VALUABLE WORKS,

Printed by J. & J HARPER, New-York, and for sale by the Booksellers generally in the United States.

THE HISTORICAL WORKS of the Rev. WIL-LIAM ROBERTSON, D.D.; comprising his HIS-TORY of AMERICA; CHARLES V.; SCOTLAND, and INDIA. In 3 vols. 8vo. Embellished with Plates. (Stereotyped.)

Harper's edition of these valuable standard works is far superior, in every respect, to any other edition ever published in this country; and is to be preferred to Jones's University edition, as the type is larger, the printing and paper are equally good, and they are sold for less than the cash price of that condensed edition. Each volume is a separate history in itself; and may be purchased separately, or bound uniformly with the other volumes in sets.

GIBBON'S HISTORY of the DECLINE and FALL of the ROMAN EMPIRE. In 4 vols. 8vo. With Plates.

Harper's edition of Gibbon's History is stereotyped, and great care has been taken to render it correct and perfect. The dates originally introduced by the Author are preserved in the Tables of Contents prefixed to the Volumes, and also imbodied in the text. This will render the present edition decidedly preferable to the English edition in four volumes, as in the latter the dates and Tables of Contents are entirely omitted.

THE HISTORY OF MODERN EUROPE; with a View of the Progress of Society, from the Rise of the Modern Kingdoms to the Peace of Paris, in 1763. By William Russell, LL.D., and from the Peace of Paris, in 1763, to the Treaty of Amiens, in 1802. By William Jones, Esq. In 3 vols. 8vo. With Engravings. (Stereotyped. Uniform with the works of Robertson and Gibbon.)

HOOPER'S MEDICAL DICTIONARY. From the last London Edition. With additions, by Samuel Akerly, M.D. 8vo. (Stereotyped.)

In order to render this stereotype edition of Hooper's Medical Dictionary more acceptable to the medical public of the United States, considerable additions have been made, particularly on Materia Medica, Mineralogy, Botany, Chymistry, Biography, &c. &c.

GOOD'S (Dr. John Mason) STUDY OF MEDI-CINE. In 5 vols. 8vo. A new edition. With additions by Samuel Cooper, M.D.

THE BOOK OF NATURE; being a popular Illustration of the general Laws and Phenomena of Creation, in its Unorganized and Organized, its Corporeal and Mental Departments. By John Mason Good, M.D. and F.R.S. In one vol. 8vo. (Stereotyped.)

"-the work is certainly the best philosophical digest of the kind which we have seen."-London Monthly Review.

COOPER'S DICTIONARY of PRACTICAL SUR-GERY. Revised and Enlarged. In 2 vols. 8vo. (Stereotyped.)

BROWN'S DICTIONARY OF THE HOLY BIBLE. From the last genuine Edinburgh edition. Containing the Author's last additions and corrections, and further enlarged and corrected by his Sons; with a Life of the Author; and an Essay on the Evidence of Christianity. Two volumes in one, 8vo.

A CONCORDANCE to the HOLY SCRIPTURES of the OLD and NEW TESTAMENTS; by the Rev. John Brown, of Haddington. Printed on Diamond type, in the 32mo. form. (Stereotyped.)

This convenient and beautiful little pocket volume contains, verbalim, the same as the original duodecimo edition.

ENGLISH SYNONYMES, with copious Illustrations and Explanations, drawn from the best writers. By George Crabb, M.A. A new Edition, enlarged. 8vo. (Stereotyped.)

DOMESTIC DUTIES; or Instructions to Young Married Ladies, on the Management of their Household, and the Regulation of their Conduct in the various relations and duties of Married Life. By Mrs. William Parkes. Fifth American from the last London Edition, with Notes and Alterations adapted to the American Reader. 12mo. (Stereotyped.)

DR. KITCHINER'S COOK'S ORACLE and HOUSE-KEEPER'S MANUAL. Containing Receipts for Cookery, and Directions for Carving, &c. &c.; being one Result of actual Experiments instituted in the Kitchen of WILLIAM KITCHINER, M.D. Adapted to the American Public, by a Medical Gentleman. 12mo. (Stereotyped.)

SERMONS ON IMPORTANT SUBJECTS, by the late Rev. and pious Samuel Davies, A.M., some time President of the College of New-Jersey. To which are prefixed, Memoirs and Character of the Author: and two Sermons on occasion of his Death, by the Rev. Drs. Gibbon and Finley. Fourth American Edition, containing all the Author's Sermons ever published. In 3 vols, 8vo.

ELEMENTS OF SURVEYING. With Copperplate Engravings. By Charles Davies, Professor of Mathematics, U. S. Military Academy. 8vo. (The Tables carefully revised and stereotyped.)

GIBSON'S SURVEYING. Improved and enlarged. By James Ryan, Teacher of Mathematics, &c. 8vo.

HISTORICAL VIEW of the LITERATURE of the SOUTH OF EUROPE. By M. De Sismondi. Translated from the Original, with Notes. By Themas Roscoe, Esq. In 2 vols. 8vo.

THE WORKS of the Rev. JOHN WESLEY, A.M. With his LIFE. Complete in 10 vols. 8vo. From the last London Edition.

WESLEY'S MISCELLANEOUS WORKS. Containing his Tracts, Letters, &c. &c. From the last London Edition. In 3 vols. 8vo.

WESLEY'S SERMONS. Containing several Sermons never before published in this country. In 3 volumes. 8vo.

THE HISTORY of the JEWS, from the earliest period to the present time. By Rev. H. II. MILMAN. With numerous Maps and Engravings. In 3 vols. 18mo. (Stereotyped.)

THE HISTORY of NAPOLEON BUONAPARTE, With numerous Engravings. In 2 vols. 18mo. (Stereotyped.)

PELHAM; or, THE ADVENTURES OF A GENTLEMAN. A Novel. In 2 vols. 12mo. (By the Author of "The Disowned," and "Devereux.") From the second London Edition. (Stereotyped.)

THE DISOWNED. By the Author of "Pelham," and "Devereux." A Novel. In 2 vols. (Stereotyped.)
DEVEREUX. A Novel. In 2 vols. 12mo By the

DEVEREUX. A Novel. In 2 vols. 12mo By the Author of "Pelham," and "The Disowned." (Stereotyped.)

WAVERLEY; or, 'Tis Sixty Years Since. A Novel. In 2 vols. 12mo. Revised, corrected, and enlarged, by the Author.

** Harper's stereotype edition of Waverley contains upwards of thirteen thousand words, in alterations and additions, not in any former edition.

LETTERS FROM THE ÆGEAN. By James Emerson, Esq. In 1 vol. 8vo.

THE LITERARY REMAINS OF THE LATE HENRY NEELE, Author of the "Romance of History," &c. &c.—consisting of Lectures on English Poetry, Tales, and other Miscellaneous Pieces in Prose and Verse. 8vo.

PRESENT STATE OF CHRISTIANITY, and of the Missionary Establishments for its Propagation, in all Parts of the World. Edited by Frederic Schoberl. 12mo.

COMPLETE WORKS of Dr. SAMUEL JOHN-SON. Comprising the Rambler—Idler—Rasselas— Lives of the Poets—Letters—Poems—Miscellanies, &c. With an Essay on his Life and Genius, by Arthur Murphy, Esq. In 3 vols. 8vo. [In Press.]

VAN HALEN'S NARRATIVE of his Imprisonment in the Dungeons of the Inquisition, his Escape, his Journey to Madrid, &c. &c. 8vo.

THE REMINISCENCES OF THOMAS DIBDIN.
Author of the "Cabinet," &c. &c. 2 vols. in 1. 8vo.

THE CONDITION OF GREECE, in 1827 and 1828. By J. P. Miller. 19mo.

THE RIVALS OF ESTE, AND OTHER POEMS. By James G. Brooks and Mary E. Brooks. 12mo.

Popular Works Recently Published.

THE LIFE OF NELSON. By Robert Southey, Esq. 18mo. with a Portrait. (Stereotyped.)

THE LIFE OF ALEXANDER THE GREAT. By Rev. J. Williams. 18mo. with a Map. (Stereotyped.)

PAUL CLIFFORD. A Novel. By the Author of "Pelham," &c. In 2 vols. 12mo. (Stereotyped.)

O'NEIL. A Poem. With several Pieces in Prose. 12mo. (Stereotyped.)

FALKLAND. A Novel. 12mo. By the Author of "Pelham," &c. (Stereotyped.)

LIFE OF LORD BYRON. By Thomas Moore, Esq. In 2 vols. 8vo. (Stereotyped.)

LIVES OF THE SIGNERS of the Declaration of Independence. By N. Dwight. 12mo. (Stereotyped.)

OVID DELPHINI, and SMART'S HORACE. Correct Editions.

THE LIFE and REMAINS of Dr. CLARKE. 8vo. An interesting and useful work.

WALTER COLYTON. A Novel. In 2 vols. 12mo. By the Authorof "Brambletye House," "Zillah," &c.

THE BARONY. A Novel. In 2 vols. 12mo. By Miss A. M. Porter.

CLOUDESLEY. A Novel. In 2 vols. 12mo. By the Author of "Caleb Williams," &c.

ADVERTISEMENT

TO

THE FOURTH AMERICAN EDITION.

In order to render the Fourth American Edition of Hooper's Medical Dictionary more acceptable to the Medical public of the United States, considerable additions have been made, selected from American authors, particularly on Materia Medica, Mineralogy, &c. &c. For these additions an acknowledgment is due to Dr. James Thacher, for the extracts we have made from his Medical Biography, to Dr. John W. Webster, of Boston, for the same liberty taken with his Manuel of Chemistry, and to Dr. Jacob Bigelow, for the use of his Treatise on the Materia Medica. Copious extracts have also been made from Professor Cleaveland's Mineralogy, and recourse has been had to the New-York Medical Repository, Burns's Mineralogical Journal, Eaton's Geology, and other works, for the purpose of introducing new and interesting articles. A number of obsolete terms have been omitted, but lest it might be thought by some to injure the work as a standard of modern as well as of ancient Medical terms, the words omitted have been inserted in the form of an Appendix.

NEW-YORK, October, 1829.

PREFACE.

In the present edition of the Medical Dictionary, the principal additions and improvements are in the introduction of the terms of Botany and those of Mineralogy, and the most modern discoveries in Chemistry and Physiology. The work, therefore, will now be found to contain an account of every article connected with the study of medicine.

In conducting this laborious undertaking, particular attention has been given to,

- 1. The accentuation, in order that the proper pronunciation of the words may be obtained.
- 2. The derivation of the terms, and the declension of the words in common use.
 - 3. The definitions, which are from the most approved sources.
- 4. The introduction of all the modern discoveries in the several branches of medical science

In the selection and arrangement of the most compendious, the most clear, and the most perfect account of the several articles of Anatomy, Biography, Botany, Chemistry, the Materia Medica, Midwifery, Mineralogy, Pathology, Pharmacy, and Physiology; the Compiler has again to acknowledge his obligations to Abernethy, Accum, Aikin, Albinus, Bell, Brande, Bergius, Blanchard, Burns,

Burserius, Callisen, Casselli, Cooper, Cruickshank, Cullen, Davy, Denman, Duncan, the Editors of the London and Edinburgh Dispensaries, and of Rees' Cyclopædia, and Motherby's Medical Dictionary, Fourcroy, Good, Haller, Henry, Hoffman, Innis, Latta, Larcy, Lavoisier, Lewis, Linnæus, Majendie, Meyer, Murray, Nicholson, Orfila, Pott, Richerand, Richter, Saunders, Sauvage, Scarpa, Smith, Sæmmering, Swediaur, Symonds, Thomas, Thompson, Turton, Ure (from whose condensed and comprehensive work on chemistry large extracts have been made), Vaughan, Vossius, Willan, Woodville, &c. &c.

It was his original intention to give to each writer the merit of the particular description selected from his work: but having occasion to consult, frequently to abridge, and sometimes to alter, various passages; and finding it difficult, and in many instances impossible, to discover the original writer of several articles; and convinced at the same time that it would be attended with no particular advantage, he has preferred making a general acknowledgment to particularizing the labours of each individual. If he has been so fortunate as to have compressed within the narrow limits of the present publication much general and useful information, his object will be fully answered.

A NEW

MEDICAL DICTIONARY.

ABB

A 1. In composition this letter, the a in Greek and a in Latin, signifies without: thus aphonia, without voice, acaulis, without stem, aphyllus, with-

2. A. AA. (From ava, which signifies of each.) Abbreviations of ana, which word is used in prescriptions after the mention of two or more ingredients, when it implies, that the quantity mentioned of each ingredi-

ent should be taken; thus, R. Potassæ nitratis—
Sacchari albi ää 3 j. Take nitrate of potassa and white sugar, of each one drachm.

AA'RON. A physician of Alexandria, author of thirty books in the Syriac tongue, containing the whole practice of physic, chiefly collected from the Greek writings, and supposed to have been written before A. D. 620. He first mentioned, and described, the small-pox and measles, which were probably brought thither pox and measles, which were probably brought thither by the Arabians. He directed the vein under the tongue to be opened in jaundice, and noticed the white colour of the fæces in that disease. His works are lost, except some fragments, preserved by Rhazes.

AA'VORA. The fruit of a species of palm-tree which grows in the West Indies and Africa. It is of

the size of a hen's egg, and included with several more in a large shell. In the middle of the fruit there is a hard nut, about the size of a peach stone, which contains a white almond, very astringent, and useful

against a diarrhœa.

Aba'crus. Abigeatus. Among the ancient physicians, this term was used for a miscarriage, procured by art, or force of medicines, in contradistinction to abortus, which meant a natural miscarriage.

A'BACUS. (From a Hebrew word, signifying dust.)
A table for preparations, so called from the usage of
mathematicians of drawing their figures upon tables sprinkled with dust.

ABAI'SIR. Abasis. Ivory black; and also calcare-

ous powder.

ABALIENA'TIO. Abalienation; or a decay of

the body, or mind.

ABALIENA'TUS. 1. Corrupted.

2. A part so destroyed as to require immediate ex-

3. The total destruction of the senses, whether external or internal, by disease.

ternal or internal, by disease.

Anaptr'sta. (From a, priv. and βαπτω, to plunge.)

Abaptiston. 1. The shoulders of the old trepan.

2. This term is employed by Galen, Fabricius ab Aquapendente, Scultetus, and others, to denote the conical saw with a circular edge, (otherwise called modiolus, or terebra,) which was formerly used by surgeons to perforate the cranium.

Anaptr'ston. See Abaptista.

Achemical term formerly used in the transmutation of metals, signifying lung pleng, margues.

transmutation of metals, signifying luna plena, magnes,

ABARTICULATION. (From ab, and articulus, a joint.) A species of articulation which has evident motion. See Diarthrosis.

motion. See Diarthrosis.

ABA'SIS. See Abaisir.

ABBREVIATION. The principal uses of medicinal abbreviations are in prescriptions, in which they are certain marks, or half words, used by physicians for despatch and conveniency when they prescribe; thus:—B. readily supplies the place of recipe—h. s. that of hora somni—n. m. that of nux moschata—elect. that of electarium, &c.; and in general all the names of compound medicines, with the several ingredients, are frequently wrote only up to their first or second syllable, or sometimes to their third or fourth, to make them clear and expressive. Thus Oroc. Anglic. stands

ABD

for Crocus Anglicanus—Conf. Aromat. for Confectio Aromatica, &c. A point being always placed at the end of such syllable, shows the word to be incomplete. ABBREVIATUS. Abbreviate; shortened. A term

ABBREVIATUS. Abbreviate; shortened. A term often used in botany.

ABDO MEN. (Abdomen, inis. n.; from abdo, to hide; because it hides the viscera. It is also derived from abdere, to hide, and omentum, the caul; by others omen is said to be only a termination, as from lego, legumen, so from abdo, abdomen.) The belly. The largest cavity in the body, bounded superiorly by the diaphragm, by which it is separated from the chest; inferiorly by the bones of the pubes and ischium; on each side by various muscles, the short ribs and ossailii; anteriorly by the abdominal muscles, and posteriorly by the vertebræ of the loins, the os sacrum and os coccygis. Internally it is invested by a smooth memcoccygis. Internally it is invested by a smooth mem-brane, called peritoneum, and externally by muscles and common integuments.

In the cavity of the belly are contained,

Anteriorly and laterally,

1. The epiploon. 2. The stomach. 3. The large and small intestines. 4. The mesentery. 5. The lacteal vessels. 6. The pancreas. 7. The spleen. 8. The liver and gall-bladder.

Posteriorly, without the peritoneum, 1. The kidneys. 2. The supra-renal glands. 3. The ureters. 4. The receptaculum chyli. 5. The descending aorta. 6. The ascending vena cava.

Inferiorly in the pelvis, and without the peritoneum. In men, 1. The urinary bladder. 2. The spermatic vessels. 3. The rectum.

In women, besides the urinary bladder and intestinum rectum, there are,

1. The uterus. 2. The four ligaments of the uterus.

3. The two ovaria. 4. The two Fallopian tubes. 1. The uterus. The two ovaria.

The fore part of this cavity, as has been mentioned, is covered with muscles and common integuments, in the middle of which is the navel. It is this part of the body which is properly called abdomen; it is distinguished, by anatomists, into regions. See Body.

The posterior part of the abdomen is called the loins, and the sides the flanks.

ABDOMINALIS. (From abdomen, the belly.) Abdesired the sides the bells are the bells.

dominal; pertaining to the belly.

Abdominal hernia. See Hernia.

Abdominal muscles. See Muscles.

Abdominal regions. See Body.

Abdominal ring. See Annulus Abdominis.

ABDU'CENS. See Abducent.

ABDUCENS LABIORUM. See Levator anguli oris.
ABDUCENT. (Abducens; from ab, from, and ducere, to draw.) The name of some muscles which draw parts back in the opposite direction to others. See Abductor.

Abducent muscles. See Abductor.

Abducent muscles. See Nervi abducentes.

ABDUCTOR. (From abduce, to draw away.) Abducents. A muscle, the office of which is to pull back or draw the member to which it is affixed from some other. The antagonist is called adductor.

ABDUCTOR AURICULARIS. See Posterior auris.

ABDUCTOR AURIS. See Posterior auris.

ABDUCTOR BREVIS ALTER. See Abductor pollicis

ABDUCTOR INDICES MANUS. An internal interos seous muscle of the fore-finger, situated on the hand. Abductor of Douglas; Semi-interosseous indices of Winslow; Abductor indices of Cowper. It arises from the superior part of the metacarpal bone, and the os tra

pezium, on its inside, by a fleshy beginning, runs to-wards the metacarpal bone of the fore-finger, adheres to it, and is connected by a broad tendon to the superior part of the first phalanx of the fore-finger. Sometimes it arises by a double tendon. Its use is to draw the fore-finger from the rest, towards the thumb, and to bend it somewhat towards the palm.

ABDUCTOR INDICIS PEDIS. An internal interosseous muscle of the fore-toe, which arises tendinous and fleshy, by two origins, from the root of the inside of the metatarsal bone of the fore-toe, from the outside of the root of the metatarsal bone of the great toe, and from the os cuneiforme internum, and is inserted tendinous into the inside of the root of the first joint of the fore-toe. Its use is to mail the fore-toe inwards from the

toe. Its use is to pull the fore-toe inwards, from the rest of the small toes.

ABDUCTOR LONGUS POLLICIS MANUS. See Extensor

ossis metacarpi pollicis manus.

ABDUCTOR MEDII DIGITI PEDIS. An interosseous muscle of the foot, which arises tendinous and fleshy, from the inside of the root of the metatarsal bone of the middle toe internally, and is inserted tendinous into the inside of the root of the first joint of the middle toe. Its use is to pull the middle toe inwards.

ABDUCTOR MINIST DIGITI MANUS. A muscle of the little finger, situated on the hand. Carpo-phalangien du petit doigt of Dumas; Extensor tertii internodii minimi digiti of Douglas; Hypothenar minor of Winslow. It arises fleshy from the pisiform bone, and from that part of the ligamentum carpi annulare next it, and is inserted, tendinous, into the inner side of the upper end of the first bone of the little finger. Its use is to draw the little finger from the rest

is to draw the little finger from the rest.

ABDUCTOR MINIMI DIGITI PEDIS. A muscle of the little toe. Calcaneo-phalangien du petit doigt of Dumas; Adductor of Douglas; Parathenar major of Winslow, by whom this muscle is divided into two, Parathenar major and metatarscus; Adductor minimi digiti of Cowper. It arises tendinous and fleshy, from the semicicular edge of a cavity on the inferior part of the protuberance of the organica and from the rest of the protuberance of the os calcis, and from the rest of the metatarsai bone of the little toe, and is inserted into the root of the first joint of the little toe externally. Its use is to bend the little toe, and its metatarsal bone, downwards, and to draw the little toe from the rest.

ABDUCTOR OCULI. See Rectus externus oculi.
ABDUCTOR POLLICIS MANUS. A muscle of the thumb, situated on the hand. Scaphosus-phalangien du pouce of Dumas; Adductor pollicis manús, and Adductor brevis alter of Albinus; Adductor thenar Rioláni of Douglas (the adductor brevis alter of Albinus is the inner portion of this muscle); Adductor pollicis of Cowper. It arises by a broad tendinous and fleshy begianing, from the ligamentum carpi annulare, and from the os trapezium, and is inserted tendinous into the outer side of the root of the first bone of the thumb. Its use is, to draw the thumb from the fingers.

ABDUCTOR POLLICIS PEDIS. A muscle of the great toe situated on the foot. Calcaneo-phalangien du pouce of Dumas; Abductor of Douglas; Thenar of Winslow; Abductor pallicis of Cowper. It arises fleshy, from the inside of the root of the protuberance of the os calcis, where it forms the heel, and tendinous from the same bone, where it joins the os naviculare; and is inserted tendinous into the internal sesamoid bone and root of the first joint of the great toe. Its use is to pull the great toe from the rest.

ABDUCTOR TERTIL DIGITI PEDIS. Ap interesseous

ABDUCTOR TERTII DIGITI PEDIS. An interosseous muscle of the foot, that arises tendinous and fleshy from the inside and the inferior part of the root of the metatarsal bone of the third toe; and is inserted ten-dinous into the inside of the root of the first joint of the third toe. Its use is to pull the third toe inwards.

ABEBE'OS. (From a, neg. and βεβαιος, firm.) Abeby Hippocrates, de Signis.

ARERE US. See Abeboos.

ABELMO'SCHUS. (An Arabian word.) See Hibiscus Abelmoschus.

Abelmosch. See Hibiscus Abelmoschus. Abelmusk. See Hibiscus Abelmoschus. ABERRA'TIO. (From ab and erro, to wander

from.) Formerly applied to some deviations from what was natural, as a dislocation, and monstrosities. ABE'SSL (An Arabian term which means filth.)

The alvine excrements.

A'BESUM. Quicklime.

ABEVACUA TIO. (From ab, dim, and evacue, to pour out.) A partial or incomplete evacuation of the pec-

out.) A partial or incomplete evacuation of the peccant humours, either naturally or by art.

Absolute. The thyroid cartilage.

A'BIES. (Abies, etis. fem.; from abeo, to proceed, because it rises to a great height; or from aπιος, a wild pear, the fruit of which its cones something resemble.) The fir. See Pinus.

Abies Canadensis. See Pinus Balsamea.

Abiotos. (From a, neg. and βιοω, to live.) Deadly. A name given to hemlock, from its deadly qualities. See Conium maculatum.

ABLACTA'TIO. (From ab, from, and lac, milk.)

ABLACTA'TIO. (From ab, from, and lac, milk.)
Ablactation, or the weaning of a child from the breast.
ABLATION. (Ablatio; from aufero, to take away. 1. The taking away from the body whatever is hurtful. A term that is seldom used but in its general sense, to clothing, diet, exercise, &c. In some old writings; it expresses the intervals between two fits of a fever, or the time of remission.
2. Formerly chemists employed this term to signify

Formerly chemists employed this term to signify the removal of any thing that is either finished or else

no longer necessary in a process.

ABLUE'NT. (Abluens; from ablue, to wash away.) Abstergent. Medicines which were formerly supposed to purify or cleanse the blood.

ABLUTION. (Ablutio; from ablue, to wash off.) 1. A washing or cleansing either of the body or the intestines.

2. In chemistry it signifies the purifying of a body, by repeated affusions of a proper liquor.

ABOLI'TIO. (From aboleo, to destroy.) The separation or destruction of diseased parts.

ABORTIENS. Miscarrying.

In botany, it is sometimes used synonymously with sterilis, sterile or barren.

ABORTION. (Abortical from steries to be sterile.)

ABORTION. (Abortio; from aborior, to be sterile.)
Aborsus; Amblosis; Diaphthora; Ectrosis; Exambloma; Examblosis; Apopallesis; Apopalsis; Apophthora. Miscarriage, or the expulsion of the fætus from the uterus, before the seventh month, after which it is called premature labour. It most commonly occurs between the eighth and eleventh weeks of pregnancy, but may happen at a later period. In early gestation, the ovum sometimes comes off entire; sometimes the fætus is first expelled, and the placenta afterwards. It is preceded by floodings, pains in the back, loins, and lower part of the abdomen, evacuation of the water, shivermgs, palpitation of the heart, nausea, anxiety, syncope, subsiding of the breasts and belly, pain in the inside of the thighs, opening and moisture of the os tincæ. The principal causes of miscarriage are blows or falls; great exertion or fatigue; sudden frights and other violent emotions of the mind; a diet too sparing or too nutritious; the abuse of spirituous liquors; other discarriage are between the particular the particular that the particular that are the particular that the particular that a particular that the particular nutritious; the abuse of spirituous liquors; other dis-eases, particularly fevers, and hæmorrhages; likewise excessive bleeding, profuse diarrhea or cholic, parti-cularly from accumulated faces; immoderate venery, &c. The spontaneous vomiting so common in preg-nancy, rarely occasions this accident: but when in-duced and kept up by drastic medicines, it may be very likely to have that effect. Abortion often haveners likely to have that effect. Abortion often happens without any obvious cause, from some defect in the uterus, or in the fœtus itself, which we cannot satisfactorily explain. Hence it will take place repeatedly in the same female at a particular period of pregnancy perhaps in some pressure from the influence. nancy; perhaps in some measure from the influence of habit.

The treatment of abortion must vary considerably according to the constitution of the patient, and the causes giving rise to it. If the incipient symptoms should appear in a female of a plethoric habit, it may be proper to take a moderate quantity of blood from the arm, then clear the bowels by some mild cathartic, as the sulphas magnesiæ in the infusum rosæ, afterwards exhibiting small doses of nitrate of potash, directing the patient to remain quiet in a recumbent position, kept as cool as possible, with a low diet, and the antiphlogistic regimen in other respects. Should there be much flooding, cloths wetted with cold water ought to be applied to the region of the uterus, or even The treatment of abortion must vary considerably ought to be applied to the region of the uterus, or even introduced into the vagina, to obstruct the escape of the blood mechanically. Where violent forcing pains attend, opium should be given by the mouth, or in the form of glyster, after premising proper evacuations.

Should these means not avail to check the discharge of the forcing pains, and particularly if the water be evathe forcing pains, and particularly if the water be eva-cuated, there can be no expectation of preventing the miscarriage; and where there is reason for believing the feetus dead, from the breasts having previously subsided, the morning sickness gone off, the motion stopped, &c. it will be proper rather to encourage it by manual assistance.

If on the other hand females of a delicate and irritable habit, rather deficient in blood, be subject to abor-tion; or where this accident is threatened by profuse evacuations and other debilitating causes, it may be of digestion, with tonic medicines, and the use of the cold bath, attending at the same time to the state of the bowels, giving opium if pain attend, and carefully avoiding the several exciting causes.

[When a female has suffered several abortions, it becomes almost impossible to prevent a repetition at the same period of gestation in a subsequent pregnancy. Nothing, however, will be so successful in preventing a recurrence of a similar misfortune, as in allowing the uterine vessels to recover their tone; for which purpose a sufficient time must intervene before the next conception, otherwise the remedies above re-

the next conception, otherwise the remedies above recommended will have little or no effect. A.]

ABORTIVE. (Abortivus; from aborior, to be
sterile.) That which is capable of occasioning an abortion, or miscarriage, in pregnant women. It is now
generally believed, that the medicines which produce
a miscarriage, effect it by their violent operation on
the system, and not by any specific action on the womb.
[From the violent operation of the secale cornutum,
or spurred rye, upon the gravid uterus, it has been
thought that it would act at any period of gestation as
an abortive; but the experiments and trials made with
it, have proved it to be inert, having no specific action
upon the uterus, except in time of labour. A.] upon the uterus, except in time of labour. A.]

ABORTUS. A miscarriage.

ABRA'SA. (From abrado, to shave off.) Ulcers at tended with abrasion.

ABRASION. (Abrasio; from abrado, to tear off.) This word is generally employed to signify the destruction of the natural mucus of any part, as the stomach, intestines, urinary bladder, &c. It is also applied to any part slightly torn away by attrition, as the

A'BRATHAN. Corrupted from abrotanum, southern-

wood. See Artemisia abrotanum.

A'BRETTE. See Hibiscus Abelmoschus.

ABRO'MA. (From a, neg. and βρωμα, food;' i. c. ot fit to be eaten.) A tree of New South Wales, not fit to be featen.)

which yields a gum.

ABRO TANUM. (Αδροτανον; from a, neg. and βροτος, mortal; because it never decays; or from aβρος, soft, and τονος, extension; from the delicacy of its texture.) Common southernood. See Artemisia.

ABROTANUM MAS. See Artemisia.

ABROTONI'TES. (From abrotanum.) A wine mentioned by Dioscorides, impregnated with abrotanum, or southernwood, in the proportion of about one bundred ounces of the dried leaves, to about seven

ABRUPTE. Abruptly. Applied to pinnate leaves which terminate without an odd leaf or lobe:-folia

abrupte pinnata.

ABSCEDE'NTIA. (From abscedo, to separate.) Decayed parts of the body, which, in a morbid state, are

separated from the sound.

ABSCESS. (Abscessus; from abscedo, to depart: because parts, which were before contiguous, become separated, or depart from each other.) Abscessio; Imposthuma. A collection of pus in the cellular membrane, or in the viscera, or in bones, preceded by in-flammation. Abscesses are variously denominated flammation. Abscesses are variously denominated according to their seat: as empyema, when in the cavity of the pleura; vomica, in the lungs; panaris, in any of the ingers; hypopyon, in the anterior chamber of the eye; arthropuosis, in a joint; lumbar abscess, &c.

The formation of an abscess is the result of inflammation.

mation terminating in suppuration. This is known by a throbbing pain, which lessens by degrees, as well as the heat, tension, and reduces of the inflamed part; and if the pus be near the surface, a cream-like whiteness is soon perceived, with a prominence about the middle, or at the inferior part, then a fluctuation may be felt, which becomes gradually more distinct, till at

part of importance to life, there are usually rigours, or sudden attacks of chiliness, followed by flushes of heat; and unless the matter be soon discharged, and the abscess healed, hectic fever generally comes on. When abscesses form in the cellular membrane in persons of a tolerably good constitution, they are usually circumscribed, in consequence of coagulable lymph having been previously effused, and having obliterated the communication with the adjoining cells; but in those of a weakly, and especially a scrophulous constitution, from this not occurring, the pus is very apt to diffuse itself, like the water in anasarca. Another circumstance, which may prevent its readily reaching the surface, is its collecting under an aponeurosis, or other part of dense structure, when the process of ulceration will rather extend in another direction; thus pus accumulating in the loins, may descend to the lower part of the thigh.

When suppuration occurs, if the inflammation have not yet subsided, it may be necessary to employ means calculated to moderate this, in order to limit the extent of the abscess: but evacuations must not be carried too far, or there will not be power in the system to heal it afterwards. If the disease be near the surface, fo-mentations or warm emollient poultices should be employed, to take off the tension of the skin, and promote the process of ulceration in that direction. As mote the process of ulceration in that direction. As soon as fluctuation is obvious, it will be generally proper to make an opening, lest contiguous parts of importance should be injured; and often at an earlier period, where the matter is prevented from reaching the surface by a fascia, &c., but it is sometimes advisable to wait awhile, especially in large spontaneous abscesses, where the constitution is much debilitated, till by the use of a nutritious diet, with bark and other tonic means, this can be somewhat improved. There are different modes of opening abscesses. I. By incision or puncture: this is generally the best as being are different modes of opening abscesses. 1. By incision or puncture; this is generally the best, as being least painful, and most expeditious, and the extent of the aperture can be better regulated. 2. By caustic; this may be sometimes preferable when suppuration goes on very slowly in glandular parts, (especially in scrophulous and venereal cases,) lessening the subjacent tumour, giving free vent to the matter, and exciting more healthy action in the sore; but it sometimes causes much deformity, it can hardly reach deep seated abscesses, and the delay may be often dangerous. 3. By seton; this is sometimes advantageous in superfiabscesses, and the delay may be often dangerous. 3. By seton; this is sometimes advantageous in superficial abscesses, (where suppuration is likely to continue,) about the neck and face, leaving generally but a small scar; likewise when near joints, or other important parts liable to be injured by the scalpel or caustic. See Lumbar Abscess, and Ulcer.

ABSCES'SUS. See Abscess.

ABSCISSION. (Abscissio; from ab, and scindo, to cut.) 1. The cutting away some morbid, or other part, by an edged instrument. The abscission of the prepuce makes what we call circumcision.

2. Abscission is sometimes used by medical writers to

2. Abscission is sometimes used by medical writers to denote the sudden termination of a disease in death,

before it arrives at its decline

3. Celsus frequently uses the term abscissa voz to

express a loss of voice.

Absinthiated, Something tinged or impregnated with the virtues of absin-

thium or wormwood.

ABSI'NTHIUM. (Absinthium, thii, n. αψινθιον; from a, neg. and ψινθος, pleasant: so called from the disagreeableness of the taste.) Wormwood. See Artemisia.

Common Wormwood. ABSINTHIUM COMMUNE. See Artemisia Absinthium.

Sea Wormwood. See ABSINTHIUM MARITIMUM. Artemisia Maritima.

ABSINTHIUM PONTICUM. Roman Wormwood. See Artemisia Pontica.

ABSINTHIUM VULGARE. Common Wormwood. See

ABSINTHIOM VILIARE. Common Worldwood. See
Artemisia Absinthium.

ABSORBENS. See Absorbent.

ABSORBENT. (Absorbens; from absorbeo, to suck
up.) 1. The small, delicate, transparent vessels, which
take up substances from the surface of the body, or
from any cavity, and carry it to the blood, are termed
absorbents or absorbing vessels. They are denominated, according to the liquids which they convey

lacteals and lymphatics. See Lacteal and Lym-

2. Those medicines are so termed, which have no acrimony in themselves, and destroy acidities in the stomach and bowels; such are magnesia, prepared chalk, oyster-shells, crabs' claws, &c.

3. Substances are also so called by chemists, which

have the faculty of withdrawing moisture from the

atmosphere.

atmosphere.

Absorbing vessels. See Absorbent.

ABSORPTION. (Absorptio; from absorbeo, to suck up.) 1. A function in an animated body, arranged by physiologists under the head of natural actions. It signifies the taking up of substances applied to the mouths of absorbing vessels; thus the nutritious part of the food is absorbed from the intestinal canal by the lacteals; thus mercury is taken into the system by the lymphatics of the skin, &c. The principle by which this function takes place, is a power inherent in the mouths of the absorbents, a vis insita, dependent on the degree of irritability of their internal membrane has which they contract and proved their contracts. by which they contract and propel their contents for-

2. By this term chemists understand the conversion of a gaseous fluid into a liquid or solid, on being united with some other substance. It differs from condensation

with some other substance. It differs from condensation in this being the effect of mechanical pressure. [Absorption by plants.—In 1804, Dr. Foote sent to Dr. Mitchill of New-York, a peach, with the following account of it:—"I present you with a peach by the bearer. You will readily perceive that I could not be induced to this from any thing very promising in its aspect, the richness of its flavour, or the singularity of its species. On tasting, you will find it highly charged with muriate of soda: and when I inform you that it has undergone no artificial management, but possessed has undergone no artificial management, but possessed this property when plucked from the tree, you may

"This peach was presented to me by Mr. Solomon Brewer, of Westchester Co., New-York, my former residence. Mr. B. is a respectable man, and the pre-sent clerk of the town in which he lives. The history sent clerk of the town in which he lives. The history he gives me of this natural salt-peach is, that it grew in his neighbourhood, on a tree, around the body and roots of which had been accidentally poured a quantity of pork or beef-brine; that its fruit ripens in the month of September; that the effect of the brine had been, to produce a sickness and decay in the tree; and that at this time (Sept. 1804) it presents the singular fact of a tree hanging tolerably full of salt peaches. He was unable to inform me of the precise time of the occurrence, but that it was the fore-part of summer, and after the fruit had obtained its shape and some size. This fact, as respects the vegetable kingdom, is in my mind an isolated one.

" I have felt the more interest in noticing this fact, as it contributes much to strengthen and confirm the opinion you long since advanced, that certain vegetables, as wheat, partake much of the properties of the manure which is used as their aliment, and thence urge with much propriety the importance of the sub-ject to agriculturists."—See Med. Repos. of New-York,

vol. viii. p. 209. A.]

ABSTEMIOUS. (Abstemius; from abs, from, and temetum, wine.) Refraining absolutely from all use of wine; but the term is applied to a temperate mode of living, with respect to food generally.

ABSTENIO. Caling Applications

ABSTE'NTIO. Cælius Aurelianus uses this word to express a suppression, or retention: thus, abstention stercorum, a retention of the excrements, which he mentions as a symptom very frequent in a satyriasis. In a sense somewhat different, he uses the word abstenta, applying it to the pleura, where he seems to mean that the humour of the inflamed pleura is prevented, by the adjacent bones, from extending

ABSTERGENT. (Abstergens; from abstergo, to cleanse away.) Any application that cleanses or clears away foulness. The term is seldom employed by

ABSTRACTION. (From abstraho, to draw away.)
A term employed by chemists in the process of humid
distillation, to signify that the fluid body is again drawn

blood from a plethoric person. A term used by some old writers

ACA'CIA. (Acacia, α. f. ακακια; from ακαζω, to sharpen.) The name of a genus of plants in the Linnæan system. Class, Polygamia; Order, Monacia. næan system.

The Egyptian thorn.

ACACIA CATECHU. This plant affords a drug, formerly supposed to be an earthy substance brought from Japan, and therefore called terra Japonica, or Japan earth; afterwards it appeared to be an extract prepared in India, it was supposed till lately, from the juice of the Mimosa catechu, by boiling the wood and evaporating the decoction by the heat of the sun. But the shrub is now ascertained to be an acacia, and is termed Acacia catechu. It grows in great abundance in the Acacia catechu. If grows in great abundance in the kingdom of Bahar, and catechu comes to us principally from Bengal and Bombay. It has received the following names: Acachou; Faufel; Catchu; Caschu; Catchu; Caschu; Catchu; Casthou; Cashou; Catchu; Casthou; Catchu; Catchu; Catchu; Catchu; Catchu; Cashou; Catchu; Catchu; Cashou; Catchu; Castou; Cachu; Catchu; Cashou; Cashou; Catchu; Castou; Cashou; Cashou internally of a shining dark brown, tinged with a red-dish hue; in the mouth it discovers considerable adstringency, succeeded by a sweetish mucilaginous taste. It may be advantageously employed for most purposes where an adstringent is indicated; and is particularly useful in alvine fluxes, where astringents are required. Besides this, it is employed also in uterine profluvia, in laxity and debility of the viscera in general; and it is an excellent topical adstringent, when suffered to dissolve leisurely in the mouth, for laxities and ulcerations of the gums, apththous ulcers in the mouth, and similar affections. This extract is the basis of several formulæ in our pharmacopæias, particularly of a tincture: but one of the best forms under which it can be exhibited, is that of simple infusion in warm water with a proportion of cimiamon, for by this means it is at once treed of its impurities and improved by the addionce freed of its impurities and improved by the addition of the aromatic.

Fourcroy says that catechu is prepared from the seeds of a kind of palm, called areca. Sir Humphrey Davy has analyzed catechu, and from his examination it appears, that from Bombay is of uniform texture, redbrown colour, and specific gravity 1.39; that from Bengal is more friable and less consistent, of a chocolate colour externally, but internally chocolate streaked with red-brown, and specific gravity 1.28. The catechu from either place differs little in its properties. Its taste is astringent, leaving behind a sensation of sweetness. It is almost wholly soluble in water. Two hundred grains of picked catechu from Bombay afforded 109 grains of tannin, 66 extractive matter, 13 mucilage, 10 residuum, chiefly sand and calcareous earth. The same quantity from Bengal; tannin 97 grains, extractive matter 73, mucilage 16, residual matter, being sand, with a small quantity of calcareous and aluminous earths, 14. Of the latter, the darkest parts appeared to afford most tannin, the lightest most extractive matter. The Hindoos prefer the lightest coloured, which has probably

most sweetness, to chew with the betel-nut.

Of all the astringent substances we know, catechu appears to contain the largest proportion of tannin; and Mr. Purkis found, that one pound was equivalent to seven or eight of oak bark for the purpose of tanning

[The tinctura Japonica is a powerful and useful astringent in looseness of the bowels. Many persons take this preparation when they are not aware of it, and when there is no occasion. It is used to colour fictitious and imitation brandies made in the United States, and from the quantity used, these liquors al-

ways produce costiveness. A.]
Acacia Germanica. German acacia.

1. The name of the German black-thorn or sloe-tree, the Prunus spinosa of Linnaus.

2. The name of the inspissated juice of the fruit, as made in Germany; which, as well as the tree, is there called also Acacia nostras. It is now fallen into disuse.

ACACIA INDICA. See Tamarindus Indica. ACACIA NOSTRAS. See Acacia Germanica.
ACACIA VERA. 1. The systematic name of the tree

off from the solid, which it had dissolved.

A'BSUS. The Egyptian lotus.

ABVACUA'TIO. (From abvacuo, to empty.) A morbid discharge; a large evacuation of any fluid, as of

The Egyptian Thorn. This tree yields the true Acacla Gum, or Gum-Arabic, called also Gummi acanthinum; Gummi thebaicum; Gummi scorpionis; Gum-lamac;

Gummi senega, or senica, or senegalense. Cairo and Alexandria were the principal marts for gum-arabic, till the Dutch introduced the gum from Senegal into Europe, about the beginning of the seven-teenth century, and this source now supplies the greater part of the vast consumption of this article. The tree which yields the Senegal gum, grows abundantly on the sands, along the whole of the Barbary coast, and par-ticularly about the river Senegal. There are several species, some of which yield a red astringent juice, but others afford only a pure, nearly colourless, insipid cum, which is the great article of commerce. These trees are from eighteen to twenty feet high, with thorny branches. The gum makes its appearance about the middle of November, when the soil has been thoroughly saturated with periodical rains. The gummy juice is seen to ooze through the trunk and branches, and, in seen to coze through the trunk and branches, and, in about a fortnight, it hardens into roundish drops, of a yellowish white, which are beautifully brilliant where they are broken off, and entirely so when held in the mouth for a short time, to dissolve the outer surface. No clefts are made, nor any artificial means used by the Moors, to solicit the flow of the gum. The lumps of gum-senegal are usually about the size of partridge eggs, and the harvest continues about six weeks. This gum is a very wholesome and nutritious food; thou-sands of the Moors support themselves entirely upon it during the time of harvest. About six ounces is sufficient to support a man for a day; and it is, besides, mixed with milk, animal broths, and other victuals. The gum-arabic, or that which comes directly from Egypt and the Levant, only differs from the gum-sene-

gal in being of a lighter colour, and in smaller lumps; and it is also somewhat more brittle. In other respects,

they resemble each other perfectly.

Gum-arabic is neither soluble in spirit nor in oil; but, in twice its quantity of water, it dissolves into a mucilaginous fluid, of the consistence of a thick syrup, and in this state answers many useful pharmaceutical purposes, by rendering oily, resinous, and pinguious substances miscible with water. The glutinous quality of gum-arabic renders it preferable to other gums and mucilages as a demulcent in coughs, hoarsenesses, and other catarrhal affections. It is also very generally employed in ardor urinæ, diarrhœas, and calculous complaints.

2. The name Acacia vera has also been used to denote the expressed juice of the immature pods of the tree termed Acacia veravel. This inspissated juice is brought from Egypt in roundish masses, wrapped up in thin bladders. It is considered as a mild astringent medicine. The Egyptians give it, in spitting of blood, in the quantity of a drachm, dissolved in any convenient liquor, and repeat this dose occasionally. They likewise employ it in collecte, for strangeles in a collected of the property of the collected of the property of th likewise employ it in collyria, for strengthening the eyes, and in gargles, for quinsies. It is now seldom used as a medicine, being superseded by the use of

catechu, or kino.

ACACIA VERAVEL. See Acacia vera.

ACACIA ZEYLONICA. See Hamatozylon Campechia-

See Acacia vera.

Acacos. The thrush. See Aphtha.

ACALYCINUS. (From a, priv. and calyx, a flower-Without a calyx.

cup.) Without a calyx.

ACALYCIS. (From a, priv. and calyx, a flower-cup.) Without a calyx or flower-cup. Applied to

plants which have no calyx.

Aca Matos. (From a, neg. and καμνω, to grow weary.) A perfect rest of the muscles, or that disposition of a limb which is equally distinct from flexion and extension.

ACA'NTHA. (Aκανθα; from ακη, a point.)

1. A thorn; or any thing pointed.

2. Sometimes applied to the spina dorsi.

Acantha Bolus. (From aκανθα, athorn; and βαλλω, An instrument, or forceps, for taking out or removing thorns, or whatever may stick in the flesh. -Paulus . Egineta.

ACA'NTHE. The name of the artichoke in ancient

ACA'NTHINUM. (From akarba, a thorn.) Gumarabic was called gummi acanthinum, because it is produced from a thorny tree. See Acacia Vera.

ACA'NTHULUS. (From ακανθα, a thorn.) surgical instrument to draw out thorns or splinters, or to remove any extraneous matter from wounds.

ACA'NTHUS. (Acanthus, i. m. ακανθος; from aκανθα, a thorn; so named from being rough and prickly.) The name of a genus of plants in the Linnean system. Class, Didynamia; Order, Angiospermia. Bear's-breech.

ACANTHUS MOLLIS. The systematic name of the bear's breech, or brank-ursine. Acanthus: -foliis sinuatis inermibus, of Linnaus. Branca ursina of the shops. The leaves and root abound with a mucilage, which is readily extracted by boiling or infusion. The roots are the most mucilaginous. Where this plant is common, it is employed for the same purposes to which althma and other vegetables possessing similar qualities are applied among us. It is fallen into disuse. The herb-women too often sell the leaves of bear's-foot, and of cow's parsnip, for the bear's-breech.

Aca'PNON. (From a, priv. and καπνος, smoke.) 1. Common wild marjoram.

2. Unsmoked honey. ACAROIS. The name of a genus of plants, from New South Wales.

Acarois Resinifera. The name of a tree which affords the Botany bay gum. See Botany bay.

[Gum Acaroides, New Holland resin, or earthy gum-lac. This is the produce of the tree called Acarois resinifera, or resin-bearing Acarois. The tree grows abundantly in New Holland, near Botany bay. The substance under consideration is usually found in the ground near the trees from which it has spontaneously exuded. From some resemblance it bears (though by no means a near one) to the article called gum-lac, it has been known as the earthy gum-lac. It is of yellowish, brownish, or yellowish brown colour, and sometimes contains roots, sticks, and other foreign substances. It has been distinguished in commerce by the term Ratany how resim. They refer its important the term Botany bay resin. They refer its importa-tion into England to the year 1799. An account of its chemical properties was published by Lichtenstein in Crell's Journal, and afterwards by Dr. Thompson, in the fourth volume of his Chemistry, p. 138. It was known to the early navigator Tasman, and was brought to New York, and presented to Dr. Mitchill many to New-York and presented to Dr. Mitchill many years ago by some of our navigators. For some time past it has been regarded in Massachusetts as a powerful restorative, or an invigorating medicine in cases of gastric or genera! debility.

Gum Acaroides is insoluble in water: alcohol or distilled spirits is its proper menstruum. Even in pow-der its use is improper, as it is not acted upon by the intestinal or alimentary fluids. It is therefore neither administered in substance, infusion, or decoction. It is mostly prescribed in the form of tincture: Tinctugummi acaroidis. Tincture of New Holland resin.

The proper rule is to make a saturated tincture, of which a tea-spoon full may be given once in three or four hours, according to the circumstances, in milk, jelly, or syrup, water being apt to decompose it. From Kite's essay upon this production, it appears,

1. That dyspepsia has been exceedingly relieved by

it, and even wholly removed.

2. That it is an excellent restorative in the debility consequent upon the depletion and exhaustion of acute

3. It is said to have done good in hysteria

Cholera, with cramps of the lower extremities, is reported to have yielded to its powers.
 The morbid evacuations and commotions of diar-

rhœa are reported to have yielded to its virtue, after opium had failed.

6. Chronic and atonic catarrhs have been benefitted

by its administration. 7. It is alleged to have been remarkably serviceable in incipient dysentery, as well as in that of long duration.

8. In various spasmodic affections, such as stitches in the sides, cramp of the stomach, rheumatic twinges, &c., it has often afforded relief after opiates had failed.

It must be observed, however, that it is not to be prescribed in cases of high action, or phlogistic diathesis, nor during the prevalence of inflammatory symptoms.

From this abstract of the practice with this remedy, no doubt can be entertained of its value, nor of the

as worthy to be considered among the happy events attending the modern Materia Medica .- Mitchill's MS.

Lectures. A.]
A'CARUS. (From akapys, small.) The tick. An insect which breeds in the skin. A very numerous genus of minute insects which infest the skin of animals, and produce various complaints. Those which are found on the human body are

The acarus domesticus, or domestic tick.
 The acarus scabiei, or itch tick.

3. The acarus autumnalis, or harvest-bug.

ACATALE PSIA. (From a, neg. and καταλαμβανω, to apprehend.) Uncertainty in the prognosis or judgment of diseases.

ACA'TALIS. (From a, neg. and $\chi a\tau \epsilon \omega$, to want.) The juniper tree: so named from the abundance of its

ACATA POSIS. (From a, neg. and καταπινω, to swallow.) Difficult deglinition.

Aca's Tatos. (From a, neg. and καθιστημι, to determine.) Inconstant.

1. Fevers were so called which are anomalous in their appearance and irregular in their paroxysms.

2. Turbid urine without sediment.

ACAULIS. (From a, priv. and caulis, a stem.)
Without stem. Plants destitute of stem are called
acaules, stemless; as Cypripedium acaule, and Cardaus acaulis. This term must not be too rigidly un-

ACCELERA'TOR. (From accelere, to hasten or ropel.) The name of a muscle of the penis.

propel.) The name of a muscle of the penis.

ACCELERATOR URINE. A muscle of the penis.

Ejaculator Seminis; Bulbo-syndesmo-caverneux of Dumas; Bulbo-cavernosus of Winslow. It arises fleshy from the sphincter ani and membranous part of the urethra, and tendinous from the crus, near as far forwards as the beginning of the corpus cavernosum penis; the inferior fibres run more transversely, and the superior descend in an oblique direction. It is inserted into a line in the middle of the bulbous part of the urethra, where each joins with its fellow; by which the bulb is completely closed. The use of these muscles is to drive the urine or semen forward, and by grasping the bulbous part of the urethra, to push the blood towards its corpus cavernosum, and the glans,

by which they are distended.

ACCESSION. (Accesso; from accedo, to approach.)

The commencement of a disease. A term mostly applied to a fever which has paroxysms or exacerbations: thus the accession of fever, means the commencement

or approach of the febrile period.

ACCESSO'RIUS. (From accede to approach: so called from the course it takes.) Connected by contact or approach.

ACCESSORIUS LUMBALIS. A muscle of the loins.

See Sacro-lumbalis.

Accessorius nervus. The name given by Willis to two nerves which ascend, one on each side, from the second, fourth, and fifth cervical pairs of nerves, through the great foramen of the occipital bone, and pass out again from the cranium through the foramina lacera, with the par vagum, to be distributed on the trapezius muscle.
ACCI'PITER. (From accipio, to take.)

1. The hawk; so named from its rapacity. 2. A bandage which was put over the nose: so called from its likeness to the claw of a hawk, or from the

tightness of its grasp.

ACCIPITRI'NA. (From accipiter, the hawk.) The herb hawk-weed: which Pliny says was so called because hawks are used to scratch it, and apply the juice to their eyes to prevent blindness

ACCLI'VIS. A muscle of the belly, so named from the oblique ascent of its fibres. See Obliquus internus abdominis.

Accouchement. The French word for the act of delivery.

Accoucheur. The French for a midwife.

ACCRETIO. (From ad, and cresco, to increase.) Accretion.

1. Nutrition; growth.

The growing together of parts naturally separate, as the fingers or toes

ACCUBA'TIO. (From accumbo, to recline.) Child-

bed; rectining.

Ace' DIA. (From α, priv. and κηδος, care.) Careless-

propriety of considering the discovery of its qualities, | ness, neglect in the application of medicines. Hippo-

reases sometimes uses this word, in his treatise on the glands, to signify fatigue or trouble.

ACE PHALUS. (Acephalus, i. m. ακεφαλος; from a, priv. and κεφαλη, a head.) Without a head. A term applied to a lusus naturæ, or monster, born without a head.

[This term is also applied by modern naturalists to a certain portion of the gelatinous or soft bodied animals, which were formerly classed among the Vermes of Linnaus. They are now termed Acephalous Mollusce, or headless mollusce, having no distinct part

A'CER. (Acer, eris. neut.; from acer, sharp: because of the sharpness of its juice.) The name of a genus of plants in the Linnaan system. Class Polyga-

mia; Order, Monacia.

ACER CAMPESTRE. The common maple. This tree yields a sweetish, soft, milky sap, which contains a salt with basis of lime, possessed, according to Sherer, of peculiar properties. It is white, semitransparent, not altered by the air, and soluble in one hundred parts of cold, or fifty of boiling water.

ACER PSEUDOPLATANUS. The maple-tree, falsely

ACER PSEUDOPLATANUS. The maple-tree, falsely named sycamore. It is also called Platanus traga. This tree is common in England, though not much used in medicine. The juice, if drank while fresh, is said to be a good antiscorbutic. All its parts contain a sac-charine fluid; and if the root or branches be wounded in the spring, a large quantity of liquor is discharged, which, when inspissated, yields a brown sort of sugar

and syrup like molasses.

ACER SACCHARINUM. The sugar maple-tree. Large quantities of sugar are obtained from this tree in New-England and Canada, which is much used in France, where it is commonly known by the name of Saccharum Canadense or Saccharum Acernum, maple sugar. It has been supposed that all Europe might be supplied from the maple of America, which grows in great quantities in the western counties of all the middle States of the American Union. It is as tall as the oak, and from two to three feet in diameter; puts forth a white blossom in the spring, before any appearance of leaves; its small branches afford sustenance for cattle, and its ashes afford a large quantity of excellent pot and its ashes abord a large quantity of excelent pot-ash. Twenty years are required for it to attain its full growth. Tapping does not injure it; but, on the con-trary, it affords more syrup, and of a better quality, the oftener it is tapped. A single tree has not only survived, but flourished, after tapping, for forty years. Five or six pounds of sugar are usually afforded by the sap of one tree; though there are instances of the quantity exceeding twenty pounds. The sugar is separated from the sap either by freezing, by spontaneous evaporation, or by boiling. The latter method is the most used. Dr. Rush describes the process; which is simple, and practised without any difficulty by the farmers.

From frequent trials of this sugar, it does not appear to be in any respect inferior to that of the West Indies. It is prepared at a time of the year when neither insect, nor the pollen of plants, exists to vitiate it, as is the case with common sugar. From calculations grounded on facts, it is ascertained, that America is now capable of producing a surplus of one eighth more than its

own consumption.

[The Acer Saccharinum, or sugar-maple tree, abounds in the state of New-York and many other parts of the United States. It furnishes a great amount of rough sugar in the interior of the country and the new settlements, where foreign and refined sugars are but little used. Very little effort has heretofore been made to introduce it into market as an article of com-merce. But in 1828 several hundred barrels of this sugar, from the Territory of Michigan, reached the city of New-York by way of the great Western ca-It was sold at auction for six cents per pound; and when refined and converted into loaf sugar, it afforded a reasonable profit to the refiner.

ACERATE. Aceras. A salt formed of the acid of the Acer campestre with an alkaline, earthy, or

metallic base

ACE'RATOS. From a, neg. and κεραω, οτ κεραν-ννμι, to mix.) Unmixed; uncorrupted. This term is applied sometimes to the humours of the body by Hip pocrates. Paulus Ægineta mentions a plaster of this

ACERB. (Acerbus; from acer, sharp.) A species

of taste which consists in a degree of acidity, with an present practised in Paris. The wine destined for addition of roughness; properties common to many immature fruits.

ACE'RBITAS. Acerbness.

ACERIC ACID. A peculiar acid, said to exist in the juice of the common maple, Acer campestre of Linnæus. It is decomposed by heat, like the other

ACERIDES. (From a, priv. and κερος, wax.) Soft plasters, made without wax.

ACEROSUS. (From acus, a needle.) 1. Acerose: having the shape of a needle. Applied to leaves which are so shaped, as in Pinus sylvestris and Juniperus communis.

2. (From acus, chaff.) Chaffy: applied to coarse

bread, &cc.

ACESCENT. (Acescens; from aceo, to be sour or tart.) Turning sour or acid. Substances which readily run into the acid fermentation, are so said to be, as some vegetable and animal juices and infusions. The suddenness with which this change is effected, during a thunder-storm, even in corked bottles, has not been accounted for. In some morbid states of the stomach, also, it proceeds with astonishing rapidity.

ACE STA. (From ακτομαι, to cure.) Distempers which are easily cured.

Ace'stis. Borax. ACETA'BULUM. (Acetabulum, i. n.; from acetum, vinegar: so-called because it resembles the acetabulum, or old saucer in which vinegar was held for the use of the table.) A name given by Latin writers to the cup-like cavity of the os innominatum, which receives the head of the thigh-bone. See Innomina-

ACETA'RIUM. (From acetum, vinegar: because it is mostly made with vinegar.) A sallad or pickle. ACE'TAS. (Acetas, tis; f. from acetum, vinegar.) An acetate A salt formed by the union of the acetic acid, with a salifiable base. Those used in medicine are the acetates of ammonia, lead, potassa, and zinc. Acetats Ammonia. See Ammonia acetatis liquor.

Ammonia acetatis liquor.

ACETAS PLUMBI. Acetate of lead. See Plumbi acetas and Plumbi acetatis liquor.
ACETAS POTASS #. Acetate of potassa. See Potass #.

acctas.

ACETAS ZINCI. A metallic salt composed of zinc and acetic acid. It is used by some as an astringent against inflammation of the eyes, urethra, and vagina, diluted in the same proportion as the sulphate of zinc.

Acetate. See Acetas. Acetate of Ammonia. See Ammonia acetatis

liquor.

Acetate of Potassa. See Potassa acetas.
Acetate of Zinc. See Acetas zinci.
Acetated vegetable Alcali. See Potassa acetas.
Acetaled volatile Alcali. See Ammonia acetatis

liquor

ACETIC ACID. Acidum aceticum. which, in a very dilute and somewhat impure state, which, in a very dilute and somewhat impure state, is called vinegar. Acetic acid is found combined with potassa in the juices of a great many plants; particularly the Sambucus nigra, Phanix dactilifera, Galium verum, and Rhus typhinus. "Sweat, urine, and even fresh milk, contain it. It is frequently generated in the stomachs of dyspeptic patients. Almost all dry vegetable substances, and some animal, sub-jected in close vessels to a red heat, yield it copiously. It is the result likewise of a spontaneous fermentation, to which liquid vegetable and animal matters are Strong acids, as the sulphuric and nitric, develope the acetic by their action on vegetables. It was long supposed, on the authority of Boerhaave, that the fermentation which forms vinegar is uniformly preceded by the vinous. This is a mistake: cabbages sour in water, making sour crout; starch, in starch-makers' sour waters; and dough itself, without any previous production of wine.

"The varieties of acetic acid known in commerce are four: 1. Wine vinegar. 2. Malt vinegar. 3. Sugar vinegar. 4. Wood vinegar.

"We shall describe first the mode of making these commercial articles, and then that of extracting the absolute acetic acid of the chemist, either from these vinegars, or directly from chemical compounds, of which it is a constituent.

"The following is the plan of making vinegar at

vinegar is mixed in a large tun with a quantity of wine lees, and the whole being transferred into clothsacks, placed within a large iron-bound vat, the liquid matter is extruded through the sacks by superincum-bent pressure. What passes through is put into large casks, set upright, having a small aperture in their top. In these it is exposed to the heat of the sun in summer, or to that of a stove in winter. Fermenta-tion supervenes in a few days. If the heat should then rise too high, it is lowered by cool air and the addition of fresh wine. In the skilful regulation of the fermen-tative temperature consists the art of making good wine vinegar. In summer the process is generally completed in a fortnight: in winter, double the time is requisite. The vinegar is then run off into barrels, which contain several chips of birch-wood. In about a fortnight it is found to be clarified, and is then fit for

the market. It must be kept in close casks.
"The manufacturers at Orleans prefer wine of a year old for making vinegar. But if by age the wine has lost its extractive matter, it does not readily undergo the acetous fermentation. In this case, acetification, as the French term the process, may be deter-mined by adding slips of vines, bunches of grapes, or

green woods.

"Almost all the vinegar of the north of France being prepared at Orleans, the manufactory of that place has acquired such celebrity, as to render their process worthy of a separate consideration. The Orleans' casks contain nearly 400 pints of wine. Those which have been already used are preferred. They are placed in three rows, one over another, and in the top have an aperture of two inches' diameter, kept always open. The wine for acetification is kept in adjoining casks, containing beech shavings, to which the less open. The wine for acetification is kept in adjoining casks, containing beech shavings, to which the less adhere. The wine, thus clarified, is drawn off to make vinegar. One hundred pints of good vinegar, boiling hot, are first poured into each cask, and left there for eight days, till the vessels are full. The vinegar is allowed to remain in this state followed to remain in this state followed to remain in this state. is allowed to remain in this state fifteen days before it

is exposed to sale.
"The used casks, called mothers, are never emptied more than half, but are successively filled again, to more than half, but are successively filled again, to acetify new portions of wine. In order to judge if the mother works, the vinegar-makers plunge a spatula into the liquid; and according to the quantity of froth which the spatula shows, they add more or less wine. In summer, the atmospheric heat is sufficient. In winter, stoves heated to about 75° Fahr. maintain the requisite temperature in the manufactory.

"In some country districts the recole teen in a

"In some country districts, the people keep, in a place where the temperature is mild and equable, a winegar cask, into which they pour such wine as they wish to acetify; and it is always preserved full by replacing the vinegar drawn off, by new wine. To establish this household manufacture, it is only necessitable to the control of the control

sary to buy at first a small cask of good vinegar.

"At Gand, a vinegar from beer is made, in which
the following proportions of grain are found to be

most advantageous :-

1880 Paris lbs. malted barley. 700 buckwheat. 500

These grains are ground, mixed, and boiled, along with twenty-seven casks full of river water, for three hours. Eighteen casks of good beer for vinegar are obtained. By a subsequent decoction, more fermentable liquid is extracted, which is mixed with the former. The whole brewing yields 3000 English quarts.

"In this country, vinegar is usually made from malt. By mashing with hot water, 100 gallons of wort are extracted in less than two hours from 1 boll of malt. When the liquor has fallen to the temperature of 75° Fahr. 4 gallons of the barm of beer are added. After thirty-six hours it is racked off into casks, which are held on their pides and arroadd with their bungare laid on their sides, and exposed, with their bung-holes loosely covered, to the influence of the sun in summer; but in winter they are arranged in a stovesummer; but in winter they are arranged if a stoveroom. In three months this vinegar is ready for the
manufacture of sugar of lead. To make vinegar for
domestic use, however, the process is somewhat different. The above liquor is racked off into casks
placed upright, having a false cover, pierced with
notes fixed at about a foot from their bottom. On this a considerable quantity of rape, or the refuse from the

ACE ACE

makers of British wine, or otherwise a quantity of low-priced raisins, is laid. The liquor is turned into ano-ther barrel every twenty-four hours, in which time it has begun to grow warm. Sometimes, indeed, the vinegar is fully fermented, as above, without the rape, which is added towards the end, to communicate flavour. Two large casks are in this case worked together, as is described long ago by Boerhaave, as follows

" Take two large wooden vats or hogsheads; and in each of these, place a wooden grate or hurdle, at the distance of a foot from the bottom. Set the vessel upright; and on the grate, place a moderately close layer of green twigs, or fresh cuttings of the vine. Then fill up the vessel with the footstalks of grapes, commonly called the rape, to the top of the vessel,

which must be left quite open.
"'Having thus prepared the two vessels, pour into them the wine to be converted into vinegar, so as to fill one of them quite up, and the other but half-full. Leave them thus for twenty-four hours, and then fill up the half-filled vessel with liquor from that which is quite full, and which will now in its turn only be left half-full. Four-and-twenty hours afterwards, repeat the same operation; and thus go on, keeping the ves-sels alternately full and half-full during twenty-four hours, till the vinegar be made. On the second or third day, there will arise in the half-filled vessel a fermentative motion, accompanied with a sensible heat, which will gradually increase from day to day. On the contrary, the fermenting motion is almost im-perceptible in the full vessel; and as the two vessels are alternately full and half-full, the fermentation is by this means in some measure interrupted, and is only renewed every other day in each vessel.

" When this motion appears to have entirely ceased, even in the half-filled vessel, it is a sign that the fermentation is finished; and therefore the vinegar is then to be put into casks close stopped, and kept in

"'A greater or less degree of warmth accelerates or checks this, as well as the spirituous fermentation. In France, it is finished in about fifteen days, during the summer; but if the heat of the air be very great, and exceed the twenty-fifth degree of Reaumur's thermometer (88 1-4° Fahr.) the half-filled vessel must be filled up every twelve hours; because, if the fermentation be not so checked in that time, it will become violent, and the liquor will be so heated, that many of the spirituous parts, on which the strength of the vine-gar depends, will be dissipated, so that nothing will remain after the fermentation but a vapid liquor, sour indeed, but effete. The better to prevent the dissipation of the spirituous parts, it is a proper and usual precaution to close the mouth of the half-filled vessel in which the liquor ferments, with a cover made of oak wood. As to the full vessel, it is always left open, that the air may act freely on the liquor it contains: for it is not liable to the same inconveniences, because it ferments but very slowly.'

"Good vinegar may be made from a weak syrup, consisting of 18 oz. of sugar to every gallon of water. The yeast and rape are to be here used as above described. Whenever the vinegar (from the taste and flavour) is considered to be complete, it ought to be decanted into tight barrels or bottles, and well secured from access of air. A momentary ebullition before it is bottled is found favourable to its preservation. In a

large manufactory of malt vinegar, a considerable revenue is derived from the sale of yeast to the bakers.

"Vinegar obtained by the preceding methods has more or less of a brown colour, and a peculiar but rather grateful smell. By distillation in glass vessels the colouring matter, which resides in a mucilage, is separated, but the fragrant odour is generally replaced by an empyreumatic one. The best French wine vinegars, and also some from malt, contain a little alcohol, which comes over early with the watery part, and renders the first product of distillation scarcely denser, sometimes even less dense, than water. It is accordingly rejected. Towards the end of the distillation the empyreuma increases. Hence only the intermediate portions are retained as distilled vinegar. Its specific gravity varies from 1.005 to 1.015, while that of common vinegar of equal strength varies from 1.010

"A crude vinegar has been long prepared for the

calico printers, by subjecting wood in iron retorts to a strong red heat."

"The acetic acid of the chemist may be prepared in the following modes; 1st. Two parts of fused acetate of potassa with one of the strongest oil of vitriol yield, by slow distillation from a glass retort into a refrige-rated receiver, concentrated acetic acid. A small portion of sulphurous acid, which contaminates it, may be removed by re-distillation, from a little acetate of lead. 2d. Or four parts of good sugar of lead, with one part of sulphuric acid treated in the same way, afford a slightly weaker acetic acid. 3d. Gently cal-cined sulphate of iran, or green vitriol, mixed with cined sulphate of iron, or green vitriol, mixed with sugar of lead in the proportion of 1 of the former to 2 1-2 of the latter, and carefully distilled from a porce-

2 1-2 of the latter, and carefully distilled from a porce-lain retort into a cooled receiver, may be also consi-dered a good economical process. Or without distilla-tion, if 100 parts of well-dried acetate of lime be cautiously added to 60 parts of strong sulphuric acid, diluted with 5 parts of water, and digested for 24 hours, and strained, a good acetic acid, sufficiently strong for every ordinary purpose, will be obtained. "The distillation of acetate of copper, or of lead per se, has also been employed for obtaining strong acid. Here, however, the product is mixed with a portion of the fragrant pyro-acetic spirit, which it is troublesome to get rid of. Undoubtedly the best pro-cess for the strong acid is that first described, and the cheapest the second or third. When of the utmost possible strength its sp. gravity is 1.062. At the tem-perature of 50° F. it assumes the solid form, crystal-lizing in oblong rhomboidal plates. It has an extremely pungent odour, affecting the nostrils and eyes even pungent odour, affecting the nostrils and eyes even painfully, when its vapour is incautiously snuffed up. Its taste is eminently acid and acrid. It excoriates and

inflames the skin.

"The purified wood vinegar, which is used for "The purified wood vinegar, which is used for pickles and culinary purposes, has commonly a specific gravity of about 1.009; when it is equivalent in acid strength to good wine or malt vinegar of 1.014. It contains about 1-20 of its weight of absolute acetic acid, and 19-20 of water. But the vinegar of fermentation=1.014 will become only 1.023 in acetate, from which, if 0.005 be subtracted for mucilage or extractive, the remainder will agree with the density of the the remainder will agree with the density of the acetate from wood. A glass hydrometer of Fahrenheit's construction is used for finding the specific gravities. It consists of a globe of about 3 inches' diameter, having a little ballast ball drawn out beneath, and a stem above of about 3 inches long, containing a slip of paper with a transverse line in the middle, and surmounted with a little cup for receiving weights or poises. The experiments on which this instrument, called an Acetometer, is constructed, have been detailed in the sixth volume of the Journal of Science."

"An acetic acid of very considerable strength may also be prepared by saturating perfectly dry charcoal with common vinegar, and then distilling. The water easily comes off, and is separated at first; but a stronger heat is required to expel the acid. by exposing vinegar to very cold air, or to freezing mixtures, its water separates in the state of ice, the interstices of which are occupied by a strong acetic acid, which may be procured by draining. The acetic acid, or radical vinegar of the apotnecaries, in which they dissolve a little camphor, or fragrant essential oil, has a specific gravity of about 1.070. It contains fully 1 part of water to 2 of the crystallized acid. The pungent smelling salt consists of sulphate of potash moistened with that acid.

"Acetic acid acts on tin, iron, zinc, copper, and nickel; and it combines readily with the oxydes of many other metals, by mixing a solution of their sulphates with that of an acetate of lead."

"Acetic acid dissolves resins, gum-resins, camphor, and essential oils."

"Acetic acid and common vinegar are sometimes fraudulently mixed with sulphuric acid to give them strength. This adulteration may be detected by the addition of a little chalk, short of their saturation. With pure vinegar the calcareous base forms a limpid solution, but with sulphuric acid a white insoluble gypsum. Muriate of barytes is a still nicer test. British forwarded integrates are allowed by law to British forwarded integrates. tish fermented vinegars are allowed by law to contain a little sulphuric acid, but the quantity is frequently exceeded. Copper is discovered in vinegars by supersaturating them with ammonia, when a fine blue

colour is produced; and lead by sulphate of soda, hydrosulphurets, sulphuretted hydrogen, and gallic acid. None of these should produce any change on genuine vinegar." See Lead.

"Salts consisting of the several bases, united in definite proportions to acetic acid, are called acetates. They are characterized by the pungent smell of vinegar, which they exhale on the affusion of sulphuric acid; and by their yielding on distillation in a moderate red heat a very light, odorous, and combustible liquid called pyro-acetate (spirit); which see. They are all soluble in water; many of them so much so as to be uncrystallizable. About 30 different acetates have been formed, of which only a very few have been applied to the uses of life. been applied to the uses of life.

"The acetic acid unites with all the alkalies and most of the earths; and with these bases it forms compounds, some of which are crystallizable, and others have not yet been reduced to a regularity of figure. The salts it forms are distinguished by their great solubility; their decomposition by fire, which carbonizes them; the spontaneous alteration of their solution; and their decomposition by a great number of acids, which extricate from them the acetic acid in It unites likewise with most of a concentrated state.

the metallic oxides.

" With barytes the saline mass formed by the acetic acid does not crystallize; but, when evaporated to dryness, it deliquesces by exposure to air. This mass evaporation, however, it will crystallize in fine transparent prismatic needles, of a bitterish acid taste, which do not deliquesce when exposed to the air, but

rather effloresce.

'With potassa this acid unites, and forms a deli-quescent salt scarcely crystallizable, called formerly foliated earth of tartar, and regenerated tartar. The solution of this salt, even in closely stopped vessels, is spontaneously decomposed: it deposites a thick, mucous, flocculent sediment, at first gray, and at length black; till at the end of a few months nothing remains in the liquor but carbonate of potassa, rendered impure by a little coaty oil.

"With soda it forms a crystallizable salt, which does not deliquesce. This salt has very improperly been called mineral foliated earth. According to the new nomenclature, it is acetate of soda.

"The salt formed by dissolving chalk or other calcareous earth in distilled vinegar, formerly called salt of chalk, or fixed vegetable sal ammoniac, and by Bergman calx acetata, has a sharp bitter taste, appears in the form of crystals resembling somewhat ears of corn, which remain dry when exposed to the air. corn, which remain dry when exposed to the air, unless the acid has been superabundant, in which case they deliquesce.

Of the acctate of strontian little is known, but that it has a sweet taste, is very soluble, and is easily

decomposed by a strong heat.

"The salt formed by uniting vinegar with ammonia, called by the various names of spirit of Mindererus, liquid sal ammoniac, acetous sal ammoniac, and by Bergman alkali volatile acetatum, is generally in a liquid state, and is commonly believed not to be crystallizable, as in distillation it passes entirely over interest. tallizable, as in distillation it passes entirely over into the receiver. It nevertheless may be reduced into the form of small needle-shaped crystals, when this liquor is evaporated to the consistence of a syrup."
"With magnesia the acetic acid unites, and after a

"With magnesia the acetic acid unites, and after a perfect saturation, forms a viscid saline mass, like a solution of gum-arabic, which does not shoot into crystals, but remains deliquescent, has a taste sweetish at first, and afterwards bitter, and is soluble in spirit of wine. The acid of this saline mass may be separated by distillation without addition.

"Glucine is readily dissolved by acetic acid. This solution, Vauquelin informs us, does not crystallize; but is reduced by evaporation to a gummy substance, which slowly becomes dry and brittle; retaining a kind of ductility for a long time. It has a saccharine and pretty strongly astringent taste, in which that of vinegar, however, is distinguishable.

"Yttria dissolves readily in acetic acid, and the solution yields by evaporation crystals of acetate of yttria."

"Alumine, obtained by boiling alum with alkali, and edulcorated by digesting in an alkaline lixivium, is dissolved by distilled vinegar in a very inconsiderable quantity."

"Acetate of zircone may be formed by pouring acetic acid on newly precipitated zircone. It has an astringent taste."

"Vinegar dissolves the true gums, and partly the

"Vinegar dissolves the true gums, and partly the gum-resins, by means of digestion.

"Boerhaave observes, that vinegar by long boiling dissolves the flesh, cartilages, bones, and ligaments of animals."—Ure's Chemical Dictionary.

Moderately rectified pyrolignous acid has been recommended for the preservation of animal food; but the empyreumatic taint it communicates to bodies in the more sed in it, is not quite reproved by their subsequent. mersed in it, is not quite removed by their subsequent

ebullition in water. See Acid, Pyrolignous.

The utility of vinegar as a condiment for preserving and seasoning both animal and vegetable substances in various articles of food is very generally known. It in various articles of food is very generally known. It affords an agreeable beverage, when combined with water in the proportion of a table-spoonful of the former to half a pint of the latter. It is often employed as a medicine in inflammatory and putrid diseases, when more active remedies cannot be procured. Relief has likewise been obtained in hypochondriacal and hysteric affections, in vomiting, fainting, and hiccough, by the application of vinegar to the mouth. If this fluid be poured into vessels and placed over the gentle heat of a lamp in the apartments of the sick, it greatly contributes to disperse foul or mephitic vapours, and contributes to disperse foul or mephitic vapours, and consequently to purify the air. Its anticontagious powers are now little trusted to, but its odour is em-Its anticontagious ployed to relieve nervous headache, fainting fits, or

sickness occasioned by crowded rooms.

As an external application, vinegar proves highly efficacious when joined with farinaceous substances, and applied as a cataplasm to sprained joints; it also forms an eligible lotion for inflammations of the surforms an eligible lotion for inflammations of the surface, when mixed with alcohol and water in about equal proportions. Applied to burns and scalds, it is said to be highly serviceable whether there is a loss of substance or not, and to quicken the exfoliation of carious bone. (Gloucester Infirmary.) Mixed with an infusion of sage, or with water, it forms a popular and excellent gargle for an inflamed throat, also for an injection to moderate the fluor albus. Applied cold to the nose in cases of hemorrhage, also to the loins and abdomen in menorrhagia, particularly after parturition, it is said to be very serviceable. An imprudent use of vinegar internally is not without considerable inconveniences. Large and frequent doses injure the use of vinegar internally is not without considerable inconveniences. Large and frequent doses injure the stomach, coagulate the chyle, and produce not only leanness, but an atrophy. When taken to excess by females, to reduce a corpulent habit, tubercles in the lungs and a consumption have been the consequence.

["When any of the vinous liquors are exposed to the free access of atmospheric air, at a temperature of 80 to 85 degrees, they undergo a second fermentation, terminating in the production of a sour liquid, called vinegar. During this process a portion of the oxygen of the air is converted into carbonic acid: hence, un-

of the air is converted into carbonic acid; hence, unlike vinous fermentation, the contact of the atmosphere is necessary, and the most obvious phenomenon is the removal of carbon from the beer or wine. Vinegar is usually obtained from malt liquor or cider, while wine is employed as its source in those countries where the grape is abundantly cultivated .- Webster's

Manuel of Chemistry.

Vinegar for ordinary use may also be made from sugar, molasses, raisins, or other fruits, or from the re-

fuse of fruits, as follows

"Take the skins of raisins after they have been used in making wine, and pour three times their own quantity of water upon them; stir them well about, and then set the cask in a warm place, also covered, and the liquor in a few weeks' time will become a sound vinegar, which drawn off from its sediments, put into another cask, and well bunged down, will be a good vinegar for the table."—Beastall's Useful Guide. A.1

ACETIFICATION. (Acetificatio; from acetum, vinegar, and fio, to make.) The action or operation by which vinegar is made.

ACETOMETER. An instrument for estimating the strength of vinegars. See Acetic Acid.

ACETO'SA. (From aceseo, to be sour.) Sorrel. A genus of plants in some systems of botany. See Rumez.

ACETOSE'LLA. (From acetosa, sorrel: so called from the acidity of its leaves.) Wood-sorrel. See Oracles acetosella. Oxalis acetosella.

Of or belonging to vinegar.

Acetous Acid. See Acetum.

Acetous Acid. See Acetum.

Acetous Fermentation. See Fermentation.

ACE'TUM. (Acetum, i. n.; from acer, sour.) Vinegar. A sour liquor obtained from many vegetable substances dissolved in boiling water, and from fermented and spirituous liquors, by exposing them to heat and contact with air; under which circumstances they undergo the acid fermentation, and afford the liquor called vinegar. Common vinegar consists of acetic acid combined with a large portion of water, and acetic acid combined with a large portion of water, and with this are in solution portions of gluten, mucilage, sugar, and extractive matter, from which it derives its colour, and frequently some of the vegetable acids, par-ticularly the malic and the tartaric. See Acetic Acid.

ACRIUM AROMATICUM. Aromatic vinegar. A pre-paration of the Edinburgh Pharmacopæia, thought to be an improvement of what has been named thieves'

Take of the dried tops of rosemary, the dried leaves of sage, of each four ounces; dried lavender flowers, two ounces; cloves, two drachms; distilled vinegar, eight pounds. Macerate for seven days, and strain the expressed juice through paper. Its virtues are anti-septic, and it is a useful composition to smell at in crowded courts of justice, hospitals, &c. where the air is offensive.

ACETUM COLCHICI. Vinegar of meadow-saffron. Take of fresh meadow-saffron root sliced, an ounce; Vinegar of meadow-saffron. acetic acid, a pint; proof spirit, a fluid ounce. Macerate the meadow-saifron root in the acid, in a covered glass vessel, for three days; then press out the liquor and set it by, that the feculencies may subside; lastly, add the spirit to the clear liquor. The dose is from

ACETUM DISTILLATUM. See Acidum aceticum di-

lutum

ACETUM SCILLE. Vinegar of squills. Take of squills recently dried, one pound; dilute acetic acid, six pints; proof spirit, half a pint. Macerate the squils with the vinegar in a glass vessel, with a gentle heat for twenty-four hours; then express the liquor and set it aside until the faces subside. To the decanted liquor add the spirit. This preparation of squills is employed as an attenuant, expectorant, and diuretic. Dose, xv. to lx. drops. Dose, xv. to lx. drops.

A'CHEIR. (From a, neg. and xeip, hand.) With-

out hands.

Acnt'colum. By this word Cælius Aurelianus, Acut. lib. iii. cap. 17, expresses the sudatorium of the ancient baths, which was a hot room where they used

ACHILLE'A. (Achillea, α, f. Αχιλλεια: from Achilles, who is said to have made his tents with it, or to have cured Telephus with it.) 1. The name of a genus of plants in the Linnæan system. Class Syn-Αχιλλεια: genesia; Order, Polygamia superflua.
2. The pharmaceutical name of the milfoil.

Achillea millefolium,

Achillea Ageratum. Maudlin, or maudlin tansy. Balsamita famina; Eupatorium Mesues This plant, the ageratum of the shops, is described by Linnaus as Achillea;—foliis lanceolatis, obtusis, acutoserratis. It is esteemed in some countries as anthelminthic and

alterative, and is given in hepatic obstructions. It possesses the virtues of tansy.

ACHILLEA MILLEFOLIUM. The systematic name of ACHILLEA MILLEFOLIUM. The systematic name of the common yarrow, or milfoil. Achillea; Myriophyllon; Chiliophyllon; Lumbus veneris; Militaris herba; Stratioles; Carpentaria; Speculum veneris. The leaves and flowers of this indigenous plant, Achillea foliis bipinnatis nudis; laciniis linearibus dentatis; caulibus superne sulcatis of Linnaus, have an agreeable, weak, aromatic smell, and a bitterish, rough, and somewhat pungent taste. They are both directed for medicinal use in the Edinburgh Pharmacopæia; in the present practice, however, they are almost wholly neglected.

glected.

ACHILLEA PTARMICA. The systematic name of the sneeze-wort, or bastard pellitory. Pseudopyrethrum; Pyrethrum sylvestre; Draco sylvestris; Tarchon sylvestris; Sternutamentoria; Dracunculus pratensis. The flowers and roots of this plant, Achillea—foliis lanceolatis, acuminatis, argute serratis, have a hot biting taste, approaching to that of pyrethrum, with which they also agree in their pharmaceutical properwhich they also agree in their pharmaceutical proper-

ACETOUS. (Acetosus; from acetum, vinegar.) | ties. Their principal use is as a masticatory and ster-

Achillea foliis pinnatis. See Genipi verum.

ACHI'LLES. The son of Peleus and Thetis, one of the most celebrated Grecian heroes. A tendon is named after him, and also a plant with which he is said to have cured Telephus.

ACHILLIS TENDO. The tendon of the gastrocnemii muscles. So called, because, as fable reports, Thetis, the mother of Achilles, held him by that part when she The tendon of the gastrocnemii dipped him in the river Styx, to make him invulne-rable. Homer describes this tendon, and some writers suppose it was thus named by the ancients, from their custom of calling every thing Achillean, that had any extraordinary strength or virtue. Others say it was named from its action in conducing to swiftness of pace, the term importing so much. The tendon of Achilles is the strong and powerful tendon of the heel which is formed by the important of the heel which is formed by the junction of the gastrocnemius and soleus muscles, and which extends along the pos-terior part of the tibia from the calf to the heel. See Gastrocnemius externus, and Gastrocnemius internus.

When this tendon is unfortunately cut or ruptured, as it may be in consequence of a violent exertion, or spasm of the muscles of which it is a confinuation, the use of the leg is immediately lost, and unless the part be afterwards successfully united, the patient must remain a cripple for life. When the tendon has been main a cripple for life. When the tendon has been cut, the division of the skin allows the accident to be seen. When the tendon-has been ruptured, the patient hears the sound like that of the smack of a whip, at the moment of the occurrence. In whatever way the tendon has been divided, there is a sudden incapacity, or at least an extreme difficulty, either of standing or walking. Hence the patient falls down, and cannot get up again. Besides these symptoms there is a very palpable depression between the ends of the tendon; which depression is increased when the foot is bent, and diminished, or even quite removed when the foot is extended. The patient can spontaneously bend When the tendon- has been ruptured, the pafoot is extended. The patient can spontaneously bend his foot, none of the flexor muscles being interested. The power of extending the foot is still possible, as the peronei muscles, the tibialis posticus, and long flexors, peronei muscles, the tibialis posticus, and long flexors, remain perfect, and may perform this motion. The indications are to bring the ends of the divided parts together, and to keep them so, until they have become firmly united. The first object is easily fulfilled by putting the foot in a state of complete extension; the second, namely, that of keeping the ends of the ten don in contact, is more difficult. It seems unneces sary to enumerate the various plans devised to ac complish these ends. The following is Desault's me thod: After the ends of the tendon had been brough into contact by moderate flection of the knee are into contact by moderate flection of the knee, and complete extension of the foot, he used to fill up the hollows on each side of the tendon with soft lint and compresses. The roller applied to the limb, made as much pressure on these compresses as on the tendon, and hence this part could not be depressed too much against the adjacent parts. Desault next took a compress about two inches broad, and long enough to reach from the toes to the middle of the thigh, and placed it under the foot, over the back of the leg and lower part of the thigh. He then began to apply a few circles of a roller round the end of the foot, so as to fix the lower extremity of the longitudinal compress; after covering the whole foot with the roller, he used to make the bandage describe the figure of 8, passing it under the foot and across the place where the tendon was ruptured, and the method was finished by encircling the tured, and the method was finished by entireming the limb upward with the roller as far as the upper end of the longitudinal compress.

A'CHLYS. ($\lambda\lambda\nu_{\varsigma}$.) Darkness; cloudiness. An obsolete term, generally applied to a close, foggy air,

or a mist,

Hippocrates, de Morbis Mulierum, lib. ii. significs

by this word air, condensed air in the womb.

2. Galen interprets it of those, who, during sickness, lose that lustre and loveliness observed about the pupil

of the eye in health.

3. Others express it by an ulcer on the pupil of the eye, or the scar left there by an ulcer.

 4. It means also an opacity of the cornea; the same as the caligo cornea of Dr. Cullen.
 ACHME'LLA. See Spilanthus aemella.
 A'CHOLUS. (From a, priv. and χολη, bile.) ficient in bile,

A'CHOR. (Achor, oris. m. αχωρ, qu. αχνωρ; from light, white, flaky matter. Its properties are likewise αχνη, bran; according to Blanchard it is derived from entirely altered by this transformation; from being a, priv. and χωρος, space, as occupying but a smail compass.) Lactumen; Abas; Acores; Cerion; Favus; Crusta lactea of authors. The scald-head; so called from the branny scales thrown off it. A disease which attacks the hairy scalp of the head, for the most part of young children forms and scale. the most part, of young children, forming soft and scaly eruptions. Dr. Willan, in his description of different kinds of pustules, defines the achor, a pustule of interkinds of pustules, defines the achor, a pustule of intermediate size between the phlyzacium and psydracium, which contains a straw-coloured fluid, having the appearance and nearly the consistence of strained honey. It appeared most frequently about the head, and is succeeded by a dull white or yellowish scab. Pustules of this kind, when so large as nearly to equal the size of phlyzacia, are termed ceria or favi, being succeeded by a yellow semi-transparent, and sometimes cellular, scab, like a honeycomb. The achor differs from the favus and tinea only in the degree of virulence. It is called favus when the perforations are large; and tinea called favus when the perforations are large; and tinea when they are like those which are made by moths in cloth; but generally by tinea is understood a dry scab on the hairy scalp of children, with thick scales and an offensive smell. When this disorder affects the face, it is called crusta lactea or milk scab. Mr. Bell, in his Treatise on Ulcers, reduces the tinea capitis and crusta lactea to some species of herpes, viz. the herpes pus-tulosus, differing only in situation.

ACHORISTOS. Inseparable. This term was ap-

plied by the ancients, to symptoms, or signs, which are inseparable from particular things. Thus, softness is inseparable from humidity; hardness from fragility; and a pungent pain in the side is an inseparable symp-

and a pungent pain in the side is an inseparable symptom of a pleurisy.

ACHRAS. The name of a genus of plants in the Linnæan system. Class, Hexandria; Order, Monogynia. The sapota plum-tree.

ACHRAS SAPOTA. The systematic name of the tree which affords the oval-fruited sapota, seeds of which are sometimes given in the form of emulsion in calculous complaints. It is a native of South America, and lous complaints. It is a native of South America, and bears a fruit like an apple, which has, when ripe, a luscious taste, resembling that of the marmalade of quinces, whence it is called natural marmalade. The bark of this, and the Achras mammosa is very astringent, and is used medicinally under the name of Cor-

ACHREI'ON. Useless. Applied by Hippocrates to the limbs which, through weakness, become useless.

ACHROI'A. A paleness. A'CHYRON. Αχυρον. A'CHYRON. Αχυρου. This properly signifies bran, or chaff, or straw. Hippocrates, de Morbis Mulierum, most probably means by this word, bran. Achyron also signifies a straw, hair, or any thing that

Action also signifies a straw, harry or any timing that sticks upon a wall.

A'CIA. (From ακη, a point.) A needle with thread in it for chirurgical operations.

A'CICYS. Weak, infirm, or faint. In this sense it is used by Hippocrates, de Morb. lib. iv.

ACID. (Acidum, i. n.) 1. That which impresses upon the organs of taste a sharp or sour sensation. The word sour, which is usually employed to denote the simple impression, or lively and sharp sensation produced on the tongue by certain bodies, may be regarded as synonymous to the word acid. The only difference which can be established between them, is, that the one denotes a weak sensation, whereas the other comprehends all the degrees of force, from the least per-ceptible to the greatest degree of causticity: thus we say that verjuice, gooseberries, or lemons, are sour; but we use the word acid to express the impression which the nitric, sulphuric, or muriatic acids make upon the tongue.

2. Acids are an important class of chemical com pounds. In the generalization of facts presented by Lavoisier and the associated French chemists, it was the leading doctrine that acids resulted from the union of a peculiar combustible base called the radical, with of a peculiar combustible base called the raacat, with a common principle technically called oxygen, or the acidifier. This general position was founded chiefly on the phenomena exhibited in the formation and decomposition of sulphuric, carbonic, phosphoric, and nitric acids; and was extended by a plausible analogy to other acids, the radicals of which were unknown. "I have already shown," says Lavoisier, "that phosphorus is changed by combustion into an extremely B 2

light, white, flaky matter. Its properties are likewise entirely altered by this transformation; from being insoluble in water, it becomes not only soluble, but so greedy of moisture as to attract the humidity of the air with astonishing rapidity. By this means it is converted into a liquid, considerably more dense, and of more specific gravity than water. In the state of phosphorus before combustion, it had scarcely any sensible taste; by its union with oxygen it acquires an extremely sharp and sour taste; in a word, from one of the class of combustible bodies, it is changed into an incombustible substance, and becomes one of those bodies called acids. bodies called acids.

"This property of a combustible substance, to be converted into an acid by the addition of oxygen, we shall presently find belongs to a great number of bodies. Wherefore strict logic requires that we should adopt a common term for indicating all these operations which produce analogous results. This is the true way to simplify the study of science, as it would be quite impossible to bear all its specific details in the memory if they were not classically arranged. For this reason we shall distinguish the conversion of phosphorus into an acid by its union with oxygen, and in general every combination of oxygen with a combustible substance, by the term oxygenation; from this I shall adopt the verb to oxygenate; and of consequence shall say, that in oxygenating phosphorus, we convert it into an acid. "Sulphur also, in burning, absorbs oxygen gas; the resulting acid is considerably heavier than the

sulphur burnt; its weight is equal to the sum of the weights of the sulphur which has been burnt, and of the oxygen absorbed; and, lastly, this acid is weighty, in-combustible, and miscible with water in all proportions.

"I might multiply these experiments, and show, by a numerous succession of facts, that all acids are formed by the combustion of certain substances; but I am prevented from doing so in this place by the plan which I have laid down, of proceeding only from facts already ascertained to such as are unknown, and of already ascertained to such as are unknown, and of drawing my examples only from circumstances already explained. In the mean time, however, the examples above cited may suffice for giving a clear and accurate conception of the manner in which acids are formed. By these it may be clearly seen that oxygen is an element common to them all, and which constitutes or produces their acidity; and that they differ from each other according to the several natures of the oxygenated or acidified substances. We must, therefore, in every acid, carefully distinguish between the acidifia-

nated or acidified substances. We must, therefore, in every acid, carefully distinguish between the acidifable base, which de Morveau calls the radical, and 'the acidifying principle or oxygen.'" Elements, p. 115.

"Although we have not yet been able either to compose or to decompound this acid of sea salt, we cannot have the smallest doubt that it, like all other acids, is composed by the union of oxygen with an acidifiable base. We have, therefore, called this unknown substance the muriatic base, or muriatic radical." P. 122, 5th Edition.

5th Edition.

Berthollet maintains, that Lavoisier had given too much latitude to the idea of oxygen being the universal acidifying principle. "In fact," says he, "it is car-rying the limits of analogy too far to infer, that all acidity, even that of the muriatic, fluoric, and boracic acids, arises from oxygen, because it gives acidity to a great number of substances. Sulphuretted hydrogen, which really possesses the properties of an acid, proves directly that acidity is not in all cases owing to oxygen. There is no better foundation for concluding oxygen. There is no better foundation for concluding that hydrogen is the principle of alcalinity, not only in the alcalies, properly so called, but also in magnesia, lime, strontian, and barytes, because ammonia appears to owe its alcalinity to hydrogen.

