sponge, the proximity of the results to those of varecks and other seaweeds, and more especially the detection and cially the detection and presence of iodine, is in favour

of the vegetable character of sponge.

Here regetable character of sponge.

Burnt sponge was admitted into the Edinburgh New Dispensatory, for the first time, in 1786, by reason of the reputation it had acquired as a remedy for scrofulous and cutaneous diseases, for removing obstruc-tions in the glands, and among others, for lessening and removing the bronchocele. There the process for reducing it to ashes is detailed. The dose is a scruple several times a-day.

Now, since the discovery of iodine in the ashes of sponge, modern physicians have ascribed the chief vir-tue, against the aforesaid disorders, to this ingredient. The conjecture is a rational one; for it is more probable its efficacy proceeds from the iodine than from the charcoal and neutral salts.

Upon the faith of this interpretation, it was con-ceived better to prescribe the iodine by itself, or in known and exact combination, than in form of burnt sponge, and as sponge contained this active principle, it was naturally concluded, that the iodine would be in all respects as good when prepared from the sea-

in all respects as good when prepared from the sea-wrecks as from sponges.

In that ugly and obstinate disorder, the goitre, Dr.
Coindet, of Geneva, (in Switzerland,) has prescribed iodine with remarkable success. The preparation he employs requires explanation, by reason of its chemi-cal intricacy. To understand the receipt we must recapitulate. The forms of iodine are,

1. Simple iodine. 2. Oxide of iodine, by starch or other feculae. 3. Iodic-acid. 4. Hydro-iodic acid. 5. Hydro-iodate of potash, by burning, &c.

Hydro-iodate of potash, by burning, &c.

Dr. Coindet prescribes what is termed "Ioduretted hydro-iodate of potash." To prepare this the hydro-iodic acid must first be procured, which is done thus: Take of alkoholic spirit, pure iodine, any quantities. Then pass sulphuretted hydrogen through the solution. This forms the hydro-iodic acid. The next process is, to take potash and hydro-iodic acid, and combine them to saturation. This forms Dr. Coindet's medicine. The hydro-iodate of potash.—To reduce this into a form for medicinal prescription, he proceeds as follows: Take of the hydro-iodate of potash, grs. 36. Pure iodine, grs. 10. Distilled water, \(\frac{z}{2}\)j. m.

This is the ioduretted hydro-iodate of potash. It is so active a preparation, that a full dose is from 5 to 10 drops three times a-day in syrup. The dose may be

drops three times a-day in syrup. The dose may be gradually increased, according to circumstances, but with great caution, to the extent of 20 drops. It must be remembered, whenever it is administered, an overdose must be avoided, as it acts with an extreme and

dangerous effect upon the constitution.

They say, that after a few weeks' skilful administra-tion, the external swelling will gradually disappear. Should the patient, while under a course of it, experi-ence any considerable quickening of the pulse, a rapid loss of flesh, palpitation of the heart, a dry cough, restlessness, and want of sleep, and in certain cases with an increase of appetite for food, though the swell-ing shall undergo diminution. It will be precessare to ing shall undergo diminution, it will be necessary to intermit the medicine for some days; and afterward resume the use of it when the health and safety of the patient will permit -Notes from Mitchill's Lects. on

IODO-SULPHURIC ACID. "When sulphuric acid is poured, drop by drop, into a concentrated and hot aqueous solution of iodic acid, there immediately results a precipitate of iodo-sulphuric acid, possessed of peculiar properties. Exposed gradually to the action of a gentle heat, the iodo-sulphuric acid melts, and crysfallizes on cooling into rhomboids of a pale yellow

colour. When strongly heated, it sublimes, and is partially decomposed; the latter portion being converted into oxygen, iodine, and sulphuric acid. colour.

Phosphoric and nitric acids exhibit similar phenomena. These compound acids act with great energy on the metals. They dissolve gold and platinum."