"These considerations prove that oxygen may be regarded as the most usual principle of acidity, but that this species of affinity for the alcalies may belong to substances which do not contain oxygen; that we must not, therefore, always infer, from the acidity of acute the contains oxygen, although this a substance, that it contains oxygen, although this may be an inducement to suspect its existence in it; may be an inducement to suspect its existence in it; still less should we conclude, because a substance contains oxygen, that it must have acid properties; on the contrary, the acidity of an oxygenated substance shows that the oxygen has only experienced an incomplete saturation in it, since its properties remain pre-

This generalization of the French chemists concern-

ing oxygen, was first experimentally combated by Sir Humphry Davy, in a series of dissertations published in the Philosophical Transactions.

"His first train of experiments was instituted with "His first train of experiments was instituted with the view of operating by voltaic electricity on muriatic and other acids freed from water. Substances which are now known by the names of chlorides of phosphorus and tin, but which he then supposed to contain dry muriatic acid, led him to imagine that intimately combined water was the real acidifying principle, since acid properties were immediately developed in the above substances by the addition of that fluid, though previously they exhibited no acid powers. In July, 1810, however, he advanced those celebrated views concerning acidification, which, in the aminion of the concerning acidification, which, in the opinion of the best judges, display an unrivalled power of scientific research. The conclusions to which these led him, were incompatible with the general hypothesis of Lavoisier. He demonstrated that oxymuniatic acid is, Lavoisier. He demonstrated that oxymuniatic acid is, as far as our knowledge extends, a simple substance, which may be classed in the same order of natural bodies as oxygen gas, being determined like oxygen to the positive surface in voltaic combinations, and like oxygen combining with inflammable substances, producing heat and light. The combinations of oxymuriatic acid with inflammable bodies were shown to be analogous to oxydes and acids in their preservices. be analogous to oxydes and acids in their properties and powers of combination, but to differ from them in being, for the most part, decomposable by water; and, finally, that oxymuriatic acid has a stronger attraction finally, that oxymuriatic acid has a stronger attraction for most inflammable bodies than oxygen. His preceding decomposition of the alcalies and earths having evinced the absurdity of that nomenclature which gives to the general and essential constituent of alcaline nature, the term oxygen or acidifier; his new discovery of the simplicity of oxymuriatic acid, showed the theoretical system of chemical language to be equally vicious in another respect. Hence this philosopher most judiciously discarded the appellation oxymuriatic acid, and introduced in its place the name chlorine, which merely indicates an obvious and permanent character of the substance, its greenish yellow colour. The more recent investigations of chemists on fluoric, hydriodic, and hydrocyanic acids, have brought powerful analogies in support of the chloridic theory, by showing that hydrogen alone can convert certain undecompounded bases into acids well characterized, without the sid of every " without the aid of oxygen."

"After these observations on the nature of acidity, we shall now state the general properties of the acids.
"I. The taste of these bodies is for the most part

sour, as their name denotes; and in the stronger

species t is acrid and corrosive.

"2. They generally combine with water in every proportion, with a condensation of volume and evolution of heat.

"3. With a few exceptions they are volatilized or

decomposed at a moderate heat.

"4. They usually change the purple colours of vege-tables to a bright red.

tables to a bright red.

"5. They unite in definite proportions with the alcalies, carths, and metallic oxydes, and form the important class of salts. This may be reckoned their characteristic and indispensable property."

"Thenard has lately succeeded in communicating to many acids apparently a surcharge of oxygen, and thus producing a supposed new class of bodies, the exygenized acids, which are, in reality, combinations of the ordinary acids with oxygenized water, or with the deutoxide of hydrogen."

the deutoxide of hydrogen."
"The class of acids has been distributed into three "The class of acids has been distributed into three orders, according as they are derived from the mineral, the vegetable, or the animal kingdom. But a more specific distribution is now requisite. They have also been arranged into those which have a single, and also been arranged into those which have a single, and the statement of the statemen those which have a compound basis or radical. This arrangement is not only vague, but liable in other respects to considerable objections. The chief advantage of a classification is to give general views to beginners in the study, by grouping together such sub-stances as have analogous properties or composition. These objects will be tolerably well attained by the following divisions and subdivisions.

"1st. Acids from inorganic nature, or which are procurable without having recourse to animal or

vegetable products.

22d. Acids elaborated by means of organization.

"The first group is subdivided into three families: 1st. Oxygen acids; 2d. Hydrogen acids; 3d. Acids destitute of both these supposed acidifiers.

Family 1st.-Oxygen acids. Section 1st, Non-metallic.

11. Hypophosphorus. 1. Boracic. 12. Phosphorus. Carbonic. 3. Chtoric. 13. Phosphatic. 14. Phosphoric. Perchloric ? Hyposulphurous.
 Sulphurous. Chloro-Carbonic. Nitrous. 17. Hyposulphuric. 18. Sulphuric. Hyponitric. Nitric. 19. Cyanic ? Iodic.

10. Iodo-Sulphuric.

Section 2d, Oxygen acids.-Metallic. 6. Columbic.

Arsenic. Molybdic. Arsenious. Antimonious Molybdous. Tungstic. Antimonic

Chromic.

Family 2d.-Hydrogen acids.

6. Hydroprussic, or 1. Fluoric. Hydriodic. Hydro-cyanic. Hydrosulphurous. 3. Hydrochloric, or Muria-8. Hydrotellurous. 4. Ferroprussic. 5. Hydroselenic. 9. Sulphuroprussic.

Family 3d.—Acids without Oxygen or Hydrogen.
Chloriodic.
Chloroprussic, or
4. Fluosilicic.

1. Chloriodic. 2. Chloroprussic, or Chlorocyanic.

Division 2d .- Acids of Organic Origin.

24. Meconic. Aceric. Menispermic. 2. Acetic. Margaric. Amniotic. Benzoic. Melassic? Boletic. Mellitic. 29 Moroxylie Butyric. 30. Mucic. Camphorie. Caseic. Nanceic? Nitro-leucic. Nitro-saccharie Cevadic. 32. 10. Cholesterie. 33. Oleic. 34. Citric.

Oxalic. 35. 12. Delphinic. Purpuric.
Pyrolithic.
Pyromalic.
Pyrotartaric. 36. 13. Ellagie? 37. Formic. 14. Fungic. 15. 16. Gallic. 17. Igasuric. 18. Kinic. Rosasic. 41. Saclactic. 19. Laccic. Sebacic. 43. Suberic. 20. Lactic. 44. Succinic. 21. Lampic. 45. Sulphovinic ? 46. Tartaric.

Lithic, or Uric.

23. Malic.

The acids of the last division are all decomposable at a red heat, and afford generally carbon, hydrogen, oxygen, and, in some few cases, also nitrogen. The mellitic is found like amber in wood coal, and, like it, is undoubtedly of organic origin."

Acid, aceric. See Aceric acid. Acid, acetic. See Acetum. Acid, acetuc. See Acetum.
Acid, acetous. See Acetum.

ACIDIFIABLE. Capable of being converted into an
                                                                                                                                                                                                                                ACIDIFIABLE. Capable of being converted into an acid by an acidifying principle. Substances possessing this property are called radicals and acidifiable bases. ACIDIFICATION. (Acidificatio; from acidum, an acid.) The formation of an acid; also the impregnation of any thing with acid properties. ACIDIFYING. See Acid. ACIDIMETRY. The measurement of the strength of acids. This is effected by saturating a given weight of them with an alkaline base; the quantity of which requisite for the purpose, is the measure of their power.
                                                                                                                                                                                                                                   power
                                                                                                                                                                                                                                 ACIDITY. Aciditas. Sourness.
ACIDIULOUS. Acidula, Latin; acidule, French.
Slightly acid; applied to those salts in which the base
is combined with such an excess of acid, that they
manifestly exhibit acid properties, as the supertartrate
and the supersulphate of potassa.
Acidulous waters. Mineral waters, which contain
so great a quantity of carbonic acid gas, as to render
them acidulous or gently last to the taste. See Mine-
                                                                                                                                                                                                                                   them acidulous, or gently tart to the taste. See Mine-
                                                                                                                                                                                                                                   ral waters
                                                                                                                                                                                                                                  ACIDULUS. Acidulated. Any thing blended with an acid juice in order to give it a coolness and brisk
                                                                                                                                                                                                                                            A'CIDUM. (Acidum, i. n.; from aceo, to be sour.)
                                                                                                                                                                                                                                   An acid. See Acid.
                                                                                                                                                                                                                                           ACIDUM ACETICUM. See Acidum aceticum dilutum.
ACIDUM ACETICUM DILUTUM. Dilute acetic acid.
                                                                                                                                                                                                                                 Take of vinegar, a gallon.

Distil the acetic acid in a sand bath, from a glass retort into a receiver also of glass, and kept cold; throw away the first pint, and keep for use the six succeeding pints, which are distilled over.

In this distillation, the liquor should be kept modeling the same process of the same process.
                                                                                                                                                                                                                                   rately boiling, and the heat should not be urged too
                                                                                                                                                                                                                                 rately boiling, and the heat should not be urged too far, otherwise the distilled acid will have an empyreumatic smell and taste, which it ought not to possess. If the acid be prepared correctly, it will be colourless, and of a grateful, pungent, peculiar acid taste. One fluid ounce ought to dissolve at least ten grains of carbonate of lime, or white marble. This liquor is the acetum distillatum; the acidum acctosum of the Longita
and in English by ic : e. g. acidum nitricum, or nitric
```

don Pharmacopæia of 1787, and the acidum accticum | cools, precipitates 19-20ths of what it had dissolvedof that of 1822, and the acidum accticum dilutum of the present. The compounds of the acid of vinegar, directed to be used by the new London Pharmaco-paia, are acetum colchici, acetum scilla, ceratum plumbi acetatis, liquor ammonia acetatis, liquor plumbi acetatis, liquor plumbi acetatis dilutis, oxymel, oxymel scillæ, potasse acetas, and the cataplasma sinapis.

ACIDUM ACETICUM CONCENTRATUM. acid of vinegar is greatly concentrated, that is, de-prived of its water, it is called concentrated acid of vinegar, and radical vinegar.

Distilled vinegar may be concentrated by freezing:

the congelation takes place at a temperature below 28 degrees, more or less, according to its strength; and the congealed part is merely ice, leaving, of course, a stronger acid. If this be exposed to a very intense cold, it shoots into crystals; which being separated, liquefy, when the temperature rises and the liquor is limpid as water, extremely strong, and has a highly pungent acetous odour. This is the pure acid of the vinegar; the foreign matter remaining in the uncongealed liquid.

gealed liquid.

Other methods are likewise employed to obtain the pure and concentrated acid. The process of Westendorf, which has been often followed, is to saturate soda with distilled vinegar; obtain the acetate by crystal-lization; and pour upon it, in a retort, half its weight of sulphuric acid. By applying heat, the acetic acid is distilled over; and, should there be any reason to suspect the presence of any sulphuric acid, it may be distilled a second time, from a little acctate of soda. According to Lowitz, the best way of obtaining this acid pure, is to mix three parts of the acetate of soda with eight of supersulphate of potassa; both salts being

perfectly dry, and in fine powder, and to distil from this mixture in a retort, with a gentle heat.

It may also be obtained by distilling the verdigris of commerce, with a gentle heat. The concentrated acid procured by these processes, was supposed to differ materially from the acctous acids obtained by distilling the verdigris of the concentrated acid procured by these processes, was supposed to differ materially from the acctous acids obtained by distilling the concentrated acids. ling vinegar; the two acids were regarded as differing in their degree of oxygenizement, and were after-ward distinguished by the names of acetous and ace-tic acids. The acid distilled from verdigris was supposed to derive a quantity of oxygen from the oxyde of copper, from which it was expelled. The experiments of Adet have, however, proved the two acids to be identical; the acetous acid, therefore, only differs from the acetic acid in containing more water, rendering it a weaker acid and of a less active nature. There exists, therefore, only one of acid vinegar, which is the acetic; its compounds are termed acetates.

ACIDUM ACETOSUM. See Acetum.

ACIDUM ETHEREUM. See Sulphuric acid.

ACIDUM ETHEREUM. (See Sulphuric acid.)

ACIDUM ATHEREUM. See Sulphuric acid.

ACIDUM ALUMINOSUM. (So called because it exists in alum.) See Sulphuric acid.

ACIDUM ARSENICUM. See Arsenic.

ACIDUM BENZOICUM. BENZOIC acid. The London Pharmacopæia directs it to be made thus:—Take of gum benzoin a pound and a half: fresh lime, four ounces: water, a gallon and a half: smuriatic acid, four fluid ounces. Rub together the benzoin and lime; then boil them in a gallon of the water, for half an hour, constantly stirring; and, when it is cold, pour off the then boil them in a gallon of the water, for half an hour, constantly stirring; and, when it is cold, pour off the liquor. Boil what remains a second time, in four pints of water, and pour off the liquor as before. Mix the liquors, and boil down to half, then strain through paper, and add the muriatic acid gradually, until it ceases to produce a precipitate. Lastly, having poured off the liquor, dry the powder in a gentle heat; put it into a proper vessel, placed in a sand bath; and by a very gentle fire, sublime the benzoic acid. In this process a solution of benzoate of lime is first obtained; the muriatic acid then, abstracting the lime, precipitates the benzoic acid, which is crystallized by sublimation.

The Edinburgh Pharmacopæia forms a benzoate of

The Edinburgh Pharmacopæla forms a benzoate of soda, precipitates the acid by sulphuric acid, and afterward crystallizes it by solution in hot water, which dissolves a larger quantity than cold.

Benzoic acid-has a strong, pungent, aromatic, and peculiar edour. Its crystals are ductile, not pulverizable; it sublimes in a moderate heat, forming a white irritating smoke. It is soluble in about twenty-four times its weight of boiling water, which, as it

It is soluble in alcohol.

Benzoic acid is very seldom used in the cure of dis-cases; but now and then it is ordered as a stimulant against convulsive coughs and difficulty of breathing. The dose is from one grain to five.

ACIDUM SULPHURICUM DILUTUM. Acidum vitrio-licum dilutum. Spiritus vitrioli tenuis. Take of sulphuric acid a fluid ounce and a half; distilled water, fourteen fluid ounces and a half. Add the

water gradually to the acid.

ACIDUM TARTARICUM. See Tartaric acid. ACIDUM VITRIOLICUM. See Sulphuric acid.

ACIDUM VITRIOLICUM DILUTUM. See Acidum sulphuricum dilutum.

ACIES. Steel.

ACINACIFORMIS. (From acinaces, a Persian scimitar, or sabre, and forma, resemblance.) Acinaciform; shaped like a sabre, applied to leaves: as those of the mysembryanthemum acinaciforme.

ACINE'SIA. (From acingua, immobility.) A loss of motion and strength.

ACINIFORMIS. (From acinus, a grape, and

ACINIFORMIS. (From acinus, a grape, and forma, a resemblance.) Aciniform. A name given by the ancients to some parts which resembled the colour and form of an unripe grape, as the uvea of the eye, which was called tunica acinosa, and the choroid membrane of the eye, which they named tunica

A'CINUS. (Acinus, i. m.; a grape.) 1. In anatomy, those glands which grow together in clusters are called by some acini glandulosi.

2. In botany, a small berry, which, with several others, composes the fruit of the mulberry, black-berry, &c. berry, &c.

Acinus billosus. The small glandiform bodies of the liver, which separate the bile from the blood, were formerly called acini biliosi: they are now, however, termed penicilli. See Liver.

ACMA'STICOS. A species of fever, wherein the heat continues of the same tenor to the end. Actuarius.

A'CME. (From $a\kappa\mu\eta$, a point.) The height or crisis. A term applied by physicians to that period or state of a disease in which it is at its height. The ancients distinguished diseases into four stages: 1. The Arche, the beginning or first attack. 2. Anabasis, the growth. 3. Acme, the height. 4. Paracme, or the decline of the

ACME'LLA. See Spilanthus.

ACME'LLA. See Spilanthus.

A'CNE. ακιη. Acna. A small pimple, or hard tubercle on the face. Foesius says, that it is a small pustule or pimple, which arises usually about the time that the body is in full vigour.

ACME'STIS. (From α, priv. and κναω, to scratch.) That part of the spine of the back, which reaches from the metaphrenon, which is the part between the shoulder-blades, to the loins. This part seems to have been originally called so in quadrupeds only, because they cannot reach it to scratch.

cannot reach it to scratch.

A'COE. ακοη. The sense of hearing.

ACOE'LIUS. (From α, priv. and κοιλια, the belly.)

Without belly. It is applied to those who are so wasted, as to appear as if they had no belly. Galen.

ACOE'TUS. Ακοιτος. An epithet for honey, men tioned by Pliny; because it has no sediment, which is

ACO'NION. AROHOV. A particular form of medicine among the ancient physicians, made of powders levigated, and probably like collyria for the disorders

ACONITA. (Aconita, e, f.; from aconitum, the

name of a plant.) A poisonous vegetable principle, probably alcaline, recently extracted from the aconitum napellus, or wolf's bane, by Mons. Brandes. The

details have not yet reached this country.

ACONITE. See Aconitum.

ACONITUM. (Aconitum, i. m.) Aconite. 1. A genus of plants in the Linnman system, all the species of which have powerful effects on the human body.

of which have powerful effects on the human body. Class, Polyandria; Order, Trygynia.

2. The pharmacopæial name of the common, or blue, wolf's-bane. See Aconitum napellus.

Aconitum anthora. The root of this plant Aconitum—floribus pentagynus, foliorum laciniis linearibus of Linnæus, is employed medicinally. Its virtues are similar to those of the aconitum napellus.

Aconitum napellus. Monk's hood. Aconite. Wolf's-bane. Camorum. Canicida. Cynoctanum. Actonitum —foliorum laciniis linearibus, superne.

Actonitum; -foliorum laciniis linearibus, superne latioribus, linea exaratis of Linnæus. This plant is cultivated in our gardens as an ornament, but is spontaneously produced in Germany, and some other northern parts of Europe. Every part is strongly poisonous, but the root is unquestionably the most pow-erful; and, when first chewed, imparts a slight sensation of acrimony; but afterward, an insensibility or stupor at the apex of the tongue, and a pungent heat of the lips, gums, palate, and fauces are perceived, followed with a general tremor and sensation of chilli-The juice applied to a wound seemed to affect the whole nervous system; even by keeping it long in the hand, or on the bosom, we are told unpleasant symptoms have been produced. The fatal symptoms brought on by this poison are, convulsions, giddiness, insanity, violent purgings, both upwards and down-wards, faintings, cold sweats, and death itself. Dr. Stoerk appears to be the first who gave the wolf's-bane internally, as a medicine; and since his experiments were published, 1762, it has been generally and successfully employed in Germany and the northern parts of Europe, particularly as a remady for obstincts. of Europe, particularly as a remedy for obstinate rheumatisms; and many cases are related where this disease was of several years' duration, and had withstood the efficacy of other powerful medicines, as mercury, opium, antimony, hemlock, &c. yet, in a short time, was entirely cured by the aconitum. Instances are also given us of its good effects in gout, scrofulous swellings, venereal nodes, amaurosis, intermittent fevers, paralysis, ulceration, and scirrhus. This plant has been generally prepared as an extract or inspis-sated juice, after the manner directed in the Pharmacopæla: its efficacy is much diminished on being long kept. Like all virulent medicines, it should first be administered in small doses. Stoerk recommends two grains of the extract to be rubbed into a powder, with two drachms of sugar, and to begin with ten grains of this powder, two or three times a day. We find, however, that the extract is oftener given from one grain to ten for a dose; and Stoll, Scherekbecker, and others, increased this quantity considerably. Instead of the extract, a tincture has been made of the dried leaves macerated in six times their weight of spirits of wine, and forty drops given for a dose. Some writers say that the napellus is not poisonous in Sweden, Poland, &c.; but it should be noted that the species which is not poisonous, is the aconitum lycoctonum of Linnæus.

ACOPA. Dioscorides's name for the buck-bean or

Acopa. Dioscorides's name for the buck-bean or Menyanthes trifoliata of Linnæus.

A'COPON. (From a, priv. and κοπος, weariness.) It signifies originally whatever is a remedy against weariness, and is used in this sense by Hippocrates. Aph. viii. lib. ii. But in time, the word was applied to certain ointments. According to Galen and Paulus Ægineta, the Acopa pharmaca are remedies for indispositions of body which are caused by long or vehement motion.

ment motion.

Acoros. The name of a plant in Pliny, supposed to be the buck-bean or Menyanthes trifoliata of

Linnæus

A'COR. (Acor, oris, m.; from acco to be sour.)
Acidity. It is sometimes used to express that sourness in the stomach contracted by indigestion, and from whence flatulencies and acid belching arise. ACOR DINA.

Imifan tutty. (From α, priv. and κορεω, to satiate.) Insatiability. In Hippocrates, it means good appetite and digestion.

ACORN. See Quercus robur.

A'CORUS. (Acorus, i. m.; akopov, from koon, the pupil; because it was esteemed good for the disorders of the eyes.) The name of a genus of plants in the Linnaran system. Class, Hexandria. Order, Digynia.

Acorus Callamus. The systematic name of the

plant which is also called Calamus aromaticus; Acorus verus; Calamus odoratus; Calamus avmaticus; Acorus; Diringa; Jacerantatinga; Typha aromatica; Clava rugosa. Sweet-flag, or acorus. Acorus; Scapi mucrone longissimo foliacco of Liangus. The root has been long employed medicinally. It has a moderately strong aromatic smell; a warm, pungent, bitterish taste; and is deemed useful as a warm stomachic. Powdered, and mixed with some absorbent, it forms a useful and pleasant dentifrice.

Acorus Palustris. See Iris palustris. Acorus verus. See Acorus calamus.

ACORUS VULGARIS. See Iris palustris. A'COS. (Akos, from akcopat, to heal.) A remedy

ACO'SMIA. (From α, neg. and κοσμος, beautiful.) Baldness; ill-health: irregularity, particularly of the

Acotyle DON. (Acotyledon, onis, n. from a,

ACOTYLE DON. (Acotyledon, onis, n. from a, priv. and κοτυληθων. Without a cotyledon; applied in botany to a seed or plant which is not furnished with a cotyledon; Semen acotyledon.) All the mosses are planta acotyledones.

ACOU'STIC. (Acousticus: from ακουω, to hear.)

Belonging to the ear or to sound.

2. That which is employed with a view to restore the sense of hearing, when wanting or diminished. No remedies of this kind, given internally, are known to produce any uniform effect.

to produce any uniform effect.

Acoustic nerve. See Portio mollis.

Acoustic duct. See Meatus auditorius.

ACRA'PALOS. See Meraipala.

ACRA'PALOS. See Meraipala.

ACRA'PALOS. (Ακραιπαλος. From a, neg. and κραιπαλη, surfeit.) Remedies for the effects of a debauch ACRA'SIA. (From a, and κεραω, to mix.) Unbeatthnesses interpressure. ACRA'SIA. (From α, as healthiness; intemperance.

ACRATI'A. (From a, and κρατος, strength.) Weak-

ness or intemperance.

ACRATI'SNA. (From apparon, unmixed wine. The derivation of this word is the same as Acrasia, because the wine used on the occasion was not mixed A breakfast among the old Greeks, with water.) consisting of a morsel of bread, soaked in pure unmixed wine.

ACRATO'MELL. (From ακρατον, pure wine; and μελι, honey.) Wine mixed with honey.

A'CRE. (From ακρος, extreme.) The extremity

of the nose or any other part.

A'CREA. (From ακρος, extreme.) Acroteria. The extremities; the legs, arms, nose, and ears.

ACRIBEI'A. (From ακριδης, accurate.) An exact and accurate description and diagnosis, or distinction,

ACRID. Acris. A term employed in medicine to express a taste, the characteristic of which is pungency

joined with heat.

ACRIMONY. (Aerimonia, from aeris, acrid.) quality in substances by which they irritate, corrode, or dissolve others. It has been supposed until very lately, there were acid and alkaline acrimonies in the blood, which produced certain diseases; and although the humoral pathology is nearly and improperly ex-ploded, the term venereal acrimony, and some others,

are still and must be retained.
A'CRIS. 1. Acrid. See Acrid.
2. Any fractured extremity.

Acri'sia. (From α, priv. and κρινω, to judge or separate.) A turbulent state of a disease, which will scarcely suffer any judgment to be formed thereof.

A'critus. (From α, neg. and κρινω, to judge.) A disease without a regular crisis, the event of which it is begrathers to judge.

is hazardous to judge.

ACROBY STIA. (From aκρος, extreme, and βυω, to cover.) The prepuce which covers the extremity of the penis.

ACROCHEIRE'SIS. (From axpos, extreme, and $\chi axpos$, a hand.) An exercise among the ancients. Probably a species of wrestling, where they only held by the hands.

ACROCHEI'RIS. (From ακρος, extreme, and χτιρ, a hand.) Gorræus says, it signifies the arm from the elbow to the ends of the fingers; χτιρ signifying the arm, from the scapula to the fingers' end.

ACROCHO'RDON.' (From ακρος, extreme, and χορόη, a string.) Galen describes it as a round excrescence on the skin, with a siender base; and that it hath its name because of its situation on the surface of the skin. The Greeks call that excrescence an achrochordon, where something hard concretes under achrochordon, where something hard concretes under acarocoraon, where something hard concretes under the skin, which is rather rough, of the same colour as the skin, slender at the base and broader above. Their size rarely exceeds that of a bean.

ACROCO'LIA. (From ακρος, extreme, and κωλον, a limb.) These are the extremities of animals which are used in food, as the feet of calves, swine, sheep, over a lambs and of the break of which in life.

oxen, or lambs, and of the broths of which jellies are frequently made. Castellus from Budæus adds, that the internal parts of animals are also called by this

ACHROLE'NION. Castellus says it is the same as

ACROMA'NIA. (From aκρος, extreme, and μανια, madness.) Total or incurable madness.

ACRO'MION. (From aκρον, extremity, and ωμος, the shoulder.) A process of the scapula or shoulder-blade. See Scapula.

ACROMPHA'LIUM. (Ακρομφαλον; from ακρος, extreme, and ομφαλος, the navel.) Acromphalon. The tip of the navel.

tip of the navel.

ACRO'MPHALON. See Acromphalium.

ACRO'NIA. (From ακρον, the extremity.) The amputation of an extremity, as a finger.

ACRO'PATHOS. (From ακρος, extreme, and παθος, a disease.) Acropathus. It signifies literally a disease at the top or superior part. Hippocrates in his treatise De Superfectatione, applies it to the internal orifice of the uterus; and in Prædict. lib. ii. to cancers which appear on the surface of the body.

which appear on the surface of the body.

ACRO PATHUS. See Acropathos.

A'CROPIS. (From ακρον, the extremity, and οψ, the voice.) Imperfect articulation, from a fault in the

ACROPO'STHIA. (From ακρος, extreme, and ποσθη, the prepuce.) The extremity of the prepuce; or that part which is cut off in circumcision.

ACRO'PSILON. (From ακρος, extreme, and ψιλος, naked.) The extremity of the denuded glans penis.

ACRO'SPELOS. (From ακρος, extreme, and πελος, black, so called because its ears, or tops, are often of a blackish colour.) Acrospelus. The bromus discordis, or wild out grass.

or wild oat grass.

ACRO'SPELUS. See Acrospelos.

ACROTE'RIA. (From axoo, extreme.) The extreme parts of the body; as the hands, feet, nose, ears,

ACROTERIA'SMUS. (From akpos, summus.)

ACROTERIA'SMUS. (From ακρος, summus.)
The amputation of an extremity.
ACROTHY'MIA, See Acrothymion.
ACROTHY'MION. (From ακρος, extreme, and 3υμος, thyme.) Acrothymia. Acrothymium. A sort of wart, described by Celsus, as hard, rough, with a narrow basis, and broad top; the top of the colour of thyme; it easily splits and bleeds.
ACROTHYMIUM. See Acrothymion.

ACROTHYMIUM. See Acrothymion.
ACROTICUS. (From aκρος, summus; whence exρότης, ητος; summitas; cacumen.) A disease affect ing the external surface.
ACROTICA. The name of an order in Good's No-

sology.

ACROTISMUS. Acrotismus; (From a. priv. and κροτος, pulsus, defect of pulse.) Acrotism or pulselessness. A term synonymous with asphyxia, and applied to a species of entasia in Good's Nosology.

ACTÆ'A. (From aγω, to break.) Acte. The elder-tree, so called from its being easily broken. See Sambucus nigra.

A'CTINE. The herb Bunias, or Napus.

ACTINOBOLI'SMUS. (From ακτιν, a ray, and βαλω, to cast out.) Diradiatio. Irradiation. It is applied to the spirits, conveying the inclinations of the mind to the body.

viewed in the extremes, do in other cases insensibly pass into each other. The actynolite has usually a greater transparency, a more lively green colour, arising from the chrome which it contains, and differs also in the result of fusion by the blow-pipe

"The actynolite occurs in prismatic crystals which are commonly long and incomplete, sometimes extremely minute and even fibrous, and variously aggregated into masses more or less large. Its prevailing colour is green, sometimes pure emerald vailing colour is green, sometimes pure emerald green, but varying from a dark or leek green to a pale green, which is sometimes shaded with gray, yellow, or brown. Its colours are liable to change in consequence of decomposition. It scratches grass, but its prisms are often very brittle in a transverse direction. Its cross fracture is often a little chonchoidal, and more shining than that of common hornblende. Its specific gravity is about 3.30.

"It melts by the blow-pipe into a gray or yellowish-gray enamel. It contains, according to Langier, of

Its green colour is derived from the chrome, often modified by the large quantity of iron which is present. It presents the following varieties, which pass into each other: 1. common actynolite · 2. glassy;

3. acicular; 4. fibrous.

"Actynolité is found in primit've rocks, or in veins which traverse them; it is sometimes in metallic beds. It is perhaps most common in minerals which contain magnesia. Its more distinct crystals occur in talc,

magnesia. Its more distinct crystais occur in taic, quartz, and limestone.

"It is found in various parts of the United States. In Maryland, near Baltimore, all its varieties occur in granite or gneiss. In Pennsylvania, at Concord in Chester county, in large masses of an emerald-green colour. In Connecticut, near New-Haven, in serpentine; its structure generally radiated. In Maine, at Brunswick, all its varieties occur, sometimes in granite Brunswick, all its varieties occur, sometimes in granite

Brunswick, all its varieties occur, sometimes in granite and gneiss, but more frequently in limestone."—

Cleaveland's Mineralogy. A.]

ACTION. (Actio, nis. f.; from ago, to act.) 1.

The operation or exertion of an active power.

2. Any faculty, power, or function. The actions or functions of the body are usually divided by physiologists into vital, natural, or animal. 1. The vital functions, or actions, are those which are absolutely necessary to life, and without which animals cannot exist; as the action of the heart, lungs, and arteries.

2. The natural functions are those which are instrumental in repairing the several losses which the body sustains: digestion, and the formation of chyle, &c. fall under this head. 3. The animal actions are those which we perform at will, as muscular motion, and all the voluntary motions of the body.

Independently of these properties, each part may be said to have an action peculiar to itself—for instance, the liver, by virtue of a power which is peculiar to it, forms continually a liquid which is called bile: the same thing takes place in the kidneys with regard to the urine. The voluntary muscles, in certain states be

same thing takes place in the kidneys with regard to the same thing takes place in the kidneys with regard to the urine. The voluntary muscles, in certain states, become hard, change their form, and contract. These are, however, referrible to vitality. It is upon these the attention of the physiologist ought to be particularly fixed. Vital action depends evidently upon nutrition, and reciprocally, nutrition is influenced by vital action.—Thus, an organ that ceases to nourish, loses at the same time its faculty of acting; consequently the organs, the action of which is oftenest requently the organs, the action of which is oftenest re-peated, possess a more active nutrition; and, on the contrary, those that act least, possess a much slower nutritive motion.

The mechanism of vital action is unknown. There passes into the organ that acts an insensible molecular

applied to the spirits, conveying the inclinations of the mind to the body.

ACTINOLITE. The name of a mineral which is found in primitive districts.

["This mineral possesses all the essential characters of hornblende. In fact, common hornblende and activation, which is as little susceptible of description as the nutritive motion. Every vital action, however simple, is the same in this respect.

ACTUAL. This word is applied to any thing endued with a property or virtue which acts by an immediate power inherent in it; it is the reverse of potential; thus, a red-hot iron or fire is called an actual

cautery, in contradistinction from caustics, which are into the right ventricle of the heart, in cases of called potential cauteries. Boiling water is actually asphyxia, must create that sensation.—See Cooper's

cautery, in contradistinction from caustics, which are called potential cauteries. Boiling water is actually hot; brandy, producing heat in the body, is potentially hot, though of itself cold

Actual cautery. The red-hot iron, or any red-hot substance. See Actual.

ACTUA'RIUS. This word was originally a title of dignity given to physicians at the court of Constantinople; but became afterward the proper name of a celebrated Greek physician, John, (the son of Zachary, a Christian writer,) who flourished there about the 12th or 13th century. He is said to be the first Greek author who has treated of mild cathartics, as manna, cassia, &c., though they were long before in use among author who has treated of mild cathartics, as manna, cassia, &c., though they were long before in use among the Arabians. He appears also to have first noticed distilled waters. His works, however, are chiefly compiled from his predecessors.

ACTUATION. (From ago, to act.) That change wrought on a medicine, or any thing taken into the body, by the vital heat, which is necessary, in order to make it act and have its effect.

ACTUATES. Actingony

ACUITAS. Acrimony.
Acuito. (From acuo, to sharpen.) The sharpening an acid medicine by an addition of something more acid; or, in general, the increasing the force of

more acid; or, in general, the increasing the force of any medicine, by an addition of something that hath the same sort of operation in a greater degree.

ACULEA'TUS. (From aculcus, a prickle.) Prickly; covered with sharp-pointed bodies: applied to stems covered with sharp-pointed bodies, the prickles of which separate with the epidermis, as in Rosa centifolia.

ACU'LEUS. (From acus, a needle; from akn, or aki; cuspis, a point.) A prickle or sharp point. A species of armature with which the stems, branches, and other parts of several plants are furnished; as in the rose, raspberry, gooseberry. The part on which it grows is said to be aculeated, thus:—

Caulis aculeatus; as in the Rosa canina.

Caulis aculeatus ; as in the Rosa canina. Folia aculeata; as in Solanum marginatum.
Calix aculeatus; as in Solanum aculeatum.
Stipula aculeata; as in Rosa cinnamomia.
Legumen aculeatum; as in Scorpiurus muricata.
From the direction it has:—

Aculeus rectus, not curved; as in Rhamnus spina christi, and Rosa eglanteria.

Aculeus incurvus, curved inward; as in Mimosa

Aculeus recurvus, curved downward; as in Rubus fruticosus, and Rosa rubiginosa.

From the number in one place :-Aculeus solitarius ; as in Rosa canina.

Aculeus bifidus, or geminatus, in pairs; there being two joined at the basis; as in Rhamnus spina christi. Aculeus trifidus, three in one; as in Barbaris vul-

A'culon. (From a, neg. and κυλοω, to roll round;) so called because its fruit is not involved in a cup, or sheath, like others.

sheath, like others.

Aculos. The fruit or acorn of the ilex.

A'culos. See Aculon.

ACU'MEN. 1. A point.

2. The extremity of a bone.

ACUMINATUS. (From acuo, to point.) Acuminate; or terminated by a point somewhat elongated. Applied by botanists to several parts of plants. An acuminate leaf is seen in the Syringa vulgaris. Acuminate leaf-stalk; as that of Sazifraga stellaris.

ACUPUNCTU'RA. (From acus, a needle, and punctura, a prick.) Acupuncture. A bleeding performed by making many small punctures.

[The operation of making small punctures in certain parts of the body with a needle, for the purpose of

relieving diseases, is practised in Siam, Japan, and other oriental countries, for the cure of headaches, lethargies, convulsions, colics, &c. The practice of acupuncture is not followed in England nor America. In a modern French work it has been highly commended; but, the author sets so rash an example, and is so wild in his expectations of what may be done by the thrust of a needle, that the tenor of his observations will not meet with many approvers. For instance, in one case he ventured to pierce the engastric region. in one case, he ventured to pierce the epigastric region so deeply, that the coats of the stomach were supposed to have been perforated: this was done for the cure of an obstinate cough, and is alleged to have effected a cure. But if this be not enough to excite wonder,

Surg. Dict. A.]
A cunos. (From a, neg. and κυρω, to happen.) A name of the Alisma, because it produces no effect if

ACUSPASTO'RIS.

A name of the Scandiz an-

thriscus, the shepherd's needle, or Venus's comb.

ACUTANGULARIS. Acutangulatus. Acutangular: applied to parts of plants, as caulis acutan-

ACUTE'. Sharply. Applied in natural history to express form; as folium acut dentatum; acuté emarginatus, which means sharply dentate, and with sharp divisions.

ACUTENA'CULUM. (From acus, a needle, and tenaculum, a handle.) The handle for a needle, to Heister calls the portaiguille by this name.

ACUTUS. Sharp. 1. Used by naturalists to designate form; thus acute-leaved; as in rumez acutus,

2. In pathology, it is applied to a sharp pungent pain; and to a disease which is attended with violent symptoms, terminates in a few days, and is attended with danger. It is opposed to a chronic disease, which is slow in its progress, and not so generally

dangerous.
ACY ISIS. (From a, neg. and κυω, to conceive.)

A defect of conception, or barrenness in women.

A 'cyrus. (From a, priv. and **vpos*, authority; so named from its little note in medicine.) The German leopard's-bane. See Arnica montana.

leopard's-bane. See Arnica montana.

ADÆMO'NIA. (From a, priv. and δαιμων, a genius of fortune.) See Ademonia.

Adam's Apple. See Pomum Adami.

ADAM'S NEEDLE. The roots of this plant, Fucca gloriosa of Linnæus, are thick and tuberous, and are used by the Indians instead of bread; being first reduced into a coarse meal. This, however, is only in times of scarcity.

ADAMANTINE SPAR. A stone remarkable for its extreme hardness, which comes from the peninsula of Hither India, and also from China.

[Its colour is dark brown, and its internal lustre usually very strong. It comes from China, and almost always contains grains of magnetic oxide of iron, A specimen was found by chemists to contain,

Oxide of iron

The corundum appears to belong to primitive rocks, and particularly to granite, into the composition of which it sometimes enters; hence scales of mica and particles of feldspar sometimes adhere to its surface. In the United States, it is by some supposed to exist in Maryland, near Baltimore; and in Connecticut, at Haddam, in the same granite, which contains chryso-bears!

haddam, in the same grantte, which contains chrysoberyl, &c. It may be employed, like emery, in polishing hard substances.—Cleav. Min. A.]

A'DAMAS. (From a neg. and δαμαω, to conquer; as not being easily broken.) The adamant or diamond, the most precious of all stones, and which was formerly supposed to possess extraordinary cordial virtues.

ADAMITA, or Adamitum. A hard stone in the bladder.

bladder.

[ADAMS, DR. SAMUEL, was the only son of Samuel Adams, late governor of Massachusetts. He was born at Boston, in October, 1751. His preparatory education was at a Latin school in his native town. He entered Harvard University at the age of fourteen years, and was graduated in 1770. His professional education was acquired under the direction of Dr. Joseph Warren, and he practised in Boston. When hostilities commenced with Great Britain, in 1775, Dr. Adams, imbued with the patriotic spirit of his father, engaged as surgeon in the hospital department of the United States' army. Commencing his public services at Cambridge, by attending the soldiers who were wounded at Lexington and Bunker's Hill, he afterward proposed to Dasbury and surgeonical. he afterward removed to Danbury, and successively to various stations in several of the states, and continued in the service during the revolutionary war; after which he returned to his native town with a I am sure the author's suggestion to run a long needle | broken constitution, and unable to recommence his

ADE ADD

and a generous heart; and his greatest pleasure was to do good to his fellow-men.—Thacher's Med. Biography. A.] ADANSO NIA.

(From Adanson who first de-ADANSO NIA. (From Idanson who first described the Ethiopian sour gourd, a species of this genus.) The name of a genus of plants. Class, Polyandria; Order, Monadelphia. Monkeys' bread.

Adansonia digitata. This is the only species of the genus yet discovered. It is called the Ethiopian sour gourd and monkeys' bread. Babbab. Bahbabab.

It grows mostly on the west coast of Africa, from the Niger to the kingdom of Benin. The bark is called lalo: the negroes dry it in the shade; then powder and keep it in little cotton bags; and put two or three pinches into their food. It is mucilaginous, and generally promotes perspiration. The mucilage obtained from this bark is a powerful remedy against the epidemic fevers of the country that produces these trees; so is a decoction of the dried leaves. The fresh fruit

is as useful as the leaves, for the same purposes.

ADA'RCES. (From a, neg. and $\delta \varepsilon \rho \kappa \omega$, to see.) A saltish concretion found about the reeds and grass in marshy grounds in Galatia, and so called because it hides them. It is used to clear the skin with, in leprosies, tetters, &c. Dr. Plott gives an account of this production in his Natural History of Oxfordskire. It was formerly in repute for cleansing the skin from

freckles.

freckles.

Adarticulation. See Arthrodia.

ADDEPHA'GIA. (From αδην, abundantly, and φαγω, to eat.) Insatiability. A voracious appetite. See Bulimia.

ADDER. See Coluber berus.

ADDITAME'NTUM. (From addo, to add.) An addition to any part, which, though not always, is sometimes found. A term formerly employed as synonymous with epiphysis, but now only applied to two portions of sutures of the skull. See Lambdoidal and Squamous Sutures. and Squamous Sutures.

ADDITAMENTUM COLI. See Appendicula caci ver-

ADDUCENS. (From ad, and duco, to draw.) The name of some parts which draw those together to which they are connected.

ADDUCENS OCULI. See Rectus internus oculi.

ADDUCTOR. (From ad, and duco, to draw.) A drawer or contractor. A name given to several muscles, the office of which is to bring forwards or draw together those parts of the body to which they are annexed.

ADDUCTOR BREVIS FEMORIS. A muscle of the thigh, which, with the adductor longus and magnus femoris, forms the triceps adductor longus and magnus femoris, forms the triceps adductor femoris. Adductor femoris secundus of Douglas; Triceps secundus of Winslow. It is situated on the posterior part of the thigh, arising tendinous from the os pubis, near its joining with the opposite os pubis below, and behind the adductor longus femoris, and is inserted tendinous and fleshy, into the inner and upper part of the linea agrees, from a little below the trochanter minor to aspera, from a little below the trochanter minor, to the beginning of the insertion of the adductor longus femoris. See Triceps adductor fembris.
ALDUCTOR FEMORIS PRIMUS. See Adductor longus

ADDUCTOR FEMORIS SECUNDUS. See Adductor brevis femoris.

ADDUCTOR FEMORIS TERTIUS. See Adductor magnus femoris.

ADDUCTOR FEMORIS QUARTUS. See Adductor magnus femoris.

An external interrosse ADDUCTOR INDICIS PEDIS. ous muscle of the fore-toe, which arises tendinous and fleshy by two origins, from the root of the inside of the metatarsal bone of the fore-toe, from the outside of the root of the metatarsal bone of the great toe, and from the os cunciforme internum. It is inserted, ten-dinous, into the inside of the root of the first joint of the fore-toe. Its use is to pull the fore-toe inwards from the rest of the small toes.

A muscle situated ADDUCTOR LONGUS FEMORIS. on the posterior part of the thigh, which, with the adductor brevis, and magnus femoris, forms the triceps adductor femoris. Adductor femoris primus of Douglas. Triceps minus of Winslow. It arises by a pretty strong roundish tendon, from the upper and alchymist. Such are called so as pretend to some

professional pursuits: he died on the 17th of January, 1788. He possessed a substantial mind, social feelings, and a generous heart; and his greatest pleasure was to do greed to his fellow man. The state of the professional pursuits: he died on the 17th of January, interior part of the os pubis, and ligament of its syn chondrosis, on the inner side of the pectineus, and is inserted along the middle part of the linea asperator described by the possessional pursuits: he died on the 17th of January, interior part of the os pubis, and ligament of its syn chondrosis, on the inner side of the pectineus, and is

See Triceps adductor femoris.
Adductor magnus femoris. ADDUCTOR MAGNUS FEMORIS. A muscle which, with the adductor brevis femoris, and the adductor longus femoris, forms the Triceps adductor femoris; Adductor femoris tertius et quartus of Douglas. Triceps magnus of Winslow. It arises from the symphysis publs, and all along the flat edge of the thyroid foramen, from whence it goes to be inserted into the linea aspera throughout its whole length. See Triceps adductor femoris. ceps adductor femoris.

ADDUCTOR MINIMI DIGITI PEDIS. An internal inter-rosseous muscle of the foot. It arises, tendinous and fleshy, from the inside of the root of the metatarsal bone of the little toe. It is inserted, tendinous, into the inside of the root of the first joint of the little toe.

Its use is to pull the little toe inwards.

ADDUCTOR OCULL See Rectus internus oculi.
ADDUCTOR POLLICIS. See Adductor pollicis manûs. ADDUCTOR POLLICIS MANUS. A muscle of the thumb, situated on the hand. Adductor pollicis; Adductor ad minimum digitum. It arises, fleshy, from almost the whole length of the metacarpal bone that sustains the middle finger; from thence its fibres are collected together. It is inserted, tendinous, into the inner part of the root of the first bone of the thumb. Its use is to pull the thumb towards the fingers.

ADDUCTOR POLLICIS PEDIS. A muscle of the great toe, situated on the foot. Antithenar of Winslow. It arises, by a long, thin tendon, from the os calcis, from the os cuboides, from the os cuneiforme externum, and from the root of the metatarsal bone of the second toe. It is inserted into the external os sesamoideum, and root of the metatarsal bone of the great toe. Its use is

to bring this toe nearer to the rest.

ADDUCTOR PROSTATE. A name given by Sanctorini to a muscle, which he also calls Levator prostate, and which Winslow calls Prostaticus superior. Albinus, from its office, had very properly called it

Compressor prostatæ.

ADDUCTOR TERTII DIGITI PEDIS. An external interesseous muscle of the foot, that arises, tendinous and fleshy, from the roots of the metatarsal bones of the third and little toe. It is inserted, tendinous, into the outside of the root of the first joint of the third toe lits use is to pull the third toe outward.

ADE LPHIA. ('Αδελφεα, a relation.) Hippocrates calls diseases by this name that resemble each other.

ADEMO NIA. (From a, priv. and δαιμων, a genius, or divinity, or fortune.) Adamonia. Hippocrates uses this word for uneasiness, restlessness, or anxiety felt in acute diseases, and some hysteric fits.

A'DEN. (Aden, enis, m.; αδην, a gland.)

1. A gland. See Gland.

2. A bubo. See Bubo.

Adender and destroy the glands.

ADENIFORMIS. (From aden, a gland, and forma, resemblance.) Adeniform.

1. Glandiform, or resemblance. bling a gland.

A term sometimes applied to the prostate gland.
 ADENO GRAPHY. (Adenographia; from αόην, a gland, and γραφω, to write.) A treatise on the

glands.

ADENOI DES. (From αδην, a gland, and αιδος, resemblance.) Glandiform: resembling a gland. An epithet applied also to the prostate gland.

ADENOI LOGY. (Adenologia; from αδην, a gland, and λονος, a treatise.) The doctrine of the glands.

ADENOUS. (Adenosus, from αδην, a gland.)

ADEPHA'GIA. (From aδην, abundantly, and φαγω, to eat.) Insatiable appetite. See Bulimia.
A'DEPS. (Adeps, ipis, m. and f.) Fat. An oily secretion from the blood into the cells of the cellular membrane. See Fat.

ADEPS ANSERTNUS. Goose-grease.

Prepared lard. Cut the lard ADEPS PRÆPARATA. into small pieces, melt it over a slow fire, and press it through a linen cloth.

ADEPS SUILLA. Hog's lard. This forms the basis

extraordinary skill in chemistry; but these have too | wards of three centuries. It could not be foreseen often proved enner enthusiasts or impostors.

2. The professors of the Adepta Philosophia, that philosophy the end of which is the transmutation of metals, and a universal remedy, were also called

3. So Paracelsus calls that which treats of the diseases that are contracted by celestial operations, or communicated from heaven.

ADFLATUS. A blast; a kind of erysipelas, or St. Anthony's fire.

ADHÆSION. (Adhesio; from adhæro, to stick ADHÆSION. (Adhesio; from adhæro, to stick.) The growing together of parts.

ADHÆSIVE. (Adhæsivus; from adhæro, to stick

to.) Having the property of sticking.

ADHESIVE INFLAMMATION. That species of inflam mation which terminates by an adhesion of the inflamed surfaces.

Adhæsive plaster. A plaster made of common litharge plaster and resin, is so called because it is used for its adhesive properties. See *Emplastrum resinæ*.

Adhato'da. (A Zeylanic term, signifying expelling a dead festus.) See *Justicia adhatoda*.

Adiachy'tos. (From a, neg. and διαχύω, to diffuse, scatter, or be profuse.) Decent in point of dress. Hippocrates thinks the dress of a fop derogatory from the

pocrates thinks the dress of a fop derogatory from the

physician, though thereby he hide his ignorance, and obtain the good opinion of his patients.

ADIA'NTHUM. (Adiantum, i. n. αδιαν/γον; from α, neg. and διαινω, to grow wet: so called, because its leaves are not easily made wet.) The name of a genus of plants in the Linngan system. Class Centergy. of plants in the Linnæan system Class, Cryptoga-mia; Order, Filices. Maiden-hair.

ADIANTHUM AUREUM The golden maiden-hair.

See Polytrichum.

ADIANTHUM CAPILLUS VENERIS. Maiden-hair. The leaves of this plant are somewhat sweet and austere to the palate, and possess mucilaginous qualities. A syrup, the syrop de capillaire is prepared from them, which is much esteemed in France against catarrhs. Orange-flower water, and a proportion of honey, it is said, are usually added. It acts chiefly as a demulcent, sheathing the inflamed sides of the glottis.

ADIANTHUM PEDATUM. Adianthum canadense. This plant is in common use in France for the same purposes as the common adianthum capillus veneris in

this country, and appears to be far superior to it.

ADIAPHOROUS. Adiaphorus. A term which implies the same with neutral; and is particularly used of some spirits and salts, which are neither of an

used of some spirits and saits, which are neither of an acid nor alcaline nature.

ADIAPNEU'STIA. (From the privative particle a, and διαπνεω, perspiro.) A diminution or obstruction of natural perspiration, and that in which the ancients chiefly placed the cause of fevers.

ADIARRHŒ'A. (From a, priv. and διαββεω, to flow out or through.) A suppression of the necessary evacuations from the bowels.

ADIPOCURE. (Adiances a. f. from adeas for

ADIPOCURE. (Adipocera, &. f.; from adeps, fat, and cera, wax.) A particular spermaceti or fat-like substance formed by the spontaneous conversion of animal matter, under certain conditions. This conversion has long been well known, and is said to have been mentioned in the works of Lord Bacon. "On the occasion of the removal of a very great number of human bodies from the ancient burying-place des Innocens at Paris, facts of this nature were observed in the most striking manner. Fourcroy may be called the scientific discoverer of this peculiar matter, as well as the saponaceous ammoniacal substance contained in bodies abandoned to spontaneous destruction in large masses. This chemist read a memoir on the subject in the year 1789 to the Royal Academy of Sciences, from which the general contents are here abstracted.

"At the time of clearing the before-mentioned burying-place, certain philosophers were specially charged to direct the precautions requisite for securing the health of the workmen. A new and singular object of research presented itself, which had been necessity the securing the health of the workmen. sarily unknown to preceding chemists. It was impossarily unknown to preceding chemists. It was impossible to foretell what might be the contents of a soil overloaded for successive ages with bodies resigned to the putrefactive process. This spot differed from common burying grounds, where each individual object is surrounded by a portion of the soil. It was the burying-ground of a large district, wherein successive generations of the inhabitants had been deposited for upthat the entire decomposition might be retarded for more than forty years; neither was there any reason to suspect that any remarkable difference would arise from the singularity of situation.

"The remains of the human bodies immersed in this "The remains of the human bodies immersed in this mass of putrescence, were found in three different states, according to the time they had been buried, the place they occupied, and their relative situations with regard to each other. The most ancient were simply portions of bones, irregularly dispersed in the soil, which had been frequently disturbed. A second state, in certain bodies which had always been insulated, exhibited the skin, the muscles, the tendons, and apoexhibited the skin, the muscles, the tendons, and apo-neurosis, dry, brittle, hard, more or less gray, and similar to what are called mummies in certain caverns where this change has been observed, as in the catacombs at Rome, and the vault of the Cordeliers at Toulouse.

"The third and most singular state of these soft parts was observed in the bodies which filled the common graves or repositories. By this appellation are understood cavities of thirty feet in depth, and twenty on each side, which were dug in the burying-ground of the Innocents, and were appropriated to contain the bodies of the poor; which were placed in very close rows, each in its proper wooden bier. The necessity for disposing a great number, obliged the men charged with this employment to arrange them so near each other that these cavities might be considered when filled, as an entire mass of human bodies separated only by two planks of about half an inch thick. Each cavity contained between one thousand and fifteen hundred. When one common grave of this magnitude was filled a covering of about one foot deep of earth was laid upon it, and another excavation of the same sort was made at some distance. Each grave remained open about three years, which was the time required to fill it. According to the urgency of circumstances, the graves were again made on the same spot after an interval of time, not less than fifteen years, nor more than thirty. Experience had taught the workmen, that this time was not sufficient for the entire destruction of the bodies, and had shown them the progressive changes which form the object of Fourcroy's me-

"The first of these large graves, opened in the pre-sence of this chemist, had been closed for fifteen years. The coffins were in good preservation, but a little set-tled, and the wood had a yeilow tinge. When the covers of several were taken off, the bodies were ob-served at the bottom, leaving a considerable distance between their surface and the cover, and flattened as if they had suffered a strong compression. The linen which had covered them was slightly adherent to the bodies; and with the form of the different regions exhibited on removing the linen, nothing but irregular masses of a soft ductile matter of a gray-white colour. These masses environed the bones on all sides, which had no solidity, but broke by any sudden pressure. The appearance of this matter, its obvious composition, and its softness, resembled common white cheese; and the resemblance was more striking from the print which the threads of the linen had made upon its surface. This white substance yielded to the touch, and became soft when rubbed for a time between the

"No very offensive smell was emitted from these bodies. The novelty and singularity of the spectacle, and the example of the grave-diggers, dispelled every idea either of disgust or apprehension. These men idea either of disgust or apprehension. These men asserted that they never found this matter, by them called gras (fat,) in bodies interred alone; but that the accumulated bodies of the common graves only were subject to this change. On a very attentive ex-amination of a number of bodies passed to this state, Fourcroy remarked, that the conversion appeared in Fourcroy remarked, that the conversion appeared in different stages of advancement, so that, in various bodies, the fibrous texture and colour, more or less red, were discernible within the fatty matter; that the masses covering the bones were entirely of the same nature, offering indistinctly in all the regions a gray substance, for the most part soft and ductile, sometimes dry, always easy to be separated in porous fragments, penetrated with cavities, and no longer exhibiting any traces of membranes, muscles, tendons, vossels, or nerves. On the first inspection of these

ADI ADI

white masses, it might have been concluded that they were simply the cellular tissue, the compartments and vesicles of which they very well represented.

"By examining this substance in the different re-

gions of the body, it was found that the skin is particu-larly disposed to this remarkable alteration. It was afterward perceived that the ligaments and tendons afterward perceived that the ligaments and fendons no longer existed, or at least had lost their tenacity; so that the bones were entirely unsupported, and left to the action of their own weight. Whence their relative places were preserved in a certain degree by mere juxtaposition; the least effort being sufficient to separate them. The grave-diggers availed the miselves of this circumstance in the second of the miselves of this circumstance in the removal of the bodies. For they rolled them up from head to feet, and by that means separated from each other the extremities of the bones, which had formerly been articulated. In all those bodies which were changed into the fatty matter, the abdominal cavity had disappeared. The teguments and muscles of this region being converted into the white matter, like the other soft parts, had subsided upon the vertebral column, and were so flattened as to leave no place for the viscera; and accordingly there was scarcely ever any trace observed in the almost obliterated cavity. This observation was for a long time matter of astonishment to the incestigators. In vain did they seek in the greater numvestigators. In vain did they seek in the greater number of bodies, the place and substance of the stomach, the intestines, the bladder, and even the liver, the spleen, the kidneys, and the matrix in females. All these viscera were confounded together, and for the most part no traces of them were left. Sometimes only certain irregular masses were found, of the same nature as the white matter, of different bulks, from that of a nut to two or three inches in diameter, in the

that of a nut to two or three inches in diameter, in the regions of the liver or of the spleen.

"The thorax likewise offered an assemblage of facts no less singular and interesting. The external part of this cavity was flattened and compressed like the rest of the organs; the ribs, spontaneously luxated in their articulations with the vertebræ, were settled upon the dorsal column; their arched part left only a small space on each side between them and the vertebræ. The pleura, the mediastinum, the large vessels, the aspera arteria, and even the lungs and the heart. tebræ. The pleura, the mediastinum, the large vessels, the aspera arteria, and even the lungs and the heart, were no longer distinguishable; but for the most part had entirely disappeared, and in their place nothing was seen but some parcels of the fatty substance. In this case, the matter which was the product of decomposition of the viscera charged with blood and various humours, differs from that of the surface of the body, and the long bones, in the red or brown colour possessed by the former. Sometimes the observers found in the thorax a mass irregularly rounded, of the same nature as the latter, which appeared to them to have arisen from the fat and fibrous substance of the heart. They supposed that this mass, not constantly found in They supposed that this mass, not constantly found in all the subjects, owed its existence to a superabundance of fat in this viscus, where it was found. For the general observation presented itself, that, in similar circumstances, the fat parts undergo this conversion more evidently than the others, and afford a larger quantity of the white matter.

"The external region in females exhibited the six

quantity of the white matter.

"The external region in females exhibited the glandular and adipose mass of the breast converted into the fatty matter, very white and very homogeneous.

"The head was, as has already been remarked, environed with the fatty matter; the face was no longer distinguishable in the greatest number of subjects; the mouth, disorganized, exhibited neither tongue nor palate; and the jaws, luxated and more or less displaced, were environed with irregular layers of the white matter. Some pieces of the same matter usually occupied the place of the parts situated in the mouth; the cartilages of the nose participated in the general alteration of the skin; the orbits, instead of eyes, contained white masses; the ears were equally disorganized; and the hairy scalp, having undergone a similar alteration to that of the other organs, still retained the hair. Fourcroy remarks incidentally, that the hair appears to resist every alteration much longer than any other part of the body. The cranium constantly contained the brain contracted in bulk; blackish at the surface, and absolutely changed like the other organs. In a great number of subjects which were examined, this viscus was never found wanting, and it was always in the above-mentioned state; which proves

that the substance of the brain is greatly disposed to be converted into the fat matter.

"Such was the state of the bodies found in the burial-ground des Innocens. Its modifications were also various. Its consistence in bodies lately changed, that is to say, from three to five years, was soft and very ductile, containing a great quantity of water. In other subjects converted into this matter for a long time, such as those which occupied the cavities which had been closed thirty at forty years this matter is drier, prove as those which occupied the cavities which had been closed thirty or forty years, this matter is drier, more brittle, and in denser flakes. In several, which were deposited in dry earth, various portions of the fatty matter had become semitransparent. The aspect, the granulated texture, and brittleness of this dried matter, bore a considerable resemblance to wax.

"The period of the formation of this substance had likewise an influence on its properties. In general, all

likewise an influence on its properties. In general, all that which had been formed for a long time was white, that which had been formed for a long time was white, uniform, and contained no foreign substance, or fibrous remains; such, in particular, was that afforded by the skin of the extremities. On the contrary, in bodies recently changed, the fatty matter was neither so uniform nor so pure as in the former; but it was still found to contain portions of muscles, tendons, and ligaments, the texture of which, though already altered and changed in its coiour, was still distinguishable. Accordingly, as the conversion was more or less advanced, these fibrous remains were more or less penetrated with the fatty matter, interposed as it were between the interstices of the fibres. This observation shows, that it is not merely the fat which is thus changed, as was natural enough to think at first sight. Other facts confirm this assertion. The skin, as has Other facts confirm this assertion. The skin, as has been remarked, becomes easily converted into very pure white matter, as does likewise the brain, neither of which has been considered by anatomists to be fat. It is true, nevertheless, that the unctuous parts, and bodies charged with fat, appear more easily and speedily to pass to the state under consideration. This was seen in the marrow, which occupied the cavities of the longer bones. And again, it is not to be supposed but that the greater part of these bodies had been emaciated by the illness which terminated their lives; notwithstanding which, they were all absolutely turned

into this fatty substance.

"An experiment made by Poulletier de la Salle, and Fourcroy likewi e, evinced that a conversion does not take place in the fat alone. Poulletier had suspended take place in the fat alone. Poulletter had suspended in his laboratory a small piece of the human liver, to observe what would arise to it by the contact of the air. It partly putrefied, without, however, emitting any very noisome smell. Larvæ of the dermestes and bruchus attacked and penetrated it in various directions; at last it became dry, and after more than ten years' suspension, it was converted into a white friable substance, resembling dried again, which might have substance resembling dried agaric, which might have been taken for an earthy substance. In this state it had no perceptible smell. Poulletier was desirous of knowing the state of this animal matter, and experiment soon convinced him and Fourcroy that it was far from being in the state of an earth. It melted by hear ment soon convinced him and Fourcroy that it was far from being in the state of an earth. It melted by heat, and exhaled in the form of vapour, which had the smell of a very fetid fat; spirit of wine separated a concrescible oil, which appeared to possess all the properties of spermaceti. Each of the three alcalies converted it into soap; and, in a word, it exhibited all the properties of the fatty matter of the burial-ground of the Innocents exposed for several months to the air. properties of the fatty matter of the burnal-ground of the Innocents exposed for several months to the air. Here then was a glandular organ, which in the midst of the atmosphere had undergone a change similar to that of the bodies in the burying-place; and this fact sufficiently shows, that an animal substance which is very far from being of the nature of grease, may be totally converted into this fatty substance. "Among the modifications of this remarkable sub-stance in the burying-ground before-mentioned, it was

stance in the burying-ground before-mentioned, it was observed that the dry, friable, and brittle matter, was most commonly found near the surface of the earth, and the soft, ductile matter at a greater depth. Four-croy remarks, that this dry matter did not differ from

the other merely in containing less water, but likewise by the volatilization of one of its principles."

The grave-diggers assert, that near three years are required to convert a body into this fatty substance. But Dr. Gibbes of Oxford found, that lean beef secured in a running stream, was converted into this fatty matter at the end of a month. He judges from facts, that run-

ning water is most favourable to this process. He took three lean pieces of mutton, and poured on each a quantity of the three common mineral acids. At the end of three days, each was much changed: that in the nitric acid was very soft, and converted into the fatty matter; that in the muriatic acid was not in that time so ter; that in the muriatic acid was not in that time so much altered; the sulphuric acid had turned the other black. Lavoisier thinks that this process may hereafter prove of great use in society. It is not easy to point out what animal substance, or what situation, might be the best adapted for an undertaking of this kind.

The result of Fourcroy's inquiries into the ordinary changes of bodies recently deposited in the earth, was not very extensive. The grave-diggers informed him, that those bodies interred do not perceptibly change colour for the first seven or eight days: that the putrid pro-

lour for the first seven or eight days; that the putrid pro-cess disengages elastic fluid, which inflates the abdomen, and at length bursts it; that this event instantly causes vertigo, faintness, and nausea in such persons as un-fortunately are within a certain distance of the scene where it takes place; but that when the object of its action is nearer, a sudden privation of sense, and fre-quently death, is the consequence. These men are taught by experience, that no immediate danger is to be feared from the disgusting business they are engaged in, excepting at this period, which they regard with the utinost terror. They resisted every inducement and persuasion which these philosophers made use of, to prevail on them to assist their researches into the nature of this active and pernicious vapour. Fourcroy takes occasion from these facts, as well as from the pallid and unwholesome appearance of the grave-diggers, to reprobate burials in great towns or their

Such bodies as are interred alone, in the midst of a great quantity of humid earth, are totally destroyed by passing through the successive degrees of the ordi-nary putrefaction; and this destruction is more speedy, the warmer the temperature. But if these insulated bodies be dry and emaciated; if the place of deposition be likewise dry, and the locality and other circumstances such, that the earth, so far from receiving moisture from the atmosphere, becomes still more effectually parched by the solar rays;—the animal juices are volatilized and absorbed, the solids contract and harden, and a peculiar species of mummy is produced. But every circumstance is very different in the com-mon burying-grounds. Heaped together almost in con-tact, the influence of external bodies affects them scarcely at all, and they become abandoned to a peculiar disorganization, which destroys their texture and produces the new and most permanent state of combination here described. From various observa-tions, it was found, that this fatty matter was capable of enduring in these burying-places for thirty or forty years, and is at length corroded and carried off by the

aqueous putrid humidity which there abounds.

Among other interesting facts afforded by the chemical examination of this substance are the following from experiments by Fourcroy.

1. This substance is fused at a less degree of heat than

that of boiling water, and may be purified by pressure through a cloth, which disengages a portion of fibrous and bony matter. 2. The process of destructive dis-tillation by a very graduated heat was begun, but not completed, on account of its tediousness, and the little promise of advantage it afforded. The products which came over were water charged with volatile alcali, a fat oil, concrete volatile alcali, and no elastic fluid during the time the operation was continued. 3. Fragments of the fatty matter exposed to the air during the hot and dry summer of 1786 became dry, brittle, and almost pulverulent at the surface. On a careful examination, certain portions were observed to be semitransparent, and more brittle than the rest. These possessed all the apparent properties of wax, and did not afford volatile alcali by distillation. 4. With water this fatty matter exhibited all the appearances of soap, and afforded a strong lather. The dried substance did not form the saponaceous combination with the same facility or perfection as that which was re-cent. About two-thirds of this dried matter separated from the water by cooling, and proved to be the semi-transparent substance resembling wax. This was taken from the surface of the soapy liquor, which being then passed through the filter, left a white soft shining matter, which was fusible and combustible.

5. Attempts were made to ascertain the quantity of volatile alcali in this substance, by the application of lime, and of the fixed alcalies, but without success: for it was difficult to collect and appreciate the first portions which escaped, and likewise to disengage the last portions. The caustic volatile alcali, with the assistance of a gentle heat, dissolved the fatty matter, and the solution became perfectly clear and transparent at the boiling temperature of the mixture, which was at 185° F. 6. Sulphuric acid, of the specific gravity of 2.0, was poured upon six times its weight of the fatty matter, and mixed by agitation. Heat was 5. Attempts were made to ascertain the quantity of of the fatty matter, and mixed by agitation. Heat was produced, and a gas or effluvium of the most insupportable putrescence was emitted, which infected the air of an extensive laboratory for several days. croy says, that the smell cannot be described, but that it is one of the most horrid and repulsive that can be imagined. It did not, however, produce any indispo-sition either in himself or his assistants. By dilution with water, and the ordinary processes of evaporation and cooling, properly repeated, the sulphates of am-monia and of lime were obtained. A substance was separated from the liquor, which appeared to be the waxy matter, somewhat altered by the action of the acid. 7. The nitrous and muriatic acids were also applied, and afforded phenomena worthy of remark, but which for the sake of conciseness are here omitted. 8. Alcohol does not act on this matter at the ordinary temperature of the air. But by boiling it dissolves one-third of its own weight, which is almost totally separable by cooling as low as 55°. The alcohol, after this process, affords by evaporation a portion of that waxy matter which is separable by acids, and is therefore the only portion soluble in cold alcohol. The quantity of fatty matter operated on was 4 ounces, or 2304 grains, of which the boiling spirit took up the whole except 26 grains, which proved to be a mixture of 20 grains of ammoniacal soap, and 6 or 8 grains of the phosphates of soda and of line. From this experiment, which was three times repeated with similar results, it appears that alcohol is well suited to afford an analysis of the fatty matter. It does not dissolve the neutral salts; when cold, it dissolves that portion of concrete animal oil from which the volatile alcali ordinary temperature of the air. But by boiling it of concrete animal oil from which the volatile alcali had flown off; and when heated, it dissolves the whole of the truly saponaceous matter, which is afterward completely separated by cooling. And accordingly it was found, that a thin plate of the fatty matter, which had lost nearly the whole of its volatile alcali, by exposure to the air for three years, was almost dissolved by the cold alcohol.

The concrete oily or waxy substance obtained in these experiments constitutes the leading object of research, as being the peculiar substance with which the other well-known matters are combined. It separates spontaneously by the action of the air, as well as by that of acids. These last separate it in a state of greater purity, the less disposed the acid may be to operate in the way of combustion. It is requisite there. greater purity, the less disposed the acid may be to operate in the way of combustion. It is requisite, therefore, for this purpose, that the fatty matter should be previously diffused in 12 times its weight of hot water; and the muriatic or acetous acid is preferable to the sulphuric or the nitrous. The colour of the waxy matter is grayish; and though exposure to the air, and also the action of the oxygenated muriatic acid did produce an apparent whiteness, it nevertheless disdid produce an apparent whiteness, it nevertheless dis-appeared by subsequent fusion. No method was dis-covered by which it could be permanently bleached. The nature of this wax or fat is different from that

of any other known substance of the like kind. When slowly cooled after fusion, its texture appears crystalline or shivery, like spermaceti; but a speedy cooling gives it a semitransparency resembling wax. Upon the whole, nevertheless, it seems to approach more nearly to the former than to the latter of these bodies. nearly to the former than to the latter of these bodies. It has less smell than spermaceti, and melts at 127° F.; Dr. Bostock says 92°. Spermaceti requires 6° more of heat to fuse it, (according to Dr. Bostock 20°.) The spermaceti did not so speedily become brittle by cooling as the adipocire. One ounce of alcohol of the strength between 39 and 40 segrees of Baume's aerometer, dissolved when boiling hot 12 gros of this substance, but the same quantity in like circumstances dissolved only 30 or 36 grains of spermaceti. The separation of these matters was also remarkably different, the spermaceti being more speedily deposited, and in a much more regular and crystalline form. Ammonia dissolves ADI ADN

crete oil separated from the fatty matter; and by heat it forms a transparent solution, which is a true soap. But no excess of ammonia can produce such an effect

with spermaceti.

Fourtroy concludes his memoir with some specu-lations on the change to which animal substances in peculiar circumstances are subject. In the modern chemistry, soft animal matters are considered as a composition of the oxydes of hydrogen and carbonated azote, more complicated than those of vegetable matters, and therefore more incessantly tending to alteration. If then the carbon be conceived to unite with the oxygen, either of the water which is present, or of the other animal matters, and thus escape in large quantities in the form of carbonic acid gas, we shall perceive the reason why this conversion is attended with so great a loss of weight, namely, about nine-tenths of the whole. The azote, a principle so abundant in animal matters, will form ammonia by combining with the hydrogen; part of this will escape in the vaporous form, and the rest will remain fixed in the fatty mat-ter. The residue of the animal matters deprived of a great part of their carbon, of their oxygen, and the whole of their azote, will consist of a much greater proportion of hydrogen, together with carbon and a minute quantity of oxygen. This, according to the theory of Fourcroy, constitutes the waxy matter, or adipocire, which, in combination with ammonia, forms the animal soap, into which the dead bodies are thus converted.

Muscular fibre, macerated in dilute nitric acid, and afterward well washed in warm water, affords pure adipocire, of a light yellow colour, nearly of the consistence of tallow, of a homogeneous texture, and of course free from ammonia. This is the mode in which it is now commonly procured for chemical experiment.

Ambergris appears to contain adipocire in large countries as the contain adipocire in large countries as the contain adipocire in large.

quantity, rather more than half of it being of this sub-

Adipocire has been more recently examined by Chevreul. He found it composed of a small quantity of ammonia, potassa, and lime, united to much margarine, and to a very little of another fatty matter different from that. Weak muriatic acid seizes the three alcaline bases. On treating the residue with a solution of a pearly substance, while the other fat remains dissolved. Fourcroy being of opinion that the fatty matter of animal carcasses, the substance of biliary calculi, and spermaceti, were nearly identical, gave them the same name of adipocire; but it appears from the researches of Chevreul that these substances are

very different from each other.

In the Philosophical Transactions for 1813, there is a the ramosophical Transactions for fells, there is a very interesting paper on the above subject by Sir E. Home and Mr. Brande. He adduces many curious facts to prove that adipocire is formed by an incipient and incomplete putrefaction. Mary Howard, aged 44, died on the 12th May, 1790, and was buried in a grave ten feet deep at the east end of Shoreditch churchyard, ten feet to the east of the great common sewer, which runs from north to south, and has always a current of water in it, the usual level of which is eight feet below water in it, the usual level of which is eight her below the level of the ground, and two feet above the level of the coffins in the graves. In August, 1811, the body was taken up, with some others buried near it, for the purpose of building a vault, and the flesh in all of them was converted into adipocire or spermaceti. At the full and new moon the tide raises water into the graves, which at other times are dry. To explain the extraordinary quantities of fat or adipocire formed by animals of a certain intestinal construction, Sir E. observes, that the current of water which passes through their colon, while the loculated lateral parts are full of solid matter, places the solid contents in somewhat similar circumstances to dead bodies in the banks of a common sewer.

The circumstance of ambergris, which contains 60 er cent. of fat, being found in immense quantities in the lower intestines of the spermaceti whales, and never higher up than seven feet from the anus, is an undeniable proof of fat being formed in the intestines; and ar ambergris is only met with in whales out of health it is most probably collected there from the ab-sorbents, under the influence of disease, not acting so as to take it into the constitution. In the human

with singular facility, and even in the cold, this con- | colon, solid masses of fat are sometimes met with in a diseased state of that canal. A description and analysis by Doctor Ure of a mass of ambergris, extracted in Perthshire from the rectum of a living woman, were published in a London Medical Journal in September, 1817. There is a case communicated by Dr. Babington, of fat formed in the intestines of a girl four and a half years old, and passing off by stool. Mr. Brande found, on the suggestion of Sir E. Home, that muscle digested on the suggestion of Sir E. Home, that muscle algested in bile, is convertible into fat, at the temperature of about 100°. If the substance, however, pass rapidly into putrefaction, no fat is formed. Fæces voided by a gouty gentleman after six days' constipation, yielded, on infusion in water, a fatty film. This process of forming fat in the lower intestines by means of bile, throws considerable light upon the possible and the same considerable light upon the same considerable light upon the same considerable and the sam throws considerable light upon the nourishment de rived from clysters, a fact well ascertained, but which could not be explained. It also accounts for the wasting of the body, which so invariably attends all complaints of the lower bowels. It accounts too for all the varieties in the turns of the colon, which we meet with in so great a degree in different animals. property of the bile explains likewise the formation of fatty concretions in the gall bladder so commonly met with, and which, from these experiments, appear to be produced by the action of the bile on the mucus secreted in the gall bladder; and it enables us to understand how want of the gall bladder in children, from mal-formation, is attended with excessive leanness, notwithstanding a great appetite, and leads to an early death. Fat thus appears to be formed in the intestines and from thence received into the circumintestines, and from thence received into the circulation, and deposited in almost every part of the body. And as there appears to be no direct channel by which any superabundance of it can be thrown out of the body, whenever its supply exceeds the consumption, its accumulation becomes a disease, and often a very

distressing one.
[In the New-York Medical Repository, vol. ii. p. 325, is related the case of a person who was drowned, and whose body was converted into this substance after lying in the mud of a river for a year. We have seen a piece of meat raised out of a well by pumping, into which it had fallen, and where it was completely changed into adipocire. A barrel of meat, which had undergone a change and become adipocire, was raised from the British frigate Hussar, sunk near Hell-Gate during the revolutionary war, where it had remained in eight or ten fathoms of salt water near fifty years. A single body of a female, consisting of a solid mass of adipocire, was dug up in dry ground, near the City Hall in New-York. A box of candles, taken from a sunken wreck on the coast of Brazil, was changed in appearance and consistence, and had become a mass of adipocire. The bones of a huge cetaceous animal were dug up in the low grounds about New-Orleans: when they were exhibited as a show in New-York, in 1828, adipocire was discovered in the cells of the

spongy part of the jaw-bone. A.]
ADI POSE. (Adiposus; from adeps, fat.) Fatty; as adipose membrane, &c.

ADIPOSE MEMBRANE. Membrana adiposa. fat collected in the cells of the cellular membrane.

fat collected in the cells of the cellular membrane.

ADIPSA. (From a, neg. and διψa, thirst.) 1. So the Greeks called medicines, &c. which abate thirst.

2. Hippocrates applied this word to oxymel.

ADIPSIA. (From a, neg. and διψa, thirst.) A want of thirst. A genus of disease in the class locales, and order dysorexiæ of Cullen's Nosology. It is mostly symptomatic of some disease of the brain.

ADIPSOS. So called because it allays thirst.) 1. The Egyptian palm-tree, the fruit of which is said to be the Myrobalans, which quench thirst.

2. Also a name for liquorice.

ADJUTO'RIUM. (From ad and juvo, to help.) A name of the humerus, from its usefulness in lifting up the fore-arm.

ADJUVA'NTIA. Whatever assists in preventing

or curing disease.

ADNATA TUNICA. Albuginea oculi; Tunica albuginea oculi. A membrane of the eye mostly confounded with the conjunctiva. It is, however, thus formed: five of the muscles which move the eye, take their origin from the bottom of the orbit, and the sixth arises from the edge of it; they are all inserted by a tendinous expansion, into the anterior part of the tunica selerotica, which expansion forms the adnata, and

gives the whiteness peculiar to the fore-part of the other on the same stem, as in valerian, teasel, honey-It lies between the sclerotica and conjunctiva.

ADNA'TUS. (From adnesser, to grow to.) A term applied to some parts which appear to grow to others: as tunica adnata, stipulæ adnatæ, folium

ADOLESCE'NTIA. See Age.

ADO'NION. (From Αδωνις, the youth from whose blood it was feigned to have sprung.) Adonium. See Artemisia abrotanum.

ADONIUM. See Adonion. ADO'PTER. Tubus intermedius. A chemical vessel with two necks, used to combine retorts to the cucurbits or matrasses in distillation, with retorts instead of receivers.

A'DOR. A sort of corn, called also spelta.
A'DOS. Forge water, or water in which red-hot

iron is extinguished.

AD PONDUS OMNIUM. The weight of the whole.

AD PONDUS OMNIUM. The weight of the whole. These words are inserted in pharmaceutical preparations, or prescriptions, when the last ingredient ought to weigh as much as all the others put together.

ADPRESSUS. Approximated. A term in botany, applied to branches of leaves when they rise in a direction nearly parallel to the stem, and are closely applied to them, as in the branches of the Genista tinctoria and leaves of the Thlaspi campestris.

ADRA RHYZA. Blancard says the root of the Aristolochia is thus named.

ADRA CHINE. The strawberry bay-tree. A species

ADRA'CHNE. The strawberry bay-tree. A species of Arbutus.

ADRARA'GI. An Indian name for our garden-saffron. ADROBO'LON. (From αόρος, large, and βωλος, a globe, bole, or mass.) Indian bdellium, which is coarser than the Arabian. See Bdellium.

ADSCENDENS. See Ascendens.

ADSTRICTION. Costiveness.

ADSTRINGENT. See Astringent.

[ADULARIA. This is the most perfect variety of feldspar, and bears to common feldspar, in many respects, the relation of rock crystal to common quartz. ADRARA'GI. An Indian name for our garden-saffron.

Adularia is more or less translucent, and sometimes transparent and limpid. Its colour is white, either a little milky, or with a tinge of green, yellow, or red. But it is chiefly distinguished by presenting, when in certain positions, whitish reflections, which are often slightly tinged with blue or green, and exhibit a pearly or silver lustre. These reflections, which are often confined to certain spots, proceed in most cases from the interior of the crystal.

Adularia is sometimes cut into plates and polished. The fish's eye, moonstone, and argentine, of lapidaries, come chiefly from Persia, Arabia, and Ceylon, and belong to adularia, as do also the water opal and girasole of the Italians.—Cleavi. Min.

It has been found in the states of Maryland, Popper

It has been found in the states of Maryland, Pennsylvania, New-York, and Massachusetts. A.]
ADUSTION. Adustio. 1. An inflammation about

the brain, and its membranes, with a hollowness of the eyes, a pale colour, and a dry body; obsolete.

2. In surgery, adustion signifies the same as cauter-2. In surgery, adustion signifies the same as cauterization, and means the application of any substance to the animal body, which acts like fire. The ancient surgeons, especially the Arabians, were remarkably fond of having recourse to adustion in local diseases; but the use of actual heat is very rarely admitted by the moderns.

ADVENTITIOUS. (Adventitius; from advenio, ADVENTITIOUS. (Abecutas, in a decidentally, and not in the common course of natural causes, happens to make a part of another. Something accruing or befalling a person or thing from without. It is used in medicine in opposition to hereditary; as when diseases may be transmitted from the parent and also acquired, as is the case with gout and scrofula. They are some-

times hereditary, and very often adventitious.

ADVERSIFO'LIA. (From adversus, opposite, and

folium, a leaf.) A plant with alternate leaves.

ADVERSIFO LIÆ PLANTÆ. 1. Plants the leaves of which stand opposite to each other on the same stem

2. The name of a class in Sauvages' Methodus Fo-orum. Valerian, teasel, honey-suckle, &c. are

ADVERSUS. Opposite. Applied in natural history to parts which stand opposite to each other; as plants adversifolia, the leaves standing opposite to each is sedative, and was formerly applied to mitigate pains 31 examples.

suckle, &c.

ADYNA'MIA. (Adynamia, &, f.; Aδυναμια, from a, priv. and δυναμις, power.) A defect of vital power. ADYNA'MIE. (The plural of Adynamia.) The second order of the class neuroses of Cullen's Nosology; *it comprehends syncope, dyspepsia, hypochondriasis, and chlorosis.

ADY NAMON. (From a, neg. and covants, strength.)
Adynamum. Among ancient physicians, it signified a
kind of weak factitious wine, prepared from must,
boiled down with water; to be given to patients to
whom pure or genuine wine might be hurtful.

ADYNAMUM. See Adynamom.

[ÆDELITE. A mineral described by Kirwan, containing, according to Bergman, silex from 62 to 69 parts, alumine from 18 to 20, lime from 8 to 16, water

arts, atumine from 18 to 20, time from 8 to 16, water 3 to 4.—Clear. Min. A.]

ÆDOľ A. (From αιδως, modesty; or from a, neg. and αιδαω, to see; as not being decent to the sight.)

The pudenda, or parts of generation.

ÆDOPSO PHIA. (From αιδοια, pudenda; and ψοφω, to break wind.) A term used by Sauvages and Sagar, to signify a flatus from the bladder, or from the womb, making its escape through the vagina.

from the womb, making its escape through the vagina.

ÆDOPTO'SIS. (Ædoptosis; from αιδοίον, the groin; pl. αιδοία, pudenda; and πςωσις, a falling down.) Genital prolapsi. The name of a genus of diseases in Good's Nosology.

ÆGAGRO'PILUS. (From αιγαγρος, a wild goat, and pila, a ball.) Ægagropila.

1. A ball found in the stomach of deer, goats, hogs, horned cattle, as cows, &c. It consists of hairs which they have swallowed from liking themselves. They was of different degrees of hardness, but have no medi-

are of different degrees of hardness, but have no medi-cinal virtues. Some rank these balls among the Bezoars. Hieronymus Velschius wrote a treatise on the virtues of this.

2. A species of conferva found in Wallenfenmoor, from its resembling these concretions, is also so named.

ÆGIAS. A white speck on the pupil of the eye, which occasions a dimness of sight.

AEGIDES. Aglia. A disorder of the eyes mentioned by Hippocrates. Foesius thinks the disease consists of small cicatrices in the eye, caused by an afflux of corrosive humours upon the part. But in one passage of Hippocrates, Foësius says it signifies small white concretions of humours which stick upon the pupil, and obscure the sight.

ÆGI DION. A collyrium or ointment for inflamma-

tions and defluxions of the eyes.

Æ'GILOPS. 1. The same as Ægylops.

2. Wild fescue grass, so called from its supposed virtue in curing the disorder named Ægylops. It is a

virtue in curing the disorder named Ægylops. It is a species of Bromus in the Linnaan system.

ÆGINETA, PAULUS. A celebrated surgeon of the island of Ægina, from which he derived his name. He is placed by Le Clerc in the fourth century; by others in the seventh. He was eminently skilled in his profession, and his works are frequently cited by Fabricius ab Aquapendente. He is the first author that notices the cathartic quality of rhubarb. He hegins his book with the description of the diseases of women; and is said to be the first that deserves the appellation and is said to be the first that deserves the appellation of a man midwife.

ÆGINE'TIA. Maiabrian broom rape. A species of

Orobancha.

ÆGIS. A film on the eye.
ÆGO'CERAS. (From αιξ, a goat, and κερας, a horn; so called, because the pods were supposed to resemble the horns of a goat.) Fœnugreek. See

Trigmella Fænumgræcum.
ÆGO'LETHRON. (From αιξ, a goat, and ολεθρος, destruction: so named from the opinion of its being poisonous to goats.) Tournefort says it is the Chapter of Linnaus.

poisonous to goats.) Tournefort says it is the Chamærododendron, now the Azelæa pontica of Linnæus.

ÆGO'NYCHON. (From ait, a goat, and orvit, a hoof: because of the hardness of the seed.) See Lithospermum officinale.

ÆGOPO'DIUM. (Ægopodium, i. n.; from ait, a goat, and wors, a foot: from its supposed resemblance to a goat's foot.) A genus of plants in the Linnæan system. Class, Pentandria; Order, Digynia. Goatweed. The following species was formerly much esteemed.

its earlier state it is tender and esculent.

Agorroso'ros. (From αιζ, a goat, and προσωπον, a face: so called because goats are subject to defects in the eyes, or from having in it some ingredients named after the goat.) A name of a lotion for the

named after the goat.) A name of a lotion for the eyes, when inflamed.

EGYLOPS. (**Egylops, opis, m.; from at, a goat, and \(\omega \psi, \) an eye.) **Anchilops.** A disease so named from the supposition that goats were very subject to it. The term means a sore just under the inner angle of the eye. The best modern surgeons seem to consider the agylops only as a stage of the fistula lachrymalis. Paulus **Egineta calls it anchilops, before it bursts, and agylops after. When the skin covering the lachrymal sac has been for some time inflamed, or the lachrymal sac has been for some time inflamed, or subject to frequent returning inflammations, it most commonly happens that the puncta lachrymalia are affected by it; and the fluid, not having an opportunity of passing off by them, distends the inflamed skin, so that at last it becomes sloughy, and bursts exter-nally. This is that state of the disease which is called

nally. This is that state of the disease which is called perfect aigylops, or agylops.

ÆGYPTIA MUSCATA. See Hibiscus abelmoschus.

ÆGYPTI ACUM. A name given to different unguents of the detergent or corrosive kind. We meet guents of the detergent or corrosive kind. We meet with a black, a red, a white, a simple, a compound, and a magistral ægyptiacum. The simple ægyptiacum, which is that usually found in our shops, is a composition of verdigris, vinegar, and honey, boiled to a consistence. It is usually supposed to take its name from its dark colour, wherein it resembles that of the natives of Egypt. It is improperly called an unguent, as there is no oil, or rather far in it.

ÆOY PTIUM PHARMACUM AD AURES. Actius speaks of this as excellent for deterging fortid ulcers of the ears, which he says it cures, though the patient were AEIPATHEI'A. (From act, always, and παθος, a disease.) Diseases of long duration.

ÆNEA. (From act, brass, so called because it was formerly made of brass.) A catheter.

ÆO'NION. The common house leek. See Sempervivum tectorum.

ÆO'RA. (From αιωρεω, to lift up, to suspend on high.) Exercise without muscular action; as swinging. A species of exercise used by the ancients, and of which Actius gives the following account. Gestation, while it exercises the body, the body seems to be at rest. Of this motion there are several kinds. First, swinging in a hammock, which, at the decline of a fever, is beneficial. Secondly, being carried in a litter, in which the patient either sits or lies along. It is useful when the gout, stone, or such other disorder attends, as does not admit of violent motions. Thirdly, attends, as does not admit of violent motions. Thirdly, riding in a chariot, which is of service in most chronical disorders; especially before the more violent exercises can be admitted. Fourthly, sailing in a ship or boat. This produces various effects, according to the different agitation of the waters, and, in many tedious chronical disorders, is efficacious beyond what is observed from the most skilful administration of drugs. These are instances of a passive exercise.

ÆQUA'LIS. Equal. Applied by botanists to distinguish length; as filimenta equalia; pedunculi equales, &c.

Æ'QUE. Equally. The same as ana.

#QUE. Equally. The same as ana.

#QUIVALVIS. #Quivalve. A botanical term, implying, composed of equal valves.

A'ER. (Aer, eris, m.; from ano.) The fluid which surrounds the globe. See Air and Atmosphere.

E'RA. Darnel, or lolium. Erated alkaline water. An alkaline water impreg-

nated with carbonic acid.

ARIAL. Belonging to air.

Erial Acid. See Carbonic acid.

Erial plants. Those plants are so called which, after a certain time, do not require that their roots should be fixed to any spot in order to maintain their life, which they do by absorption from the atmosphere. Such are a curious tropical tribe of plants called cacti, the epidendrum, flos aris, and the ficus australis.

ARITIS. The Anagallis, or pimpernell.

EROLITE. A meteoric stone.

AEROLOGICE. See Aerology.

AEROLOGY. (Aerologia, &, f.; from app, the air, and hoyos, a discourse.) Aerologice. That part

of gout, and to relieve piles, but not now employed. In | of medicine which treats of the nature and proper ties of air.

ARRO'MELL. Honey dew; also a name for manna.

ÆROMETER. An instrument for making the necessary corrections in pneumatic experiments to ascertain the mean bulk of the gases.

ÆROPHO'BIA. Fear of air or wind.

1. Said to be a symptom of phrenitis and hydro-

2. A name of Hydrophobia.

AERO PHOBUS. (From ano, air, and oobos, fear.)
According to Ceelius Aurelianus, some phrenetic patients are afraid of a lucid, and others of an obscure air; and these he calls aerophobi.

AERO SIS. The aerial vital spirit of the ancients.

EROSTATION. Erostatio. A name commonly, but not very correctly, given to the art of raising heavy bodies into the atmosphere, by buoyancy of heated air, or gases of small specific gravity, enclosed in a bag, which from being usually of a spherical form, is called a balloon.

ÆRO'SUS LAPIS. So Pliny calls the Lapis calaminaris, upon the supposition that it was a copper ore.

ÆRU'CA. Verdigris.

ÆRU'GO. (Ærugo, ginis, f., from æs, copper.)

ÆRU'GO. (Ærugo, ginis, f., from æs, copper.)
The rust of any metal, particularly of copper.

2. Verdigris. See Verdigris.
ÆRUGO ÆRIS. Rusts of copper or verdigris. See

ÆRUGO PREPARA'TA. See Verdigris.

Bras

ÆSCULA'PIUS, said to be the son of Apollo, by the nymph Coronis, born at Epidaurus, and educated by Chiron, who taught him to cure the most dangerous by Chiron, who taught him to cure the most dangerous diseases, and even raise the dead; worshipped by the ancients as the god of medicine. His history is so involved in fable, that it is useless to trace it minutely. His two sons, Machaon and Podalirius, who ruled over a small city in Thessaly, after his death accompanied the Greeks to the siege of Troy: but Homer speaks merely of their skill in the treatment of wounds; and diving honours were not paid to their father till a and divine honours were not paid to their father till a latter period. In the temples raised to him, votive tablets were hung up, on which were recorded the dis-

eases cured, as they imagined, by his assistance.

ESCULUS. (**Assculus**, t. m.; from *esca**, food.)

The name of a genus of plants in the Linnæan system

Class, **Heptandria*; Order, **Monogynia**. Horse-

Esculus hippocastanum. The systematic name for the common horse-chesnut tree. Castanea equina, pavina. Æsculus—foliolis septenis of Linnæus. The fruit of this tree, when dried and powdered, is recommended as an errhine. The bark is highly esteemed on the continent as a febrifuge; and is, by some, considered as being superior in quality to the Peruvian bark. The bark intended for medical use is to be taken from those branches which are neither very young nor very old, and to be exhibited under similar forms and doses, as directed with respect to the Peruvian bark. It rarely disagrees with the stomach; but its astringent effects generally require the occasional administration of a laxative. During the late scarcity of grain, some attempts were made to obtain starch from the horse-chesnut, and not without success.

ÆSTHE TICA. (From αισθάνομαι, to feel, or perceive.) Diseases affecting the sensation. The name of an order of diseases in Good's Nosology. See Nosology. ÆSCULUS HIPPOCASTANUM. The systematic name

ÆSTIV'ALIS. (From æstas, summer.) Æstival; belonging to summer. Diseases of animals and plants which appear in the summer.

ÆSTIVALES PLANTE. Plants which flower in summer. A division according to the seasons of the year.
ÆSTIVATIO. Æstivation; the action of the summer, or its influence on things.

ÆSTPHARA. Incineration, or burning of the flesh,

AESTHARA. Incineration, or burning of the flesh, or any other part of the body.

AESTUA'RIUM. A stove for conveying heat to all parts of the body at once. A kind of vapour bath. Ambrose Pare calls an instrument thus, which he describes for conveying heat to any particular part. Palmarius, De Morbis Contagiosis, gives a contrivance under this name, for sweating the whole body.

AESTUA'TIO. The boiling up, or rather the fermenticular ligners when mixed.

ÆSTUA'TIO. The boiling ing of liquors when mixed.

A STUS. Astus, us, m.; from the Hebrew ash,

heat. Heat; applied to the feeling merely of heat, and seometimes to that of inflammation in which there is heat and redness.

ÆSTUS VOLATICUS. 1. Sudden heat, or scorching, which soon goes off, but which for a time reddens the

2. According to Vogel, synonymous with phlogosis.

3. Erythema volaticum of Sauvages.

Æ TAS. See Age.
Æ'THER. (Æther, eris, m.; from aιθηφ: a supposed fine subtile fluid.) Æther. A volatile liquor, obtained by distillation, from a mixture of alcohol and a concentrated acid.

The medical properties of ather, when taken internally, are antispasmodic, cordial, and stimulant. Against nervous and typhoid fever, all nervous diseases, but especially tetanic affections, soporose diseases from debility, asthma, palsy, spasmopic colic, hysteria, &c. it always enjoys some share of reputations and typhology and the properties of the p tion. Regular practitioners seldom give so much as empirics, who sometimes venture upon large quantiempirics, who sometimes venture upon large quantities, with incredible benefit. Applied externally, it is of service in the headache, toothache, and other painful affections. Thus employed, it is capable of producing two very opposite effects, according to its management; for, if it be prevented from evaporating, by covering the place to which it is applied closely with the hand, it proves a powerful stimulant and rubefacient, and excites a sensation of burning heat, as is the case with solutions of camphor in alcohol, or turpentine. In this way it is frequently used for removing pains in the head or teeth. On the contrary, if it be dropped on any part of the body, exposed freely fit be dropped on any part of the body, exposed freely to the air, its rapid evaporation produces an intense degree of cold; and, as this is attended with a proportional diminution of bulk in the part, applied in this way, it has frequently contributed to the reduction of the intention of the proportional diminution of the proportional diminution of the production of the production in the intention in cases of extended the product of the the intestine, in cases of strangulated hernia.

ÆTHER RECTIFICATUS. Æther vitriolicus. Rectified æther. Take of sulphuric æther, fourteen fluid ounces. Fused potash, half an ounce. Distilled water, eleven fluid ounces.

First dissolve the potash in two ounces of the water,

and add thereto the æther, shaking them well together, until they are mixed. Next, at a temperature of about 200 degrees, distil over twelve fluid ounces of rectified æther, from a large retort into a cooled receiver. Then shake the distilled æther well with nine fluid ounces of water, and set the liquor by, so that the water may subside. Lastly, pour off the supernatant rectified æther, and keep it in a well-stopped bottle. Sulphuric æther is impregnated with some sulphu-

reous acid, as is evident in the smell, and with some setherial oil: and these require a second process to separate them. Potash unites to the acid, and requires to be added in a state of solution, and in sufficient quantities, for the purpose of neutralizing it; and it also forms a soap with the oil. It is advantage-

and it also forms a soap with the oil. It is advantageous also to use a less quantity of water than exists in the ordinary solution of potash; and therefore the above directions are adopted in the last London Pharmacopæia. For its virtues, see Æther.

ÆTHER SULPHURICUS. Naphtha vitrioli; Æther vitriolicus. Sulphuric æther. Take of rectified spirit, sulphuric acid, of each, by weight, a pound and a half. Pour the spirit into a glass retort, then gradually add to it the acid, shaking it after each addition, and taking care that their temperature, during the mixture, may not exceed 120 degrees. Place the retort very cautiously into a sand bath, previously heated to 200 degrees, so that the liquor may boil as speedily as possible, and the æther may pass over into a tubulated receiver, to the tubulure of which another receiver is applied, and kept cold by immersion in ice, or water. applied, and kept cold by immersion in ice, or water. Continue the distillation until a heavier part also begins to pass over, and appear under the other in the bottom of the receiver. To the liquor which remains in the retort, pour twelve fluid ounces more of rectified spirit, and repeat the distillation in the same manner.

It is mostly employed as an excitant, nervine, antispasmodic, and diuretic, in cases of spasms, cardialgia, enteralgia, fevers, hysteria, cephalalgia, and spasmodic asthma. The dose is from min. xx to 3 ij. Externally, it cures toothache, and violent pains in the head.

ATHER VITRIOLICUS. See Æther sulphuricus and

C

JEther rectificatus.

ÆTHE'REA HERBA. The plant formerly so called is supposed to be the Eryngium.

ÆTHERIAL OIL. See Oleum Ætherium.

Æ'THIOPS. A term applied formerly to several preparations, because of a black colour, like the skin of an Æthiorian. of an Æthiopian.

ÆTHIOPS ANTIMONIA'LIS. A preparation of anti-mony and mercury, once in high repute, and still em-ployed by some practitioners in cutaneous diseases A few grains are to be given at first, and the quantity increased as the stomach can bear it.

ETHOPS MARTIALIS. A preparation of iron, for merly in repute, but now neglected.

Ethiops mineral. The substance heretofore known by this name, is called by the London College, Hydrargyri sulphuretum nigrum.

ETHMOID. See Ethmoid.

Ethmoid Artery. See Ethmoid Artery.

Ethmoid Bonc. See Ethmoid Bonc.

Ethmoid Artery. See Ethmoid Artery.
Ethmoid Bone. See Ethmoid Bone.
ETHU'SA. (Æthusa, &, f.; from albova, beggarly.) The name of a genus of plants of the Linnaan system. Class, Pentandria; Order, Digynia.
Ethusa meum. The systematic name of the meum of the Pharmacopaias. Called also Meum athamanticum; Meu; Spignel; Baldmoney. The root of this plant is recommended as a carminative, stomachic, and for attenuating viscid humours, and appears to be nearly of the same nature as lovage, differing in its smell, being rather more agreeable, somewhat like that of parsnips, but stronger, and being in its taste less sweet, and more warm, or acrid.
ETIOLOGY. (Ætiologia, a, f.; atriologia: from al7ia, a cause, and loyos, a discourse.) The doctrine of the causes of diseases.

of the causes of diseases.

ÆTITES. Eagle stone. A stone formed of oxyde of iron, containing in its cavity some concretion which rattles on shaking the stone. Eagles were said to carry them to their nest, whence their name: and su-perstition formerly ascribed wonderful virtues to them.

[This is now arranged among the ores of iron by the name of the nodular argillaceous oxide of iron.

See Cleav. Min. A.]

AE'TIUS. A physician, called also Amidenus, from the place of his birth. He flourished at Alexandria, about the end of the fifth century, and left sixdria, about the end of the fifth century, and left sixteen books, divided into four tetrabiblia, on the practice of physic and surgery, principally collected from Galen and other early writers, but with some original observations. He appears very partial to the use of the cautery, both actual and potential, especially in palsy; which plan of treatment Mr. Pott revived in paraphlegia; and it has since often been adopted with success. Actius is the earliest writer who ascribed medical efficacy to the external use of the magnet paraphlesis. medical efficacy to the external use of the magnet, particularly in gout and convulsions; but rather on the report of others, than as what he had personally experienced.

Æ'ro'cion. Ætolium. The granum cnidium. See

Daphne mezercon.

ATO'NYCHUM. See Lithospermum.

AFFECTION. (Affectio, onis, f: This is expressed in Greek by ωαθος: hence pathema, passio.) Any existing disorder of the whole body, or a part of it; as hysterics, leprosy, &c. Thus, by adding a descriptive epithet to the term affection, most distempers may be expressed. And hence we say febrile affection, cutaneous affection, &c., using the word affection synony-mously with disease.

AFFINITY. (Affinitas, atis, f.; a proximity of relationship.) The term affinity is used indifferently with attraction. See Attraction.

AFFINITY OF AGGREGATION. See Attraction.
AFFINITY, AFFROYRIATE. See Affinity, intermediate.
AFFINITY OF COMPOSITION. See Attraction.
AFFINITY, COMPOUND. When three or more bodes,

on account of their mutual affinity, unite and form one homogeneous body, then the affinity is termed compound affinity or attraction: thus, if to a solution of sugar and water be added spirits of wine, these three bodies will form a homogeneous liquid by compound affinity.

AFFINITY, DIVELLENT. See Affinity, quiescent.
AFFINITY, DOUBLE. Double elective attraction.
When two bodies, each consisting of two elementary
parts, come into contact, and are decomposed, so that
their elements become reciprocally united, and pro-

duce two new compound bodies, the decomposition is

then termed decomposition by double affinity: thus, if we add common salt, which consists of muriatic acidwe add common sait, which consists of muratic acid and soda, to nitrate of silver, which is composed of nitric acid and oxyde of silver, these two bodies will be decompounded; for the nitric acid unites with the soda, and the oxyde of silver with the muriatic acid, and thus may be obtained two new bodies. The common salt and nitrate of silver therefore mutually decompose each other by what is called double affinity.

AFFINITY, INTERMEDIATE. Appropriate affinity.
Affinity of an intermedium is, when two substances of different kinds, that show to one another no component affinity, do, by the assistance of a third, combine, and unite into a homogeneous whole: thus, oil and water are substances of different kinds, which, by means of alcali, combine and unite into a homogeneous sub-stance: hence the theory of lixiviums, of washing, &c.

See Attraction.

AFFINITY, QUIESCENT. Mr. Kirwan employs the term Quiescent affinity to mark that, by virtue of which, the principle of each compound, decomposed by double affinity, adhere to each other; and Divellent affinity, to distinguish that by which the principles of one body unite and change order with those of the other. of the other: thus, sulphate of potash is not com-pletely decomposed by the nitric acid or by lime, when either of these principles is separately presented; but if the nitric acid be combined with lime, this nitrate of lime will decompose the sulphate of potash. In this last case, the affinity of the sulphuric acid with the alcali is weakened by its affinity to the lime. This acid, therefore, is subject to two affinities, the one which retains it to the alcali, called quiescent, and the other which attracts it toward the lime, called divellent affinity.

AFFINITY, RECIPROCAL. When a compound of two bodies is decomposed by a third, the separated principle being in its turn capable of decomposing the new combination: thus ammonia and magnesia will sepa-

rate each other from muriatic acid.

AFFINITY, SIMPLE. Single elective attraction. It a body, consisting of two component parts, be decomposed on the approach of a third, which has a greater affinity with one of those component parts than they have for each other, then the decomposition is termed decomposition by simple affinity: for instance, if pure potash be added to a combination of nitric acid and lime, the union which existed between these two bodies will cease, because the potash combines with the nitric acid, and the lime, being disengaged, is precipitated. The reason is, that the nitric acid has a greater affinity for the pure polarsh that for the limit of the li greater affinity for the pure potash than for the lime, therefore it deserts the lime, to combine with the potash. When two bodies only enter into chemical union, the affinity, which was the cause of it, is also termed simple or single elective attraction; thus the solution of sugar and water is produced by simple affi-

solution of sugar and water is produced by simple affinity, because there are but two hodies.

AFFLA'TUS. (From ad and fare, to blow.) A vapour or blast. A species of erysipelas, which attacks people suddenly, so named upon the erroneous supposition that it was produced by some unwholesome wind blowing on the part.

AFFUSION. (Affusio; from ad, and fundo, to pour upon.) Pouring a liquor upon something. The affusion of cold water, or pouring two or three quarts on the patient's head and body, is sometimes practised by physicians, but lately introduced by Dr. Currie, of Liverpoot, in the treatment of typhus fever, and which appears to possess a uniformity of success, which we look for in vain in almost any other branch of medical practice. The remedy consists merely in placing the patient in a bathing-tub, or other convenient vessel, practice. The remedy consists merely in patient in a bathing-tub, or other convenient vessel, and pouring a pailful of cold water upon his body; after which he is wiped dry, and again put to bed.

after which he is wiped dry, and again put to bed. It should be noted,

First, That it is the low contagious fever in which the cold affusion is to be employed: the first symptoms of which are a dull headache, with restlessness and shivering; pains in the back, and all over the body, the tongue foul, with great prostration of strength; the headache becoming more acute, the heat of the body, by the thermometer, 102° to 105°, or more; general restlessness, increasing to delirium, particularly in the night.

Secondly, That it is in the early stage of the disease we must employ the remedy; and generally in the state of the greatest heat and exacerbation.

of the greatest heat and exacerbation.

Thirdly, It is affusion, not immersion, that must be

employed.

Since the first publication of Dr. Currie's work, the practice of affusion has been extended throughout England; and its efficacy has been established in some stages of the disease, from which the author had origin ally proscribed the practice of it. One of the cautionary injunctions which had been given for the affusion ary injunctions which had been given for the anusom of cold water in fever, was never to employ it in cases where the patient had a sense of chiliness upon him, even if the thermometer, applied to the trunk of the body, indicated a preternatural degree of heat. In his last edition of Reports, however, Dr. Currie has given the particulars of a case of this kind, in which the cold affusion was so managed as to produce a successful

In fevers arising from, or accompanied by, topical inflammation, his experience does not justify the use of cold affusion; though, in a great variety of these cases, the warm affusion may be used with advantage. "And," says he, "though I have used the cold affusion in some instances, so late as the twelfth or fourteenth day of contagious fever, with safety and success, yet it can only be employed, at this advanced period, in the instances in which the heat keeps up steadily above the natural standard, and the respiration continues free. In such cases, I have seen it appease agitation and restlessness, dissipate delirium, and, as it were, snatch the patient from impending dissolution. But it is in the carly stages of fever (let me again repeat) that it ought always to be employed, if again repeat) that it ought always to be employed, if possible; are where, without any regard to the heat of the patient, it is had recourse to in the last stage of fever, after every other remedy has failed, and the case appears desperate, (of which I have heard several interests, can it appears surprising that the issue should sometimes be unfavourable?"

Numerous communications from various practitioners, in the West and East Indies, in Egypt and America, also show the efficacy of affusion in the raging fevers of bol countries.

rica, also show the efficacy of affusion in the raging fevers of hot countries.

AFORA. (From a, priv. and fores, a door.) Having a door or valve: applied to plants, the seed vessel of which is not furnished with a valvule.

AFTER-BIRTH. See Placenta.

A'GA CRETENSIUM. The small Spanish milk-thistle.

AGALACTA'TIO. See Agalactia.

AGALA'CTIA. (Αγαλακ)ια; from a, priv. and γαλα, milk.) Agalaxis; Agalactio; Agalactatio. A defect of milk in-childbirth.

AGALA'CTOS. (From a, priv. and γαλα, milk.) An epithet given to women who have no milk when they lie in.

they lie in.
AGALA'XIS. See Agalactia. AGALLOCHUM. See Lignum aloes. AGALLOCHUM VERUM. See Lignum aloes. AGA'LLUGE. * See Lignum aloes. See Lignum alocs. LITE. See Figurestone. AGALLUGUM.

AGALMATOLITE. See Figurestone.
AGARIC. See Agaricus.
AGARICOT DES. (From αγαρικος, the agaric, and τιλος, resemblance.) A species of fungus like the

AGA'RICUS. Agaric. The name of a genus of plants in the Linna an system. Class, Cryptogamia; Order, Fungi. The plants of this genus appear to approach nearer to the nature of animal matter than any other productions of the vegetable kingdom, as, beside hydrogen, oxygen, and carbon, they contain a consi-derable postion of nitrogen, and yield ammonia by dis-tiliation. Prof. Proust has likewise discovered in

tiliation. Prof. Proust has likewise discovered in them the benzoic acid, and phosphate of lime.

The mushrooms, remarkable for the quickness of their growth and decay, as well as for the feetor attending their spontaneous decomposition, were unaccountably neglected by analytical chemists, though capable of rewarding their trouble, as is evinced by the recent investigations and discoveries of Messrs. Vauquelin and Braconnot. The insoluble fungous portion of the mushroom, though- it resembles woody fibre in some respects, yet being less soluble than it in alcalies, and mushroom, though-it resembles woody here in some respects, yet being less soluble than it in alcalies, and yielding a nutritive food, is evidently a peculiar product, to which accordingly the name of fungin has been given. Two new vegetable acids, the boletic and fungic, were also fruits of these researches.

The six following species have been submitted to chemical analysis; the results are affixed to each. 1.

Agaricus campestris, an ordinary article of foo analyzed by Vauquelin, gave the following constituents:

1. Adipocire. On expressing the juice of the agaric, and subjecting the remainder to the action of boiling alkohol, a fatty matter is extracted, which falls down in white flakes as the alkohol cools. It has a dirty white colour; a fatty feel, like spermaceti; and, exposed to heat, soon melts, and then exhales the odour of grease. 2. An oily matters 3. Vegetable albumen. 4. The sugar of mushrooms, 5. An animal matter soluble in water and alkohol: on being heated, it evolves the odour of roasting meat, like osmazome. 6. An animal matter not soluble in alkohol. 7. Fungin. 8. Acetate of potash.

2. Agaricus volvaceus afforded Braconnot fungin, gelatin, vegetable albumen, much phosphate of potash, some acetate of potash, sugar of mushrooms, a brown oil, adipocire, wax, a very fugacious deleterious matter, uncombined acid, supposed to be the acetic, benzoic acid, muriate of potash, and a deal of water; in all

14 ingredients.

3. Agaricus acris, ot piperatus, was found by Bra-connot, after a minute analysis, to contain nearly the same ingredients as the preceding, without the wax and benzoic acid, but with more adipocire.

 Agaricus stypticus. From twenty parts of this Braconnot obtained of resin and adipocire 1.8, fungin 16.7, of an unknown gelatinous substance, a potash

salt, and a fugacious acrid principle, 1.5.

Agaricus bulbosus, was examined by Vauquelin, who found the following constituents: an animal matter insoluble in alkohol; osmazome; a soft fatty matter of a yellow colour and acrid taste; an acid salt, (not a phosphate.) The insoluble substance of the agaric yielded an acid by distillation.

6. Agaricus theogolus. In this, Vauquelin found sugar of mushrooms; osmazome; a bitter acrid fatty matter; an animal matter not soluble in alkohol; a

salt containing a vegetable acid.

AGARICUS ALBUS. See Boletus laricis.

AGARICUS CAMPESTRIS. There are several species of the agaric, which go by the term mushroom; as the Agaricus chantarellus, deliciosus, violaceus, &c.; but that which is eaten in this country is the Agaricus campestris of Linnaus. Similar to it in quality is the champignon, or Agaricus pratensis. Broiled with salt and pepper, or stewed with cream and some aromatic, they are extremely delicious, and, if not eaten to excess, salubrious. Great care should be taken to ascertain that they are the true fungus, and not those of a poisonous nature. Catchup is made by throwing salt on mushrooms, which causes them to part with their juice.

AGARICUS CHANTARELLUS. A species of fungus, esteemed a delicacy by the French. Broiled with salt and pepper, it has much the flavour of a roasted cockle.

AGARICUS CHIRURGORUM. See Boletus igniarius. AGARICUS CINNAMOMEUS. Brown mushroom. This species of agaric is of a pleasant smell. When broiled, it gives a good flavour.

AGARICUS DELICIOSUS. This fungus, well seasoned, and then broiled, has the exact flavour of, a roasted

muscle. It is in season in September.

AGARICUS MINERALIS A mineral; the mountain milk, or mountain meal, of the Germans. It is one of the purest of the native carbonates of lime, found chiefly in the clefts of rocks, and at the bottom of some lakes, in a loose or semi-indurated form. It has been used internally in hamorrhages, strangury, gravel, and dysenteries; and externally as an application to old ulcers, and weak and watery eyes.

[It is composed of very minute particles, feebly cohering, fine or soft to the touch, and soiling the fingers. Its texture is spongy, and hence it usually swims for a moment when placed on water. Its colour is white, either pure, or tinged with yellow, &c. It is

a very pure carbonate of lime.

Agaric mineral undoubtedly proceeds from the gradual disintegration of other varieties of carbonate of lime, and is deposited from water in the cavities or

fissures of other calcareous rocks.

Var. 1. Fossil Farina. This variety differs but little from that just described, and has probably a similar origin. It appears in thin, white crusts, light as cotton, and very easily reducible to powder. These crusts are attached to the lateral or lower surfaces of beds of shell, limestone, &c.—Cleav. Min. A.]

Agaricus Muscarius. Bug agaric; so called from its known virtue in destroying bugs. This reddish his known virtue in destroying bugs. This reddish fungus is the Agaricus—stipitatus, lamellis dimidiatis solitarus, stipite volvato, apiee dilatato, basi ovato, of Linnæus. It is not much known in this country. Haller relates that six persons of Lithuania perished at one time, by eating this kind of mushroom; and that in others it has caused delirium. The following account from Orfila, of the effects of this species in the animal economy, is interesting. Several French the animal economy, is interesting. Several French soldiers ate, at two leagues from Polosck, in Russia, mushrooms of the above kind. Four of them, of a robust constitution, who conceived themselves proof against the consequences under which their feebler companions were beginning to suffer, refused obsti-nately to take an emetic. In the evening, the following symptoms appeared. Anxiety, sense of suffocation, ardent thirst, intense griping pains, a small and irregular pulse, universal cold sweats, changed expression of countenance, violet tint of the nose and lips, general trembling, feetid stools. These symptoms becoming worse, they were carried to the hospital. Coldness and livid colour of the limbs, a dreadful delirium, and acute pains, accompanied them to the last moment. One of them sunk a few hours after his admission into the hospital; the three others had the same fate in the course of the night. On opening their dead bodies, the stomach and intestines displayed large spots of inflammation and gangrene; and putrefaction seemed advancing very rapidly. It is employed externally to strumous phagedenic, and fistulous ulcers, as an escha-

Agaricus piperatus. The plant thus named by Linnæus, is the pepper mushroom; also called pepper agaric. It is the Fungus piperatus albus, lactor-succo turgens of Ray. Fungus albus acris. When freely taken, fatal consequences are related by several writers to have been the result. When this vegetable has even lost its acrid juice by drying, its caustic quality still remains. remains.

AGARICUS PRATESSIS. The champignon of Hud-son's Flora Anglica. This plant has but little smell, and is rather dry, yet when broiled and stewed, com-municates a good flavour.

AGARICUS VIOLACEUS. Violet mushroom. fungus requires much broiling, but when sufficiently done and seasoned, it is as delicious as an oyster. Hudson's bulbosus is only a variety of this,

AGATE. A mineral found chiefly in Siberia and Saxony, which consists of chalcedony blended with variable proportions of jasper, amethyst, quartz, opal,

heliotrope, and carnelion.

[This name is usually applied to an aggregate of [This name is usually applied to an aggregate of certain quartzy or siliceous substances, intimately combined, possessing a great degree of hardness, a compact and fine texture, agreeable colours, variously arranged and intermixed, and susceptible of a good polish. The minerals which most frequently enter into the composition of agates, are common chalcedony, carnelion, and jasper, to which are sometimes added flint, hornstone, common quartz, amethyst, heliotrope, and opal. The chalcedony, however, is the most common and abundant ingredient, and may frequently be considered the base of the agate; in fact. quently be considered the base of the agate; in fact, some agates are composed entirely of chalcedony dif ferently coloured. In most cases, only two or three of the aforementioned ingredients occur in the same agate; but, though variously intermixed, each ingredient usually remains perfectly distinct.

Agates exhibit the colours already mentioned, while describing the simple minerals which compose them. But these colours are often so arranged, as to present the resemblance of some well-known object. Hence arises much of the beauty of agates; and hence also arises much of the beauty of agates; and hence also most of the distinctive names they have received in the arts. Of these a few will be mentioned. I. Onyx agate. 2. Eyed agate. 3. Dotted agate. 4. Moss agate. 5. Dendritic agate. 6. Spotted or figured agate. 7. Breccia agate. 8. Fortification agate. 9. Ribband agate, &c. Clear. Min. A.]