IOLITE. Dichroite. Prismato-rhomboidal quartz of Mohs. This is of a colour Intermediate between black, blue, and violet-blue. When viewed in the direction of the axis of the crystals, the colour is dark indige blue; but perpendicular to the axis of the crystals. indigo-blue; but perpendicular to the axis of the crystals, pale brownish-yellow. It comes from Finland.
I'onis. (From 101 a violet.) A carbuncle of a violet

colour.

IO NTHUS. (From tov, a violet, and aveos, a flower.)

A pimple in the face, of a violet colour.

10TACI'SMUS. (From ωτα, the Greek letter ι.)

A defect in the tongue or organs of speech, which renders a person incapable of pronouncing his letters.

IPECACUA'NHA. (An Indian word.) See Calli-

cocca ipecacuanha.

IRI'TIS. (Iritis, idis. f.; from iris, the name of the membrane.) Inflammation of the iris: it produces the symptoms of deep-seated or internal inflammation of the eye. See Ophthalmia.

symptoms of deep-seated or internal infiammation of the eye. See Ophthalmia.

IRON. Ferrum. Of all the metals, there is none which is so copiously and so variously dispersed through nature as iron. In animals, in vegetables, and in all parts of the mineral kingdom, we detect its presence. Mineralogists are not agreed with respect to the exist-ence of native iron, though immense masses of it have been discovered, which could not have been the products been discovered, which could not have been the products of art; but there is much in favour of the notion that these specimens have been extracted by subterraneous fire. A mass of native iron, of 1600 pounds weight, was found by Pallas, on the river Denisel, in Siberia; and another mass of 300 pounds was found in Paraguay, of which specimens have been distributed everywhere. A piece of native iron, of two pounds weight, has been also met with at Kamsdorf, in the territories of Neustadt, which is still preserved there. These masses evidently did not originate in the places where they were found.

[Specimens of native iron have been found in several places in America, in situations which give rise to the places in America, in situations which give rise to the conjecture, that they were of meteoric origin. One of the largest of these has been deposited by its owner, Colonel Gibs, in the Cabinet of the New-York Lyceum of Natural History. It is an irregular mass, weighing upwards of 3000 lbs. "Its surface, which is covered by a blackish crust, is greatly indented, from which it would appear that this mass had been in a soft state. On removing the crust, the iron, on exposure to moisture, soon becomes oxidated. Sp. gr. 7.400.

"It appears to consist entirely of iron, which possesses a high degree of malleability; experiments have been made without detecting nickel or any other

have been made without detecting nickel or any other metal. This enormous mass of iron is said to have been found near the Red river, in Louisiana."-Bruce's

Min. Journal. A.]

There are a vast variety of iron ores: they may, however, be all arranged under the following genera; namely, sulphurets, carburets, oxides, and salts of iron. The sulphurets of iron form the ores called Pyrites, of which there are many varieties. Their colour is, in general, a straw-yellow, with a metallic lustre; sometimes brownish, which sort is attracted by the magnet. They are often amorthous, and often also crystallized. times brownish, which sort is attracted by the magnet. They are often amorphous, and often also crystallized. Iron, in the state of a carburet, forms the graphite of Werner (plumbago). This mineral occurs in kidneyform lumps of various sizes. Its colour is a dark irongray, or brownish-black; when cut, bluish-gray. It has a metallic lustre. Its texture is fine-grained. It is very brittle. The combination of iron with oxygen is very abundant. The common magnetic ironstone, or load-stone, belongs to this class; as does specular iron ore, and all the different ores called hæmatites, or blood-stone. Iron, united to carbonic acid, exists in the sparry iron ore. Joined to arsenic acid, it exists in the ores called arseniate of iron, and arseniate of iron and copper.

niate of iron and copper.

[The different varieties of the ores of iron are arranged as follows in Cleaveland's Mineralogy, which is a standard work on the subject in the United States:—

Species 1. Native iron. 2. Arsenical iron.

a. Argentiferous arsenical iron: 3. Sulphuret of iron. Iron Syrites.
a. Common sulphuret of iron.

b. Radiated .. c. Hepatic

Sub-species 1. Magnetic sulphuret of iron. 2. Arsenical

4. Magnetic oxide of iron a. Native magnet.b. Iron sand.

c. Green iron earth. Arseniate of iron.