[Agartizer wood. This substance appears to have been produced by the process common y called the performance of the produced by the process common y called the performance of the produced by the process common y called the performance of the process common y called the performance of the process common y called the performance of the pe

[Agartized wood. This substance appears to have been produced by the process common y called the petrifaction of wood. It is essentially composed of siliceous earth, which it is highly probable has been gradually deposited, as the vegetable matter was decomposed and removed. Both its form and texture indicate its origin. Thus it presents more or less distinctly,

the form of the trunk, branches, roots, or knofs, which once belonged to the vegetable. The surface is rough or longitudinally striated. Its texture is fibrous, and the fibres often intertwined like those of wood. Its longitudinal fracture is usually fibrous or splinnery, and the core fracture imperfectly concluded with little

its cross fracture is usuany infous or spinnery, and its cross fracture imperfectly conchoidal, with little or no lustre.—Cleav. Min.

Agatized wood has been found in various parts of the United States. We have seen in the possession of Dr. Mitchill some remarkable specimens of siliceous petrifactions or agatized madrepores, echini, &c. from

the West-Indian islands. A.]

AGE. .Etas. The ancients reckoned six stages of

1. Pueritia, childhood, which is to the fifth year

of our age.

2. Adolescentia, youth, reckoned to the eighteenth, and youth properly so called, to the twenty-fifth year.

3. Juventus, reckoned from the twenty-fifth to the thirty-fifth year.

4. Virilis atas, manhood, from the thirty-fifth to

the fiftieth year.

5. Senectus, old age, from fifty to sixty.
6. Crepita atas, decrepit age, which ends in death.
AGENE'SIA. (Αγενησια; from a, neg. γενναω, or
γεναμαι, to beget.) Male sterility, or impotency in
man. A term employed by Vogel and Good. See Nosology.

A'GER. (Ager, gri. m.; from aypos.) The com-

mon earth or soil.

AGER NATURE. The womb.

AGE'RATUM. (Αγηραγον; from a, priv. and γηρας, senectus: never old, evergreen; because its flowers preserve their beauty a long time.) See Achillaa

AGEU'STIA. (From a, neg. and γενομαι, gusto, AGEU'STIA. (From a, neg. and ytvopat, gusto, to taste.) Agheustia; Apogeustia; Apogeustia. Apogeustia defect or loss of taste. A genus of disease in the class locales, and order dysasthesia of Cullen. The causes are fever or palsy, whence he forms two species: the latter he calls organic, arising from some affection in the membrane of the tongue, by which relishing things, or those which have some taste, are prevented from coming into contact with the nerves; the other atonic,

coming into contact with the herves; the other atonic, arising without any affection of the tongue.

AGGLUTINA'NTIA. Adhesive medicines which heal by causing the parts to stick together.

AGGLUTINA'TION. (Agglutinatio; from ad and glutino, to glue together.) The adhesive union or sticking together of substances.

AGGLUTI'TIO. Obstruction in the esophagus, or a difficulty in swallowing.

AGGREGATE. (Aggregatus; from aggrege, to assemble together.) Aggregated or added together.

1. When bodies of the same kind are united, the only consequence is, that one larger body is produced. In this case, the united mass is called an aggregate, and does not differ in its chemical properties from the bo-dies from which it was originally made. Elementary writers call the smallest parts into which an aggregate can be divided without destroying its chemical pro-perties, integrant parts. Thus the integrant parts of common salt are the smallest parts which can be con-ceived to remain without change; and beyond these, any further subdivision cannot be made without deve-laring the component parts, parts, parts, the clean and the loping the component parts, namely, the alcali and the acid; which are still further resolvable into their constituent principles.

2. A term applied to glands, flowers, gems, &c. An aggregate flower is one which consists of a number of smaller flowers or fructifications, collected into a head by means of some part common to them all. In this view aggregate flowers are opposed to simple flowers which have a single fructification, complete in its parts, nine of which are common to many flowers.

AGGREGATE GEM. A term applied in botany when two, three, or even more gems appear at the same

AGGREGATE GLANDS. (From aggrego, to assemble together.) Glandulæ aggregatæ. An assemblage of glands, as those on some parts of the internal surface of the intestines.

AGGREGATE PEDUNCLE. Clustered flower stalks, so called when several grow together, as in verbascum

nigrum.
Aggregation, affinity of. See Attraction.
Aggregation, attraction of. See Attraction.
36

AGGREGATUS. See Aggregate.
AGHEU'STIA. See Aggustia.
AGITATO'RIA. Convulsive diseases:
AGLACTA'TIO. Defect of milk.
AGLA'XIS. Defect of milk.
AGLIUM. 1. A shining tubercle or pustule on the

2. A white speck on the eye. See Ægides.
A'GNACAL. A tree, which, according to Ray, grows about the isthmus of Darien, and resembles a peartree, the fruit of which is a great provocative to venery.

AGNA'TA. See Adnata tunica.

AGNI'NA. (Agnina; from agnus, a lamb.)

Actius calls one of the membranes which involve the fætus by the name of membrana agnina, which he derives from its tenderness. See Amnios.

AGNOI'A. (From a, priv. and γινωσκώ, to know.)

Forgetfulness.
A'GNUS. A lamb.
AGNUS CASTUS. (Called agnus, from the down upon its surface, which resembles that upon a lamb's skin; and castus, because the chaste matrons, at the

reasts of Ceres, strewed them upon their beds and lay upon them.) See Vitez agnus castus.

[AGNUS TARTARICUS. This is a vegetable production, and belongs to the ferns. It is the root of the Polypodium Barometz, belonging to the class Crypto-gamia, and order Felices of Linnæus. The root of this gamía, and order Felices of Linnæus. The root of this plant is covered with a sort of orange-coloured wool among the radicals, and has a peculiar oblong figure, which, when put in a proper position, has a remote resemblance to a sheep. When pulled up by the roots, the stipes of the leaves, except four, are cut away, and those left behind are trimmed to resemble legs, and this Chinese juggle has had great sway in the world, and has deceived even Dr. Darwin, who has figured and noticed it in his Botanic Garden as a plant growing in the form of an animal.—Notes from Mitchill's ing in the form of an animal .- Notes from Mitchill's Lectures. A.]

AGOMPHI'ASIS. A looseness of the teeth.

AGOMPHI'ASIS. A looseness of the teeth.

A'GONE. (Αγονη; from α, neg. and γόνος, offspring: so called because it was supposed to cause barrenness.)

Henbane. See Hyasciamus niger.

AGO'NIA. Sterility, impotence, agony.

AGONI'STICUM. (Αγωνιζικον; from αγωνιαω, to struggle.) A term used by ancient physicians to signify water extremely cold, which was directed to be given in large quantities, in acute erysipelatous fevers, with a view of overpowering or struggling with the febrile heat of the blood.

A'GONOS. (From α, priv, and γονος οτ γονο, and

A'GONOS. (From a, priv. and yovos, or yovo, an offspring.) Barren. Hippocrates calls those women so who have no children, though they might have if

the impediment were removed.

AGRE'STIS. 1. Pertaining to the field; the trivial name of many plants.

2. In the works of some old writers, it expresses an ungovernable malignity in a disease.

A'GRIA. 1. A name of the Rex aquifolium, or com-

mon holly.

2. A malignant pustule, of which the ancient sur geons, and particularly Celsus, describe two sorts; one which has been so called, is small, and casts a roughness or redness over the skin, slightly corroding it; smooth about its centre; spreads slowly; and is of a round figure. The second ulcerates, with a violent redness and corrosion, so as to make the hair fall off :

it is of an unequal form, and turns leprous.

AGRIA'MPELOS. (From αγριος, wild, and αμπελος, a vine.) The wild vine, or white bryony. See

λος, a vine.) The wild vine, or white bryony. See Bryonia.

AGRIELE'A. (From αγριος, wild, and ελαια, the oiive-tree.) The oleaster, or wild olive.

AGRIFOLIUM. (From ακις, a prickle, and φυλ-λόν, a leaf.) The holly-tree. Which should rather be called acifolium, from its prickly leaves.

AGRIMO'NIA. (Agrimonia, α, f.; from αγρος, a field, and μονος, alone: so named from its being the chief of all wild herbs.) Agrimony.

1. The name of a genus of plants in the Linnæan system. Class, Dodecandria; Order, Digynia.

2. The pharmacopæial name of the common agrimony. See Agrimonia enpatoria.

AGRIMONIA EUPATORIA. The systematic name of the common agrimony. Agrimonai of the pharmacopæias; Agrimonia—foliis caulinis pinnatis, foliolis undique serratis, omnibus minutis interstinctis, frucundique serratis, omnibus minutis interstinctis, fructibus hispidis of Linnæus. It is common in fields about hedges and shady places, flowering in June and July. It has been principally regarded in the character of a mild astringent and corroborant, and many authors mild astringent and corroborant, and many authors mild astringent and dealest weather correctly in heaving recommend it as a deobstruent, especially in hepatic and other visceral obstructions. Chomel relates two instances of its successful use in cases where the liver was much enlarged and indurated. It has been used with advantage in hamorrhagic affections, and to give tone to a lax and weak state of the solids. In cutane-ous disorders, particularly in scabies, we have been told that it manifests great efficacy. For this purpose it was given infused with liquorice in the form of tea: but, according to Alston, it should be always exhibited in the state of powder. It is best used while fresh, and the tops, before the flowers are formed, possess the most virtue. Cullen observes that the agrimony has some astringent powers, but they are feeble; and pays

little attention to what has been said in its favour.

AGRIMONY, See Agrimonia.

Agrimony hemp. See Bidens tripartita.

AGRIOCA'RDAMUM. (From ayo105, wild, and kapodapo, the nasturtium.) Sciatica cresses, or wild

garden cress.

AGRIOCA'STANUM. (From ayριος, wild, and κας ανου, the chestnut.) Earth of pig-nut. See Bunium bulbo-castanum.

AGRIOCI'NARA. (From ayριος, wild, and κιναρα, artichoke.) Wild artichoke; not so good as the cultivated for any purpose. See Cinara scolymus.

AGRIOCOCCIME'LA. (From ayριος, wild, κοκκος, a berry, and μηλια, an apple-tree.) The Prunus spinosa of Linnæus.

AGRIOME'LA. The crab-apple.

AGRIOME LA. The crab-apple.
A'GRION. Agriophyllon. The peucedanum silaus, or hog's fennel.

AGRIOPASTINA'CA. (From αγριος, wild, and pastinaca, a carrot.) Wild carrot, or parsnip.

AGRIOPHY'LLON. See Agrion.

AGRIORI'GANUM. (From αγριος, wild, and οριγανον, marjoram.) Wild marjoram. See Origanum

vulgare.
AGRIOSELI'NUM. (From aγριος, wild, and σελι-νον, parsley.) Wild parsley. Lee Smyrnium olusa-

AGRIOSTA'RI. (From aγριος, wild, and ςαις, wheat.) Field-corn, a species of Triticum.

AGRIPA'LMA. (From aγριος, wild, and waλμα, a palm-trge.) Agripalma gallis. The herb motherwort, or wild-palm.

AGRIPA'LMA GALLIS. See Agripalma.
AGRI'PPÆ. Those children which are born with AGRIPPÆ. Those children which are born with their feet foremost are so called, because that was said to be the case with Agrippa the Roman, who was named ab agro partu, from his difficult birth.

A'GRIUM. An impure sort of natron. The purer sort was called halmyrhaga.

AGROSTEMMA. (Αγρου ζεμμα, the garland of the field.) The name of a genus of plants. Class Decandria; Order, Pentagynia. Cockle.

AGROSTEMMA GITHAGO. This plant has been called Nigellastrum: Pseudo melanthium: Luchnis

AGROSTEMMA GITHAGO. This plant has been called Nigellastrum; Pseudo melanthium; Lychnis segetum major; Githago; Nigella officinarum; Lychnoides segetum. Cockle. It has no particular virtues, and is fallen into disuse.

AGROSTIS. (From ayoos, a field.) The name of a genus of plants. Class, Triandria; Order, Digynia.

Bentgrass.

AGRU'MINA. Leeks; wild onions.

AGRY'PNIA. (From a, priv. and υπνος, sleep.)

Watchfulness; sleeplessness. The name of a genus in Good's Nosology. See Nosology.

AGRYPNOCO MA. (From αγουπνος, without sleep, and κωμα, a lethargy.) A lethargic kind of watchfulness, in which the patient is stupidly drowsy, and yet cannot sleep.

cannot sleep.

AGUE. See Febris Intermittens.

Ague cake. The popular name for a hard tumour, most probably the spleen on the left side of the belly, lower than the false ribs in the region of the spleen, said to be the effect of intermittent fevers. However frequent it might have been formerly, it is now very rare, and although then said to be owing to the use of bark, it is now less frequent since the bark has been

generally employed.

Ague drop. A medicine sold for the cure of agues, composed of arsenite of potassa in solution in water.

The regular substitute for the quack medicine called the tasteless ague drop, which has cured thousands of that complaint, is the liquor arsenicalis, or Fowler's arsenical solution.

arsenical solution.

Ague-free. A name given by some to sassafras, on account of its supposed febrifuge virtue.

AGUSTINE. (From a, priv. and yuşta, taste, that is tasteless.) Augustina. A new earth discovered in the Saxon beryl, or beryl of Georgien Stadt, (a stone greatly resembling the beryl of Siberia) by Professor Tromsdorff, of Erfurth, in Germany, to which he has given the name of agustine, on account of the property of forming salts which are nearly destitute of taste. This earth is white and insipid: when moistened with water, it is somewhat ductile, but is not ened with water, it is somewhat ductile, but is not soluble in that fluid. Exposed to a violent heat, it becomes extremely hard, but acquires no taste. It combines with acids, forming salts which have little or no taste. It does not combine either in the humid or dry way with alcalies, or with their carbonates. It retains carbonic acid but feebly. It dissolves in acids equally well after having been hardened by exposure to heat, as when newly precipitated. With sulphuric acid it forms a salt which is insipid, and scarcely soluble, but an excess of acid renders it soluble, and capable of crystallizing in stars. With an excess of phosphoric acid it forms a very soluble salt. With nitrous acid it forms a salt scarcely soluble.

AGUTIGUEPOO'BI BRAZILIENSIS. the arrow-root. See Maranta. An Indian name

of the arrow-root.

[AIGUE MARINE, called by some aqua marina; one of the precious stones which has been found in various parts of the United States. It is a name sometimes employed to designate the beryl. A.]

AIMATEI'A. A black bilious and blood-like dis-charge from the bowels.

AlmorrhoE'A. See Hamorrhagia.
Almo'rrhoIs. See Hamorrhois.
Alpathel'A. (From act, always, and waθος, a

disease.) Diseases of long continuance.

Al'PI. Aipima coxera. Aipipoca for Cassada. See Jatropha manihot. Aipipoca. Indian words

AIR. This term was, till lately, used as the generic name for such invisible and exceedingly rare fluids as possess a very high degree of elasticity, and are not condensible into the liquid state by any degree of cold hitherto produced; but as this term is commonly em-ployed to signify that compound of aëriform fluids which constitutes our atmosphere, it has been deemed advisable to restrict it to this signification, and to em-ploy as the generic term the word Gas, for the different kinds of air, except what relates to our atmospheric compound.

AIR, ATMOSPHERIC. "The immense mass of permanently elastic fluid which surrounds the globe we in-habit," says Dr. Ure, "must consist of a general says Dr. Ure, "must consist of a general assemblage of every kind of air which can be formed by the various bodies that compose its surface. Most of these, however, are absorbed by water; a number of them are decomposed by combination with each other; and some of them are seldom disengaged in considerable quantities by the processes of nature. Hence it is that the lower atmosphere consists chiefly of oxygen and nitrogen, together with moisture and the occasional vapours or exhalations of bodies. The upper atmosphere seems to be composed of a large procession of ballogeness of ballogs are presented. portion of hydrogen, a fluid of so much less specific gravity than any other, that it must naturally ascend to the highest place, where, being occasionally set on fire by electricity, it appears to be the cause of the aurora borealis and fire-balls. It may easily be understood, that this will only happen on the confines of the respective masses of common atmospherical air, and of the inflammable air; that the combustion will extend progressively, though rapidly, in flashings from the place where it commences; and that when by any means a stream of inflammable air, in its progress toward the upper atmosphere, is set on fire at one end, its ignition may be much more rapid than what happens higher up, where oxygen is wanting, and at the same time more definite in its figure and progression, so as to form the appearance of a fire-ball.

That the air of the atmosphere is so transparent as to be invisible except by the blue colour it reflects when in very large masses, as is seen in the sky or region above us, or in viewing extensive landscapes; that it is without smell, except that of electricity,

AIR

which it sometimes very manifestly exhibits; altogether without taste, and impalpable; not condensible by any degree of cold into the dense fluid state, though easily longer than atmospherical air, bulk for bulk. changing its dimensions with its temperature; that it gravitates and is highly elastic; are among the numerous observations and discoveries which do honour to the sagacity of the philosophers of the seventeenth century. They likewise knew that this fluid is indispensably necessary to combustion, but no one, except the great, though neglected, John Mayow, appears to have formed any proper notion of its manner of act-

ing in that process.

The air of the atmosphere, like other fluids, appears
the air of the atmosphere, like other fluids, appears
that process. up water in considerable quantities, with a diminution of its own specific gravity: from which circumstance, as well as from the consideration that water rises very plentifully in the vaporous state in vocuo, it seems probable, that the air suspends vapour, not so much by a real solution, as by keeping its particles asunder, and preventing their condensation. Water likewise dissolves or absorbs air.

Mere heating or cooling does not affect the chemical properties of atmospherical air; but actual combus-tion, or any process of the same nature, combines its oxygen, and leaves its nitrogen separate. Whenever a process of this kind is carried on in a vessel contain ing atmospherical air, which is enclosed either by inverting the vessel over mercury, or by stopping its aperture in a proper manner, it is found that the process ceases after a certain time; and that the remain-ing air (if a combustible body capable of solidifying the oxygen, such as phosphorus, have been employed,) has lost about a fifth part of its volume, and is of such a nature as to be incapable of maintaining any combustion for a second time, or of supporting the life of animals. From these experiments it is clear, that one of mals. From these experiments it is clear, that one of the following deductions must be true:—i. The combustible body has emitted some*principle, which, by combining with the air, has rendered it unfit for the purpose of further combustion; or, 2. It has absorbed part of the air which was fit for that purpose, and has left a residue of a different nature; or, 3. Both events have happened; namely, that the pure part of the air has been absorbed, and a principal has been emitted, which has changed the original properties of the remainder. mainder.

The facts must clear up these theories. induction cannot be true, because the residual air is not only of less bulk, but of less specific gravity, than The air cannot therefore have received much as it has lost. The second is the doctrine of the philosophers who deny the existence of philogiston, or a principle of inflammability; and the third must be adopted by those who maintain that such a principle escapes from bodies during combastion. This residue was called phlogisticated air, in consequence of such

an opinion.

In the opinion that inflammable air is the phlogiston. it is not necessary to reject the second inference that the air has been no otherwise changed than by the mere subtraction of one of its principles; for the pure or vital part of the air may unite with inflammable air supposed to exist in a fixed state in the combustible body; and if the product of this union still continues fixed, it is evident, that the residue of the air, after combustion, will be the same as it would have been if the vital part had been absorbed by any other fixed body. Or, if the vital air be absorbed while inflammable air or phlogiston is disengaged, and uniter with the aëriform residue, his residue will not be heavier than before, unless the inflammable air it has raised exceeds in weight the vital air it has lost and gained exceeds in weight the vital air it has lost; and if the inflammable air falls short of that weight, the residue will be lighter.

These theories it was necessary to mention; but it has been sufficiently proved by various experiments, that combustible bodies take oxygen from the atmosphere, and leave nitrogen; and that when these two fluids are again mixed in due proportions, they compose a mixture not differing from atmospherical air.

The respiration of animals produces the same effect on atmospherical air as combustion does, and their constant heat appears to be an effect of the same When an animal is included in a limited quantity of atmospherical air, it dies as soon as the oxygen is consumed; and no other air will maintain

longer than atmospherical air, bulk for bulk.

It is to be particularly observed, however, that, in many cases of combustion, the oxygen of the air, in combining with the combustible body, produces a compound, not solid, or liquid, but aëriform. The residual air will therefore be a mixture of the nitrogen of the atmosphere with the consumed oxygen, converted into another gas. Thus, in burning charcoal, the carbonic acid gas generated, mixes with the residual nitrogen and makes up exactly, when the effect dual nitrogen, and makes up exactly, when the effect of heat ceases, the bulk of the original air. The breathing of animals, in like manner, changes the oxygen into carbonic acid gas, without altering the atmospherical reliable of the control of

pherical volume.

There are many provisions in nature by which the proportion of oxygen in the atmosphere, which is con-tinually consumed in respiration and combustion, is again restored to that fluid. In fact there appears, as far as an estimate can be formed of the great and general operations of nature, to be at least as great an emission of oxygen as is sufficient to keep the general mass of the atmosphere at the same degree of purity. Thus, in volcanic eruptions, there seems to be at least as much oxygen emitted or extricated by fire from various minerals, as is sufficient to maintain the combustion, and perhaps even to meliorate the atmosphere. And in the bodies of plants and animals, which appear in a great measure to derive their sustenance and augmentation from the atmosphere and its contents, it is found that a large proportion of nitrogen exists. Most plants emit oxygen in the sunshine, from which it is highly probable that they imbibe and decompose the air of the atmosphere retaining carbon and genitting the of the atmosphere, retaining carbon, and emitting the vital part. Lastly, if to this we add the decomposition of water, there will be numerous occasions in which this fluid will supply us with disengaged oxygen; while, by a very rational supposition, its hydrogen may be considered as having entered into the bodies of plants for the formation of oils, sugars, mucilages, &c., from which it may be again extricated.

To determine the respirability or purity of air, it is evident that recourse must be had to its comparative

efficacy in maintaining combustion, or some other

equivalent process.

From the latest and most accurate experiments, the proportion of oxygen in atmospheric air is by measure about 21 per cent.; and it appears to be very nearly the same, whether it be in this country or on the coast of Guinea, on low plains or lofty mountains, or even at the height of 7250 yards above the level of the sea, as ascertained by Gay Lussac, in his acrial voyage in September, 1805. The remainder of the air is nitrogen, with a small portion of aqueous vapour, amountains to about one present in the driest weether.

gen, with a small portion of aqueous vapour, amounting to about one per cent. in the driest weather, and a still less portion of carbonic acid, not exceeding a thousandth part of the whole.

As oxygen and nitrogen differ in specific gravity in the proportion of 135 to 121, according to Kirwan, and of 139 to 120, according to Davy, it has been presumed, that the oxygen would be more abundant in the lower regions, and the nitrogen in the higher, if they constituted a mere mechanical mixture, which appears contrary to the fact. On the other hand, it appears contrary to the fact. On the other hand, it has been urged, that they cannot be in the state of chemical combination, because they both retain their distinct properties unaltered, and no change of temperature or density takes place on their union. But perhaps it may be said, that, as they have no repug-nance to mix with each other, as oil and water have, the continual agitation to which the atmosphere is exposed, may be sufficient to prevent two fluids, differing not more than oxygen and nitrogen in gravity, from separating by subsidence, though simply mixed. On the contrary, it may be argued, that to say chemical combination cannot take place without producing new properties, which did not exist before in the component parts, is merely begging the question; for though this generally appears to be the case, and often in a very striking manner, yet combination does not always produce a change of properties, as appears in M. Biot's experiments with various substances; of which we may instance water, the refraction of which is precisely the mean of that of the oxygen and hydrogen, which are indisputably combined in it.

To get rid of the difficulty, Mr. Dalton of Manchester

framed an ingenious hypothesis, that the particles of different gases neither attract nor repel each other; so that one gas expands by the repulsion of its own particles, without any more interruption from the presence of another gas, than if it were in a vacuum. This would account for the state of atmospheric air, it is true; but it does not agree with certain facts. In the case of the carbonic acid gas in the Grotto del Cano, and over the surface of brewers' vats, why does not this gas expand itself freely upward, if the superincumbent gases do not press upon it? Mr. Dalton himself, too, instances as an argument for his hypothesis, that oxygen and hydrogen gases, when mixed by agitation, do not separate on standing. But why should either oxygen or hydrogen rèquire agitation, to diffuse it through a vacuum; in which, according to Mr. Dalton, it is placed?

The theory of Berthollet appears consistent with all the facts, and sufficient to account for the phenomenon. If two bodies be capable of chemical combination, their particles must have a mutual attraction for that one gas expands by the repulsion of its own par-

non. If two bodies be capable of chemical combination, their particles must have a mutual attraction for each other. This attraction, however, may be so opposed by concomitant circumstances, that it may be diminished in any degree. Thus we know, that the affinity of aggregation may occasion a body to combine slowly with a substance for which it has a powerful affinity, or even entirely prevent its combining with it; the presence of a third substance may equally prevent the combination; and so may the absence of a certain quantity of caloric. But in all these cases the attraction of the particles must subsist, though diminished or counteracted by opposing circumstances. Now ed or counteracted by opposing circumstances. Now we know that oxygen and nitrogen are capable of combination; their particles, therefore, must attract each other; but in the circumstances in which they are placed in our atmosphere, that attraction is prevented from exerting itself, to such a degree as to form them into a chemical compound, though it operates with sufficient force to prevent their separating by their difference of specific gravity. Thus the state of the atmosphere is accounted for, and every difficulty obviated, without any new hypothesis.

The exact specific gravity of atmospherical air, compared to that of water, is a very nice and important problem. By reducing to 60° Fahr, and to 30 inches of the barometer, the results obtained with great inches of the barometer, the results obtained with great care by Biot and Arago, the specific gravity of aumospherical air, appears to be 0.001220, water being represented by 1.000000. This relation expressed fractionally is 1-820, or water is 820 times denser than atmospherical air. Mr. Rice, in the 77th and 78th numbers of the Annals of Philosophy, deduces from Sir George Shuckburgh's experiments 0.00120855 for the specific gravity of air. This number gives water to air as 827.437 to 1. If with Mr. Rice we take the cubic inch of water=252.525 gr., then 100 cubic inches of air by Biot's experiments will weigh 30.808 grains, and by Mr. Rice's estimate 30.519. He considers with Dr. Prout the atmosphere to be a compound of 4 volumes of nitrogen, and 1 of oxygen; the specific gravity of the first being to that of the second as 1.1111 to 0.9722. Hence

Hence
0.8 vol. nitr. sp. gr. 0.001166=0.000933
0.2 oxy, 0.001340=0.000268

The numbers are transposed in the Annals of Phi-

and that of nitrogen 0.96913
air being reckoned, 1.00000
Or compared to water as unity,—
Nitrogen is 0.001182338

Oxygen, 0.001346379
And 0.8 nitrogen =0.00094587 0.2 oxygen =0.00026927

0.00121514

And 0.79 nitrogen =0.000934 =0.0002830.21 oxygen

0.001217

A number which approaches very nearly to the result of experiment. Many analogies, it must be confessed, favour Dr. Prout's proportions; but the greater num-

ber of experiments on the composition and density of the atmosphere agree with Biot's results. Nothing can decide these fundamental chemical proportions, except a new, elaborate, and most minutely accurate series of experiments. We shall then know whether the atmosphere contains in volume 20 or 21 per cent. of oxygen."—Ure's Chem. Dict.

Air, alcaline. See Ammonia.

Air, alcaline. See Ammonia. Air, azotic. See Nitrogen. Air, fixed. See Carbonic acid.

AISTHETE'RIUM. (From aicharopai, to perceive.)
The sensorium commune, or common sensory, or seat, or origin of sensation.

or origin of sensation

AIX LA CHAPE'LLE. Called Aken by the Germans. A town in the south of France, where there is a sulphureous water, Thermæ Aquis-granensis, the most striking feature of which, and what is almost peculiar to it, is the unusual quantity of sulphur it conpecuniar to it, is the unusual quantity of sulphur it contains: the whole, however, is so far united to a gaseous basis, as to be entirely volatilized by heat; so that none is left in the residuum after evaporation. In colour it is pellucid, in smell sulphureous, and in taste saline, bitterish, and rather alcaline. The temperature of these waters varies considerably, according to the distance from the source and the spring itself. In the well of the better that, it is executioned a large. distance from the source and the spring itself. In the well of the hottest bath, it is, according to Lucas, 1360, Monet, 1469; at the fountain where it is drank, it is 1129. This thermal water is much resorted to on the Continent for a variety of complaints. It is found essentially serviceable in the numerous symptoms of disorders in the stomach and biliary organs, that follow a life of high indulgence in the luxuries of the table; in nephritic cases, which produce pain in the loins, and thick mucous time with difficult micturition. As the heating qualities of this water are as decided as in any of the mineral springs, it should be avoided in any of the mineral springs, it should be avoided in cases of a general inflammatory tendency, in hectic fever and ulceration of the lungs; and in a disposition to active himorrhagy. As a hot bath, this water is even more valuable and more extensively employed than as an internal remedy. The baths of Aix la Chapelle may be said to be more particularly medicated than any other, that we are acquainted with. They possess both temperature of any degree that can be borne; and a strong impregnation with sulphur in its most active forms; and a quantity of alcali, which is sufficient to give it a very soft soapy feel, and to render it more detergent than common water. From these der it more detergent than common water. From these circumstances, these baths will be found of particular service in stiffness and rigidity of the joints and liga-ments, which is left by the inflammation of gout and rheumatism, and in the debility of palsy, where the highest degree of heat which the skin can bear is re-quired. The sulphureous ingredient renders it highly active in almost every cutaneous eruption, and in general in every foulness of the skin; and here the internal use of the water should attend that of the bath. These waters are also much employed in the distressing debility which follows a long course of mercury and excessive salivation. Aken water is one of the few natural springs that are hot enough to be employed as a vapour bath, without the addition of artificial heat. It is employed in cases in which the het bath heat. It is employed in cases in which the hot bath is used; and is found to be a remarkably powerful auxiliary in curing some of the worst species of cuta-neous disorders. With regard to the dose of this wa-ter to be begun with, or the degree of heat to bathe in, it is in all cases best to begin with small quantities and low degrees of heat, and gradually increase them, agreeably to the effects and constitution of the patient. The usual time of the year for drinking these waters is from the beginning of May to the middle of June, or from the middle of August to the latter end of September 1.

Alzo'on. (From att, always, and ξω, to live.) Aizo-um. 1. An evergreen aquatic plant, like the aloe, said to possess antiscorbutic virtues.

2. The house leek. See Sempervivum tectorum.

AIZOUM. See Aizoon.

AJA'VA. An ancient name of a seed used in the East

as a remedy for the colic.

AJUGA. (From a, priv. and Zvyov, a yoke.) 1.

The name of a genus of plants in the Linnwan system.

2. The pharmacopeial name of the creeping bugloss.

See Ajuga pyramidalis.
AJUGA PYRAMIDALIS. AJUGA PYRAMIDALIS. Consolida media. Bugula. Upright bugloss. Middle consound. This plant, Ajuga-caule tetragono foliis radicalibus maximis, of Linnæus, possesses subadstringent and bitter qualities: and has been recommended in phthisis, aphtha, and

and has been recommended in phthisis, aphtha, and cynanche.

[AKANTICONE. The name of a mineral synonymous with the epidote of Haüy, pistazit of Werner, glassy actynolite of Kirwan, &c. A.]

A'KENSIDE, MARK. An English physician, born at Newcastle-upon-Tyne, in 1721; but more distinguished as a poet, especially for his "Pleasures of the Imagination." After studying at Edinburgh, and graduating at Leyden, he settled in practice; but though appointed physician to the queen, as well as to St. Thomas's Hospital, he is said not to have been very successful. He died of a putrid fever, in his 49th year. He has left a Dissertation on Dysentery in Latin, admired for its elegance; and several small Tracts in the Philosophical and London Medical Transactions.

AL. The Arabian article, which signifies the; it is applied to a word by way of eminence, as the Greek o is. The Easterns express the superlative by adding God thereto, as the mountain of God, for the highest mountain; and it is probable that Al relates to the word Alla, God: so Alchemy, may be the chemistry of God, or the most exalted perfection of chemical science.

science.

A'LA. 1. The wing of a bird.

2. The arm-pit, so called because it answers to the pit under the wing of a bird.

3. An accidental part of the seed of a plant; consisting of a membraneous prolongation from the side of the seed, and distinguished by the number into Semina monoterygia: one-winged, as in Bignonia. Dipterygia: two-winged, as in Betula.

Tripterygia: three-winged.

Tetrapterygia: four-winged.

Polypterigia: many-winged, or Molendinacea: windmill-winged, for so the many-winged seeds of some umbelliferous plants are termed.

some umbelliferous plants are termed.

4. The two lateral or side petals of a papilionaceous

4. The two lateral or side petals of a papilionaceous or butterfly-shaped flower.

Ala auris. The upper part of the external ear.

Ala interna minor. See Nympha.

Ala nasi. 1. The cartilage of the nose which forms the outer part of the nostrils.

2. The sides of the nose are called ala nasi.

Ala vespertitionis. That part of the ligament of the womb, which lies between the tubes and the ovarium; so called from its resemblance to the wing of a bat.

of a bat.

ALABASTER. Among the stones which are known by the name of marble, and have been distinguished by a considerable variety of denominations by statuaries and others, whose attention is more directed to their external character and appearance than their component parts, alabasters are those which have a greater or less degree of imperfect transparency, a granular texture, are softer, take a duller polish than marble, and are usually of a white colour. Some stones, however, of a veined and coloured appearance, nave been considered as alabasters, from their possessing the first-mentioned criterion; and some transpa-.ng the first-mentioned criterion; and some transpa-rent and yellow sparry stones have also received this appellation.

Alabaster is a variety of compact gypsum. [Alabaster is a variety of compact gypsam. It is found in compact masses of a fine grain, whose fracture is even, or splintery, and nearly or quite dull, or sometimes a little foliated. It is nearly opaque, and its colours are commonly white or gray, sometimes shaded with yellow, red, &c. or variously mingled. Its specific gravity is sometimes only 1.87. It is sometimes in consections

times in concretions.

Compact gypsum, and some varieties of granular gypsum, are employed in sculpture and architecture, under the name of alabaster. The same name is also given to certain varieties of carbonate of lime. It may

be well to employ the term gypseous and calcareous

alubaster.—Cleav. Min.
The cabinet of the New-York Lyceum of Natural History contains some very fine specimens of gypeous alabaster, from various parts of the United States. A.J. ALÆFO'RMIS. (Alaformis; from Ala, a wing, and forma, resemblance.) Wing-like. Any thing like

ALAI'A PHTHI'SIS. (From αλαιος, blind, and φθισις, a wasting.) A consumption from a flux of humours from the head.
[ALALITE. A rare mineral, consisting principally

[ALALITE. A rare mineral, consisting principally of silex, magnesia, and lime, found in the form of prismatic crystals, otherwise called diopside. A.]

ALANDAHLA. The Arabian for bitter. The bitter apple. See Cucumis colocynthis.

ALANFU'TA. An Arabian name of a vein between the chin and lower lip, which was formerly opened to prevent fætid breath.

ALARIA OSSA. The wing-like processes of the sphe-

ALA'RIS. (Alaris; from ala, a wing.) Formed like, or belonging to a wing.

ALARIS EXTERNUS. Musculus alaris externus. A name of the external pterygoid muscle; so called because it takes its rise from the wing-like process of the sphenoid bone.

ALARIS VENA. The innermost of the three veins in

the bend of the arm.

ALATE'RNUS. A species of rhamnus:
ALAT'RUS. (From alm, a wing.) Winged. I Applied to stems and leaf-stalks, when the edges or angles are longitudinally expanded into leaf-like borders; as in Enopordium acanthium; Lathyrus latifolius, &c. and the leaf-stalk of the orange tribe, citrus, &c.
2. One who has prominent scapulæ like the vings of hirds

ALBAGRAS NIGRA. So Avicenna names the Lepra hthyosis, or Lepra Gracorum. ALBAME'NTUM. (From albus, white.)

white of an egg.

ALBA'NUM. Urinous salt.

ALBA'TIO. (From albus, white.) Albificatis The calcination or whitening of metals.

A'LBICANS. (From albico, to grow white) Inclining to white. Whitish.

ALBICA'NTIA CO'RPORA. Corpora albicantia Wil-lisii. Two small round bodies or projections from the base of the brain, of a white colour.

ALBIN. A mineral found in Bohemia; so called

from its white colour.

ALBI'NUM. See Gnaphalium dioicum.

ALBI'NUS BERNARD SIEGFRED, son of a physician, ALBI'NUS BERNARD SIEGFRED, son of a physician, and professor at Leyden of the same name, was born near the end of the 17th century, and prosecuted his studies with so much zeal and success, that he was appointed, on the recommendation of Boerhaave, professor of anatomy and surgery, when only 20 years old. This office he filled for half a century, and acquired a greater reputation than any of his predecessors. He has left several valuable anatomical works; and particularly yery accurate descriptions, and plates and particularly very accurate descriptions, and plates of the muscles and bones, which are still highly esteemed.

A'LBORA. A sort of itch; or rather of leprosy. Paracelsus says, it is a complication of the morphew, serpigo, and leprosy. When cicatrices appear in the face like the serpigo, and then turn to small blisters of the nature of the morphew, it is the albora. It terminates without ulceration, but by fœtid evacuations in the mouth and nostrils; it is also scated in the root of

ALBUCA'SIS, an Arabian physician and surgeon ALBUCA'SIS, an Arabian physician and surgeon of considerable merit, who lived about the beginning of the twelfth century. He has copied much from preceding writers, but added also many original observations; and his works may be still perused with pleasure. He insisted on the necessity of a surgeon being skilled in anatomy to enable him to operate with success, as well as acquainted with the materia medica, that he may apply his remedies with propriety. He appears to have extracted polypi from the nose, and performed the operation of bronchotomy. He is the first who left distinct descriptions and delineations of the instruments used in surgery, and of the manner of the instruments used in surgery, and of the manner of

ALBUGI'NEA. (Albuginia; from albus, white: so

called on account of its white colour.) The membrane of the eye and of the testicle.

ALBUGINEA OCULI. See Adnata tunica.
ALBUGINEA TESTIS. Tunica albuginea testis. The innermost coat of the testicle. A strong, white, and dense membrane, immediately covering the body or substance of the testicle. On its outer surface it is smooth, but rough and uneven on the inner. See

ALBU'GO. A white opacity of the cornea of the eye. The Greeks named it leucoma; the Latins, albugo, nebula, and nubecula. Some ancient writers have ALBU'GO. acould, and nubecula. Some ancient writers have called it pterygium, janua oculi, onyx, unguis, and agides. It is a variety of Cullen's Caligo cornec.

[Albugo, (from albus, white.) It is a white opacity of the cornea, not of a superficial kind, but affecting the very substance of this membrane. A.]

ALBUM BALSAMUM. The balsam of copaiba. See

Copaiba.

ALBUM GRÆCUM. The white dung of dogs. It was formerly applied as a discutient, to the inside of the throat, in quinsies, being first mixed with honey; medicines of this kind have long since justly sunk into

ALBUM OLUS. See Valeriana locusta.

ALBU'MEN. Albumine. 1. Coagulable lymph.

This substance, which derives its name from the Latin for the white of an egg, in which it exists abundantly, and in its purest natural state, is one of the chief constituent principles of all the animal solids. Beside the white of egg, it abounds in the serum of blood, the vitreous and crystalline humours of the eye, and the fluid of draws. Fourtrey claims to himself the become of dropsy. Fourcroy claims to himself the honour of having discovered it in the green feculæ of plants in general, particularly in those of the cruciform order, in very young ones, and in the fresh shoots of trees, though Rouelle appears to have detected it there long before. Vauquelin says it exists also in the mineral water of **Plombieres**

Seguin has found it in remarkable quantity in such regetables as ferment without yest, and afford a vinous liquor; and from a series of experiments, he infers, that albumen is the true principle of fermentation, and that its action is more powerful in proportion to its solubility, three different degrees of which he found it to

The chief characteristic of albumen is its coagulability by the action of heat: If the white of an egg be exposed to a heat of about 134° F, white fibres begin to appear in it, and at 160° it coagulates into a solid mass In a heat not exceeding 212 it dries, shrinks, and assumes the appearance of horn. It is soluble in cold water before it has been coagulated, but not after; and which diluted with a very large portion, it does not coagulate easily. Pure alcalies dissolve it, even after coagulation. It is precipitated by muriate of mercury, nitro-muriate of tin, acetate of lead, nitrate of silver, muriate of gold, infusion of galls and tannin. The acids and metallic oxydes coagulate albumen. On the addition of concentrated sulphuric acid, it becomes black, and exhales a nauseous smell. Strong muriation acid gives a violet tinge to the coagulum, and at length becomes saturated with ammonia. Nitric acid, at 700 F, disengages from it abundance of azotic gas; and if the heat be increased, prussic acid is formed; after which carbonic acid and carburetted hydrogen are evolved, and the residue consists of water containing a little oxalic acid, and covered with a lemon-coloured fat oil. If dry potassa or soda be triturated with albumen, either liquid or solid, ammoniacal gas is evolved, and the calcination of the residuum yields an alcaline

On exposure to the atmosphere in a moist state, albumen passes at once to the state of putrefaction.

Solid albumen may be obtained by agitating white of egg with ten or twelve times its weight of alcohol. This seizes the water which held the albumen in solu-This seizes the water which held the albumen in solution; and this substance is precipitated under the form of white flocks or filaments, which cohesive attraction renders insoluble, and which consequently may be freely washed with water. Albumen thus obtained is like fibrine, solid, white, insipid, inodorous, denser than water, and without action or vegetable colours. It dissolves in potassa and soda more easily than fibrine; but in acetic acid and ammonia, with more difficulty. but in acetic acid and ammonia, with more difficulty. When these two animal principles are separately dissolved in potassa, muriatic acid added to the albumi-

The name of a | nous, does not disturb the solution, but it produces a cloud in the other.

Fourcroy and several other chemists have ascribed the characteristic coagulation of albumen by heat to its oxygenation. But cohesive attraction is the real cause oxygenation. But conesive attraction is the real cause of the phenomenon. In proportion as the temperature rises, the particles of water and albumen recede from each other, their affinity diminishes, and then the albumen precipitates. However, by uniting albumen with a large quantity of water, we diminish its coagulating account to such a degree, that heat wades the solution property to such a degree, that heat renders the solution merely opalescent. A new-laid egg yields a soft coagu-lum by boiling; but when, by keeping, a portion of the water has transuded so as to leave a void space within the shell, the concentrated albumen affords a firm coagulum.

An analogous phenomenon is exhibited by acetate of alumina, a solution of which, being heated, gives a precipitate in flakes, which re-dissolve as the caloric which cipitate in flakes, which re-dissolve as the caloric which separated the particles of acid and base escapes, or as the temperature falls. A solution containing 1-10 of dry albumen forms by heat a solid coagulum; but when it contains only 1-15, it gives a glary liquid. One-thousandth part, however, on applying heat, occasions opalescence. Putrid white of egg, and the pus of ulcers, have a similar smell. According to Dr. Bostock, a drop of a saturated solution of corrosive sublimate let fall into water containing 1-2000 of albumen, occasions a milkiness and curdy precipitate. On adding a slight excess of the mercurial solution to the albuminous liquid, and applying heat, the precipitate which falls. liquid, and applying heat, the precipitate which falls, being dried, contains in every 7 parts 5 of albumen. Hence that salt is the most delicate test of this animal product. The yellow pitchy precipitate occasioned by tannin, is brittle when dried, and not liable to putrefaction. But tannin, or infusion of galls, is a much nicer test of gelatin than of albumen.

The cohesive attraction of coagulated albumen makes it resist putrefaction. In this state it may be kept for weeks under water without suffering change. By long digestion in weak nitric acid, albumen seems convertible into gelatin. By the analysis of Gay Lussac and Thénard, 100 parts of albumen are formed of 52.883 carbon, 23.872 oxygen, 7.540 hydrogen, 15.705 nitrogen; or, in other terms, of 52.883 carbon, 27.127 oxygen and hydrogen, in the proportion for constituting water, 15.705 nitrogen, and, 4.285 hydrogen in excess. The negative pole of a voltaic pile in high activity coagulates albumen; but if the pile be feeble, coagulation goes on only at the positive surface. Albumen, in such a state of concentration as it exists in serum of blood, can dissolve some metallic oxydes, particularly the pro-toxide of iron. Orfila has found white of egg to be the best antidote to the poisonous effects of corrosive sublimate on the human stomach. As albumen occasions precipitates with the solutions of almost every metallic salt, probably it may act beneficially against other spe-

cies of mineral poison.

From its coagulability albumen is of great use in clarifying liquids.

It is likewise remarkable for the property of rendering leather supple, for which purpose a solution of whites of eggs in water is used by leather-dressers.—

Ure's Chem. Dict.

2. In botany, the term albumen is applied to a farinaceous, fleshy, or horny substance, which makes up the chief bulk of some seeds, as grapes, corn, palms, lilies, never rising out of the ground, nor assuming the office of leaves, being destined solely to nourish the germinating embryo, till its roots perform their office. the date palm, this part is nearly as hard as stone, in murabilis it is like wheat-flour. It is wanting in several tribes of plants, as those with compound or with cruciform flowers, and the cucumber or gourd kind, according to Gardner. Some few leguminous plants have it, and a great number of others, which, like them, have cotyledons besides. We are not, however, to suppose, that so important an organ is altogether wanting even in the above-mentioned plants. The farinaing, even in the above-mentioned plants. The farina-ceous matter destined to nourish their embryos, is un-questionably lodged in their cotyledons, the sweet taste of which, as they begin to germinate, often evinces its presence, and that it has undergone the same change as in barley. The allumen of the nutmer is remarkable in barley. The albumen of the numer is remarkable for its eroded variegated appearance, and aromatic quality; the cotyledons of this plant are very small.— Smith-

ALBUMEN OVI. Albugo ovi ; Albumen albor ovi ; | Ovi albus liquor; Ovi candidum albumentum; Cla-reta. The white of an egg.

ALBURNUM. (From albus, white.) The soft

white substance, which, in trees, is found between the liber, or inner bark, and the wood. In process of time it acquires solidity, becoming itself the wood. While soft, it performs a very important part of the functions of growth, which ceases when it becomes hard. A new circle of alburnum is annually formed over the old, so that a transverse section of the trunk presents a pretty correct register of the tree's age, each zone marking one year. From its colour and comparative softness, it has been called by some writers, the adeps arborum. The alburnum is found in largest quantities in trees that are vigorous. In an oak six inches in diameter this substance is oak six inches in diameter, this substance is nearly

equal in bulk to the wood.

A'LBUS, White. This term is applied to many parts, from their white colour; as linea alba, lepra

alba, macula alba, &c.

A'LCAHEST. An Arabic word to express a universal dissolvent, which was pretended to by Paracelsus and Van Helmont. Some say that Paracelsus first used this word, and that it is derived from the German words al and geest, i. e. all spirit: and that Van Hel-mont borrowed the word, and applied it to his inven-tion, which he called the universal dissolvent.

A'LCALI. (Arabian.) This word is spelt indif-ferently with a c or a k. See Alkali.

ALCALIZATION. The impregnating any spritu-

ous fluid with an alcali.

ALCANNA. (Indian word.) See Anchusa.
A'LCANNA. (Indian word.) See Anchusa.
A'LCAOL. The solvent for the preparation of the philosopher's stone.
ALCARRAZES. A species of porous pottery.

made in Spain.

A'LCEA. (Alcea, α. f.; from αλκη, strength.) The name of a genus of plants in the Linnwan system. Class, Monadelphia; Order, Polyandria. Hollyhock. ALCEA ÆGYPTIACA VILLOSA. See Hibiscus Abel-

moschus.

ALCEA INDICA. See Hibiscus Abelmoschus.
ALCEA ROSEA. Common hollyhock. The flowers of this beautiful tree are said to possess adstringent and mutcilaginous virtues. They are seldom used me-

ALCHEMI'LLA. (Alchemilla, a. f. So called be-cause it was celebrated by the old alchemists.)

The name of a genus of plants in the Linnean system. Class, Tetrandria; Order, Monogynia. La-

dies' mantle.

2. The pharmacopeial name of the plant called la-

dies' mantle. Sea Alchemilla vulgaris.

Alchemilla' vulgaris. Ladies' mantle. This plant, Alchemilla:—Foliis lobatis of Linnieus, was formerly esteemed as an adstringent in hæmorrhages, fluor albus, &c. given internally. It is fallen into distis

ALCHEMIST. One who practises the mystical

A'LCHEMY. Alchemia; Alchimia; Alkima. That branch of chemistry which relates to the transmuta-tion of metals into gold;—the forming a panacea or universal remedy,—an alcahest, or universal men-struum,—a universal ferment, and many other [absurdities.

ALCHIMIA. See Alchemy.
ALCHIMI'LLA. See Alchemilla.
A'LCHITRON. 1. Oil of Juniper.

Also the name of a dentifrice of Messue.

A'LCHYMY. Alchemy.
A'LCOHOL. See Alkohol.
ALCYO'NIUM. It is difficult to say what the Greeks called by this name. Dioscorides speaks of five sorts of it. It is a spongy plant-like substance, met with on the sea-shore, of different shapes and colours. This bastard sponge is calcined with a little salt, as a dentifrice, and is used to remove spots on the skip.

ALDER. See Betula alnus.

Alder, berry-bearing. See Rhamnus frangula.
Alder wine. See Betula alnus.
Alderwine. See Alzum.
ALDUM. See Alzum.
ALDUM. See Alzum.
ALE. Cerevisia; Liquor cereris; Vinum bordea-

ceum. A fermented liquor made from malt and hops, and chiefly distinguished from beer, made from the same ingredients, by the quantity of hops used therein, which is greater in beer, and therefore renders the liquor more bitter, and fitter for keeping. Ale, when well fermented, is a wholesome beverage, but seems to disagree with those subject to asthma, or any disorder of the reaminative or irregularity in the disestive to disagree with those subject to asthma, or any disorder of the respiration, or irregularity in the digestive organs. The old dispensatories enumerate several medicated ales, such as cerevisia azydorica, for the eyes; cerevisia antiarthritica, against the gout; cephalica, epileptica, &c. See Beer.

ALEΓON. (Αλειον, copious.) Hippocrates uses this word as an epithet for water.

ALEΓPHA. (From αλειφω, to anoint.) Any medicated oil.

ALELAI'ON. (From αλς, salt, and ελαιον, oil.) Oil beat up with salt, to apply to tumours. Galen fre-

Oil beat up with salt, to apply to tumours. Galen frequently used it.

ALE'MA. (From a. priv. and \(\lambda\tuo\), hunger.)
Meat, food, or any thing that satisfies the appetite.

ALE'MBIC. (Alembicus. Some derive it from the Arabian particle al, and apbit; from apbavo, to ascend. Avicenna declares it to be Arabian.) Moorshead. A chemical utensil made of glass, metal, or earthenware, and adapted to receive volatile products from retorts. It consists of a body to which is fitted a conical head, and out of this head descends laterally a beak to be inserted into the receiver.

ALE'MBROTH. (A Chaldee word, importing the key of art.) 1. Some explain it as the name of a salt, sal mercurii, or sal philosophorum & artis; others say it is named alembrot and sal fusionis or sal faxionis. Alembroth desiccatum is said to be the salt tartari; hence this word seems to signify alkaline salt, which opens the bodies of metals by destroying their sulphurs,

opens the bodies of metals by destroying their sulphurs, and promoting their separation from the ores. From analogy, it is supposed to have the same effect in conquering obstructions and attenuating viscid fluids in

the human body.

2. A peculiar earth, probably containing a fixed alkali, found in the island of Cyprus, has also this ap-

pellation.

3. A solution of the corrosive sublimate, to which the muriate of ammonia has been added, is called sal alembroth.

ALEPE'NSIS. A species of ash-tree, which produces

A'LES. (From αλς, salt.) A compound salt.
ALEU'RON. (From αλεω, to grind.) Meal.
ALEXANDERS. See Smyrnium olusatrum.
Alexanders, round-leaved. See Smyrnium perfo-

ALEXA'NDRIA. Alexandrina. (Alexandria.)

The bay-tree, or laurel, of Alexandria.

Alexa norium. Emplastrum viride. A plaster described by Celsus, made with wax, alum, &c.

ALEXICA CUM. (From αλεξω, to drive away, and κακον, evil.) An antidote or amulet, to resist poison. poison

ALEXIPHA'RMIG. (Alexipharmicum; from αλεξω, to expel, and φαρμακον, a poison.) Antipharmicum; Caco-alexiteria. A medicine supposed to preserve the body against the power of poisons, or to correct or ex-pel those taken. The ancients attributed this propel those taken. The ancients attributed this property to some vegetables and even waters distilled from them. The term, however, is now very seldom used. ALEXIPYRE TICUM. (From αλεξω, to drive away, and πυρετος, fever.) A febrifuge. ALEXIPYRETOS. Alexipyretum. A remedy for

a fever.

ALE'XIR. An elixir.

ALEXITE'RIUM. (Alexiterium, i.n.; from αλεξω, to expel, and τηρεω, to preserve.) A preservative medicine against poison, or contagion.

ALGA. A sea-weed.

ALGE. 1. The name of an order or division of the

ALGE. 1. The name of an order of division of the class Cryptogamia in the Linnæan system of plants. The name of one of the seven families or natural tribes into which the whole vegetable kingdom is divided by Linnæus in his Philosophia Botanica. He defines them plants, the roots, leaves, and stems of which are all in one. Under this description are comprehended all the sea-weeds and some other aquatic plants.

2. In the sexual system of plants Alga constitute

2. In the sexual system of plants Alga constitute the third order of the class, Cryptogamia. From their admitting of little distinction of root, leaf, or stem, and

the parts of their flowers being equally incapable of description, the genera are distinguished by the situation of what is supposed to be the flowers or seeds, or by the resemblance which the whole plant bears to some other substance.

The parts of fructification of the algae are in caly-cules of which there are three varieties:—

1. Pelta, target; a flat, oblong fruit, seen in the Li-

2. Scutella, the saucer; a round, hollow, or flat fruit, as in Lichen stellaris.

3. Tuberculum, the tubercle; a hemispherical fruit, observable in Lichen geographicus.

In the fuci, the parts of fructification are sometimes

in hollow bladders; and in some of the ulvæ, it is dis-persed through the whole substance of the plant.

A'LGAROTH. (So called from Victorius Algaroth, a physician of Verona, and its inventor.) Algarot; Algaroth; Mercurius vitæ; Pulvis Algaroth; Pulvis angelicus; Mercurius mortis. The antimonial part of the butter of antimony, separated from some of its acid by washing it in water. It is violently emetic in doses of two or three grains, and is preferred by many for making the sweet factor.

preferred by many for making the emetic tartar.

ALGE'DO. (From αλγος, pain.) A violent pain about the anus, perinæum, testes, urethra, and bladder, arising from the sudden stoppage of a virulent go-

der, arising from the sudden stoppage of a virulent gonorrhæa. A term very seldom used.

ALGE'MA. (From αλγεω, to be in pain.) Algemodes; Algematodes. Uneasiness; pain of any kind.

A'LGOR. A sudden chillness or rigour.

ALGOSAREL. The Arabian term for the wild carrot.

See Dancus sylvestris.

ALHA'GI. (Arabian.) A species of Hedysarum.

The leaves are but and number the flowers pure

The leaves are hot and pungent, the flowers purgative.

ALHA'NDALA. An Arabian name for the colocynth,

or bitter apple.

Alha'ser. (Arabian.) Alhasaf. A sort of fætid

pustule, called also Hydroa.

A'LIA SQUILLA. (From aλιος, belonging to the sea, and σκιλλα, a shrimp.) The prawn. A species of the genus cancer.

A'LICA. (From alo, to nourish) In general signification, a grain, a sort of food admired by the ancients. It is not certain whether it is a grain or, a preparation of some kind thereof.

ALICASTRUM. (From alica, as siliquastrum from siliqua.) A kind of bread mentioned by Celsus.

A'LICES. (From αλιζω, to sprinkle.) Little red

spots in the skin, which precede the eruption of pustules in the small-pox.

ALIENA'TIO MENTIS. Estrangement of the mind. ALIENA'TION. (Alienatio; from alieno, to estrange.) A term applied to any wandering of the

ALIENA'TUS. Alienated. A leaf is so termed when the first leaves give way to others totally different from them, and the natural habit of the genus, as

is the case in many of the mimosæ from New Holland.
ALIFO'RMIS. Alæform, or wing-like. A name given by anatomists and naturalists to some parts from their supposed resemblance, as aliform muscles, &c. See Alaformis.

ALIMENT. (Alimentum; from alo, to nourish.)
The name of aliment is given generally to every substance, which being subjected to the action of the organs of digestion, is capable by itself of affording nourishment. In this sense an aliment is extracted necessarily from vegetables or animals: for only those bodies that have possessed life are capable of serving usefully in the nutrition of animals during a certain time. This manner of regarding aliments appears rather too confined. Why refuse the name of aliments to substances which, in reality, cannot of them-selves afford nourishment, but which contribute efficaciously to nutrition, since they enter into the compociously to nutrition, since they enter into the compo-sition of the organs, and of the animal fluids? Such are the muriate of soda, the oxyde of iron, silicia, and particularly water, which is found in such abundance in the bodies of animals, and is so necessary to them. It appears preferable to consider as an aliment every substance which can serve in nutrition; establishing, however, the important distinction between substances which can nourish of themselves, and those which are useful to nutrition only in concert with the former.

In respect to their nature, aliments are different oysters.

from each other, by the proximate principles which predominate in their composition. They may be distinguished into nine classes:

1st, Farinaceous aliments: wheat, barley, oats, rye, maize, potato, sago, salep, peas, haricots,

rice, rye, maize, potato, sago, salep, peas, haricots, lentils, &c.

2d, Mucilaginous aliments: carrots, salsafy, (goats-beard) beet-root, turnip, asparagus, cabbage, lettuce, artichoke, cardoons, pompions, melons, &c.

3d, Sweet aliments: the different sorts of sugar figs, dates, dried grapes, apricots, &c.

4th, Acidulous aliments: oranges, gooseberries, cherries, peaches, strawberries, raspberries, mulberriès, grapes, prunes, pears, apples, sorrel. &c.

grapes, prunes, pears, apples, sorrel, &c.
5th, Fatty and oily aliments: cocoa, olives, sweet almonds, nuts, walnuts, the animal fats, the oils,

butter, &c.
6th, Caseous aliments: the different sorts of milk,

7th, Gelatinous aliments: the tendons, the aponeurosis, the chorion, the cellular membrane, young animals, &c

8th, Albuminous aliments: the brain, the nerves,

9th, Fibrinous aliments: the flesh and the blood of different animals

We might add to this list a great number of substances that are employed as medicines, but which doubtless are nutritive, at least in some of their im-mediate principles; such are manna, tamarinds, the pulp of cassia, the extracts and saps of vegetables, the animal or vegetable decoctions.

Among aliments there are few employed such as nature presents them; they are generally prepared, and disposed in such a manner as to be suitable to the and disposed in such a manner as to be surface action of the digestive organs. The preparations which they undergo are infinitely various, according to the sort of aliment, the people, the climates, customs, the degree of civilization: even fashion is not without its influence on the art of preparing aliments.

In the hand of the skilful cook, alimentary substances almost entirely change their nature:-form, consistence, odour, taste, colour, composition, &c., every thing is so modified that it is impossible for the most delicate tastes to recognise the original substance

of certain dishes.

The useful object of cookery is to render aliments agreeable to the senses, and of easy digestion; but it rarely stops here: frequently with people advanced in civilization its object is to excite delicate palates, or difficult tastes, or to please vanity. Then, far from being a useful art, it becomes a real scourge, which occasions a great number of diseases and here for occasions a great number of diseases, and has frequently brought on premature death.

We understand by drink, a liquid which, being in-troduced into the digestive organs, quenches thirst, and so by this repairs the habitual losses of our fluid humours: the drinks ought to be considered as real

aliments.

The drinks are distinguished by their chemical composition:

1st, Water of different sorts, spring water, river wa-

ter, water of wells, &c.
2d, The juices and infusions of vegetables and animals, juices of lemon, of gooseberries, whey, tea, coffee, &c.
3d, Fermented liquors: the different sorts of wine,

beer, cider, perry, &c.
4th, The alcoholic liquors: brandy, alcohol, ether,

rum, sack, ratafia.
ALIMENTARY. Alimentarius. Nourishing or

belonging to food.

ALIMENTARY CANAL. Canalis alimentarius. Alimentary duct. A name given to the whole of those passages which the food passes through from the mouth to the anus. This duct may be said to be the true characteristic of an animal; there being no animal without it, and whatever has it, being properly ranged under the class of animals. Plants receive their nourishment by the numerous fibres of their roots, but nourishment by the numerous nores of their roots, but have no common receptacle for digesting the food received, or for carrying off the excrements. But in all, even the lowest degree of animal life, we may observe a stomach, if not also intestines, even where we cannot perceive the least formation of any organs of the senses, unless that common one of feeling, as in ALIMENTARY DUCT. 1. The alimentary canal. See

Alimentary canal.
2. The thoracic duct is sometimes so called. See Thoracic duct.

ALIMOS. Common liquorice.

A'LIMUM. A species of arum.

ALIPA'SMA. (From αλειφω, to anoint.) An ointment rubbed upon the body to prevent sweating.

ALIPOW. A species of turbith, found near Mount Ceti, in Languedoc. It is a powerful purgative, used instead of senna, but is much more active.

ALIPTÆ. (From αλειφω, to anoint.) Those who

anointed persons after bathing.

anomied persons after batting.

"Alisanders. The same as alexanders.

ALI'SMA. (Alisma; from αλς, the sea.) The name of a genus of plants in the Linnæan system.

Class, Hezandria; Order, Polygynia. Water-plantain.

ALISMA PLANTAGO AQUATICA. The systematic

name of the water-plantain, now fallen into disuse.

A'LIT. Alith. Asafætida.

A'LKAHAT GLAUBE'RI. Ån alkaline salt.

A LEANLEST. An imaginary universal menstruum, or solvent. See Alcahest.

A'LKAHEST GLAUBE'RI. An alkaline salt.
ALKALESCENT. Alkalescens. Any substance in which alkaline properties are beginning to be developed, or to predominate, is so termed.

A'LKALI. (Alcali, in Arabic, signifies burnt; or from al and kali, i. e. the essence, or the whole of kali, the plant from which it was originally prepared, though now derived from plants of every kind. Alcali;

alifi; alafor; alafort; calcadis.

Alkalies may be defined, those bodies which combine with acids, so as to neutralize or impair their activity, and produce salts. Acidity and alkalinity are therefore two correlative terms of one species of combine with a combine and the combine and th bination. When Lavoisier introduced oxygen as the acidifying principle, Morveau proposed hydrogen as the alkalifying principle, from its being a constituent of volatile alcali or ammonia. But the splendid discovery by Sir H. Davy, of the metallic basis of potassa and soda, and of their conversion into alkalies, by combination with oxygen, has banished for ever that hypothetical conceit. It is the mode in which the constituents are combined, rather than the nature of the constituents themselves, which gives rise to the acid or alkaline condition. Some metals combined with oxygen in one proportion, produce a body possessed of alkaline properties; in another proportion, of acid properties. And on the other hand, ammonia and prussic acid prove that both the alkaline and acid conditions can exist independent of oxygen. conditions can exist independent of oxygen. These observations, by generalizing our notions of acids and alkalies, have rendered the definitions of them very imperfect. The difficulty of tracing a limit between the acids and alkalies is still increased, when we find a body sometimes performing the functions of an acid, sometimes of an alkali. Nor can we diminish this sometimes of an alkali. Nor can we diminish this difficulty by having recourse to the beautiful law discovered by Sir H. Davy, that oxygen and acids go to the positive pole, and hydrogen alkalies, and inflammable bases to the negative pole. We cannot in fact give the name of acid to all the bodies which go to the first of these poles, and that of alkali to those that go to the second; and if we wished to define the alkalies by beinging into their clerking course. to the second; and if we wished to define the alkanes by bringing into view their electric energy, it would be necessary to compare them with the electric energy which is opposite to them. Thus we are always reduced to define alkalinity by the property which it has of saturating acidity, because alkalinity and acidity are two correlative and inseparable terms. M. Gay Lussac conceives the alkalinity which the metallic oxides enjoy, to be the result of two opposite properties, the alkalifying property of the metal, and the acidifying of oxygen, modified both by the combination and by the proportions.

The alkalies may be arranged into three classes:

1st, Those which consist of a metallic basis combined with oxygen. These are three in number, potassa, soda, and lithia. 2d, That which contains no oxygen, viz. ammonia. 3d, Those containing oxygen, hydrogen, and carbon. In this class we have aconita, atropia, brucia, cicuta, datura, delphia, hyosciama, morphia, strychnia, and perhaps some other truly vegeta-ble alkalies. The order of vegetable alkalies may be as numerous as that of vegetable acids. The earths, lime, barytes, and strontites, were enrolled among the

alkalies by Fourcroy, but they have been kept apart by other systematic writers, and are called alkaline earths. Besides neutralizing acidity, and thereby giving birth to salts, the first four alkalies having the following properties:

1st, They change the purple colour of many vegeta-bles to a green, the reds to a purple, and the yellows to a brown. If the purple have been reddened by acid,

alkalies restore the purple.

2d, They possess this power on vegetable colours after being saturated with carbonic acid, by which criterion they are distinguishable from the akaline

3d. They have an acrid and urinous taste.

4th, They are powerful solvents or corrosives of animal matter; with which, as well as with oils in general, they combine, so as to produce neutrality

5th, They are decomposed, or volatilized, at a strong

6th, They combine with water in every proportion,

and also largely with alcohol.

7th, They continue to be soluble in water when neutralized with carbonic acid; while the alkaline earths

thus become insoluble.

It is needless to detail at length Dr. Murray's speculations on alkalinity. They seem to flow from a par-tial view of chemical phenomena. According to him, either oxygen or hydrogen may generate alkalinity, but the combination of both principles is necessary to either oxygen or hydrogen may generate alkalinity, but the combination of both principles is necessary to give this condition its utmost energy. "Thus the class of alkalies will exhibit the same relations as the class of acids. Some are compounds of a base with oxygen; such are the greater number of the metallic oxydes, and probably of the earths. Ammonia is a compound of a base with hydrogen. Potassa, soda, barytes, strontites, and probably lime, are compounds of bases with oxygen and hydrogen; and these last, like the analogous order among the acids, possess the highest power." Now, perfectly dry and caustic barytes, lime, and strontites, as well as the dry potassa and soda obtained by Gay Lussac and Thenard, are not inferior in alkaline power to the same bodies after they are slacked or combined with water. 100 parts of lime destitute of hydrogen, that is, pure oxyde of calcium, neutralize 78 parts of carbonic acid. But 132 parts of Dr. Murray's strongest lime, that is, the hydrate, are required to produce the same alkaline effect. If we ignite nitrate of barytes, we obtain, as is well known, a perfectly dry barytes, or protoxide of barium; but if we ignife crystallized barytes, we obtain the same alkaline earth combined with a prime equivalent of water. These two different states of barytes were demonstrated by M. Berthollet in an excellent paper published in the 2d volume of the Memoirs D'Arcueil, so far back as 1809. "The first barytes," (that from crystallized barytes) says he, "presents all the characters of a combination; it is engaged with a substance which diminishes its action on other bodies, the characters of a combination; it is engaged with a substance which diminishes its action on other bodies, which renders it more fusible, and which gives it by fusion the appearance of glass. This substance is nothing else but water; but in fact, by adding a little water to the second barytes (that from ignited nitrate) water to the second barytes (that from ignited nitrate) and by urging it at the fire, we give it the properties of the first." Page 47. 100 parts of barytes void of hydrogen, or dry barytes, neutralize 28 1-2 of dry carbonic acid. Whereas 111 2-3 parts of the hydrate, or what Dr. Murray has styled the most energetic, are required to produce the same effect. In fact, it is not hydrogen which combines with the pure barytic earth, but hydrogen and oxygen in the state of water. The but hydrogen and oxygen in the state of water. The proof of this is, that when carbonic acid and that hydrate unite, the exact quantity of water is disengaged. The protoxide of barium, or pure barytes, has never been combined with hydrogen by any chemist.— Ure's Chem. Dict.

ALKALI CAUSTICUM. Caustic alkali. An alkali is so called when deprived of the carbonic acid it usually contains, for it then becomes more caustic, and more violent in its action.

Alkali, caustic valatile. See Ammonia.

Alkali, phlogisticated. Prussian alkali. When a fixed alkali is ignited with bullock's blood, or other animal substances, and lixiviated, it is found to be in a great measure saturated with prussic acid: from the theories formerly adopted respecting this combination, it was called phlogisticated alkali.

ALKALI FIXUM. Fixed alkali. Those alkalies are

so called that emit no characteristic smell, and cannot be volatilized, but with the greatest difficulty. Two kinds of fixed alkalies have only hitherto been made known, namely potassa and soda. See Potassa and

Alkali, fossile. See Soda.

Alkali, mineral. See Soda.

Alkali, Prussian. See Alkali, phlogisticated.

Alkali, vegetable. See Potassa.

Alkali, volatile. See Ammonia.

ALKALI'NA. Alkalines. A class of substances described by Cullen as comprehending the substances otherwise termed antacida. They consist of alkalies, and other substances which neutralize acids. The principal alkalines in use, are the carbonates and sub-carbonates of soda and potassa, the subcarbonate of ammonia, lime-water, chalk, magnesia and its car-

ALKALIZATION. Alkalizatio. The impreg-nating any thing with an alkaline salt, as spirit of

ALKALOMETER. The name of an instrument for determining the quantity of alkali in commercial potassa and soda.

A'LKANET. (Alkanah, a reed, Arabian.) See Anchusa tinctoria.

ALEA'NNA. See Anchusa.

ALEA'NNA ve'ra. See Lawsonia'inermis.

ALKEKE'NGI. (Arabian.) The winter-cherry.

See Physalis alkekengi.

ALKE'RMES. A term borrowed from the Arabs, denoting a celebrated remedy, of the form and consistence of a confection, whereof the kermes is the basis. See Kermes.

ALKIMA. See Alchemy.
A'LKOHOL. (An Arabian word, which signifies antimony: so called from the usage of the Eastern ladies to paint their eyebrows with antimony, reduced to a most subtile powder; whence it at last came to signify any thing exalted to its highest perfection.)
Alcohol; Alkol; Spiritus vinosus rectificatus; Spiritus vini rectificatus; spiritus vini concentratus; Spiritus vini rectificatissimus.

1. This term is applied in strictness only to the pure spirit obtainable by distillation and subsequent rectifi-cation from all liquids that have undergone vinous fermentation, and from none but such as are susceptible of it. But it is commonly used to signify this spirit more or less imperfectly freed from water, in the state in which it is usually met with in the shops, and in which, as it was first obtained from the juice of the grape, it was long distinguished by the name of spirit of wine. At present it is extracted chiefly from grain or molasses in Europe, and from the juice of the sugar cane in the West Indies; and in the diluted state in which it commonly occurs in trade, constitutes the basis of the several spirituous liquors called brandy, rum, gin, whiskey, and cordials, however variously denominated or disguised.

As we are not able to compound alkohol immediately from its ultimate constituents, we have recourse to the process of fermentation, by which its principles are first extricated from the substances in which they were combined, and then united into a new compound; to distillation, by which this new compound, the alkohol, is separated in a state of dilution with water, and contaminated with essential oil; and to rectification,

by which it is ultimately freed from these.

It appears to be essential to the fermentation of alkohol, that the fermenting fluid should contain saccharine matter, which is indispensable to that species of fermentation called vinous. In France, where a great deal of wine is made, particularly at the commencement of the vintage, that is too weak to be a saleable commodity, it is a common practice to subject this wine to distillation, in order to draw off the spirit; and as the essential oil that rises in this process is of a more pleasant flavour than that of malt or molasses, the French brandies are preferred to any other; though even in the flavour of these there is a difference, according to the wine from which they are produced. In the West Indies a spirit is obtained from the juice of the sugar-cane, which is highly impregnated with its essential oil, and well known by the name of rum. The distillers in this country use grain, or molasses, whence they distinguish the products by the name of malt spirits, and melasses spirits. It is said that a very good spirit may be extracted from the husks of gooseberries or currants, after wine has been made from them.

As the process of malting developes the saccharine principle of grain, it would appear to render it fitter for the purpose; though it is the common practice to use the purpose; though it is the common practice to use about three parts of raw grain with one of malt. For this two reasons may be assigned: by using raw grain, the expense of malting is saved, as well as the duty on malt; and the process of malting requires some nicety of attention, since, if it be carried too far, part of the saccharine matter is lost, and if it be stopped too soon, this matter will, not be wholly developed. Resides, if saccharine matter is lost, and if it be stopped too soon, this matter will not be wholly developed. Besides, if the malt be dried too quickly, or by any unequal heat, the spirit it yields will be less in quantity, and more unpleasant in flavour. Another object of economical consideration is, what grain will afford the most spirit in proportion to its price, as well as the best in quality. Barley appears to produce less spirit than wheat; and if three parts of raw wheat be mixed with one of malted harley, the produce is said to be particularly. malted barley, the produce is said to be particularly fine. This is the practice of the distillers in Holland for producing a spirit of the finest quality; but in England they are expressly prohibited from using more than one part of wheat to two of other grain. Rye, however, affords still more spirit than wheat.

Other articles have been employed, though not generally, for the fabrication of spirit, as carrots and potatoes; and we are lately informed by Professor Proust, that from the fruit of the carob tree he has obtained good brandy in the proportion of a pint from five pounds of the dried fruit.

To obtain pure alkohol, different processes have been recommended; but the purest rectified spirit obtained as above described, being that which is least contaminated with foreign matter, should be employed. Rouelle recommends to draw off half the spirit in a water bath; to rectify this twice more, drawing off two-thirds each time; to add water to this alkohol, which will turn it milky by separating the essential oil remaining in it; to distil the spirit from this water; and finally rectify it by one more distillation.

Baumé sets apart the first running, when about a

Baumé sets apart the first running, when about a fourth is come over, and continues the distillation till he has drawn off about as much more, or till the liquor runs off milky. The last running he puts into the still again, and mixes the first half of what comes over with the preceding first product. This process is again repeated, and all the first products being mixed together, are distilled afresh. When about half the liquor is come over, this is to be set apart as pure

Alkohol in this state, however, is not so pure as when, to use the language of the old chemists, it has when, to use the language of the old chemists, it has been dephlegmated, or still further freed from water, by means of some alkaline salt. Boerhaave recommended, for this purpose, the muriate of soda, deprived of its water of crystallization by heat, and added hot to the spirit. But the subcarbonate of potassa is preferable. About a third of the weight of the alkohol should be added to it in a glass vessel, well shaken, and then suffered to subside. The salt will be moistened by the water absorbed from the alkohol; which being decanted, more of the salt is to be added, and being decanted, more of the salt is to be added, and this is to be continued till the salt falls dry to the bottom of the vessel. The alkohol in this state will be reddened by a portion of the pure potassa, which it will hold in solution, from which it must be freed by

distillation in a water bath. Dry muriate of lime may be substituted advantageously for the alkali.

As alkohol is much lighter than water, its specific gravity is adopted as the test of its purity. Fourcroy considers it as rectified to the highest point when its specific gravity is 829, that of water being 1000; and perhaps this is nearly as far as it can be carried by the process of Rouelle or Baumé simply. Bories found the first measure that came over from twenty of spirit at 836 to be 820, at the temperature of 71° F. Sir Charles Blagden, by the addition of alkali, brought it to 813, at 60° F. Chaussier professes to have reduced it to 798; but he gives 998.35 as the specific gravity of water. Lowitz asserts that he has obtained it at 791, by adding as much alkali, as pearly to absorb the water. Lowitz asserts that he has obtained by adding as much alkali as nearly to absorb the spirit by adding as much alkali as nearly to absorb the spirit but the temperature is not indicated. In the shops, it is about 835 or 840: according to the London College

it should be 815. It is by no means an easy undertaking to determine

the strength or relative value of spirits, even with sufficient accuracy for commercial purposes. The fol-lowing requisites must be obtained before this can be well done: the specific gravity of a certain number of mixtures of alkohol and water must be taken so near each other, as that the intermediate specific gravities may not perceptibly differ from those deduced from the supposition of a mere mixture of the fluids; the expansions or variations of specific gravity in these mixtures must be determined at different temperatures; some easy method must be contrived of determining the presence and quantity of saccharine or oleaginous matter which the spirit may hold in solution, and the effect of such solution on the specific gravity; and lastly, the specific gravity of the fluid must be ascertained by a proper floating instrument with a graduated stem or set of weights; or, which may be more convenient with both venient, with both.

The most remarkable characteristic property of alkohol, is its solubility or combination in all proportions with water; a property possessed by no other comwith water; a property possessed by no other com-bustible substance, except the acetic spirit obtained by distilling the dry acetates. When it is burned in a chimney which communicates with the worm-pipe of a distilling apparatus, the product, which is condensed, is found to consist of water, which exceeds the spirit in weight about one-eighth part; or more accurately, 100 parts of alkohol, by combustion, yield 136 of water. If alkohol be burned in closed vessels with vital air, the product is found to be water and car-bonic acid. Whence it is inferred that alkohol con-sists of hydrogen, united either to carbonic acid, or its sists of hydrogen, united either to carbonic acid, or its acidifiable base; and that the oxygen uniting on the one part with the hydrogen, forms water; and on the other with the base of the carbonic acid, forms that

The most exact experiments on this subject are those recently made by De Saussure. The alkohol he used had, at 62.80, a specific gravity or 0.8302; and by Richter's proportions, it consists of 13.8 water, and 86.2 of absolute alkohol. The vapour of alkohol was made to traverse a narrow porcelain tube ignited; from which the products passed along a glass tube about six feet in length, refrigerated by ice. A little charcoal was deposited in the porcelain, and a trace of oil in the glass tube. The resulting gas being analyzed in an exploding eudlometer, with oxygen, was found to resolve itself into carbonic acid and water. Three volumes of oxygen disappeared for every two volumes of carbonic acid produced; a proportion which obtains in the analysis by oxygenation of olewhich obtains in the analysis by oxygenation of ole-gas of this peculiar constitution, and condensed water equal to 1000-4064 of the original weight of the alkohol, we may conclude that vapour of water and olefiant gas are the sole constituents of alkohol. Subtracting the 13.8 per cent. of water in the alkohol at the beginning of the experiment, the absolute alcohol of Richter will consist of 13.7 hydrogen, 51.98 carbon, and 31.32 oxygen. Hence Gay Lussac infers, that alkohol, in vapour, is composed of one volume olefiant gas, and one volume of the vapour of water, condensed by chemical affinity into one volume.

of aqueous vapour is.....0.62500

Sum=1.60304

And alkoholic vapour is=1.6133 These numbers approach nearly to those which would result from two prime equivalents of olefant gas, combined with one of water; or ultimately, three of hydrogen, two of carbon, and one of oxygen.

The mutual action between alkohol and acids produces a light, volatile, and inflammable substance, called æther. Pure alkalies unite with spirit of wine, and form alkaline tinctures. Few of the neutral salts unite with this fluid, except such as contain ammonia. The carbonated fixed alkalies are not soluble in it. From the strong attraction which exists between alkohol and water, it unites with this last in saling solutions. hol and water, it unites with this last in saline solu-tions, and in most cases precipitates the salt. This is a pleasing experiment, which never fails to surprise those who are unacquainted with chemical effects. If, for example, a saturated solution of nitre in water be taken, and an equal quantity of strong spirit of wine be poured upon it, the mixture will constitute a weaker spirit, which is incapable of holding the nitre in solu-

tion; it therefore falls to the bottom instantly, in the

form of minute crystals.

The degree of solubility of many neutral salts in alkohol have been ascertained by experiments made by Macquer, of which an account is published in the Memoirs of the Turin Academy.

All deliquescent salts are soluble in alkohol. hol holding the strontitic salts in solution, gives a flame of a rich purple. The cupreous salts and boracic acid give a green; the soluble calcareous, a reddish; the

barytic, a yellowish.
The alkohol of 0.825 has been subjected to a cold of

— 916 without congealing.

When potassium and sodium are put in contact with the strongest alkohol, hydrogen is evolved. When chlorine is made to pass through alkohol in a Woolfe's contact with the strongest alkohol, hydrogen is evolved. apparatus, there is a mutual action. Water, an oily looking substance, muriatic acid, a little earbonic acid and carbonaceous matter, are the products. This oily substance does not redden turnsole, though its analysis by heat shows it to contain muriatic acid. It is white,

by heat shows it to contain muriatic acid. It is white, denser than water, has a cooling taste analogous to mint, and a peculiar, but not æthereous odour. It is very soluble in alkohol, but scarcely in water. The strongest alkalies hardly operate on it.

It was at one time maintained, that alkohol did not exist in wines, but was generated and evolved by the heat of distillation. On this subject Gay Lussac made some decisive experiments. He agitated wine with litharge in fine powder, till the liquid became as limpid as water, and then saturated it with subcarbonate of potassa. The alkohol immediately separated and as water, and then saturated it with subcarbonate of potassa. The alkohol immediately separated and floated on the top. He distilled another portion of wine in vacuo, at 59° Fahr., a temperature considerably below that of fermentation. Alkohol came over. Mr. Brande proved the same position by saturating wine with subacetate of lead, and adding potassa.

Adem and Duportal have substituted for the redistillations used in converting wine or beer into alkohol, a single process of great elegance. From the capital of the still a tube is led into a large copper recipient. This is joined by a second tube to a second recipient.

This is joined by a second tube to a second recipient, and so on through a series of four vessels, arranged like a Woolfe's apparatus. The last vessel communicates with the worm of the first refrigeratory. This, the body of the still, and the two recipients nearest it, are charged with the wine or fermented liquor. When ebullition takes place in the still, the vapour issuing from it communicates soon the boiling temperature to the liquor in the two recipients. From these the volatilized alkohol will rise and pass into the third vessel, which is empty. After communicating a certain heat to it, a portion of the finer or less condensible spirit will pass into the fourth, and thence, in a little, into the worm of the first refrigeratory. The wine round the worm will likewise acquire heat, but more slowly. The vapour that in that event may pass uncondensed through the first worm, is conducted into a second, surrounded with cold water. Whenever the still is worked off, it is replenished by a stop-cock from the nearest recipient, which, in its turn, is filled from the second, and the second from the first worm tub. It is evident, from this arrangement, that by keeping the third and fourth recipients at a certain temperature, we may cause alkohol, of any degree of lightness, to form directly at the remote extremity of the apparatus. The utmost economy of fuel and time is also secured, and a better flavoured spirit is obtained. The arrière gout of bad spirit can scarcely be destroyed by infu-sion with charcoal and redistillation. In this mode of operating, the taste and smell are excellent, from the first. Several stills on the above principle have been constructed at Glasgow for the West India distillers, and have been found extremely advantageous. The excise laws do not permit their employment in the home trade.

If sulphur in sublimation meet with the vapour of alkohol, a very small portion combines with it, which communicates a hydrosulphurous smell to the fluid. The increased surface of the two substances appears to favour the combination. It had been supposed, that this was the only way in which they could be united; but Favre has lately asserted, that having digested two drachms of flowers of sulphur in an ounce of alkohol, over a gentle fire not sufficient to make it boil, for twelve hours, he obtained a solution that gave twenty-three grains of precipitate. A similar mixture left to

stand for a month in a place exposed to the solar rays, afforded sixteen grains of precipitate; and another from which the light was excluded, gave thirteen grains. If alkohol be boiled with one-fourth of its weight of sul-phur for an hour, and filtered hot, a small quantity of minute crystals will be deposited on cooling; and the clear fluid will assume an opaline hue on being diluted with an equal quantity of water, in which state it will pass the filter, nor will any sediment be deposited for several hours. The alkohol used in the last-mentioned experiment did not exceed 840.

Phosphorus is sparingly soluble in alkohol, but in greater quantity by heat than in cold. The addition of water to this solution affords an opaque milky fluid, which becomes clear by the subsidence of the phos-

Earths seem to have scarcely any action upon alkohol. Quicklime, however, produces some alteration in this fluid, by changing its flavour, and rendering it of a yellow colour. A portion is probably taken up.

Soaps are dissolved with great facility in alkohol, with which they combine more readily than with

water. None of the metals, or their oxydes, are acted upon by this fluid. Resins, essential oils, camphor, bitumen, and various other substances, are dissolved with great facility in alkohol, from which they may be precipitated by the addition of water. From its property of dissolving resins, it becomes the menstruum of some varnishes.

Camphor is not only extremely soluble in alkohol, but assists the solution of resins in it. Fixed oils, when rendered drying by metallic oxydes, are soluble in it, as well as when combined with alkalies.

Wax, spermaceti, biliary calculi, urea, and all the animal substances of a resinous nature, are soluble in alkohol; but it curdles milk, coagulates albumen, and hardens the muscular fibre and coagulum of the blood.

The uses of alkohol are various. As a solvent of resinous substances and essential oils, it is employed both in pharmacy and by the perfumer. When diluted with an equal quantity of water, constituting what is called proof spirit, it is used for extracting tinctures from vegetable and other substances, the alkohol dissolving the resinous parts, and the water the gununy. From giving a steady heat without smoke when burnt. in a lamp, it was formerly much employed to keep water boiling on the tea-table. In thermometers, for measuring great degrees of cold, it is preferable to mer-cury, as we cannot bring it to freeze. It is in common use for preserving many anatomical preparations, and certain subjects of natural history; but to some it is injurious, the molluscæ for instance, the calcareous covering of which it in time corrodes. It is of considerable use, too, in chemical analysis, as appears under the different articles to which it is applicable.

From the great expansive power of alkohol, it has been made a question, whether it might not be applied with advantage in the working of steam engines. From a series of experiments made by Betancourt, it appears, that the steam of alkohol has, in all cases of equal temperature, more than double the force of that of water; and that the steam of alkohol at 174° F. is equal to that of water 212°; thus there is a considerable diminution of the consumption of fuel, and where this is so expensive as to be an object of great importance, by contriving the machinery so as to prevent the alkohol from being lost, it may possibly at some future time be used with advantage, if some other fluid of great expansive power, and inferior price, be not found more

Afkohol may be decomposed by transmission through a red-hot tube: it is also decomposable by the strong acids, and thus affords that remarkable product, ETHER,

and OLEUM VINI .- Ure's Chem. Dict

and OLEUM VINI.—Ure's Chem. Dict.

2. The alkohol of the London Pharmacopæia is directed to be made thus.—Take of rectified spirit, a gallon; subcarbonate of potassa, three pounds. Add a pound of the subcarbonate of potassa, previously heated to 300°, to the spirit, and macerate for twenty-four hours, frequently stirring them; then pour off the spirit, and add to it the rest of the subcarbonate of potassa heated to the same degree charle, with the aid. potassa heated to the same degree; lastly, with the aid of a warm bath, let the alkohol distil over, keep it in a well-stopped bottle. The specific gravity of alkohol is to the specific gravity of distilled water, as 815 to

ALLAGITE. A carbosilicate of manganese.

ALLANITE. A mineral, first recognised as a distinct species by Mr. Allan of Edinburgh. It is massive and of a brownish black colour.

[Before the blowpipe it froths, and is converted into scoria. In nitric acid it forms a jully. It contains silex 35.4, lime 9.2, oxide of cerium 33.9, alumine 4.1, oxide of iron 25.4, volatile matter 4.0. It is found in Greenland, and associated with mica and feldspar. A.]

ALLANTOL'DES. (From allantolides, and toos, likeness: because in some brutal animals it is long and thick.) Membrana allantolides. A membrane of the feetus, peculiar to brutes, which contains the urine discharged from the bladder.

urine discharged from the bladder.

ALLELUI'A. (Hebrew. Praise the Lord.) So named from its many virtues. See Ozalis acetosella. ALL-GOOD. See Chenopodium bonushenricus. ALL-HEAL. See Heraclium and Stachys.

ALLIA CEOUS. (Alliaceus; from allium, garlick.)

Pertaining to garlick.

ALLIA'RIA. (From allium, garlick: from its smell resembling garlick.) See Erysimum alliaria.

A'LLIUM. (Allium, i. n.; from oleo, to smell; because it stinks: or from αλεω, to avoid; as being unpleasant to most people.) Garlick.

1. The name of a genus of plants in the Linnæan system. Class. Herandria: Order. Monogumia.

em. Class, Hexandria; Order, Monogynia.

2. The pharmacopæial name of garlick. See Allium

sativum.

ALLIUM CEPA. Cepa, Allium:—scapo nudo infernè ventricoso longiore, foliis teretibus, of Linnœus. The Onion. Dr. Cullen says, onions are acrid and stimulating, and possess very little nutriment. With bilious constitutions they generally produce flatulency, thirst, headache, and febrile symptoms: but where the temperament is phlegmatic, they are of infinite service, by stimulating the habit and promoting the natural secretions, particularly expectoration and urine. They are tions, particularly expectoration and urine. They are recommended in scorbutic cases, as possessing antiscorbutic properties. Externally, onions are employed in suppurating poultices, and suppression of urine in children is said to be relieved by applying them, roasted, to the pubes.

ALLIUM PORRUM. The Leek or Porret. Every part of this plant, but more particularly the root, abounds with a peculiar odour. The expressed juice ossesses diuretic qualities, and is given in the cure of dropsical diseases, and calculous complaints, asthma, and scurvy. The fresh root is much employed for

culinary purposes.

ALLIUM SATIVUM. Allium; Theriaca rusticorum. Garlick. Allium:—caule planifolio bulbifero, bulbo composito, staminibus tricuspidatis, of Linnæus. This species of Garlick, according to Linnæus, grows spontaneously in Sicily; but, as it is much employed for culinary and medicinal purposes, it has been long very generally cultivated in gardens. Every part of the plant, but more especially the root, has a pungent acrimonious taste, and a peculiarly offensive strong smell. This odour is extremely penetrating and diffusive; for, on the root being taken into the stomach, the alliaceous scent impregnates the whole system, and is discoverable in the various excretions, as in the urine, perspiration, milk, &c. Garlick is generally allied to the onion, from which it seems only to differ in being more powerful in its effects, and in its active matter, being in a more fixed state. By stimulating the stomach, they both favour digestion, and, as a stimulus, are readily diffused over the system. They may, therefore, be con-sidered as useful condiments with the food of phlegmatic people, or those whose circulation is languid, and secretions interrupted; but with those subject to inflam-matory complaints, or where great irritability prevails, these roots, in their acrid state, may prove very hurtful. The medicinal uses of garlick are various; it has been long in estimation as an expectorant in pituitous asthmas, and other pulmonary affections, unattended with inflammation. In hot bilious constitutions, therefore, garlick is improper: for it frequently produces flatu-lence, headache, thirst, heat, and other inflammatory symptoms. A free use of it is said to promote the piles in habits disposed to this complaint. Its utility as a in habits disposed to this complaint. Its atmix as a diuretic in dropsies is attested by unquestionable authorities; and its febrifuge power has not only been experienced in preventing the paroxysms of intermittents, but even in subduing the plague. Bergius says quartans have been cured by it; and he begins by giving one bulb, or clove, morning and evening, adding

ALL ALL

every day one more, till four or five cloves be taken at a dose: if the fever then vanishes, the dose is to be diminished, and it will be sufficient to take one or two cloves, twice a day, for some weeks. Another virtue of garlick is that of an anthelminthic. It has likewise been found of great advantage in scorbutic cases, and in calculous disorders, acting in these not only as a diuretic, but, in several instances, manifesting a lithontriptic power. That the juice of alliaceous plants, in general, has considerable effects upon human calculi, is to be inferred from the experiments of Lobb; and we are abundantly warranted in asserting that a decoction of the beards of leeks, taken, liberally, and its use persevered in for a length of time, has been found remarkably successful in calculous and gravelly complaints. ably successful in calculous and gravelly complaints. The penetrating and diffusive acrimony of garlick, renders its external application useful in many disorders, as a rubefacient, and more especially as applied to the soles of the feet, to cause a revulsion from the head or breast, as was successfully practised and recommended by Sydenham. As soon as an inflammation appears, the garlick cataplasm should be removed, and one of bread and milk be applied, to obviate excessive pain. Garlick has also been variously employed externally, to tumours and cutaneous diseases: and, in certain cases of deafness, a clove, or small bulb of this root, wrapt in gauze or muslin, and introduced into the meatus auditorius, has been found an efficacious remedy. Garlick may be administered in different forms; swallowing the clove entire, after being dipped in oil, is recommended as most effectual; where this cannot be done, cutting it into pieces without bruising it, and swallowing these may be found to answer equally well, producing thereby no uneasiness in the fauces. On being beaten up and formed into pills, the active parts of this medicine soon evaporate: this Dr. breast, as was successfully practised and recommended active parts of this medicine soon evaporate: this Dr. Woodville, in his Medical Botany, notices, on the authority of Cullen, who thinks that Lewis has fallen into a gross error, in supposing dry garlick more active than fresh. The syrup and oxymel of garlick, which formerly had a place in the British Pharmacopecias, are now expunged. The cloves of garlick are by some bruised, and applied to the wrists, to cure agues, and to the bend of the arm to cure the toothache: when held in the hand, they are said to relieve hiccough: when beat with common oil into a poultice, they re-solve sluggish humours; and, if laid on the navels of children, they are supposed to destroy worms in the intestines.

ALLIUM VICTORIALE. Victorialis long a. The root, which when dried loses its alliaceous smell and taste, is said to be efficacious in allaying the abdominal

spasms of gravid females.

ALLOCHROITE. A massive opaque mineral of a grayish, yellowish, or reddish colour.

This mineral resembles certain varieties of the garnet in some of its physical characters, but more parti-cularly in composition. It contains silex 37.0, lime 30.0, alumine 5.0, oxide of iron 18.5, oxide of manga-nese 6.25;=96.75. Cleav. Min. A.] ALLOEO'SIS. (From aλλος, another.) Alteration

in the state of a disea

Allogo Tica. (From αλλος, another.) Alteratives. Medicines which change the appearance of the dis-

ease.

ALLOGNO'SIS. (From αλλος, another, and γινωσκω, to know.) Delirium; perversion of the judgment; incapability of distinguishing persons.

ALLOPHANE. A mineral of a blue, and sometimes a green or brown colour.

ALLOPHASIS. (From αλλος, another, and φαω, to speak.) According to Hippocrates, a delirium, where the patient is not able to distinguish one thing from another.

from another.

ALLOTRIOPHA'GIA. (From αλλοτριος, foreign, and φαγω, to eat.) In Vogel's Nosology, it signifies the greedily eating unusual things for food. See Pica.

ALLOY. Allay. I. Where any precious metal is mixed with another of less value, the assayers call the latter the alloy, and do not in general consider it in any other point of view than as debasing or diminishing the value of the precious metal.

2. Philosophical chemists have availed themselves of this term to distinguish all metallic compounds in general. Thus brass is called an alloy of copper and

neral. Thus brass is called an alloy of copper and zinc; bell metal an alloy of copper and tin.

Every alloy is distinguished by the metal which pre-

dominates in its composition, or which gives it its value. Thus English jewellery trinkets are ranked under alloys of gold, though most of them deserve to be placed under the head of copper. When mercury is one of the component metals, the alloy is called amalgam. Thus we have an amalgam of gold, silver, tin, gam. Thus we have an amargam or good, &c. Since there are about thirty different permanent &c. Since there are about thirty different permanent metals, independent of those evanescent ones that constitute the bases of the alkalies and earths, there ought to be about 870 different species of binary alloy. But only 132 species have been hitherto made and examined. Some metals have so little affinity for others, that as yet no compound of them has been effected, whatever pains have been taken. Most of these obstacles to alloying, arise from the difference in fusibility and volatility. Yet a few metals, the melting point of which is nearly the same, refuse to unite. It is obvious that two bodies will not combine, unless their affinity or reciprocal attraction be stronger than the cohenity or reciprocal attraction be stronger than the cohenity of reciprocal attraction be stronger than the cohesive attraction of their individual particles. To overcome this cohesion of the solid bodies, and render affinity predominant, they must be penetrated by caloric. If one be very difficult of fusion, and the other very volatile, they will not unite unless the reciprocal attraction be exceedingly strong. But if their degree of fusibility be almost the same, they are easily placed in the circumstances most favourable for making an allow. If we are therefore far from knowing all the alloy. If we are therefore far from knowing all the binary alloys which are possible, we are still further removed from knowing all the triple, quadruple, &c. which may exist. It must be confessed, moreover, that this department of chemistry has been imperfectly cultivated.

cultivated.

Besides, alloys are not, as far as we know, definitely regulated like oxydes in the proportions of their component parts. 100 parts of mercury will combine with 4 or 8 parts of oxygen, to form two distinct oxydes, the black and the red; but with no greater, less, or intermediate proportions. But 100 parts of mercury will unite with 1, 2, 3, or with any quantity up to 100 or 1000, of tin or lead. The alloys have the closest relations in their physical properties with the metals. They are all solid at the temperature of the atmosphere exemt some amalgams; they necessary metallic. They are all solid at the temperature of the atmosphere, except some amalgams; they possess metallic fustre, even when reduced to a coarse powder: are completely opaque, and more or less dense, according to the metals which compose them; are excellent conductors of electricity; crystallize more or less perfectly; some are brittle, others ductile and malleable; some have a peculiar odour; several are very sonorous and elastic. When an alloy consists of metals differently fusible, it is usually malleable while cold, but brittle while hot; as is exemplified in brass.

The density of an alloy is sometimes greater some.

The density of an alloy is sometimes greater, some-times less than the mean density of its components, showing that, at the instant of their union, a diminu-tion or augmentation of volume takes place. The relation between the expansion of the separate metals and that of their alloys, has been investigated only in a very few cases. Alloys containing a volatile metal are decomposed, in whole or in part, at a strong heat. This happens with those of arsenic, mercury, tellurium, and zinc. Those that consist of two differently fusible and zinc. Those that consist of two differently fusible metals, may often be decomposed by exposing them to a temperature capable of melting only one of them. This operation is called eliquation. It is practised on This operation is cancer enquation. It is practised on the great scale to extract silver from copper. The argentiferous copper is melted with 3 1-2 times its weight of lead; and the triple alloy is exposed to a sufficient heat. The lead carries off the silver in its fusion, and leaves the copper under the form of a spongy lump. The silver is afterward recovered from the lead by another operation.

Some alloys oxydize more readily by heat and air, than when the metals are separately treated. Thus 3

than when the metals are separately treated. Thus 3 of lead and 1 of tin, at a dull red, burn visibly, and are almost instantly oxydized. Each by itself in the same circumstances, would oxydize slowly, and without the disengagement of light.

The formation of an alloy must be [regulated by the nature of the particular metals.

The degree of affinity between metals may be in some measure estimated by the greater or less facility with which, when of different degrees of fusibility or volatility, they unite, or with which they can after union be separated by heat. The greater or less tendency to separate into different proportional alloys, by long-con-

tinued fusion, may also give some information on this subject. Mr. Hatchett remarked, in his admirable researches on metallic alloys, that gold made standard with the usual precautions by silver, copper, lead, antimony, &c. and then cast into vertical bars, was by no means a uniform compound; but that the top of the means a uniform compound; but that the top of the bar, corresponding to the metal at the bottom of the crucible, contained the larger proportion of gold. Hence, for thorough combination, two red-hot crucibles should be employed; and the liquified metals should be alternately poured from the one into the other. And to prevent unnecessary oxydizement by exposure to air, the crucibles should contain, besides the metal a mixture of common selt and rounded the metal, a mixture of common salt and pounded charcoal. The melted alloy should also be occasion-

ally stirred up with a rod of pottery

The most direct evidence of a chemical change having taken place in the two metals by combination, is when the alloy melts at a much lower temperature than the fusing points of its components. Iron, which is nearly infusible, when alloyed with gold acquires almost the fusibility of this metal. Tin and lead form solder, an alloy more fusible than either of its components; but the triple compound of tin, lead, and bis-muth, is most remarkable on this account. The anamuth, is most remarkable on this account. The analogy is here strong, with the increase of solubility which salts acquire by mixture, as is exemplified in the uncrystallizable residue of saline solutions, or mother waters, as they are called. Sometimes two me-tals will not directly unite, which yet, by the interven-tion of a third, are made to combine. This happens with mercury and iron, as has been shown by Messrs. Aiken, who effected this difficult amalgamation by previously uniting the iron to tin or zinc.

The tenacity of alloys is generally, though not always, inferior to the mean of the separate metals. One part of lead will destroy the compactness and tenacity of a thousand of gold. Brass made with a small proportion of zinc, is more ductile than copper itself; but when one-third of zinc enters into its com-

position, it becomes brittle.

In common cases, the specific gravity affords a good criterion whereby to judge of the proportion in an alloy, consisting of two metals of different densities .-

ALLSPICE. See Myrtes Pimenta.
ALLUVIAL. That which is deposited in valleys, or in plains, from neighbouring mountains, or the overflowing of rivers. Gravel, loam, clay, sand, brown coal, wood coal, bog iron ore, and calc tuff, compose the alluvial deposites.

A'LMA. The first motion of a fætus to free itself

from its confinement. 2. Water.-Rulandus

ALMABRI. A stone like amber.

ALMA'NDA CATHARTICA. A plant growing on the shores of Cayenne and Surinam, used by the inhabitants as a remedy for the colic; supposed to be cathartic.

ALME'NE. Rock salt.

ALMOND. See Amygdalus.

Almond, bitter. See Amygdalus.

Almond, sweet. See Amygdalus.

Almond paste. This cosmetic for softening the skin and preventing chops, is made of four ounces of blanched bitter almonds, the white of an egg, rose wable to be a six and pasts as much as is sufter and rectified spirits, equal parts, as much as is suf-

Almonds of the cars. A popular name for the tonsils, which have been so called from their resemblance to an almond in shape. See Tonsils.

Almonds of the throat. A vulgar name for the ton-

sils. See Tonsils.

ALNABATI. In Avicenna and Serapion, this word means the siliqua dulcis, a gentle laxative. See Ce-

ratonia siliqua.
A LNUS. (Alno, Italian.) The alder. The pharmacoporial name of two plants, sometimes used in medicine, though rarely employed in the present practice.

dicine, though rarely employed in the present practice.

1. Alnus retundifolia; glutinosa; viridis. The common alder-tree. See Betula alnus.

2. Alnus nigra. The black or berry-bearing alder. See Rhamnus Frangula.

A'LOE. (Alot, &s. fr. from ahlah, a Hebrew word, signifying growing near the sea.) The name of a genus of plants of the Linnaan system. Class Hexandria; Order, Monogynia. The Aloe.

Alor Guincensis. See Alor perfoliata.

Alor Guincensis. See Alor perfoliata.

Alor Perfoliata. Alor Succotorina; Alor Zocotorina. Succotorine aloes is obtained from a variety of the Alor perfoliata of Linnmus:—foliis caulinis dentatis, amplexicaulibus vaginantībus, floribus corymbosis cernuis, pedunculatis subcylindricis. It is brought over wrapped in skins, from the Island of Socotora, in the Indian Ocean; it is of a bright surface, and in some degree pellucid; in the lump of a yellowish red colour, with a purplish cast; when reduced into powder, it is of a golden colour. It is hard and friable in very cold weather; but in summer it softens very easily between the fingers. It is extremely bitter, and also accompanied with an aromatic flavour, but not so much as to cover its disagreeable taste. Its scent is rather agreeable, being somewhat similar to that of myrrh. Of late this sort has been very scarce, that of myrrh. Of late this sort has been very scarce, and its place in a great measure supplied by another variety, brought from the Cape of Good Hope, which is said to be obtained from the Aloc spicata of Linneus, by inspissating the expressed juice of the leaves,

whence it is termed in the London Pharmacopaia Extractum aloës spicata.

The Aloë hepatica, vel Barbadensis, the common or Barbadoes or hepatic aloes, was thought to come from a variety of the Aloë perfoliata described:—floribus pedunculatis, cernuis corymbosis, subcylindricis, foliis spinosis, confertis, dentatis, vagimentibus, planis, maculatis: but Dr. Smith has announced, that it will be shown in Sikhbaro's Flora Graca, to be from a distinct shown in Sibthorp's Flora Græca, to be from a distinct species, the Alož vulgaris, or true αλοη of Dioscorides; and it is therefore termed in the London Pharmaco-pœia, Aložs vulgaris extractum. The best is brought from Barbadoes in large gourd-shells; an inferior sort in pots, and the worst in casks. It is darker coloured than the Socotorine, and not so bright; it is also drier and more compact, though sometimes the sort in casks is soft and clammy. To the taste it is intensely bitter and nauseous, being almost wholly without that aro-ma which is observed in the Socotorine. To the smell

it is strong and disagreeable.

The Aloë caballina, vel Guincensis, or horse-aloes, is easily distinguished from both the foregoing, by its strong rank smell; in other-respects it agrees pretty much with the hepatic, and is now not unfrequently sold in its place. Sometimes it is prepared so pure and bright as scarcely to be distinguishable by the eye, even from the Socotorine, but its offensive smell be-trays it; and if this also should be dissipated by art, its wanting the aromatic flavour of the finer aloes will be a sufficient criterion. This aloe is not admitted into the materia medica, and is employed chiefly by farriers

The general nature of these three kinds is nearly the same. Their particular differences only consist in the different proportions of gum to their resin, and in their flavour. The smell and taste reside principally in the gum, as do the principal virtues of the aloes. Twelve ounces of Barbadoes aloes yield nearly 4 ounces of resin, and 8 of gummy extract. The same quantity of Socotorine aloes yields 3 ounces of resin and 9 of gummy extract.

my extract.

Aloes is a well-known stimulating purgative, a pro-perty which it possesses not only when taken internally, but also by external application. The cathartic quality of aloes does not reside in the resinous part of the drug, but in the gum, for the pure resin has little or no purgative power. Its medium dose is from 5 to 15 grains nor does a larger quantity operate more effectually. Its operation is exerted on the large intestines; principally on the rectum. In small doses long contiprincipally on the rectain. In sale and irritation, particularly about the anus, from which it sometimes occasions a bloody discharge; therefore, to those who were subject to piles, or of an hæmorrhagic diathesis, or even in a state of pregnancy, its exhibition has been productive of considerable mischief; but on the contrary, by those of a phlegmatic constitution, or those suffering from uterine obstructions (for the stimulant action of aloes, it has been supposed, may be extended to the uterus) and in some cases of dyspepsia, palsy, gout, and worms, aloes may be employed as a laxative with peculiar advantage. In all diseases of the bilious tribe, aloes is the strongest purge, and the best preparations for this purpose are the pilula ex aloe cum myrrha, the tinctura aloes, or the extractum colocynthidis nued, it often produces much heat and irritation, par-

compositum. Its efficacy in jaundice is very considerable, as it proves a succedaneum to the bile, of which in that disease there is a defective supply to the which in that disease there is a defective supply to the intestine either in quantity or quality. Aloes therefore may be considered as injurious where inflammation or irritation exists in the bowels or neighbouring parts, in pregnancy, or in habits disposed to piles; but highly serviceable in all hypochondriac affections, cachectic habits, and persons labouring under oppression of the stomach caused by irregularity. Aromatics cor-The canella alba answers tolerably, and without any inconvenience; but some rather prefer the essential oils for this purpose. Dr. Cullen says, "If any medicine be entitled to the appellation of a stomach purge, it is certainly aloes. It is remarkable with regard to it, that it operates almost to as good a purpose in a small as in a large dose; that one or two grains will produce one considerable dejection, and 20 grains will do no more, except it be that in the last dose the operation will be attended with gripes, &c. Its chief use is to render the peristaltic motion regular, and it is one of the best cures in habitual costiveness. There is The canella alba answers tolerably, and without any one of the best cures in habitual costiveness. There is a difficulty we meet with in the exhibition of purgatives, viz. that they will not act but in their full dose, and will not produce half their effect if given in half the dose. For this purpose we are chiefly confined to aloes. Neutral salts in half their dose will not have half their effect; although even from these, by large dilution, we may obtain this property; but besides them and our present medicine, I know no other which has any title to it except sulphur. Aloes sometimes cannot be employed. It has the effect of stimularing the rectum more than other purges, and with justice has been accused of exciting hæmorrhoidal swellings, so that we ought to abstain from it in such cases, except when we want to promote them. Aloes one of the best cures in habitual costiveness. cases, except when we want to promote them. Aloes has the effect of rarifying the blood and disposing to hemorrhagy, and hence it is not recommended in uterine fluxes. Fortid gums are of the same nature in rine fluxes. Fortid gums are of the same nature in producing hamorrhagy, and perhaps this is the foundation of their emmenagogue power." Aloes is administered either simply in powders, which is too nauseous, or else in composition;—I. With purgatives, as soap, scammony, colocynth, or rhubarb. 2. With aromatics, as canella, giager, or essential oils. 3. With bitters, as gentian. 4 With emmenagogues, as iron, myrrh, wine, &c. It may be exhibited in pills as the most convenient form, or else dissolved in wine, or diluted alkohol. The officinal preparations of aloes diluted alkohol. The officinal preparations of aloes are the following:

Pitulæ Aloës.
 Pitulæ Aloës Composita
 Pitulæ Aloës cum Assafætidå.
 Pitulæ Aloës cum Colocynthide.
 Pitula Aloës cum Myrrha.

11. Decoctum Aloës Compositum.
12. Pulvis Aloës Compositus.
13. Pulvis Aloës cum Canella.
14. Pulvis Aloës cum Guaiaco. Tinctura Aloës Composita. Extractum Colocyntindis Compositum.

Tinctura Benzoini Composita.

Alož Zototorina. See Alož perfoliata.

Alož Zototorina. See Alož perfoliata.

ALOEDA'RIA. (From αλοη, the aloe.) Compound urging medicines; so called from having aloes as the chief ingredient.

ALORPHANGINA. Medicines formed by a combina-

ALOES Aloes and aromatics.

ALOES Fel nature. The inspissated juice of the aloe plant. Aloes is distinguished into three species, socotorine, hepatic, and caballine; of which the two first are directed for officinal use in our pharmacoprias. See Alor perfoliata.

ALOE'TIC. A medicine wherein aloes is the chief or fundamental ingredient.

Alogotro'Phia. (From aλογος, disproportionate, and τοςφω, to nourish.) Unequal nourishment, as in the rickets.

ALO PECES. (From αλωπηξ, the fox.) The psoce

muscles are so called by Fallopius and Vesalius be-

muscles are so caned by Fahophus and Vesalus because in the fox they are particularly strong.

ALOPE'CIA. (From $a\lambda \omega \pi \eta \xi$, a fox: because the fox is subject to a distemper that resembles it; or, as some say, because the fox's urine will occasion bald ness.) Ealdness, or the falling off of the hair. A genus of disease in Sauvages' Nosology.

ALOPECUROIDEA. (From alopecurus, the fox-tail grass.) Resembling the alopecurus. The name of a division of grasses.

of a division of grasses

ALO'SA. (From αλισκω, to take: because it is ravenous.) See Clupsa alosa.

ALOSA'NTHI. (From αλς, salt, and ανθος, a flower.)

Alosanthum. Flowers of salt.

A'LOSAT. Quicksilver.

Alosanoc. Quicksilver.

ALPHITA. (Alphita, the plural of αλφιτον, the meal of barley in general.) By Hippocrates this term is applied to barley-meal either toasted or fried. Galen says that κριμνα is coarse meal, αλιυρον is fine meal, and αλφιτα is a middling sort.

ALPH'TIDON. Alphitedum. It is when a bone is broken into small fragments like alphite or bran.

ALPHI TIDON. Application. It is when a some is broken into small fragments like alphite or bran.

Alpho'nsin. The name of an instrument for extracting balls. It is so called from the name of its inventor, Alphonso Ferrier, a Neapolitan physician. It consists of three branches, which separate from each other by their elasticity, but are capable of being closed by means of a tube in which they are included.

ALPHOSIS. The specific name of a disease in the genus Epichrosis of Good's Nosology.

A'LPHUS. (Αλφος; from αλφαινω, to change: because it changes the colour of the skin.) A species of leprosy, called by the ancients vitilago, and which they divided into alphus, melas, and leuce. See Lepra.

A'LPINI BALSAMUM. Balm of Gilead.

ALPI'NUS, PROSPER, a Venetian, born in 1553, celebrated for his skill in medicine and botany. After graduating at Padua, he went to Egypt, and during three years carefully studied the plants of that country, and the modes of treating diseases there; of which he afterward published a very learned account. He and the modes of treating diseases there; of which he afterward published a very learned account. He has left also some other less important works. He was appointed physician to the celebrated Andrew Doria; and subsequently botanical professor at Padua, which office he retained till his death in 1616.

A'LSINE. (Alsine, es. f.; from αλσος, a grove: so called because it grows in great abundance in woods and shady places.) The man of a genus of plants in the Linneau system. Class Penjandria: Order Tri-

the Linnean system. Class, Pentandria; Order, Tri-

gynia. Chickweed.

ALSINE MEDIA. Morsus galling centunculus. The systematic name for the plant called chickweed, which, if boiled tender, may be eaten like spinach, and forms

also an excellent emollient poultice.

also an excellent emothent poultice.

ALSTON, Charles, born in Scotland in 1683, was early attached to the study of botany, and distinguished himself by opposing the sexual system of Linneus. He afterward studied under Boerhaave at Leyden. then returning to his native country, was materially instrumental, in conjunction with the cclebrated Alexander Monro, in establishing the medical school at Edinburgh, where he was appointed professor of botany and materia medica. He died in 1760. His "Lectures on the Materia Medica," a posthumous work, abound in curious and useful facts, which will long preserve their reputation.

long preserve their reputation.

A'LTERATIVE. (Alterans; from altero, to change.) Alterative medicines are those remedies which are given with a view to re-establish the healthy functions of the animal economy, without producing

any sensible evacuation.

ALTERNE PLANTE. Alternate leaved plants. The name of a class of plants in Sauvages' Methodus foliorum

ALTERNANS. Alternate; placed alternately. A term applied by botanists to leaves, gems, &c.
ALTERNUS. Alternate. In botany, this term is applied to branches and leaves when they stand singly applied to branches and leaves when they stand singly on each side, in such a manner that between every two on one side there is but one on the opposite side, as on the branches of the Althan officinalis, Rhamnus catharticus, and leaves of the Malva rotundifolia.

ALTHÆ'A. (Althan, a. f.; from aλθεω, to heal: so called from its supposed qualities in healing.) 1

The name of a genus of plants of the Linnæan system

Class, Monadelphia; Order, Polyandria. Marshmallow.

2. The pharmacopoial name of the marsh-mallow.

See Althea Officinalis.

ALTHEA OFFICINALIS. The systematic name of the marsh-mallow. Malvaviscus; Aristalthwa. Althwa:—foliis simplicibus tomentosis. The mucilaginous matter with which this plant abounds, is the medicinal part of the plant; it is commonly employed for its emollient and demulcent qualities in tickling coughs, hopersoness and catagories in description. conghs, hoarseness, and catarrhs, in dysentery, and difficulty and heat of urine. The leaves and root are generally selected for use. They refax the passages in hephritic complaints, in which last case a decoction is the best preparation. Two or three ounces of the fresh roots may be hoiled in a sufficient quantity of water to a quart, to which one causes of gumaraphic water to a quart, to which one ounce of gum-arabic may be added. The following is given where it is required that large quantities should be used. An ounce of the dried roots is to be boiled in water, enough to leave two or three pints to be poured off for use: if more of the root be used, the liquor will be disagreeably slimy. If sweetened, by adding a little more of the root of liquorice, it will be very palatable. The root had formerly a place in many of the compounds in the pharmacopæias, but now it is only directed in the form of syrup.

the form of syrup.

Althe 'xis. (From αλθειν, to cure, or heal.) Hippocrates often uses this word to signify the cure of a

ALUDEL. A hollow sphere of stone, glass, or earthenware, with a short neck projecting at each end, by means of which one globe might be set upon the other. The uppermost has no opening at the top. They were used in former times for the sublimation of several substances.

ALUM. See Alumen.

ALUM EARTH. A massive mineral of a blackish brown colour, a dull lustre, an earthy and somewhat slaty fracture, sectile and rather soft, containing charcoal silica, alumina, oxyde of iron, sulphur, sulphates of lime, potassa, and iron, magnesia, muriate of po-tassa, and water.

ALUM SLATE. A massive mineral of a bluish black colour, or slate containing alum.

ALUMEN. (Alum, an Arabian word.) Assos; Azub; Aseb; Elanula; Sulphas alumina acidulus cum potassa; Super-sulphas alumina et potassa; Argilla vitriolata. Alum. This important salt has been the object of innumerable researches both with regard to its choicestion and composition. It is proregard to its fabrication and composition. It is produced, but in a very small quantity, in the native state; and this is mixed with heterogeneous matters. It effloresces in various forms upon ores during calcination, but it seldom occurs crystallized. The greater

tion, but it seldom occurs crystallized. The greater part of this salt is factitious, being extracted from minerals called alum ores, such as,

1. Sulphuretted clay. This constitutes the purest of all aluminous ores, namely, that of La Tolfa, near Civita Vecchia, in Italy. It is white, compact, and as hard as indurated clay, whence it is called petra aluminaris. It is tasteless and mealy; one hundred parts of this ore contain above forty of sulphur and fifty of clay, a small quantity of potassa, and a little iron. Bergman says it contains forty-three of sulphur in one hundred, thirty-five of clay, and twenty-two of siliceous hundred, thirty-five of clay, and twenty-two of siliceous earth. This ore is first torrefied to acidify the sulphur,

which then acts on the clay, and forms the alum.

2. The pyritaceous clay, which is found at Schwemsal, in Saxony, at the depth of ten or twelve feet. It is a black and hard, but brittle substance, consisting of clay, pyrites, and bitumen. It is exposed to the air for two years, by which means the pyrites are decomposed, and the alum is formed. The alum ores of Hesse and Liege are of this kind; but they are first torrefied, which is said to be a disadvantageous

3. The schistus aluminaris contains a variable proportion of petroleum and pyrites intimately mixed with it. When the last are in a very large quantity, this ore is rejected as containing too much iron. Professor Bergman very properly suggested, that by adding a proportion of clay, this ore may turn out advantage-busly for producing alum. But if the petrol be considerable, it must be torrefied. The mines of Becket in Normandy, and those of Whitby, in Yorkshire, are of this species.

4. Volcanic aluminous ore. Such is that of Salfaterra near Naples. It is in the form of a white saline earth, after it has effloresced in the air; or else it is in a stony form.

5. Bituminous alum ore is called shale, and is in the form of a schistus, impregnated with so much oily matter, or bitumen, as to be inflammable. It is found in Sweden, and also in the coal mines at Whitehaven,

and clsewhere.

Chaptal has fabricated alum on a large scale from Chaptal has fabricated alum on a large scale from its component parts. For this purpose he constructed a chamber 9I feet long, 48 wide, and 31 high in the middle. The walls are of common masonry, lined with a pretty thick coating of plaster. The floor is paved with bricks, bedded in a mixture of raw and burnt clay; and this pavement is covered with another, the joints of which overlap those of the first, and instead of mortar, the bricks are joined with a cement of equal parts of pitch, turpentine, and wax, which, after having been boiled till it ceases to swell, is used hot. The roof is of wood, but the beams are very close together, and grooved lengthwise, the intermediate space being filled up by planks fitted into the grooves, so that the whole is put together without a grooves, so that the whole is put together without a nail. Lastly, the whole of the inside is covered with three or four successive coatings of the cement abovementioned, the first being laid on as hot as possible; mentioned, the first being laid on as hot as possible; and the outside of the wooden roof was varnished in the same manner. The purest and whitest clay being made into a paste with water, and formed into balls half a foot in diameter, these are calcined in a furnace, broken to pieces, and a stratum of the fragments laid on the floor. A due proportion of sulphur is then ignited in the chamber, in the same manner as for the fabrication of sulphuric acid; and the fragments of burnt clay, imbibing this as it forms, begin after a few days to crack and open, and exhibit an efforescence of sulphate of alumina. When the earth has completely effloresced, it is taken out of the chamber, exposed for some time in an open shed, that it may be posed for some time in an open shed, that it may be the more intimately penetrated by the acid, and is then lixiviated and crystallized in the usual manner. The cement answers the purpose of lead on this occasion very effectually, and, according to Chaptal, costs no more than lead would at three farthings a pound.

Curaudau has lately recommended a process for making alum without evaporation. One hundred parts of clay and five of muriate of soda are kneaded parts of clay and hive of muriate of soda are kneaded into a paste with water, and formed into loaves. With these a reverberatory furnace is filled, and a brisk fire is kept up for two hours. Being powdered, and put into a sound cask, one-fourth of their weight of sulphuric acid is poured over them by degrees, stirring the mixture well at each addition. As soon as the muriatic gas is dissipated, a quantity of water equal to the acid is added, and the mixture stirred as equal to the acid is added, and the mixture stirred as before. When the heat is abated, a little more water is poured in; and this is repeated till eight or ten times as much water as there was acid is added. When the whole has settled, the clear liquor is drawn off into leaden vessels, and a quantity of water equal to this liquor is poured on the sediment. The two liquors being mixed, a solution of potassa is added to them, the alkali in which is equal to one-fourth of the weight of the sulphuric acid. Sulphate of potassa may be used, but twice as much of this as of the alkali is used, but twice as much of this as of the alkali is necessary. After a certain time, the liquor, by cooling, atfords crystals of alum equal to three times the weight of the acid used. It is refined by dissolving it in the smallest possible quantity of boiling water. The residue may be washed with more water, to be employed in lixiviating a fresh portion of the ingre-

Its sp. gravity is about 1.71. It reddens the veg table blues. It is soluble in 16 parts of water at 600, and in 3-4 of its weight at 2120. It effloresces superfiand in 3-4 of its weight at 2120. It effloresces superficially on exposure to air, but the interior remains long unchanged. Its water of crystallization is sufficient at a gentle heat to fuse it. If the heat be increased it froths up, and loses fully 45 per cent. of its weight in water. The spongy residue is called burnt or calcined alum, and is used by surgeons as a mild escharotic. A violent heat separates a great portion of its acid. Alum was thus analyzed by Berzelius: 1st, 20 parts (grammes) of pure alum lost, by the heat of a spirit lamp, 9 parts, which gives 45 per cent. of water. The dry salt was dissolved in water, and its acid precipi-

tated by muriate of barytes; the sulphate of which, obtained after ignition, weighed 20 parts; indicating in 100 parts 34.3 of dry sulphuric acid. 2d, Ten parts of alum were dissolved in water, and digested with an of alum were dissolved in water, and digested with an excess of ammonia. Alumina, well washed and burned, equivalent to 10.67 per cent. was obtained. In another experiment, 10.86 per cent. resulted. 3d, Ten parts of alum dissolved in water, were digested with carbonate of strontites, till the earth was completely separated. The sulphate of potassa, after ignition, weighed 1.815, corresponding to 0.981 potassa, or in 100 earts to 9.81. 100 parts to 9.81.

Alum, therefore, consists of Sulphuric acid 34.33 Alumina..... 10.86 Potassa 9.81 Water 45.00 or, Sulphate of alumina...... 36.85 Sulphate of potassa...... 18.15

100.00

Theonrd's analysis, Ann. de Chimie, vol. 59, or Ni-cholson's Journal, vol. 18, coincides perfectly with that of Berzelius in the product of sulphate of barytes. From 400 parts of alum, he obtained 490 of the ignited barytic salt; but the alumina was in greater propor-tion, equal to 12.54 per cent. and the sulphate of po-tassa less, or 15.7 in 100 parts.

Vauquelin, in his last analysis, found 48.58 water;

and by Thenard's statement there are indicated

34.23 dry acid, 7.14 potassa, 12.54 alumina, 46.09 water.

100.00

If we rectify Vauquelin's erroneous estimate of the If we rectify vauquelin's erroneous estimate of the sulphate of barytes, his analysis will also coincide with the above. Alum, therefore, differs from the simple sulphate of aiumina previously described, which consisted of 3 prime equivalents of acid ami 2 of earth, merely by its assumption of a prime of sulphate of potassa. It is probable that all the aluminous salts have a similar constitution. It is to be observed, moreover, that the number 34.36 resulting from the theoretic proportions, is, according to Gilbert's re-

moreover, that the number 34.36 resulting from the theoretic proportions, is, according to Gilbert's remarks on the Essay of Berzelius, the just representation of the dry acid in 100 of sulphate of barytes, by a corrected analysis, which makes the prime of barytes 9.57.

Should ammonia be suspected in alum, it may be detected, and its quantity estimated, by mixing quick-lime with the saline solution, and exposing the mixture to heat in a retort, connected with a Woolfe's apparatus. The water of ammonia being afterward apparatus. The water of ammonia being afterward saturated with an acid, and evaporated to a dry salt, will indicate the quantity of pure ammonia in the alum. A variety of alum, containing both potassa and ammonia, may also be found. This will occur where urine has been used, as well as muriate of potassa, in its fabrication. If any of these bisulphates of allumina and potassa be acted on in a watery solution, by gelatinous alumina, a neutral triple salt is formed, which precipitates in a nearly insoluble state.

When alum in powder is mixed with flour or sugar, and calcined, it forms the pyrophorus of Homberg.

Mr. Winter first mentioned, that another variety of

alum can be made with soda, instead of potassa. This sait, which crystallizes in octabedrons, has been also made with pure muriate of soda, and bisulphate of alumina, at the laboratory of Hurlett, by Mr. W. Wilson. It is extremely difficult to form, and effloresc

son. It is extremely difficult to form, and effloresces like the sulphate of soda.

On the subject of soda-alum, Dr. Ure published a short paper in the Journal of Science for July, 1822. The form and taste of this salt are exactly the same as those of common alum; but it is less hard, being easily crushed between the fingers, to which it imparts an appearance of moisture. Its specific gravity is 1.6. 100 parts of water at 60° F. dissolve 110 of it; forming a solution, whose sp. gravity is 1.296. In this respect, potassa alum is very different. For 100 parts of water dissolve only from 8 to 9 parts, forming a saturated solution, the specific gravity of which is no more than 1.0465. Its constituents are, by Dr. Ure's analysis,— Its constituents are, by Dr. Ure's analysis,-

Sulphuric acid	34.00 4	primes, 33.96
Alumina	10.75 3	- 10.82
Soda		- 6.79
Water	49.00 25	- 48.43
_	-	

Or it consists of 3 primes sulphate of alumina+1 sul-phate of soda. To each of the former, 5 primes of water may be assigned, and to the latter 10, as in

Glauber's salts.

The only injurious contamination of alum is sulphate of iron. It is detected by ferro-prussiate of

Oxymuriate of alumina, or the chloride, has been proposed by Mr. Wilson of Dublin, as preferable to solution of chlorine, for discharging the turkey-red die.

Alum is used in large quantities in many manufactories. When added to tallow, it renders it harder. Printer's cushions, and the blocks used in the calico manufactory, are rubbed with burnt alum to remove any greasiness, which might prevent the ink or colour from sticking. Wood sufficiently soaked in a solution of alum does not easily take fire; and the same is true of paper impregnated with it, which is fitter to keep gunpowder, as it also excludes moisture. Paper impregnated with alum is useful in whitening silver, and in silvering brass without heat. in silvering brass without heat. Alum mixed in milk helps the separation of its butter. If added in a very small quantity to turbid water, in a few minutes it renders it perfectly limpid, without any bad taste or quality; while the sulphuric acid imparts to it a very sensible acidity, and does not precipitate as soon, or so well, the opaque earthy mixtures that render it turbid. well, the opaque earthy mixtures that render it turbid. It is used in making pyrophorus, in tanning, and in many other manufactories, particularly in the art of dying, in which it is of the greatest and most important use, by cleansing and opening the pores on the surface of the substance to be died, rendering it fit for receiving the colouring particles, (by which the alum is generally decomposed,) and at the same time making the colour fixed. Crayons generally consist of the earth of alum, powdered and tinged for the purpose.—

Ure's Chem. Dict.

In medicine it is employed internally as a powerful

In medicine it is employed internally as a powerful astringent in cases of passive hitmorrhages from the womb, intestines, nose, and sometimes lungs. In bleedings of an active nature, i. e. attended with fever, bleedings of an active nature, i. e. attended with fever, and a plethoric state of the system, it is highly improper. Dr. Percival recommends it in the colica pictonum and other chronic disorders of the bowels, attended with obstinate constipation. (See Percival's Essays.) The dose advised in those cases is from 5 to 20 grains, to be repeated every four, eight, or twelve hours. When duly persisted in, this remedy proves gently laxative, and mitigates the pain.

Alum is also powerfully tonic, and is given with this view in the dose of 10 grains made into a bolus three times a day, in such cases as require powerful tonic

times a day, in such cases as require powerful tonic and astringent remedies. Another mode of administering it is in the form of whey made by boiling a drachm of powdered alum in a pint of milk for a few minutes, and to be taken in the quantity of a tea-cup full three times a day. Dr. Cullen thinks it ought to be employed with other astringents in diarrheas. In active homographeres, was cleared in increase. active hemorrhages, as was observed, it is not useful, though a powerful medicine in those which are passive. It should be given in small doses, and gradually increased. It has been tried in the diabetes without increased. It has been tried in the manetes without success; though, joined with nutmeg, it has been more successful in intermittents, given in a large dose, an hour or a liule longer, before the approach of the paroxysm. In gargles, in relaxation of the uvula, and other swellings of the mucous membrane of the fauces, other swellings of the mucous membrane of the fauces. divested of acute inflammation, it has been used with advantage

Externally, alum is much employed by surgeons as Externally, alum is much employed by surgeons as a lotion for the eyes, and is said to be preterable to sulphate of zinc or acetate of lead in the ophthalmia membranarum. From two to five grains dissolved in an ounce of rose-water, forms a proper collyrium. It is also applied as a styptic to bleeding vessels, and to ulcers, where there is too copious a secretion of pus. It has proved successful in inflammation of the eyes, in the form of cataplasm, which is made by stirring or shaking a lump of alum in the whites of two seers, till they form a coagulum, which is applied to eggs, till they form a coagulum, which is applied to the eye between two pieces of thin linen rag. Alum

is also employed as an injection in cases of gleet or of the alumina not decompounded; and in this mass

When deprived of its humidity, by placing it in an earthen pan over a gentle fire, it is termed burnt alam, alumen exsiccatum, and is sometimes employed by surgeons to destroy fungous flesh, and is a principal ingre-

dient in most styptic powders.

Alum is also applied to many purposes of life; in this country, bakers mix a quantity with the bread, to render it white; this mixture makes the bread better adapted for weak and relaxed bowels; but in opposite states of the alimentary canal, this practice is highly

The officinal preparations of alum are:

1. Alumen exsiccatum.

Solutio sulphatis cupri ammoniati.

ALU'MINA. Alumine. Terra Alumina. Earth of alum. Pure clay. One of the primitive earths, which, as constituting the plastic principle of all clays, loams, and boles, was called argil or the argillaceous loams, and boles, was called argit or the arginaceous earth, but now, as being obtained in greatest purity from alum, is styled alumina. It was deemed elementary matter till Sir H. Davy's celebrated electro-elemical researches led to the belief of its being, like barytes and lime, a metallic oxyde.

The purest native alumina is found in the oriental gems, the sapphire and ruby. They consist of nothing half this earth, and a small portion of colouring matter.

but this earth, and a small portion of colouring matter. The native porcelain clays or kaolins, however white and soft, can never be regarded as pure alumina. They usually contain fully half their weight of silica, and frequently other earths. To obtain pure alumina we dissolve alum in 20 times its weight of water, and add to it a little of the solution of carbona'e of soda, to throw down any iron which may be present. We then drop the supernatant liquid into a quantity of the water of ammonia, taking care not to add so much of the aluminous solution as will saturate the ammonia. The volatile alkali unites with the sulphuric acid of the alum, and the earthy basis of the latter is separated in a white spongy precipitate. This must be thrown on a filter, washed, or edulcorated, as the old chemists expressed it, by repeated affusions of water, and then dried. Or if an alum, made with ammonia instead of potassa, as is the case with some French aiums, can be got, simple ignition dissipates its acid and alkaline constituents, leaving pure alumina.

Alumina prepared by the first process is white, pulverulent, soft to the touch, adheres to the tongue, forms a smooth paste without grittiness in the mouth, insipid, inodorous, produces no change in vegetable colours, insoluble in water, but mixes with it readily in every proportion, and retains a small quantity with considerable force; is infusible in the strongest heat of a furnace, experiencing merely a condensation of volume and consequent hardness, but is in small quantities melted by the oxyhydrogen blowpipe. Its specific gravity is 2.000 in the state of powder, but by ignition

it is augmented.

Every analogy leads to the belief that alumina contains a peculiar metal, which may be called aluminum. The first evidences obtained of this position are presented in Sir H. Davy's researches. Iron negatively electrified by a very high power being fused in contact with pure alamina, formed a globule whiter than pure iron which effervesced slowly in water, becoming covered with a white powder. The solution of this in muriatic acid, decomposed by an alkali, afforded alumina and oxyde of iron. By passing potassium in vapour through alumina heated to whiteness, the greatest part of the potassium became converted into potassa, which formed a coherent mass with that part

there were numerous gray particles, having the metallic lustre, and which became white when heated in the air, and which slowly effervesced in water. In a similar experiment made by the same illustrious chemist, a strong red heat only being applied to the alu-nina, a mass was obtained, which took fire spontamina, a mass was obtained, which took fire spontaneously by exposure to air, and which effervesced violently in water. This mass was probably an alloy of aluminum and potassium. The conversion of potassium into its deutoxyde, dry potassa, by alumina, proves the presence of oxygen in the latter. When regarded as an oxyde, Sir H. Davy estimates its oxygen and basis to be to one another as 15 to 33; or as 10 to 22. The prime equivalent of alumina would thus appear to be 1.0.+2.2=3.2. But Berzelius's analysis of sulphate of alumina seems to indicate 2.136 as the sulphate of alumina seems to indicate 2.136 as the quantity of the earth which courbines with five of the acid. Heace aluminum will come to be represented by 2.135—1=1.136.

Alamina which has lost its plasticity by ignition, recovers it by being dissolved in an acid or alkaline meastruom, and then precipitated. In this state it is called a hydrate, for when dried in a steam heat it retains much water; and therefore resembles in composition wavellite, a beautiful mineral, consisting almost entirely of alumina, with about 28 per cent. of

Alumina is widely diffused in nature. It is a constifuent of every soil, and of almost every rock. the basis of porcelain, pottery, bricks, and crucibles. Its affinity for vegetable colouring matter, is made use of in the preparation of lakes, and in the arts of dying and calico printing. Native combinations of alumina, constitute the fullers' earth, othres, boles, pipe-

clays, &c. . The salts of alumina have the following general

1. Most of them are very soluble in water, and their solutions have a sweetish acerb taste.

2. Ammonia throws down their earthy base, even though they have been previously acidulated with mariatic acid.

3. At a strong red heat they give out a portion of their acid.

4. Phosphate of ammonia gives a white precipitate. Hydriodate of potassa produces a flocculent precipitate of a white colour, passing into a permanent

yellow

6. They are not affected by oxalate of ammonia, tartaric acid, ferroprussiate of potassa, or tincture of galis: by the first two tesis they are distinguishable from yttria; and by the last two, from that earth and glucina.
7. If bisulphate of potassa be added to a solution of an aluminous salt moderately concentrated, octahedral

crystals of alum will form.

ALUMINITE. A mineral of a snow white colour, dull, opaque, and having a fine earthy fracture. consists of sulphuric acid, alumina, water, silica, lime, and oxyde of iron.
ALUMINOUS. Pertaining to alum.

Aluminous waters. Waters impregnated with par ticles of alum.

ALUMINUM. See Alumina.
ALUSIA. (From alvers, a wandering.) Alysis; Illusion; Hallucination. A term used by Good to a species of his genus Empathemata. See Nosology.
ALVEAR IUM. (From alveare, a bee-hive.) That part of the meatus auditorius externus is so called,

which contains the wax of the ear.

ALVE'OLUS. (A diminutive of alveus, a cavity.) The socket of a tooth.

ALVEUS. (Alveus, i. m., a cavity.) A cavity.

ALVEUS AMPULLESCENS. That part of the duct conveying the chyle to the subclavian vein, which swells

ALVEUS COMMUNIS. The common duct, or commu-nication of the ampulla of the membranaceous semicircular canals in the internal ear, is so termed by

ALVIDU'CA. (From alvus, the belly, and duco, to

draw.) Purging medicines.
ALVIFLUXUS. (From alvus, and fluo, to flow.)

A diarrhora, or purging.

ALVUS. (Aleus, i. f. and sometimes m. ab alluendo, guá sordes alluentur.) The belly, stomach, and

(From alvw, to be anxious.) That

anxiety which attends low fevers.

ALY'PIA. (From a, neg. and λυπη, pain.) Without pain; applied to a purgation of the humours, with-

out pain.
ALY PIAS. Alypum. ALYPIAS. Alypum. A species of turbith, the globularia alypum; so called because it purges with-

out pain.
ALYSIS. See Alusia.

ALY'SMUS. (From αλυω, to be restless.) Rest-

ALY'SSUM. (From a, neg. and huova, the bite of a mad dog; so called because it was foolishly thought to be a specific in the cure of the bite of a mad-dog.) Mad-wort. See Marrubium alyssum.

ALYSSUM GALENI. See Marrubium verticillatum.

ALYSSUM PLINII. See Galium album.

ALYSSUM VERTICILLATUM. The Marrubium verti-

cillatum.

A'LZUM. Aldum; Aldrum. The name of the tree which produces gum bdellium, according to some ancient authors.

A'MA. (Aua, together.) A word used in compo-

AMADINE. A substance, the properties of which are intermediate between those of starch and gum.

AMADOU. A variety of the boletus igniarius, found on old ash and other trees. It is boiled in water to extract its soluble parts, then dried and beat with a mallet to loosen its texture. It has now the appearance of very spongy doe-skin leather. It is lastly impregnated with a solution of nitre, and dried, when it is called spunk, or German tinder; a substance much used on the continent for lighting fires, either from the collision of flint and steel, or from the sudden conden-

sation of air in the atmospheric pyrophorus.

AMA'LGAM. (Amalgama; from aµa and γaµttv, to marry.) A substance produced by mixing mercury with a metal, the two being thereby incorporated.

AMAME'LIS. (From ana, and unhea, an apple.)

The bastard mediar of Hippocrates.

AMANI'TÆ. (From a, priv. and µavia, madness; so called, because they are eatable and not poisonous, like some others.) A tribe of fungous productions, called mushrooms, truffles, and morells, and by the French, champignons.

French, champignons.

AMARA DULCIS. See Solanum dulcamara.

AMA'RACUS. (From a, neg. and μαραινω, to decay: because it keeps its virtues a long time.) Marjoram.

Amaranth, esculent. See Imaranthus oleraceus.

AMARA'NTHUS. (Amaranthus, i. m.; from a, neg. and μαραινω, to decay: because the flower, when out, does not soon decay.) The name of a genus of plants in the Linnæan system. Class, Monæcia; Order Pentandria. Order, Pentandria.

AMARANTHUS OLERACEUS. Esculent amaranth.

The leaves of this, and several other species, are eaten in India the same as cabbage is here.

AMA'RUS. Bitter. See Bitter. The principal

bitters used medicinally are,

1. The pure bitters; gentiana lutea, humulus lu-pulus, and quassia amara.

Styptic bitters; cinchona officinalis, croton cas-carilla, quassia simarouba.

3. Aromatic bitters; artemisia absinthium, anthemis nobilis, hyssopus, &c. (From amo, to love.) See AMATORIA FEBRIS.

Chlorosis.

Anatoria venericia. (From amo, to love, and veneficium, witchcraft.) Philters. Love powders.

Anato'rius. A term given to a muscle of the eye, by which that organ is moved in ogting. See Rectus

inferior oculi.

AMATZQUI'TI. An Indian term. See Arbutus unedo. AMAURO'SIS. (Amaurosts, is. f. Αμαυρωσις; AMATZQUI TI. An indian term. See Aroutas uacao.

AMAURO'SIS. (Amauroses, is. f. Aμαυρωσις; from αμαυρωσι, to darken or obscure.) Gutta serena; Amblyopia. A disease of the eye attended with a diminution or total loss of sight, without any visible injury to the organ, and arising from a paralytic affection of the retina and optic nerve. A genus of disease in the class locales, and order dysæsthesiæ of Cullen. It arises generally from compression of the optic nerves; amaurosis compressionis; from debility, amaurosis amaurosis compressionis; from debility, amaurosis atonica; from spasm, amaurosis spasmodica; or from poisons, amaurosis venenata.

The symptoms of amaurosis are noted for being very The symptoms of amaurosis are noted for being very irregular. In many cases, the pupil is very much dilated, immoveable, and of its natural black colour. Sometimes, however, in the most complete and incurable cases, the pupil is of its natural size, and the iris capable of free motion. In some cases, the pupil has a dull, glassy, or horny appearance. Sometimes its colour is greenish, occasionally whitish and opaque, so as to be liable to be mistaken for an incipient cataract. Richter mentions a degree of strabismus, as the only symptom, except the loss of sight, as invariably only symptom, except the loss of sight, as invariably attendant on amaurosis.

The bindness produced by amaurosis, is generally preceded by an imaginary appearance of numerous insects, or substances, like cobwebs, interposing themselves between objects and the eye. The origin of a cataract on the other hand, is usually attended with a simple cloudiness of vision.

Violent contusions of the head, apoplectic fits, flashes of lightning, frequent exposure to the rays of the sun, severe exercise, strong passions, drunkenness, and other causes of paralytic affections, are enumerated as producing this complaint. Sometimes tumours within the cranium, bony projections, &c. have been found compressing the optic nerves: but in many instances no morbid appearance could be traced, to account for the blindness

The disorder is generally difficult to be removed: but is sometimes much benefited by general and local stimulants, persevered in for a considerable time, there are marks of congestion in the head, local bleeding, active purging, and other evacuations, would be proper in the first instance. Blisters and issues behind the ear or neck should also be tried. Richter speaks the ear or neck should also be tried. Richter speaks of much success from the use of medicines acting steadily on the bowels, after premising an emetic. Mr. Ware observes, that in some cases the pupil is contracted, indicating probably, internal inflammation; and then the internal use of mercury, especially the oxymariate, will be most beneficial. Electricity has been sometimes serviceable, taking the aura or sparks, or even gentle shocks: but galvanism is certainly preferable. Errhines are often useful, as the compound powder of asarabacca; Mr. Ware particularly recommends the hydrargyrus vitriolatus of the former London Pharmacopæia. Stimulants have been sometimes usefully applied to the eye itself, as the vapour of oil of turpentine, an infusion of capsicum, &c. Where the intention of a blister is to stimulate it is best and the intention of a blister is to stimulate, it is best ap-

plied to the temple on the affected side

AMBER. Succinum. A beautiful bituminous substance, which takes a good polish, and, after a slight rubbing, becomes so electric, as to attract straws and small bodies; it was called ηλικτρον, electrum, by the ancients, and hence the word electricity. "Amber is a hard, brittle, tasteless substance, sometimes perfectly a nara, brittle, tasteless substance, sometimes perfectly transparent, but mostly semitransparent or opaque, and of a glossy surface: it is found of all colours, but chiefly yellow or orange, and often contains leaves or insects; its specific gravity is from 1.065 to 1.100; its fracture is even, smooth, and glossy; it is capable of a fine polish, and becomes electric by friction; when rubbed or heated, it gives a peculiar agreeable smell, particularly when it melts, that is at 550° of Fahrenbeit, but it then loses its transparency; projected on heit, but it then loses its transparency; projected on burning coals, it burns with a whitish flame, and a whitish-yellow smoke, but gives very little soot, and leaves brownish ashes; it is insoluble in water and alcohol, though the latter, when highly rectified, extracts a reddish colour from it; but it is soluble in the sulphuric acid, which then acquires a reddish-purple colour, and is precipitable from it by water. No other acid dissolves it, nor is it soluble in essential or expressed oils, without some decomposition and long digestion; but pure alkali dissolves it. By distillation it affords a small quantity of water, with a little acetous acid, an oil, and a peculiar acid. The oil rises at first colourless: but, as the heat increases, becomes brown, thick, and empyreumatic. The oil may be rectified by successive distillations, or it may be obtained very light and limpid at once, if it be put into a glass alembic with water, as the elder Rouelle directs, and distilled at a heat not greater than 212° Fahr. It requires to be kept in stone bottles, however, to retain this state; for in glass vessels it becomes brown by the action of light. it affords a small quantity of water, with a little aceaction of light.

Amber is met with plentifully in regular mines in

some parts of Prussia. The upper surface is composed of sand, under which is a stratum of loam, and under this a bed of wood, partly entire, but chiefly mouldered or changed into a bituminous substance. Under the wood is a stratum of sulphuric or rather aluminous mineral, in which the amber is found. Strong sulphuric archivel in the offs.

reous exhalations are often perceived in the pits.

Detached pieces are also found occasionally on the sea-coast in various coantries. It has been found in gravel beds near London. In the Royal Cabinet at Berlin there is a mass of 18lbs. weight, supposed to be the largest ever found. Jussieu asserts, that the deli-cate insects in amber, which prove the tranquillity of its formation, are not European. Hady has pointed out the following distinctions between mellite and copal, the bodies which most closely resemble amber. Mellite is infusible by heat. A bit of copal heated at the end of a knife takes fire, melting into drops, which the end of a knife takes fire, melting into drops, which flatten as they fall; whereas amber burns with spitting and frothing; and when its liquefied particles drop, they rebound from the plane which receives them. The origin of amber is at present involved in perfect obscurity, though the rapid progress of vegetation absolutes promises soon to throw light on it. Vable chemistry promises soon to throw light on it. Various frauds are practised with this s.p. stance. Neumann states as the common practices of workmen, the two following: The one consists in surrounding the amber with sand in an iron pot, and cementing it with a gradual fire for forty hours, some small pieces placed near the sides of the vessel being occasionally taken out for judging of the effect of the operation: the second method, which he says is that most generally practised, is by digesting and boiling the amber about twenty hours with rapeseed oil, by which it is rendered both sleer and hard. both clear and hard.

Werner has divided it into two sub-species, the white and the yellow: but there is little advantage in the distinction. Its ultimate constituents are the same with those of vegetable bodies in general; viz. carbon,

hydrogen, and oxygen.

In the second volume of the Edinburgh Philosophical Journal, Dr. Brewster has given an account of some optical properties of amber, from which he considers it established beyond a doubt that amber is an indurated vegetable juice; and that the traces of a regular structure, indicated by its action upon polarized light, are not the effect of the ordinary laws of crystallization by which mellite has been formed, but are produced by the same causes which influence the mechanical condition of gum-arabic, and other gums, which are known to be formed by the successive deposition and induration of vegetable fluids."—Ure's Chem.

Dict. See Oleum Succini, and Succinic Acid.

[Amber has heretofore been chiefly obtained from the shores of the Baltic in Prussia. It has however

been found in other countries.

In the state of New-Jersey, on Crosswick's creek, four miles from Trenton, it occurs in alluvial soil. The amber is both yellow and whitish, and occurs in grains or small masses, seidom exceeding an inch in length.
It rests on lignite or carbonated wood, or even penetrates it, and is sometimes connected with pyrites. The stratum of lignite, which contains the amber, rests on a coarse, ferruginous sand, and is covered by a soft bluish clay, embracing masses of pyrites. Above the clay is a bed of sand. Amber exists also near Woodbury, in the same state, in large plates in a bed of marl; also at Camden, opposite Philadelphia, where a transparent specimen, almost white, and several inches in diameter, has been found in a stratum of gravel. diameter, has been found in a stratum of gravel.

Most naturalists are induced to believe that amber is a resinous juice, which once proceeded from certain trees, but has since been gradually mineralized in the interior of the earth. It occurs in masses, whose weight usually varies from a fraction of an ounce to a few pounds; and its largest masses, which are extremely rare, do not much exceed 20lbs.—Cleav. Min.

tremely rare, do not much exceed 20lbs.—Cleav. Min.
The largest mass perhaps ever seen, was recently found between Memel and Koningsberg, measuring 14 inches in length, by 9 1-4 in breadth, and weighing 21lbs.—Month. Mag. Oct. 1811. A.]
AMBER SEED. See Hibiscus abelmoschus.
AMBERGRIS. (Ambragrisea, &. f.) A concrete, found in very irregular masses, floating on the sea near the Molucca islands, Madagascar, Sumatra, on the coast of Coromandel, Brazil, America, China, and Japan. It has also been taken out of the intestines of

the Physeter macrocephalus, the spermaceti whale. As it has not been found in any whales but such as are dead or sick, its production is generally supposed to be owing to disease, though some have a little too peremptorily affirmed it to be the cause of the morbid affection. As no large piece has ever been found without a greater or less quantity of the beaks of the Sepia octopodia, the common food of the spermaceti whale, interspersed throughout its substance, there can be little doubt of its originating in the intestines of the whale; for if it were occasionally swallowed by it only, and then caused disease, it would be frequently found without these, when it is met with floating or

thrown upon the shore.

Ambergris is found of various sizes, generally in small fragments, but sometimes so large as to weigh near two hundred pounds. When taken from the whale it is not so hard as it becomes afterward on exposure to the air. Its specific gravity ranges from 780 to 926. If good, it adheres like wax to the edge of a knife with which it is scraped, retains the impression knife with which it is scraped, retains the impression of the teeth or nails, and emits a fat odoriferous liquid on being penetrated with a hot needle. It is generally brittle; but, on rubbing it with the nail, it becomes smooth like hard soap. Its colour is either white, black, ash-coloured, yellow, or blackish; or it is variegated, namely, gray with black specks, or gray with yellow specks. Its smell is peculiar, and not easy to be counterfeited. At 144° it melts, and at 212° is volatilized in the form of a white vapour. But, on a red-bat coal it harms, and is entirely dissipated. Wared-hot coal, it burns, and is entirely dissipated. Water has no action on it; acids, except nitric, act feebly on it; alkalies combine with it, and form a soap; ather and the volatile oils dissolve it; so do the fixed oils, and also ammonia, when assisted by heat; alkohol dissolves a portion of it, and is of great use in analyzing it, by separating its constituent parts. Ac cording to Boillon la Grange, who has given the latest analysis of it, 3820 parts of ambergris consist of adipocire 2016 parts, a resinous substance 1167, benzoic acid 425, and coal 212. But Bucholtz could find no benzoic acid in it. Dr. Ure examined two different specimens with considerable attention. The one yielded benzoic acid, the other, equally genuine to all appearance, afforded none.

An alkoholic solution of ambergris, added in minute quantity to lavender water, tooth powder, hair powder, wash balls, &c. communicates its peculiar fragrance. Its retail price being in London so high as a guinea per oz. leads to many adulterations. These consist of various mixtures of benzoin, labdanum, meal, &c. scented with musk. The greasy appearance and smell which heated ambergris exhibits, afford good criteria, joined to its solubility in hot æther and alkohol.

It has occasionally been employed in medicine, but its use is mostly confined to the perfumer. Dr. Swediaur took thirty grains of it without perceiving any sensible effect. A sailor, who took half an ounce of it, found it a good purgative.—Ure's Chem. Dict.

[Ambergris, which is a concretion from the intestines of the expressed; whale also contains a considerable

of the spermaceti whale, also contains a considerable portion of fatty matter, amounting in some specimens to 60 per cent. It is only found in the unhealthy animal. Its chief constituent is a substance very analogous to cholesterine, and to which Peltier and Caventou have given the name of ambreine. By digestion in nitric acid, ambreine is converted into a peculiar acid called the ambreic acid. Webster's Manual of Chem.

The medical qualities of ambergris are stomachic, cordial, and antispasmodic. It is very seldom used in this country.

(Αμβλωσις ; from αμβλοω, to cause AMBLO'SIS.

abortion.) A miscarriage.

Αμβλωτικα; from αμβλοω, to cause abortion.) Medicines which were supposed to occasion abortion.

AMBLYGONITE. A greenish-coloured mineral that occurs in granite, along with green topaz and tourmaline, near Pinig, in Saxony. It seems to be a

species of spodumine.

AMBLYO'PIA. (Amblyopia, a. f.; from aμβλος, duil, and ωψ, the eye.) Amblyosmus; Amblytes. Hippocrates means by this word, dimness of sight to which old people are subject. Paulus Actuarius, and the best modern writers, seem to think that amblyopia

means the same thing as the incomplete amaurosis. I See Amaurosis.

AMBLYO'SMUS. See Amblyopia.

AMBLYTES: See Amblyopia.

A'MBO. An Indian name of the mango.

A'mbon. (From αμβαινω, to ascend.) Celsus uses this term to signify the margin or tip of the sockets in which the heads of the large bones are lodged.

A'MBONE. The same as ambe.
A'MBRA. Amber. Also an aromatic gum.
AMBRA CINERACEA. Ambergris and gray amber.

AMBRA GRISEA. Ambergris.

Amber.

AMBREINE. See Ambergris.
AMBREIC ACID. See Ambergris. A.]
AMBRE'TTE. See Hibiscus abelmoschus.

Ambulati'va. (From ambulo, to walk.) A species of herpes; so called because it walks or creeps, as it were, about the body.

were, about the body.

AMBUSTIO. (Ambustio, onis. f.; from amburo, to burn.) See Burn.

AMBUSTUM. A burn or scald.

AME'LLA. The same as achmella.

AMENORRHCA. (Amenorrhaa, w. f.; from a, priv. µpp., a month, and bto, to flow.) A partial or total obstruction of the menses in women from other causes than programery and old age. The menses causes than pregnancy and old age. The menses should be regular as to quantity and quality; and that should be regular as to quantity and quality; and that this discharge should observe the monthly period, is essential to health. When it is obstructed, nature makes her efforts to obtain for it some other outlet. When these efforts of nature fail, the consequence may be, pyrexia, pulmonic diseases, spasmodic affections, hysteria, epilepsia, mania, apoplexia, chlorosis, according to the general habit and disposition of the patient. Dr. Cullen places this genus in the class locales, and order epischeses. His species are, 1. Emansio mensium; that is, when the menses do not appear so early as is usually expected. See Chlorosis. 2. Suppressio mensium, when, after the menses ap-2. Suppressio mensium, when, after the menses appearing and continuing as usual for some time, they cease without pregnancy occurring. 3. Amenorrhaa difficilis, vel Menorrhagia difficilis, when this flux is too small in quantity, and attended with great

The causes of a suppression of the menses appear mostly to operate by inducing a constriction of the ex-treme vessels; such as cold, fear, and other depressing passions, an indolent life, the abuse of acids, &c. It is sometimes symptomatic of other diseases, in which considerable debility occurs, as phthisis pulmonalis. When the discharge has been some time interrupted, particularly in persons previously healthy, hæmor-rhages will often happen from other outlets, the nose, stomach, lungs, &c. even in some instances a periodical discharge of blood from an ulcer has occurred. The patient generally becomes obstinately costive, often dyspeptic; colicky pains, and various hysterical symptoms likewise are apt to attend. The means of chief efficacy in restoring the uterine function are those calculated to relax spasm, assisted sometimes by such as increase arterial action, particularly in protracted cases. The former will be employed with most probability of success, when symptoms of a mensural effort appear. They are, especially the hip-bath, foeffort appear. They are, especially the hip-bath, fo-mentations to the hypogastrium, sitting over a vessel of hot water, so that the vapour may be applied to the pudenda; with antispasmodic medicines, as the com-pound galbanum pill, castor, &c. but especially opium. If the patient be plethoric, venæsection should be pre-mised. In cases of long standing, the object will be to bring about a determination of blood to the uterus. This may be accomplished by emmenagogues, of which savine and cantharis are most to be relied upon; though the latter would be improper, if hæmaturia had occurred. Certain cathartics are also very useful, particularly aloes, which appear to operate especially on the rectum, and thus sympathetically influence the uterus. Electric shocks passed through the hypogas-tric region, may likewise contribute to the cure.

In cases of scanty and painful menstruation, the means pointed out above as calculated to take off constriction of the uterine vessels, should be resorted to;

especially the hip-bath, and the free use of opium.

AMENTACE E PLANT &. Amentaceous plants. vision of plants in natural arrangements of bota-

..pists.

AMENTA'CEUS. Having an amentum or catkin, as the willow, birch, beech, poplar, &c.

AME'NTIA. (Amentia, &. f.; from a, priv. and mens, the mind.) Imbecility of intellect, by which the relations of things are either not perceived, or not recollected. A disease in the place recovery, and order. recollected. A disease in the class neuroses, and order vesanic of Cullen. When it originates at birth, it is called amentia congenita, natural stupidity; when from the infirmities of age, amentia senilis, dotage or childishness; and when from some accidental cause, amentia

acquisita.

AME'NTUM. (Derived from its fancied resemblance to a cat's-tail, and by Festus, from the Greek auna, a bond or thong.) Julus; Nucamentum; Catulus. Catkin. A species of inflorescence, considered by some as a species of calyx. It is a simple peduncle covered with numerous chaffy scales, under which are the flowers or parts of fractification. The distinctions

of catkins are into,

1. Cylindrical: as in Corylus evellana; Beta alba;

2. Globose as in Fagus sylvatica; Platanus orien-

talis; Urtica pilulifera.

3. Ovate; as in the Female Pinus sylvestris.

4. Filiform: Seen in Fagus pumila and Castanea pumila.

5. Attenuate, slender towards the end: as in Fagus castanea.

6. Thick: in Juglans regia.
7. Imbrecate, scaly: as in Juniperus communis, and

Salix fusca.

8. Paleaceous, chaffy: as in Pinus sylvestris.

9. Naked: the scales being so small or wanting, that the parts of fructification appear naked, as in Excoccaria.

American balsam. See Myroxylum Peruiferum.
[AMERICAN CENTAURY. This is the Chironia angularis of Linnaus. It is a native of damp, rich soils, in the middle and southern parts of the United States, where it is commonly known by the name of centaury Every part of the plant is a pure, strong bitter, and communicates its qualities to both water and alkohol. It appears to be a remedy in considerable use at the south for intermittent fever. On the stomach it exerts an invigorating influence, and promotes appetite and direction. digestion. It may be given in powder, in doses of ten or twenty grains, or in infusion, which is the more common mode.—Bigelow's Sequel, &c. A.]

[AMERICAN COLUMBO. This is the Frasera Walteri

Michaux. It is a tall, rank, perennial plant, growing spontaneously in the southern and western parts of the United States. It is the Swertia frazera of Smith, in Rees's Cyclopedia. The root, which is large and fleshy, has a considerable degree of bitterness, and when cut in slices and dried, has some resemblance to the imported columbo. Owing to its comparative cheapness, it has been substituted in druggists' shops for columbo, to which it is incomparable inferior in for columbo, to which it is incomparably inferior in bitterness. It is however an article of considerable tonic powers, and, when fresh, is said to be emetic and cathartic .- Big. Seq.

thartic.—Big. Seq. A.]
[AMERICAN HELLEBORE. Veratrum viride. The plant bearing this name grows on wet meadows, and on the banks of brooks throughout the United States. It sends up a tuft of large plaited leaves early in the spring, and in June produces a panicle of green flowers. It is often designated by the name of poke-root, though a very different plant from the Phytolacca.

Its properties resemble those of the Veratrum Album

of Europe, to which plant it is so closely allied in appearance, that many botanists have considered them the same species. The root has a bitter taste, accompanied with acrimony, and leaves a permanent impression on the mouth and fauces. It abounds with a resinous juice, which adheres closely to a knife with a resinous juice, which adheres closely to a knife with which it has been cut. This is taken up by alkohol, and precipitated by water. The decoction has an intensely bitter taste, probably owing to an extractive principle. The distilled water has a slightly unpleasant taste, without bitterness or pungency. Very probably prints in this root. ratrine probably exists in this root.

Like the white Hellebore, it is an acrid emetic, and powerful stimulant, followed by sedative effects. From the sum of my observations respecting it, I am satisfied that the root, when not impaired by long keeping or exposure, is, in sufficient doses, a strong emetic, commencing its operation tardily, but contiAMM AMM

nuing it in many instances for a long time; in large | Join to the beak of the retort, by a collar of caout-doses affecting the functions of the brain and nervous | chouc, (a neck of an Indian rubber bottle answers system, in a powerful manner, producing giddiness, impaired vision, prostration of strength, and diminu-

tion of the vital powers,

From three to six grains in powder will commonly occasion vomiting, the activity being in some degree proportionate to the freshness of the article. Dr. Ware found, that doses somewhat larger did not act with undue violence, in the case of some alms-house patients. A wine, prepared like that of white heliebore, has produced relief in gout and rheumatism, in doses

flas produced relief in gout and rheumatism, in doses of less than a fluid drachm.—Big. Mat. Med. A.]

[American Senna. Cassia Marilandica. This is a tall plant, with yellow flowers, growing in most parts of the United States. Its botanical affinity to the Cassia Senna, probably first led to a suspicion of its cathartic powers. Its leaves abound with resin, and have also some extractive and volatile matter. An owner of the defiel leaves infused in water proves ounce of the dried leaves, infused in water, proves cathartic, and the plant, being easy of acquisition, is not unfrequently used for this purpose by country practitioners.—Big. Seq. A.]

AMERICA'NUM TUBEROSUM. The potatoe. See

Solanum toberosum.

Solanum toberosum.

Amethy'sta pharmaca. (From a, neg. and μεθυ, wine.) Medicines which were said either to prevent or remove the effects of wine.—Galen.

AMETHY'STUS. (From a, neg. and μεθυσκω, to be inebriated: so called, because in former times, according to Plutarch, it was thought to prevent drunkenness.—Ruland. in Lex. Chem.) The amethyst. "A gem of a violet colour, and great brilliancy, said to be as hard as the ruby or sapphire, from which it only differs in colour. This is called the oriental amethyst, and is very rare. When it inclines to the purple or rosy colour, it is more esteemed than when it is nearer to colour, it is more esteemed than when it is nearer to the blue. These amethysts have the same figure, hardness, specific gravity, and other qualities, as the hardness, specine gravity, and other qualities, as the best sapphires or rubies, and come from the same places, particularly from Persia, Arabia, Armenia, and the West Indies. The occidental amethysts are merely coloured crystals or quartz."

AMIANTHUS. See Asbestos.

AMICULUM. A little short cloak. It is the same as the amnios, but anciently meant a covering for the pubes of boys, when they exercised in the gymnasium:

—Rhadius.

AMIDINE. A substance produced, according to Saussure, when we abandon the paste of starch to itself, at the ordinary temperature, with or without the contact of air.

A'MIDUM. See Amylum.

A MIDUM. See Amylum.

AMINÆ'UM. A wine produced in Aminæa, formerly a province of Italy; called also Salernum. Also a strong wine vinegar. Galen mentions Aminæum Neapolitanum, and Aminæum Siculum.

A'MMI. (Ammium, i. n. Αμμι; from αμμος, sand, from its likeness to little gravel-stones.) 1. The name of a genus of plants in the Linnean system.

2. The pharmaconomial name of the berk historical.

2. The pharmacopeial name of the herb bishop's weed, of which there are two sorts. See Sison ammi

Ammi majus.

Ammi majus. The systematic name for the ammi vulgare of the shops. The seeds of this plant, Ammi-foliis inferioribus pinnatis, lanceolatis serratis; superioribus, multifidis, linearibus, of Linnæus; are less powerful than those of the Sison ammi, but were exhibited with the same views.

Ammi ve'rum. See Sison Ammi.

Ammi vulgare. See Ammi majus.

Ammion. Ammium. Cinnabar.

Ammocno'sia. (From aμμος, sand, and χεω, to pour.) A remedy for drying the body by sprinkling it with bot sand. Orihazius.

with hot sand .- Oribasius.

AMMO'NIA. (Ammonia, x. f; so called because it is obtained from sal ammoniac, which received its name from being dug out of the earth near the temple name from being dug out of the earth near the temple of Jupiter Ammon.) Ammonia gas. The substance so called is an aëriform or alkaline air. "There is a saline body, formerly brought from Egypt, where it was separated from soot by sublimation, but which is now made abundantly in Europe, called sal ammoniac. From this salt pure ammonia can be readily obtained by the following process: Mix unslacked quicklime with its own weight of sal ammoniac, each in fine powder, and introduce them into a glass retort.

Join to the beak of the retort, by a collar of caoutchouc, (a neck of an Indian rubber bottle answers
well,) a glass tube about 18 inches long, containing
pieces of ignited muriate of lime. This tube should
lie in a horizontal position, and its free end, previously
bent obliquely by the blowpipe, should dip into dry
mercury in a pneumatic trongh. A slip of porous
paper, as an additional precaution, may be tied round
the tube, and kept moist with ether. If a gentle heat
from a charcoal chaffer or lamp be now applied to the
bottom of the retort, a gaseous body will bubble up
through the mercury. Fill a hitle glass tube, scaled at
one end, with the gas, and transfer it, closely stopped
at the other end, into a basin containing water. If the
water rise instantly and fill the whole tube, the gas is
pure, and may be received for examination.

Animonia is a transparent, colourless, and conse-

Animonia is a transparent, colourless, and consequently invisible gas, possessed of elasticity, and the other mechanical properties of the atmospherical air. Its specific gravity is an important datum in chemical researches, and has been rather differently stated. Now as no aeriform body is more easily obtained in a pure state than ammonia, this diversity, among accurate experimentalists, shows the nicety of this statical operation. Biot and Arago make it = 0.59669 by experiment, and by calculation from its elementary gases, they make it = 0.59438. Kirwan says that 100 white inches in the control of the control cubic inches weigh 18.16 gr. at 30 inches of bar. and 61° F., which compared to air reckoned 30.519, gives 0.59540. Sir H. Davy determines its density to be = 0.590, with which estimate the theoretic calculations of Dr. Prout, in the sixth volume of the Annals of Philosophy, agree.

This gas has an exceedingly pungent smell, well known by the old name of spirits of hartshorn. An animal plunged into it speedily dies. It extinguishes combustion, but being itself to a certain degree combustible, the flame of a taper immersed in it is enlarged before going out. It has a very acrid taste. Water condenses it very rapidly. Water is capable of dissolving easily about one-third

of its weight of ammoniacal gas, or 450 times its bulk. Hence, when placed in contact with a tube filled with this gas, water rushes into it with explosive velocity.

Annoniacal gas, perfectly dry, when mixed with oxygen, explodes with the electric spark, and is con-verted into water and nitrogen, as has been shown in an ingenious paper by Dr. Henry. But the simplest, and perhaps most accurate mode of resoiving ammonia into its elementary constituents, is that first practised by Berthollet, the celebrated discoverer of its composition. This consists in making the pure gas traverse very slowly an ignited porcelain tube of a small discoverer. small diameter.

The alkaline nature of ammonia is demonstrated, not only by its neutralizing acidity, and changing the vegetable reds to purple or green, but also by its being When a pretty strong electric power is applied to ammonia in its liquid or solid combinations, simple decomposition is effected; but in contact with mercury, very mysterious phenomena occur. If a globale of mercury be surrounded with a little water of ammonia or placed in a little water of a little water of a little water or placed in a little nia, or placed in a little cavity in a piece of sal ammoniac, and then subjected to the voltaic power by two wires, the negative touching the mercury, and the positive the ammoniacal compound, the globule is instantly covered with a circulating film, a white smoke rises from it, and its volume enlarges, while it shoots out ramifications of a semi-solid consistence over the salt. The amalgam has the consistence of soft butter, and may be cut with a knife. Whenever the electrization is suspended, the crab-like fibres retract towards the central mass, which soon, by the constant formation of white saline films, resumes its pristine globular shape and size. The enlargement of volume seems to amount occasionally to ten times that of the mercury, when a small globule is employed. Sir H. Davy, Berzela, and Gay Lussac and Thenard, have studied this singular phenomenon with great care. They produced the very same substance by putting an amalgan of mercury and potassium into the moistened cupel of sal ammoniae. It becomes five or six times larger, assumes the consistence of butter, while it retains its metallic lustre.

What takes place in these experiments? In the second case, the substance of metallic aspect which we

obtain is an ammoniacal hydruret of mercury and po-tassium. There is formed, besides, muriate of potassa. Consequently a portion of the potassium of the amalgam decomposes the water, becomes potassa, which itself decomposes the muriate of ammonia. Thence result hydrogen and ammonia, which, in the nascent result hydrogen and ammonia, which, in the hascent state, unite to the undecomposed amalgam. In the first experiment, the substance which, as in the second, presents the metallic aspect, is only an ammoniacal hydruret of mercury; its formation is accompanied by the perceptible evolution of a certain quantity of chlorine at the positive pole. It is obvious, therefore, that the salt is decomposed by the electricity. The hydrogen of the muriatic acid, and the ammonia, both combine with the mercury.

Ammonia is not affected by a cherry-red heat. According to Guyton de Morveau, it becomes a liquid at about 40°-0°, or at 0° the freezing point of mercury; but it is uncertain whether the appearances he observed may not have been owing to hygrometric water, as happens with chlorine gas. The ammoniacal liquid loses its pungent smell as its temperature sinks, till at —50° it gelatinizes, if suddenly cooled; but

if slowly cooled it crystallizes.

Oxygen, by means of electricity, or a mere red heat, esolves ammonia into water and nitrogen. When there is a considerable excess of oxygen, it acidifies a portion of the nitrogen into nitrous acid, whence many fallacies in analysis have arisen. Chlorine and ammonia exercise so powerful an action on each other, that when mixed suddenly, a sheet of white flame pervades them. The simplest way of making this fine experiment, is to invert a matress, with a wide mouth and conical neck, over another with a taper neck, containing a mixture of sal ammoniac and lime, heated by a lamp. As soon as the upper vessel seems to be full of ammonia, by the overflow of the pungent gas, it is to be cautiously lifted up, and inserted, in a perpendicular direction, into a wide-mouthed glass decanter or flask, filled with chlorine. On seizing the two vessels thus joined with the two hands covered with gloves, and suddenly inverting them, like a sand-glass, the heavy chlorine and light ammonia rushing in the heavy chlorine and light ammonia, rushing in opposite directions, unite, with the evolution of flame. As one volume of ammonia contains, in a condensed state, one and a half of hydrogen, which requires for its saturation just one and a half of chlorine, this quantity should resolve the mixture into muriatic acid and nitrogen, and thereby give a ready analysis of the alkaline gas. If the proportion of chlorine be less, sal ammoniac and nitrogen are the results. The same thing happens on mixing the aqueous solutions of ammonia and chlorine. But if large bubbles of chlorine be let up in ammoniacal water of moderate strength, luminous streaks are seen in the dark to pervade the liquid, and the same reciprocal change of the ingredients is effected.

Gay Lussac and Thenard state, that when 3 parts of ammoniacal gas and I of chlorine are mixed together, they condense into sal ammoniac, and azote, equal to

1-10 the whole volume, is given out.

Iodine has an analogous action on ammonia; seizing a portion of its hydrogen to form hydriodic acid, whence hydriodate of ammonia results; while another portion of iodine unites with the liberated nitrogen to

form the explosive pulverulent iodine.

Cyanogen and ammoniacal gas begin to act upon each other whenever they come into contact, but some hours are requisite to render the effect complete. They unite in the proportion nearly of 1 to 1 1-2, forming a compound which gives a dark orange-brown colour to water, but dissolves in only a very small quantity of water. The solution does not produce prussian blue water. The solution with the salts of iron.

By transmitting ammoniacal gas through charcoal

ignited in a tube, prussic or hydrocyanic acid is formed.

The action of the alkaline metals on gaseous ammonia, is very curious. When potassium is fused in that gas, a very fusible olive-green so stance, consisting of potassium, nitrogen, and ammonia is formed; and a volume of hydrogen remains exactly equal to what would result from the action on water of the quantity of notassium employed. Hence according to Themard. of potassium employed. Hence, according to Thenard, the ammonia is divided into two portions. One is decomposed, so that its nitrogen combines with the potassium, and its hydrogen remains free, while the other is absorbed in whole or in part by the nitroguret

of potassium. Sodium acts in the same manner. The olive substance is opaque, and it is only when in plates of extreme thinness that it appears semitransparent; it has nothing of the metallic appearance; it is heavier than water; and, on minute inspection, seems impe-fectly crystallized. When it is exposed to a heat progressively increased, it melts, disengages ammonia, and hydrogen, and nitrogen, in the proportions constituting ammonia; then it becomes solid, still preserving its green colour, and is converted into a nitroguret of potassium or sodium. Exposed to the air at the ordinary temperature, it attracts only its humidity, but not its oxygen, and is slowly transformed into ammoniacal gas, and potassa or soda. It burns vividly when projected into a hot crucible, or when heated in a vessel containing oxygen. Water and acids produce also sudden decomposition, with the extrication of heat. Alkalies or aikaline salts are produced. Alkohol likewise decomposes it with similar results. The pre-ceding description of the compound of ammonia with potassium, as prepared by Gay Lussac and Thenard, was controverted by Sir H. Davy.

The experiments of this accurate chemist led to the conclusion, that the presence of moisture had modified their results. In proportion as more precautions are taken to keep every thing absolutely dry, so in propor-tion is less ammonia regenerated. He seldom obtained as much as 1-10 of the quantity absorbed; and he never could procure hydrogen and nitrogen in the proportions constituting ammonia; there was always an excess of nitrogen. The following experiment was conducted with the utmost nicety. 31-2 gr. of potassium were heated in 12 cubic inches of ammoniacal gas; 7.5 were absorbed, and 3.2 of hydrogen evolved. On distilling the olive-coloured solid in a tube of plation disting the onve-coloured sona in a time of plan-na, 9 cubical inches of gas were given off, and half a cubical inch remained in the tube and adapters. Of the nine cubical inches, one-fifth of a cubical inch only was ammonia; 10 measures of the permanent gas mixed with 7.5 of oxygen, and acted upon by the electrical spark, left a residuum of 7.5. He infers that the results of the analysis of ammonia, by electricity and potassium, are the same.

On the whole we may legitimately infer, that there is something yet unexplained in these phenomena. The potassium separates from ammonia as much hy-drogen, as an equal weight of it would from water. If two volumes of hydrogen be thus detached from the alkaline gas, the remaining volume, with the volume of nitrogen, will be left to combine with the potassium, forming a triple compound, somewhat analogous to the cyanides, a compound capable of condensing am-

When ammoniacal gas is transmitted over ignited wires of iron, copper, platina, &c. it is decomposed completely, and though the metals are not increased in weight, they have become extremely brittle. Iron, at the same temperature, decomposes the ammonia, with double the rapidity that platinum does. At a high temperature, the protoxyde of nitrogen decomposes

Of the ordinary metals, zinc is the only one which liquid ammonia oxydizes and then dissolves. But it acts on many of the metallic oxydes. At a high temacts on many of the metallic oxydes. At a high temperature the gas deoxydizes all those which are reducible by hydrogen. The oxydes soluble in liquid ammonia, are the oxyde of zinc; the protoxyde and peroxyde of copper; the oxyde of silver; the third and fourth oxydes of antimony; the oxyde of tellurium; the protoxides of nickel, cobalt, and iron, the peroxyde of tin, mercury, gold, and platinum. The first five are very soluble, the rest less so. These combinations can be obtained by evaporation, in the dry state, only with copper, antimony, mercury, gold, platinum, and with copper, antimony, mercury, gold, platinum, and silver; the four last of which are very remarkable for their detonating property. See the particular metals. All the acids are susceptible of combining with am-

monia, and they almost all form with it neutral com-Gay Lussac made the important discovery, that whenever the acid is gaseous, its combination with ammoniacal gas takes place in a simple ratio of determinate volumes, whether a neutral or a subsalt

2d, They are generally soluble in water, and crys-

3d, They are all decomposed at a moderate red neat; and if the acid be fixed, as the phosphoric or

boracic, the ammonia comes away pure.

Ammoniac it was brought.) Gum-ammoniac.

A concrete gummy resinous juice, composed of little lumps, or lears, of a strong and somewhat ungrateful lumps, or tears, of a strong and somewhat ungrateful smell, and nauseous taste, followed by a bitterness. There has, hitherto, been no information had concerning the plant which affords this drug; but Wildenow considers it to be the Heracleum gummiferum, having raised that plant from the seeds, which are sometimes raised that plant from the seeds, which are sometimes found in the drug. It is imported here from Turkey, and from the East Indies. It consists, according to Braconnot, of 70 resin, 18.4 gum. 4.4 glutinous matter, 6 water, and 1.2 loss in 100 parts. Gum ammoniacum is principally employed as an expectorant, and is frequently prescribed in asthma and chronic catarrh. Its dose is from 10 to 30 grains. It is given in the form of the catarrh is given in the form of the catarrh is given in the form of pill or diffused in water, and is frequently combined with squill, or tartarized antimony. In large doses it proves purgative. Externally, it is applied as a discutient, under the form of plaster, to white swellings of the knee, and to indolent tumours. The officinal preparations are ammoniacum purificatum. Emplastrum ammoniaci; Empl. ammoniaci cum hydrargyro; Mistura ammoniaci.

Ammonia acettatis Liquor. A solution of acetate of ammonia; formerly called Aqua ammonia acetata. Take of sub-carbonate of ammonia, two ounces; dilute acetic acid, four pints. Add the acid to the salt, until bubbles of gas shall no longer arise, and mix. The effervescence is occasioned by the escape of carbonic acid gas, which the acetic usid gas and not acre. bonic acid gas, which the acetic acid expels, and neu-

tralizes the ammonia.

If the acid rather predominate, the solution is more grateful to the taste; and provided that acid be correctly prepared, the proportions here given will be found sufficient; where the acid cannot be depended on, it will be right to be regulated rather by the cessa-

tion of effervescence than by quantity.

This preparation was formerly known in the shops under the name of spirit of Mindererus. When assisted by a warm regimen, it proves an excellent and powerful sudorific; and, as it operates without quickening the circulation, or increasing the heat of the body, it is admissible in febrile and inflammatory diseases, in which the use of stimulating sudorifics are attended with danger. Its action may likewise be determined to the hidrons. to the kidneys, by walking about in the cool air. The common dose is half an ounce, either by itself, or along with other medicines, adapted to the same in-

AMMONIÆ CARBONAS. See Ammoniæ subcarbonas.

AMMONIÆ LIQUOR. Liquor of Ammonia. Take of muriate of ammonia eight ounces; lime newly prepared, six ounces; water, four pints. Pour on the lime a pint of the water, then cover the vessel, and set them by for an hour; then add the muriate of ammonia, and the remaining water previously made boiling hot, and cover the vessel again; strain the liquor when it has cooled; then distil from it twelve fluid ounces of the solution of ammonia into a receiver cooled to the temperature of 50°. The specific gravity of this solution should be to that of distilled water, as 4.960 to 1000.

Lime is capable of decomposing muriate of ammo-

nia at a temperature much below that of boiling water; so that when the materials are mixed, a solution of ammonia and of muriate of lime is obtained. This being submitted to distillation, the ammonia passes over with a certain portion of the water, leaving be-hind the muriate of lime dissolved in the rest. The proportion of water directed seems, however, unnecessarily great, which obliges the operator to employ larger vessels than would otherwise suffice. But the process now directed is certainly much easier, more economical and more uniform in its results than that of cal, and more uniform in its results, than that of former pharmacopæias.

This preparation is colourless and transparent with a strong peculiar smell; it parts with the ammonia in the form of gas, if heated to 130 degrees, and requires to be kept, with a cautious exclusion of atmospherical air, with the carbonic acid of which it readily unites: on this latter account, the propriety of keeping it in small bottles instead of a large one, has been sug-

gested.

This is the aqua ammonia pura of the shops, and the alcali volatile causticum.

Water of ammonia is very rarely given internally, although it may be used in doses of ten or twenty drops, largely diluted, as a powerful stimulant in asphyxia and similar diseases. Externally it is applied to the skin as a rubefacient, and in the form of gas to the nostrils, and to the eyes as a stimulant: in cases of torpor, paralysis, rheumatism, syncope, hysteria, and elvronic orbitalpaia. chronic ophthalmia.

AMMONIÆ MURIAS: See Sal ammoniace.

AMMONIE NITRAS. Alcali volatile nitratum; Sal ammoniacus nitrosus; Ammonia nitrata. A salt composed of the nitric acid and ammonia, the virtues of which are internally diuretic and deobstruent, and

externally resolvent and sialogogue.

AMMONIE SUBCARBONAS. Subcarbonate of ammonia. This preparation was formerly called ammonia praparata, and sal volatilis salis ammoniaci, and sal volatilis. It is made thus:—Take of muriate of ammonia, a pound: of prepared chalk dried a pound. monia, a pound: of prepared chalk, dried, a pound and a half. Reduce them separately to powder; then mix them together, and sublime in a heat gradually raised, till the retort becomes red. In this pre-paration a double decomposition takes place, the car-bonic acid of the chalk uniting with the ammonia, and forming subcarbonate of ammonia, which is volatilized while muriate of lime remains in the vessel.

This salt possesses nervine and stimulating powers, and is highly beneficial in the dose of from two to

eight grains, in nervous affections, debilities, flatulency, and acidity from dyspepsia.

Ammonia subcarbonatis Liquor. Liquor ammonia carbonatis. Solution of subcarbonate of ammonia. Take of subcarbonate of ammonia, four ounces; distilled water a pint. Dissolve the subcarbonate of ammonia in the water, and filter the solution through paper. This preparation possesses the properties of ammonia in its action on the human body. See Ammonia subcarbonas.

Ammonicated copper, liquor of. See Cupri ammoniati liquor.

miati liquor.

Ammo'nion. (From αμμος, sand.) Ačtius uses this term to denote a collyrium of great virtue in many diseases of the eye, which was said to remove sand or

gravel from the eyes.

AMMONITES. Petrifactions, which have likewise been distinguished by the name of cornua ammonis, and are called snake-stones by the vulgar, consist chiefly of lime-stone. They are found of all sizes, from the breadth of half an inch to more than two feet in diameter; some of them rounded, others greatly compressed, and lodged in different strata of stones and clays. They appear to owe their origin to shells of the nautilus kind.

AMMO'NIUM. Berzelius first gave this name to a supposed metal which with oxygen he conceives to form the alkali called ammonia. It is now generally used by all chemists. See Ammonia.

AMNE'SIA. (From a, priv. and μνησις, memory.) Amnestia. Forgetfulness; mostly a symptomatic affection.

affection.

AMNE'STIA. See Amnesia.

A'MNIOS. (From aµvos, a lamb, or lamb's skin.)

Amnion. The soft internal membrane which surrounds the fœtus. It is very thin and pellucid in the early stage of pregnancy, but acquires considerable

name.) Of or belonging to the amnios.

Amniotic acid. Acidum amnioticum. A peculiar acid found in the liquor of the amnios of the cow. It exists in the form of a white pulverulent powder. It is slightly acid to the taste, but sensibly reddens vegetable blues. It is with difficulty soluble in cold, but readily soluble in boiling water, and in alkohol. When exposed to a strong heat, it exhales an odour of ammonia and of prussic acid. Assisted by heat, it decomposes carbonate of potassa, soda, and ammonia. It produces no change in the solutions of silver, lead, or mercury, in nitric acid. Amniotic acid may be obtained by evaporating the liquor of the amnios of the cow to a fourth part, and suffering it to cool; crystals of amniotic acid will be obtained in considerable quantity. Whether this acid exists in the liquor of the amnios of other animals, is not yet known. nios of other animals, is not yet known.

AMO'MUM. (Amomum, i. n.; from an Arabian word, signifying a pigeon, the foot of which it was thought to resemble.) The name of a genus of plants in the Linnman system. Class Monanaria; Order,

Monogynia.

Amonum Cardamomum. The former systematic name for the cardamomum minus. See Elettaria

cardamomum.

AMOMUM GRANUM PARADISI. The systematic name of the plant which affords the grains of paradise. Cardamonum majus; Melegraetta; Maniguetta; Cardamonum piperatium. Grains of paradise, or the
greater cardamom seeds, are contained in a large
brown, somewhat triangular flask, the thickness of
one's thumb, and pyramidal. The seeds are angular,
and of a reddish brown colour, smaller than pepper,
and resemble very much the seeds of the cardamonum minus. They are extremely hot, and similar in virtue to pepper.

Amonum verum. True stone parsley. The fruit is about the size of a grape, of a strong and grateful aromanic taste, and penetrating smell. The seeds have

been given as a carminative.

Anomem zingiber. The former systematic name of the plant which affords ginger. See Zingiber offici-

Amo'nge. See Amurca.

AMPELITE. The aluminous ampelite, is the alum slate; and the graphic, the graphic slate.

AMPELOSA GRIA. (From αμπελος, a vine, and

ayotos, wild.) See Bryonia alba.

AMPHEMERI NA. See Amphemerinos.

AMPHEMERI'NOS. (Form aμφι, about and ημερα, aday.) Amphemerina. A fever of one day's du-

AMPHIARTHRO'SIS. Αμφιερθρωσις; from αμφι, both, and αρθρωσις, an articulation: so called from its partaking both of diarthrosis and synarthrosis.) A mixed species of connexion of bones, which admits of an obscure motion, as is observed in the metacarpal and metatarsal bones, and the vertebræ.

AMPHIBIUM. (From aμφt, ambo, and βιος, vita.) An amphibious animal, or one that lives both on land and in the water.

An amphibious animal, or one that lives both on land and in the water. The amphibious animals, according to Linnæus, are a class, the heart of which is furnished with one ventricle and one auricle, in which respiration is in a considerable degree voluntary.

AMPHIBLESTROIDES. (From αμφιβλιεγον, a net, and αδος, a resemblance.) Reteform or net-like; a term which has been applied to the retina.

AMPHIBLE. Some species of actionsite and hornblende have this name.

This is the name given by Haüy, to a mineral, the

synonyms of which are:— Tremolith of Werner,

La Tremolithe of Brochant, Grammatite of Brogniart, Tremolite of Cleaveland. A.]

Tremolite of Cleaveland. A.]

Amphibolites. Trap rocks are so called in geology, the basis of which is hornblende.

AMPHIBRA'NCHIA. (From αμφι, about, and βρανχια, the jaws.) The fauces or parts about the tonsils, according to Hippocrates and Foësius.

Amphicau'stis. (From αμφι, about, and καυςις,

ripe corn.) 1. A sort of wild barley.

thickness and strength in the latter months. The amnios contains a thin watery fluid, in which the fætus is suspended. See Liquor amnii.

AMNIOTIC. (Amnioticus; from amnios: so called because it is obtained from the membrane of that because it is obtained from the membrane of that the fætus is obtained from the membrane of that the factor of a woman.

AMPHIDIARTHRO'SIS. The same as Amphiar-

AMPHIGENE. A name of Vesuvian.

[This name is given by Hauy to that crystalline substance, frequently found among volcanic productions, and which other mineralogists have called Leu-

cite. A.] AMPHIMERI'NA. (From aμφι, about, and ημερα, a day.) A fever of one day's continuance. AMPHIME TRION. (From aμφι, about, and μητρα, the womb.) Amphimetrium. The parts about

ine womb. Hippocrates.

A'mphiplex. (From apφι, about, and πλεκτω, to connect.) According to Rufus Ephesius, the part situated between the scrotum and anus, and which is connected with the thighs.

connected with the thighs.

Amphipmeuma. (From aμφι, about, and πνευμα, breath.) A difficulty of breathing.—Hippocrates.

AMPHIPOLIS. (From aμφι, about, and πολεω, to attend.) Amphipolus. One who attends the bed of a sick person, and administers to him.—Hippocrates.

Amphismi'la. (From aμφι, on both sides, and σμιλη, an incision-knife.) A dissecting knife, with an edge on both sides. Galen.

AMPLECTENS. Embracing, clasping.

AMPLECTENS. (From amplector, to sur-

AMPLEXICAULIS, (From amplector, to surround, and caulis, a stem.) Embracing or clasping the stem. Folium amplezicaule is a leaf, the base of which surrounds the stem, as in Papaver somniferum and Carduus marianus; and the Senesio hirsutus, has a leaistalk which embraces the stem as its base.

AMPU'LLA. (Αμβολλα; from αναβαλλω, to swell it.) A bottle.

out.) A bottle.

1. All bellied vessels are so called in chemistry, as

bolt-heads, receivers, cucurbits, &c.
2. In anatomy this term is applied by Scarpa to the dilated portions of the membranaceous semicircular canals, just within the vestibulum of the ear.

3. In botany; it is a small membranaceous bag attached to the roots and the emersed leaves of some

aquatic plants, rendering them buoyant.—Thompson.
AMPULLE'SCENS. (From ampulla, a bottle.)
The most tumid part of the thoracic duct is called al-

AMPUTA'TIO. (From amputo, to cut off.) Ectome. Amputation; a surgical operation, which consists in the removal of a limb or viscus: thus we say, a leg, a finger, the penis, &c. when cut off, are amputated; but when speaking of a tumour or excrescence, it is

but when speaking of a tumour or excrescence, it is said to be removed, or dissected out.

AMULE TUM. (From αμμα, a bond; because it was tied round the person's neck; or rather from αμυνω, to defend.) An amulet, or charm; by wearing which the person was supposed to be defended from the admission of all evil: in particular, an antidote

against the plague.

Amu'rca. (From αμτργω, to press out.) Amorge. A small herb, whose expressed juice is used in AMU'RCA

dying.

2. The sediment of the olive, after the oil has been pressed from it; recommended by Hippocrates and Galen as an application to ulcers.

AMUTICA. (From αμυτ 7ω, to scratch.) Medicines that, by vellicating or scratching, as it were, the bronchia stimulate it to the discharge of whatever is to chia, stimulate it to the discharge of whatever is to be thrown off the lungs.

A'MYCHE. (From αμυσσω, to scratch.)

1. A superficial laceration or exulceration of the skin: a slight wound.—Hippocrates.

2. Scarification.—Galen.

AMY GDALA. (Amygdala, æ. f.; Αμυγδαλη; fróm αμυσσω, to lancinate: so called, because after the green husk is removed from the fruit, there appear upon the shell certain fissures, as it were lacerations.

1. The fruit called the almond. See Amygdalis

2. The tonsil glands of the throat are sometimes termed, from their resemblance, Amygdala.

AMYGDALA AMARA. The bitter almond. See Amyg-

dalus communis.

dalus communis.

AMYGDALE OLEUM. See Amygdalus communis.

AMYGDALOID. (Amygdaloides; from amygdalus, an almond, and tidos, resemblance.) Almond-like.

1. A name given to some parts of the body and to parts of vegetables and minerals, which resemble almonds.

2. A compound mineral consisting of spheroidal particles or vesicles of lithomarge, green earth, calc spar, steatite imbedded in a basis of fine-grained greenstone or wacke, containing sometimes, also, crystals of

[Amygdaloid is a compound rock, composed of a basis, in which are imbedded various simple minerals. But these imbedded minerals are not crystals and grains, apparently of cotemporaneous origin with the basis itself, as in the case of porphyry. On the contrary, their form, though sometimes irregular, is usually spheroidal or oval, like that of an almond; and hence the name of this rock, (from Amygdala, an almond.) -Cleav. Min. A.] AMY GDALUS.

AMY'GDALUS. (Amygdalus, i. m.; from amygdala, the derivation of which look to.) The name of a genus of plants in the Linuxan system. Class Icosandria; Order, Monogynia. The almond-tree.

Amygdalus communis. The systematic name of the plant which affords the common almond. Amygdalus common almond.

dalus-foliis serratis infimis glandulosis, floribus ses-

silibus geminis of Linnaus.

The almond is a native of Barbary. The same tree produces either bitter or sweet. Sweet almonds are more in use as food than medicine; but they are said to be difficult of digestion, unless extremely well comminuted. Their medicinal qualities depend upon the oil which they contain in the farinaceous matter, and which they afford on expression, nearly in the proportion of half their weight. It is very similar to olive oil; perhaps rather purer, and is used for the same purposes. The oil thus obtained is more agreeable to the palate than most of the other expressed oils, and is therefore preferred for internal use, being generally employed with a view to obtund acrid juices, and to employed with a view to obtund acria juices, and to soften and relax the solids, in tickling coughs, hoarseness, costiveness, nephritic pains, &c. Externally, it is applied against tension and rigidity of particular parts. The milky solutions of almonds in watery liquors, usually called emulsions, possess, in a certain degree, the emollient qualities of the oil, and have this advantage over pure oil, that they may be given in acute or inflammatory disorders, without danger of the ill effects which the oil might sometimes produce by turning rancid. The officinal preparations of almonds are the expressed oil, the confection, and the emuision; to the latter, the addition of gum-arabic is sometimes directed, which renders it a still more useful demui-

cent in catarrhal affections, stranguries, &c.

Bitter almonds yield a large quantity of oil, perfectly similar to that obtained from sweet almonds, but the matter remaining after the expression of the oil, is more powerfully bitter than the almond in its entire state. Great part of the bitter matter dissolves by the assistance of heat, both in water and rectified spirit; and a part arises also with both menstrua in distilla-tion. Bitter almonds have been long known to be poisonous to various brute animals; and some authors have alleged that they are also deleterious to the human species; but the facts recorded upon this point appear to want further proof. However, as the noxious quality seems to reside in that matter which gives it the bitterness and flavour, it is very probable, that when this is separated by distillation, and taken in a sufficiently concentrated state, it may prove a poison to man, as is the case with the common laurel, to which it appears extremely analogous. Bergius tells us, that bitter almonds, in the form of emulsion, cured obstinate intermittents, after the bark had failed. A simple water is distilled from bitter almonds, after the oil is pressed out, which possesses the same qualities,

oil is pressed out, which possesses the same qualities, and in the same degree, as that drawn from cherrystones. These afforded, formerly, the now-exploded aqua cerasorum nigrorum, or black cherry-water.

Anygoalus Persica. The systematic name of the common peach-tree. The fruit is known to be grateful and wholesome, seldom disagreeing with the stomach, unless this organ is not in a healthy state, or the fruit has been eaten to excess, when effects similar to those

AMYGDALA DULCIS. The sweet almond. See Amygodus communis.

AMYGDALE OLEUM. See Amygdalus communis.

AMYGDALE OLEUM. See Amygdalus communis. cinal purposes. These have an agreeable but weak smell, and a bitterish taste. Boulduc observes, "that when distilled, without addition, by the heat of a water-bath, they yield one-sixth their weight, or more, of a whitish liquid, which communicates to a considerable quantity of other liquids a flavour like that of the kernels of fruits. These flowers have a cathartic effect, and especially to children, have been successfully given in the character of a vermituge; for this purpose, an infusion of a drachm of flowers dried, or half an ounce in their recent state, is the requisite dose. The leaves of the peach are also found to possess anthelmintic power, and from a great number of experiments appear to have been given with invariable sucleaves and flowers of this plant manifest, in some de-gree, the quality of those of the laurocerasus, they ought to be used with caution."

A'MYLA. (From amylum, starch.) This term has been applied to some chemical fecula, or highly pul-

verized residuum. Obsolete.

AMY'LEON. Amylion. Starch.
A'MYLUM. (Amylum, i. n. Αμυλον; from a, priv. and μυλη, a mill; because it was formerly made from wheat, without the assistance of a mill.) Amy-

leon; Amylion. See Starch.

AMY RIS. (From a, intensive, and pupor, ointment, or balm; so called from its use, or smell.) The name of a genus of plants in the Linnæan system. Class, Octandria; Order, Monogynia, of which two species are used in medicine.

AMYRIS ELEMIFERA. The systematic name of the plant from which it is supposed we obtain the resin called gum-elemi. The plant is described by Linnæus:
Amyris:—foliis ternis quinato pinnatisque subtus tomentosis. Elemi is brought here from the Spanish West Indies: it is most esteemed when softish, somewhat transparent, of a pale whitish colour, inclining a little to green, and of a strong, though not unpleasant smell. It is only used in ointments and plasters, and is a powerful digestive.

AMNRIS GILEADENSIS. The systematic name of the plant from which the opobalsamum is obtained. It has been called by a variety of names, as Balsamum genuinum antiquorum; Balsamelæon; Ægyptiacum balsa-mum; Balsamum Asiaticum; Balsamum Judaicum, Balsamum Syriacum; Balsamum e Mecca; Balsamum Alpini; Oleum balsami; Carpobalsamum; Xylobal-samum. Balsam, or balm of Gilead; Balsam of Mecca. A resinous juice, obtained by making integerrimis, bark of the Amyris: -folics ternatis integerrimis, This tree A resinous juice, obtained by making incisions into the grows spontaneously, particularly near to Mecca, on the Asiatic side of the Red Sea. The juice of the fruit is termed carpobalsamum in the pharmacoposias, and that of the wood and branches zylobalsamum. The best sort is a spontaneous exudation from the tree, and is held in so high estimation by the Turks, that it is rarely, if ever, to be met with genuine among us. The medicinal virtues of the genuine balsam of Gilead, have been highly rated, undoubtedly with much exaggera-tion. The common balsam of Mecca is scarcely used; but its qualities seem to be very similar to those of the balsam of Tolu, with perhaps more acrimony. dose is from 15 to 50 drops.

A'MYUM. (From a, priv. and \(\rho \varphi_0\), muscle.) A limb so emaciated that the muscles scarcely appear.

ANA. In medical prescriptions it means "of each." See A.

Ana'Basis. (From avabatro, to ascend.)

1. An ascension, augmentation, or increase of a disease, or paroxysm. It is usually meant of fevers.— Galen.

2. A species of the equisetum, or horse-tail plant, Anaba Tica. (From arcbarra, to ascend.) An epithet formerly applied to a continual fever, when it increases in malignity.

ANABE XIS. (From aναδηττω, to cough up.) An expectoration of matter by coughing.

ANABLE PSIS. (From aνα and βλεπω, to see again.) The recovery of sight after it has been lost.

ANABLYSIS. (From ανα and βλυζω, to gush out again.) Ebullition or effervescence.

Ana nois. (From avabaddo, to cast up.)

distharge of any thing by vomit; also dilatation, or sense of touch. extension.-Galen.

ANABROCHE'SIS. (From ava and βροχεω, to reabsorb.) The reabsorption of matter.

Anabrochi smos. (From αναδοοχεω, to reabsorb.) Anabrochismus. The taking up and removing the hair on the eyelids, when they become troublesome.—

Galen, Ægineta, and others.

ANABRO'SIS. (From αναβροσκω, to devour.) A corrosion of the solid parts, by sharp and biting

humours .- Galen

ANACA RDIUM. (From aya, without, and καρδια, a heart.) Without heart; because the pulp of the fruit, instead of having the seed enclosed, as is usually the case, has the nut growing out of the end of it. The name of a genus of plants. Class, Enneandria; Order,

Monogynia.

ANACARDIUM OCCIDENTALE. The cashewnut. The oil of this nut is an active caustic, and employed as such in its native country: but neither it, nor any part of the fruit, is used medicinally in this country. It is a useful marking ink, as any thing written on linen or cotton with it, is of a brown colour, which gradually grows blocker, and is very durable. grows blacker, and is very durable.

ANACARDIUM ORIENTALE. The Malacca bean. See

ANACATHA'RSIS. (From ava, and καθαιρομαι, to purge up.) An expectoration of pus, or a purgation by spitting, contra-distinguished from catharsis, or evacuation downwards. In this sense the word is used by Hippocrates and Galen. Blanchard denotes, by this word, medicines which operate upwards, as vomiting the vomiting, &c.
ANACATHA'RTIC. (Anacatharticus; from ava-

καθαιρομαι, to purge upwards.) Promoting expecto-

ration, or vomiting

ANA'CHRON. Mineral alkali. ANA'CLASIS. (From ayaghaw, to bend back.) reflection or recurvature of any of the members, accord-

ing to Hippocrates.

ANA'CLISIS. (From ανακλενω, to recline.) A couch, or sick-bed.—Hippocrates.

ANACO'CHE. (From ανακωχεω, to retard.) Delay in the administration of medicines; also slowness in

the progress of a disease.—Hippocrates.

ANACŒLIA'SMUS. (From ανα, and κοιλια, the

bowels.) A gentle purge, which was sometimes used to relieve the lungs.

Anacolle'ma. (From ανα, and κολλαω, to glue together.) A collyrium made of agglutinant substances, and stuck on the forehead.—Galen.

Anaconcholi'smos. (From ανακογχολιζω, to sound as a shell.) A gargarism: so called, because the noise made in the throat is like the sound of a shell.—Galen.

ANACTE'SIS. (From ανακτασμαι, to recover.)

Restoration of strength; recovery from sickness.—

Hippocrates.
ANACUPHI'SMA. (From ανακουφίζω, to lift up.)
A kind of exercise mentioned by Hippocrates, which
consists in lifting the body up and down, like our weigh jolt, and dumb bells.

Anacyce sis. (From ανατυκαω, to mix.) The mixture of substances, or medicines, by pouring one

upon another.

ANACY CLEON. (From avakuklow, to wander about.) Anacycleus. A mountebank, or wandering

ANACYRIOSIS. (From ava, and svoos, authority.) By this word, Hippocrates means that gravity and authority which physicians should preserve among

sick people and their attendants.

ANADIPLO SIS. (From αναδιπλοω, to reduplicate.) A reduplication or frequent return of a parox-

ysm, or disease. — Galen.

Ana posis. (From arω, upwards, and διζωμι, to

give.) 1. A vomit.
2. The distribution of aliment all over the body.

3. Digestion.

Ana Drome. (From ανω, upwards, and δρεμω, to run.) A pain which runs from the lower extremities

run.) A pain which runs from the lower extremities to the upper parts of the body.—Hippocrates.

Anπ'des. (From a, priv. and aιδως, a shame.) Shameless. Hippocrates uses this word metaphorically for without restraint; and applies it to water rushing into the aspera arteria.

ANÆSTHE'SIA. (Anæsthesia, æ. f. Δναισθησια; from a, priv. and αισθανομαι, to feel.) Loss of the

sense of touch. A genus of disease in the class Locales, and order Dysasthesia of Cullen.

ANAGA'LLIS. (From αναγελαω, to laugh; because, by curing the spleen, it disposes persons to be cheerful.) 1. The name of a genus of plants in the Linnæan system.

2. The pharmacopæial name of the anagallis

arvensis.

Anagallis—folius indivisis, caule procumbente of Linneus. A small and delicately formed plant, which does not appear to possess any particular properties.

Anagargali στυμ. (From ανα, and γαργαρεων, the throat.) A gargarism, or wash for the throat.

Anagareant stum. A gargle.

ANAGLY PHE. (From αιαγλυφω, to engrave.)

A part of the fourth ventricle of the brain was formerly thus called, from its resemblance to a pen, or style.

thus called, from its resemblance to a pen, or style.

ANAGNO'SIS. (From αναγινωσκω, to know.)
The persuasion, or certainty, by which medical men judge of a disease from its symptoms.—Hippocrates.

ANA'GRAPHE. (From αναγραφω, to write.) A prescription or receipt.

ANALCINE. Cubic zeolite. A mineral found in granite, gneiss, trap rocks, and lavas, at Calton Hill, Edinburgh, in Bohemia, and Ferroe islands. From its becoming feebly electrical by heat, it has got this name. [Derived from Αναλκις. Weak.]

ANALE'NTIA. A fictitious term used by Paracelsus for epilepsy.

for epilepsy.

ANALE PSIA. (From ava, and λαμβανω, to take again.) A species of epilepsy, which proceeds from a disorder of the stomach, and with which the patient is

disorder of the stomach, and with which the patient is apt to be seized very often and suddenly.

ANALE'PSIS. (From αναλαμβανω, to restore.) A recovery of strength after sickness.

ANALE'PTIC. (Analepticus; from αναλαμβανω, to recruit or recover.) That which recovers the strength which has been lost by sickness.

ANALO'SIS. (From αναλισκω, to consume.) A consumption, or wasting.

ANA'LY'SIS. (Αναλυσις; from αναλυω, to resolve.) The resolution by chemistry, of any matter into its

The resolution by chemistry, of any matter into its primary and constituent parts. The processes and exprimary and constituent parts. The processes and experiments which chemists have recourse to, are extremely numerous and diversified, yet they may be reduced to two species, which comprehend the whole art of chemistry. The first is, analysis, or decomposition; the second, synthesis, or composition. In analysis, the parts of which bodies are composed, are separated from each other; thus, if we reduce cinnabar, which is composed of sulphur and mercury, and exhibit these two hodies in a separate state, we say exhibit these two bodies in a separate state, we say we have decomposed or analyzed cinnabar. But if, on the contrary, several bodies be mixed together, and a new substance be produced, the process is then terma new substance be produced, the process is then termi-ed chemical composition, or synthesis: thus, if by fusion and sublimation, we combine mercury with sulphur, and produce cinnabar, the operation is termed chemical composition, or composition by synthesis. Chemical analysis consists of a great variety of opera-tions. In these operations the most extensive knowledge of such properties of bodies as are already discovered must be applied, in order to produce simplicity of effect, and certainty in the results. Chemical anaof effect, and certainty in the results. Chemical analysis can hardly be executed with success, by one who is not in possession of a considerable number of simple substances in a state of great purity, many of which, from their effects, are called reagents. The word analysis is often applied by chemists to denote that series of operations, by which the component parts of hodies are determined, whether they be merely separated, or exhibited apart from each other; or whether these distinctive properties be exhibited by causing them to enter into new combinations, without the percentible distinctive properties be exhibited by causing them to enter into new combinations, without the perceptible intervention of a separate state; and, in the chemical examination of bodies, analysis or separation can scarcely ever be effected, without synthesis taking place at the same time.

ANAMNE'SIS. (From αναμιμνησκώ, to remember.) Remembrance, or recollection of what has been done.

ANAMNE STIC. (From the same.) A remedy for bad memory, or whatever strengthens the memory. ANA NAS. The egg-shaped pine-apple. See Bromelia Ananas.

ANA'NCE. (From avayxaço, to compel.)

sity. It is applied to any desperate operation .- Hip- gross to pass by these, it raises the cuticle in small

Anaphalanti'asis. (From αναφαλαντος, bald.) Λ thinness of hair upon the eyebrows.—Gorræus.

ANA PHORA. (From αναφερω, to bring up.) It is applied to a person who spits blood.—Gorræus.

ANAPHORY'XIS. (From αναφορυσσω, to grind

down.) The reducing of any thing to dust, or a very

ANAPHRODI'SIA. (Anaphrodista, &. f.; from a, priv. and appoolista, the feast of Venus.) Impotence. A genus of disease in the class Locales, and order Dysorexia of Cullen. It either arises from paralysis, anaphrodisia paralytica; or from gonorrhea, anaphrodisia gonorrhoica.

ANAPHRO'MELL. (From a, neg. appos, froth, and

μελι, boney.) Clarified honey.

ANAPLA'SIS. (From αναπλασσω, to restore again.)

A restoration of flesh where it has been lost; also the

reuniting a fractured bone.—Hippocrates.

ANAPLERO'SIS. (From αναπληροω, to fill again.)
The restitution or filling up of wasted parts.—Galen.

ANAPLERO TICA. (From the same.) Medicines re-

newing flesh: incarnatives, or such medicines as fill up a wound so as to restore it to its original shape.

Anapleu'sis. (From αναπλευω, to float upon.) The rotting of a bone, so that it drops off, and lies upon the flesh. Exfoliation, or separation of a bone.—Hippocrates, Ægineta, &c.

ANAPNEU'SIS. (From αναπνευω, to respire.) Res-

piration.

ANA'PNOE. Respiration.

ANAPTO'SIS. (From αναπιπ7ω, to fall back.) A

Ana Prysis. The same as Anacatharsis.

Anarrhegni'mia. (From ava, and βηγνυμι, to break again.) Anarrhexis. A fracture; the fresh opening of a wound.

ANARRHŒ A. (From ανα, upwards, and ρεω, to

flow.) A flux of humours from below upwards. Schneider de Catarrho.

ANARRHO'PIA. (From ανα, upwards, and ρεπω, to creep.) A flux of humours, from below upwards.— Hippocrates.

ANAS. (Anas, tis. f.; from vtw, to swin nando.) A genus of birds in the Linnwan system. to swim, a

Anas cygnus. The swan. The flesh of the young swan or cygnet is tender, and a great delicacy.

Anas domestica. The tame duck. The flesh of this bird is difficult of digestion, and requires that warm and stimulating condiments be taken with it to

enable the stomach to digest it.

ANASA'RCA. (Anasarca, a.f.; from ava, through, and saot, flesh.) Sarcites. A species of dropsy from a serous humour, spread between the skin and flesh, or rather a general accumulation of lymph in the cel-Dr. Cullen ranks this genus of disease in the class Cachezia, and the order Intumescentia. He enumerates the following species, viz. 1. Anasarca serosa: as when the due discharge of serum is suppressed, &c. 2. Anasarca oppilata: as when the blood-vessels are considerably pressed, which happens to many pregnant women, &c. 3. Anasarca exantheto many pregnant women, &c. 3. Anasarca exanthematica: this happens after ulcers, various eruptive disorders, and particularly after the erysipelas. 4. Anasarca anamia happens when the blood is rendered extremely poor from considerable losses of it. 5. Anasarca debilium: as when feebleness is induced by long illness, &c.

This species of dropsy shows itself at first with a swelling of the feet and ancles towards the evening, which, for a time, disappears again in the morning The tumefaction is soft and inelastic, and when pressed upon by the finger, retains its mark for some time, the skin becoming much paler than usual. By degrees the swelling ascends upwards, and occupies the trunk of the body; and at last, even the face and eyelids appear the body; and at last, even the face and eyelids appear full and bloated; the breathing then becomes difficult, the urine is small in quantity, high coloured, and deposites a reddish sediment; the belly is costive, the perspiration much obstructed, the countenance yellow, and a considerable degree of thirst, with emaciation of the whole body, prevails. To these symptoms succeed torpor, heaviness, a troublesome cough, and a slow fever. In some cases the water oozes out, through the pores of the cuticle; in others, being too

blisters; and sometimes the skin, not allowing the water to escape through it, is compressed and hardened, and is at the same time so much distended as to give the tumour a considerable degree of firmness.

For the causes of this disease, see Hydrops.

In those who have died of anasarca, the whole of the cellular membrane has been distended with a fluid, mostly of a serous character. Various organic dis-eases have occurred; and the blood is said to be altered in consistence, according to the degree of the disease. In general a cure can be more readily effected when it arises from topical or general debility, than when occa-sioned by visceral obstruction; and in recent cases, than in those of long continuance. The skin becoming somewhat moist, with a diminution of thirst, and increased flow of urine, are very favourable. In some few cases the disease goes off by a spontaneous crisis by vomiting, purging, &c. The indications of treat-ment in anasarca are, 1. To evacuate the fluid already collected. 2. To prevent its returning again. first object may be attained mechanically by an opera-tion; or by the use of those means, which increase the action of the absorbents: the second by removing any exciting causes, which may still continue to operate; and at the same time endeavouring to invigorate the system. Where the quantity of fluid collected is such to disturb the more important functions, the best mode of relieving the patient is to make a few small incisions with a lancet, not too near each other, through the integuments on the fore and upper part of each thigh; the discharge may be assisted by pressure, and when a sufficient quantity has been evacuated, it is better to heal them by the first intention. In the use of issues or blisters, there is some risk of inducing gangrene, especially if applied to the legs; and the same has happened from scarifications with the cupping instrument. Absorption may be promoted by friction, and bandaging the parts, which will at the same time obviate farther effusion; but most powerfully by the use of different evacuating remedies, especially those which occasion a sudden considerable discharge of fluids. Emetics have been often employed with advantage; but it is necessary to guard against weakening the stomach by the frequent repetition of those which produce much nausea; and perhaps the benefit results not so much from the evacuation produced by the mouth, as from their promoting other exerctions; antimonials in particular inducing perspiration, and squill increasing the flow of urine, &c.; for which purpose they may be more safely given in smaller doses; in very torpid habits, mustard may claim the prefer ence. Cathartics are of much greater and more general utility; where the bowels are not particularly irritable, the more drastic purgatives should be employed and repeated as often as the strength will allow; giving, for example, every second or third morning, jalap, scammony, colocynth, or gamboge, joined with calo mel or the supertartrate of potassa and some aromatic, to obviate their griping. Elaterium is perhaps the most powerful, generally vomiting as well as purging the patient, but precarious in its strength and there fore better given in divided doses, till a sufficient effect is produced. Diuretics are universally proper, and may be given in the intervals, where purgatives can be borne, otherwise constantly persevered in; but un-fortunately the effects of most of them are uncertain. Saline saus-tances in general appear to stimulate the kidneys, whether acid, alkaline, or neutral; but the acetate, and supertartrate of potassa, are chiefly resorted to in dropsy. Dr. Ferriar, of Manchester, has made an important remark of the latter salt, that its diuretic power is much promoted by a previous opera tion on the bowels, which encourages the more liberal use of it; indeed, if much relied upon, a drachm or two should be given three times or oftener in the day. It is obviously, therefore, best adapted to those cases, in which the strength is not greatly impaired; and the same holds with the nauscating diuretics, squill, colchicum, and tobacco. The latter has been strongly recommended by Dr. Fowler of York, in the form of tincture; the colchicum, as an oxymel by some German physicians; but the squill is most in use, though certainly very precarious if given alone. In languid and debilitated habits, we prefer the more stimulant diuretics, as juniper, horseradish, mustard, garlicathe spiritus atheris nitrici, &c.; even turpentine, or the same holds with the nauscating diuretics, squill, col-

the the third is, may be proper, where milder means have failed. Digitalis is often a very powerful remedy, from the utility of which in inflammatory diseases we might expect it to answer best in persons of great natural strength, and not much exhausted by the disorder; but Dr. Withering expressly states that its diuretic effects appear most certainly and beneficially, where the pulse is feeble or intermitting, the counte-nance pale, the skin cold, and the tumours readily pitting on pressure; which has been since confirmed by other practitioners: it should be begun with in small doses two or three times a day, and progressively in-creased till the desired operation on the kidneys ensues, unless alarming symptoms appear in the mean time. Opium and some other narcotics have been occasionally useful as diuretics in dropsy, but should be only regarded as adjuvants, from their uncertain effects. In the use of diurctics, a very important rule is, not to restrict the patient from drinking freely. This was formerly thought necessary on theoretical grounds; whereby the thirst was aggravated to a distressing degree, and the operation of remedies often prevented, especially on the kidneys. Sir Francis Milman first taught the impropriety of this practice, which is now generally abandoned; at least so long as the flow of urine is increased in proportion to the drink taken, it is considered property to indule the is considered proper to indulge the patient with it. Another evacuation, which it is very desirable to promote in anasarca, is that by the skin, but this is with difficulty accomplished; nauscating emetics are the most powerful means, but transient in their effect, and most powerful means, but transpert in their effect, and their frequent use cannot be borne. If a gentle diaphoresis can be excited, it is as much as we could expect; and perhaps on the whole most beneficial to the patient. For this purpose the compound powder of ipecacuanha, saline substances, and antimonials in small doses, assisted by tepid drink, and warmth applied to the surface, may be had recourse to. Sometimes much relief is obtained by promoting perspiration locally by means of the vapour-bath. Mercury tion locally by means of the vapour-bath. Mercury has been much employed in dropsy, and certainly appears often materially to promote the operation of other evacuants, particularly squill and digitalis; but its chief utility is where there are obstructions of the viscera, especially the liver, of which, however, ascites is usually the first result: its power of increasing ab-sorption hardly appears, unless it is carried so far as to affect the mouth, when it is apt to weaken the system so much as greatly to limit its use. The other indication of invigorating the constitution, and particularly the exhalant arteries, may be accomplished by tonic medicines, as the several vegetable bitters, chalybeates in those who are remarkably pale, and, if there be a anguid circulation, stimulants may be joined with them: a similar medification will be proper in the dict, which should be always as nutritious as the patient can well digest; directing also in torpid habits pungent articles, as garlic, onions, mustard, horseradish, &c. to be freely taken, which will be farther useful. moting the urine. Rhenish wine, or punch made with holtands and supertartrate of potassa, may be allowed for the drink. Regular exercise, such as the patient can bear, (the limbs being properly supported, especially by a well-contrived laced stocking) ought to be enjoined or diligent friction of the skin, particularly of the affected paris, employed when the tumefaction is usually least, namely, in the morning. The cold bath, duly regulated, may also, when the patient is convalescent, materially contribute to obviate a

ANASPA'SIS. (From ava, and σπαω, to draw to-gether.) Hippocrates uses this word to signify a con-

traction of the stomach.

Ana'ssyros. (From ara, upwards, and σευσμαι, to agitate.) Anassytus. Driven forcibly upwards. Hippocrates applies this epithet to air rushing violently upwards, as in hysteric fits.

Anasta'ltica. (From araycλλω, to contract.)

Anasta Ltica. (From αναςτλλω, to contract.)