13. Chromate of iron. a. Crystallized chromate of iron.

b. Granular

c. Amorphous

Properties of iron.—Iron is distinguished from every other metal by its magnetical properties. It is attracted by the magnet, and acquires, under various conditions, the property of attracting other iron. Pure iron is of a whitish gray, or rather bluish colour, very slightly livid; but when polished, it has a great deal of brilliancy. Its texture is either fibrous, fine-grained or in liancy. Its texture is either fibrous, fine-grained, or in dense plates. Its specific gravity varies from 7.6 to 7.8. It is the hardest and most elastic of all the metals. It is extremely ductile, and may therefore be drawn into It is extremely ductile, and may therefore be drawn into wire as fine as a human hair; it is also more tenacious than any other metal, and yields with facility to pressure. It is extremely infusible, and when not in contact with the fuel, it cannot be melted by the heat which any furnace can excite; it is, however, softened by heat, still preserving its ductility; and when thus softened, different pieces may be united; this constitutes the valuable property of welding. It is very dilatable by heat. It is the only metal which takes fire by the collision of flint. Heated in contain with air it becomes oxidized. If intensely and briskly heated, it takes fire with scintillation, and becomes a black oxide. It combines with carbon, and forms what is it takes fire with scintillation, and becomes a black oxide. It combines with carbon, and forms what is called steel. It combines with phosphorus in a direct and an indirect manner, and unites with sulphur readily by fusion. It decomposes water in the cold slowly, but rapidly when ignited. It decomposes most of the metallic oxides. All acids act upon iron. Very concentrated sulphuric acid has little or no effect upon it, but when diluted it oxidizes it rapidly. The nitric acid oxidizes it with great vehemence. Muriate of ammonia is decomposed by it. Nitrate of potassa detonates very vigorously with it. Iron is likewise dissolved by alkaline sulphurets. It is capable of combining with a number of metals. It does not unite with lead or bismuth, and very feebly with mercury. It detonates by percussion with the oxygenated muriates. percussion with the oxygenated muriates.

percussion with the oxygenated muriates.

Method of obtaining iron.—The general process by which iron is extracted from its ores, is first to roast them by a strong heat, to expel the sulphur, carbonic acid, and other mineralizers which can be separated by heat. The remaining ore, being reduced to small pieces, is mixed with charcoal, or coke; and is then exposed to an intense heat, in a close furnace, excited by bellows; the oxygen then combines with the carbon, forming carbonic acid gas during the process, and the oxide is reduced to its metallic state. There are likewise some fluxes necessary in order to facilitate the separation of the melted metal. The matrix of the iron ore is generally either argillaceous or calcareous, or sometimes a portion of siliceous earth; but whichiron ore is generally either argiliaceous or calcareous, or sometimes a portion of siliceous earth; but whichever of these earths is present, the addition of one or both of the others makes a proper flux. These are therefore added in due proportion, according to the nature of the ores; and this mixture, in contact with the fuel, is exposed to a heat sufficient to reduce the oxide to its metallic state.

The metal thus obtained, and called smelted, pig, or cast iron, is far from being pure, always recaping a

cast iron, is far from being pure, always retaining a considerable quantity of carbon and oxygen, as well as several heterogeneous ingredients. According as one or other of these predominates, the property of

the metal differs. Where the oxygen is present in a the metal differs. Where the oxygen is present in a large proportion, the colour of the iron is whitish gray; it is extremely brittle, and its fracture exhibits an appearance of crystallization: where the carbon exceeds, it is of a dark gray, inclining to blue, or black, and is less brittle. The former is the white, the latter the black crude iron of commerce. The gray is intermediate to both. In many of these states, the iron is much more fusible than when pure; hence it can be fused and cast into any form; and when suffered to cool slowly, it crystallizes in octahedra; it is also cool slowly, it crystallizes in octahedra: it is also much more brittle, and cannot therefore be either flattened under the hammer, or by the laminating