Styptic or refrigerating medicines.
ANA'STASIS. (From αναςτημι, to cause to rise.)
1. A recovery from sickness; a restoration of health.
2. It likewise signifies a migration of humours, when

ther.—Hippocrates.

ANASTOMO'SIS. (From ara, through, and 50µa, a mouth.) The communication of vessels with one another.

ANASTOMO'TIC. (Anastomoticus; from ara, through, and $\varsigma o\mu a$, the mouth.) That which opens the pores and mouths of the vessels, as cathartics, diuretics, deobstruents, and sudorifies.

ANATASE. A mineral found only in Dauphiny

and Norway.

This name is given by Hauy and Brogniart, to the octahedral oxide of Titanium, which has been found in various parts of the United States, in the forms of

The oxide of titanium, The ferruginous oxide,

The silico-calcareous oxide. See Bruce's Mineralogical Journal, in which numerous specimens are figured and described by him. A.]

ANA'TES. (From nates, the buttocks.) A disease of the anus. Festus, &c.

ANATO'MIA. See Anatomy.

ANA'TOMY. (Ανατομία, οτ ανατομη, Anatomia, σ. f. and Anatome, es; from ανα, and τεμνώ, to cut up.) Anarotomy. The dissection or dividing of orthogonal analogonal ana ganized substances to expose the structure, situation, and uses of parts. Anatomy is divided into that of animals strictly so called, also, denominated zootomy,

and that of vegetables or phytotomy.

The anatomy of brute animals and vegetables is comprised under the term comparative anatomy, because their dissection was instituted to illustrate or compare by analogy their structure and functions with

those of the human body.

ANATOMY, COMPARATIVE. Zootomy. The dissection of brutes, fishes, polypi, plants, &c. to illustrate, or compare them with the structure and functions of ANATRE'SIS. (From ava, and rerease, to perforate.) A perforation like that which is made upon the skull by trepanning.

ANATRI'SE. (From average)

all over the body.

Friction all over the body .- Mos-ANATRI PSIS.

Anatri'rsis. Friction all over the body.—Moschion de Morb. Mulieb. and Galen.

Ana'tron. (Arabian.) The name of a lake in Egypt, where it was produced: See Soda.

Ana'trophe. (From ανατρεπω, to subvert.) Anatrophe; Anatropha. A relaxation or subversion of the stomach, with loss of appetite and nausea. Vomiting; indigestion.—Galen.

Ana'trum. Soda.

ANAU'DIA. (From a, priv. and ανδη, the speech.) Dumbness; privation of voice; catalepsy.—Hippocrates.

Ana xxris. (From avatoris, the sole.) The herb sorrel; so called because its leaf is shaped like the sole

of the shoe.

ANCEPS. (Anceps, ipitis. adjective.) Two-edged: that is, compressed, having the edges sharp like a two-edged sword; applied to stems and leaves of plants, as in the Sisyrinchium striatum, Iris graminea, and leaves of the Typha latifolia.

A'NCHA. (Arabian, to press upon, as being the support of the body.) The thigh.—Avicenna, Foresting for

restius, &c.

A'NCHILOPS. (From αγχι, near, and ωψ, the eye.) A disease in the inward corner of the eye. See Ægilops.

ANCHORA'LIS. (From αγκων, the elbow.) The projecting part of the elbow on which we lean, called generally the olecranon. See Ulna.

Anchoralis processus. The olecranon, a process

ANCHOVY. See Clupea encrasicolus.

Anchovy Pear. See Grias cauliflora.

Anchovy Pear. See Grias cauliflora.

ANCHU'SA. (Anchusa, & f.; from ayxtiv, to strangle; from its supposed constringent quality; or, as others say, because it strangles serpents.) I. The name of a genus of plants in the Linnaan system. Class, Pentandria; Order, Managynia.

2. The name in some pharmacopæias for the alkanet root and bugloss. See Anchusa officinalis, and declaration integring.

Anchusa tinctoria.

Anchusa tinctoria.

Anchusa officinalis. The officinal bugloss. In some pharmacopæias it is called Buglossa; Buglossum angustifolium majus; Buglossum vulgare majus; Buglossum sylvestre; Buglossum sativum. Anchusa—foliis lanceolatis strigosis, spicis secundis imbricatis, calycibus quinque partitis, of Linnæus; it was formerly esteemed as a cordial in melancholic and hypochondriacal diseases. It is seldom used

in modern practice, and then only as an aperient and I

Anchusa Tinctoria. The systematic name for the anchusa or alkanna of the pharmacopæias. This plant grows wild in France, but is cultivated in our gardens. The root is externally of a deep purple colour. To oil, wax, turpentine, and alkohol, it imparts a beautiful deep red colour, for which purpose it is used. Its medicinal grounding are carrely percent used. Its medicinal properties are scarcely percep-

A'NCHYLE. See Ancyle. ANCHYLOMERI'SMA. (From αγχυλομαι, to

bend.) Sagar uses this term to express a concretion, or growing together of the soft parts.

ANCHYLO'SIS. (From αγχυλομαι, to bend.) A stiff joint. It is divided into the true and spurious, according as the motion is entirely or but partly lost. cording as the motion is entirely or but partly lost. This state may arise from various causes, as tumefaction of the ends of the bones, caries, fracture, dislocation, &c. also dropsy of the joint, fleshy excrescences, aneurisms, and other tumours. It may also be owing to the morbid contraction of the flexor muscles, induced by the limb being long kept in a particular position, as a relief to pain, after burns, mechanical injution, as a rener to pain, after burns, mechanical injuries, &c. The rickets, white swellings, gout, rheumatism, palsy, from lead particularly, and some other disorders, often lay the foundation for anchylosis: and the joints are very apt to become stiff in advanced life. Where the joint is perfectly immoveable, little can be done for the patient; but in the spurious form of the complaint, we must first endeavour to remove any cause mechanically obstructing the motion of the joint, and then to get rid of the mothid contraction of the and then to get rid of the morbid contraction of the muscles. If inflammation exist, this must be first subdued by proper means. Where extraneous matters have been deposited, the absorbents must be excited to have been deposited, the absorbents must be excited to remove them: and where the parts are preternaturally rigid, emollient applications will be serviceable. Fomentations, gentle friction of the joint and of the muscles, which appear rigid, with the camphor linament, &c. continued for half an hour or more two or three times a day; and frequent attempts to move the joint to a greater extent, especially by the patient exerting the proper muscles, not with violence, but steadily for some time, are the most successful means: but no rapid improvement is to be expected in general. but no rapid improvement is to be expected in general. Sometimes, in obstinate cases, rubbing the part with warm brine occasionally, or applying stimulant plasters of ammoniacum, &c. may expedite the cure; and in some instances, particularly as following rheumatism, pumping cold water on the part every morning has proved remarkably beneficial. Where there is a great tendency to contraction of the muscles, it will be useful to obviate this by some mechanical contrivance. It is proper to bear in mind, where, from the nature of the case, complete anchylosis cannot be prevented, that the patient may be much less inconvenienced by its being made to occur in a particular position; that is in the upper extremities generally a bent, but in the hip or knee an extended one.

A'ncr. A term formerly applied to those who have

a distorted elbow.

A'NCINAR. Borax.

ANCIPITIUS. (From Anceps.) Two-edged: applied to a leaf which is compressed and sharp at both

edges, as that of the Typha latifolia.

Ancirome'le. See Ancylomele.

A'NCON. (From αγκαζομαι, to embrace; απο του αγκεισθαι ετερω ος εω το ος εον: because the bones meeting and there uniting, are folded one into another.)

ANCONE'US. (From $a\gamma\kappa\omega\nu$, the elbow.) A small triangular muscle, situated on the back part of the elbow. Anconeus minor of Winslow; Anconeus vel cubitalis Riolani of Douglas. It arises from the ridge, and from the external condyle of the humerus, by a thick, strong, and short tendon: from this it become fleshy, and, after running about three inches obliquely backward, it is inserted by its oblique fleshy fibres into the back part or ridge of the ulna. Its use is to extend the fore-arm.

Anconeus externus. See Triceps extensor cubiti.
Anconeus internus. See Triceps extensor cubiti.
Anconeus major. See Triceps extensor cubiti.
Anconeus minor. See Anconeus.
ANCONOID. (Anconoideus; from ayrov, the elbow.) Belonging to the elbow.

ANCONOID PROCESS. See Ulna.

A'NOTER. (Αγκτης, a bond, or button.) A fibula or button, by which the lips of wounds are held to-

ANCTERIA'SMUS. (From ayx7110, a button.) The operation of closing the lips of wounds together by

operation of closing the lips of wounds together vyloops, or buttons.—Galen.

Ancu'bitus. A disease of the eyes with a sensation as if sand were in them.—Joh. Anglic. Ros. Ang.

A'NCYLE. (From aγκυλος, crooked.) Anchyle.

A species of contraction, called a stiff joint.—Galen

ANCYLOBLE PHARON. (Ancyloblepharum, i. n.;
from aγκυλη, a hook, and βλεφαρον, an eyelid.) A

disease of the eye, by which the eylids are closed together.—Ačtius.

ANCYLOGLO'SSUM. (Ancyloglossum, i.n.; from αγκυλη, a hook, and γλωσσα, the tongue.) Ancylion of Ægmeta. Tongue-tied. A contraction of the fræmulum of the tongue.

ANCYLOME LE. (From αγκυλος, crooked, and μηλη, a probe.) Ancyromele: Anciromele. A crooked probe, or a probe with a hook, with which surgeons

search wounds.— Galen, &c.

ANCYLO'SIS. See Anchylosis.

ANCYLO'TOMUS. (From αγκυλη, a hook, and τεμνω, to cut.) A crooked chirurgical knife, or bistoury. A

knife for loosening the tongue, not now used.

A'NCYRA. (Αγκυρα, an anchor.) A chirurgical hook. Epicharmus uses this word for the membrum

virile, according to Gorræus.

ANCYROIDES. (Ancyroides processus; from αγκυρα, an anchor, and ειδος, a likeness.) A process of the scapula was so called, from its likeness to the beak of an anchor. The coracoid process of the sca-

beak of an anchor. The coracon process of the scapula. See Scapula.

ANCYROME'LE. See Ancylomele.

ANDALUSITE. A massive mineral, of a flesh, and sometimes rose-red colour, belonging to primitive countries, and first found in Andalusia in Spain.

[It has been found also in the United States. The hardness of this mineral is nearly equal to that of corundum. Its specific gravity is 3.16. Its structure is rundum. Its specific gravity is 3.16. Its structure is more or less distinctly crystalline. It is perfectly infusible by the blow-pipe. It contains alumine 52, silex 38, potash 8, iron 2.

It differs from feldspar by its greater hardness and

its infusibility; and from corundum, by its structure and less specific gravity. Some mineralogists, how-ever, are inclined to believe this mineral to be feldspar intimately mixed with corundum; and hence its hard-

intimately mixed with corundum; and hence its hardness.—Clear. Min. A.]

Anderson's pills. These consist of Barbadoes aloes, with a proportion of jalap, and oil of aniseed.

[ANDERSON, ALEXANDER, M.D. Dr. Anderson, of the city of New-York, received his degree of Doctor in Medicine from the Medical faculty of Columbia College. He afterward turned his attention to the subject of engraving in wood, and finally abandoned his profession of a physician for the employment of an engraver, jin which he now stands preeminent, being a self-taught artist. His wood engravings are excellent, and many of them equal copperplate. He has made this art subservient to his first profession, by engravings illustrating the intesfirst profession, by engravings illustrating the intestines, blood-vessels, &c., as well as subjects of botany and natural history. He is a modest, unassuming man, and is now (1829) in the height of his reputation

(ANDERSON, JAMES, M.D. Having successfully terminated his academical pursuits at an early age, Dr. Anderson commenced the study of medicine under the direction of his father, a very respectable physician from Scotland. He attended a course of lectures, by Professors Shippen and Morgan, in the school of Philadelphia, then in its infancy; and next sailed for Edinburgh, at that time the focus of medical literature. Edinburgh, at that time the focus of medical literature. Circumstances, which it is unnecessary to mention, not permitting him to remain long enough to obtain a degree, he returned to this country with an ample certificate, signed by his preceptors, Cullen, the elder Munro, and the whole board of professors. Immediately on his return, he commenced the practice of physic in conjunction with his father. Deeply versed in general, and particularly in medical science, and devoted almost beyond example to the performance of his professional duties, he soon obtained a reputation,

unenjoyed by any of his competitors. For a period of upwards of thirty years, he retained a practice of an extent certainly without a parallel in this section of the country. Advancing tapidly toward his sixtieth year, and feeling the infirmities consequent on a For a period life so laborious, he retired to his seat near Chestertown. In this situation, however, he was not allowed the repose which he anticipated. Though the native vigour of his constitution was broken down by the invasion of disease, and by those accidents to which his course of life subjected him, he attended almost to the close of it, to the calls of his patients. He died December 8th, 1820, at his seat in the vicinity of Chestertown, Maryland, in the 69th year of his age.— Thacher's Med. Biog. A.]
ANDI'RA. A tree of Brazil, the fruit of which is

bitter and astringent, and used as a vermifuge.

ANDRANATO MIA. (From ανηφ, a man, and τεμνω, to cut.) Andranatome. The dissection of the human body, particularly of the male .- M. Aur. Scverinus, Zootome Democrit.

ANDRAPODOCAPE LUS. (From ανδροποδον, a slave, and καπηλος, a dealer.) A crimp. Galen calls by this name the person whose office it was to anoint and slightly to wipe the body, to cleanse the skin from foul-

ANDREOLITE. A species of crop-stone.

ANDROCŒTE'SIS. (From ανερ, a man, and κοιτιω, to cohabit with.) 1. The venereal act.

2. The infamous act of sodomy.—Moschion, &c. ANDRO GYNUS. (From ανερ, a man, and γυνη,

a woman.)

1. An hermaphrodite.

2. An effeminate person.—Hippocrates.

3. A plant is said to be androgenous, which produces both male and female flowers from the same root, as

the walnut, beech, horn-beam, nettle, &c.
ANDRO MACHUS, of Crete, was physician to the
emperor Nero. He invented a composition, supposed emperor Nero. He invented a composition, supposed to be an antidote against poison, called after him, Theriaca Andromachi, which he dedicated to that emperor in a copy of Greek verses still preserved. This complicated preparation long retained its reputation, but is now deservedly abandoned.

Andronium. A kind of plaster used by Ægineta for carbuncles, invented by Andron.

ANDROPO'GON. (From ανηφ, a man, and πωγων, a beard.) The name of a genus of plants in the Linnæan system. Class, Polygamia: Order, Monacia.

Andropogon nardus. The systematic name of Indian nard or spikenard. Spica nardi; Spica Indica. The root of this plant is an ingredient in the mithridate and theriaca; it is moderately warm and pungent, accompanied with a flavour not disagreeable. It is said to be used by the Orientals as a spice.

It is said to be used by the Orientals as a spice.

Andropogon schenanthus. The systematic name ANDROYGON SCHAMANTHUS. The systematic haine of the camel-hay, or Sweet-rush. Juncus odoratus; Fanum camelorum; Juncus aromaticus. The dried plant is imported into this country from Turkey and Arabia. It has an agreeable smell, and a warm, bitterish, not unpleasant taste. It was formerly employed as a stomachic and deobstruent.

ANDROYTOMIA Andrease Human dissertion

ANDRO TOMIA. Androtome. Human dissection,

ANDRO TOMIA. Androtome. Human dissection, particusarly of the male.

ANDRY, NICHOLAS, a physician, born at Lyons in 1658. He was made professor of medicine at Paris in 1701, and lived to the age of 84. Besides a Treatise on Worms, and other minor publications, and contributions in the Medical and Philosophical Journals, he was author of a work, still esteemed, called "Orthopedie," or the art of preventing and removing deformities in children; which he proposed to effect by regimen, exercise, and various mechanical contrivances.

Ane BIUM. (From ayabatro, to ascend.) The herb alkanet, so called from its quick growth. See

ANELE'SIS. (From averlew, to roll up.) Aneile-

An involution of the guts, such as is caused by

flatulence and gripes. - Hippocrates.

ANE MIA. (From avepos, wind.) Flatulence.
ANE MONE. (From avepos, wind; so named, because it does not open its flowers till blown upon by the wind.) The name of a genus of plants in the Linnar system. Class, Polyandria; Order, Polyginia. The wind flower. The wind flower.

tatis. Hepatica, or herb trinity. This plant possesses mildly adstringent and corroborant virtues, with which intentions infusions of it have been drunk as tea, or the powder of the dry leaves given to the quantity of

half a spoonful at a time.

Anemone nemorosa. The systematic name of the ranunculus albus of the pharmacopæias. The bruised leaves and flowers are said to cure tinea capitis applied to the part. The inhabitants of Kamskatka, it is believed, poison their arrows with the root of this

Anemone pratensis. The systematic name for the Pulsatilla nigricans of the pharmacopæias. This plant, Incmone—pedunculo involucrato, petalis apice reflexis, foliis bipinnatis, of Linnæus, has been received into the Edinburgh pharmacopæia upon the authority of Baron Stoerck, who recommended it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amaurosis, cataract, and affecting the eye, particularly amaurosis, cataract, and opacity of the cornea, proceeding from various causes. He likewise found it of great service in venereal nodes, nocturnal pains, ulcers, caries, indurated glands, suppressed menses, serpiginous eruptious, melancholy, and palsy. The plant, in its recent state, has scarcely any smell; but its taste is extremely acrid, and, when the wed, it corrodes the topsue and fauces.

chewed, it corrodes the tongue and fauces.

ANENCE PHALUS. (From a. priv. and εγκεφαλος, the brain.) A monster without brains. Foolish.—

Galen de Hippocrate.

A'NEOS. A loss of voice and reason.

ANEPITHY'MIA. (From a. priv. and επιθυμια, desire) I see Constitution.

desire.) Loss of appetite.

A'NESIS. (From ανιημι, to relax.) A remission, or relaxation, of a disease, or symptom. Aetius, &c.

ANE SUM. See Anisum.

ANE THUM (Anethum, i. n. Ανεθον; from ανευ, afar, and βεω, to run; so called because its roots run out a great way.)

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

2. The pharmacopeial name of the common dill.

2. The pharmacopoial name of the common din. See Anethum graveolens.

Anethum Feniculum. The systematic name for the faniculum of the shops. Sweet fennel, Anethum—fructibus ovatis of Linnaeus. The seeds and roots of this indigenous plant are directed by the colleges of London and Edinburgh. The seeds have an aromatic smell, and a warm sweetish taste, and contain a large proportion of essential oil. They are stomachic and carminative. The root has a sweet taste, but very little aromatic warmth, and is said to be pectoral and diuretic.

Anethum Graveolens. The systematic name of the Anethum of the shops. Anethum-fructibus compressis, of Linnæus.—Dill. Anet. This plant is a native of Spain, but cultivated in several parts of England. The seeds are directed for use by the London and Edinburgh Pharmacopæias: they have a moderately warm, pungent taste, and an aromatic, but sickly smell. There is an essential oil, and a distilled water prepared from them, which are given in flatu-lent colics and dyspepsia. They are also said to pro-mote the secretion of milk.

ANE TICA. (Aneticus; from avinpai, to relax.)
Medicines which assuage pain, according to Andr

Tiraquell.

ANETUS. (From avinu, remitto.) A name given by Good, in his Study of Medicine, to a genus of diseases which embraces intermittent fevers. See No.

sology.

ANEURISMA. (Ancurisma, matis, neut. Avevρυσμα; from ανευρυνω, to dilate.) An aneurism; a preternatural tumour formed by the dilatation of an artery. A genus of disease ranked by Cullen in the class Locales, and order Tumores. There are three species of aneurism: 1. The true aneurism, aneurisma verum, which is known by the presence of a pulsating tumour. The artery either seems only enlarged at a small part of its tract, and the tumour has a determinate border, or it seems dilated for a considerable length, in which circumstance the swelling is oblong, and loses itself so gradually in the surrounding parts, that its margin cannot be exactly ascertained. first, which is the most common, is termed circumscribed true aneurism; the last, the diffused true aneu-rism. The symptoms of the circumscribed true aneu-Anemone Hepatica. The systematic name for the rism. The symptoms of the circumscribed true aneuhepatica nobilis of the pharmacopæias. Herba triniism, take place as follows: the first thing the patient

perceives is an extraordinary throbbing in some par-ticular situation, and, on paying a little more attention, he discovers there a small pulsating tumour, which he discovers there a small pulsating tumour, which entirely disappears when compressed, but returns again as soon as the pressure is removed. It is commonly unattended with pain or change in the colour of the skin. When once the tumour has originated, it continually grows larger, and at length attains a very considerable size. In proportion as it becomes larger, its pulsation becomes weaker, and, indeed, it is almost quite lost, when the disease has acquired much magnitude. The diminution of the pulsation has been ascribed to the coats of the artery, losing their dilatable and elastic quality, in proportion as they are distended and elastic quality, in proportion as they are distended and indurated; and, consequently, the aneurismal sac being no longer capable of an alternate diastole and systole from the action of the heart. The fact is also imputed to the coagulated blood, deposited on the inner surface of the sac, particularly in large aneurisms, in which some of the blood is always interrupted in its motion. In true aneurisms, however, the blood does not coagulate so soon, nor so often, as in false ones. Whenever such coagulated blood lodges in the sac, pressure can only produce a partial disappearance of the swelling. In proportion as the aneurismal sac grows larger, the communication into the artery beyond the tumours is lessened. Hence, in this state, the pulse below the swelling becomes weak and small, and the limb frequently cold and ædematous. On dissection, the lower continuation of the artery is found preternaturally small, and contracted. of the tumour on the adjacent parts also produces a variety of symptoms, ulcerations, caries, &c. Some-times an accidental contusion, or concussion, may detach a piece of coagulum from the inner surface of the cyst, and the circulation through the sack be obstructed by it. The coagulum may possibly be impelled quite into the artery below, so as to induce important changes. The danger of an aneurism arrives when it is on the point of bursting, by which occurrence the patient usually bleeds to death; and this sometimes happens in a few seconds. The fatal event may generally be foreseen, as the part about to give way becomes particularly tense, elevated, thin, soft, and of a dark purple colour. 2. The false or spurious aneurism, aneurisma spurium, is always owing to an aperture in the artery, from which the blood gushes into the cellular substance. It may arise from an artery being lacerated in violent exertions; detach a piece of coagulum from the inner surface of from an artery being lacerated in violent exertions but the most common occasional cause is a wound. This is particularly apt to occur at the bend of the arm, where the artery is exposed to be injured in attempting to bleed. When this happens, as soon as the puncture has been made, the blood gushes out with unusual force, of a bright scarlet colour and in an irregular stream, corresponding to the pulsation of the artery. It flows out, however, in an even and less rapid stream when pressure is employed higher up than the wound. These last are the most decisive marks of the artery being opened; for blood often flows from a vein with great rapidity, and in a broken current, when the vessel is very turgid and situated immediately over the other which imports its motion to it. The surgeon artery, which imparts its motion to it. The surgeon endeavours precipitately to stop the hæmorrhage by pressure; and he commonly occasions a diffused false ancurism. The external wound in the skin is closed, so that the blood cannot escape from it; but insinuates itself into the cellular substance. The swelling thus produced is uneven, often knotty, and extends upwards and downwards, along the tract of the vessel. The skin is also usually of a dark purple colour. Its size increases as long as the internal hemorrhage continues, and, if this should proceed above a certain pitch, mortification of the limb ensues. 3. The varicose aneurism, aneurisma varicosum: this was first described by Dr. W. Hunter. It happens when the brachial artery is punctured in opening a vein: the blood then rushes into the vein, which becomes varicose. Aneurisms may happen in any part of the body, except the latter species, which can only take place where a vein runs over an artery. When an artery has been punctured, the tourniquet should be applied, so as to stop the flow of blood by compressing the vessel above; then the most likely plan of obviating the production of spurious ancurism appears to be applying a firm compress immediately over the wound, and securing it by a bandage, or in any other way, so as effectually to close £ 2

examining daily that no extravasation has happened, which would require the compress being fixed more which would require the compress being fixed more securely, previously applying the tourniquet, and pressing the effused blood as much as possible into the vessel. If there should be much coldness or swelling of the limb below, it will be proper to rub it frequently with some spirituous or other stimulant embrocation. It is only by trial that it can be certainly determined when the wound is closed; but always better not to discontinue tife pressure prematurely. The same plan may answer, when the disease has already come on, if the blood can be entirely, or even mostly, pressed if the blood can be entirely, or even mostly, pressed into the artery again; at any rate, by determining the into the artery again; at any late, of will give greater circulation on collateral branches, it will give greater.

There is another mode, stated to have sometimes succeeded, even when there was much coagulated blood; namely, making strong pressure over the whole limb, by a bandage applied uniformly, and moistened to make it sit closer, as well as to obviate inflammation; but this does not appear so good a plan, at least in slighter cases. If however the tumour be very large, and threatens to burst, or continues spreading, the opera-tion should not be delayed. The tourniquet being applied, a free incision is to be made into the tumour, the extravasated blood removed, and the artery tied both above and below the wound, as near to it as may both above and below the wound, as near to it as may be safe; and if any branch be given off between, this must be also secured. It is better not to make the ligatures tighter, than may be necessary to stop the flow of blood; and to avoid including any nerve if possible. Sometimes, where extensive suppuration or caries has occurred, or gangrene is to be apprehended, amputation will be necessary; but this must not be prematurely resolved upon, for often after several weeks the pulse has returned in the limb below. In the true aneurism, when small and recent, cold and the true aneurism, when small and recent, cold and astringent applications are sometimes useful; or making pressure on the tumour, or on the artery above, making pressure on the tumour, or on the artery above, may succeed; otherwise an operation becomes necessary to save the patient's life; though unfortunately it oftener fails in this than in the spurious kind; gangrene ensuing, or hæmorrhage; this chiefly arises from the arteries being often extensively diseased, so that they are more likely to give way, and there is less vital power in the limb. A great improvement has been made in the mode of operating in these cases by Mr. John Hunter, and other modern surgeons, namely, instead of proceeding as already explained in the souinstead of proceeding as already explained in the spuinstead of proceeding as already explained in the spurious aneurism, securing the artery some way above, and leaving the rest in a great measure to the powers of nature. It has been now proved by many instances, that when the current of the blood is thus interrupted, the tumour will cease to enlarge, and often be considerably diminished by absorption. There is reason for believing too, that the cures effected spontaneously, or by pressure, have been usually owing to the trunk or by pressure, have been usually owing to the trunk above being obliterated. There are many obvious advantages in this mode of proceeding; it is more easy, sooner performed, and disorders the system less, particularly as you avoid having a large unhealthy sore to be healed; besides there is less probability of the vessel being diseased at some distance from the tumour. In the popliteal aneurism, for example, the artery may be secured rather below the middle of the thigh, where it is easily come at. The tourniquet therefore being applied, and the vessel exposed, a strong ligature is to be passed round it; or, which is perhaps preferable, two ligatures between them, when the two portions contract among the surrounding flesh. It is proper to avoid including the nerve or vein, but not unnecessarily detach the vessel from its attachments. For greater security one and of each ligature after being tied, may be passed end of each ligature, after being tied, may be passed through the intercepted portion of artery, that they may not be forced off. Then the wound is to be closed by adhesive plaster, merely leaving the ends of the ligatures hanging out, which will after some time come away. However it must be remembered that hæmorrhage is liable to occur, when this happens, even three or four weeks after the operation; so that proper presentation are required to check it as soon as well. or loar wees alter cautions are required, to check it as soon as possible; likewise the system should be lowered previously, and kept so during the cure. When a true aneurism

changes into the spurious form, which is known by the tumour spreading, becoming harder, and with a less distinct pulsation, the operation becomes immediately necessary. When an aneurism is out of the reach of an operation, life may be prolonged by occasional bleeding, a spare diet, &c.; and when the tumour becomes apparent externally, carefully guarding it from injury. In the varicose aneurism an operation will be very seldom if ever required, the growth of the tumour being limited.

Aneurisma spurium. See Aneurisma. Aneurisma varicosum. See Aneurisma. ANEURISMA VERUM. See Ancurisman

ANE'XIS. (From ανεχω, to project.) A swelling,

or protuberance.
ANGEIOLO'GY. (Angeiologia, a. f.: from ayyeuov,

a vessel, and λογος, a discourse.) A dissertation, or reasoning, upon the vessels of the body.

ANGEIOTI'SMUS. (From αγγειον, a vessel, and τεμνω, to cut.) An angeiotomist, or skilful dissector of

ANGEIO TOMY. (Angeiotomia; from αγγειον, a vessel, and τεμνω, to cut.) The dissection of the blood-vessels of an animal body; also the opening of a vein,

ANGE LICA. (So called from its supposed angelic virtues.) 1. The name of a genus of plants in the Linnwan system. Class Pentandria; Order, Digynia.

2. The pharmacopæial name of the garden angelica.

See Angelica archangelica.

The systematic name ANGELICA ARCHANGELICA. for the angelica of the shops. Milzadella Angelica-foliorum impari lobato of Linnæus. A plant, a native of angelica have a fragrant, agreeable smell, and a bitterish, pungent taste. The stalk, leaves, and seeds, which are also directed in the pharmacoporias, possess which are also directed in an inferior degree. Their the same qualities, though in an inferior degree. virtues are aromatic and carminative. A sweatmeat is made, by the confectioners, of this root, which is extremely agreeable to the stomach, and is surpassed

only by that of ginger.

Angelica, garden. See Angelica archangelica.

Angelica Pilula. Anderson's Scots pill.

Angelica sativa. See Angelica sylvestris.

Angelica Sylvestris. Angelica sativa. Wild angelica. Angelica-folis aqualibus ovato-lanceolatis serratis, of Linneus. This species of angelica possesses similar properties to the garden species, but in a much inferior degree. It is only used when the latter cannot be obtained. The seeds, powdered and

put in the hair, kill lice.

Angelica, wild. See Angelica sylvestris.

ANGELICUS. (From angelus, an angel.) Some plants, &c. are so called, from their supposed superior virtues.

ANGELICUS PULVIS. Submuriate of mercury

ANGELIUS POLYS. Submittate of mercary.

ANGELI'NA. Angelina zanoni acosta. A tree of vast size, sometimes above sixteen feet thick, growing in rocky and sandy places in Malabar in the East Indies. It bears ripe fruit in December. The dried leaves heated are said to alleviate pain and stiffness of the joints, and dismiss swelling of the testes caused by external violence; and are also said to be useful in the cure of venereal complaints.

ANGELINE CORTEX. The name of the tree from which the Cortex Angeline is procured. It is a native of Grenada. This bark has been recommended as an

anthelmintic for children.

ANGELOCA'COS. The purging Indian plum. See Myrobalanus.

A'sot. (From angor, anguish; because of their pain.) Buboes in the groin.-Fallopius de Morbo Gallico.

ANGIGLO SSUS. (From αγκυλη, a hook, and γλωσσα, the tongue.) A person who stammers.

ANGINA. (Angina, α. f.; from αγχω, to strangle; because it is often attended with a sense of strangu-

lation.) A sore throat. See Cynanche.

ANGINA LINI. A name used by some of the later Greeks writers to express what the more ancient writers of this nation called linozostres, and the Latins epilinum: which is the cuscuta or dodder, growing on the linum or flax, as that on the thyme was called epithymum. See Cuscuta.

Angina Malignan. Malignant or putrid sore throat. See Cynanche maligna.

Anoina Parotidea. The mumps. See Cynanche parotidea.

Angina Pectoris. Syncope ang nosa of Dr. Parry. An acute constrictory pain at the lower end of the sternum, inclining rather to the left side, and extending up into the left arm, accompanied with great anxiety Violent palpitations of the heart, laborious breathings, and a sense of suffocation, are the characteristic symptoms of this disease. It is found to attack men much more frequently than women, particularly those who have short necks, who are inclinable to corpulency, and who, at the same time, lead an inactive and seden-Although it is sometimes met with in persons under the age of twenty, still it more frequently occurs in those who are between forty and fifty. In slight cases, and in the first stage of the disorder, the fit comes on by going up hill, up stairs, or by walking at a quick pace after a hearty meal; but as the disease advances, or becomes more violent, the paroxysms are apt to be excited by certain passions of the mind; by slow walking, by riding on horseback, or in a carriage; or by sneezing, coughing, speaking, or straining at stool. In some cases, they attack the patient from two to four in the morning, or whilst sitting or standing, without any previous exertion or obvious cause. On a sudden, he is seized with an acute pain in the breast, or rather at the extremity of the sternum, inclining to the left side, and extending up into the arm, as far as the insertion of the deltoid muscle, accompanied by a sense of suffocation, great anxiety, and an dea that its continuance or increase, would certainly be fatal. In the first stage of the disease, the uneasy sensation at the end of the sternum, with the other unpleasant symptoms, which seemed to threaten a suspension of life by a perseverance in exertion, usually go off upon the person's standing still, or turning from the wind; but, in a more advanced stage, they do not so readily recede, and the paroxysms are much more violent. During the fit, the pulse sinks, in a greater or less degree, and becomes irregular; the face and extremities are pale, and bathed in a cold sweat, and, for a while, the patient is perhaps deprived of the powers of sense and voluntary motion. The disease having recurred more or less frequently during the space of some years, a violent attack at last puts a sudden period to his existence. Angina pectoris is attended with a considerable degree of danger; and it usually happens that the person is carried off suddenly. It mostly depends upon an ossification of the coronary arteries, and then we can never expect to effect a radical cure. During the paroxysms, considerable relief is to be obtained from fomentations, and administering powerful antispasmodics, such as opium and ather combined together. The application of a blister to the breast is likewise attended sometimes with a good effect. As the painful sensation at the extremity of the sternum often admits of a temporary relief, from an evacuation of wind by the mouth, it may be proper to give frequent doses of carminatives, such as peppermint, carraway, or cinnamon water. Where these fail in the desired effect, a few drops of ol. anisi, on a little sugar, may be substituted.

With the view of preventing the recurrence of the disorder, the patient should carefully guard against passion, or other emotions of the mind: he should use a light, generous diet, avoiding every thing of a heating nature; and he should take care never to overload the stomach, or to use any kind of exercise immediately after eating. Besides these precautions, he should endeavour to counteract obesity, which has been considered as a predisposing cause; and this is to be effected most safely by a vegetable diet, moderate exercise at proper times, early rising, and keeping the body perfectly open. It has been observed that angina pectoris is a disease always attended with considerable danger, and, in most instances, has proved fatal under every mode of treatment. We are given, how-ever, to understand, by Dr. Macbride, that of late, several cases of it have been treated with great success, and the disease radically removed, by inserting a large issue on each thigh. These, therefore, should never be neglected. In one case, with a view of correcting, or draining off the irritating fluid, he ordered, instead of issues, a mixture of lime water with a little of the spirituous juniperi comp., and an alterative pro-portion of Huxham's antimonial wine, together with a plain, light, perspirable diet. From this course the

patient was soon apparently mended; but it was not | dica, and pharmacy, it was frequently employed to until after the insertion of a large issue in each thigh, denote its great efficacy: hence anima, hepates, aloes, that he was restored to perfect health.

Angina Trachealis. See Cynanche tonsillaris.

Angina Trachealis. See Cynanche trachealis.

ANGIOCARPI. The name given by Persoon to a division of funguses which bear their seeds internally.

They are either hard or membranous, tough and leather

ANGIOLO'GY. (Angiologia; from αγγειον, a vessel, and λογος, a discourse.) The doctrine of the vessels of the human body.

ANGIOSPERMIA. (From αγγος, a vessel, and οπερμα, a seed.) The name of an order of plants in the class Didynamia of the sexual system of Linnæus, the seeds of which are lodged in a pericarpium. or seed-vessel.

ANGIOSPERMÆ HERBÆ. Those plants, the seeds of

which are enclosed in a covering or vessel.

A'NGLICUS. (From Inglia, England.) The sweating sickness, which was so endemic and fatal in England, was called Sudor Anglicanus. See Sudor Anglicus.
Ango'LAM. A very tall tree of Malabar, possessing

vermifuge powers.

Ango'ng. (From αγχω, to strangle.) A nervous sort of quinsy, or hysteric suffocation, where the fauces are contracted and stopped up without inflam-

A'NGOR. (Angor, oris. m.: from Ango.) Agony or intense bodily pain. — Galen.

A'NGOS. (Ayyos, a vessel.) A vessel. A collection of humours.

ANGULATUS. Angled.—A term used to design nate stem, leaves, petioles, &c. which present several acute angles in their circumference. There are several varieties of angular stems

1. Triangulatus, three-angled; as in Cactus trian-

2. Quadrangulatus, four-angled; as in Cactus tetragonus.

3. Quinqueangulatus, five-angled; as in Cactus pentagonus.

4. Hexangulatus, six-angled; as in Cactus hexa-

gonus 5. Multiangulatus, many-angled; as in Cactus

6. Obtusangularis, obtuse-angled; as in Scrofularia nodosa.

7. Acutangulatus, acute-angled; as in Scrofularia

aquatica. 8. Caulis triqueter, three-sided, but with flat sides; as in Hedysarum triquetrum, Viola mirabilis, Carez

9. Caulis tetaquetrus, quadrangular with flat sides;

as in Hypericum quadrangulare, Mentha officinalis.
For angular leaves, See Leaf, Petiole, &c.
ANGULOSUS. Angular.
ANGUSTU'R & CORTEX. A bark imported from An-

gustura. See Cusparia.

ANHELA'TION. (Anhelatio; from anhelo, to breathe with difficulty.) Anhelitus. Shortness of

breathing

ANHYDRITE. Anhydrous gypsum. There are six varieties of this mineral su bate of lime. 1. The compact.—2. The granular. 3. The fibrous. 4. The radiated. 5. The sparry or cube spar. 6. The siliciferous or vulpinite.

ANHYDROS. A name given by the ancient Greeks, to express one of those kinds of Stryckna or night-shades, which, when taken internally, caused madness. ANHYDROUS. (From a, neg. and νόωρ, water.

Without water.

Anice Ton. (From a, priv. and νικη, victory.) A name of a plaster invented by Crito, and so called because it was thought an infallible or invincible remedy for achores, or scald-head. It was composed of litharge, alum, and turpentine, and is described by Galen.

Anil. The name of the Indigo plant.

Anil. The name of the Indigo plant.

A'NIMA. A soul: whether rational, sensitive, or vegetative. The word is pure Latin, formed of avenues, breath. It is sometimes used by physicians to dewas used figuratively for the volatile principle in bodies, whereby they were capable of being raised by the fire; and by the old writers on botany, materia merhabarbari, &c.

ANIMA ALOES. Refined aloes.

Anima articulorum. A name of the Hermodactyles. See Hermodactylus.

ANIMA HEPATIS. Sal martis.

Anima Pulmonum. The soul of the lungs. A name given to saffron, on account of its use in asthmas.

Anima Rhabarbari. The best rhubarb.

Anima saturni. A preparation of lead.

Anima veneris. A preparation of copper.

ANIMAL. An organized body endowed with life

and voluntary motion. The elements which enter into the composition of the bodies of animals are solid,

liquid, gaseous, and inconfinable.

Solid Elements. Phosphorus, sulphur, carbon, iron, manganese, potassium, lime, soda, magnesia, silica,

and alumina.

Liquid Elements. Muriatic acid; water, which in this case may be considered as an element, enters into the organization, and constitutes three-fourths of the bodies of animals.

Gascous Elements. Oxygen, hydrogen, azote. Inconfinable Elements. Caloric, light, electric, and magnetic fluids.

These diverse elements, united with each other, three and three, four and four, &c. according to laws still unexplained, form what we name the proximate principles of animals.

Proximate Materials, or Principles. These are di-vided into azotized, and non-azotized.

The azotized principles are: albumen, fibrin, gela tin, mucus, cheese-curd principle, urea, uric acid, osmazome, colouring matter of the blood.

The non-azotized principles are: the acetic, benzoic, lactic, formic, oxalic, rosacic, acids; sugar of milk, sugar of diabetic urine, picromel, yellow colouring matter of bile, and of other liquids or solids which become yellow accidentally, the blistering principle of cantharides, spermaceti, biliary calculus, the odoriferous principles of ambergris, musk, castor, civet, &c. which are scarcely known, except for their faculty of acting on the organ of smell.

Animal fats are not immediate, simple, proximate principles. It is proved that human fat, that of the pig, of the sheep, &c. are principally formed by two fatty bodies, stears, and elain, which present very different characters that may be easily separated.

Neither is the butter of the cow a simple body; it

contains acetic acid, a yellow colouring principle, an odorous principle, which is very manifest in ferment-

We must not reckon among these substances, adipocire, a matter which is seen in bodies long buried in the earth; it is composed of margarine, of a fluid acid fat, of an orange colouring principle, and of a peculiar odorous substance. Nor must this substance be con-founded with spermaceti, and the biliary calculus, which are themselves very different from each other. It does not contain a single principle analogous to them.

Organic Elements. The materials or principles above mentioned combine among themselves, and from their combination arise the organic elements, which are solid or liquid. The laws or forces that govern these combinations are entirely unknown.

Organic Solids. The solids have sometimes the

form of canals, sometimes that of large or small plates, at other times they assume that of membranes. In man the total weight of solids is generally eight or nine times less than that of liquids. This proportion is nevertheless variable according to many circumstances.

The ancients believed that all the organic solids might be reduced by ultimate analysis to simple fibres which they supposed were formed of earth, oil, and iron. Haller, who admitted this idea of the ancients, owns that this fibre is visible only to the eye of the mind. Invisibilis est ea fibra sola; mentis acie dis-tinguimus. This is just the same as if he had said that it does not exist at all, which nobody at present

doubts.

The ancients also admitted secondary fibres, which they supposed to be formed by particular modifications of the simple fibre. Thence, the nervous, muscular, parenchymatous, osseous fibre.

Chaussier has lately proposed to admit four sorts of | hearth of the furnace, or in any other situation where fibres, which he calls luminary, nerval, muscular, and albuginous.

Science was nearly in this state when Pinel conceived the idea of distinguishing the organic solids, not by fibres, but by tissues or systems. Bichat applied it to all the solid parts of the bodies of animals: the classification of Bichat has been perfected by Dupuytren and Richerand.

Classification of the Tissues.

1. Cellular.... Arterial. Venous. 2. Vascular Lymphatic. Cerebral. 3. Nervous Ganglaic. 4. Osseous Fibrous. Fibro-cartilaginous. 5. Fibrous Dermoid. Voluntary. Voluntary. 6. Muscular 7. Erectile 8. Mucous..... 9. Serous 10. Horny or \ Hairy. Epidemic \ Epidermoid. 11. Parenchymatous, Glandular.

These systems, associated with each other and with

the fluids, compose the organs or instruments of life.
When many organs tend by their action toward a common end, we name them, collectively considered, an apparatus. The number of apparatus, and their disposition, constitute the differences of animals.— Magendie.

Animal actions. Actiones animales. Those actions, or functions, are so termed, which are performed through the means of the mind. To this class belong the external and internal senses, the voluntary action of muscles, voice, speech, watching, and sleep.

Animal Heat. See Heat, animal.

Animal (Economy. See Economy, animal.

Animal Oil. Oleum animale. Oleum animale Dippolii. An empyreumatic oil, obtained from the bones of animals, recommended as an anodyne and antispasmodic.

A'NIME GUMMI. The substance which bears this name in the shops is a resin. See Hymenaa courbaril.

A'NIMI DELIQUIUM. (From animus, the mind, and delinquo, to leave.) Fainting. See Syncope.

A'NIMUS. This word is to be distinguished from anima; which generally expresses the faculty of reasoning, and animus, the being in which that faculty resides.

Anin'ga. A root which grows in the Antilles islands, and is used by sugar-bakers for refining their

ANISCA'LPTOR. (From anus, the breech, and scalpo, to scratch.) The latissimus dorsi is so called, because it is the muscle chiefly instrumental in per-

perduse it is the muscle chiefly instrumental in performing this office.—Bartholin.

Anisotachys. (From ανισος, unequal, and ταχυς, quick.) A quick and unequal pulse.—Gorræus.

ANISUM. (From a. neg. and ισος, equal.) See Pimpinella anisum.

Anisum sinense. See Illicium anisatum.

Anisum Stellatum. See Illicium.
Anisum vulgare. See Pimpinella anisum.
ANNEAL. We know too little of the arrangement of particles to determine what it is that constitutes or produces brittleness in any substance. In a considerable number of instances of bodies which are capable of undergoing ignition, it is found that sudden cooling renders them hard and brittle. This is a real inconvenience in glass, and also in steel, when this metalic substance is required to be soft and flexible. The inconveniences are avoided by cooling them very gradually, and this process is called annealing. Glass vessels, or other articles, are carried into an oven or apartment near the great furnace, called the leer, where they are permitted to cool, in a greater or less time, according to their thickness and bulk. The annealing of steel, or other metallic bodies, consists simply in heating them and suffering them to cool again, either upon the

the heat is moderate, or at least the temperature is not

See Bixa orleana.

ANNUAL. (Annuas, yearly.) A term applied in botany to plants and roots, which are produced from the seed, grow to their full extent, and die in one year or season, as Papaver somniferum, Helianthus annuas,

Hordeum triticum, &c.

Annue'ntes. (From annuo, to nod.) Some muscles of the head were formerly so called, because they perform the office of nodding, or bending the head

downwards.—Couper, &c.

ANNULAR. (Annularis; from Annulus, a ring, because it is ring-like, or the ring is worn on it, or it surrounds any thing like a ring; thus, annular bone, &c.

Annular bone. Circulus osseus. A ring-like bone,

placed before the cavity of the tympanum in the fœtus.

Annular cartilage. See Trackwa.

ANNULA'RIS. Annularis digitus. The ring-finger. The one between the little and middle fingers.

Annularis processus. See Pons varolii.
A'NNULUS. (Annulus, i. m., a ring.) A ring. In botany applied to the slender membrane surrounding the stem of the fungi.

The abdominal ring. ANNULUS ABDOMINIS. oblong separation of tendinous fibres, called an openoblong separation of tendinous fibres, called an opening, in each groin, through which the spermatic chord in men, and the round ligament of the uterus in women, pass. It is through this part that the abdominal viscera fall in that species of hernia, which is called bubonocele. See Obliquus externus abdominis.

A'NO. (Ανω, upwards; in opposition to κατω, downwards.) Upwards.

ANOCATHA'RTIC. (From ανω, upwards, and καθαιρω, to purge.) Emetic, or that which purges upwards.

wards.

ANOCHETLON. (From ανω, upwards, and χειλος, the lip.) The upper lip.

Ano dia. (From a, neg. and οδος, the way.) Hippocrates uses this word for inaccuracy and irregularity in the description and treatment of a disease.

ANO DYNA. See Anodyne.

ANODYNE. (Anodynus; from a, priv. and ωδυνη, pain.) Those medicines are termed Anodynes, which ease pain and procure sleep. They are divided into three sorts; paregorics, or such as assuage pain; hypnotics, or such as relieve by procuring sleep; and narcotics, or such as ease the patient by stupifying him.

ANO DYNUM MARTIALE. Ferrum ammoniatum precipitated from water by potassa.

cipitated from water by potassa.

ANO DYNUM MINERALE. Sai prunella.
ANOMALOUS. (From a. priv. and vouos, a law.) This term is often applied to those diseases, the symp toms of which do not appear with that regularity which is generally observed in diseases. A disease is also said to be anomalous, when the symptoms are so varied as not to bring it under the description of any known affection.

ANO MPHALOS. (From a, priv. and ομφαλος, the navel.) Anomphalus. Without a navel.

ANO NYMUS. (Anonymus, from a, priv. and ονομα, name.) Nameless; some eminences of the brain are called columns anonyms; and it was formerly applied to one of the cricoid muscles.

ANO RCHIDES. (From a, priv. and cover the

ANO RCHIDES. (From a, priv. and opxis, the testicle.) Children are so termed which come into the world without testicles. This is a very common occurrence. The testicles of many male infants at the

time of birth are within the abdomen. The time of their descent is very uncertain, and instances have occurred where they have not reached the scrotum at

ANORE XIA. (Anorexia, &, f.; from a, priv. and oocts, appetite.) A want of appetite, without loathing of food. Cullen ranks this genus of disease in the class Locales, and order Dysorexia. He believes it to be generally symptomatic, but enumerates two species, viz. the Anorezia humoralis, and the Anorezia atonica.

See Dyspepsia.

ANO SMIA. (Anosmia, ω, f.; from a, neg. and οζω, to smell.) A loss of the sense of smelling. This genus of disease is arranged by Cullen in the order Locales, and order Dysæsthæsiæ. When it arises from a disease of the Schneiderian membrane, it is termed Anosease of the Schneiderian membrane, and when from the schneiderian membrane is the schneiderian membrane and schneiderian membrane. mia organica; and when from no manifest cause Anosmia atonica.

A'NSER. (Anser, eris. m.; a goose or gander.)
The name of a genus of birds.

Anser dome sticus. The tame goose. The flesh of this bird is somewhat similar to that of the duck, and requires the assistance of spirituous and stimu-lating substances, to enable the stomach to digest it.

lating substances, to enable the stomach to digest it. Both are very improper for weak stomachs.

ANSERI'NA. (From anser, a goose; so called because geese eat it.) See Potentilla anserina.

ANT. See Formica rufa.

Ant, acid of. See Formic acid.

ANTACID. (Antacidus; from av7t, against, and acidus, acid.) That which destroys acidity. The action of antacids in the human stomach, is purely chemical, as they merely combine with the acid present, mical, as they merely combine with the acid present, and neutralize it. They are only palliatives, the generation of acidity being to be prevented by restoring the tone of the stomach and its vessels. Dyspepsia and diarrhoea are the diseases in which they are employed. The principal antacids in use are the alkalies; e. g. Liquoris potassæ, gutt. xv. or from 5 to 15 gr. of subcarbonate of potassa, or soda dissolved in water. The solution of soda called double soda-water, or that of solution of soda called double soda-water, or that or potassa supersaturated with carbonic acid, is more frequently used, as being more pleasant. Ammonia has been recommended as preferable to every other antacid, from 10 to 20 drops of the liquor ammoniæ in a cupful of water. The liquor calcis, or lime water, is likewise used to correct acidity, two or three ounces being taken accordingly. Creta preparata alone or being taken occasionally. Creta præparata alone, or with the addition of a small quantity of any aromatic -chelæ cancrorum præparatæ; magnesia also and its

carbonate, are used for the same purpose.

ANTAGONIST. (Antagonistus, counteracting.) A term applied to those muscles which have opposite functions. Such are the flexor and extensor of any limb, the one of which contracts it, the other stretches it out; and also the abductors and adductors. Solitary muscles are those without any antagonist, as the

heart, &c.

ANTA'LGIC. (Antalgicus; from αν7ι, against, and αλγος, pain.) That which relieves pain.

ANTA'LKALINE. (Antalkalinus; from αν7ι, against, and alkali, an alcali.) That which possesses the power of neutralizing alkalies. All the acids are

of this class.

ANTAPHRODISI'AC. Antaphrodisiacus; from aν 7ι, against, and Αφροδι 7η, Venus. Antivenereal, or whatever extinguishes amorous desires.

ANTAPHRODI'TIC. The same.

ANTAPHRODI'TIC. The same.

ANTAPHRODI'TIC. The same. cate.) A vicissitude, or return of the paroxysm of fevers.—Hippocrates. Called by Galen eipidosis. Antarthru Tic. See Antiarthritic.

ANTARTHRITIC. See Antiartaritic.

ANTASTHMA'TIC. See Antiasthmatic.

ANTATRO PHIC. See Antiatrophic.

ANTECHE'SIS. (From av / txouat, to resist.) A violent stoppage in the bowels, which resists all efforts

to remove it.—Hippocrates.

Antela'Bium. (From ante, before, and labium, a

ANTELLA BIUM. (From ante, before, and tabrum, a lip.) The extremity of the lip.

ANTE MBASIS. (From aντι, mutually, and εμβαινω, to enter.) A coalescence, or union of bone.—Galen.

ANTEME TIC. See Antiemetic.

ANTENEA'SMUS. (From αντι, against, and τεινεσμος, implacable). That species of madness in which the

implacable.) That species of madness in which the patient endeavours to destroy himself.

ANTEPHIA'LTIC. See Antiphialtic.
ANTEPHIA'LTIC. See Antiepileptic.
ANTE'RIOR. Before. A term applied to what may be situated before another of the same kind, as a

may be situated before another of the same kind, as a muscle, a projection, eminence, lobe, artery, &c.

ANTERIOR AURIS. Musculus anterior auris. One of the common muscles of the ear, situated before the external ear. It arises thin and membranous, near the posterior part of the zygoma, and is inserted into a small eminence on the back of the helix, opposite to the conclusion, which it decreases a little forwards and remarks. concha, which it draws a little forwards and upwards.

ANTERIOR INTERCOSTAL. Nervus intercostalis an-rior. Splanchnic nerve. A branch of the great interior. Splanchnic nerve. A branch e tercostal that is given off in the thorax.

ANTERIOR MALLEI. See Laxator tympani.

ANTHE LIX. See Antikeliz.

ANTHE LMA. (From αντι, against, and ελμινς, a worm; so called, because it was thought of great virtue in expelling worms.) See Spigelia antheimia, and Marilandica.

ANTHELMINTIC. (Anthelminticus; from avrt, against, and $\epsilon\lambda\mu\nu\nu$, a worm.) Whatever procures the evacuation of worms from the stomach and intestines. The greater number of anthelmintics act mechanically, dislodging the worms, by the sharpness or roughness of their particles, or by their cathartic operation. Some seem to have no other qualities than those of powerful bitters by which they either prove noxious to these animals, or remove that debility of the digestive organs, by which the food is not properly assimilated, or the secreted fluids poured into the intestines are not properly prepared; circumstances from which it has been supposed the generation of worms may arise. The principal medicines belonging to this class, are, mercury, gamboge, Geoffræa inermis, tanacetum, po lypodium filix mas, spigelia marilandica, artemisia santonica, olea Europæa, stannum pulverisatum, ferri limature, and dolichos pruriens; which see under their respective heads.

A'NTHEMIS. (Anthemis, midis. fcm.; from ay-θεω, floreo; because it bears an abundance of flowers.) 1. The name of a genus of plants in the Linnman system. Class, Syngenesia; Order, Polygamia su-

perflua.

2. The name in the London Pharmacopæia for cha-

momile. See Anthemis nobilis.

ANTHEMIS COTULA. The systematic name of the ANTHEMIS COTULA. The systematic name of the plant called Cotula fatida: Chamamelum fatidum, in the pharmacopæias. Mayweed. Stinking chamomile. This plant, Anthemis:—receptaculis conicis paleis setaceis, seminibus nudis, of Linnæus, has a very disagreeable smell; the leaves, a strong, acrid, bitterish taste; the flowers, however, are almost insipid. It is said to have been useful in hysterical affec-

Anthemis nobile: Chamamelum nobile; Chamomilla romana; Euanthemon of Galen. Anthemis of the last London pharmacopeia. Common chamomile. Anthem mis-foliis pinnato-compositis linearibus acutis sub-villosis, of Linnæus. Both the leaves and flowers of this indigenous plant have a strong though not ungrateful smell, and a very bitter, nauseous taste; but the latter are the bitterer, and considerably more aromatic. They possess tonic and stomachic qualities, and are much employed to restore tone to the stomach and intestines, and as a pleasant and cheap bitter.

They have been long successfully used for the cure of intermittents, as well as of fevers of the irregular nervous kind, accompanied with visceral obstructions. The flowers have been found useful in hysterical af-

wous kind, accompanied with visceral obstructions. The flowers have been found useful in hysterical affections, flatulent or spasmodic colies, and dysentery; but, from their laxative quality, Dr. Cullen tells us they proved hurtful in diarrheas. A simple infusion is frequently taken to excite vomiting, or for promoting the operation of emetics. Externally they are used in the decoctum pro fomento, and are an ingredient in the decoctum malvæ compositum.

Anthemis pyrethrum of the pharmacopaias; Asterantium; Buphthalmum creticum; Bellis montana putescens acris; Dentaria; Herba salivaris; Pes Alexandrinus. Spanish Chamomile; pellitory of Spain. Anthemis:—caulibus simplicibus uniforis decumbentibus—foliis pinnato-multifidis, of Linnæus. This root, though cultivated in this country, is generally imported from Spain. Its taste is hot and acrid, its acrimony residing in a resinous principle. The ancient Romans, it is said, employed the root of this plant as a pickle. In its recent state, it is not so pungent as when dried, and yet, if applied to the skin, it produces inflammation. Its qualities are stimulant; but it is never used, except as a masticatory, for relieving toothaches, rheumatic affections of the face, and paralysis of the tongue, in which it affords relief by stimulating the excretory ducts of the salival glands.

ANTHERA. (From arθos, a flower.)

1. A compound medicine used by the ancients; so called from its florid colour.—Galen. Ægineta.

2. The male part of the fructification of plants:—so called by Linnæus, by way of eminence. The male genital organ of plants consists of three parts, the filament, anther, and pollen. The anthera is the little head or extremity which rests on the filament.

Different terms are applied to the anthers from their figure:

1. Oblong; as in Lilium candidum.

1. Oblong ; as in Lilium candidum.

2. Globose; as in Morcurialis annua.

3. Semilunar; as in Fragaria vesca. 4. Angular; as in Tulipa gesneriana.

Linear; as in the grasses and Protea.
 Didymous; as in Digitalis purpurea.

7. Arrow-shaped; as in Crocus satious.

8 Bifid, parted half way down in two; as in the grasses and Erica.

9. Shield-like, or peltate, of a round shape; as in Taxus baccata.

10. Dentate, with a tooth-like margin; as in Taxus

baccata.

11. Hairy; as in Lamium album

12. Bicorn, with two divisions like horns; as in Arbutus upa ursi and Vaccinium myrtillus.

Cristate, having cartilaginous points.
 Crucial; as in Mellitis.

Double or twin-like; as in Callisia and Hura.
 Rostrate; as in Osbeckia.

17. Subulate, or awl-shaped; as in the genus Ro-

18. Cordate; as in Cupraria. 19. Reniform, kidney-shaped; as in Tradescantia and Ginora.

20. Trigonal, or three-cornered; as in the Rose. Tetragonal, or four-cornered, as in Cannabis and Dictamnus.

From their situation:

22. Erect, with its base upon the apex of the filament; as in Tulipa gesneriana.

23. Incumbent, lying horizontally upon the filament, as in Amaryllis formossima.

24. Versatile, when the incumbent anther adheres so loosely to the filament, that the least agitation of the plant puts it in motion; as in Secale correlations. the plant puts it in motion; as in Secale cereale.

25. Lateral, adhering laterally to the filament; as

in Dianthera.

26. Sessile, the filament almost wanting; as in Aristolochia clematitis.

27. Free, not united to any other anther.

28. Connate, united together; as in Viola odorata.

ANTHODIUM. A species of calyx, which contains many flowers being common to them all.

It is distinguished from its structure into,

Monophyllous, consisting of one leaflet perfect at its base, but cut at its limb or margin; as in Trago-

2. Polyphyllous, consisting of several leaflets; as in Carduus and Centaurea. 3. Simple, consisting of one series of leaflets; as in

Cacalia porophyllum.
4. Equal, when all the leaves of the Anthodium

simplex are of the same length, as in Ethulia.
5. Imbrecate or squamose, as in Centaurea cyanus 6. Squarrose, the leaflets bent backward at their extremities.

7. Scabrous, rough, consisting of dry leaflets; as in

7. Scabrous, rough, consisting of dry leaflets; as in Centaurea glastifolia and jacea.
8. Spinous, the leaflets having thorns; as in Cynaa scolymus and Centaurea sonchifolia.
9. Turbinate; as in Tarconanthus camphoratus.
10. Globose; as in Centaurea calcitrapa.
11. Hemispherical, round below and flat above; as in Anthemis and Chrysocoma.
12. Culindrical long and round; as with Eugate.

12. Cylindrical, long and round; as with Eupato-

13. Calcyculate, the basis surrounded by another small leafy anthodium; as in Leontodon taraxacum, Scnecio, and Crepis.

ANTHOPHYLLITE. A massive mineral, of a

brown colour, found at Konigsberg, in Norway.

[This substance has been observed only in amor-

phous masses, whose longitudinal fracture is foliated, or radiated, and whose cross fracture is uneven. The lustre of the most perfect laminæ is somewhat metallic. lustre of the most perfect laminæ is somewhat metallic. Its natural joints, of which two are much more perfect than the others, are parallel to the faces of a rectangular four-sided prism. It is rather difficult to break, and strongly scratches fluate of lime, but produces little or no effect on glass. It is feebly translucent at the edges, and its colour is brown, tinged with violet. Its powder is whitish, and rough to the touch. Its specific gravity varies from 3.11, to 3.29. Before the blow-pipe it js infusible. It contains silex 62.66, alumine 13.33, magnesia 4.0, lime 3.33, oxide of iron 12.00, manganese 3.25, water 1.43. It is softer, lighter, and manganese 3.25, water 1.43. It is softer, lighter, and has less lustre, than Labrador stone.—Cleav. Min. A.]

ANTHOPHY LLUS. (From ανθος, a flower, and φυλλον, a leaf; so called from the fragance of the flowers and the beauty of the leaves.) The clove is so termed when it has been suffered to grow to matu-

(From aveos, a flower, and ANTHOPHY'LLUS.

φιλεω, to love.) A florist.
A'NTHORA. (Quasi antithora. Αντιθορα; from avre, against, and Sopa, monkshood: so called, because it is said to counteract the effects of the thorn or monkshood.) A species of Wolfsbane. See Accnitum anthora.

A NTHOS FLORES. The flowers of the resmarinus are so termed in some pharmacopaias. See Resma-

ANTHRA'CIA. 1. The name of a genus of diseases

in Good's Nosology. See Nosology.

2. A name of the carbuncle. See Anthrax.

ANTHRACITE. Blind coal, Kilkenny coal, or glance coal. There are three varieties, conchoidal, slaty, and columnar.

(When pulverized and heated, it becomes red, and slowly consumes with a very light lambent flame, without smoke, and when pure emits no sulphureous or bituminous odour; it leaves a variable proportion of reddish ashes. Slaty glance coal consists of carbon, with from 3 to 30 per cent of earth and iron. This mineral occurs in imbedded masses, beds, or veius, in primitive, transition, and floetz rocks. It is found in gneiss, in micaceour shistus, in mineral veius, with calcareous spar, pative silver mineral veius. with calcareous spar, native silver, mineral pitch, and red iron ore; and has been discovered by Jameson in the independent coal formation in the Isle of Arran.-

Phillips's Min.

The coal of Rhode-Island is mingled with quartz, and occasionally with fibrous asbestos; yet it has but little hydrogen, and less bitumen. It is overlaid by coarse shale, containing numerous and strong impres-

sions of ferns.

In Pennsylvania there are two great coal formations: one situated S. E. of the mountains, and the other N. W. The former is the Anthracite or glance coal, ex-tending almost from Delaware along the head waters of the Lehigh and Schuylkill, and to Wilkesbarre on the Susquehannah, and along the Juniata .- Mitchill's Notes to Phil. Min.

This formation of Anthracite has been traced for ninety or a hundred miles in the state of Pennsylvania, and mines have been opened in many places on the branches of the Susquehannah, Schuylkill, and Delaware rivers, and some of them bordering on the states of New-Jersey and New-York. In many places it is near the surface, and appears to be inexhaustible. It is now extensively used as fuel, and its consumption is increasing. A.]

ANTHRACO'SIS OCULI. A red, livid, burning, sloughy, very painful tumour, occurring on the eyelids .- Ægi-

neta

ANTHRAX. (Anthrax, acis. m.; from avbpat, a burning coal.) Anthracia; Anthrocosia; Anthrocoma; Carbunculus; Carbo; Rubinus versus; Codiscella; Granatristum; Pruna; Persicus ignus of Avicenna. A hard and circumscribed inflammatory tubercle like a boil, which sometimes forms on the cheek nack are back and in a few days becomes cheek, neck, or back, and in a few days becomes highly gangrenous. It then discharges an extremely feetid sanies from under the black core, which, like a burning coal, continues destroying the surrounding parts. It is supposed to arise from a peculiar miasma, s most common in warm climates, and often attends

ANTHROPOGRA'PHY. (Anthropographia; from ανθοωπος, a man, and γραφω, to write.) Description of the structure of man.

ANTHROPOLO'GY. (Anthropogogia; from ανθοωπος, a man, and λογος, a discourse.) The description of man.

(Anthypnoticus; from av71, ANTHYPNO'TIC. against, and vavos, sleep.) sleep or drowsines

ANTHYPOCHONDRI'AC. (Anthypochondriacus; from aν/ι, against, and ὑποχονδοια, the hypochondria.) That which is adapted to cure low-spiritedness or disorders of the hypochondria.

ANTHYSTERIC. (Anthystericus; from αν/ι, against, and υςτοα, the womb.) That which relieves the hysteric passion

the hysteric passion

A'NTI. (Aν7ι, against.) There are many names compounded with this word, as Antiasthmatic; Antihysteric; Antidysenteric, &c.; which signify medicines against the asthma, hysterics, dysentery, &c.

ANTIA'GRA. (From αν7ιας, a tonsil, and αγοα, a prey.) Antiagri. A tumour of the tonsils.—Ulpian, Roland, &c.

ANTIARTHRI'TIC. (Antiarthriticus; from αν7ι, against, and αρθον γις, the good.) Antiarthritic.

av7ι, against, and αρθρι7ις, the gout.) Antiarthritic.

Against the gout.
ANTIASTHMATIC. (Antiasthmaticus); from av7ι, against, and aσθμα, an asthma.) Antasthmatic. Against the asthma.

ANTIATROPHIC. (Antiatrophicus; from av71,

against, and αγροφια, an atrophy.) Against an atrophy or wasting away.

ANTICACHE'CTIC. (Anticachecticus; from ανγι, against, and καχεξια, a cachexy.) Medicines against a cachexy, or bad habit of body.

ANTICA'RDIUM. (From ανγι, against, or opposite, and καρεξια, the heart.) The hollow at the bottom of the breast, commonly called scrobiculus cordis, or the the breast, commonly called scrobiculus cordis, or the pit of the stomach.

ANTICATARRHA'L. (Anticatarrhalis; from σι 7ι, against, and κα 7αρρος, a catarrh.) That which

relieves a catarrh.
ANTICAUSO TIC. ANTICAUSO TIC. (From αν7ι, against, and καυσος, a burning fever.) Remedies against burning fevers. We read, in Corp. Pharm. of Junken, of a

syrupus anticausoticus.

A'nticheir. (From aν7ι, against, and χειρ, the hand.) The thumb.—Galen.

Anticne'mion. (From aντι, against, or opposite, and κνημη, the calf of the leg.) That part of the tibia which is bare of flesh, and opposite the calf of the leg.

which is bare of flesh, and opposite the calf of the leg. The shin-bone.—Galen.

ANTICO'LIC. (From αντι, against, and κωλικη, the colic.) Remedies against the colic.

ANTIDIA'STOLE. (From αντι, against, and διαςτλλω, to distinguish.) An exact and accurate distinction of one disease, or symptom, from another.

ANTIDI'NIC. (From αντι, against, and δινος, circumgyration.) Medicines against a vertigo, or giddiness.—Blanchard.

ANTIDOTARIUM. (Antidotarium, i. n.: from

ANTIDOTARIUM. (Antidotarium, i. n.; from arricoros, an antidote.) A term used by former writers for what we now call a dispensatory; a place where antidotes are prescribed and prepared. There are antidotaries extant of several authors, as those of Nicholaus, Mesue, Myrepsus, &c.
ANTI DOTUS. From αντι, against, and διδωμι,

to give.) 1. An antidote.

2. A preservative against sickness.

3. A remedy.—Galen.

ANTIDYSENTE'RIC. (Antidysentericus; from avre, against, and δυσεντερια, a flux.) Medicines

against a dysentery.

ANTIEMETIC. (Antiemeticus; from αντι, against, and εμεω, to vomit.) Antemetic. That which pre-

vents or stops vomiting.

ANTIEPHIALTIC. (Antiephialticus; from αντι, against, and εφιαλτης, the nightmare.) - Antephialtic.

Against the nightmare.
ANTIEPILEPTIC. (Antiepilepticus; from avri,

Against, and επιληψις, the epilepsy.) Antepileptic. Against epilepsy.

ANTIFEBRI'LE. (Antifebrilis; from αντι, against, and febris, a fever.) A febrifuge, a remedy against

ANTIHE CTIC. (Antihecticus; from αντι, against, and ἐκτικος, a hectic fever.) A remedy against a hec-

ANTIHE CTICUM POTERII. Antimonium diaphore-ticum Joviale. A medicine invented by Poterius, formerly extolled as effectual in heetic fevers, but now disregarded. It is an oxyde of tin and chaly-beated regulus of antimony, in consequence of their deflaration with cities.

Deafed regulus of antimony, in consequence of their deflagration with nitre.

ANTIHE'LIX. (Antihelix, licis. m.; from aντι, against, and ελιξ, the helix.) The inner circle of the external ear, so called from its opposition to the outer circuit, called the helix.

ANTIHELMINTIC. See Anthelmintic.

ANTIHYSTER'IC. (Antihystericus; from aντι, against, and δετρικα, hysterics.) Medicines which prevent or relieve hysterics.

ANTILE'PRIS. (From aντιλαμβανω, to take hold of.) ANTILE PSIS. (From arrilaubave, to take hold of.)

The securing of bandages or ligatures from allpping.

The securing of bandages or ngatures from suppling—Hippocrates.

ANTILO BIUM. (From αντι, opposite, and λοδος, the bottom of the ear.) The tragus or that part of the ear which is opposite the lobe.

ANTILOF MIC. (Antiloimicus; from αντι, against, and λοιμος, the plague.) Remedies or preventives against the plague.

ANTILOPUS. The antelope. An African beast resembling a deer, the hoofs and horns of which were formerly given in hysteric and epilectic cases. formerly given in hysteric and epilectic cases.

ANTILY'SSUS. (From art, against, and hyster.)

the bite of a mad dog.) A medicine or remedy against

the bite of a mad dog.

ANTIMONIA'L. (Antimonialis; from antimo-nium, antimony.) An antimonial or composition in which antimony is a chief ingredient. A preparation of antimony.

Antimonial powder. See Antimonialis pulvis. ANTIMONIA LIS PULVIS. Antimonial powder.

of sulphuret of antimony, powdered, a pound; harts-horn shavings, two pounds. Mix and throw them into a broad iron pot heated to a white heat, and stir the mixture constantly until it acquires an ash colour. the mixture constantly until it acquires an ash colour. Having taken it out, reduce it to powder, and put it into a coated crucible, upon which another inverted crucible, having a small hole in its bottom, is to be luted. Then raise the fire by degrees to a white heat, and keep it so for two hours. Reduce the residuary mass to a very fine powder. The dose is from five to ten grains. It is in high esteem as a febrifuge, sudorific, and antispasmodic. The diseases in which it is mostly exhibited are, most species of asthenic and exanthematous fevers, acute rheumatism, gout, diseases arising from obstructed perspiration, dysuria, nervous affections, and spasms. nervous affections, and spasms

This preparation was introduced into the former London pharmacopæia as a substitute for a medicine of extensive celebrity, Dr. James's powder; to which, however, the present form more nearly assimilates in its dose, and it is more manageable in its administration, by the reduction of the proportion of antimony

to one-half.

Antimonic acid. See Antimony.

Antimonic acid. See Antimony.

Antimonic acid. See Antimony.

This preparation is now directed to be made by dissolving an ounce of tartarized antimony, and two drams of subcarbonate of ammonia, separately in distilled water, mixing the solutions and boiling, till the oxyde of antimony is precipitated, which is to be washed with water, and dried. This must not be confounded with the old calcined or disphoretic antimony, being a much more active preparation. See Antimony.

a much more active preparation. See Antimony.

In its effects, it will be found to agree pretty much with the antimonium tartacizatum; but it is very

little employed.

ANTIMONII SULPHURETUM PRÆCIPITATUM. Sulphur antimonic praccipitatum. Precipitated sulphuret of antimony. This preparation of antimony appears to have rendered that called kermes mineral unnecessary. It is made thus:—Take of sulphuret of antimony, in powder, two pounds;—of the solution of potassa, four pints:—of distilled water, three pints.

Mix; and boil the mixture over a slow fire for three hours, stirring it well, and occasionally adding distil-

hours, stirring it well, and occasionally adding distilled water, so that the same measure may be preserved. Strain the solution quickly through a double linen cloth, and while it is yet hot, drop in gradually, as much sulphuric acid as may be required to precipitate the powder; then wash away the sulphate of potassa by hot water; dry the precipitated sulphuret of anti-mony, and reduce it to powder. In this process part of the water is decomposed, and its oxygen unites partly with the antimony; the oxyde of antimony, as well as the potassa, combines with sulphur and hydrowell as the potassa, combines with sulphur and hydrogen, forming hydrosulphuret of antimony and hydroguretted sulphuret of potassa: if the solution be allowed to cool, the former of these partly precipitates, constituting the kermes mineral; but the addition of the
sulphuric acid throws down the whole of it at once,
mixed with some sulphur, furnished with the decomposition of the hydroguretted sulphuret of potassa.

As an alterative and sudorific, it is in high estimation, and given in diseases of the skin and glands;
and, joined with calomel, it is one of the most power
ful and penetrating alteratives we are in possession of

ful and penetrating alteratives we are in possession of

Antimonii tartarizati vinum. Wine of tartarized antimony, one scruple; boiling distilled water, eight fluid ounces; rectified spirit, two fluid ounces. Dissolve the tartar-bium. A metal found native, but very rarely; it has, rectined spirit, two hund offices. Dissoive the tartar-ized antimony in the boiling distilled water, and add the spirit to the filtered liquor. Four fluid drachms of this contain one grain of tartarized antimony.

ANTIMONITE. A salt formed by the combination of the antimonous acid with alkaline and other bases. Sec Antimony.

ANTIMO'NIUM. See Antimony

Antimonium calcinatum. An oxyde of antimony. Antimonium diaphoreticum. An old name for an oxyde of antimony.

Antimonium tartarizatum. Tartarus emeticus; Tartarum emeticum; Tartarus antimonialus; Tartris antimonii cum potassa; Tartarum stibiatum. Tartar emetic. It is obtained by boiling the fusible oxyde of antimony with supertartrate of potassa, the oxyde of antimony with supertartrate of potassa, the excess of tartaric acid dissolves the oxyde, and a triple salt is obtained by crystallization. The London Pharmacopæia directs thus Take of glass of antimony finely legivated, supertartrate of potassa in powder, of each a pound; boiling distilled water a gallon; mix each a pound; boiling distilled water a gailon; mix the glass of antimony and the supertartrate of potassa well together, and then add them by degrees to the distilled water, which is to be kept boiling and constantly stirred; boil the whole for a quarter of an hour, and then set it by. Filter it when cold, and evaporate the filtered liquor so that crystals may form in it. A solution of this salt in dilute wine is ordered in it. A solution of this salt in dilute wine is ordered in the Pharmacopæia. See Antimonii tartarizati

vinum.

Tartar emetic is the most useful of all the antimonial preparations. Its action is not dependent on the state of the stomach, and, being soluble in water, its dose is easily managed, while it also acts more speedily. In doses of from one to three, four, or five grains, it generally acts proved by a constant of the state of the it generally acts powerfully as an emetic, and is employed whenever we wish to obtain the effects which result from full vomiting. As patients are differently affected by this medicine, the safest mode of exhibiting

affected by this medicine, the safest mode of exhibiting it is: R. Antimonii tartarazati, gr. iii. Aqua distillata, ziv. Misce et cola. Dosis z ss. omni hora quadrante, donec supervenerit vomitus.

For children, emetic tartar is not so safe for an emetic as ipecacuanha powder: when great debility of the system is present, even a small dose has been known to prove fatal. Sometimes it proves cathartic. In smaller doses it excites nausea, and proves a powerful diaphoretic and expectorant. As an emetic it is erful diaphoretic and expectorant. As an emetic it is chiefly given in the beginning of fevers and febrile diseases; when great debility is present, and in the advanced stages of typhoid fever, its use is improper, and even sometimes fatal. As a diaphoretic, it is given in small doses, of from an eighth to a quarter of a grain; and as an expectorant, in doses still smaller. Emetic tartar, in small doses, combined with calomel, has been found a powerful yet safe alterative in obstinate eruptions of the skin. B. Antimonii tartarizati, gr iv. Hydrargyri submuriatis, gr. xvi. Confectionis rosæ gallicæ, q. s. Divide in pil. xxiv. Capiat i. mane nocteque ex thea sassafras.

In the form of powder, or dissolved in water, it is applied by a pencil to warts and obstinate ulcers: it is also given in the form of clyster, with a view to produce irritation in soporose diseases, apoplexy, ileus, and strangulated hernia. The powder mixed with any fluid, and rubbed on the scorbiculus cordis, excites vomiting. Another property which tartar emetic has, when rubbed on the skin, is that of producing a crop of pustules very like to the small-pox, and with this view it is used against rheumatic pains, white, and other obstinate swellings. The best antidote against the bad effects of too large a quantity of this and other the bad effects of too large a quantity of this and other antimonial preparations, is a decoction of the bark of cinchona; in defect of which, tea and other astringents may be used. In a larger dose, this salt is capable of acting as a violent poison. The best antidotes are demulcent drinks, infusions of bark, tea, and sulphuretted hydrogen water, which instantly converts the energetic salt into a relatively mild sulphuret: anodynes are useful afterward. anodynes are useful afterward.

Glass of antimony. ANTIMONIUM VITRIFACTUM.

An oxyde of antimony, with a little sulphuret.

ANTIMONY. (Antimonium, i. n. Avro The origin of this word is very obscure. The most

bium. A metal found native, but very rarely; it has, in that state, a metallic lustre, and is found in masses of different shapes; its colour is white, between those of tin and silver. It generally contains a small portion of arsenic. It is likewise met with in the state of an oxyde, antimonial ochre. The most abundant ore of it is that in which it is combined with sulphur, the gray ore of antimony, or suiphuret of antimony. The colour of this ore is bluish, or steel-gray, of a metallic lustre, and is often extremely beautifully variegated. Its texture is either compact, foliated, or striated. The striated is found both crystallized, massive, and disseminated: there are many varieties of this ore.

Properties of Antimony.—Antimony is a metal of a grayish white, having a slight bluish shade, and very brilliant. Its texture is lamellated, and exhibits plates crossing each other in every direction. Its surface is covered with herbarisations and foljage. Its specific gravity is 6.702. It is sufficiently hard to scratch all the soft metals. It is very brittle, easily broken, and pulverizable. It fuses at 810° Fahr. It can be volatilized, and burns by a strong heat. When perfectly fused, and suffered to cool gradually, it crysperfectly fused, and suffered to cool gradually, it crystallizes in octahedra. It unites with sulphur and phosphorus. It decomposes water strongly at a red heat. It is soluble in alkaline sulphurets. Sulphuric acid, boiled upon antimony, is feebly decomposed. Nitric acid dissolves it in the cold. Muriatic acid scarcely acts upon it. The oxygenated muriatic acid gas inflames it, and the liquid acid dissolves it with facility. Argenic acid dissolves it by heat with diff. gas inflames it, and the liquid acid dissolves it with facility. Areenic acid dissolves it by heat with difficulty. It unites, by fusion, with gold, and renders it pale and brittle. Platina, silver, lead, bismuth, nickel, copper, arsenic, iron, cobalt, tin, and zinc, unite with antimony by fusion, and form with it compounds, more or less brittle. Mercury does not alloy with it easily unless very pure. We are little acquainted with the action of alkalies upon it. Nitrate of potassa is decomposed by it. It fulminates by percussion with oxygenated muriate of potassa. Antimony forms three, probably four, distinct combinations with oxygen:

The protoxyde, a blackish gray powder obtained from a mixture of powder of antimony and water at the positive pole of a voltaic circuit.

The deutoxyde, obtained by digesting the metal 2. The deutoxyde, obtained by digesting the metal in powder, in muriatic acid, and pouring the solution in water of potassa. Wash and dry the precipitate. It is a powder of a dirty white colour which melts in a moderate red heat, and crystallizes as it cools.

3. The tritoxyde, or antimonious acid, which as immediately produced by the combustion of the metal, and the formed in fine white colour the acid.

immediately produced by the combustion of the metal, called formerly, from its fine white colour, the argentine flowers of antimony. It forms the salts called antimonites with the different bases.

4. The peroxyde, or antimonic acid. This is formed when the metal in powder is ignited along with six times its weight of nitre in a silver crucible. The excess of potassa and nitre being afterward separated by hot water, the antimoniate of potassa is then to be decomposed by muriatic acid, when the insoluble antimonic acid of a straw colour will be obtained.

Methods of obtaining antimony. 1. To obtain antimony, heat 32 parts of filings of iron to redness, and project on them, by degrees, 100 parts of antimony; when the whole is in fusion, throw on it, by degrees, 20 parts of nitrate of potassa, and after a few minutes

20 parts of nitrate of potassa, and after a few minutes quiet fusion, pour it into an iron melting cone, pre-viously heated and greased.

2. It may also be obtained by melting eight parts of

the ore mixed with six of nitrate of potassa, and three of supertartrate of potassa, gradually projected into a red-hot crucible, and fused.

To obtain perfectly pure antimony, Margraaf melted some pounds of the sulphuret in a luted crucible, and thus scorified any metals it in that contain. Of the antimony thus purified, which lay at the bottom, he took sixteen ounces, which he oxydized cautiously first with a slow, and afterward with a strong heat, until it ceased to smell of sulphur, and acquired a grayish-white colour. Of this gray powder he took four ounces, mixed them with six drachms of supertartrate of potassa, and three of charcoal, and kept them in

fusion in a well-covered and luted crucible, for one | solve in boiling water the result of the evaporation, nour, and thus obtained a metallic button that weighed one ounce, seven drachms, and twenty grains

The metal, thus obtained, he mixed with half its weight of desiccated subcarbonate of soda, and covered the mixture with the same quantity of the subcar-bonate. He then melted it in a well-covered and luted crucible, in a very strong heat, for half an hour, and thus obtained a button which weighed one ounce, six drachms, and seven grains, much whiter and more beautiful than the former. This he again treated with one and a half ounce of subcarbonate of soda, and obtained a button, weighing one ounce, five drachms, and six grains. This button was still purer than the foregoing. Repeating these fusions with equal weights of subcarbonate of soda three times more, and an hour and a half each time, he at last obtained a button so pure as to amalgamate with mercury with ease, very hard, and in some degree malleable; the scorie formed in the last fusion were transparent, which indicated that they contained no sulphur, and hence it is the obstinate adherence of the sulphur that renders

the purification of this metal so difficult.

"Chlorine gas and antimony combine with combustion, and a bichloride results. This was formerly prepared by distilling a mixture of two parts of corrosive sublimate with one of antimony. The substance which came over having a fatty consistence, was called butter of antimony. It is frequently crystal-lized in four-sided prisms. It is fusible and volatile at a moderate heat; and is resolved by water alone into the white oxyde and muriatic acid. Being a bichloride, it is eminently corrosive, like the bichlo-ride of mercury from which it is formed. It consists ride of mercury, from which it is formed. It consists of 45.7 chlorine + 54.3 antimony, according to Dr. John Davy's analysis, when the composition of the sulphuret is corrected by its recent exact analysis by suppuret is corrected by its recent exact analysis by Berzelius. But 11 antimony + 2 primes chlorine = 9.0, give the proportion per cent. of 44.1 + 55.5; a good coincidence, if we consider the circuitous process by which Dr. Davy's analysis was performed. Three parts of corrosive sublimate, and one of metallic antimony, are the equivalent proportions for making butter of antimony.

Iodine and antimony combine by the aid of heat into a solid iodine, of a dark red colour.

The phosphuret of this metal is obtained by fusing The phosphuret of this metal is obtained by fusing it with solid phosphoric acid. It is a white semicrystalline substance. The sulphuret of antimony exists abundantly in nature. It consists, according to Berzelius, of 100 antimony + 37.25 sulphur. The proportion given by the equivalent ratio is 100 + 36.5. The only important alloys of antimony are those of lead and tin; the former constitutes type-metal, and contains about one-sixteenth of antimony; the latter allow is employed for making the plates on which the alloy is employed for making the plates on which music is engraved.

The salts of antimony are of two different orders; in the first, the deutoxyde acts the part of a salifiable base; in the second, the tritoxide and peroxide act the part of acids, neutralizing the alkaline and other bases, to constitute the antimonites and antimoniates.

The only distinct combination of the first order entitled to our attention, is the triple salt called tartrate of potassa and antimony, or tartar emetic, and which, by Gay Lussac's new views, would be styled cream-tartrate of antimony. This constitutes a valuable and powerful medicine, and therefore the mode of preparing it should be correctly and clearly defined. the dull white deutoxyde of antimony is the true basis of this compound salt, and as that oxyde readily passes by mismanagement into the tritoxide or antimonious acid, which is altogether unfit for the purpose, ade-quate pains should be taken to guard against so capital an error. In the British pharmacopæias, the glass of antimony is now directed as the basis of tartar emetic. More complex and precarious formulæ were formerly introduced. The new edition of the Pharmacopée Française has given a recipe, which appears, with a slight change of proportions, to be unexceptionable. Take of the sulphuretted vitreous oxide of antimony, levigated and acidulous tartrate of potassa, equal parts. From a powder, which is to be put into an earthen or silver vessel, with a sufficient quantity of pure water. Boil the mixture for half an hour, adding boiling water from time to time. Silver the hot lighter boiling water from time to time; filter the hot liquor, and evaporate to dryness in a porcelain capsule; dis-

evaporate till the solution acquires the spec. grav. 1.161, and then let it repose, that crystals be obtained, which, by this process, will be pure. By another recipe, copied, with some alteration, from Mr. Phillips's prescription, into the appendix of the French Pharmacopæia, a subsulphate of antimony is formed first of all, by digesting two parts of sulphuret of antifirst of all, by digesting two parts of sulphuret of antimony in a moderate heat, with three parts of oil of vitriol. This insoluble subsulphate being well washed, is then digested in a quantity of boiling water, with its own weight of cream of tartar, and evaporated at the density 1.161, after which it is filtered hot. On cooling, crystals of the triple tartrate are obtained. One might imagine, that there is a chance of obtaining by this process a mixture of sulphate of potassa, and perhaps of a triple sulphate of antimony, along with the tartar emetic. Probably this does not happen, for it is said to yield crystals, very pure, very white, and without any mixture whatever. without any mixture whatever.

Pure tartar emetic is in colourless and transparent tetrahedrons or octohedrons. It reddens littnus. Its taste is nauseous and caustic. Exposed to the air, it effloresces slowly. Boiling water dissolves half its weight, and cold water a fifteenth part. Sulphuric, nitric, and muriatic acids, when poured into a solution of this salt, precipitate its cream of tartar; and soda, potassa, ammonia, or their carbonates, throw down its oxyde of antimony. Barytes, strontites, and lime waters occasion not only a precipitate of oxyde of antimony, like the alkalies, but also insoluble tartrates of these earths. That produced by the alkaline hydrosulphurets is wholly formed of kermes; while that caused by sulphuretted hydrogen, contains both kermes and cream of tartar. The decortions of several varies. caused by sulphuretted hydrogen, contains both kermes and cream of tartar. The decoctions of several varieties of cinchona, and of several bitter and astringent plants, equally decompose tartar emetic; and the precipitate then always consists of the oxyde of antimony, combined with the vegetable matter and cream of tartar. Physicians ought, therefore, to beware of such incompatible mixtures. When tartar emetic is exposed to a red heat, it first blackens, like all organic compounds, and afterward leaves a residuum of men compounds, and afterward leaves a residuum of metallic antimony and subcarbonate of potassa. From this circumstance, and the deep brownish red precipi-tate, by hydrosulphurets, this antimonial combination may readily be recognised. The precipitate may further be dried on a philter, and ignited with black flux, when a globule of metallic artimony will be obtained. Infusion of galls is an active precipitant of tartar emetic.

The composition of this salt, according to M. Thenard, is 35.4 acid, 39.6 oxyde, 16.7 potassa, and 8.2 water. The presence of the latter ingredient is obvious, from the undisputed phenomenon of efflorescence. If we adopt the new views of M. Gay Lussac, this salt may be a compound of a prime equivalent of tartar = 23.825, with a prime equivalent of deutoxide of anti-mony = 13. On this hypothesis, we would have the following proportions:

2 primes acid, = 5.95prime potassa, 16.2 prime water, 1.125 3.1 4 oxyde of antimony, = 13.0035.3 36,825 100.0

But very little confidence can be reposed in such atomical representations.

The deutoxyde seems to have the property of combining with sulphur in various proportions. To this species of compound must be referred the liver of antimony, glass of antimony, and crocus metallorum of the ancient apothecaries. Sulphuretted hydrogen forms, with the deutoxide of antimony, a compound which possessed at one time great celebrity in medicine, and of which a modification has lately been introduced into the art of calico printing. By dropping hydrosulphuret of potassa, or of ammonia, into the cream tartrate, or into mild muriate of antimony, the hydrosulphuric of the metallic oxyde precipitates of a beautiful deep orange colour. This is kermes mineral. beautiful deep orange colour. This is kermes mineral.
Cluzel's process for obtaining a fine kermes, light, velvety, and of a deep purple-brown, is the following: one part of pulverized sulphuret of antimony, 22 1-2 parts of crystallized subcarbonate of soda, and 200 parts of water, are to be boiled together in an iron pot. Filter the hot liquor into warm earthen pans, and 75 ANT ANT

allow them to cool very slowly. At the end of va wash it with water which had been boiled and then cooled out of contact with air. Dry the kermes at a temperature of 85°, and preserve in corked phials. Whatever may be the process employed, by boiling the liquor, after cooling and filtration, on new sulphuret of antimony, or upon that which was left in the former operation, this new liquid will deposite, on cooling, a new quantity of kermes. Besides the hydrosulphuretted oxyde of antimony, there is formed a sulphuretted hydrosulphuret of potassa or soda. Consequently the alkali seizes a portion of the sulphur from the antimonial sulphuret, water is decomposed; and, while a a portion of its hydrogen unites to the alkaline sulphuret, its oxygen, and the other portion of its hydrogen, combine with the sulphuretted antimony. It seems, that the resulting kermes remains dissolved in the sulphuretted hydrosulphuret of potassa or soda; but as it is less soluble in the cold than the hot, it is partially precipitated by refrigeration. If we pour into the supermatant liquid, after the kermes is deposited and removed, any acid, as the dilute nitric, sulphuric, are muriatic we decompose the sulphuretted hydrosulor muriatic, we decompose the sulphuretted hydrosulphuret of potassa or soda. The alkaline base being laid hold of, the sulphuretted hydrogen and sulphur to which they were united are set at liberty; the sulphur and kermes fall together, combine with it, and form and retimes tail together, combine with it, and form an orange-coloured compound, called the golden sul-phuret of antimony. It is a hydroguretted sulphuret of antimony. Hence, when it is digested with warm muriatic acid, a large residuum of sulphur is obtained, amounting sometimes to 12 per cent. Kermes is com-posed, by Thenard, of 20.3 sulphuretted hydrogen, 4.15 sulphur, 72.76 oxyde of antimony, 2.79 water and loss; and the golden sulphuret consists of 17.87 sulphuretted

hydrogen, 68.3 oxyde of antimony, and 12 sulphur.
By evaporating the supernatant kermes liquid, and cooling, crystals form, which have been lately employed by the calico printer to give a topical orange. These crystals are dissolved in water, and the solution, being thickened with paste or gum, is applied to cloth in the usual way. When the cloth is dried, it is passed through a dilute acid, when the orange precipitate is deposited and fixed on the vegetable fibres.

An empirical antimonial medicine, called James's powder, has been much used in this country. inventor called it his fever powder, and was so suc-cessful in his practice with it, that it obtained very great reputation, which it still in some measure retains. Probably, the success of Dr. James was in a great measure owing to his free use of the bark, which he always gave as largely as the stomach would bear, as soon as he had completely evacuated the primæ viæ by the use of his antimonial preparation, with which at first he used to combine some mercurial. His speci-fication, lodged in chancery, is as follows: "Take antimony, calcine it with a continued protracted heat, in a flat, unglazed, earthen vessel, adding to it from in a flat, unglazed, earthen vessel, anding to it from time to time a sufficient quantity of any animal oil and salt, well dephlegmated; then boil it in melted nitre for a considerable time, and separate the powder from the nitre by dissolving it in water." The real recipe has been studiously concealed, and a false one published in its stead. Different formulæ have been offered for imitating it. That of Dr. Pearson furnishes a mere mixture of an oxyde of antimony, with phosphate of lime. The real powder of James, according to this chemist, consists of 57 oxyde of antimony, with 43 phosphate of lime. It seems highly probable that superphosphate of lime would act on oxyde of antimony in a way somewhat similar to cream of tartar, and produce a more chemical combination than what can be derived from a precarious ustulation, and cal-cination of hartshorn shavings and sulphuret of anticination of hartshorn shavings and sulphuret of antimony, in ordinary hands. The antimonial medicines
are powerful deobstruents, promoting particularly the
cuticular discharge. The union of this metallic oxyde
with sulphuretted hydrogen, ought undoubtedly to
favour its medicinal agency in chronic diseases of the
skin. The kermes deserves more credit than it has
hitherto received from British physicians.

The compounds, formed by the antimonious and
antimonic acids with the bases, have not been applied
to any use. Muriate of barytes may be employed as a

to any use. Muriate of barytes may be employed as a test for tartar emetic. It will show, by a precipitate insoluble in nitric acid, if sulphate of potassa be pre-

At the end of 24 sent. If the crystals be regularly formed, more tartar hrow it on a filter, need not be suspected."—Ure's Chem. Dict.

The preparations of antimony formerly in use were very many: those now directed to be kept are; -

Oxydum antimonii.

Sulphuretum antimonii precipitatum.

Antimonium tartarizatum. Vinum antimonii tartarizati.

Pulvis antimonialis.

ANTI MORIS. (From avrt, against, and μορος, death, or disease.) A medicine to prolong life.

ANTINEPHRITIC. (Antinephriticus; from arri, against, and νεφριτις, a disease of the kidneys.) A remedy against disorders of the kidneys.

ANTIODONTALGIC. (Antiodontalgicus; from

aντι, against, and οδονταλγια, the toothache.) Against

ANTIODONTA'LGICUS. An insect described by Germi in a small work published at Florence 1794, so called from its property of aliaying the toothache. It is a kind of curculio found on a species of thistle, Carduus spinosissimus. If twelve or fifteen of these insects, in the state of larva, or when come to perfection, be bruised and rubbed slowly between the fore-finger and thumb until they have lost their moisture, and if the painful tooth, where it is hollow, be touched with that finger, the pain ceases sometimes instantaneously. A piece of shamoy leather will answer the same pur-pose with the finger. If the gums are inflamed, the remedy is of no avail. Other insects possess the proremedy is of no avail. Other insects possess the property of curing the toothache; such as the Scarabeus ferrugineus of Fabricius; the Coccinella septempunetata, or lady-bird; the Chrysomela populi, and the Chrysomela sanguinolenta. This property belongs to several kinds of the Colcoptera.

ANTIPARALY TIC. (Antiparalyticus; from aντι, against, and παραλυσις, the palsy.) Against the nalsy.

ANTIPATHY. (Antipathia, α. f. Αντιπαθης, from αντιπαθεω, to have a natural repugnance or dislike; from avre, against, and malos, an affection.) 1. An aversion to particular objects.

The name of a genus of diseases in some classifi-

cations

ANTIPERISTA'LTIC. (Antiperistalticus; from αντι, against, and προςτλλω, to contract.) Whatsoever obstructs the peristaltic motion of the intestines.

Antiperi's tatis. (From αντι, against, and περιζη-μι, to press.) A compression on all sides. Theo-

ANTIPHA RMIC. (Antipharmicus; from αντι, against, and φαρακον, a poison.) The same as alexipharmic. Remedies or preservatives against poison.—

ANTIPHLOGI'STIC. (Antiphlogisticus; from avτι, against, and φλεγω, to burn.) A term applied to those medicines, plans of diet, and other circumstances, which tend to oppose inflammation, or which, in other words, weaken the system by diminishing the activity

of the vital power.

ANTIPHTHI'SIC. (Antiphthisicus; from artı, against, and $\phi\theta\iota\sigma\iota\varsigma$, consumption.) Against a con-

sumption.

ANTI PHTHORA. (From art, against, and φθορα, corruption.) A species of wolfsbane which resists corruption. See Aconitum anthora.

ANTIPHY'SIC. (Antiphysicus; from art, against,

and φυσαω, to blow.) A carminative or remedy

ANTIPLEURI'TIC. (Antipleuriticus ; from avrt, against, and πλευριτις, pleurisy.) Against a pleurisy.

ANTIPODA GRIC. (Antipodagricus; from αντι, against, and ποδαγρα, the gout.) That which relieves or removes the gout.

ANTIPRAXIA. (From avr. against, and πρασσω, to work.) A contrariety of functions and temperaments

in divers parts. Contrariety of symptoms.

ANTIPYRE'TIC. (Antipyreticus; from αντι, against, and πυρετος, fever.) Against a fever.

ANTIQUARTANA'RIA. (From αντι, against, and quartana, a quartan fever.) Remedies against quartan agues.

ANTIQUA'RTICUM. The same as Antiquartanaria. ANTIRRHI'NUM. (Aντιβρίνου; from αντι against, and ρι, the nose: so called because it represents the nose of a calf.) The name of a genus of plants in the

ANTIRRHINUM ELATINE. The systematic name of the plant we call flue![es], or female speedwell. Elatine of the shops. The leaves of this plant have a roughish bitter taste, but no smell. It was formerly much used against scurvy and old ulcerations, but now

wholly forgotten.

wholly lorgotten.

Antirrhinum Linaria. The systematic name for the linaria of the pharmacopaias. Osyris; Urina ria; Antirrhinum—foliis lanceolatis linearibus confertis, caule erccto, spicis terminalibus-sessilibus, floribus imbricatis of Linnaus. Common toad-flax. A perennial indigenous plant, common in barren pastures, hedges, and the sides of roads, flowering from July to September. The leaves have a bitterish and somewhat saline taste, and when rubbed between the somewhat saline taste, and when rubbed between the They are said to be diuretic and cathartic, and in both characters to act powerfully, especially in the first; hence the name urinaria. They have been recommended in dropsies and other disorders requiring powerful evacuations. The linaria has also been used as a resolvent in jaundice, and such diseases as were supposed to arise from visceral obstructions. But the plant has been chiefly valued for its effects when externally applied, especially in hamorrhoidal affections, ternally applied, especially in hæmorrhoidal affections, for which both the leaves and flowers have been employed in various forms of ointment, fomentation, and poultice. Dr. Wolph first invented an ointment of this plant for the piles. The Landgrave of Hesse, to whom he was physician, constantly interrogated him, to discover its composition; but Wolph obstinately refused, till the prince promised to give him a fat ox annually for the discovery; hence, to the following verse, which was made to distinguish the linaria from the escula, viz.

"Escula lactescit, sine lacte linaria crescit." The

"Escula lactescit, sine lacte linaria crescit." The hereditary Marshal of Hesse added,

"Escula nil nobis, sed dat linaria taurum."

ANTISCO'LIC. (Antiscolicus; from αντι, against, and σκωληξε a worm.) Remedies against worms.

See Anthelmintic.

ANTISCORBU'TIC. (Antiscorbuticus, from avr., against, and scorbutus, the scurvy.) Medicines which

ANTISEPTIC. (Antisepticus, from αντι, against, and σηπω, to putrefy.) Whatever possesses a power of preventing animal substances from passing into a state of putrefaction, and of obviating putrefaction when already begun. This class of medicines comprehends four orders:

1. Tonic antiseptics; as cinchona, cusparia, cha-mæmelum, &c. which are suited for every condition

of body, and are, in general, preferable to other anti-septics, for those with relaxed habits.

2. Refrigerating antiseptics; as acids, which are principally adapted for the young, vigorous, and plethoric.

Stimulating antiseptics; as wine and alkohol, best adapted for the old and debilitated.

4. Antispasmodic antiseptics; as camphor and asafeetida, which are to be selected for irritable and hysterical habits.

["The presence of air, though not necessary to putrefaction, materially accelerates it, and those gases which contain no oxygen, are very efficient in checking or altogether preventing the process. Carbonic acid also remarkably retards putrefaction; and if boiled meat be carefully confined in vessels containing that gas, it remains for a very long time unchanged, as seen in Mr. Appert's method of preserving meat."

"There are several substances which, by forming

"There are several substances which, by forming new combinations with animal matter, retard or pre-vent putrefaction; such as chlorine, and many of the saline and metallic compounds; sugar, alkohol, volatile oils, acetic acids, and many other vegetable substances, also stand in the list of antiputrefactives, though their mode of operating is by no means understood."Webster's Man. of Chem.

The alkaline earths and salts are antiseptics, and act by absorbing the acids formed in the process of putre-faction. Carbon or charcoal of wood is one of the most powerful antiseptics. It will restore tainted meat, and purify offensive water. Casks are now charred to contain water on long sea voyages, and it will continue pure and sweet in these for a long time.

Linnean system. Class, Didynamia; Order, Angio- Charcoal in powder is successfully used in the cure of looseness of the bowels, and it has been known to cure intermittent fevers. A.]

cure intermittent fevers. A.]

Anti'spasis. (From aντι, against, and σπαω, to draw.) A revulsion. The turning the course of the humours, while they are actually in motion.—Galen.

ANTISPASMODIC. (Antispasmodicus; from aντι, against, and σπασμος, a spasm.) Possessing the power of allaying, or removing, inordinate motions in the system, particularly those involuntary contractions which take place in muscles, naturally subject to the command of the will. Spasm may arise from various causes. One of the most frequent is a strong irritation, continually applied; such as dentition, or worms. In these cases, narcotics prove useful, by diminishing these cases, narcotics prove useful, by diminishing irritability and sensibility. Sometimes spasm arises from mere debility; and the obvious means of removing this is by the use of tonics. Both narcotics and tonics, therefore, are occasionally useful as antispasmodics, such as opium, camphor, and ather, in the one class, and zinc, mercury, and Peruvian bark, in the other. But there are, farther, several other substances, which cannot be with propriety referred to either of these classes; and to these, the title of an-tispasmodics is more exclusively appropriated. The principal antispasmodics, properly so called, are moschus, castoreum, oleum animale empyreumaticum, chus, castoreum, oleum animale empyreumaucum, petroleum, ammonia, asafœtida, sagapenum, galbanum, valeriana, crocus, melaleuca leucadendron. The narcoties, used as antispasmodics, are æther, opium, camphor. The tonics, used as antispasmodics, are cuprum, zincum, hydrargyrum, cinchona.

ANTITHENAR. (From avri, against, and 3evap, the palm of the hand or foot.) A muscle of the foot.

See Adductor politicis pedis.

ANTITRA GICUS. Antitragus. One of the proper muscles of the ear, the use of which is to turn up the tip of the antitragus a little outwards, and to depress the extremity of the antihelix towards it.

ANTITRAGUS. (Antitragus, i. m. from αντι, and τραγος, the tragus.) An eminence of the outer ear, opposite to the tragus.

ANTIVENET PLAT. (From any paging)

ANTIVENE'REAL. (From art, against, and venereus, venereal.) Against the venereal disease.

ANTO NII SANCTI IGNIS. (So called because

St. Anthony was supposed to cure it miraculously. In the Roman missal, St. Anthony is implored as being the preserver from all sorts of fire.) St. Anthony's

fire. See Erysipelas.

Antophy'llon. (From αντι, against, and φυλλον a leaf; so called because its leaves are opposite.) The

male caryophyllus.

A'NTRUM. (Antrum, i. n. a den or cave.) 1 A cavity which has a small opening into it.

Antrum genz. See Antrum of Highmore.
Antrum Highmorianum. See Antrum of Highmore.

Antrum of Highmore. (From the name of an anatomist, who gave the first accurate description of it.) Antrum Highmorianum; Antrum genæ; Sinus maxillaris pituitarius; Antrum maxillæ superioris. Maxillary sinus. A large cavity in the middle of each superior maxillary bone, between the eye and the roof of the mouth, lined by the mucous membrane of the

nose. See Maxillare superius, os.

One or both antra are liable to several morbid affecone or both antia are hand to several morbid anections. Sometimes their membranous lining inflames and secretes pus. At other times, in consequence of inflammation, or other causes, various excrescences and fungi are produced in them. Their bony parietes are occasionally affected with exostosis, or caries. Extraneous bodies may be lodged on them, and it is Extraneous bodies may be lodged on them, and it is even asserted that insects may be generated in them, and cause, for many years, afflicting pains. Abscesses in the antrum are by far the most common. Violent blows on the cheek, inflammatory affections of the adjacent parts, and especially of the pituitary membrane lining the nostrils, exposure to cold and damp, and, above all things, bad teeth, may induce inflammation and suppuration in the antrum. The first symptom is a pain, at first imagined to be a toothache, particularly if there should be a carious tooth at this part of the jaw. This pain, however, extends more into the nose than that usually does which arises from a decayed tooth; it also affects, more or less, the from a decayed tooth; it also affects, more or less, the

ANY ANU

But even such symptoms are insufficient to characterize the disease, the nature of which is not unequivocally evinced, till a much later period. The complaint is, in general, of much longer duration than one en-tirely dependent on a caries of the tooth, and its violence increases more and more, until at last a hard tumour becomes perceptible below the cheek-bone. The swelling by degrees extends over the whole cheek; but it afterward rises to a point, and forms a very cir-cumscribed hardness, which may be felt above the back grinders. This symptom is accompanied by red-ness, and sometimes by inflammation and suppuration ness, and sometimes by inflammation and suppuration of the external parts. It is not uncommon also, for the outward abscess to communicate with that within the antrum. The circumscribed elevation of the tumour, however, does not occur in all cases. There are instances in which the matter makes its way towards the palate, causing the bones of the part to wards the palate, causing them, carious, unless wards the palate, causing the bones of the part to swell, and at length rendering them carious, unless timely assistance be given. There are other cases, in which the matter escapes between the fangs and sockets of the teeth. Lastly, there are other examples, in which matter, formed in the antrum, makes its exit at the nostril of the same side when the patient is lying with his head on the opposite one, in a low position. If this mode of evacuation should be frequently represented it respectively. quently repeated, it prevents the tumour both from pointing externally, and bursting, as it would do if the purulent matter could find no other vent. This evacuation of the pus from the nostril is not very com-mon. The method of cure consists in extracting one of the dentes molares from the affected side; and then perforating through the socket into the bony cavity. A mild injection may afterward be employed to cleanse the sinus occasionally.

ANTRUM MAXILLE. See Antrum of Highmore.
ANTRUM MAXILLARE. See Antrum of Highmore.
ANTRUM PYLORI. A concavity of the stomach approaching the pylorus.
ANTY'LION. (From Antyllus, its inventor.) An astringent application, recommended by Paulus Ægitete.

A'NUS. (Anus, i. masc. quasi onus; as carrying the burden of the bowels.)

1. The fundament; the lower extremity of the great intestine, named the rectum, is so called; and its office is to form an outlet for the faces. The anus is furnished with muscles which are peculiar to it, viz. the sphincter, which forms a broad circular band of fibres, and keeps it habitually closed, and the levatores ani, which serve to dilate and draw it up to its natural situation, after the expulsion of the faces. It is also surrounded, as well as the whole of the neighbouring intestine, with muscular fibres, and a very loose sort of cellular substance. The anus is subject to various diseases, especially piles, ulceration, abscesses, excrescences, prolapsus; and imperforation in new-born

2. The term anus is also applied to a small opening of the third ventricle of the brain, which leads into

[Fissure of the anus. In the New-York Medical and Physical Journal, a very interesting case of this malady is related by the patient himself. He was successfully operated upon by Professor Alexander H. Stevens, M.D., of the College of Physicians and Surgeons of New-York. The fissure was on one side, and the incision was made directly upon it and through the sphincter. The relief from the most agonizing pain was immediate and permanent. We find a note on the subject of this disease in the Philadelphia edition of Cooper's First Lines of the Practice of Surgery, which [Fissure of the anus. In the New-York Medical Cooper's First Lines of the Practice of Surgery, which

quote.

"Baron Boyer has recently called the attention of Surgeons to what he has denominated fissure of the anus. Though this disease was noticed by Ætius, it of Sabatier, who imperfectly described it. Baron Boyer has met with many cases of it, and it is now understood by all the surgeons of Paris, where it is said to be not uncommon. It has been generally confounded with ulcerated piles, blind fistula, or other diseases of the rectum. The symptoms it occasions have been considered inexplicable by the surgeon, though exceedingly distressing to the patient. Fissure of the anus is an oblong ulceration of the extremity of the rectum,

eye, the orbit, and the situation of the frontal sinuses. | just where the mucous membrane joins the skin. The ulceration is generally a little above the anus, so that it is not easily discovered, unless the sides of the rectum are drawn outwards, and the gut partially everted. Moreover, the fissure is superficial, and presents nothing striking to the eye, and is, therefore, more likely to pass unobserved. The mucous membrane is more red than natural at the edges of the ulcerated portion, which is entirely absorbed; but there is nothing unnatural to be felt with the fingers, except a very remarkable constriction, which accompanies, or rather precedes, this disease. It would appear, that this constriction is, indeed, the cause of the malady,

which results from the efforts to expel hardened faces through the contracted passage. The introduction of the finger causes exquisite pain."

"The first symptom of the disease, is pain felt in evacuating the rectum, greatly aggravated by costiveness, and rendered most excruciating by the hardness of the faces. Hence the sufferer is led to use injections and mild laxative medicines. In the commencement, the pain subsides at the expiration of about half an the pain subsides at the expiration of about half an hour; in its progress, the paroxysms lengthen to several hours' duration, and the patients writhe in agony, not knowing what position to put themselves in. They suffer least in bed, and remain there several days without leaving it. The pain has accessions without any known cause, and often ceases in the same manner."

"The pain appears to be owing to a retention of excrementitious matter near the extremity of the rectum, the expulsion of which is prevented by the constriction of the sphincter ani. The faces are, sometimes, streaked with a line of blood, especially if they be hard; but this is not always the case: sometimes there is a discharge per anum of a white liquid matter, in small quantities; this is what would be expected from an inflamed or ulcerated mucous membrane, but occasionally the ulceration extends to the muscular

coat of the intestine."

"These symptoms vary in different patients. In delicate and nervous women, a variety of remote symptoms occur, and often conceal the origin of the primary complaint, which is mistaken for cancer of the rectum, ulceration of the womb, &c."

"In this disease there are two distinct occurrences: viz. constriction of the anus, and ulceration or fissure. The former is the cause of the latter. Ulceration without constriction, as we every day see in fistula in ano, does not occasion so severe pain as is felt in this com-plaint. With respect to the treatment of this com-plaint, if it be slight, it will sometimes yield to laxative medicines and the application of leeches to the perinæum. But these means are not generally sufficient. It is then necessary to divide with the knife the whole of the sphincter ani, and that if possible, immediately at the seat of the fissure. The incision should be at least one-third of an inch deep, especially near the verge of the anus, and an inch long. After the operation, or at any rate, before cicatrization begins, a tent is to be introduced and kept in the rectum, without which the operation would be unsuccessful. When the fissure is in the anterior part of the anus, as the sphincter could not be safely divided in that direction, it is best to cut towards the coccyx. After the cure the rectum is found more ample than before." A.]