To obtain the iron more pure, or to free it from the carbon with which it is combined in this state, it must be refined by subjecting it to the operations of melting and forging. By the former, in which the metal is kept in fusion for some time, and constantly kneaded and stirred, the carbon and oxygen it contains are partly combined, and the produced carbonic acid gas is expelled: the metal at length becomes viscid and stiff; it is then subjected to the action of a very large hammer, or to the more equal, but less forcible pres-sure of large rollers, by which the remaining oxide of iron, and other impurities, not consumed by the fusion, are pressed out. The iron is now no longer granular nor crystallized in its texture; it is fibrous, soft, duc-tile, malleable, and totally infusible. It is termed forged, wrought, or bar iron, and is the metal in a purer state, though far from being absolutely pure.

The compounds of iron are the following:

1. Oxides; of which there are two, or perhaps three.

1st, The oxide, obtained either by digesting an excess of iron filings in water, by the combustion of iron wire in oxygen, or by adding pure ammonia to solution of green copperas, and drying the precipitate out of contact of air, is of a black colour, becoming white by its union with water, in the hydrate, attractible by the magnet, but more feebly than iron. By a mean of the experiments of several chemists, its composition seems to be,

100 28.5 77.82 22.18 Iron,

Oxygen, 28.5 22.18 1.0

2d, Deutoxide of Gay Lussac. He forms it by exposing a coil of fine iron wire, placed in an ignited porcelain tube, to a current of steam, as long as any hydrogen comes over. There is no danger, he says, of generating peroxide in this experiment, because iron, once in the state of deutoxide, has no such affinity for oxygen as to enable it to decompose water. It may also, he states, be procured by calcining strongly a mixture of 1 part of iron and 3 parts of the red oxide in a stoneware crucible, to the neck of which a tube is adapted to cut off the contact of air. But this process is less certain than the first, because a portion of peroxide may escape the reaction of the iron. But we may dispense with the trouble of making it, adds Thenard, because it is found abundantly in nature. He refers to this oxide, the crystallized specular iron ore of Elba, Corsica, Dalecarlia, and Sweden. He also classes under this oxide all the magnetic iron ores; and says, that the above-described protoxide does not exist in nature. From the synthesis of this oxide by steam, Gay Lussac has determined its composition to be,

37.5

Oxygen, 37.5 27.28

3d, The red oxide. It may be obtained by igniting the nitrate, or carbonate; by calcining iron in open vessels; or simply by treating the metal with strong nitric acid, then washing and drying the residuum. Colcothar of vitriol, or thorough calcined copperas, may be considered as peroxide of iron. It exists abundantly native in the red iron ores. It seems to be a compound of,

70 = 4 primes. 30 = 3 primes. 100 43 Oxygen,

Chlorides of iron; of which there are two, first examined in detail by Dr. John Davy.

The protochloride may be procured by heating to redness, in a glass tube with a very small orifice, the residue which is obtained by evaporating to dryness the green muriate of iron. It is a fixed substance, requiring a red heat for its fusion. It has a grayish, variegated colour, a metallic splendour, and a lamellar tex-

The deutochloride may be formed by the combustion of iron wire in chlorine gas, or by gent y heating the green muriate in a glass tube. It is the volatile compound described by Sir H. Davy in his celebrated Bakerian lecture on oxymuriatic acid. It condenses after sublimation, in the form of small brilliant iridescent plates. descent plates.

3. For the iodide of iron, see Iodine.
4. Sulphurets of iron; of which, according to Porrett, there are four, though only two are usually de-

scribed, his protosulphuret and persulphuret.

5. Carburets of iron. These compounds form steel, and probably cast-iron; though the latter contains also some other ingredients. The latest practical researches on the constitution of these carburets, are those of Daniel.

6. Salts of iron.

Satts of iron.