ANUS, ARTIFICIAL. An accidental opening in the parietes of the abdomen, to which opening some part of the intestinal canal leads, and through which the fæces are either wholly or in part discharged. When strangulated hernia occurs, in which the intestine is simply pinched, and this event is unknown; when it has not been relieved by the usual means; or when the necessary operation has not been practised in time; the protruded part becomes gangrenous, and the faces escape. But if the patient should be at last operated upon, his faces are discharged through the wound, and the intestines are more easily emptied. In both cases, the excrement continues to be discharged from the artificial opening. In this way an artificial anus is formed, through which the excrement is evacuated during life.

ANY DRION. (From α, priv. and υδωρ, water; so called, because they who eat of it become thirsty.) A species of night-shade, according to Blancard.

ANYPEU THYNUS. (From α, neg. and υπευθυνος, blanneable.) Hippocrates, in his Precepts, uses this blaneable.

word to signify an accidental event, which cannot be

charged on the physician, and for which he is not ac- of diseases in Good's classification constituted by

AO'RTA. (Aorta, α. f.; from αηρ, air, and τηρεω, to keep: so called because the ancients supposed that only air was contained in it.) The great artery of the body, which arises from the left ventricle of the heart, forms a curvature in the chest, and descends

APALACHI'NE GALLIS. (From απαλακω, to repel; because it is supposed to repel infection.) See Hex

APARI'NE. (From ρινη, a file; because its bark is rough, and rasps like a file.) Goose-grass. See Ga-

APARTHRO'SIS. (From απο and τρθρον, a joint.)

Articulation.

APATITE. A phosphate of lime mineral, of a white wine, yellow, green and red colour, found in primitive rocks in Cornwall and Devonshire.

[There are several varieties of the phosphate of lime. The first variety (apatite) yielded klaproth, lime 55.00, phosphoric acid, 45.00.

Its solubility in acids, and inferior hardness, may serve to distinguish it from the chrysoberil, tourmaline, serve to distinguish it from the chrysoberil, tourmaline, the chrysoberil is the control of the chrysoberil of the chrysoberil in the chrybor in the chrysoberil in the chrybor in the chrysoberil in the topaz, chrysolite, beryl, emerald, and some varieties of quartz; all of which it more or less resembles, especially the *emerald*, *beryl*, and *chrysolite*. From carbonate of lime it differs by its greater hardness, and want of effervescence in acids; and it does not, like the fluate of lime, when its powder is thrown into warm nuate of time, when its powder is thrown into warm sulphuric acid, yield a gas capable of corroding glass, unless from the accidental presence of a small quantity of that salt. The variety of phosphate of lime, called apatite, usually in crystals, sometimes presents a low six-sided prism, the primitive form.

The same gangure, which contains the crystals, often embraces grains or small granular masses, having a crystalling structure, but, nearly or quite destitute of a

crystalline structure, but nearly or quite destitute of a regular form. The apatite occurs in veins, or is disseminated in granite, gneiss, or other primitive rocks. It is associated with quartz, feldspar, fluate of lime,

It is associated with quartz, feldspar, fluate of lime, garnets, the oxydes of iron, tin, &c.

Apatite has been found in Maryland, Pennsylvania, and New-York; also in the States of Connecticut and Maine.—Cl. Min. A.]

APE'LLA. (From a, priv. and pellis, skin.) Shortness of the prepuce. Galen gives this name to all whose prepuce, either through disease, section, or otherwise, will not cover the glans.

APE'PSIA. (Apepsia, & f. Aπεψιa; from a, priv. and πεπτω, to digest.) Indigestion. See Dyspepsia.

APE'RIENS PALPEBRARUM RECTUS. See Levator palpebra superioris.

APERIENS PALPEBRARUM RECTUS. See Levator palpebræ superioris.

APERIEN'T. (Aperiens; from aperio, to open.)

1. That which gently opens the bowels.

2. Applied also to muscles, the office of which is to open parts; as the levator palpebræ superioris, which is called, in some anatomical works, aperiens palpebræ. APERI'STATUS. See Aperistatus.

APERI'STATUS. (From a, neg. and περιξημι, to surround.) Aperistaton. An epithet used by Galen, of an ulcer which is not dangerous, nor surrounded by

an ulcer which is not dangerous, nor surrounded by inflammation.

APE'RTOR OCULI. See Levator palpebræ superioris. APETALUS. (From α, priv. and petalum, a petal.)

Without a petal or corol.

APETALE PLANTE. Plants without petals. name of a division of plants in most systems of botany. APEUTHY SMENUS. (From απο and ευθυς, straight.)

A name formerly given to the intestinum rectum, or straight gut.

A PEX. 1. The extremity of a part; as the apex of

the tongue, apex of the nose, &c.
2. The extremity of a leaf, apex folii.

3. The anthera of a flower of Tournefort, Rivinus, and Ray.

APHANI'SMUS. (From αφανίζω, to remove from the sight.) The removal, or gradual decay, of a disorder. APHANITE. The name given by Haüy to a rock apparently homogeneous, but really compound, in

which amphibole is the predominant principle.

APHÆ RESIS. (From αφαιρεω, to remove.) This term was formerly much used in the schools of surgery, to signify that part of the art which consists in taking off any diseased or preternatural part of the body.

APHELXIA. (Aphelxia, α. f.; from αφελεω, abstraho to separate or abstract.) Revery. A genus

absence or abstraction of mind. See Nosology

APHEPSE'MA. (From ατο, and εψω, to boil.) A

A PHESIS. (From αφιημε, to remit.) The remission or termination of a disorder.

Aprilste'sis. (From αφιζημι, to draw from.) An

Aphlogistic lamp. One which burns without flame.
A'phodos. (From απο, and οδος, departure.) Excrement. The dejection of the body.
APHO'NIA. (Αφωνια; from α, priv. and φωνη, the voice.) A suppression of the voice, without either syncope or coma. A genus of disease in the class Locales, and order Dyscinesia, of Cullen.

1. When it takes place from a tumour of the fauces, or about the glottis, it is termed aphonia gutturalis.
2. When from a disease of the traches, and order Dyscinesia.

2. When from a disease of the trachea, aphonia trachealis.

3. And when from a paralysis, or want of nervous

And when from a paralysis, or want of nervous energy, ophonia atonica.

APHORIA. (Aphoria, α. f.; from α, negative, and φτοω, fero, paris.) Barrenness. The name of a genus of diseases in Good's new classification. See Noso-

logy.
A'PHORISM. (Aphorismus; from αφοριζω, to distinguish.) A maxim, or principle, comprehended in a

short sentence.

APHRITE. Earth foam. A carbonate of lime usually found in calcareous veins at Gera in Misnia and

Thuringia

[APHRIZITE. A variety of schorl, sometimes in nine-sided prisms, terminated at one extremity by three faces, and at the other by six, of which three are larger than the others, and stand on those three lateral

larger than the others, and stand on those three lateral edges of the prism, each of which contains an angle of 120°.—Cl. Min. A.]

APHRODI'SIA. (From Αφροδιτη, Venus.) An immoderate desire of venery.

APHRODISIAC. (Aphrodisiacus; from αφροδισια, venery.) That which excites a desire for venery.

APHRODISIA'STICON. (From αφρος, froth.) A troch so called by Galen, because it was given in dysenteries, where the stools were frothy. where the stools were frothy.

Aphropi'sius morbus. (From Αφροδίτη, Venus.)

The venereal disease.

APHTHA. (Aphtha, α. f. Αφθαι; from απτω, to inflame.) The thrush. Frog, or sore mouth. Aphtha lactucimen of Sauvages. Ulcera serpentia oris, or spreading ulcers in the mouth, of Celsus. Pustula oris. Alcola. Vesicula gingivarum, Acacos. Aphtha infantum. A disease ranked by Cullen in the class infantum. A disease ranked by Cullen in the class Pyrexiae, order Exanthemata. Children are very sub-ject to it. It appears in small, white ulcers upon the tongue, gums, and around the mouth and palate, resembling small particles of curdled milk. When the disease is mild, it is confined to these parts; but when it is violent and of long standing, it is apt to extend through the whole course of the alimentary canal, from the mouth down to the anus; and so to excite severe purgings, flatulencies, and other disagreeable symp-toms. The disease when recent and confined to the mouth, may in general be easily removed; but when of long standing, and extending down to the stomach and intestines, it very frequently proves fatal.

The thrush sometimes occurs as a chronic disease, both in warm climates and in those northern countries where the cold is combined with a considerable degree of moisture, or where the soil is of a very marshy nature. It may, in some cases, be considered as an idiopathic affection; but it is more usually symptomatic. It shows itself, at first, by an uneasy sensation, or burning heat in the stomach, which comes on by along degrees and increases gradually in violence. by slow degrees, and increases gradually in violence. After some time, small pimples, of about the size of a pin's head, show themselves on the tip and edges of the pin's head, show themselves on the tip and edges of the tongue; and these, at length, spread over the whole inside of the mouth, and occasion such a tenderness and rawness, that the patient cannot take any food of a solid nature; neither can be receive any vinous or spirituous liquor into his mouth, without great pungency and pain being excited; little febrile heat attends but there is a dry skin, pale countenance, small pulse, and cold extremities. These symptoms will probably continue for some weeks, the general health being sometimes better and sometimes worse, and then the natient will be attacked with acrid eructations, or patient will be attacked with acrid eructations, or

severe purgings, which greatly exhaust his strength, and produce considerable emaciation of the whole body. After a little time, these symptoms cease, and he again enjoys better health; but, sooner or later, the acrid matter shows itself once more in the mouth, with greater virulence than before, and makes frequent translations to the stomach and intestines, and so from these to the mouth again, until, at last, the patient is reduced to a perfect skeleton. Elderly people, and persons with a shattered constitution, are most liable to its attacks. The treatment of the thrush in children is generally to be begun with the exhibition of a gentle to its attacks. The treatment of the thrush in children is generally to be begun with the exhibition of a gentle emetic: then clear the bowels, if confined, by rhubarb and magnesia, castor oil, or other mild aperients; or sometimes in gross, torpid habits by a dose of calomel. In general the prevalence of acid in the primæ viæ appears to lead to the complaint; whence antacid remedies prove beneficial in its progress; when the patient is costive, giving the preference to magnesia; when relaxed, to chalk, which may be sometimes joined with aromatics, the mild vegetable astringents, or even a little opium, if the diarrhea be urgent. Where the child is very weak, and the aphthæ of a dark colour, the decoction of bark or other tonics must be had recourse to. The separation of the sloughs and healing of the ulcers may be promoted by washing the mouth occasionally with the honey of borax, diluted with two or three parts of rose water; or where they are of a dark colour, by the decoction of bark, aciduare of a dark colour, by the decoction of bark, acidulated with sulphuric acid. The diet should be light and nutritious, especially where there is much debility. As the complaint is subsiding, particular attention is required to obviate the bowels becoming confined. In the chronic aphthe affecting grown persons, pretty much the same plan of treatment is to be pursued: besides which, the compound powder of ipecacuanha and other diaphoretics, assisted by the occasional use of the warm bath, wearing flannel next the skin, particularly in a damp cold climate, &c. appear to be

ticularly in a damp cold climate, &c. appear to be beneficial.

APHYLLUS. (From a, priv. and \$\phiu\lambda ov\$, a leaf.) Leafless. A term applied to parts of plants which are so conditioned when similar parts of other plants have leaves. Thus a stem is said to be aphyllous when it is altogether void of leaves. Linnaus uses the term nudus. Examples are found in Cuscuta Europza, dodder; Asphodelus fistulosus, &c.

APHYLLE PLANTE. Aphyllous plants, or plants without leaves. Some plants being entirely devoid of leaves, are naturally arranged under one head, to which this name is given.

APIS. The name of a genus of insects in the Linnaus system. The bee.

APIS MELLIFICA. The systematic name of the honey-bee. It was formerly dried and powdered, and thus given internally as a diuretic. It is to the industry of this little animal that we are indebted for honey and wax. See Mel and Cera. The venom of the bee, according to Fontana, bears a close resemblance to that of the viper. It is contained in a small vesicle, and has a hot acrid taste like that of the scorpion.

APIUM. (Apium, i. n.; from \$\eta \text{tom} \te

tem. Class, Pentandria; Order, Digynia.

2. The pharmacopæial name of the herb smallage.

See Apium graveolens.

See Apium graveolens. The systematic name for the apium of the pharmacopæias. Apium—foliolis caultuis, cunciformibus, umbellis, sessilibus, of Linnæus. Smallage The root, seeds, and fresh plant, are aperient and carminative.

APIUM HORTANSE. See Apium petroselinum.
APIUM PETROSELINUM. The systematic name for the petroselinum of the pharmacopæias. Petroselinum the petrosclinum of the pharmacopæias. Petrosclinum vulgare. Apium hortense. Common parsley. Apium —foliis caulinis linearibus, involucellis minutis, of Linneus. Both the roots and seeds of this plant were formerly directed by the London College for medicinal use, and the root is still retained in the Edinburgh Pharmacopæia: the former have a sweetish taste, accompanied with a slight warmth or flavour, somewhat resembling that of carrot; the latter are in taste warmer and more aromatic than any other part of the plant, and manifest considerable bitterness. The roots are said to be aperient and diuretic, and have been employed in nephritic pains and obstructions of urine. From a mo, and λνω, to release.) The removal of a bandage.—Erotianus.

APOMA'GMA. (From aπο, and ματτω, to cleanse from.) Any thing used to cleanse and wipe away filth from sores, as sponge, &c.—Hippocrates.

APOMATHE'MA. (From aπο, neg. and μανθανω, to cleanse from.) Hippocrates expresses, by this term, a forget fulness of all that has been learnt.

APO'NELL. (From aπο, and λνω, to release.) The removal of a bandage.—Erotianus.

APOMA'GMA. (From aπο, and ματτω, to cleanse from.) Any thing used to cleanse and wipe away filth from sores, as sponge, &c.—Hippocrates.

APOMATHE'MA. (From aπο, neg. and μανθανω, to cleanse from.) Hippocrates expresses, by this term, a forget fulness of all that has been learnt.

APO'NELL. (From aπο, and λνω, to release.) The removal of a bandage.—Erotianus.

The seeds possess aromatic and carminative powers, but are seldom prescribed.

[APLOME of Hauy, Brochant, Brogniart. This very rare mineral has been observed only in dodecaedrons with rhombic faces, marked by strise, parallel to the shorter diagonals. This dodecaedron is supposed to the derived form a subset by one of the most simple laws. be derived from a cube by one of the most simple laws of decrement; viz. that of a single range of particles parallel to all the edges of a cube. Hence its name

parallel to all the edges of a cube. Hence its name from the Greek Aπλοος, simple.

The Aplome gives fire with steel, and feebly scratches quartz. Its specific gravity is 3.44. Its fracture in some parts is uneven and nearly dull; while in others it is shining and slightly conchoidal. Its colour is usually a deep brown, sometimes yellowish green. It is usually opaque, but the small crystals often transmit an orange-coloured light.

It is fusible by the blow-pipe into a blackish glass. It is composed of silex, 40.0, alumine 20.0, hime 14.5, oxyde of iron 14.5, manganese 2.0, ferruginous silex

oxyde of iron 14.5, manganese 2.0, ferruginous silex 2.0; = 93.00.

It differs from the garnet in the direction of its striæ and its inferior specific gravity. It has been found in Siberia and Saxony.—Cl. Min. A.]

APLONÆ. A deep orange-brown mineral, mostly considered to be a variety of the garnet.

APNEU'STIA. (From α, and πντω, to breathe.)

A defect or difficulty of respiration, such as happens in a cold, &c. Forsius.

cold, &c. Foesius.

Apnæa'. The same.—Galen.

Apocapni'smus. (From απο, and καπνος, smoke.) A fumigation.

Apocalma Rsis. (From απο, and καθαίρω, to purge.) An evacuation of humours. A discharge downwards, and sometimes applied, with little discrimination, to

Apocaulize'sis. (From αποκαυλξιω, to break transversely.) A transverse fracture.—Hippocrates.

APOCENO'SIS. (From απο, and κενοω, to evacuate.) 1. A flow or evacuation of any humour.

2. The name of an order in the class Locales of Cullen, which embraces diseases characterized by a superabundant flux of blood, or other fluid, without pyrexia.

Apo'cope. (From απο, and κοπτω, to cut from.) Abscission, or the removal of a part by cutting it off. Apo'crisis. (From απο, and κρινω, to secrete from.) A secretion of superabundant humours.— Hippocrates.

APOCRU'STICON. See Apocrustinum.

APOCRU'STINUM: (From αποκρουω, to repel.) Apocrusticon. An astringent or repellent medicine.-

Apocyg'sis. (From απο, and κυω, to bring forth.) Parturition, or the bringing forth of a child.—Galen.

Parturition, or the bringing forth of a child.—Galen.

Apodacry'tica. (From aπο, and δακρυ, a tear)
Medicines which, by exciting tears, remove superfluous humours from the eyes, as onions &c.—Pliny.

Apogeu'sis. See Agcustia.

Apogeu'sis. (From απογινομαι, to be absent.)
The remission or absence of a disease.—Hippocrates.

Apoglauco'sis. (From απο, and γλατκος, skycoloured; so called because of its bluish appearance.)
See Glaucoma.

See Glaucoma.

Apo'gonum. (From aπο, and γινομαι, to beget.) A living feetus in the womb.—Hippocrates.

Apolep'sis. (From aπο, and λαμδανω, to take from.) An interception, suppression, or retention of urine, or any other natural evacuation.—Hippocrates

Apolino'sis. (From απο, and λινον, flax.) The method of curing a fistula, according to Ægineta, by the application of raw flax.

Apo'lysis. (From απο, and λνω, to release.) The solution or termination of a disease. The removal of

was formed by the expansion of a nerve.) A tendinous expansion. See Muscle.

APO'NIA. (From α, priv. and πονος, pain.) Free-

(From a, priv. and πονος, pain.) Free-

dom from pain.

Aponitrao'sis. (From απο, and νιτρον, nitre.) The sprinkling an ulcer over with nitre.

Apopalle'sis. (From αποπαλλω, to throw off APOPALLE SIS. (From αποπαλλω, to throw off hastily.) An abortion, or premature expulsion of a fœtus.—Hippocrates.

APOPALSIS. See Apopallesis.

APOPALSIS. (From απο, and πηδαω, to jump from.) A luxation.

APOPHLEGMA'SIA. (From απο, and φλεγμα, phlegm.) A discharge of phlegm or maters.

phlegm.) A discharge of phlegm or mucus.

APOPHLEGMA'TIC. (Apophlegmaticus; from aπο, and φλεγμα, phlegm.) Apophlegmatizantia; Apophlegmatizanta. 1. Medicines which excite the secretion of mucus from the mouth and nose.

Masticatories.

Errhines.

APOPHLEGMATIZANTIA. See Apophlegmatic. APOPHLEGMATIZONTA. See Apophlegmatic. APOPHRA'XIS. (From απο, and φρασσω, to interrupt.)

A suppression of the menstrual discharge

Αρορητικ' και. (From απο, and φθειρω, to corrupt.) A medicine to procure abortion.

Αρορητικ' και. (From αποφθεγγομαι, to speak eloquently.) A short maxim, or axiom; a rule.

Αρογητικαι. (From αποφθειρω, to be abortive.)

An abortion. APOPHY'ADES. The ramifications of the veins and

arteries .- Hippocrates.

Apo'Phyas. (From αποφυω, to proceed from.) Any thing which grows or adheres to another, as a wart to the finger.

APOPHYLLITE. Ichthyophthalmite. Fish-eye stone. A mineral composed of silex, potassa, and water, found in the iron mine of Utoe, in Sweden. [This mineral occurs in laminated masses, or in

regular crystals, having a strong, and peculiar external lustre, which is intermediate between vitreous and lustre, which is intermediate between vitreous and pearly. When exposed to the flame of a lamp it exfoliates. Before the blow-pipe it melts with some difficulty into a white enamel. Its fragments, placed in cold nitric acid, are gradually converted into a whitish, flaky substance. Its powder forms a jelly in nitric or muriatic acid. It contains silex 51, lime 28, potash 4, water 17. It is lighter and harder than sulphate of barytes, but much less hard than adularia, both of which it may resemble.—Cl. Min. A.]

APO'PHYSIS. (From αποφυω, to proceed from.)

1. In anatomy. Appendix; Probole; Ecphysis; Processus; Productio; Projectura; Protuberantia. A process, projection, or protuberance of a bone beyond a plain surface; as the nasal apophysis of the frontal bone, &c.

In botany, this word is applied to a fleshy tuber-cle under the basis of the capsule or dry fruit adhering to the frondose mosses.

APOPLE CTA VENA. A name formerly applied to the internal jugular vein; so called because in apoplexies

it appears full and turgid.—Bartholin.
APOPLE CTIC. (From αποπληξια (From αποπληξια, an apoplexy.)

APOPLE XY. (Apoplexy, α. f.; from απο, and πλησσω, to strike or knock down; because persons, when seized with this disease, fall down suddenly.) A sudden abolition, in some degree, of the powers of sense and motion, the patient lying in a sleep-like state; the action of the heart remaining, as well as the respiration, often with a stertorous noise. Cullen arranges it in the class Neuroses, and order Comata:

When it takes place from a congestion of blood,

It is termed Apoplexia sanguinea.

2. When there is an abundance of serum, as in persons of a cold phlegmatic temperament, Apoplexia

3. If it arise from water in the ventricles of the brain, it is called Apoplexia hydrocephalica. See Hydrocephalus.
4. If from a wound, Apoplexia traumatica.
5. If from poisons, Apoplexia venenata.
6. If from the action of suffocating exhalations,

Apoplexia sufficata.
7. If from passions of the mind, Apoplexia mentalis.
8. And when it is joined with catalepsy, Apoplexia cataloptica.

Apoplexy makes its attack chiefly at an advanced period of life; and most usually on those who are of a corpulent habit, with a short neck, and large head; and who lead an inactive life, make use of a full diet, or drink to excess. The immediate cause of apoplexy, is a compression of the brain, produced either by an accumulation of blood in the vessels of the head, and accumulation of blood in the vessels of the head, and distending them to such a degree, as to compress the medullary portion of the brain; or by an effusion of blood from the red vessels, or of serum from the exhalants; which fluids are accumulated in such a quantity as to occasion compression. These states of tity as to occasion compression. These states, of overdistension and of effusion, may be brought on by whatever increases the afflux, and impetus of the blood in the arteries of the head; such as violent fits of passion, great exertions of muscular strength, severe exercise, excess in venery, stooping down for any length of time, wearing any thing too tight about the neck, overloading the stomach, long exposure to excessive cold, or a vertical sun, the sudden suppression of any long-accustomed evacuation, the application of the fumes of certain narcotic and metallic substances, such as opium, alkohol, charcoal, mercury, &c. and by blows, wounds, and other external injuries: in short, apoplexy may be produced by whatever deter-mines too great a flow of blood to the brain, or pre-

mines too great a flow of blood to the brain, or prevents its free return from that organ.

The young, and those of a full plethoric habit, are most liable to attacks of the sanguineous apoplexy; and those of a phlegmatic constitution, or who are much advanced in life, to the serous. Apoplexy is sometimes preceded by headache, giddiness, dimness of sight, loss of memory, faltering of the tongue in speaking, numbness in the extreinities, drowsiness, stupor, and nightmare, all denoting an affection of the brain; but it more usually happens that, without much previous indisposition, the person falls down suddenly, the countenance becomes florid, the face appears swelled and puffed up, the vessels of the head, particularly of the neck and temples, seem turgid and distended with blood; the eyes are prominent and fixed, the breathing is difficult and performed with a snorting noise, and the pulse is strong and full. and need, the breathing is difficult and performed with a snorting noise, and the pulse is strong and full. Although the whole body is affected with the loss of sense and motion, it nevertheless takes place often more upon one side than the other, which is called hemiplegia, and in this case, the side least affected with palsy is somewhat convulsed.

In forming an opinion as to the event, we must be guided by the violence of the symptoms. If the fit is of long duration, the respiration laborious and steriorous, and the person much advanced in years, the disrous, and the person much advanced in years, the dis-ease, in all probability, will terminate fatally. In some cases, it goes off entirely; but it more frequently leaves a state of mental imbecility behind it, or termi-nates in a hemiplegia, or in death. Even when an attack is recovered from, it most frequently returns again, after a short period of time, and in the end proves fatal. In dissections of apoplexy, blood is often found effused on the surface and in the cavities of the brain; and in other instances, a turgidity and distenbrain; and in other instances, a turgidity and disten-tion of the blood-vessels are to be observed. In some cases, tumours have been found attached to different parts of the substance of the brain, and in others, no traces of any real affection of it could be observed.

On an attack of sanguineous apoplexy, all compression should be removed from the neck, the patient aid with his head a good deal raised, and a free admission of cool air allowed. Then blood should be taken freely from the arm or the temporal artery, or the jugular vein; which it may be sometimes necessary to repeat, if the symptoms continue, and the patient is still plethoric; or if blood can less be spared, cupping or leeches may lessen the congestion in the brain. The next object should be thoroughly to evacuate the bowels by some active purgative, as calomel joined with jalap, or with extract of colocynth, or followed by infusion of senna and some neutral salt, with a little tartarized, antimorn or tierture of jalap research the tartarized antimony or fincture of jalap repeated every two hours till it operates; or a draught of tinc-ture of senna and wine of aloes, where the bowels are very torpid, may answer the purpose. Stimulant clysters will also be proper, particularly if the patient cannot swallow, as common sait and syrup of buckthorn, with a proper quantity of gruel, infusion of senna or infusion of colocynth; or a turpentine clyster in elderly torpid habits. Cold should then be applied

assiduously to the scalp, the hair being previously lent, irregular fracture of a tendon, ligament, &c-+
shaved, and a blister to the back of the neck; and Galen. diaphoretic medicines may be exhibited, avoiding, however, those which contain oplum. Sinapisms to the feet may also be useful, particularly if these are cold. If under these means, the sensibility does not gradually return, some of the gentle diffusible stimulants will be proper, as ammonia, mustard, ether, camphor, &c.: and at this period, a blister to the scalp may come in aid. By some practitioners emetics are recommended, but their use is hazardous, especially if sufficient evacuations be not premised: and the same may be observed of sternutatories. In the serous form of the disease, general bleeding is inadmissible, and even the local abstraction of blood should be very sparingly made; the bowels should be kept open, especially by aloetic or mercurial formulæ, but not procuring profuse discharges; and the other secretions maintained, especially by the use of the diffusible stimulants already mentioned; blisters to the head, and errhines may be here also useful. When apoplectic symptoms have been occasioned by opium, or By some practitioners emetics are recommended, plectic symptoms have been occasioned by opium, or other narcotics, the timely discharge of this by an active emetic will be the most important measure; but in a plethoric habit, bleeding should be premised; subsequently various stimulants may be employed, as ammonia, vinegar, &c. endeavouring to procure a determination to the surface, and rousing the patient from his torpid state. The prevention of the san-guineous form of the disease will be best attempted by abstemiousness, regular moderate exercise, and keeping up the evacuations; an issue or seton may also be useful; but under urgent circumstances, bleeding, especially topical, must be resorted to. In leucophlegmatic habits, a more nutritious diet will be proper.

APOPNI'XIS. (From αποπνιγω, to suffocate.) A

suffocation.—Meschion.

APOPSOPHE'SIS. (From απο, and ψοφεω, to emit wind.) The emission of wind by the anus or uterus, according to Hippocrates.

APOPSY CHIA. (From ωπο, from, and ψυχη, the mind.) The highest degree of deliquium, or fainting,

according to Galen.

APO'PTOSIS. (From αποπιπτω, to fall down.) A prolapsus, or falling down of any part through relaxa-

tion.—Erotian.

Aporn's xis. (From απο, and ορεγω, to stretch out.)

A play with balls, in the gymnastic exercises.

Apo'ria. (From α, priv. and πορος, a duct.) Restlessness, uneasiness, occasioned by the interruption of perspiration, or any stoppage of the natural secretions.

Aporant'rsis. (From αποβρίπτω, to cast off.) Hippocrates used this word to signify that kind of insanity where the patient tears off his clothes, and casts them from him.

APOSCEPARNI'SMUS. (From απο, from, and σκεπαο-νίζω, to strike with a hatchet.) Deasciatio. A spe-cies of fracture, when part of a bone is chipped off.—

Aposcha'sis. (From aπo, and σχαζω, to scarify.)
Aposchasmus. A scarification. Venesection.—Hip-

[APOSEPEDINE. The products of the fermentation of cheese have been examined by M. Bracconnot, who has shown that the substance, called by Proust who has shown that the substance, called by Proust caseous oxide, has no claim to such a title, and proposes to call it Aposepedine, from απο, and σηπεόων, fresult of putrefaction). To obtain this substance, the curd of skim-milk, spontaneously coagulated, is to be mixed with water, and exposed in an open vessel until the putrefaction has fully obtained its height. By filtration, a liquor is obtained which, on being con-By filtration, a liquor is obtained which, on being concentrated by evaporation, yields a product of a very fætid odour, owing apparently to the presence of an oily substance. Towards the close of the evaporation, vapours of acetic acid pass over, and a liquid of the consistence of syrup remains; which, on cooling, concretes into a granulated, reddish mass like honey, and of a saline bitter taste. Treated by alkohol, it is separated into a soluble and insoluble portion. The latter of a saline bitter taste. Treated by alkohol, it is separated into a soluble and insoluble portion. The latter is the Aposepedine of M. Bracconnot; the former is the cascate of ammonia of Proust.—Webster's Man. Chem. A.]

APOSI'TIA. (From ano, from, and ouros, food.)

Apositios. A loathing of food.—Galen.

A vio-

Apostaios. A loathing of food.—Gelen.
Aposta'sMa. (From αποσπαω, to tear off.) A vio-

Aposphaceli'sis. (From ano, and sparthos, a mortification.) Hippocrates uses this word to denote a mortification of the flesh in wounds, or fractures,

caused by too tight a bandage.
 APO'STASIS. (From aπο, and ιςημι, to recede from.)
 1. An abscess, or collection of matter.
 2. The coming away of a fragment of bene by frac-

3. When a distemper passes away by some outlet,

Hippocrates calls it an apostasis by exerction.

4. When the morbific matter, by its own weight, falls and settles on any part, an apostasis by settle-

5. When one disease turns to another, an epostasis

APOSTA'XIS. (From αποςαζω, to distil from.) Hippocrates uses this word to express the defluxion or distillation of any humour, or fluid: as blood from the

APOSTELUS. An apostle. An ointment and other things were formerly so designated from some famous inventer; as unguentum apostelorum, because

thas twelve ingredients in it.

APOSTEMA. (Apostema, atis. n.; from αφιζημι, to recede.) The term given by the ancients to abscesses in general. See Abscess.

APOSTEMA TIAI. Those who, from an inward abscess, void pus downward, are thus called by Arcters. Aretæus.

APOSTERI'GMA. (From αποςηριγω, fulcio.) Galen uses this word to denote a rest of a diseased part, a cushion.

Apo'strophe. (From απο, and ςρεφω, to turn from.) Thus Paulus Ægineta expresses an aversion for food.

APOSYRINGE'SIS. (From απο, and συριγζ, a fistula.) The degeneracy of a sore into a fistula.—

Hippocrates.
APOSY'RMA. (From aπο, and συρω, to rub off.)
An abrasion or disquamation of the bones or skin.—

APOTANEUSIS. (From απο, and τεινω, to extend.) An extension, or elongation, of any member or substance.

or substance.

APOTELME'SIS. (From aπο, and τελμα, a bog.) An expurgation of filth, or faces.

APOTHE'CA. (Αποθηκη; from αποτιθημι, to reposit.) A shop, or vessel, where medicines are sold, or deposited.

APOTHECA'RY. (Apothecarius; from aπο, and

 $\tau\iota\partial\eta\mu\iota$, pono, to put: so called from his employ being to prepare, and keep in readiness, the various articles in the Materia Medica, and to compound them for the Physician's use; or from αποθηκη, a shop.) In every European country, except Great Britain, the apothecary is the same as we name in England the druggist and chemist.

APOTHERAPEI'A. (From απο, and Βεραπευω, to

APOTHERAPET A. (From απο, and ξεραπευω, to cure.) A perfect cure, according to Hippocrates.

Apotherapeu'tica. (From αποθεοαπευω, to heal.) Therapeutics. That part of medicine which teaches the art of curing disorders.

Apothe rmum. (From απο, and θερμη, heat.) An acrimonious pickle, with mustard, vinegar, and oil.—

APO THESIS. (From aπo, and τιθημι, to replace.) The reduction of a dislocated bone, according to Hip-

APOTHLI'MMA. (From απο, and Βλιδω, to press APOTHLI MAIA. (From aπο, and SAPOS, to press from.) The dregs or expressed juice of a plant.

Apothrau'sis. (From aπο, and Βρανω, to break.)

The taking away the splinters of a broken bone.

Apo'rocus. (From aπο, and τικτω, to bring forth.)

Abortive; premature.—Hippocrates.

Aportne Psis. (From απο, and τρεπω, to turn from.)

A resolution or reversion of a suppurating tumour.

Apotrop π'A. (From αποτρέπω, to avert.) An amulet, or charm, to avert diseases.—Foësius.

A POZEM. (Αροτεπα. From απο, and ζεω, to boil.) A decoction.

APOZEU'XIS. (From απο, and ζευγνυμι, to separate.) The separation or removal of morbid parts.—

Hippocrates.
Apo'zymos. (From aπο, and ζυμη, ferment.) Fer-

APPARA'TUS. (From appares, to appear, or be ready at hand.) This term is applied to the instruments and the preparation and arrangement of every APPARA'TUS. thing necessary in the performance of any operation, medical, surgical, or chemical.

APPARATUS ALTUS. See Lithotomy.
APPARATUS MAJOR. See Lithotomy.
APPARATUS MINOR. See Lithotomy.
APPARATUS, PNEUMATIC. The discovery of acri-

form fluids has, in modern chemistry, occasioned the necessity of some peculiar instruments, by means of which those substances may, in distillations, solutions, or other operations, be caught, collected, and properly managed. The proper instruments for this are styled the pneumatic apparatus. Any kind of air is specifithe pneumatic apparatus. Any kind of air is specifically lighter then any liquid; and, therefore, if not decomposed by it, rises through it in bubbles. On this principle rests the essential part of the apparatus, adapted to such operations. Its principal part is the pneumatic trough, which is a kind of reservoir for the liquid, through which the gas is conveyed and caused to rise, and is filled either with water or with quicksilver. Some inches below its brim a horizontal shelf is fastened, in dimension about half or the third part of the trough, and in the water-trough this is provided on its foremost edge with a row of holes, into which, from underneath, short-necked funnels are fixed. The trough is filled with water sufficient to cover the shelf, to support the receivers, which being previously filled with water are placed invertedly, their open end turned down upon the above-mentioned holes, through which afterward the gases, conveyed there and directed by means of the funnels, rise in the form of air bubbles.

In some cases the trough must be filled with quick-silver, because water absorbs or decomposes some kinds of air. The price and specific gravity of that metal make it necessary to give to the quicksilver trough smaller dimensions. It is either cut in marble, or made of wood well joined. The late Karsto has contrived an apparatus which to the advantage of contrived an apparatus, which, to the advantage of saving room, adds that of great conveniency.

To disengage gases, retorts of glass, either common or tubulated, are employed, and placed in a sand-bath, or heated by a lamp. Earthen, or coated glass retorts, are put in the naked fire. If necessary, they are joined with a metallic or glass conveying pipe. When, besides the aëriform, other fluids are to be collected, the middle or intermediate bottle finds its use; and to prevent, after cooling, the rising of the water from the trough into the disengaging vessel, the tube from the trough into the disengaging vessel, the tube of safety is employed. For the extrication of gases taking place in solutions, for which no external heat is required, the bottle called disengaging bottle, or proof, may be used. For receivers, to collect disengaged airs, various cylinders of glass are used, whether graduated or not, either closed at one end or open at both; and in this last case, they are made air-tight by a stopper fitted by grinding. Besides these, glass bells and common bottles are employed.

To combine with water, in a commodious way.

To combine with water, in a commodious way, some gases that are only gradually and slowly absorbed by it, the glass apparatus of Parker is ser-

APPENDI'CULA. A little appendage.
APPENDICULA CÆCI VERMIFORMIS. A APPENDICULA CECI VERMIFORMIS. A vermicular process, about four inches in length, and the size of a goose-quill, which hangs to the intestinum cacum of the human body.

APENDICULE EPPILOICE. Appendices coli adiposa. The small appendices of the colon and rectum, which are filled with adipose substance. See Omentum.

APPENDICULA TUS. Applied to leaves, leaf-stalks, &c. that are furnished with an additional organ for some particular purpose per constaller.

for some particular purpose not essential to it; as the Dionad muscipula, the leaves of which terminate each in a pair of toothed irritable lobes, that close over and imprison insects; as also the leaf of the Nepentha distillatorea, which bears a covered pitcher full of water; the leaves of our Utriculum, which have numerous bladders attached to them which seem to numerous bladders attached to them which seem to secrete air and float them; and the petiolus of the Dipsacus pilosus, which has little leaves at its base. APPENDIX. 1. An appendage; that which belongeth to any thing.

2. See Apophysis.
APPLE. See Pyrus.

Apple, actd of. See Malic acid.
Apple, pine. See Bromelia ananus.
Apple, thorn. See Datura stramonium.

Appreciation See Datara Stramonton.
Appropriate affinity. See Affinity intermediate.
APRICOT. See Prunus armeniaca.
APYRE'XIA. (From a, priv. and πυρεξια, a fever.)
Apyrexia. Without fever.—The intermission of fever-

APYRI'NUS. (From a, priv. and πυρην, nucleus, a kernel.) Without a kernel.

APYRINÆ PLANTÆ. Plants without kernels. The

name in Gerard's arrangement of a class of plants.

APYROUS. Bedies which sustain the action of a strong heat for a considerable time, without change of figure or other properties, have been called apyrous; but the word is now very seldom used. It is synony

mous with refractory.

A'QUA. See Water.

Water impregnated with fixed AQUE ARRIS FIXI. Water impregnated with fixed air. This is liquid carbonic acid, or water impregnated with carbonic acid. It sparkles in the glass, has a pleasant acidulous taste, and forms an excellent be-It diminishes thirst, lessens the morbid heat verage. It diminishes thirst, lessens the morbid heat of the body, and acts as a powerful diuretic. It is also an excellent remedy in increasing irritability of the stomach, as in advanced pregnancy, and it is one of the best anti-emetics which we possess.

AQUA ALUMINIS COMPOSITA. Compound solution of alum, formerly called aqua aluminosa bateana.

See Liquor aluminis compositus.

AQUA AMMONIÆ ACETATÆ. See Ammonia acetatis

AQUA AMMONIÆ PURÆ. See Ammonia. AQUA ANETI. See Ancthum gravcolens. AQUA CALCIS. See Calcis liquor. AQUA CARUI. See Carum carui.

AQUA CINNAMOMI. See Laurus cinnamomum. AQUA CŒLESTIS. A preparation of copper.

AQUA CUPRI AMMONIATI. See Cupri ammoniata

AQUA CUPRI VITRIOLATI COMPOSITA. paration of the Edinburgh Pharmacopæia is used externally, to stop hæmorrhages of the nose, and other parts. It is made thus: B. Cupri vitriolati, Aluminis, sing. 3ss. Aquæ puræ, 3iv. Acidi vitriolici, 3ij. Boil the salts in water until they are dissolved; then filter the liquor and add the acid.

AQUA DISTILLATA. Distilled water. This is made AQUA DISTILLATA. Distilled water. This is made by distilling water in clean vessels, until about two-thirds have come over. In nature, no water is found perfectly pure. Spring or river water always contains a portion of saline matter, principally sulphate of lime; and, from this impregnation, is unfit for a number of pharmaceutic preparations. By distillation, a perfectly pure water is obtained. The London College directs ten gallons of common water; of which, first distil four pints, which are to be thrown away. first distil four pints, which are to be thrown away; then distil four gallons. This distilled water is to be

then distil four gallons. This distilled water is to be kept in glass vessels. See Water.

AQUA FENICULI. See Anethum faniculum.

AQUA FORTIS. This name is given to a weak and impure nitric acid, commonly used in the arts. It is distinguished by the terms double and single, the single being only half the strength of the other. The artists who use these acids call the more concentrated acid, which is much stronger even than the double aqua fortis, spirit of nitre. This distinction appears to be of some utility, and is therefore not improperly retained by chemical writers. See Nitric acid.

AQUA KALI PREPARATI. See Polasse subcarbonatis liquor.

tis liquor.

AQUA KALI PURI. See Potassæ liquor. AQUA LITHARGYRI ACETATI. See Plumbi acetatis

AQUA LITHARGYRI ACETATI COMPOSITA.

Plumbi acetatis liquor dilutus.

Aqua marine. See Beryl.

Aqua menthe piperite. See Mentha piperita.

Aqua menthe sative. See Mentha viridis.

Aqua menthe viridis. See Mentha viridis.

AQUA MENTHÆ VIRIBIS. See Anestan virtus.

AQUA DE NAFOLL. See Aquetta.

AQUA PIMENTÆ. See Myrtus pimenta.

AQUA PULEGII. See Mentha Pulegium.

AQUA REGIA. Aqua regalis. This acid, which is a mixture of the nitric and muriatic acids, lately called a pitto-muriatic acid, and muriatic acids.

a mixture of the nitric and now chlorine, was formerly called nitro-muriatic, and now chlorine, was formerly called aqua regalis, because it was, at that time, the only 83

acid that was known to be able to dissolve gold. See]

AQUA ROSE. See Rosa centifolia.

AQUA STYPTICA. A name formerly given to a com-bination of powerful astringents, viz. sulphate of copper, sulphate of alum, and sulphuric acid. It has been applied topically to check hamorrhage, and, largely diluted with water, as a wash in purulent ophthalmia. See Aqua cupri vitriolati composita. Aqua Toffania. See Aquatta.

Aqua vita. Ardent spirit of the first distillation has been distinguished in commerce by this name.

has been distinguished in commerce by this name.

AQUA ZINCI VITRIOLATI CUM CAMPHORA. Aqua vitriolica camphorata. This is made by dissolving half an ounce of sulphate of zinc in a quart of boiling water, adding half an ounce of camphorated spirit, and filtering. This, when properly diluted, is a useful collyrium for inflammations of the eyes, in which there is a weakness of the parts. Externally, it is applied by surgeons to scorbutic and phagedenic ulcera-

AQUE DISTILLATE. Distilled waters. These are made by introducing vegetables, as mint, penny royal, &c. into a still with water; and drawing off as much as is found to possess the properties of the plants. London College orders the waters to be distilled from dried herbs, because fresh are not ready at all times of the year. Whenever the fresh are used, the weights are to be increased. But whether the fresh or dried herbs are employed, the operator may vary the weight according to the season in which they have been produced and collected. Herbs and seeds, kept beyond the space of a year, are improper for the distillation of waters. To every gallon of these waters, five ounces, by measure, of proof spirit are to be added.

AQUE MINERALES. See Mineral waters.
AQUE STILLETITIE SIMPLICES. Simple distilled

AQUE STILLATITIE SPIRITUOSE. Spirituous distilled waters, now called only spiritus; as spiritus

AQUÆDUCT. Aquaductus; a canal or duct, so named because it was supposed to carry a watery

AQUEDUCT OF FALLOPIUS. A canal in the petrous ortion of the temporal bone, first accurately described by Fallopius.

Aquatic nut. See Trapa natans.

AQUATICE PLANTE. Aquatic plants, or such as grow in or near water. A natural order of plants.

AQUATICUS. (From aqua, water.) Aquatic; or belonging to the water.

AQUEOUS. (Aquosus, watery.) Of the nature of,

or resembling water.

Aqueous HUMOUR. Humor Aquosus. The very limpid watery fluid, which fills both chambers of the

eye. See Eye.

AQUETTA. The name of a liquid poison, made use of by the Roman women, under the Pontificate of Alexander VII. It was prepared and sold in drops, by Tophania, or Toffania, an infamous woman who resided at Palermo, and afterward at Napies. From her, these drops obtained the name of Aqua Toffania, Aqua della Toffana; and also Aqua di Napoli. This poison is said by some to be a composition of arsenic,

and by others of opium and cantharides.

AQUIFO LIUM. (From acus, a needle, and folium, a leaf; so called on account of its prickly leaf.) See

A'QUILA. (Acros, the eagle.) 1. A species of the extensive genus Falco of ornithologists.

2. Aquila, among the ancients, had many other epithets joined with it, as rubra, salutifera, volans, &c.

3. A chemical name formerly used for sal-ammoniac.

mercurius præcipitatus, arsenic, sulphur, and the philosopher's stone.

AQUILA ALBA. One of the names given to calomel by the ancients. See Hydrargyri submurias.

AQUILA ALBA PHILOSOPHORUM. Aqua alba gany-

modis. Sublimated sal-ammoniac.

AQUILA CŒLESTIS. A panacea, or cure for all dis-

eases; a preparation of mercury. AQUILA VENERIS. A preparation of the ancients, made with verdigris and sublimed sal-ammo-

AQUILE LIGNUM. Eagle-wood. It is generally sold for the agallochum. See Lignum aloes.

AQUILE VENE. Branches of the jugular veins, which are particularly prominent in the eagle.

AQUILE GIA. (From aqua, water, and lego, to gather; so called from the shape of its leaves, which retain water.) The herb columbine.

1. The name of a genus of plants in the Linnman system. Class, Polyandria; Order, Pentagynia.

2. The name in the pharmacopeias, for the columbine. See Aquilegia vulgaris.

bine. See Aquilegia vulgaris. The systematic name of the Aquilegia vulgaris. The systematic name of the columbine. The seeds, flowers, and the whole plant, have been used medicinally, the first in exanthematous diseases, the latter chiefly as an antiscorbutic. Though retained in several foreign pharmacopeias, their utility seems to be not allowed in this country.

AQUILI'NA. (From Aquila, an eagle; so called from the resemblance of its leaves to eagle's wings.)

trivial name of a species of pteris. See Pteris.

AQUU'LA. (Diminutive of aqua.) A small quantity of very fine and limpid water. This term is applied to the pellucid water, which distends the capsule of the crystalline lens, and the lens itself. Paulus Ægineta uses it to denote a tumour consisting of a fatty substance under the skin of the eyelid.

Arabic gum. See Acacia gummi. A'RACALAN. An amulet.

A'RACA MIRA. (Indian.) A shrub growing in the Brazils, the roots of which are diuretic and antidy-

ARA'CHNE. (From arag, Hebrew, to weave; or from aραχνη, a spider.) The spider.

ARACHNOID. (Arachnoides; from αραχνη, a spider, and ειδος, likeness; so named from its resemblance to a spider's web.) Web-like.

ARACHNOID MEMBRANE. Membrana arachnoides. 1. A thin membrane of the brain, without vessels and nerves, situated between the dura and pia mater, and surrounding the cerebrum, cerebellum, medulla ob-

longata, and medulla spinalis.

2. The term is also applied by some writers to the tunic of the crystalline lens and vitreous humour of

ARACK. (Indian.) An Indian spirituous liquor, prepared in many ways, often from rice; sometimes from sugar, fermented with the juice of cocca-nuts; frequently from toddy, the juice of which flows from the cocca-nut tree by incision, and from other sub-

A'rados. (From acaδεω, to be turbulent.) Hippocrates uses this term to signify a commotion in the stomach, occasioned by the fermentation of its contents.

Arro'Tica. (From acacoω, to rarefy.) Things which rarefy the fluids of the body.

ARA'LIA. (From acac a bank in the sea; so called because it grows upon the banks near the sea.) The

name of a genus of plants in the Linnman system. Class, Pentandria; Order, Pentagynia. The berrybearing angelica. Of the several species of this tree, the roots of the nudicaulis, or naked-stalked, were brought over from North America, where it grows, and sold here for sarsaparilla.

ARA'NEA. (From αραω, to knit together.)

ARA'NEA. (From αραω, to knit together.)

1. The name of a genus of insects.

2. The spider.

ARA'NTIUS, Ju'lius Cæsar, a celebrated anatomist and physician, born at Bologna, about the year 1530. After studying under Vesalius, and others, he graduated and became professor there, and died in 1589. In his first work, "On the Human Fœtus," he described the foramen ovale, and ductus arteriosus, and corrected several errors in the anatomy of the gravid uterus, which had been generally derived from gravid uterus, which had been generally derived from the examination of brutes. He afterward showed that the blood, after birth, could only pass from the right to the left side by the heart through the vessels of the lungs, thus preparing for the discovery of the circulation of Harvey. A Treatise on Tumours, and a Commentary on part of Hippocrates, were also written by him

ARA'TRUM. The plough. A plant has this for a trivial name, because its roots are found to hinder the plough: hence remora aratri. See Ononis spinosa.

ARBOR. A tree. 1. In botany, a plant, consisting of one trunk which rises to a great height, is very durable, woody, and divided at its top into branches which do not perish in the winter; as the oak, elm, ash, &c.

2. In anatomy, it is applied to parts which ramify like a tree, as the Arbor vita of the cerebellum.

3. In chemistry, applied to crystallizations which ramify like heareness.

mify like branches.

ARBOR DIANE. See Silver.

ARBOR VITE. The tree of life.

1. The cortical substance of the cerebellum is so disposed, that, when cut transversely, it appears rami-fied like a tree, from which circumstance it is termed arbor vita.

2. The name of a tree formerly in high estimation in

medicine. See Thuya occidentalis.

Arbores. One of the natural divisions or families Arbores. One of the natural divisions or families of plants. Trees consist of a single and durable woody trunk, bearing branches, which do not perish in the winter, as Tilia, Frazinus, Pyrus, &c.

ARBUSTIVA. (From arbustum, a copse of shrubs or trees.) The name of an order of plants in Lin-

næus's natural method.

ARBUTHNOT, John, a physician, born in Scotland soon after the restoration, celebrated for his wit and learning. He graduated at Aberdeen, and settling in this metropolis, had the good fortune to be at Epsom, when Prince George of Denmark was taken ill there: whom, having restored to health, he was appointed physician to Queen Anne, but never got into very ex-"On the Choice of Aliments," and "On the Effects of Air upon Human Bodies." He died in 1735. A'RBUTUS. The name of a genus of plants in

the Linnwan system. Class, Decandria; Order, Mo-

nogynia.
Arbutus, trailing. See Arbutus uva ursi.
Arbutus unedo. Amatzquitl; Unedo papyracea. Arbutus unedo. Amatzquill; Unedo papyracea. A decoction of the bark of the root of this plant is re-

commended in fevers.

Arbutus uva ursi The systematic name for the officinal trailing Arbutus; Bear's berry; Bear's whortle-berry; Bear's whorts; or Bear's bilberries; called also Vaccaria. Arbutus—caulibus procumbentibus, foliis integerrimis, of Linnæus. This plant, though employed by the ancients in several diseases, requiring adstringent medicines, had almost entirely fallen into disuse until the middle of the present century, when it first drew the attention of physicians, as a useful remedy in calculous and nephritic complaints, which diseases it appears to relieve by its adstringent qualities.

A'RCA ARCANORUM. The mercury of the philo-

A'RCA CORDIS. The pericardium.
ARCA'NUM. A secret. A medicine, the preparation or efficacy of which is kept from the world, to enhance its value. With the chemists, it is a thing secret and incorporeal; it can only be known by experience, for it is the virtue of every thing, which operates a thousand times more than the thing itself.

ARCANUM CATHOLICUM. Bezoar, plantain, and

colchicum.

ARCANUM DUPLEX. Arcanum duplicatum. A name formerly given to the combination of potassa and sulphuric acid, more commonly called vitriolated tartar, and now sulphate of potassa.

ARCANUM TARTARI. The acetate of potassa.

ARCE'RTHOS. Juniper.

ARCHÆ'US. 1. The universal archæus, or principle of Van Helmont, was the active principle of the material world. See Vis vitæ.

2. Good health.

A'RCHE. (From αρχη, the beginning.) The earliest stage of a disease.

ARCHE'NDA. (Arabian.) A powder made of the leaves of the ligustrum, to check the fætid odour of the feet.

ARCHER, JOHN, M. D. of the state of Maryland, a celebrated practitioner of medicine. Many contributions of his, on various subjects of medical science, are to be found in the New-York Medical Repository. He was the first who introduced the Repository. He was the first who introduced the Seneca snake-root (polygala senega) as a remedy in Croup. He died in 1814. A.]

Archil. See Lichen rocella.

There are several lichens which abound in colourrocella, which grows in the south of France, and in the Canary Islands; and which affords the beautiful, but perishable blue, called litmus, archil, or turnsols.

The moss is dried, powdered, mixed with pearlash and urine, and allowed to ferment, during which it and urine, and allowed to ferment, during which it becomes red and then blue; in this state it is mixed with carbonate of potassa and chalk, and dried. It is used for dying silk and ribands; and by the chemists as a most delicate test of acids, which it indicates by passing from blue to red; the blue colour is restored by alkalies, which do not render it green. Cudbear appears to be a similar preparation of the licken tartareus.—Webster's Man. Chem. A.]

Archilla. See Lichen recella.

Archilla. See Lichen recent the chief and solve.

ARCHI THOLOS. (From aρχη, the chief, and βολος, a chamber.) The sudatorium, or principal room of the ancient baths.

ARCHOPTO MA. (From aρχος, the anus, and πιπτω, to fall down.) A bearing down of the rectum, or prolapsus ani.

A'RCHOS. (From αρχος, an arch.) The anus; so called from its shape.

ARCTA'TIO. (From arcto, to make narrow.)

1. A constipation of the intestines, from inflam-

2. A preternatural straitness of the pudendum mu-

liebre.
A'RCTIUM. (From apktos, a bear; so called from its roughness.) The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia aqualis. The burdock.
ARCTIUM LAPPA. The systematic name for the herb clot-bur, or burdock. Bardana; Arctium; Britannica; Ilaphis. The plant so called in the pharmacopæias, is the Arctium—foliis cordatis, inermibus, petiolatis, of Linnæus. It grows wild in uncultivated grounds. The seeds have a bitterish subacrid taste: grounds. The seeds have a bitterish subacrid taste: they are recommended as very efficacious diuretics, given either in the form of emulsion, or in powder, to the quantity of a drachm. The roots taste sweetish, with a slight austerity and bitterness: they are es-teemed aperient, diuretic, and sudorific; and are said to act without irritation, so as to be safely ventured upon in acute disorders. Decoctions of them have been used in rheumatic, gouty, venereal, and other disorders; and are preferred by some to those of sar-saparilla. Two ounces of the roots are to be boiled in three pints of water, to a quart; to this, two drachms of sulphate of potassa have been usually added. Of this decoction, a pint should be taken every day in scorbutic and rheumatic cases, and when intended as a diuretic, in a shorter period. ARCTIZITE. The foliat

The foliated species of scapolite.

See Scapolite.
ARCTU'RA. (From arcto, to straiten.) flammation of the finger, or toe, from a curvature of the

ARCUA'LIA. (From arcus, a bow.) Arcualis. The sutura coronalis is so named, from its bow-like shape; and, for the same reason, the bones of the sin-

ciput are called arcualia ossa.—Bartholin.

ARCUA'TIO. (From arcus, a bow.) A gibbosity of the for-parts, with a curvation of the sternum, of

the tibia, or dorsal vertebræ .- Avicenna.

A'RCULE. (A dim. or sockets of the eyes. (A dim. of area, a chest.)

A'RDAS. (From αρόνω, to defile.) Filth, excre-

ment, or refuse.—Hippocrates.

ARDENT. (Ardens; from ardeo, to burn.) Burning hot. Applied to fevers, alkohol, &c.

ARDOR. (Arder, oris. m.; from ardeo, to burn.)

A burning heat.

Ardor Pebrilis. Feverish heat.
Ardor URINE. Scalding of the urine, or a sense of heat in the urethra.

ARDOR VENTRICULI. Heartburn.

A'REA. 1. An empty space.
2. That kind of baldness where the crown of the head is left naked, like the tonsure of a monk.

ARE'CA. The name of a genus of plants of the class Palma.

ARECA INDICA. An inferior kind of nutmeg

ARECAINDICA. An interior kind of intimeg.

ARE'GON. (From αρηγω, to help; so called from its valuable qualities.) A resolvent ointment.

AREMA'ROS. Cinnabar.

ARE'NA. Sand, or gravel.

ARENA'MEL. (From ανεπα, sand; so called because it was said to be procured from sandy places.) Arenamen. Bole-armenic.

ARENA'TIO. (From arena, sand.) Saburation, or the sprinkling of hot sand upon the bodies of pa-

tients.—Baccius do Thermis.

[ARENDALITE. The same as Arendate; both of which are synonymous with Epidote. A.]

AREYNTES. See Epidote.

ARE'NTES. (From area, to dry up.) A sor cient cupping-glasses, used without scarifying.

ARE'OLA. (A diminutive of area, a void A sort of an-

(A diminutive of area, a void space.) A small red or brown circle, which surrounds the nipples of females. During and after pregnancy, it becomes considerably larger.

AREOMETER. See Hydrometer.

ARETENOI'DES. See Hydrometer.

ARETENOI'DES. See Arytenoides.

ARETE'US, of Cappadocia; a physician, who practised at Rome, but at what period is uncertain, though the most probable opinion places him between the reigns of Vespasian and Adrian. Eight books of his remain "On the Causes, Signs, and Method of treating acute and chronic Diseases," written in the Greek language, and admired for their pure style, and luminous descriptions, as well as the judicious practice generally recommended. He was partial to the use of hellebore and other drastic medicines; and appears to have been among the first to recommend pears to have been among the first to recommend

cantharides for blistering the skin.

A'RETE. (Αρετη, virtue.) Hippocrates uses this word to mean corporeal or mental vigour.

ARE'US. A pessary, invented by Ægineta.

A'RGAL. Argol. Crude tartar, in the state in which it is taken from the inside of wine-vessels, is honored in the shape by this reares.

known in the shops by this name.

ARGASY'LLIS. (From apyos, a serpent; which it is said to resemble.) The plant which was supposed to produce gum-ammoniac. See Heracleum gummi-

A'RGEMA. (From aoyos, white.) Argemon. A small white ulcer of the globe of the eye.—Erotianus.

Argentate of ammonia. Fulminating silver.

[This mineral has a laminated or rather slaty structure. Its laminæ or layers, often curved or undulated, are seldom perfectly parallel; but their surface has almost always a pearly lustre, somewhat shining. According to Bournon, these laminæ are composed of According to Bournon, these lamina are composed of minute rhombs, whose summits are so deeply truncated perpendicularly to the axis, that only a very thin portion of the rhomb remains. Indeed this mineral sometimes presents the primitive rhomb. It is translucent, at least at the edges; and its colour is white, snaded with gray, green, or red. It is easily broken; and its spec, grav. is 2.64.

It is pearly a pure carbonate of lime often contain-

It is nearly a pure carbonate of lime, often containing a little oxide of iron or manganese. Hence at red heat it often becomes reddish brown .- Cl.

Min. A.]

ARGENTI NITRAS. Argentum nitratum; Causticum lunare. Nitrate of silver. Take of silver an ounce; nitric acid, a fluid ounce; distilled water, two fluid ounces. Mix the nitric acid and water, and dissolve the silver therein on a sand bath; then increase the heat gradually that the nitrate of silver may be dried. Melt the salt in a crucible over a slow fire until the water being evaporated, it shall cease to be the recurrit quickly into moulds of convenient. boil; then pour it quickly into moulds of convenient shape. Its virtues are corrosive and astringent. Internally it is exhibited in very small quantities, in epilepsy, chorea, and other nervous affections, and externally it is employed to destroy fungous excrescences, callous ulcers, fistulas, &c. In the latter disease, it is used as an injection; from two grains to three being dissolved in an ounce of distilled water.

ARGE NTUM. (Argentum, i. m.; from apyos, white, because it is of a white colour.) Silver. See

Silver.

ARGENTUM FUSUM. Crude mercury. ARGENTUM MOBILE. Crude mercury

ARGENTUM NITRATUM. See Argenti nitras.

Argentum vivum. See Mercury.
A'Roes. (From apyos, white.) A serpent, with a whitish skin, deemed by Hippocrates exceedingly

ARGILLA. (Argilla, c. f.; from appos, white.)
Argil. White clay. See Alumina.
ARGILLA VITRIOLATA. Alum.
ARGILLACEOUS. Of or belonging to argilla, or sluminous earth. See .@lumina.

Argillaceous earth. See Alumina.

Argillaceous schistus. See Clay-slate.
ARGILLITE. See Clay-slate.
[ARGILOLITE. This mineral often strongly resembles certain varieties of compact limestone, or calcareous marl. Its texture is sometimes porous, and sometimes compact, or even slaty. Its fracture is dull and earthy, sometimes splintery or conchoidal. In hardness, also, it differs little from indurated marl, or the softer varieties of compact limestone, and is some times nearly friable. Its particles are sufficiently hard to scratch iron, although its masses may be cut by a

It adheres but slightly to the tongue, and yields an argillaceous odour when moistened. In water it gradually crumbles, but never forms a ductile paste. It is opaque; and its colour is gray, often tinged with yellow or blue; also rose, or pale red, brown, or brownish red, and sometimes greenish. It very often presents white, brown, or greenish spots, nearly round, and is sometimes striped.

It hardens by exposure to heat, but is generally infusible by the blow-pipe: some varieties melt at their surface. It does not effervesce with acids, by which it is distinguished from those minerals which it most re-

Claystone seems to approach very near to jasper, or petrosilex, in a state of decomposition, and sometimes to tripoli.—Cl. Min. A.]

ARGYRI'TIS. (From apyrpos, silver.) Litharge, or spume of silver. A kind of earth was formerly so

named, which is taken from silver mines, and is be-

spangled with many particles of silver.

ARGYRO'COME. (From αργυρος, silver, and κομη, hair.) A species of gnaphalium or cudweed was so named from its white silvery floscules.

ARGYROLI'BANOS. The white olibanum.

ARGYROLI'BANOS. The white onbanum.

ARGYROLI'BANOS. An antidote, in the composition

ARGYROLI BANDS.
ARGYROTHORA. An antidote, in the composition of which there is silver.

ARGYROTROPHE'MA. (From αργος, white, and τροφημα, food.) A white cooling food, made with milk. Milk diet.—Galen.

(From a, neg. and ρευματιζω,

ARHEUMATI'STOS. (From a, neg. and δευματιζω, to be afflicted with rheums.) Not being afflicted with

ARICY'MON. (From an and are, to be quickly impregnated.) A woman who conceives quickly and

ARILLUS. (From arère, to be dry or parched.) The seed-coat or tunic of the permanent husk that invests a seed, which drying falls off spontaneously. It is a peculiar membrane, thick, and loosely surrounds the seed.

The varieties of arilli are,

1. The succulent, pulpy; like a berry in Evonymus

- europeus and Latia.

 2. Cartilaginous; in Coffea Arabica.

 3. Dimidiate, half round; as in Taxus baccata.

 4. Lacerate, cut-like; as in the mace of the Myristica moschata.
- Reticulate, net-like, surrounding the seed like a net; as in the Orchis tribe.

Tricuspid; as in Malva coromandiliana.

7. Hirsute, hairy; as in Geranium incanum.

8. Villous; in Geranium dissectum.

ARISTA. (From areo, to dry.) The awn; a sharp beard, or point, or bristle-like filament, which proceeds from the husk or glume of grasses. Its dissections are in the state of the state tinctions are into

1. Naked, without villi; as in Stipa arguens and

Plumose, having white villi; as in Stipa pennata.
 Straight, as in Bromus secalinus, and mollis.
 Geniculate, having a knee-like bend; as with

Avena sativa.

5. Recurved, bent back; as in Holcus lanatus, and Agrostis canina.

6. Tortile, twisted like a rope; as in Agrostis rubra, and Aira montana.

Terminal, fixed to the apex of the husk : it is so in Agrostis miliacea.

Dorsal, fixed to the back or outward part of the

busk; as in Agrostis canina; Bromus; Alopecuris.

9. Uncinate, hooked; as in Panicum hirtellum.

ARISTALTHÆ'A. (From apiços, best, and αλθαία, the althæa.) The common marsh-mallow. See Althe althwa.) T

ARISTATUS. (From arista, the awn.) Awned. Applied to leaves, leaf-stalks, &c. when terminated by a long rigid spine, which in a leaf does not appear as a contraction. In Galium aristatum, the leaf-stalk

ARISTOLO'CHIA. (Aristolochia, & f.; from αριστος, good, and λοχια οτ λοχιια, parturition; so called because it was supposed to be of sovereign use in disorders incident to child-birth.) 1. The name of a genus of plants in the Linnaan system. Class, Gynandria; Order, Hexandria.

2. The pharmacopeial name of the long-rooted birthwort See Aristolochia longa.

See Aristolochia longa. ARISTOLOCHIA ANGUICIDA. Snake-killing birthwort. Aristolochia—foliis cordatis, acuminatis; caule volubili, fructicoso; pedunculis solitariis; stipulis cordatis, of Linnæus. The juice of the root of this plant has the property of so stupifying serpents, that they may be handled with impunity. One or two drops are sufficient; and if more be dropped into the mouth, they become convulsed. So ungrateful is the mouth, they become convulsed. So ungrateful is the smell of the root to those reptiles, that it is said they immediately turn from it. The juice is also esteemed as a preventive against the effects usually produced by the bite of venomous serpents.

Aristolochia clematuris. Aristolochia tenuis. The systematic name of the Aristolochia vulgaris of some pharmacopæias. An extract is ordered by the Wirtemberg Pharmacopæia, and the plant is retained in that of Edinburgh. It is esteemed as possessing

antipodagric virtues.

ARISTOLOCHIA FABACEA. See Fumaria bulbosa.
ARISTOLOCHIA LONGA. The systematic name for the aristolochia of our pharmacopeias. Aristolochia —foliis cordatis, petiolatis, integerrimis, obtusiusculis; caule infirmo, floribus solitariis. The root of
this plant only is in use; it possesses a somewhat
aromatic smell, and a warm bitterish taste, accompanied with a slight degree of pungency. The virtues
ascribed to this root by the ancients were very considerable, and it was forecastly employed in various siderable; and it was frequently employed in various diseases, but particularly in promoting the discharge of the *lockia*; hence its name. It is now very rarely used, except in gouty affections, as an aromatic stimulant.

ARISTOLOCHIA ROTUNDA. The root of this species of birthwort, Aristolochia—foliis cordatis, subsessilibus, obtusis; caule infirmo; floribus solitariis, of Linnæus; is used indiscriminately with that of the

aristolochia longa. See Aristolochia longa. Aristolochia serpentaria. The s systematic name for the Serpentaria virginiana of the pharmacopæias. Aristolockia; Colubrina virginiana; Viperina; Viperina virginiana; Pestilockia; Contrayerva virginiana. Virginian snake-root. The
plant which affords this root is the Aristolockia—
folias cardata ablancia planta to the contraction. plant which affords this root is the Aristolockia—foliis cordato oblongis planis; caulibus infirmis flexuosis teretibus; floribus solitariis. Caulus geniculata valde nodosa. Flores ad radicem of Linnæus. Snake-root has an aromatic smell, approaching to that of valerian, but more agreeable; and a warm, bitterish, pungent taste. It was first recommended as a medicine of extraordinary power, in counteracting the poisonous effects of the bites of serpents; this, however, is now wholly disregarded; but as it now however, is now wholly disregarded: but as it pos sesses tonic and antiseptic virtues, and is generally admitted as a powerful stimulant and diaphoretic, it is employed, in the present day, in some fevers where these effects are required. A tinctura is directed both by the London and Edinburgh Pharmacopæias.

ARISTOLOCHIA TENUIS. See Aristolochia elematitis. ARISTOLOCHIA TRILOBATA. Three-lobed birthwort The root, and every part of this plant, Aristolochia— foliüs trilobis, caule volubili, floribus maximis of Lin-neus, its diuretic, and is employed in America against ARISTOLOCHIA TRILOBATA.

the bite of serpents.

ARISTOLOCHIA VULGARIS. See Aristolochia ele-

ARISTOPHANEI'ON. (From Aristophanes, its inventor.) The name of an ancient emollient plaster, composed of wax, or pitch.—Gorræus.

[ARKTIZIT. This mineral is otherwise called Wernerite, after the celebrated German mineralogist

The Wernerite, a rare mineral, occurs in eight-sided risms, terminated by four-sided summits, whose faces form, with the alternate lateral planes on which they Much caution is necessary in regulating the dose, as

stand, an angle of about 1219. Or it may be called a four sided prism, truncated on its lateral edges. The primitive form appears to be a quadrangular prism, with square bases. It also occurs in irregular grains.

The Wernerite strikes fire with steel, but is scratched by feldspar. Its fracture is both imperfectly foliated and uneven, with a moderate lustre, a little pearly or

resinous. Its specific gravity is 3.60.

It is usually more or less translucent; and its colour is greenish gray, or clive green, and sometimes white. The surface of the crystals sometimes has the lustre and aspect of an enamel.

Before the blow-pipe, it froths and melts into an opaque, white enamel. A mean of two analyses, by John, gives silex 45.5, alumine 33.5, lime 13.22, oxide of iron 5.75, oxide of manganese 1.47=99.44.

Its mode of fusion by the blow-pipe, and its imperfectly foliated structure, may serve to distinguish it from most minerals which it resembles.

This mineral is sometimes in tabular masses, but most commonly in crystals which are easily recognised. The general form of these crystals, (certain small faces being neglected,) is a very oblique rhomb, or rather four-sided prism, so flattened that some of its edges become thin and sharp, like the edge of an axe. The primitive form is a four-sided prism, the bases of which are parallelograms, with angles of 101° 30′, and 78° 30′. The integrant particles are oblique, triangular prisms. M. Haüy has described five secondary forms.—Cl. Min. A.]

ARMA. (Arma, orum. pl. n. Arms.) In botany, applied to a species of armature or offensive weapons. They are one of the seven kinds of fulera, or props of nised. The general form of these crystals, (certain

They are one of the seven kinds of fulera, or props of plants enumerated by Linnæus in his Delineatio plantæ. They are pungent points in some part of a plant. In the present day, arma is used as a generic term embracing the aculeus, furca, spina, and sti-

ARMATU'RA. 1. See Arma.
2. The amnios or internal membrane which surrounds the fixtus.

ARMATURE. See Arma.

ARMATURE. See Arma.

A'RME. (From aρω, to adapt.) 1. A junction of the lips of wounds.

2. The joining of the sutures of the head.
[ARMINIAN STONE. Quartzy or calcareous substances, penetrated by the azure carbonate of copper, have been called by this name, the copper giving a most beautiful blue colour. A.]

ARMI'LLA. (Diminutive of armus, the arm.) The round ligament which confines the tendons of the

round ligament which confines the tendons of the

carpus.
ARMORA'CIA. (From Armorica, the country whence it was brought.) See Cochlearia Armoracia.
ARMSTRONG, John, a Scotch physician, born in
1709, who, after graduating at Edinburgh, settled in
London, but met with little success, having distin-London, but met with little success, having distinguished himself less in his profession than as a poet, particularly by his "Essay on the Art of Preserving Health," in blank verse. He afterward attended the army in Germany, which brought him more into notice as a physician. He attained the age of seventy, and died in pretty good circumstances. His professional publications are not of much note; the principal one is entitled "Medical Essays." He is supposed, however, to have contributed materially to a useful Treatise on the Diseases of Children, published by his Treatise on the Diseases of Children, published by his

Treatise on the Diseases of Children, published by his brother George, who, after practising many years as an apothecary, obtained a diploma in medicine.

A'RNICA. (Arnica, & f. Apvika; from aps, a lamb; because of the likeness of the leaf of this plant to the coat of the lamb.) Arnica. 1. The name of a genus of plants in the Linnxan system. Class, Syngenesia; Order, Polygamia superflua.

2. The pharmacopeial name of the Mountain arnica. See Arnica wantana.

See Arnica montana.

ARNICA MONTANA. The systematic name for the ARNICA MONTANA. The systematic name for the arnica of the pharmacopeias. Arnica folus oratis integris; caulinis geminis oppositis, of Linnaus. Doronicum Germanicum. Acyrus. The flowers of this plant are very generally employed on the Continent. Of the advantages derived from their use, in paralytic and other affections, depending upon a want of nervous energy, there are several proofs; and their extraordinary virtues, as a febrifuge and antiseptic, have been highly extolled by Dr. Collin, of Vienna. Much caption is nocessary in regulating the dose. it is a medicine very apt to produce vomiting, and much uneasiness of the stomach. See Arnica. the superarseniate of potassa, which is in solution in the superarseniate of potassa, which is superarseniate of much uneasiness of the stomach. See Arnica.
ARNICA SUEDENSIS. See Inula dysenterica.

Anno'tto. A Spanish name for a shrub. See Biza orleana.

AROMA. (Aroma, matis, neut.; from aρι, intensely, and οζω, to smell.) Spiritis rector. The odorous principle of plants, and other substances, which have their characteristic smell. This is called by the moderns, aroma. Water charged with aroma, is called the distilled water of the substance made use of: thus lavender and peppermint waters are water impregnated with the aroma of the lavender and

AROMATA. (Αρωματα, sweet spices, herbs, &c.) Aromatics.

AROMA'TIC. (Aromaticus; from apupa, an odour.) A term applied to a grateful spicy scent, and an agreeable pungent taste, as cinnamon bark, cardamoms, &c.

Aromatic vinegar. See Acetum aromaticum

AROMATICE PLANTE. Odoriferous or strong and agreeable smelling plants. The name of a class of plants in some natural arrangements.

AROMA'TICUS CORTEX. A name for canella alba.

AROMATOPO'LA. (From αρωμα, an odour, and πωλεω, to sell.) A druggist; a vender of drugs and

ARQUEBUSA'DE. (A French word, implying good for a gun-shot wound.) Aqua sclopetaria;
Aqua vulneraria; Aqua catapultarum. The name
of a spirituous water, distilled from a farrago of aro-

ARRA'CK. A spirituous liquor distilled from rice, and drunk, in the rice countries, as brandy is in this island. Its effects on the animal economy are the

ARRAGONITE. A mineral of a greenish and pearly gray colour, found at Arragon in Spain, England, and Scotland.

[Although this mineral is composed chiefly of lime and carbonic acid, yet there is reason to believe, that other ingredients are essential to its true composition. It differs from pure carbonate of lime in hardness,

specific gravity, and crystalline structure.

In nitric acid it dissolves with effervescence. The analysis of no mineral has ever so much exercised the talents, exhausted the resources, and disappointed the expectations of the most distinguished chemists of Europe, as that of arragonite. Vauquelin and Four-croy obtained lime 58.5, carbonic acid 41.5; and the analysis of Biot and Thenard, conducted with much ingenuity, scarcely differs from this, except in giving a little water. With these, both Chevenix and Kla-proth agree, in finding the arragonite to contain line proth agree, in finding the arragonite to contain lime and carbonic acid in nearly the same proportions as in the common carbonate of lime. Kirwan in his mine-ralogy, published in 1794, conjectured that the arragonite might contain strontion; and very recently Professor Stromeyer of Gottingen has discovered in this mineral between three and four per cent. of the carbonate of strontian. This discovery will very probably lead to a solution of the preceding difficulty; but it is important that the analysis should be repeated

by different chemists.—Cl. Ain. A.]

A'reaphus. (From a, priv. and $\rho a\phi \eta$, a suture.)

Without suture. It is applied to the cranium when naturally without sutures.

Arrangement of Minerals. See Minerals, arrange-

ment of.

ARRHÆ'A. (From α, neg. and ρεω, to flow.) The suppression of any natural flux, as the menses, &cc.

ARRHIZUS. (From α, priv. and ρεζα, a root: without root.) Applied to paraatical plants, which have no roots, but adhere and imbibe their nourishment by ainastomosing of the vessels; as Viscum album, and Loranthus curopeus.

ARROWHEAD. The Sagittaria sagittifolia of Linnæus. The roots of this plant are said to be esculent, but it must be in times of very great scarcity.

Arrow-root. See Maranta.
Arrow-shaped. See Leaf.
ARSE NIATE. (Arsenias, atis. m.; from arsenicum, arsenic.) A salt formed by a confoination of arsenic acid with salitiable bases; as arseniate of ammonia, which is produced by the union of ammonia with assenic acid. The only one used in medicine is

A'RSENIC. (Arsenicum, t. n.; from the Arabic term Arsanek, or from agents, for apony, masculus; from its strong and deadly powers.) The name of a from its strong and deadly powers.) The name of a metal scattered, in great abundance, over the minera. kingdom. It is found in black, heavy masses of little brilliancy, called native arsenic or testaceous arsenic. This exists in different parts of Germany. Mineralized by sulphur, it forms sulphurized arsenic. This mineral is met with in Italy, about Mount Vesuvius. There are two varieties of this ore, which differ from There are two varieties of this ore, which different pro-portions of their component parts. The one is called yellow sulphurized arsenic, or orpiment; the other, red sulphurized arsenic, or realgar, or ruby arsenic; both are met with in Hungary and different parts of Ger-many. The colour of the first ore is a lemon-yellow, inclining sometimes to a green; the colour of the latter is a ruby-red; it is more transparent than the former, and found in compact and solid masses, sometimes crystallized in bright needles. Arsenic united to oxygen, constitutes the ore called native oxyde of arsenic. This ore is scarce; it is generally found of an earthy appearance, or as an efflorescence, coating native, or metallic arsenic; its colour is a whitish gray; it is rarely met with crystallized. Arsenic exists likewise alloyed with cobalt, antimony, tin, copper, lead, and various other metals.

Method of obtaining Arsenic. In order to obtain metallic arsenic, mix two parts of the white oxyde of arsenic of commerce, with one of black flux (obtained by detonating one part of nitrate of potassa with two of supertartrate of potassa), and put the mixture into a crucible, or melting pot. Invert over this another crucible, lute the two together with a little clay and sand, and apply gradually a red heat to the lower one. The oxyde of arsenic will be reduced, and be found lining the upper crucible in small crystals of a metal-lic brilliancy.

The charcoal of the black flux takes in this process the oxygen from the white oxyde, and forms carbonic acid gas; which flies off during the process, and the oxyde becomes reduced to the metallic state. This reduction of the oxyde is greatly facilitated by the alkali of the flux.

Remark.-In order to obtain arsenic in a state of absolute purity, the metal thus obtained must be reduced to a powder, dissolved by heat in nitro-muriatic acid, and then precipitated by immersing into the solution a plate of zinc. The arsenic is thus precipitated in a fine powder, and may be reduced to a mass, by exposing it in a covered crucible to a moderate heat.

"It is among the most combustible of the metals, burns with a blue flame, and garlic smell, and sublimes

in the state of arsenious acid.

Concentrated sulphuric acid does not attack arsenic when cold; but if it be boiled upon this metal, sul-phurous acid gas is emitted, a small quantity of sulphur sublimes, and the arsenic is reduced to an oxyde. Nitrous acid readily attacks arsenic, and converts it

into arsenious acid, or, if much be employed, into ar-

senic acid.

Boiling muriatic acid dissolves arsenic, but affects it very little when cold. This solution affords precipi-tates upon the addition of alkalies. The addition of a little nitric acid expedites the solution; and this solution, first heated and condensed in a close vessel, is wholly sublimed into a thick liquid, formerly termed butter of arsenic. Thrown in powder into chlorine gas, it burns with a bright white flame, and is converted into a chloride.

None of the earths or alkalies act upon it, unless it be boiled a long while in fine powder, in a large pro-portion of alkaline solution.

Nitrates detonate with arsenic, convert it into arsenic acid, and this, combining with the base of the nitrate, forms an arseniate, that remains at the bottom of the vessel.

Muriates have no action upon it; but if three parts of chlorate of potassa be mixed with one part of arsenic in fine powder, which must be done with great precaution, and a very light hand, a very small quanprecaution, and a very light hand, a very sman quan-tity of this mixture placed on an anvil, and a truck with a hammer, will explode with flame and a con-siderable report; if touched with fire, it will burn with considerable rapidity; and if thrown into concentrated sulphuric acid, at the instant of contact a flame rises

Arsenic readily combines with sulphur by fusion and sublimation, and forms a yellow compound called orpiment, or a red called realgar. The nature of these, and their difference, are not accurately known; but Fourcroy considers the first as a combination of sulphur with the oxyde, and the second as a combination of sulphur with the metal itself, as he found the red sulphuret converted into the yellow by the action of acids.

Arsenic is soluble in fat oils in a boiling heat; the solution is black, and has the consistence of an ointment when cold. Most metals unite with arsenic: which exists in the metallic state in such alloys as possess the metallic brilliancy.

Iodine and arsenic unite, forming an iodide, of a dark, purple-red colour, possessing the properties of an acid. It is soluble in water, and its solution forms

a soluble compound with potassa.

Arsenic combines with hydrogen into a very noxious Arsenic combines with hydrogen into a very noxious compound, called arsenuretted hydrogen gas. To prepare it, fuse in a covered crucible 3 parts of granulated tin, and 1 of metallic arsenic in powder; and submit this alloy, broken in pieces, to the action of muriatic acid in a glass retort. On applying a moderate heat, the arsenuretted hydrogen comes over, and may be received in a second discount of the compound of the compoun may be received in a mercurial or water pneumatic trough. Protomuriate of tin remains in the retort.

A prime equivalent of hydrogen is to one of arsenic as 1 to 76; and 2 consequently as 1 to 38. Gehlen fell a victim to his researches on this gas; and therefore the new experiments requisite to elucidate its constitution must be conducted with circumspection. It extinguishes flame, and instantly destroys animal life. Water has no effect upon it. From the experiments of Sir H. Davy, and Gay Lussac and Thenard, there appears to be a solid compound of hydrogen and arsenic, or a hydruret. It is formed by acting with the negative pole of a voltage battery on arsenic plunged negative pole of a voltaic battery on arsenic plunged in water. It is reddish brown, without lustre, taste, and smell. It is not decomposed at a heat approaching to cherry-red; but at this temperature it absorbs oxy gen; while water and arsenious acid are formed, with the evoluton of heat and light. The proportion of the two constituents is not known.

Arsenic is used in a variety of arts. It enters into metallic combinations, wherein a white colour is required. Glass manufacturers use it; but its effect in the composition of glass does not seem to be clearly explained. Orpiment and realgar are used as pig-ments."

Arsenic and its various preparations are the most active of all poisons. That which is mostly taken, is the white oxyde, or arsenious acid. See Arsenious acid.

[Arsenical pyrites, or arsenical iron, is found in the Highlands of New-York, on the west side of the Hudson. In the town of Warwick, in Orange county, of this state, there is a huge vein of it in a mountain range, sufficient, as is said by a traveller, to poison the whole world. (A.)

the whole world. [A.]

ARSENIC ACID. Acidum arsenicum; Acidum arsenicale. "We are indebted to the illustrious Scheele for the discovery of this acid, though Macquer had before noticed its combinations. It may be obtained by various methods. If six parts of nitric acid be poured on one of the concrete arsenious acids, or white arsenic of the shops, in the pneumato-chemical apparatus, and heat be applied, nitrous gas will be evolved, and a white concrete substance, differing in its properties from the arsenious acid, will remain in the retort. This is the arsenic acid. It may equally be procured by means of aqueous chlorine, or by heating concentrated nitric acid with twice its weight of the solution of the arsenious acid in muriatic acid. The concrete acid should be exposed to a duil red heat for a few minutes. In either case an acid is obtained, that does not crystallize, but attracts the moisture of the air, has a sharp, caustic taste, reddens blue vegetable colours, is fixed in the fire, and of the specific gravity of 3 391.

If the arsenic acid be exposed to a red heat in a glass retort, it melts and becomes transparent, but assumes a milky hue on cooling. If the heat be increased, so that the retort begins to melt, the acid boils, and sublimes into the neck of the retort. If a covered crucible be used instead of the glass retort, and a vio-

into the air like a flash of lightning, which is so bright lent heat applied, the acid boils strongly, and in a set to dazzle the eye.

quarter of an hour begins to emit fumes. These, on being received in a glass bell, are found to be arsenious acid; and a small quantity of a transparent glass, difficult to fuse, will be found lining the sides of the crucible. This is arseniate of alumina.

Combustible substances decompose this acid. If two parts of arsenic acid be mixed with about one of charcoal, the mixture introduced into a glass retort, coated, and a matrass adapted to it; and the retort then gradually heated in a reverberatory furnace, till the bottom is red; the mass will be inflamed violently. the bottom is red; the mass will be inflamed violently, and the acid reduced, and rise to the neck of the

and the acid reduced, and rise to the neck of the retort in the metallic state, mixed with a little oxyde and charcoal powder. A few drops of water, devoid of acidity, will be found in the receiver.

With sulphur the phenomena are different. If a mixture of six parts of arsenic acid, and one of pow dered sulphur, be digested together, no change will take place: but on evaporating to dryness, and distilling in a glass refort, fitted with a receiver, a violent ling in a glass retort, fitted with a receiver, a violent combination will ensue, as soon as the mixture is sufficiently heated to melt the sulphur. The whole mass rises almost at once, forming a red sublimate, and sulphurous acid passes over into the receiver.

If pure arsenic acid be diluted with a small quantity of water, and hydrogen gas, as it is evolved by the action of sulphuric acid on iron, be received into this transparent solution, the liquor grows turbid, and a blackish precipitate is formed, which, being well washed with distilled water, exhibits all the phenomena of arsenic. Sometimes, too, a blackish-gray oxyde of arsenic is found in this process.

If sulphuretted hydrogen gas be employed instead of simple hydrogen gas, water and a sulphuret of arsenic are obtained.

senic are obtained.

With phosphorus, phosphoric acid is obtained, and a

phosphuret of arsenic, which sublimes.

The arsenic acid is much more soluble than the arsenious. According to Lagrange, two parts of water are sufficient for this purpose. It cannot be crystallized by any means; but, on evaporation, assumes a thick honey-like consistence.

No acid has any action upon it: if some of them dissolve it by means of the water that renders them fluid, they do not produce any alteration in it. boracic and phosphoric are vitrifiable with it by means of heat, but without any material alteration in their natures. If phosphorus acid be heated upon it for some time, it saturates itself with oxygen, and becomes phosphoric acid.

The arsenic acid combines with the earthy and alkaline bases, and forms salts very different from those

furnished by the arsenious acid.

All these arseniates are decomposable by charcoal, which separates arsenic from them by means of heat. All its salts, with the exception of those of potassa, soda, and ammonia, are insoluble in water; but except arseniate of bismuth, and one or two more, very soluble in an excess of arsenic acid. Hence, after barytes or oxyde of lead has been precipitated by this acid, its further addition re-dissolves the precipitate. This is a useful criterion of the acid, joined to its reduction to the metallic state by charcoal, and the other characters already detailed. Sulphuric acid decomposes the arseniates at a low temperature, but the sulphates are decomposed by arsenic acid at a red heat, owing to the greater fixity of the latter. Phosphoric, nitric, muriatic, and fluoric acids, dissolve, and probably convert into subsalts all the arseniates. The whole of them, as well as arsenic acid itself when decomposed at a red heat by charcoal, yield the characteristic garlic smell of the metallic vapour. Nitrate of silver gives a pulverulent brick-coloured precipitate, with arsenic acid. The acid itself does not disturb the transparency of a solution of sulphate of copper; but a neutral arseniate gives with it a bluish green precipitate; with sulphate of cobalt, a dirty red; and with sulphate of nickel, an apple-green precipitate. These precipitates redissolve, on adding a small quantity of the acid which previously held them in solution. Orfila says, that arsenic acid gives, with acetate of copper, a bluish-white precipitate, but that it exercises no action either on the muriate or acetate of cobalt; but with the ammonio-muriate, it gives a rose-coloured them, as well as arsenic acid itself when decomposed but with the ammonio-muriate, it gives a rose-coloured precipitate. Arsenic acid ought to be accounted a more violent poison than even the arsenious.

by sulphuric acid, which precipitates a sulphate of

The bin-arseniate of potassa is made on the great scale in Saxony, by fusing together equal parts of nitre and arsenious acid; dissolving the melted mass, and

of the arseniate of strontian nothing is known, but no doubt it resembles that of barytes.

With lime-water this acid forms a precipitate of arseniate of lime, soluble in an excess of its base, or in an excess of its acid, though insoluble alone. The acidulous arseniate of lime affords on evaporation little crystals, decomposable by sulphuric acid. The same salt may be formed by adding carbonate of lime to the solution of arsenic acid. This acid does not decompose the nitrate or muriate of lime: but the saturated alkaline arseniates decompose them by double affinity, precipitating the insoluble calcareous arseniate.

If arsenic acid be saturated with magnesia, a thick substance is formed near the point of saturation. This arseniate of magnesia is soluble in an excess of acid; and on being evaporated takes the form of a jelly, with-

and on being evaporated takes the form of a jelly, without crystallizing. Neither the sulphate, nitrate, nor muriate of magnesia is decomposed by arsenic acid, though they are by the saturated alkaline arseniates.

Arsenic acid, saturated with potassa, does not easily crystallize. This arseniate, being evaporated to dryness, attracts the humidity of the air, and turns the syrup of violets green, without altering the solution of litmus. It fuses into a white glass, and with a strong fire is converted into an acidule, part of the alkali being abstracted by the silex and alumina of the crucible. If exposed to a red heat with charcoal in close vessels, it swells up very much, and arsenic is sublimed. It is it swells up very much, and arsenic is sublimed. It is decomposed by sulphuric acid; but in the humid way the decomposition is not obvious, as the arsenic acid remains in solution. On evaporation, however, this acid and sulphate of potassa are obtained.

If arsenic acid be added to the preceding salt, till it ceases to have any effect on the syrup of violets, it will redden the solution of litmus; and in this state it redden the solution of litmus; and in this state it affords very regular and very transparent crystals, of the figure of quadrangular prisms, terminated by two tetraedral pyramids, the angles of which answer to those of the prisms. These crystals are the arsenical neutral salt of Macquer. As this salt differs from the preceding arseniate by its crystallizability, its reddening solution of litmus, its not decomposing the calcareous and magnesian salts like it, and its capability of absorbing an additional portion of potassa, so as to become neutral, it ought to be distinguished from it by

With soda in sufficient quantity to saturate it, arsenic acid forms a salt crystallizable like the acidulous arseniate of potassa. To form the neutral arseniate, nic acid forms a salt crystallizable like the acidulous arseniate of potassa. To form the neutral arseniate, carbonate of soda should be added to the acid, till the mixture be decidedly alkaline. This salt crystallizes from the concentrated solution. It is much more soluble in hot than in cold water. Pelletier says, that the crystals are hexaëdral prisms, terminated by planes perpendicular to their axis. This neutral arseniate of soda, however, while it differs completely from that of potassa in this respect, and in becoming deliquescent instead of crystallizable on the addition of a surplus portion of arsenic acid, resembles the arseniate of potassa in its decomposition by charcoal, by acids, and by the earths. by the earths.

Combined with ammonia, arsenic acid forms a salt affording rhomboidal crystals analogous to those of the

nitrate of soda.

The arseniate of soda and ammonia is formed by mixing the two separate arseniates; and the compound salt gives crystals with brilliant faces. If we redissolve the crystals, and then recrystallize, we should add a little ammonia, otherwise the salt will be acidulous from the escape of some ammonia.

Arsenic acid saturated with alumina forms a thick solution, which, being evaporated to dryness, yields a salt insoluble in water, and decomposable by the sulphuric, nitric, and muriatic acids, as well as by all the other earthy and alkaline bases. The arsenic acid readily dissolves the alumina of the crueibles is which readily dissolves the alumina of the crucibles in which It is reduced to a state of fusion; and thus it attacks silex also, on which it has no effect in the humid way.

By the assistance of a strong fire, as Fourcroy

The arseniate of barytes is insoluble, uncrystalliza- asserts, arsenic acid decomposes the alkaline and ble, soluble in an excess of its acid, and decomposable earthy sulphates, even that of barytes; the sulphuric earthy sulphates, even that of barytes; the sulphuric earthy surphases, even that of barytes; the surpharic acid flying off in vapour, and the arseniate remaining in the retort. It acts in the same manner on the nitrate, from which it expels the pure acid. It likewise decomposes the muriates at a high temperature, the muriatic acid being evolved in the form of gas, and the arsenic acid combining with their bases, which it saturates; while the arsenious acid is too volatile to have this effect. It acts in the same manner on the fluates, and still more easily on the carbonates, with which, by the assistance of heat, it excites a brisk on any of the neutral salts, except the sulphate of po-tassa and soda, the nitrate of potassa, and the muriates of soda and ammonia, and this by means of heat. It does not act on the phosphates, but precipitates the boracic acids from solutions of boracs when heated.

Arsenic acid does not act on gold or platina; neither does it on mercury or silver, without the aid of a strong heat; but it oxydizes copper, iron, lead, tin, zinc, bismuth, antimony, cobalt, nickel, manganese, and ar-

This acid is not used in the arts, at least directly, though indirectly it forms a part of some compositions used in dying. It is likewise one of the mineralizing acids combined by nature with some of the metallic

oxydes."—Ure's Chem. Dict.

Arsenic, oxyde of. See Arsenious acid.

Arsenic, white. See Arsenious acid.

Arse'NICAL CAUSTIC. A species of caustic said to possess useful properties, independent of those of destroying morbid parts to which it is applied. It is composed of two parts of levigated antimony to one of white arsenic. This is the caustic so extensively employed under the name of arsenical caustic, by the late

Mr Justamond, in his treatment of cancers.

[Arsenic is a powerful, a dangerous, and yet a valuable caustic. Small tumours, excrescences, warts, &c., may be easily and safely removed by it. Alone, it gives much pain; and in large quantities, and applied to an extensive surface, is extremely dangerous. Its painful action may be modified and more safely applied by mixing one part of white arsenic with one of powdered opium, and two of lapis calaminaris. A.]

ARSENICA'LIS LIQUOR. Arsenical solution. Take of sublimed oxyde of arsenic, in very fine powder, sub-carbonate of potassa from tartar, of each 64 grains; distilled water a pint. Boil them together in a glass vessel, until the arsenic be entirely dissolved. When the solution is cold, add compound spirit of lavender, four fluid drachms. Then add as much distilled water as may exactly fill a pint measure. This preparation accords with the formula of Dr. Fowler, of Stafford, who first introduced it in imitation of a celebrated popular remedy for intermittents, sold under the name of the tasteless ague-drop. The compound spirit of !avender is only intended to give some colour and of ravender is only intended by the more liable to mis-takes. Where the dose is small, and the effects so powerful, the most minute attention to its proportion and preparation becomes necessary. Each ounce contains four grains of the oxyde, and each drachm half a grain; but it will rarely be proper to go beyond one-sixteenth of a grain as a dose.

Arsenical solution. See Arsenicalis liquor.

Arsenici oxydum præparatum. See Arsenici oxy-

dum sublimatum.

Arsenicum album. Arsenici ozydum sublimatum; Arsenici oxydum praparatum. Reduce white arsenic into powder, then put it into a crucible and expose it to the fire, so as to sublime it into another crucible inthe arsenic more pure.

White arsenic. See Arsenious verted over the former. This is intended to render

ARSENICUM CRYSTALLINUM. See Arsenious acid. ARSE NIOUS ACID. White arsenic. Oxyde of arsenic. Arsenicum crystallinum, risigallum, aquala, arfar, aquila, zarnick, artaneck. Rat's bane. earliest chemists were embarrassed in the determination of the nature of the poisonous white substance known in commerce by the name of white arsenic, "Fourcroy was the first who distinguished by this name the white arsenic of the shops, which Scheele had proved to be a compound of the metal arsenic with

oxygen, and which the authors of the new chemical nomencelature had consequently termed oxyde of arsenic. As, however, it manifestly exhibits the properties of an acid, it has a fair claim to the title; for nic. As, however, it manifestly exhibits the proper-ties of an acid, it has a fair claim to the title; for many oxydes and acids are similar in this, that both consist of a base united with oxygen, and the only dif-ference between them is, that the compound in which the acid properties are manifest is termed an acid, and that in which they are not is called an oxyde.

This acid, which is one of the most virulent poisons known, frequently occurs in a native state, if not very abundantly; and it is obtained in roasting several ores, particularly those of cobalt. In the chimneys of the furnaces where this operation is conducted, it generally nerally condenses in thick semitransparent masses; though sometimes it assumes the form of a powder, or of little needles, in which state it was formerly called

flowers of arsenic.

The arsenious acid reddens the most sensible blue vegetable colours, though it turns the syrup of violets green On exposure to the air it becomes opaque, and covered with a slight efflorescence. Thrown on incan-descent coals, it evaporates in white fumes, with a strong smell of garlic. In close vessels it is volati-lized; and, if the heat be strong, vitrified. The result of this vitrification is a transparent glass, capable of crystallizing in tetraedra, the angles of which are truncated. It is easily altered by hydrogen and car-bon, which deprive it of its oxygen at a red heat, and reduce the metal, the one forming water, the other car-bonic acid with the oxygen taken from it; as it is by phosphorus, and by sulphur, which are in part converted into acids by its oxygen, and in part form an arsenical phosphuret or sulphuret with the arsenic reduced to the metallic state. Hence Margraaf and Pelletier, who particularly examined the phosphurets of metals, assert they might be formed with arsenious acid. Its specific gravity is 3.7.

It is soluble in thirteen times its weight of boiling water, but requires eighty times its weight of cold. The solution crystallizes, and the acid assumes the form of regular tetraédrons, according to Fourcroy; but, according to Lagrange, of octaédrons, and these frequently varying in figure by different laws of decrement. It crystallizes much better by slow evaporation

than by simple cooling.

The solution is very acrid, reddens blue colours, unites with the earthy bases, and decomposes the allca-line sulphurets. Arsenious acid is also soluble in oils, spirits, and alkohol; the last taking up from 1 to 2 per cent. It is composed of 9.5 of metal = 3 oxygen; and its prime equivalent is therefore 12.5. Dr. Wollaston first observed, that when a mixture of it with quicklime is heated in a glass tube, at a certain temperature, ignition suddenly pervades the mass, and metallic arse-nic sublimes. As arseniate of line is found at the bottom of the tube, we perceive that a portion of the arsenious acid is robbed of its oxygen, to complete the acidification of the rest.

There are even some metals, which act upon the solution, and have a tendency to decompose the acid so as to form a blackish precipitate, in which the arsenic

is very slightly oxydized.

The action of the other acids upon the arsenious is very different from that which they exert on the metal portion of it, which is precipitated as the solution cools. The nitric acid does not dissolve it, but by the help of heat converts it into arsenic acid. Neither the phosphoric nor the carbonic acid acts upon it; yet it enters into a vitreous combination with the phosphoric and boracic acids. The muriatic acid dissolves it by means of heat, and forms with it a volatile compound, which water precipitates; and aqueous chlorine aci-difies it completely, so as to convert it into arsenic

The arsenious acid combines with the earthy and alkaline bases, forming Arsenites. The earthy arseniates possess little solubility; and hence the solutions of barytes, strontian, and lime, form precipitates with

that of arsenious acid.

This acid enters into another kind of combination with the earths, that formed by vitrification. Though a part of this volatile acid sublimes before the glass enters into fusion, part remains fixed in the vitrified substance, to which it imparts transparency, a homogeneous density, and considerable gravity. The arse-

of quickly growing dull by exposure to the air.

With the fixed alkalies the arsenious acid forms thick arsenites, which do not crystallize; which are decomposable by fire, the arsenious acid being volati-lized by the heat; and from which all the other acids precipitate this in powder. These saline compounds were formerly termed livers, because they were sup-posed to be analogous to the combinations of sulphur with the alkalies.

With ammonia it forms a salt capable of crystallization. If this be heated a little, the ammonia is decomposed, the nitrogen is evolved, while the hydrogen, uniting with part of the oxygen of the acid, forms

Neither the earthy nor alkaline assenites have yet been much examined; what is known of them being only sufficient to distinguish them from the arseniates

The arsenious acid is used in numerous instances in the arts, under the name of white arsenic, or of arsenic simply. In many cases it is reduced, and acts in

its metallic state.

Many attempts have been made to introduce it into medicine; but as it is known to be one of the most violent poisons, it is probable that the fear of its bad effects may deprive society of the advantages it might afford in this way. An arseniate of potassa was extensively used by the late Dr. Fowler, of York, who published a treatise on it, in intermittent and remittent fevers. He likewise assured the writer, that he had found it extremely efficacious in periodical headache, and as a tonic in nervous and other disorders; and that he never saw the least ill effect from its use, due precaution being employed in preparing and adminis-tering it. Externally it has been employed as a caustic to extirpate cancer, combined with sulphur, with bole, with antimony, and with the leaves of crowfoot; but it always gives great pain, and is not unattended with danger. Febvre's remedy was water one pint, extract of hemlock 3j. Goulard's extract 5ij, tincture of opium 3j, arsenious acid gr. x. With this the cancer was wetted morning and evening; and at the same time a small quantity of a weak solution was administered internally. A still milder application of this kind has been made from a solution of one grain in a quart of water formed into a possible with group of quart of water, formed into a poultice with crumb of bread.

It has been more lately used as an alterative with advantage in chronic rheumatism. The symptoms which show the system to be arsenified are thickeess, redness, and stiffness of the palpebra, soreness of the gums, ptyalism, itching over the surface of the body, restlessness, cough, pain at stomach, and headache. When the latter symptoms supervene, the administration of the medicine ought to be immediately suspended. It has also been recommended against chincough; and has been used in considerable doses with success, to counteract the poison of venomous servents.

Since it acts on the animal economy as a deadly poison in quantities so minute as to be insensible to the taste when diffused in water or other vehicles, it has been often given with criminal intentions and fatal effects. It becomes therefore a matter of the utmost importance to present a systematic view of the phenomena characteristic of the poison, its opera-

tion, and consequences,

tion, and consequences,

It is a dense substance, subsiding speedily after agitation in water. Dr. Ure found its sp. gr. to vary from 3.728 to 3.730, which is a little higher than the number given above: 72 parts dissolve in 1000 of boiling water, of which 30 remain in it, after it cools. Cold water dissolves, however, only 3-1000 or 1-10 of the preceding quantity. This water makes the syrup of violets green, and reddens litmus paper. Lime water gives a fine white precipitate with it of arsenite of lime, soluble in an excess of the arsenious solution: of lime, soluble in an excess of the arsenious solution; sulphuretted hydrogen gas, and hydrosulphuretted water, precipitate a golden yellow sulphuret of arsenic. By this means, 1-100000 of arsenious acid may be detected in water. This sulphuret dried on a filter, and heated in a glass tube with a bit of caustic po-tassa, is decomposed in a few minutes, and converted into sulphuret of potassa, which remains at the bot

ARS ARS

tom, and metallic arsenic of a bright steel lustre, which sublimes, coating the sides of the tube. The hydrosulphurets of alkalies do not affect the arsenious solution, unless a drop or two of nitric or muriatic solution, unless a drop of two of name or muriane acid be poured in, when the characteristic golden yellow precipitate falls. Nitrate of silver is decomposed by the arsenious acid, and a very peculiar yellow arsenite of silver precipitates; which, however, is apt to be redissolved by nitric acid, and therefore a very minute addition of ammonia is requisite. Even this, however, also if in much average redissolves the silver however, also, if in much excese, redissolves the silver

As the nitrate of silver is justly regarded as one of the best precipitant tests of arsenic, the mode of using it has been a subject of much discussion. This excellent test was first proposed by Mr. Hume of Long Acre, in May 1809. Phil. Mag. xxxiii. 401. The pre-sence of muriate of soda indeed, in the arsenical solution, obstructs, to a certain degree, the operation of this reagent. But that salt is almost always present in the prime vie, and is a usual ingredient in soups, and other vehicles of the poison. If, after the water of ammonia has been added, (by plunging the end of a glass rod dipped in it into the supposed poisonous liquid,) we dip another rod into a solution of pure nitrate of silver, and transfer it into the arsenious solution, either a fine yellow cloud will be formed, or at first merely a white curdy precipitate. But at the second or third immersion of the nitrate rod, a central spot of yellow will be perceived surrounded with the white muriate of silver. At the next immersion, this yellow cloud on the surface will become very conspicuous. Sulphate of soda does not interfere in the least with the silver test.

The ammoniaco-sulphate, or rather ammoniacoacetate of copper, added in a somewhat dilute state to an arsenious solution, gives a fine grass-green and a very characteristic precipitate. This green arseniate of copper, well washed, being acted on by an excess of sulphuretted hydrogen water, changes its colour, and becomes of a brownish-red. Ferro-prussiate of potasea changes it into a blood-red. Nitrate of silver converts it into the yellow arsenite of silver.

Lastly, if the precipitate be dried on a filter, and placed on a bit of burning coal, it will diffuse a garlic odour. The cupreous test will detect 1-110000 of the

weight of the arsenic in water.

The Voltaic battery, made to act by two wires on a little arsenious solution placed on a bit of windowglass, developes metallic arsenic at the negative pole, and if this wire be copper, it will be whitened like

We may here remark, however, that the most elegant mode of using all these precipitation reagents is upon a plane of glass; a mode practised by Dr. Wo! laston in general chemical research, to an extent, and with a success, which would be incredible in other hands than his. Concentrate by heat in a capsule the suspected poisonous solution, having previously filtered it if necessary. Indeed, if it be very much disguised with animal or vegetable matters, it is better first of all to evaporate to dryness, and by a few drops of nitric acid to dissipate the organic products. clear liquid being now placed in the middle of the bit of glass, lines are to be drawn out from it in different directions. To one of these a particle of weak ammo-niacal water being applied, the weak nitrate of silver may then be brushed over it with a hair pencil. By placing the glass in different lights, either over white paper or obliquely before the eye, the slightest change of tint will be perceived. The ammoniaco-acetate should be applied to another filament of the drop, deutacetate of iron to a third, weak ammoniaco-acetate of cobalt to a fourth, sulphuretted water to a fifth, lime water to a sixth, a drop of violet-syrup to a seventh, and the two galvanic wires at the opposite edges of the whole. Thus with one single drop of solution many

exact experiments may be made.

But the chief, the decisive trial or experimentum crusis remains, which is to take a little of the dey matter, mix it with a small pinch of dry black flux, put it into a narrow glass tube sealed at one end, and after cleaning the interest of the control of the design of the control of the design of the control of the after cleansing its sides with a feather, urge its bottom with a blow-pipe till it be distinctly red-hot for a

tom. Cut the tube across at that point by means of & fine file, detach the scale of arsenic with the point of a penknife; put a tragment of it into the bottom of a small wine-glass along with a few drops of ammoniaco-acctate of copper, and triturate them well together for a few minutes with a round-headed glass rod. The mazarine blue colour will soon be transmuted into a lively grass-green, while the metallic scale will vanish. Thus we distinguish perfectly between a particle of metallic arsenic and one of animalized charcoal. Another particle of the scale may be placed be-tween two smooth and bright surfaces of copper, with a touch of fine oil; and while they are firmly pressed together, exposed to a red-heat. The tombac alloy will appear as a white stain. A third particle may be placed on a bit of heated metal, and held a little under the nostrils, when the garlic odour will be recognised. No danger can be apprehended, as the fragment need not exceed the tenth of a grain.

It is to be observed, that one or two of the precipi-

tation tests may be equivocal from admixtures of various substances. Thus tincture of ginger gives with the cupreous reagent a green precipitate;—and the writer of this article was at first led to suspect from that appearance, that an empirical tincture, put into his hands for examination, did contain arsenic. But a careful analysis satisfied him of its genuineness. Tea covers arsenic from the cupreous test. Such poisoned tea becomes, by its addition, of an obscure olive or violet red, but yields scarcely any precipitate. Sulphuretted hydrogen, however, throws down a fine

yellow sulphuret of arsenic.

The true way of obviating all these sources of fallacy, is to evaporate carefully to dryness, and expose the residue to heat in a glass tube. The arsenic sublimes, and may be afterward operated on without ambiguity. M. Orlia has gone into ample details on the modifications produced by wine, coffee, tea, broth, &c. on arsenical tests, of which a good tabular abstract is given in Mr. Thomson's London Dispensatory. But it is evident that the differences in these menstrua, as also in beers, are so great as to render precipitations and changes of colour by reagents very unsatisfactory witnesses, in a case of life and death. Hence the method of evaporation above described should never be neglected. Should the arsenic be combined with oil, the mixture ought to be boiled with water, and the oil then ecparated by the capillary action of wick-threads. If with resinous substances, these may be removed by oil of turpentine, not by alkohol, (as directed by Dr. Black,) which is a good solvent of arsenious acid. It may moreover be observed, that both tea and coffee should be freed from their tannin by gelatin, which should be freed from their tannin by gelatin, which does not act on the arsenic, previous to the use of reagent for the poison. When one part of the arsenious acid in watery solution is added to ten parts of milk, the sulphuretted hydrogen present in the latter, occasions the white colour to pass into a canary yellow; the cupreous test gives it a slight green tint, and the nitrate of silver produces no visible change, though even more arsenic be added; but the hydrosulphurets throw down a golden yellow, with the aid of a few drops of an acid. The liquid contained in the stomach of a rabbit poisoned with a solution of three grains of of a rabbit phisothesis arsenious acid, afforded a white precipitate with ni-trate of silver, grayish-white with lime water, green with the ammoniaco-sulphate, and deep yellow with sulphuretted hydrogen water.

The preceding copious description of the habitudes of arsenious acid in different circumstances, is equally applicable to the soluble arsenites. Their poisonous operation, as well as that of the arsenic acid, has been satisfactorily referred by Mr. Brodie to the suspension of the functions of the heart and brain, occasioned by the absorption of these substances into the circulation, and their constant determination to the nervous system and the alimentary canal. This proposition was established by numerous experiments on rabbits and dogs. Wounds were inflicted, and arsenic being apdogs. pited to them, it was found that in a short time death supervened with the same symptoms of inflammation of the stomach and bowels, as if the poison had been swallowed.

He divides the morbid affections into three classes: minute. Then garlic fumes will be smelt, and the steel-lustred coating of metallic arsenic will be seen in the tube about one-fourth of an inch above its bot-

ARS ARS

and general insensibility: 2d, Those which indicate disturbance in the organs of circulation; for example, the teeble, slow, and intermitting pulse, weak con-tractions of the heart immediately after death, and the impossibility of prolonging them, as may be done in sudden deaths from other causes, by artificial respiration: 3d, Lastly, those which depend on lesion of the alimentary canal, as the pains of the abdomen, nauseas, and vomitings, in those animals which were suf-fered to vomit. At one time it is the nervous system that is most remarkably affected, and at another the organs of circulation. Hence inflammation of the stomach and intestines, ought not to be considered as the immediate cause of death, by the greater number of cases of poisoning by arsenic. However, should an animal not sink under the first violence of the poison, if the inflammation has had time to be developed, there is no doubt that it may destroy life. states, that a woman who had taken arsenic resisted the alarming symptoms which at first appeared, but died on the fourth day. On opening her body the mu-cous membrane of the stomach and intestines was ulcerated to a great extent. Authentic cases of poison are recorded, where no trace of inflammation was

The effects of arsenic have been graphically represented by Dr. Black: 'The symptoms produced by a dangerous dose of arsenic begin to appear in a quarter by an hour, or not much longer, after it is taken. First sickness, and great distress at stomach, soon followed by thirst, and burning heat in the bowels. Then come on violent vomiting and severe colic pains, and excessive and painful purging. This brings on faintings, with cold sweats, and other signs of great debility. To this succeed painful cramps, and contractions of the legs and thighs, and extreme weakness, and death.' Similar results have followed the incautious sprink-Similar results have followed the incautious sprinkling of schirrous ulcers with powdered arsenic, or the
application of arsenical pastes. The following more
minute specification of symptoms is given by Orfila:
'An austere taste in the mouth; frequent ptyalism;
continual spitting; constriction of the pharynx and
asophagus; teeth set on edge; hiccups; nausea;
vomiting of brown or bloody matter; anxiety; frequent fainting fits; burning heat at the precordia; inflammation of the lips, tongue, palate, throat, stomach;
acute pain of stomach, rendering the mildest drinks
intolerable: black stools of an indescribable foctor: intolerable; black stools of an indescribable fætor; pulse frequent, oppressed, and irregular, sometimes slow and unequal; palpitation of the heart; syncope; unextinguishable thirst; burning sensation over the whole body, resembling a consuming fire; at times an icy coldness; difficult respiration; cold sweats; scanty urine, of a red or bloody appearance; altered expression of countenance; a livid circle round the eyelids; swelling and itching of the whole body, which becomes covered with livid spots, or with a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium, convulsions, sometimes accompanied with an insupportable priapism; loss of the hair; separation of the epidermis; horrible convulsions; and death.

It is uncommon to observe all these frightful symppulse frequent, oppressed, and irregular, sometimes

It is uncommon to observe all these frightful symptoms combined in one individual; sometimes they are altogether wanting, as is shown by the following case, related by M. Chaussier:—A robust man of middle age swallowed arsenious acid in large fragments, and died without experiencing other symptoms than slight died without experiencing other symptoms than slight syncopes. On opening his stomach, it was found to contain the argenious acid in the very same state in which he had swallowed it. There was no appearance whatever of crossion or inflammation in the intestinal canal. Ethicaller mentions a young girl's being poisoned by arsenic, and whose stomach and bowels were sound to all appearance, though the arsenic was found in them. In general, however, inflammation does extend along the whole canal, from the mouth to the rectum. The stomach and dwodenum present the rectum. The stomach and diodenum present frequently gangrenous points, eschars, perforations of all their coats; the villous coat in particular, by this and all other corrosive poisons, is commonly detached, as if it were scraped off or reduced into a paste of a reddish-brown colour. From these considerations we may conclude, that from the existence or non-existence of intestinal lesions, from the extent or seat of the symptoms alone, the physician should not venture to pronounce definitively on the fact of poisoning. The stomach and duodenum present the rectum.

The result of Mr. Brodie's experiments on brutes teaches, that the inflammations of the intestines and stomach are more severe when the poison has been applied to an external wound, than when it has been thrown into the stomach itself.

The best remedies against this poison in the sto-mach, are copious draughts of bland liquids of a muci laginous consistence, to inviscate the powder, so as to procure its complete ejection by vomiting. Sul-phuretted frydrogen condensed in water, is the only direct antidote to its virulence; Orfila having found, that when dogs were made to swallow that liquid, after getting a poisonous dose of arsenic, they recovered, though their æsophagus was tied to prevent vomiting; but when the same dose of poison was administered in the same circumstances, without the sulphuretted water, that it proved fatal.

When the viscera are to be subjected after death to chemical investigation, a ligature ought to be thrown round the esophagus and the beginning of the colon, and the intermediate stomach and intestines removed. Their liquid contents should be emptied into a basin; and thereafter a portion of hot water introduced into the stomach, and worked thoroughly up and down this

viscus, as well as the intestines.

After filtration, a portion of the liquid should be concentrated by evaporation in a porcelain capsule, and then submitted to the proper reagents above de-We may also endeavour to extract from the scribed. We may also endeavour to extract from the stomach by digestion in boiling water, with a little ammonia, the arsenical impregnation, which has been sometimes known to adhere in minute particles with wonderful obstinacy. This precaution ought, therefore, to be attended to. The heat will dissipate the excess of ammonia in the above operation; whereas, by adding potassa or soda, as prescribed by the German chemists, we introduce animal matter in alkaline solution, which complicates the investigation.

The matters rejected from the patient's bowels before death, should not be neglected. These, generally speaking, are best treated by cautious evaporations to dryness; but we must beware of heating the residuum to 400°, since at that temperature, and perhaps a little under it, the arsenious acid itself sublimes.

Vinegar, hydroguretted alkaline sulphurets, and oils, are of no use as counterpoisons. Indeed, when the arsenic exists in substance in the stomach, even sulphuretted hydrogen water is of no avail, however effectually it neutralize an arsenious solution. Syrups, iinseed tea, decoction of mallows, or tragacanth, and warm milk, should be administered as copiously as possible, and vomiting provoked by tickling the fauces with a feather. Clysters of a similar nature may be also employed. Many persons have escaped death by having taken the poison mixed with rich soups; and it is well known, that when it is prescribed as a medicine, it acts most beneficially when given soon after a meal. These facts have led to the prescription of butter and oils; the use of which is, however, not adviseable, as they screen the arsenical particles from more proper menstrua, and even appear to aggravate its virulence. Morgagni, in his great work on the seats and causes of disease, states, that at an Italian feast the dessert was purposely sprinkled over with arsenic instead of flour. Those of the guests who had previously ate and drank little, speedily perished; those who had their stomachs well filled, were saved by vomiting. He also mentions the case of three children who ate a He also mentions the case of three children who are a vegetable soup poisoned with arsenic. One of them who took only two spoonfuls, had no vomiting, and died; the other two, who had eaten the rest, vomited, and got well. Should the poisoned patient be incapable of vomiting, a tube of caoutchouc, capable of being attached to a syringe, may be had recourse to. The tube first serves to introduce the drink, and to withdraw it after a few instants. withdraw it after a few instants.

The following tests of arsenic and corrosive subli-

The following tests of arsenic and corrosive sublimate have been lately proposed by Brugnatelli: Take the starch of wheat boiled in water until it is of a proper consistence, and recently prepared; to this add a sufficient quantity of iodine to make it of a blue colour; it is afterward to be diluted with pure water until it becomes of a beautiful azure. If to this, some drops of a watery solution of arsenic be added, the colour changes to a reddish hue, and finally vanishes. The solution of corrosive sublimate poured into indine The solution of corrosive sublimate poured into iodine and starch, produces almost the same change as

arsenic; but if to the fluid acted on by the arsenic we add some drops of sulphuric acid, the original blue colour is restored with more than its original brilliancy, while It does not restore the colour to the corrosive sublimate

mixture. - Ure's Chem. Dict.

ARTEMISIA. (From a queen of that name, who first used it; or from Apreus, Diana; because it was formerly used in the diseases of women, over whom she presided.) The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia superflua.

ARTEMISIA ABROTANUM. The systematic name for the Abrotanum of the pharmacopæias. Abrotanum mas; Adonion; Adonium; Abrathan. Common southernwood. Artemisia—foliis setaceis ramosissimis of Linnæus. A plant possessed of a strong, and, to most people, an agreeable smell; a pungent, bitter, and somewhat nauseous taste. It is supposed to stimulate the whole system, but more particularly the uterus. It is very rarely used unless by way of fomentation, with which intention the leaves are directed.

ARTEMISIA ABSINTHIUM. The systematic name for the Absinthium vulgare of the pharmacopaias. Common wormwood. Falsely called in our markets Absinthium Romanum, or Roman wormwood. Absinthium Ponticum of Dioscorides and Pliny, according to Murray. Artemisia—foliis compositis multifidis floribus subglobosis pendulis; receptaculo villoso of Linneus. This plant is a native of Britain, and grows about rubbish, rocks, and sides of roads. The leaves of wormwood have a strong disagreeable smell: their taste is nauseous, and so intensely bitter as to be proverbial. The flowers are more aromatic and less bitter than the leaves, and the roots discover an aromatic. verbial. The flowers are more aromatic and less bitter than the leaves, and the roots discover an aromatic warmth, without bitterness. This species of wormwood may be considered the principal of the herbaceous bitters. Its virtus, (in the words of Berglus,) is antiputredinosa, antacida, anthelmintica, resolvens, tonica, spasmodica. And although it is now chiefly employed with a view to the two last-mentioned qualities, yet we are tall of its rood officers in a great variety. ties, yet we are told of its good effects in a great variety of diseases, as intermittent fevers, hypochondriasis, obstructions of the liver and spleen, gout, calculi, scurvy, dropsy, worms, &c. Cullen thinks it is possessed of a narcotic power, and that there is in every bitter, when largely employed, a power of destroying the sensibility and irritability of the nervous system.

Externally, wormwood is used in discutient and antiseptic fomentations. This plant may be taken in powder, but it is more commonly preferred in infusion. The Edinburgh Pharmacopæia directs a tincture of the flowers, which is, in the opinion of Dr. Cullen, a light of diseases, as intermittent fevers, hypochondriasis,

flowers, which is, in the opinion of Dr. Cullen, a light and agreeable bitter, and, at the same time, a strong impregnation of the wormwood.

impregnation of the wormwood.

ARTEMISIA CHINENSIS. Mugwort of China. Moza
Japonica; Musia pattræ. A soft lanuginous substance, called Moza, is prepared in Japan, from the young leaves of this species of mugwort, by beating them when thoroughly dried, and rubbing them between the hands, till only the fine fibres are left.

Moxa is celebrated in the eastern countries for presenting and curing many disorders by being huming them. venting and curing many disorders, by being burnt on the skin; a little cone of it laid upon the part, previ-ously moistened, and set on fire on the top, burns down with a temperate and glowing heat, and produces a dark-coloured spot, the ulceration of which is promoted by putting a little garlic, and the ulcer is either healed up when the eschar separates, or kept running for a length of time, as different circumstances may require.

ARTEMISIA GLACIALIS. Mountain wormwood. This is found on Alpine situations, and has similar

Virtues to common wormwood.

ARTEMISIA JUDAICA. The systematic name for the

ARTEMISIA JUDAICA. The systematic name for the Santonicum of the pharmacopæias, according to some botanists. See Artemisia santonica.

ARTEMISIA MARITIMA. The systematic name for the Absinthium maritimum of the pharmacopæias. Sea wormwood. Falsely called in our markets, Ro-Sea wormwood. Falsely called in our markets, Roman wormwood. Artemisia—foliis multipartitis, tomentosis; racemis cernuis; flosculis famineis ternis of Linnaus. This plant grows plentifully about the sea-shore, and in salt marshes. The specific differences between it and the common wormwood, artemisia absinthium, are very evident. Its taste and smell are considerably less unpleasant than those of the common wormwood, and even the essential oil, which contains the whole of its flavour concentrated, is some-

what less ungrateful, and the watery extract some what less bitter than those of the common wormwood Hence it is preferred, in those cases where the Artemisia absinthum is supposed to be too unpleasant for the stomach. A conserve of the tops of this plant was directed by the London pharmacopaia.

ARTEMISIA FONTICA. The systematic name for the Absinthium ponticum, or Roman wormwood, not now used medicinally.

used medicinally.

ARTEMISIA RUPESTRIS. The systematic name for the Genipi album of the pharmacopæias. Artemisia—folis punnatis; caulitus adscendentibus; floribus globosis, cermuis; receptaculo papposo. It has a grateful smell, and is used in some countries in the cure of intermittents and obstructed catamenia.

ARTEMISIA SANTONICA. Absinthium santonicum Alezandrinum; Sementina; Absinthium seriphium Egyptium; Scheba Arabum; Zedoaria semen; Xantolina; Lumbricorum semina; Cina; Semen contra; Semen sanctum; Artemisia Judaica. The Tartarian southernwood or wormsend. Actoriciae Coline cauli southernwood or wormseed. Artemisia—folius caulinis linearibus, pinnato-multifidis; ramis indivisis; spicis secundis reflexis; floribus quinquefloris of Linnæus. The seeds are small, light, and oval, composed of a number of thin membraneous coats of a yellowishmoon solony with a seat of however carrier frights upon of a number of thin menoraneous coats of a yellowish-green colour, with a cast of brown, easily friable, upon being rubbed between the fingers, into a fine chaffy kind of substance. They are brought from the Levant; have a moderately strong and not agreeable smell, somewhat of the wormwood kind, and a very bitter subacrid taste. Their virtues are extracted both by watery and spirituous menstrua. They are esteemed to be stomachic, emmenagogue, and anthelmintic; but it is especially for the last-mentioned powers that they are now administered, and from their efficacy in this way they have obtained the name of wormseed. To adults the dose in substance is from one to two drachms, twice a day. Lewis thinks that the spiritudrachms, twice a day. Lewis thinks that the spiritu-ous extract is the most eligible preparation of the san-

tonicum, for the purposes of an anthelmintic.

Artemisia—foliis pinnatifidis, planis, incisis, subtus tomentosis; racemis simplicibus, recurvatis; floribus radio quinquefloro of Linnaus, is slightly bitter, and, although in high esteem in former days, is now almost

wholly forgotten.

ARTEMO NUM. (From Artemon, its inventor.) A collyrium, or wash for the eyes.

ARTERIA. (Arteria, ω. f.; from anp, air, and γορω, to keep; so called because the ancients believed they contained air only.) See Artery.

ARTERI'ACA. (From αρτηρια, an artery.)

cines formerly used against disorders of the aspera arteria, or trachea.

ARTERIE ADDOSE. The arteries which secrete the fat about the kidneys are so called. They are branches of the capsula and diaphragmatic, renal, and spermatic

ARTERIE VENOSE. The four pulmonary veins were

ARTERIA VENOSA. The four pulmonary veins were so called by the ancients.

ARTERIO'SUS DUCTUS. See Ductus arteriosus.

ARTERIO'TOMY. (Arteriotomia, x. f.; from aρτηρια, an artery, and τεμνω, to cut.) The opening of an artery. This operation is frequently performed on the temporal artery.

ARTERIA Arteria A membraneous pulsating

A'RTERY. Arteria. A membraneous pulsating canal, that arises from the heart and gradually becomes less as it proceeds from it. Arteries are composed of three membranes; a common, or external; a muscular; and an internal one, which is very smooth. They are only two in number, the pulmonary artery, and the aorta, and these originate from the heart; the pulmonary artery from the right ventricle, and the aorta from the left: the other arteries are all branches of the aorta. Their termination is either in the veins, or in capillary exhaling vessels, or they anastomose with one another. It is by their means that the blood with one another. It is by their means that the blood is carried from the heart to every part of the body, for nutrition, preservation of life, generation of heat, and the secretion of the different fluids. The action of the arteries, called the pulse, corresponds with that of the heart, and is effected by the contraction of their muscular, and great elasticity of their outermost coat.

A table of the Arteries.

All the arteries originate from the pulmonary artery and the aorta.

The pulmonary artery emerges from the right ven-tricle of the heart, soon divides into a right and left branch, which are distributed by innumerable ramifications through the lungs

The aarta arises from the left ventricle of the heart, and supplies every part of the body with blood, in the following order.

a. It forms an arch.

b. It then descends along the spine; and,

c. It divides into the two iliacs.
a. The ARCH OF THE AORTA gives off three branches.
1. The arteria innominata, which divides into the

right carotid and right subclavian.

2 The left carotid.

3. The left subclavian.

The carotids are divided into external and internal.

The external carotids give off

The thyroid, The lingual,

3. The labial,

4. The inferior pharyngeal, 5. The occipital,

6. The posterior auris,

7. The internal maxillary, from which the spinous artery of the dura mater, the lower maxillary, and several branches about the palate and orbit arise,

The temporal. The internal carotid affords, The ophthalmic, The middle cerebral,

3. The communicans, which inosculates with the ver-

II. The subclavians give off the following branches. The internal mammary, from which the thymic, comes phrenici, pericardiae, and phrenico-pericar-diae arteries arise,

ascending thyroid, which gives off the trackeal, ascending thyroid, and transversalis humeri,
3. The vertebral, which proceeds within the vertebræ, and forms within the cranium the basilary artery, from which the anterior cerebelli, the posterior cerebri, and many branches about the brain, are given

4. The cervicalis profunda, 5. The cervicalis superficialis,

6. The superior intercostal, 7. The supra-scapular.

As soon as the subclavian arrives at the arm-pit, it is called the axillary artery; and when the latter reaches the arm, it is called the brachial.

The axillary artery gives off,

1. Four mammary arteries,
2. The sub-scapular,
3. The posterior circumflex,
4. The anterior circumflex, which ramify about the shoulder-joint. The brachial artery gives off,

1. Many lateral branches, 2. The profunda humeri superior,

The profunda humeri inferior,

4. The great anastomosing artery, which ramifies

about the elbow-joint.

The brackial artery then divides, about the bend of the arm, into the ulnar and radial arteries, which are ramified to the ends of the fingers.

The ulnar artery gives off,

1. Several recurrent branches,

2. The common interesseal, of which the dorsal ulnar, the palmaris profunda, the palmary arch, and the digitals, are branches.
The radial artery gives off,

1. The radial artery gives oil,
1. The radial recurrent,
2. The superficialis volæ, and then divides into the palmaris profunda, and the digitals.
b. The descending agree off,

In the breast,

1 The bronchial, 2. The asophageal, 3. The intercostals,

The inferior diaphragmatic.

Within the abdomen,
The caliac, which divides into three branches:
1. The hepatic, from which are given off, before it reaches the liver,

a. The duodeno-gastric, which sends off the right gastro-epiploic and the pancreatico-duodenal,

β. The pylorica superior hepatica;

2. The coronaria ventricult;
3. The splenic, which emits the great and small pancreatics, the posterior gastric, the left gastroepiploic, and the vasa brevia;

The superior mesenteric,

The emulgents, The spermatics,

The inferior mesenteric, The lumbar arteries,

7. The middle sacral.

c. The aorta then bifurcates into the ILIACS, each of which divide into external and internal.

The internal iliac, called also hypogastric, gives off,

The lateral sacrals,

2. The gluteal,
3. The ischiatic,
4. The pudica, from which the external hamorrhoidal, the perineal, and the arteria penis arise,

The obturatory

The external iliae gives off, in the groin,

The epigastric,

2. The circumflexia iliaca;
It then passes under Poppart's ligament, and is called the femoral artery; and sends off,

The profunda,
 The ramus anastomoticus magnus, which rune

about the knee joint; Having reached the ham, where it gives off some small branches, it is termed the popliteal. It then divides into the anterior and posterior tibial.

The tibialis antica gives off,

The recurrent, The internal malleolar,

The external malleolar,

The tarsal,
The metatarsal,
The dorsalis externa halicis. The posterior tibial sends off,

The nutritia tibia,

1. The nutritia totic,
2. Many small branches,
3. The internal plantar,
4. The external plantar, from which an arch is formed, that gives off the digitals of the toes.

ARTHANITA. (From apros, bread; because it is the food of swine.) The herb sow-bread. See Cy-

clamen Europeum.

ARTHRE MBOLUS. (From a βρον, a joint, and εμβαλλω, to impel.) An instrument for reducing luxated

ARTHRITIC. (Arthriticus; from αρθριτις, the

arthritic. (Arthriticus; from aphperis, the gout.) Pertaining to the gout.

Arthritica herba. The Agopodium podagraria, and several other plants, were so called.

ARTHRITIS. (Arthritis, tidis, fæm.; from aphpov, a joint: because it is commonly confined to the joints.) The gout. Dr. Cullen, in his Nosology, gives it the name of podagra, because he considers the foot to be the seat of idiophatic gout. It is arranged in the class Preserve and order ablest training and is divided.

to be the seat of idiophatic gout. It is arranged in the class Pyrexiae, and order phlegnasiae, and is divided into four species, the regular, atonic, retrocedent, and misplaced. See Podagra.

ARTHROCA'CE. (From αρθων, a joint, and κακη, a disease.) An ulcer of the cavity of the bone.

ARTHRO'DIA. (Arthrodia, a. f.; from αρθροω, to articulate.) A species of diarthrosis, or moveable connexion of bones, in which the head of one bone is received into the superficial cavity of another, so as to admit of motion in every direction, as the head of the humerus with the glenoid cavity of the scapula.

ARTHRODY NIA. (Arthrodynia, a. f.; from αρ, θρον, a joint, and οδυνη, pain.) Pain in a joint. It is one of the terminations of acute rheumatism. See Rheumatismus.

ARTHROPUO'SIS. (Arthropuosis, is. f.; from aρθρον, a joint, and πυον, pus.) Arthropyosis. A collection of pus in a joint. It is however frequently applied to other affections. See Lumbar abscess.

ARTHROSIA. (Arthrosiæ; from αρθρον, to articulate: whence arthrosis, arthrites.) The name of a genus of disease in Good's new classification, which embraces thematism, gout, and white swelling. See

embraces rheumatism, gout, and white swelling. See

ARTHRO'SIS. (From αρθροω, to articulate, or join together.) Articulation.

ARTICHOKE. See Cinara scolymus.

Artichoke, French. See Cinara scolymus.

Artichoke, Jerusalem. See Helianthus tuberosus. ARTICUI.A'R. (Articularis; from articulus, a joint.) Belonging to a joint.

ARTICULARIS MORBUS. A name given to a disease which more immediately infests the articula, or joints. The morbus articularis is synonymous with the Greek word arthritis, and our gout.

ARTICULARIS VENA. A branch of the basilic vein is so called because it passes under the joint of the

ARTICULATION. (Articulatio; from articulus, a joint.) The skeleton is composed of a great number of bones, which are all so admirably constructed, and of bones, which are all so admirably constructed, and with so much affinity to each other, that the extremity of every bone is perfectly adjusted to the end of the bone with which it is connected: and this connexion is termed their articulation. Anatomists distinguish three kinds of articulation; the first they name Diarthrosis; the second, Synarthrosis; and the third, Amphiarthrosis; which see, under their respective heads

ARTICULA'TUS. Articulate; jointed. A term applied to roots, stems, leaves, &c., when they are apparently formed of distinct pieces united as if one parenty formed of disance pieces timed as if one piece grew out of another, so as to form a jointed, but connected whole; in the Radix articulata, radicals shoot out from each joint, as in the Oxalis acctocella, wood sorrel. The Caulis articulata is exemplified in the Cactus flagelliformis and Lathyrus sylvestris; the Cactus opuntia and Cactus ficus indica have articulate leaves. The Oxalis acctosella articulate leaf-

ARTICULUS. (From artus, a joint; from aρθρον.)

1. A joint. See Articulation.
2. Botanists apply this term to that part of the stalk of grasses which is intercepted, or lies between two

of grasses which is intercepted, or lies between two knots; and also to the knot itself.

ARTI'SCUS. (From αρτος, bread.) A troch; so called because it is made like a little loaf.

ARTO'CREAS. (From αρτος, bread, and κρεας, flesh.) A nourishing food, made of bread and various meats, boiled together.—Gales.

ARTO'GALA. (From αρτος, bread, and γαλα, milk.) A cooling food made of bread and milk. A poultice.

ARTO MELL. (From αρτος, bread, and μελει hones.)

Actometic (From apres, bread, and μελι, honey.)
A cataplasm made of bread and honey.—Gaten.
A'RUM. (Arum, in.; from the Hebrew word jaron, which signifies a dart; so named because its leaves are shaped like a dart; or apa, injury.) 1. The name of a genus of plants in the Linnaan system. Class, Gynandria; Order, Polyandria.

2. The pharmacopaial name of the common arum.

See Arum maculatum.

ARUM DRACUNCULUS. The systematic name of the plant called, in Engish, dragon's wort, and manyplant caned, in English, diagons wort, and many leaved arum; Dracinculus polyphyllus; Colubrina dracontia; Serpentaria gallorum; Erva de Sancta Maria; Gigarus terpentaria; Arum polyphyllum. The roots and leaves of this plant are extremely acri-

The roots and leaves of this plant are extremely acrimonious, more so than the Arum maculatum, with which it agrees in medicinal virtues.

Arum Maculatum. The systematic name for common arum, or wake-robin; the arum of the pharmacopæias. Arum—aeaule; foliis hastatis, integerrimis; spadice clavato of Linnaus. Common arum or wake-robin. The root is the medicinal part of this plant, which, when recent, is very acrimonious; and upon being chewed, excites an intolerable nious; and, upon being chewed, excites an intolerable mious; and, upon teing chewed, excites an intolerable sensation of burning and prickling in the tongue, which continues for several hours. When cut in slices and applied to the skin, it has been known to produce blisters. This acrimony, however, is gradually lost by drying, and may be so far dissipated by the application of heat, as to leave the root a bland farinaceous aliment. In this state it has been made into a wholesome bread. It has also been prepared as starch. Its medicinal quality, therefore, resides wholly starch. Its medicinal quality, therefore, resides wholly in the active volatile matter, and consequently the powdered root must lose much of its power, on being long kept. Arum is certainly a powerful stimulant, and, by promoting the secretions, may be advantage-ously employed in cachectic and chlorotic cases in rheumatic affections, and in various other complaints of phlegmatic and torpid constitutions; but more especially in a weakened or relaxed state of the stoof phlegmatic and torpid constitutions; but more especially in a weakened or relaxed state of the stomach, occasioned by the prevalence of viscid mucus. If this root is given in powder, great care should be called by reason of their minuteness.) An intercutary

taken that it be young and newly dried, when it may be used in the dose of a scruple, or more, twice a day; but in rheumatisms, and other disorders requiring the a recent state; and, to cover the insupportable pun-gency it discovers on the tongue, Dr. Lewis advises us to administer it in the form of emulsion, with gum-ara-bic and spermaceti, increasing the dose from ten grains to upwards of a scruple, three or four times a day. In this way, it generally occasioned a sensation of slight warmth about the stomach, and afterward, in the re-moter parts, manifestly promoted persulvation, and moter parts, manifestly promoted perspiration, and frequently produced a plentiful sweat. Several obsti-nate rheumatic pains were removed by this medicine. nate rheumatic pains were removed by this medicine. The root answers quite as well as garlic for cataplasms, to be applied on the feet in deliriums. The London College, in their Pharmacopæia, 1788, ordered a conserve, in the proportion of half a pound of the fresh root to a pound and a half of double refined sugar, beat together in a mortar, which appears to be one of the best forms of exhibiting arum, as its virtues are destroyed by drying, and are not extracted by any menstruum. It may be given to adults in doses of a drachm.

ARUNDINACEUS. (From arundo, a reed.) Arun-

dinaceous or reed-like.

ARUNDINACE & PLANTE. Arundinaceous plants. A name given to a class of plants by Ray, from their

Annue given to a class of plants by Ray, from their appearance.

ARUNDO. (Arundo, inis, f.; supposed to be derived from areo, because it soon becomes dry.) The name of a genus of plants in the Linnæan system. Class Triandria; Order, Digynia.

ARUNDO BAMBOS. The bamboo plant. The young

shoots of this plant are prepared by the natives of both shoots of this plant are prepared by the natives of both Indies with vinegar, garlic, pepper, &c. into excellent pickles, which promote the appetite and assist digestion. A substance called *Tabashcer* or *Tabachir*, which is a concretion of the liquor in the cavities of the cane, and extracted at certain seasons, is much esteemed as a medicine by the orientalists.

ARUNDO SACCHARIFERA. The name of the sugar-

cane. See Saccharum officinale.

ARYTÆ'NO. Belonging to the arytænoid cartilage. Some muscles are so named because they are connected with this cartilage: they have also the terminal name of the part they go to; as arytano-epi-

ARYTENO-EPIGLOTTIDEUS. A muscle of the epiglottis. Aryteno-Epiglottici of Winslow. It is composed of a number of fibres running between the arytenoid cartilage and epiglottis. It pulls the side of the epiglottis towards the external opening of the glottis, and when both act, they pull it close upon the

ARYTENOI'D. (Arytenoideus and Arytenoides; from apv7aiva, a funnel, and ados, shape.) The name of some parts, from their being funnel-shapped.

ARYTENOID CARTILAGE. Cartilago arytenoidea.

The name of two cartilages of the larynx. See La-

ARYTÆNOIDE'US. Applied to some muscles,

vessels, nerves, &c.
ARYTENOIDEUS MAJOR. See Arytenoideus trans-

ARYTHNOIDEUS MINOR. See Arytenoideus obli-

ARYTENOIDEUS OBLIQUUS. A muscle of the glottis.

Arytenoideus minor of Douglas. It arises from the base of one arytenoid cartilage, and crossing its fellow, is inserted near the up of the other arytenoid car-tilage. This muscle is occasionally wanting; but when present, and both muscles act, their use is to pull the arytenoid cartilages towards each other.

ARYTENOIDEUS TRANSVERSUS. An azygos or single muscle of the glottis. Arytenoideus major of Douglas. It arises from the side of one arytenoid cartilage from near its articulation with the cricoid to near its tip. The fibres run across, and are inserted in the same manner into the other arytamoid cartilage. Its use is to shut the glottis, by bringing the two arytamoid cartilages, with their ligaments, nearer to each other

ASARABACCA. See Asarum Europaum.

A'SARUM. (Asarum, i. n.; from a, neg. and σαιρω, to adorn; because it was not admitted into the ancient coronal wreaths.)

1. The name of a genus of the Lippean ancient coronal wreaths. plants in the Linnaan system. Class, Dodecandria; Order, Monogynia.

2. The pharmacopæial name of the asarabacca.

See Asarum Europæum.

ASARUM EUROPÆUM. The systematic name of the rustica; Asarum—foliis reniformibus, obtusis, binis of Linnæus. This plant is a native of England, but not very common. Its leaves are extremely acrid, and are occasionally used, when powdered, as a sternuta-tory. For this purpose, the leaves, as being less acrid than the roots, are preferred, and in moderate doses, not exceeding a few grains, snuffed up the nose, for several evenings, produce a pretty large watery dis-charge, which continues for several days together, by which beadache, toothache, contribution and some which headache, toothache, ophthalmia, and some paralytic and soporific complaints have been effectu-

ally relieved.

Prior to the introduction of ipecacuanha, the leaves and root of this plant were frequently employed on account of their emetic power: the dose of the dried leaves was 20 grains; of the dried roots 10 grains. As they were occasionally violent in their operation, they

have fallen into disuse.

Asarum hypocistis. A parasitical plant which grows in warm climates, from the roots of the Cistus. The juice, succus hypocistidis, is a mild astringent, of no particular smell nor flavour. It has fallen into

ASBESTOS. Asbestus. A mineral of which there are five varieties, all more or less flexible and fibrous. 1. Amianthus occurs in very long, fine, flexible, elastic fibres, of a white, greenish, or reddish colour. It is somewhat unctuous to the touch, has a silky or pearly lustre, and is slightly translucent. Sectile; tough;

sp. grav. from 1 to 2.3.

The ancients manufactured cloth out of the fibres of asbestos, for the purpose, it is said, of wrapping up the bodies of the dead, when exposed on the funeral pile. Several moderns have likewise succeeded in making this cloth, the chief artifice of which seems to consist in the admixture of flax and a liberal use of all the pile which substances are afterward consumed. consist in the admixture of hax and a liberal use of oil; both which substances are afterward consumed by exposing the cloth for a certain time to a red heat. Although the cloth of asbestos, when soiled, is restored to its primitive whiteness by heating in the fire, it is found, nevertheless, by several authentic experiments, that its weight diminishes by such treatment. The fibres of asbestos, exposed to the violent heat of the blow-pipe, exhibit slight indications of fusion; though the parts, instead of running together, moulder away. the parts, instead of running together, moulder away, and part fall down, while the rest seem to disappear before the current of air. Ignition impairs the flexibility of asbestos in a slight degree.

2. Common asbestos occurs in masses of fibres of a

dull greenish colour, and of a somewhat pearly lustre. Fragments splintery. It is scarcely flexible, and greatly denser than amianthus. It is more abundant than amianthus, and is found usually in serpentine, as at Portsoy, the Isle of Anglesea, and the Lizard in Cornwall. It was found in the limestone of Glentilt, by

with black heads.

Asa'Phia. (From a, neg. and σαφης, clear.) A defect in utterance or pronunciation

ASARABACCA. See Asarum Europaum.

wood. Internal lustre glimmering. Soft, sectile, and tough; opaque; feels meagre; fusible into a black slag. Sp. grav. 2.0. It is found in the Tyrol; Dauphiny; and in Scotland, at Glentilt, Portsoy, and Kildrumle.

ASCALON'TES. A species of onion.

ASCA'RIDES. The plural of ascaris.

A'SCARIS. (Ascaris, idis; from aske, to move about; so called from its continued troublesome motion.) The name of a genus of intestinal worms. There are several species of this genus. Those which belong to the human body are:—

1. Ascaris vermicularis, the thread or maw worm, which is very small and slender, not exceeding half an inch in length; it inhabits the rectum.

2. Ascaris bumbricoides, the long and round worm,

2. Ascaris bumbricoides, the long and round worm, which is a foot in length, and about the breadth of a

goose-quill.

ASCE'NDENS. (From ad and scando, to ascend.)

Adscendens. Ascending. Applied to muscles, leaves, stalks, &c. from their direction; as musculus obliquus ascendens, folium ascendens, caulis ascendens, the leaves of the geranium vitifolium and stems of the hedysarum onobrychis, &c.

Ascendens obliquus. See Obliquus internus abdaminus.

A'SCIA. An axe or chisel. A simple bandage; so called from its shape in position.—Galen.

ASCIDIATUS. (From ascidium.) Ascidiate or pitcherform: a term applied to a leaf and other parts of plants which are so formed; the folium ascidiatum is seen in the Nepenthes Distillatoria, and in Saracenia.

ASCIDIUM. (From ασκιδίου, a small bottle.)
The pitcher. A term introduced by Willdenow into ASCIDIUM. botany to express a hollow foliaceous appendage, re-sembling a small pitcher. It is of rare occurrence, but has been found as a caulinar, foliar, and a pedun-

cular or floral appendage.

1. The caulinar belongs to the Austalasian plant Cophalotus follicularis.

 The foliar is peculiar to the genus Nepenthes.
 The peduncular on the Surubea quianensis.
 ASCITES. (Ascites, α. m.; from ασκος, a sack, or bottle; so called from its bottle-like protuberancy.)
 Dropsy of the belly. A tense, but scarcely elastic, swelling of the abdomen from accumulation of water. Cullen ranks this genus of disease in the class Ca-chexiae, and order, Intumescentiae. He enumerates

two species:

1. Ascites abdominalis, when the water is in the cavity of the peritoneum, which is known by the equal swelling of the parietes of the abdomen.

2. Asciles saccatus, or encysted dropsy, in which the water is encysted, as in the ovarium: the fluctuation is here less evident, and the swelling is at first

Ascites is often preceded by loss of appetite, slug-Ascites is often preceded by loss of appetite, sluggishness, dryness of the skin, oppression at the chest, cough, diminution of the natural discharge of urine, and costiveness. Shortly after the appearance of these symptoms, a protuberance is perceived in the hypogastrium, which extends gradually, and keeps on increasing, until the whole abdomen becomes at length uniformly swelled and tense. The distension and sense of weight, although considerable, vary somewhat according to the posture of the body, the weight being felt the most on that side on which the patient lies, while, at the same time, the distention becomes Portsoy, the Isle of Anglesca, and the Lizard in Cornwall. It was found in the limestone of Glentilt, by Dr. McCulloch, in a pasty state, but it soon hardened by exposure to air.

3. Mountain Leather consists not of parallel fibres like the preceding, but interwoven and interlaced so as to become tough. When in very thip pieces it is called mountain paper. Its colour is venowish-white, and its touch meagre. It is found at Wanlockhead, in Lanarkshire. Its specific gravity is uncertain.

4. Mountain Cork, or Elastic Asbestos, is, like the preceding, of an interlaced fibrous texture; is opaque, has a meagre feel and appearance, not unlike common cork, and like it, too, is somewhat elastic. It swims on water. Its colours are white, gray, and yellowish-brown; receives an impression from the nail; very tough; cracks when handled, and melts with difficulty before the blow-pipe.

5. Mountain Wood, or Ligniform asbestos, is usually massive, of a brown colour, and having the aspect of the posture of the blody, the weight being felt the most on that side on which the patient being felt the most on that side on which the patient being felt the most on that side on which the patient being felt the most on that side on which the patient being felt the most on that side on which the patient being felt the most on that side on which the patient being felt the most on that side on which the patient bies, while, at the same time, the distention becomes somewhat less on the opposite side. In general, the practitioner may be sensible of the fluctuation of the water, by applying bis left hand on one side of the abdomen, and then striking on the other side with his right. In some cases, it will be obvious to the ear. As the collection of water becomes more considerable, the difficulty of breathing is much increased, the countenance exhibits a pale and bloated appearance, an immoderate thirst, the skin is dry and parched, and the urine is very scanty, thick, high coloured, and the urine is very scanty, thick, high coloured, and the u

cumstances.—When the preceding symptoms gave suspicion of a general hydropic diathesis; when, at the same time, some degree of dropsy appears in other parts of the body; and when, from its first appearance, the swelling has been equally diffused over the whole belly, we may generally presume that the water is in the cavity of the abdomen. But when an ascites has not been preceded by any remarkable cachectic state of the system, and when, at its beginning, the tumour and tension had appeared in one part of the belly more than another, there is reason to suspect an encysted dropsy. Even when the tension and tumour of the belly have become general, yet, if the system or the body in general appear to be little affected; if the patient's strength be little impaired; if the appetite continue pretty entire, and the natural sleep be little interrupted; if the menses in females continue to flow as usual: if there be yet no anasarca, or, though it may have already taken place, if it be still confined to the lower extremities, and there be no leucophlegmatic paleness or sallow colour in the countenance; if there be no fever, nor so much thirst and scarcity of urine desired. be no fever, nor so much thirst and scarcity of urine as occur in a more general affection: then according as more of these different circumstances take place, as more of these different circumstances take place, there will be the stronger grounds for supposing the ascites to be of the encysted kind. The encysted form of the disease scarcely admits of a perfect cure, though its progress to a fatal termination is generally very slow; and the peritonical dropsy is mostly very obstinate, depending usually on organic disease in the liver, or other abdominal viscera. The plan of treatment agrees very much with that of anasarca; which see. The operation of paracentesis should only be performed where the distension is very great, and the respiration or other important functions impeded; and it will often be better not to draw off the whole of the it will often be better not to draw off the whole of the fluid at once; great care must be taken, too, to keep up sufficient pressure by a broad bandage over the abdomen; for even fatal syncope has arisen from the ne-glect of this. The contraction of the muscles will be promoted by friction. Cathartics are found more de-cidedly beneficial than in anasarca, where the bowels will bear their liberal use. Diuretics too, are of great importance in the treatment; and, among other means of increasing the flow of urine, long-continued gentle friction of the abdomen with oil has been sometimes very successful, probably by promoting absorption in very successful, probably by promoting absorption in the first instance; the only use of the oil seems to be that the friction is thereby better borne. In cases where visceral obstructions have led to the effusion, where visceral obstructions have led to the effusion, these must be removed, before a cure can be accomplished: and for this purpose mercury is the remedy most to be depended upon, besides that in combination with squill, or digitalis, it will often prove powerfully diuretic. Tonic medicines, a nutritious diet, and, if the complaint appears giving way, such exercise as the patient can take, without fatigue, with other means of improving the general health, ought not to be neglected.

ASCLEPI'ADES, a celebrated physician, born at Prusa, in Bithynia, who flourished somewhat before the time of Pompey. He originally taught rhetoric, but not meeting with success, applied himself to the study of medicine, in which he soon became famous from the novelty of his theory and practice. He supposes disease to arise from the motion of the particles of the blood and other fluids being obstructed by the straitness of the vessels, whence pain, fever, &c. ensued. He deprecated the use of violent remedies, as emetics and purgatives, but frequently employed clysters, when costiveness attended. In fevers, he chiefly relied on a complete abstinence from food or drink for three days or more; but when their violence abated, allowed animal food and wine. In pleurisies, and other complaints attended with violent pain, he preother complaints attended with violent pain, he prescribed bleeding; but in those of a chronic nature, depended principally on abstinence, exercise, baths, and frictions. None of his works remain at present. He is said to have pledged his reputation on the preservation of his own health, which he retained to a great age, and died at length from a fall.

ASCLE PIAS. (From Asclepias, ādis. £; so named after its discoverer; or from Esculapius, the god of medicine.) The name of agenus of plants in the Linnæan system. Class, Pentandria; Order, Digynia:

ASCLEPIAS SYRIACA. Syrian dog's bane. This plant is particularly poisonous to dogs, and also to the hu-

is particularly poisonous to dogs, and also to the hu-

man species. Boiling appears to destroy the poison iff the young shoots, which are then said to be esculent, and flavoured like asparagus.

ASCLEPIAS VINCETOXICUM. The systematic name Asclepias vincetoxicum of the pharmacopœias. Hermidinaria; Asclepias. Swallow-wort; Tame poison. The root of this plant smells, when fresh, somewhat of valerian; chewed, it imparts at first a considerable sweetness, which is soon succeeded by an unpleasant subacrid bitterness. It is given in some countries in the cure of glandular obstructions.

Ascle'rios. (From Asclepias, its inventor.) A dried smegna and collyrium described by Galen.

Asco'ma. (From usus, a bottle.) The eminence of the pubes at the years of maturity, so called from

its shape.

ASCYROIDEÆ. A name given by Scoipoli to a class of plants which resemble the Ascyrum, St. Peter's worth.

A'ser. A pustule like a millet seed. A'segon. Asegen; Asegen. Dragon's blood. See

A SEF. A pusture like a line.

A'segon. Asegen; Asogen. Dragon's blood. See Calamus rotang.

ASE'LLIUS, Gaspar, of Cremona, born about the year 1580, taught anatomy at Paris with great reputation. In 1622, he discovered the lacteals in a dog opened soon after a meal, and noticed their valves, but supposed they went to the liver. These vessels, he candidly observes, had been mentioned by some of the earliest medical writers, but not described, nor their function stated; and not being noticed by any modern anatomist previously, the discovery is properly attributed to him. His death took place four years after, subsequent to which his dissertation on the subject was published by his friends.

ASH. See Frazinus excelsior.

[Ashes. The residuum, after the incineration of wood. It is also applied to the alkali extracted by lixiviation, under the names of Pot-ash, and Pearl-ash, both of which are included in the mercantile title Ashes. A.]

Ashes. A.]

ASIATICUM BALSAMUM. Balm of Gilead.

A'SINUS. The ass. A species of the genus Equus.

Its milk is preferred to cow's and other kinds of milk, in phthisical cases, and where the stomach is weak; as containing less oleaginous particles, and being more easily converted into chyle. See Milk, Asses.

ASINI'NUM LAC. Asses' milk.

Asi'ti. (From a, neg. and σιτος, food.) Asitia.

Those are so called who take no food, for want of

appetite.
A'sjogam. (Indian.) A tree growing in Malabar and the East Indies, the juice of which is used against

the colic.

Aso'des. (Frem αόω, to nauscate.) A nausca or loathing, or a fever with much sense of heat and nausea.—Arctaus.

A suppression of urine from an im-ASPADIA'LIS.

perforated urethra.

ASPALATHUM. See Lignum aloes.
ASPALATHUS. (From a, and σπαω, because the thorns were not easily drawn out of the wounds they made.) The name of a genus of plants in the Linnaran system. Class, Diadelphia; Order, Decandria

ASPALATHUS CANARIENSIS. The systematic name of the rose-wood tree, or lignum rhodium of the ancients. An essential oil is obtained from the roots, cients. An essential oil is obtained from the roots, which is used principally as a perfume; but is an excellent cordial and carminative given internally. The best preparation is a tincture, made by macerating four ounces of the wood in a pint of rectified spirit.

ASPARAGIN. White transparent crystals, of a peculiar vegetable principle, which spontaneously form in asparagus juice which has been evaporated to the consistence of syrup. They are in the form of rhombode.

asparagus juice which has been evaporated to the con-sistence of syrup. They are in the form of rhomboidal prisms, hard and brittle, having a cool and slightly nau-seous taste. They dissolve in hot water, but sparingly in cold water, and not at all in alkohol. On being heat-ed, they swell and emit penetrating vapours, which affect the eyes and nose like wood-smoke. Their solution does not change vegetable blues; nor is it affected by hydrosulphuret of potassa, oxalate of ammonia, ace-tate of lead, or infusion of galls. Lime disengages ammonia from it; though none is evolved by triturating it with potassa. The asparagus juice should be first heated to coagulate the albumen, then filtered and left to spontaneous evaporation for 15 or 20 days. Along

with the asparagin crystals, others in needles of little consistency appear, analogous to mannite, from which the first can be easily picked out.—Vauquelin and Robiquet. Annales de Chimie, vol. lv. and Nicholn's Journal, 15. ASPA'RAGUS.

ASPA'RAGUS. (Asparagus, i. m. Ασπαραγος, a young shoot before it unfolds its leaves.) 1. The name of a genus of plants in the Linnæan system. Class, Hexandria; Order, Monogynia. Asparagus.
2. The pharmacopæial name of the sparage. S

Asparagus officinalis.

ASPARAGUS OFFICINALIS. The systematic name of the asparagus, the root of which has been esteemed as a diuretic. It is mostly employed as a food, but it contains very little nourishment. A peculiar vegetable principle, called asparagin, has been found in this

plant. See Asparagin.

[ASPARAGUS STONE. This is one of the varieties of the phosphate of lime. Vauquelin found it to contain lime 54.28, phosphoric acid 45.72; by which analysis it appears to differ but little from Apatite, the other variety, which see. A.]

Aspa'sia. (From a, for apa, together, and σπαω, to draw.) A constrictive medicine for the pudendum muliebre. Capivae.

ASPER. Rough. Applied to parts which are rough, as linea aspera, &c.

rough, as linea aspera, &c.
In the language of botany, scaber and asper are

used synonymously.

Asper caulis. Caulis scaber. Scabrous stem; is when it is thickly covered with papille which are not visible, but can be felt when running the finger along 1; as in Galium aperine, Lithospermum arvense,

ASPERA ARTERIA. (So called from the inequality of its cartilages.) See Trachea.

ASPERIFOLIZE. (From asper, rough.) Roughleaved plants. The name of a class and of an order of plants given by Boerhaave, Ray, Linnæus, &c.

ASPERULA. (A diminutive of asper, the seeds being rough.) The name of a genus of plants in the Linnæan system. Class, Tetrandria; Order, Monogania.

ASPERULA ODORATA. The systematic name for the officinal matrisylva. Woodruff. It is a low umbelliferous plant, growing wild in woods and copses, and flowering in May. It hath an agreeable odour, which is much improved by moderate drying; the taste is a little austere. It imparts its flavour to vinous liquors; and is commended, as a cordial and deshapers. and is commended as a cordial and deobstruent remedy.

ASPHALTI'TIS. 1. A kind of trefoil.
2. The last vertebra of the loins.
ASPHALTUM. Asphaltus. This substance, likewise called Bitumen Judaicum, or Jews' Pitch, is a smooth, hard, brittle, black or brown substance, which breaks with a polish, melts easily when heated, and when pure burns without leaving any ashes. It is found in a soft or liquid state on the surface of the Dead see but by age grows dry and hard. The same Dead sea, but by age grows dry and hard. The same kind of bitumen is likewise found in the earth in other parts of the world; in China; America, particularly in the island of Trinidad; and some parts of Europe, as the Carpathian hills, France, Neufchatel, &c.

According to Neumann, the asphaltum of the shops is a very different compound from the native bitumen;

and varies, of course, in its properties, according to the nature of the ingredients made use of in forming it. On this account, and probably from other reasons, the use of asphaltum, as an article of the materia medica, is totally laid aside.

The Egyptians used asphaltum in embalming, under

The Egyptians used asphaltum in embalming, under the name of mumia mineralis, for which it is well adapted. It was used for mortar at Babylon.

[This bitumen is dry and solid, and usually very brittle, but often too hard to receive an impression from the finger nail. In some varieties its fracture is more or less conchoidal, and shining with a resinous

more or less conchoidal, and shining with a resinous lustre; in others, it is earthy, or uneven, or nearly dull. The earthy variety is less hard than the others, and seems to be intermediate between Maltha and the harder kinds of Asphaltum.—Cl. Min.

The ancient bricks of Babylon, several of which I have had the best opportunities to examine, have a portion of bitumen adhering to them. This is black, and emits, by burning, a somewhat aromatic vapour. It appears to have lost none of its peculiar qualities,

during the term of 3000 or 4000 years, since it was first incorporated as a cement, in the walls and towers constructed by the ancient inhabitants of Shinaar. The specimens I possess of modern bitumen from Bosrah, or its vicinity, are substantially the same with that used of old.

that used of old.

Asphaltum of St. Antonio, at the western extremity of Cuba, is compact, deep black, and capable of supporting a flame when heated and set on fire. That from Trinidad island is not so pure; but is stated to be much more abundant. Specimens from St. Stephens, near the Alabama river, were sent me by Mr. Magoflin.—Mitchill's Notes to Philips's Min. A.]

ASPHO'DELUS. (Asphodelus, i. m. from aski, a serpent, and δελδος, fearful; because it destroys the venom of serpents: or from σποδελος, ashes, because it was formerly sown upon the graves of the dead.)

1. The name of a genus of plants in the Linnæan system. Class, Hexandria; Order, Monogynia.

2. The pharmacopæial name of the daffodil. See Asphodelus ramosus.

Asphodelus ramosus.

Asphodelus Ramosus. The systematic name for the officinal, or branched asphodel. Asphodelus: caulenudo; foliis enciformibus, carinatis, lavibus, of Linnæus. The plant was formerly supposed to be effi-cacious in the cure of sordid ulcers. It is now wholly

laid aside.

ASPHY'XIA. (Asphyxia, α. f.; from α, priv. and σφυξις, a pulse.) The state of the body, during life, in which the pulsation of the heart and arteries cannot be perceived. There are several species of asphyxia enumerated by different authors. See Syncope.

ASPIDI'SCUS. (From ασπις, a buckler.) The sphincter muscle of the anus was formerly so called from its shape.—Calius Aurelianus.

[ASPINWALL, WILLIAM, M. D. was born in Brookline, Mass., on the 23d of May, (old style,) 1743. His ancestors emigrated from England about the year 1630. He was fitted for College by the Rev. Amos

1630. He was fitted for College by the Rev. Amos Adams, minister of Roxbury, and was graduated at Harvard University, in 1764. It was the personal interest which he took in the revolutionary contest, acting upon a mind deeply imbued with a sense of acting upon a mind deeply imbued with a sense of his country's wrongs, that gave strength and tone to his sentiments in after life. Dr. Aspinwall's language on political subjects was bold and strong, his creed being that of a democratic republican. In the unhappy scenes of party excitement, he unwaveringly adhered to what he deemed original and fundamental principles; but he aimed to preserve a good conscience, and to do justice to the honest opinions, the pure motives, and undoubted integrity of his opponents. He was not a political persecutor; and, when he was in the councils of the State, resolutely declined acting with his coadjutors, who were disposed to drive from office incumbents, whose only fault was what they deemed

political heresy.

After the death of the eminent and distinguished Dr. Zabdiel Boylston, the first inoculator of small-pox in America, Dr. Aspinwall established himself in that in America, Dr. Aspinwall established himself in that undertaking, and erected hospitals for that purpose in Brookline. Perhaps no practitioner in the United States ever inoculated so many persons, or acquired such skill and celebrity in treating this malignant disease, as Dr. Aspinwall. Besides his practice in this disorder when it generally spread, he was allowed, after the year 1788, to keep a hospital open at all times, to which great numbers resorted, and from which they returned with warm expressions of satisfaction. He continued in the successful treatment of this disease, till the general introduction of vaccine inoculation. He had made ample accommodation for enlarged practice, and established what might have been justly deemed a sure foundation for proshave been justly deemed a sure foundation for prosperity, when vaccine inoculation was first introduced. perity, when vaccine inoculation was first introduced. He well knew that if vaccination possessed the virtues ascribed to it, his schemes of fortune and usefulness arising from inoculation at his hospital, were ruined; that he should be involved in loss and his anticipations of fortune would be blasted. But as an honest man and faithful physician, he deemed it his duty to inquire into the efficacy of the novel substitute. With the utmost alacrity, therefore, he gave the experiment a fair trial, promptly acknowledged its efficacy, and relinquished his own establishment. The foregoing is corroborated by the following statement, recently made by Dr. Waterhouse, in the Medical Intelligencer. made by Dr. Waterhouse, in the Medical Intelligencer.

"The late Dr. Aspiawall, a man of great sagacity, and uncommonly well grounded in the principles of his profession, gave evidence of it on the first sight of a vaccine pustule. I had invited all the elder physicians of Boston, and the vicinity of Cambridge, to see the first vaccine pustules ever raised in the new world. They gave them the ordinary inspection on the skin; all but Dr. Aspinwall, whose attention was rivetted on the pustule, its areola, and efflorescence. He came a second time, and viewed the inoculated part in every light, and reviewed it, and seemed loath to leave the sight of it. He seemed wrapped in serious thought, and said repeatedly—' This pustule is so like small-pox, and yet it is not small-pox, that should it, on scabbing, take out a portion of the true skin, so as to leave an indelible mark or pit behind, I shall be ready to conclude that it is a mild species of small-pox, hitherto unknown here.' He had been in the habit of examining the small-pox pimple and pustule through glasses, to know if it 'had taken;' and he remarked, that they were peculiar, unique, and unlike any other eruption he ever saw; but that this kinepock came the nearest to it. Some time after, I gave him a portion of the virus to make his own experiments, and observe the progress of its inoculation, and coincidence of the constitutional symptoms; when "The late Dr. Aspinwall, a man of great sagacity mm a portion of the virus to make his own experi-ments, and observe the progress of its inoculation, and coincidence of the constitutional symptoms; when he observed, that its progress, febrile affection, and mode of scabbing, were very like small-pox, and so of the indelible mark left on the arm; yet, throughout the whole visible affection, different. To crown the whole of his honourable conduct, he some time after took all those of my family whom I had vaccinated, into his small-pox hospital, the only licensed one in the state, and there tested them to his satisfaction, and one to the very verge of rigid experiment; and the state, and there tested them to his satisfaction, and one to the very verge of rigid experiment: and then he said to me and others—' This new inoculation of yours is no sham. As a man of humanity, I rejoice in it; although it will take from me a handsome annual income.' His conduct throughout was so strongly marked with superior intelligence, generosity, and honour, as to excite my esteem and respect; and I accordingly dedicate this effusion of gratitude to the memory of the Hon. William Aspinwall, M. D.; a gentleman respectable in public life as a counsellor, and an honour to his profession as a physician."—

genueman respectable in public life as a counsellor, and an honour to his profession as a physician."—
Thach. Mcd. Biog. A.]
ASPLE'NIUM. (Asplenium, ii. n.; from a, priv. σπλην, the spleen; because it was supposed to remove disorders of the spleen.) The name of a genus of plants in the Linna system. Class, Cryptogamia; Order, Filices.

Order, Filices.

ASPLENIUM CETERACH. The systematic name of the herb spleenwort. Miltwaste. Scolopendria vera; Dorodilla. This small bushy plant, Asplenium—frondibus pinnatifidis, lobis alternis confluentibus obtusis of Linnæus, grows upon old walls and rocks. It has an herbaceous, mucilaginous, roughish taste, and is recommended as a pectoral. In Spain it is given, with great success, in nephritic and calculous diseases.

ASPLENIUM RUTA MURARIA. The systematic name for the rata muraria of the pharmacopæias. It is supposed by some to possess specific virtues in the cure of ulcers of the lungs, and is exhibited in the form of

ASPLENIUM SCOLOFENDRIUM. The systematic name for the scolopendrium of the pharmacopæias. tis; Lingua cervina. Harts-tongue. This tis; Lingua cervina. Harts-tongue. This indigenous plant, Aspleaium—frondibus simplicibus, cordato lingulatis, integerrimis; stipitibus hirsutis of Linneus: grows on most shady banks, walls, &c. It has a slightly astringent and mucilaginous sweetish taste. When fresh and rubbed, it imparts a disagreeable smell. Harts-tongue, which is one of the five capillary herbs, was formerly much used to strengthen the viscers restrain between the second properties and alvine fluxes, and to

herbs, was formerly much used to strengthen the viscera, restrain harmorrhages and alvine fluxes, and to open obstructors of the liver and spleen, and for the general purposex of demulcents and pectorals.

Asplenium Themomanes. The systematic name for the trichomanes of the pharmacopelas. Common maiden-hair or spleeswort. Asplenium-frondibus pinnatis, pinnis subrotendis, crenatis of Linnaus. This plant is admitted into the Edinburgh Pharmacopelia: the leaves have a mucilaginous, sweetish, subastringent taste, without any particular flavour: they are esteemed useful in disorders of the breast, being supposed to promote the expectoration of tough supposed to promote the expectoration of tough phlegm, and to open obstructions of the viscera.

ASS. See Asinua

Assama. A shrub found on the coast of Guinea, the leaves of which are supposed to disperse bubbes.

ASSAFCE TIDA. See Ferula assafatida.

ASSARABA'CCA. See Asarum Europeum. Assa Rium. A Roman measure of twelve ounces. Assartino'sis. Articulation.

ASSAY. Essay. This operation consists in de-termining the quantity of valuable or precious metal contained in any mineral or metallic mixture, by ana-lyzing a small part thereof. The practical difference between the analysis and the assay of an ore, con-sists in this: The analysis, if properly made, deter-mines the nature and quantities of all the parts of the compound; whereas the object of the assay consists in ascertaining how much of the particular metal in question may be contained in a certain determinate quantity of the material under examination. Thus, in the assay of gold or silver, the baser metals are considered as of no value or consequence; and the prob-lem to be resolved is simply, how much of each is contained in the ingot or piece of metal intended to be

ASSIMULATION. (Assimilatio, from ad, and similis, to make like to.) The conversion of the food

into nutriment.

Assiste stres. (From ad, and sisto, to stand near.) A name of the prostate glands, so called because they lie near the bladder.

ARSO'DES. (From agaopas, to nauscate, or from escre, to burn.) Asodes. A continual fever, attended assare, to burn.) Asodes. with a loathing of food.

A'STACUS. (Astacus, i. m.; from a, neg. and ταζω, to distil; so called from the hardness and dryness of its shell.) The name of a genus of shell-fish.

ASTACUS FLUVIATILIS. The officinal crevis, or cray-fish. See Cancer astacus.

ASTACUS MARINUS. The lobster. See Cancer gam-

marus.

A'stapsis. (From ςαφις, uva passa.) A raisin.

Astera'ntium. (From αςηρ, a star.) The pellitory; so called from its star-like form. See Anthemis

pyrethrum.

pyrethrum.

Astericum. (From the star-like appearance of the flowers.) The pellitory. See Anthemis pyrethrum.

Astericum. (From a, priv. and σθενος, strength.) Extreme debility. The asthenic diseases form one great branch of the Brunonian arrangement.

Asthenology. (Asthenologia, α. f.; from a, priv. and σθενος, strength, and λογος, a treatise.) The doctrine of diseases arising from debility. The disciples of the Brunonian school, as they denominate themselves, maintain peculiar opinions on this subject. A'sthma. (Asthma, matis, neut.: from ασθμαζω, to breathe with difficulty.) Difficult respiration, returning at intervals, with a sense of stricture across the breast, and in the lungs; a wheezing, hard cough, at first, but more free towards the close of each paroxysm, with a discharge of mucus, followed by a remission. It is ranked by Cullen in the class Neurosis, and order Spasmi. There are, according to him, three species of asthma:—

1. Asthma spontaneum, when without any manifest cause.

1. Asthma spontaneum, when without any manifest

cause

Asthma plethoricum, when it arises from plethora. Asthma exanthematicum, originating from the re-pulsion of some acrid humour.

Asthma rarely appears before the age of puberty, and seems to attack men more frequently than women, particularly those of a full habit, in whom it never fails, by frequent repetition, to occasion some degree of emaciation. In some instances, it arises from an hereditary predisposition, and in many others, it seems to depend upon a particular constitution of the lungs. to depend upon a particular constitution of the lungs. Dyspepsia always prevails, and appears to be a very prominent feature in the predisposition. Its attacks are most frequent during the heats of summer, in the dog days, and in general commence about midnight. On the evening preceding an attack of asthma, the spirits are often much affected, and the person experiences a sense of fuiness about the stomach, with lassitude, drowsiness, and a pain in the head. On the approach of the succeeding evening, he perceives a sense of tightness and stricture across the breast, and a sense of straitness in the lungs, impeding respiration. a sense of straitness in the lungs, impeding respiration.

The difficulty of breathing continuing to increase for

some length of time, both inspiration and expiration are performed slowly, and with a wheezing noise; the speech becomes difficult and uneasy, a propensity to coughing succeeds, and the patient can no longer remain in a horizontal position, being as it were threatened with immediate suffocation. These symptoms usually continue till towards the approach of morning, and then a remission commonly takes place; the ing, and then a remission commonly takes place; the ing, and then a remission commonly takes place; the breathing becomes less laborious and more full, and the person speaks and coughs with greater ease. If the cough is attended with an expectoration of mucus, he experiences much relief, and soon falls asleep. When he awakes in the morning, he still feels some degree of tightness across his breast, although his breathing is probably more free and easy, and he cannot hear the least motion, without rendering this more breathing is probably more free and easy, and he cannot bear the least motion, without rendering this more difficult and uneasy; neither can he continue in bed, unless his head and shoulders are raised to a considerable height. Towards evening, he again becomes drowsy, is much troubled with flatulency in the stomach, and perceives a return of the difficulty of breathing, which continues to increase gradually, till the appears as violent as on the night before. After it becomes as violent as on the night before. some nights passed in this way, the fits at length moderate, and suffer more considerable remissions, particularly when they are attended by a copious expec ticularly when they are attended by a copious expectoration in the mornings, and this continues from time to time throughout the day; and the disease going off at last, the patient enjoys his usual rest by night, without further disturbance. The pulse is not necessarily affected in this disease, though often quickened by the difficulty of breathing; and sometimes slight pyrexia attends. In plethoric habits, the countenance is flushed and turgid during the fit; but in others rather pale and shrunk: in the former, too, some difficulty of breathing and wheezing usually remain in the interval: breathing and wheezing usually remain in the interval; in others the recovery is more complete. On this is founded the common distinction of asthma into the humid, pituitous, or catarrhal, and the dry, spasmodic, or nervous forms. The exciting causes are various: accumulation of blood, or viscid mucus in the lungs, noxicus vapours, a cold and foggy atmosphere, or a close hot air, the repulsion of gruptions, or other metastatic diseases, flatulence, accumulated faces, viofent passions, organic diseases in the thoracic viscera, cc. Sometimes the fits return at pretty regular periods; and it is generally difficult to obviate future attacks, when it has once occurred: but it often continues to recur for many years, and seldom proves fatal, except as inducing bydrothorax, phthisis, &c. The treatment must vary according to the form of the linear programs of a pletheric habit, with disease. In young persons of a plethoric habit, with great dyspacea, a flushed countenance, accelerated pulse, &c. the abstraction of blood will be found to afford marked relief; but under opposite circumstances, it might be highly injurious, and we should always avoid remarking it unpresentable. In condition stances, it might be highly injurious, and we should always avoid repeating it unnecessarily. In ambiguous cases, cupping may be preferred, or leeches to the chest, with blisters. Mild cathartics should also be employed; or where costiveness appears to induce the fits, those of a more active nature. Nauseating emetics are of considerable service, especially where the patient is distressed with viscid mucus, not only by promoting perspiration and expectoration, but also by their antispasmodic power, the return of a paroxysm may often be prevented by their timely use. Squill combined with ipecacuanha is one of the best forms. Where the disease is of the purely spasmodic character, opium will be found the most powerful palliative remedy, especially if combined with æther, though it remedy, especially if combined with ather, though it unfortunately loses some of its power by repetition; the feetid gum resins are also useful, particularly where the fætid gum resins are also useful, particularly where the bowels are torpid; and other antispasmodics may be occasionally employed. The practice of smoking, or chewing tobacco, has sometimes appeared extremely beneficial; and a cup of strong coffee has often afforded speedy relief. Means should also be employed for strengthening the system; and where there appears a tendency to serous effusion, digitalis may be very useful. But by far the most important part of the treatment But by far the most important part of the treatment consists in obviating or removing the several exciting causes, whether operating on the lungs immediately, or through the medium of the prima viæ, &c. Individual experience can alone ascertain what state of the atmosphere as to temperature, dryness, purity, &c. shall be most beneficial to asthmatics, though a good deal depends on habit in this respect: but a due regu-

lation of this, as well as of the diet, and other parts of regimen, will usually afford more permanent relief than any medicines we can employ.

A'STITES. (From ad, and sto, to stand near.)

A name given by the ancients to the prostate glands, because they are situated near the bladder.

ASTRA'GALUS. (Astragalus, i. m.; Aspayalos, a cockle, or die; because it is shaped like the die used in ancient games.) 1. The ankle-bone; a bone of the tarsus, upon which the tibia moves. Also called the sling-bone, or first bone of the foot. Ballista os; aristarsus, upon which the tibla moves. Also caned the sling-bone, or first bone of the foot. Ballista os; aristrios; talus; quatrio; tetroros; cavicula; cavilla; diabebos; pera. It is placed posteriorly and superiorly in the tarsus, and is formed of two parts, one large, which is called its body, the other small, like a process. The part where these two unite is termed the

neck.

2. The name of a genus of plants in the Linnwan system. Class, Diadelphia; Order, Decandria.

Astragalus excapus. Stemless milk-vetch. The root of this plant, Astragalus acaulis excapus; —leguminibus lunatis; foliis villosis of Linnwus, is said to care confirmed syphilis, especially when in the form of nodes and nocturnal pains.

Astragalulus Tragacantha. The former system-

ASTRAGALUS TRAGACANTHA. The former systematic name for the plant which affords the gum traga-

canth. See Astragalus verus.

ASTRAGALUS VERUS. Goat's thorn. Milk-vetch. Spina hirci; Astragalus tragacantha; Astragalus aculeatus. We are indebted to a French traveller, of the name of Olivier, for the discovery that the gum tragacanth of commerce, is the produce of a species of astragalus not before known. He describes it under the tragalus rot before known. He describes it under the tragalus verus, being different both from A. name of astragalus verus, being different both from Atragacantha of Linnæus, and from the A. gummifera of Labillardiere. It grows in the North of Persia. Gum-tragacanth, or gum dragant, or dragon, (which is forced from this plant by the intensity of the solar rays, is concreted into irregular lumps or vermicular pieces, bent into a variety of shapes, and larger or smaller proportions, according to the size of the wound from which it issues,) is brought chiefly from Turkey, in irregular lumps, or long vermicular pieces bent into a variety of shapes: the best sort is white, semi-transparent, dry, yet somewhat soft to the touch.

Gum-tragacanth differs from all the other known gums, in giving a thick consistence to a much larger

gums, in giving a thick consistence to a much larger quantity of water; and in being much more difficultly soluble, or rather dissolving only imperfectly. Put into water, it slowly imbibes a great quantity of the liquid, swells into a large volume, and forms a soft but not fluid mucilage; if more water be added, a fluid solution may be obtained by agitation but the liquor looks turbid and wheyish, and on standing, the mucilage subsides, the limpid water on the surface retaining little of the gum. Nor does the admixture of the preceding more soluble gums promote its union with the water, or render its dissolution more durable: when gum-tragacanth and gum-arabic are dissolved

together in water, the tragacanth separates from the mixture more speedily than when dissolved by itself.

Tragacanth is usually preferred to the other gums for making up troches, and other like purposes, and is supposed likewise to be the most effectual as a medicing, but on account of its imperfect solubility is ine; but on account of its imperfect solubility, is unfit for liquid forms. It is commonly given in powder, with the addition of other materials of similar intention; thus, to one part of gum-tragacanth are added one of gum-arabic, one of starch, and six of sugar.

According to Bucholtz, gum-tragacanth is composed of 57 parts of a matter similar to gum-arabic, and 48 parts of a peculiar substance, capable of swelling in cold water without dissolving, and assuming the appearance of a thick jelly. It is soluble in boiling water, and then forms a mucilaginous solution.

The demulcent qualities of this gum are to be con-

The demulcent qualities of this gum are to be considered as similar to those of gum-arabic. It is seldom given alone, but frequently in combination with more powerful medicines, especially in the form of troches, for which it is peculiarly well adapted: it gives name to an officinal compound powder, and was an ingredient in the compound powder of cerusse.

ASTRA'NTIA. (From astrov, astrum, a star; so called from the star-like shape of its flowers.) The name to a genus of plants in the Linnman system. Class, Pentandria; Order, Dyginia.

Astrantia Major. Astrantia vulgaris.
Astrantia nigra. The herb sanicle master-wort.

Astrantia nigra. The herb sanicle master-wort.

A rustic purge in the time of Gerard.

A'STRAPE. (From aspan7w, to corruscate.) Lightning. Galen rockons it among the remote causes of

ASTRICTUS. (From astringo, to bind.) When applied to the belly, it signifies costiveness; thus,

ASTRI'NGENT. (Astringens; from astringe, to constringe.) Adstringent. That which, when applied to the body, renders the solids denser and firmer, by contracting their fibres, independently of their living, or muscular power. Astringents thus serve to diminish excessive discharges; and by causing greater compression of the nervous fibrills, may lessen morbid sensibility or irritability. Hence they may tend indirectly to restore the strength, when impaired by these causes. The chief articles of this class are the acids, along lime water challs certain respections. alum, lime-water, chalk, certain preparations of cop-per, zinc, iron, and lead; the gallic acid, which is commonly found united with the true astringent principle, was long mistaken for it. Seguin first distinguished them, and, from the use of this principle in tanning skins, has given it the name of tannin. Their characteristic differences are, the gallic acid forms a black precipitate with iron; the astringent principle forms an insoluble compound with albumen.

forms an insoluble compound with albumen.

ASTRONO'MY. (Astronomia; from αςρον, a star, and νομος, a law.) The knowledge of the heavenly bodies. Hippocrates ranks this and astrology among the necessary studies of a physician.

ASTRUC, John, a learned physician, born in France, 1684. He studied and took his degrees at Montpetier, and became afterward a professor there. In 1729, he was appointed physician to the king of Poland, but soon returned to his native country, was made consulting physician to the French king, and professor of medicine at Paris, where he attained great celebrity. He was author of numerous medical and philosophical works, but especially one "on Veand philosophical works, but especially one "on Venereal Diseases," which deservedly became extremely popular, and was translated into various modern lan-

popular, and was translated into various modern languages. He lived to the advanced age of 82.

ATA'XIA. (From α, neg. and τασσω, to order.)

Want of regularity in the symptoms of a disease, or of the functions of an animal body.

ATE'CNIA. (From α, neg. and τικτω, to bring forth.) Venereal impotency: inability to procreate

ATHAMANTA. (Athamanta, & feem; so named from Athamas in Thessaly.) The name of a genus of plants in the Linnæan system. Class, Pentandria;

Order, Digynia.

ATHAMANTA CRETENSIS. The systematic name for the daucas creticus of the pharmacopæias. Myrrhus annua. Candy carrot. The seeds of this plant, Athamanta—foliolis linearibus planis, hirsutis; peta-lis bipartitis; seminibus oblongis hirsutis, of Lin-meus, are brought from the isle of Candy: they have an aromatic smell, and a slightly-biting taste; and are occasionally employed as carminatives, and diuretics in diseases of the prime viæ and urinary

ATHAMANTA OREOSELINUM. The systematic name for the officinal orcoselinum. Black mountain parsley. The root and seed of this plant, Athamanta—foliolis divaricatis of Linnæus, as well as the whole herb, were formerly used medicinally. Though formerly in so high estimation as to obtain the epithet of polychrosta, this plant is seldom used in the practice of the present day. An extract and tincture prepared the present day. An extract and tincture prepared from the root were said to be attendant, aperient, deobstruent, and lithoutriptic. The oil obtained by distillation from the seed was esteemed to allay the toothache; and the whole was recommended as an antiscorbutic and corroborant.

ATHAMANTICUM. See Æthusa meum.

ATHANA'SIA. (From a, priv. and Savaros, death; so called because its flowers do not wither easily.) 1. The immortal plant. A name given to tansy; because when stuffed up the nose of a dead corpse, it is said to prevent putrefaction. See Tanacetum vulgare.

2. It means also immortality.

3. The name of an antidote of Galen, and another of Oribasius.

4. It is the name also of a collyrhum described by Actius, and of many other compositions.

A'THARA. (From αθηρ, corn.) A panada, or pap for children, made of bruised corn.

ATHERO'MA. (Atheroma, atis, n. Αθηρομα, pulse, pap.) An encysted tumour that contains a soft substance of the consistence of a poultice.

ATHRIX. (Αθριξ, debilis, weak.)

Weakness.

 (From a, priv. and θριξ, a pair.) Baldness.
 ATHY'MIA. (From a, neg. and θυμος, courage.) 1. Pusillanimity.

 Despondency or melancholy.
 A'TLAS. (Atlas, antis, m.; from Aτλαω, to sustain, because it sustains the head; or from the fable of Atlas, who was supposed to support the world upon his shoulders.) The name of the first vertebra This vertebra differs very much from the others. See Vertebræ. It has no spinous process which would prevent the neck from being bent backwards, but in its place it has a small eminence. The great foramen of this is much larger than that of any other vertebra Its body, which is small and thin, is, nevertheless, firm and hard. It is somewhat like a ring, and is distinguished into its great arch, which serves in the place of its body, and its small posterior arch. The atlas is joined superiorly to the head by ginglymus; and inferiorly, to the second cervical vertebra, by means of the inferior oblique processes, and the odontoid process by trochoide

ATMOMETER. The name of an instrument to measure the quantity of exhalation from a humid sur-

race in a given time.

A'TMOSPHERE. (Atmosphera, æ. f.; from ατμος, vapour, and σφαιρα, a globe.) The elastic invisible fluid which surrounds the earth to an unknown height, and encloses it on all sides. Neither the properties nor the composition of the atmosphere, seem to have occupied much the attention of the ancients. Arisottelessing the second totle considered it as one of the four elements, situated between the regions of water and fire, and mingled with two exhalations, the dry and the moist; the first of which occasioned thunder, lightning, and wind; while the second produced rain, snow, and hail. The opinions of the ancients were vague conjectures,

until the matter was explained by the sagacity of Hales, and of those philosophers who followed his

Boyle proved beyond a doubt, that the atmosphere contained two distinct substances:—

1. An elastic fluid distinguished by the name of air.

2. Water in a state of vapour.

Besides these two bodies, it was supposed that the atmosphere contained a great variety of other substances which were continually mixing with it from the earth, and which often altered its properties, and rendered it noxious or fatal. Since the discovery of carbonic acid gas by Dr. Black, it has been ascertained that this elastic fluid always constitutes a part of the atmosphere.

The constituent parts of the atmosphere, therefore,

1. Air. 2. Water. 3. Carbonic acid gas. 4. Unknown bodies.

For the properties, composition, and account of the first, see Air.

2. Water .- That the atmosphere contains water, has been always known. The rain and dew which so often precipitate from it, the clouds and fogs with which it is often obscured, and which deposite moisture on all bodies exposed to them, have demonstrated its existence in every age. Even when the atmosphere is perfectly transparent, water may be extracted from it in abundance by certain substances. Thus, if concentrated sulphuric acid be exposed to air, it gradually attracts so much moisture, that its weight is increased more than three times: it is converted into diluted acid, from which the water may be separated by distillation. Substances which have the property of ab-stracting water from the atmosphere, have received the epithet of hygroscopic, because they point out the presence of that water. Sulphuric acid, the fixed alkalies, muriate of lime, nitrate of lime, and, in general ral, all deliquescent salts, possess this property. The greater number of animal and vegetable bodies likewise possess it. Many of them take water from moist air, but give it out again to the air when dry. These bodies

augment in bulk when they receive moisture, and diminish again when they part with it. Hence some of them have been employed as kygrometers, or measures of the quantity of moisture contained in the air around them. This they do by means of the increase or diminution of their length, occasioned by the addition or abstraction of moisture. This change of length is precisely marked by means of an index. The most ingenious and accurate hygrometers are those of Sausingenious and accurate hygrometers are those of Saus-sure and Deluc. In the first, the substance employed to mark the moisture is a human hair, which by its contractions and dilatations is made to turn round an contractions and dilatations is made to turn round an index. In the second, instead of a hair, a very fine thin slip of whalebone is employed. The scale is divided into 100°. The beginning of the scale indicates extreme dryness, the end of it indicates extreme moisture. It is graduated by placing it first in air made as dry as possible by means of salts, and afterward in air saturated with moisture. This gives the extremes of the scale, and the interval between them extremes of the scale, and the interval between them is divided into 100 equal parts.

The water, which constitutes a component part of the atmosphere, appears to be in the state of vapour, and chemically combined with air in the same manner as one gas is combined with another. As the quantity of the water contained in the atmosphere varies considerably, it is impossible to ascertain its amount with any degree of accuracy.

3. Carbonic acid gas.—The existence of carbonic gas as a constituent part of the atmosphere, was observed by Dr. Black immediately after he had ascertained the nature of that peculiar fluid. If we expose a pure alkali or alkaline earth to the atmosphere, it is gradually converted into a carbonate by the absorption of carbonic acid gas. This fact, which had been long known, rendered the inference that carbonic acid gas existed in the atmosphere unavoidable, as soon as the difference between a pure alkali and its carbonate had been ascertained to depend upon that acid. Not only alkalies and alkaline earths absorb carbonic acid when exposed to the air, but several of the metallic oxydes

Carbonic acid gas not only forms a constituent part of the atmosphere near the surface of the earth, but at the greatest heights which the industry of man has been able to penetrate. Saussure found it at the top of Mount Blanc, the highest point of the old continent; a point covered with eternal snow, and not exposed to the influence of vegetables or animals. Lime-water, diluted with its own weight of distilled water, formed a pellicle on its surface after an hour and three-quarters a pellicle on its surface after an hour and three-quarters exposure to the open air on that mountain; and slips of paper moistened with pure potash, acquired the property of effervescing with acids after being exposed an hour and a half in the same place. This was at a height no less than 15,668 feet above the level of the sea. Humboldt has more lately ascertained the existence of this gas in air, brought by Mr. Garnerin from a height not less than 4280 feet above the surface of the earth to which height he had risen in an air-balthe earth, to which height he had risen in an air-balloon. This fact is a sufficient proof that the presence of carbonic acid in air does not depend upon the vicinity of the earth.

Now, as carbonic acid gas is considerably heavier than air, it could not rise to great heights in the acmo-sphere unless it entered into combination with the air. sphere unless it entered into combination with the air. We are warranted, therefore, to conclude, that carbonic acid is not merely mechanically mixed, but that it is chemically combined with the other constituent parts of the atmosphere. It is to the affinity which exists between carbonic acid and air that we are to ascribe the rapidity with which it disperses itself through the atmosphere, notwithstanding its great through the atmosphere, notwithstanding its great through the atmosphere in the specific grayity. Fontana mixed 20,000 cubic inches specific gravity. Fontana mixed 20,000 cubic inches of carbonic acid gas with the air of a close room, and of carbonic acid gas with the air of a close room, and yet half an hour after he could not discover the traces of carbonic acid in that air. Water impregnated with carbonic acid, when exposed to the air, very soon loses the whole of the combined gas. And when a phial full of carbonic acid gas is left uncorked, the gas, as Bergman first ascertained, very soon disappears, and the phial is found filled with common air.

the phial is found filled with common air.

The difficulty of separating this gas from air, has hitherto prevented the possibility of determining with accuracy the relative quantity of it in a given bulk of air; but from the experiments which have been made, we may conclude with some degree, of confidence, that

it is not very different from 0.01. From the experiments of Humboldt, it appears to vary from 0.005 to 0.01. This variation will by no means appear improbable, if we consider that immense quantities of carbonic acid gas must be constantly mixing with the atmosphere, as it is formed by the respiration of animals, by combustion, and several other processes which are going on continually. The quantity, indeed, which is daily formed by these processes is so great, that at first sight it appears astonishing that it does not increase rapidly. The consequence of such an increase would be fatal, as air containing 0.1 of carbonic acid extinguishes light, and is destructive to animals. But

would be fatal, as air containing 0.1 of carbonic acid extinguishes light, and is destructive to animals. But there is reason to conclude, that this gas is decomposed by vegetables as rapidly as it forms.

4. Bodies found in the atmosphere.—From what has been advanced, it appears that the atmosphere consists chiefly of three distinct elastic fluids united together by chemical affinity; namely, air, vapour, and carbonic acid gas; differing in their proportions at different times and in different places; the average proportion of each is. different unicaproportion of each is, 98.6 air

1.0 carbonic acid 0.4 water

100.0

But besides these bodies, which may be considered as the constituent parts of the atmosphere, the existence of several other bodies has been suspected in it. It is not meant in this place to include among those bodies electric matter, or the substance of clouds and fogs, and those other bodies which are considered as the active agents in the phenomena of meteorology, but merely those foreign bodies which have been occasionally found or suspected in air. Concerning these bodies, however, very little satisfactory is known at present, as we are not in the possession of instruments sufficiently delicate to ascertain their presence. We can indeed detect several of them actually mixing with air, but what becomes of them afterward we are unable to say.

I. Hydrogen gas is said to have been found in air situated near the crater of volcanoes, and it is very possible that it may exist always in a very small propor-tion in the atmosphere, but this cannot be ascertained till some method of detecting the presence of hydrogen combined with a great proportion of air be discovered.

2. Carburetted hydrogen gas is often emitted by marshes in considerable quantities during hot weather.

But its presence has never been detected in air; so that in all probability it is again decomposed by some

unknown process.

3. Oxygen gas is emitted abundantly by plants during the day. There is some reason to conclude that this is in consequence of the property which plants have of absorbing and decomposing carbonic acid gas. Now as this carbonic acid gas is formed at the expense of as the carbonic acid gas is formed at the expense of the oxygen of the atmosphere, as this oxygen is again restored to the air by the decomposition of the acid, and as the nature of atmospheric air remains unaltered, it is clear that there must be an equilibrium between these two processes; that is to say, all the carbonic acid formed by combustion must be again decomposed, and all the oxygen abstracted must be again restored. The oxygen gas which is thus continually returning to the air, by combining with it, makes its component parts always to continue in the same ratio.

4. The smoke and other bodies which are continually carried into the air by evaporation, &c. are probably soon depolited again, and cannot therefore be considered with propriety as forming part of the atmo-

5. There is another set of bodies, which are occasionally combined with air, and which, on account of the powerful action which they produce on the human body, have attracted a great deal of attention. These

body, have attracted a great deal of attention. These are known by the name of contagions.

That there is a difference between the atmosphere in different places, as far as respects its effects upon the human body, has been considered as an established point in all ages. Hence some places have been celebrated as healthy, and others avoided as permicious, to the human constitution. It is well known that in pits and mines the air is often in such a state as to suffocate almost instantaneously those who attempt to

ATO ATO

breathe it. Some places are frequented by peculiar diseases. It is known that those who are much in the apartments of persons ill of certain maladies, are extremely apt to catch the infection; and in prisons and other places, where crowds of people are confined together, when diseases once commence they are wont to make dreadful havoc. In all these cases, it has been supposed that a certain noxious matter is dissolved by the air, and that it is the action of this

matter which produces the mischief.

This noxious matter is, in many cases, readily dis-tinguished by the peculiarly disagreeable smell which it communicates to the air. No doubt this matter differs according to the diseases which it communicates, and the substance from which it has originated.
Morveau lately attempted to ascertain its nature; but
he soon found the chemical tests hitherto discovered altogether insufficient for that purpose. He has put it beyond a doubt, however, that this contagious matter is of a compound nature, and that it is destroyed altogether by certain agents. He exposed infected air to the action of various bodies, and he judged of the result by the effect which these bodies had in destroying the fectid smell of the air. The following is the result of his experiments.

of his experiments:

1. Odorous bodies, such as benzoin, aromatic plants, &c. have no effect whatever.

2. Neither have the solutions of myrrh, benzoin, &c. in alkohol, though agitated in infected air.

3. Pyroligneous acid is equally inert.

4. Gunpowder, when fired in infected air, displaces a portion of it; but what remains, still retains its fætid odour.

5. Sulphuric acid has no effect; sulphurous acid weakens the odour, but does not destroy it. Distilled vinegar diminishes the odour, but its action is slow and incomplete.

7. Strong acetic acid acts instantly, and destroys the fætid odour of inbut its action is slow and incomplete. 7. Strong acetic acid acts instantly, and destroys the fætid odour of infected air completely. 8. The fumes of nitric acid, first employed by Dr. Carmichael Smith, are equally efficacious. 9. Muriatic acid gas, first pointed out as a proper agent by Morveau himself, is equally ineffectual. 10. But the most powerful agent is oxymuriatic acid gas, first proposed by Mr. Cruickshanks, and now employed with the greatest success in the British navy and military hospitals. navy and military hospitals.

Thus there are four substances which have the property of destroying contagious matter, and of purifying the air; but acetic acid cannot easily be obtained in sufficient quantity, and in a state of sufficient con-centration to be employed with advantage. Nitric acid is attended with inconvenience, because it is almost always contaminated with nitrous gas. Muriatic acid and oxymuriatic acid are not attended with these inconveniences; the last deserves the preference, be-cause it acts with greater energy and rapidity. All that is necessary is to mix together two parts of salt with one part of the black oxyde of manganese, to place the mixture in an open vessel in the infected chamber, and to pour upon it two parts of sulphuric acid. The fumes of oxymuriatic acid are immediately

exhaled, fill the chamber, and destroy the contagion.

Aτο' chia. (From a, neg. and τοκος, offspring; from τικτω, to bring forth.) 1. Inability to bring forth children. 2. Difficult labour.

ATOMIC THEORY. In the chemical combina-

tion of bodies with each other, it is observed that some unite in all proportions; others in all proportions as far as a certain point, beyond which combination no longer takes place; there are also many examples, in which bodies unite in one proportion only, and others in several proportions; and these proportions are definite, and in the intermediate ones no combination ensues. And it is remarkable, that when one body enters into combination with another, in several difenters into combination with another, in several dif-ferent proportions, the numbers indicating the greater proportions are exact simple multiples of that denoting the smallest proportion. In other words, if the smallest portion in which B combines with A, be denoted by 10, A may combine with twice 10 of B, or with three times 10, and so on; but with no intermediate quan-tities. Examples of this kind have of late so much increased in number, that the law of simple multiples increased in number, that the law of simple multiples bids fair to become universal with respect at least to chemical compounds, the proportions of which are definite. Mr. Dalton has founded what may be termed

tions of chemical compounds; or of the nature of the cause which renders combination in other proportions impossible. The following is a brief illustration of the impossible. The following is a brief illustration of the theory: Though we appear, when we effect the chemical union of bodies, to operate on masses, yet it is consistent with the most rational view of the constitution of bodies, to believe, that it is only between their theory is the combination takes ultimate particles, or atoms, that combination takes place. By the term atoms, it has been already stated, we are to understand the smallest parts of which bodies are composed. An atom, therefore, must be mechanically indivisible, and of course a fraction of an atom cannot exist, and is a contradiction in terms. Whether the atoms of different bodies be of the same size, or of different sizes, we have no sufficient evidence. The probability is, that the atoms of different bodies are of unequal sizes; but it cannot be determined whether their sizes bear any regular proportion to their relative weights. We are equally ignorant of their shape, but it is probable though not executed to their shape; but it is probable, though not essential to the theory, that they are spherical. This, however, requires a little qualification. The atoms of all bodies, probably consist of a solid corpuscle, forming a nucleus, and of an atmosphere of heat, by which that corpusele is surrounded, for absolute contact is never supposed to take place between the atoms of bodies. The figure of a single atom may therefore be supposed to be spherical. But in compound atoms, consisting of a single central atom surrounded by other atoms of a different kind, it is obvious that the figure (contemplating the solid corpuscles only) cannot be spherical; yet if we include the atmosphere of heat, the figure of a compound atom may be spherical, or some shape approaching to a sphere. Taking for granted that combination takes place between the atoms of bodies only, Mr. Dalton has deduced from the relative weights in which bodies unite, the relative weights of their ultimate particles or atoms. When only one combination of any two elementary bodies exists, he assumes, unless the contrary can be proved, that its elements are united atom to atom; single combinations of this sort he calls binary. But if several compounds can be obtained from the same elements, they combine, he supposes, in proportions expressed by some simple multiple of the number of atoms. The following table exhibits a view of these combinations:

1 Atom of A+1 atom of B=1 atom of C, binary.
1 Atom of A+2 atoms of B=1 atom of D, ternary.
2 Atoms of A+1 atom of B=1 atom of E, ternary.
1 Atom of A+3 atoms of B=1 atom of F, quaternary.
3 Atoms of A+1 atom of B=1 atom of G, quaternary.

A different classification of atoms has been proposed Reczelius, viz. into 1. Elementary atoms. 2. Com-A different classification of atoms has been proposed by Berzelius, viz. into 1. Elementary atoms. 2. Compound atoms. The compound atoms he divides again into three different species; namely; lst, Atoms formed of only two elementary substances, united or compound atoms of the first order. 2dly, Atoms composed of more than two elementary substances, and these, as they are only found in organic bodies, or bodies obtained by the destruction of organic matter, he calls organic atoms. 3dly, Atoms formed by the union of organic atoms. 3dly, Atoms formed by the union of two or more compound atoms; as, for example, the salts. These he calls compound atoms of the second order. If elementary atoms of different kinds were of the same size, the greatest number of atoms of it that could be combined with an atom of B would be 12; for this is the greatest number of spherical bodies that can this is the greatest number of spherical boules that can be arranged in contact with a sphere of the same diameter. But this equality of size, though adopted by Berzelius, is not necessary to the hypothesis of Mr. Dalton, and is, indeed, supposed by him not to exist. As an illustration of the mode in which the weight

of the atoms of bodies is determined, let us suppose that any two elementary substances, A and B, form a binary compound, and that they have been proved experimentally to unite in the proportion by weight, of five to the former, to four of the latter, then since (according to the hypothesis) they unite particle to particle, those numbers will express the relative weight of their atoms. But besides combining atom to atom singly, 1 atom of A may combine with 2 of B, or with 3, 4, &c. or one atom of B may combine with 2 of A, the atomic theory of the chemical constitution of bodies. Till this theory was proposed, we had no adequate explanation of the uniformity of the propor-

of B, or 5 to (4+4=) 8 or 5 to (4+4+4=) 12, &c., or contrariwise, 4 of B to 5 of A, or 4 to (5+5=) 10 or 4 to (5+5+5=) 15. Between these there ought to be no intermediate compounds, and the existence of any such (as 5 of A to 6 of B, or 4 of B to 7½ of A) would, if clearly established, militate against the hypothesis. clearly established, militate against the hypothesis. To verify these numbers, it may be proper to examine the combinations of A and B with some third substance, for example, with C. Let us suppose that A and C form a binary compound, in which analysis discovers 5 parts of A, and 3 of C. Then if C and B are also capable of forming a binary compound, the relative proportion of its elements ought to be 4 of B to 3 of C, for these numbers denote the relative weights of their atoms. Now this is precisely the method by which Mr. Dalton has deduced the relative weights of overen, hydrogen, and nitrogen, the first two from the oxygen, hydrogen, and nitrogen, the first two from the known composition of water, and the last two from the proportion of the elements of ammonia. Extend-ing the comparison to a variety of other bodies, he has obtained a scale of the relative weights of their atoms. In several instances additional evidence is acquired of the accuracy of the weight assigned to an element, by our obtaining the same number from an investigation of several of its compounds. For example,

1. In water, the hydrogen is to the oxygen as 1 to 8.

2. In olefiant gas, the hydrogen is to the carbon as

3. In carbonic acid, the oxygen is to the carbon as

Whether, therefore, we determine the weight of the atom of carbon from the proportion in which it combines with hydrogen, or with oxygen, we arive at the same number 6, an agreement which, as it occurs in various other instances, can scarcely be an accidental coincidence. In similar manner, 8 is deducible, as representing the atom of oxygen, both from the combination of the nation of that base with hydrogen, and with carbon, and I is referred to be the relative weight of the atom of hydrogen, from the two principal compounds into which it enters. In selecting the body which should be assumed as unity, Mr. Daiton has been induced to fix on hydrogen, because it is that body which unites with others in the smallest proportion. Thus in water, we have 1 of hydrogen, by weight, to 8 of oxygen; in ammonia, 1 of hydrogen to 14 of nitrogen; in carburetted hydrogen, 1 of hydrogen to 6 of carbon; and in sulphuretted hydrogen, 1 of hydrogen to 16 of sulphur. Taking for granted that all these bodies are binary compounds, we have the following scale of numbers expressive of the relative weights of the atoms of their elements: of hydrogen, from the two principal compounds into elements

Carbon

lius, on the other hand, have assumed oxygen as the decimal unit, (the first making it 10, the second 1, and the third 100,) chiefly with a view to facilitate the estimation of its contraction of the second 1. mation of its numerous compounds with other bodies. This perhaps is to be regretted, even though the change may be in some respects eligible, because it is extremely desirable that chemical writers should emextremely desirable that chemical writers should car-ploy a universal standard of comparison for the weights of the atoms of bodies. It is easy, however, to reduce the number to Mr. Dalton's by the rule of proportion. Thus, as 8, Mr. Dalton's number for oxy-gen, corrected by the latest experiments, is to 1, his number for hydrogen, so is 10, Dr. Wallaston's number for oxygen, 1.25 the number for hydrogen. Sir H. Davy for oxygen, 1.25 the number for hydrogen. Sir H. Davy has assumed with Mr. Dalton, the atom of hydrogen as unity; but that philosopher and Berzelius also have modified the theory, by taking for granted that water is a compound of one proportion (atom) of oxygen and two proportions (atoms) of hydrogen. This is founded on the fact that two measures of hydrogen gas and one of oxygen gas are necessary to form water; and on the supposition that equal measures of different gases contain equal numbers of atoms. And as in water the hydrogen is to the oxygen by weight as I to water the hydrogen is to the oxygen by weight as I to 8, two atoms or volumes of hydrogen must, on this hypothesis, weigh 1, and 1 atom or volume of hydrogen 8; or if we denote a single atom of hydrogen by 1, we must express an atom of oxygen by 16. It is objec-tionable, however, to this modification of the atomic

theory, that it contradicts a fundamental proposition of Mr. Dalton, the consistency of which with mechanical principles he has fully shown; namely, that that compound of any two elements which is with most difficulty decomposed, must be presumed, unless the contrary can be proved, to be a binary one. It is easy to determine, in the manner already explained, the reto determine, in the manner already explained, the lattive weights of the atoms of two elementary bodies which unite only in one proportion; but when one body unites in different proportions with another, it is necessary in order to ascertain the weight of its atom, that we should know the smallest proportion in which the former combines with the latter. Thus if we have that we should know the smallest proportion in which the former combines with the latter. Thus if we have a body A, 100 parts of which by weight combine with not less than 32 of oxygen, the relative weight of its atom will be to that of oxygen as 100 to 32; or reducing these numbers to their lowest terms, as 25 to 8; and the number 25 will therefore express the relative weight of the atom of A. But if, in the progress of science, it should be found that 100 parts of A are capable of uniting with 16 parts of oxygen, then the relative weight of the atom of A must be doubled; for as 100 is to 16, so is 50 to 8. This example will serve to exis to 16, so is 50 to 8. This example will serve to explain the changes that have been sometimes made in assigning the weights of the atoms of certain bodies, changes which it must be observed always consist either in a multiplication or division of the original weight by some simple number. There are, it must be acknowledged, a few cases in which one body com bines with another in different proportions; and yet the greater proportions are not multiples of the less by any entire number. For example, we have two oxydes of iron, the first of which consists of 100 iron and about 30 oxygen; the second of 100 iron and about 45 oxygen. But the numbers 30 and 45 are to each other as 1 to 1½. It will, however, render these numbers 1 and 1½ consistent with the law of simple multiples; if we multiply each of them by 2, it will change them to 2 and 3; and if we suppose that there is an oxyde of 2 and 3; and if we suppose that there is an oxyde of 2 and 3; and if we suppose that there is an oxyde of iron, though it has not yet been obtained experimentally, consisting of 100 iron and 15 oxygen; for the multiplication of this last number by 2 and 3 will then give us the known oxydes of iron. In some cases where we have the apparent anomaly of one atom of one substance united with 1½ of another, it has been proposed by Dr. Thomson to remove the difficulty by multiplying both numbers by 2, and by assuming that is such compounds we have two atoms of the one combined with 3 atoms of the other. Such combinacombined with 3 atoms of the other. Such combinations, it is true, are exceptions to a law deduced by Bors, it is true, are exceptions to a law deduced by Berzelius, that in all inorganic compounds one of the constituents is in the state of a single atom; but they are in no respect inconsistent with the views of Mr. Dalton, and are indeed expressly admitted by him to be compatible with this hypothesis, as well as confirmed by experience. Thus, it will appear in the sequel, that some of the compounds of oxygen with nitrogen are constituted in this way. Several objections have been proposed to the theory of Mr. Dalton. tions have been proposed to the theory of Mr. Dalton; of these it is only necessary to notice the most important. It has been contended that we have no evidence when one combination only of two elements exists, that it must be a binary one, and that we might equally well suppose it to be a compound of 2 atoms of the one body with one atom of the other. In answer to this objection, we may urge the probability, that when two elementary bodies A and B unite, the most energetic combination will be that in which one atom of A is combined with one atom of B; for an additional atom of B will introduce a new force, diminishing the attraction of these elements for each other, namely, the mutual repulsion of the atoms of B; and this repulsion will be greater in proportion as we increase the number of the atoms of B. 2dly, It has been said, that when more than one compound of two elements exists, we have no proof which of them is the binary exists, we have no proof which of them is the binary compound, and which the ternary. For example, that we might suppose carbonic acid to be a compound of an atom of charcoal, and an atom of oxygen; and carbonic oxyde of an atom of oxygen, with two atoms of charcoal. To this objection, however, it is a satisfactory answer that such a constitution of carbonic acid and carbonic oxyde would be directly contradictory of a law of chemical combination; namely, that it is and carbonic oxyde would be districted a law of chemical combination; namely, that it is attended, in most cases, with an increase of specific gravity. It would be absurd, therefore, to suppose carbonic acid, which is the heavier body, to be only

once compounded, and carbonic oxyde, which is the lighter, to be twice compounded. Moreover, it is universally observed, that of chemical compounds, the most simple are the most difficult to be decomposed; and this being the case with carbonic oxyde, we may naturally suppose it to be more simple than carbonic acid. 3dly, It has been remarked, that instead of supposing water to consist of an atom of oxygen united with an atom of hydrogen, and that the atom of the former is 7½ times heavier than that of the latter, we might with equal probability conclude, that in water we have 7½ times more atoms in number of oxygen than of hydrogen. But this, if admitted, would involve the absurdity that in a mixture of hydrogen and oxygen gases so contrived that the ultimate atoms of each should be required. of each should be equal in number, 7 atoms of oxygen would desert all the proximate atoms of hydrogen in order to unite with one at a distance, for which they must have naturally a less affinity.

ATONIC. Atonicus. Having a diminution of

strength.

A'TONY. (Atonia, from a, neg. and τεινω, Weakness, or a defect of muscular to extend.)

ATRABI'LIS. (Atrabilis, from atra, black, and

bilis, bile.) 1. Black bile. 2. Melancholy.

ATRABILIAR & CAPSUL &. (From atra, black, and bilis.) See Renal glands.

ATRACHE LUS. (From a, priv. and τραχηχος, the neck.) Short-necked.

ATRACE NE. See Clematis vitalba.

ATRA'SIA. (From a, neg. and τιτραω, to perforate.)

ATRA'SIA. (From a, neg. and τιτραω, to perforate.)

tresia. 1. Imperforate.

2. A disease where the natural openings, as the anus

or vagina, have not their usual orifice.

ATRETA'RUM. (From a, neg. and τραω, to perfo-

rate.) A suppression of urine from the menses being retained in the vagina.

A'TRICES. (From a, priv. and δριξ, hair.) Small tubercles about the anus upon which hairs will not grow.- Vaselius.

A'TRICI. Small sinuses in the rectum, which do not reach so far up as to perforate into its

A'TRIPLEX. (Atriplex, icis. f.; said to be named

A'TRIPLEX. (Atriplex, icis. f.; said to be named from its dark colour, whence it was called Atrum olus.) The name of a genus of plants in the Linnwan system. Class, Polygamia; Order, Monæcia.

Atriplex fetida. See Chenopodium vulvaria.

Atriplex hortensis. See Atriplex sativa.

Atriplex sativa. The systematic name for the atriplex hortensis of the pharmacopaias. Orache, the herb and seed of this plant, Atriplex—caule erecto herbacco, folis triangularibus, of Linnaus, have been exhibited medicinally as antiscorbutics, but the practice of the present day appears to have totally rejected them.

them.

ATROPA. (Atropa, &.f., from Atropass, the goddess of destiny: so called from its fatal effects.) The name of a genus of plants in the Linnæan system. Class, Peatandria; Order, Monogynia.

Atropa belladonna. The systematic name for the belladonna of the pharmacoposias. Solanum melonocerasus; Solanum lethale. Deadly nightshade or dwale. Atropa—caule herbaceo; foliis ovatis integris of Linnæus. This plant has been long known as a strong poison of the narcotic kind, and the berries have furnished many instances of their fatal effects, particularly upon children that have been tempted to eat them. The activity of this plant depends on a principle sui generis called Atropia. (See Atropia) The leaves were first used internally, to discuss scirrhous and cancerous tumours; and from the good effects attending their use, physicians were induced to employ them internally, for the same disorders; and there are a considerable number of well-authenticated facts, which prove them a very serviceable and imfacts, which prove them a very serviceable and important remedy. The dose, at first, should be small; and gradually and cautiously increased. Five grains are considered a powerful dose, and apt to promote dimensional factors.

dimness of sight, vertigo, &c.

Atropa Mandragora. The systematic name for the plant which affords the radix mandragora of the pharmacopaias. Mandrake. The boiled root is employed in the form of poultice, to discuss indolent tu-

mours.

ATROPHIA. (Atrophia, a. f.; from a, neg. and rpcpa, to nourish.) Marasmus. Atrophy. Nervous consumption. This disease is marked by a gradual wasting of the body, unaccompanied either by a difficulty of breathing, cough, or any evident fever, but usually attended with a loss of appetite and impaired digestion. It is arranged by Cullen in the class Cachexia, and order Marcores. There are four species:—

1. When it takes place from too copious evacuations, it is termed atrophia inanitorum; and tabes nutricum;—sudatoria;—a sanguifluxu, &c.

2. When from famine, atrophia famelicorum.

3. When from corrupted nutriment, atrophia casachymica.

4. And when from an interruption in the digestive

4. And when from an interruption in the digestive organs, atrophia debilium.

The atrophy of children is called paidatrophia. The causes which commonly give rise to atrophy, are a poor diet, unwholesome air, excess in venery, fluor albus, severe evacuations, continuing to give suck too long, a free use of spirituous liquors, mental uneasiness, and worms; but it frequently comes on without any evident cause. Along with the loss of appetite and impaired digestion, there is a diminution of strength, the face is pale and bloated, the natural heat of the body is somewhat diminished, and the lower extremities are ædematous. Atrophy, arise from whatever cause it may, is usually very difficult to cure, and not unfrequently terminates in dropsy.

A'TROPHY. See Atrophia.

ATROPHY. See Atrophia.

ATROPIA. A poisonous vegetable principle, probably alkaline, recently extracted from the Atropa belladonna, or deadly nightshade, by Brandes. He boiled two pounds of dried leaves of atropa belladonna in a sufficient quantity of water, pressed the decoction

in a sufficient quantity of water, pressed the decoction out, and boiled the remaining leaves again in water The decoctions were mixed, and some sulphuric acid was added, in order to throw down the albumen and similar bodies; the solution is thus rendered thinner, and passes more readily through the filter. The decoction was then supersaturated with potassa, by which he obtained a precipitate that, when washed with pure water and dried, weighed 89 grains. It con-

with pure water and dried, weighed 89 grains. It consisted of smal, crystals, from which by solution in acids, and precipitation by alkalies, the new alkaline substance, atropia, was obtained in a state of purity.

The external appearance of atropia varies considerably, according to the different methods by which is obtained. When precipitated from the decoction of the herb by solution of potassa, it appears in the form of very small short crystals, constituting a sandy powder. When thrown down by ammonia from an aqueous solution of its salts, it appears in flakes like wax, if the solution is much diluted; if concentrated, it is gelatinous like precipitated alumina: when obwax, if the solution is much alluted; if concentrated, it is gelatinous like precipitated alumina: when obtained by the cooling of a hot solution in alkohol, it crystallizes in long, acicular, transparent, brilliant crystals, often exceeding one inch in length, which are sometimes feathery, at other times star-like in appearance, and sometimes they are single crystals. Atropia, however, is obtained in such a crystalline state only when rendered perfectly pure by repeated solution in muriatic acid, and precipitation by ammonia. When pure, it has no taste. Cold water has hardly any effect upon dried atropia, but it dissolves a small quantity when it is recently precipitated; and boiling water dissolves still more. Cold alkohol dissolves but a minute position of atropia; but when holling it readily.

dissolves sulf more. Cold alkohol dissolves but a minute portion of atropia; but when boiling, it readily dissolves it. Ether and oil of turpentine, even when boiling, have little effect on atropia.

Sulphate of atropia crystallizes in rhomboidal tables and prisms with square bases. It is soluble in four or five parts of cold water. It seems to effloresce in the air, when freed as much as possible from adhering sulphuric acid, by pressure between the folds of blotting paper. Its composition by Brandes seems to be,

Water,24.55

This analysis would make the prime equivalent of atropia so low as 5.3, oxygen being 1. Muriate of atropia appears in beautiful white brilliant crystals, which are either cubes or square plates similar to the muriate of daturia. He makes the composition of this salt to be,

Water,35.41

This analysis was so conducted as to be entitled to This analysis was so conducted as to be entitled to little attention. Nitric, acetic, and oxalic acids dissolve atropia, and form acicular salts, all soluble in water and alkohol. Mr. Brandes was obliged to discontinue his experiments on the properties of this alkali. The violent headaches, pains in the back, and giddiness, with frequent nausea, which the vapour of atropia occasioned while he was working on it, had such a had effect on his week health that he has ensuch a bad effect on his weak health, that he has en-

tirely abstained from any further experiments.

He once tasted a small quantity of sulphate of atrohe once tasted a small quantity of sulphate of atro-pia. The taste was not bitter, but merely saline; but there soon followed violent headache, shaking in the limbs, alternate sensations of heat and cold, oppression of the chest, and difficulty in breathing, and diminished circulation of the blood. The violence of these symp-toms ceased in half an hour. Even the vapour of the different salts of atropia produces giddiness. When exposed for a long time to the vapours of a solution of exposed for a long time to the vapours of a solution of of the eye is dilated. This happened frequently to him, and when he tasted the salt of atropia, it occurred to such a degree, that it remained so for twelve hours, and the different degrees of light had no influence.—

Schweigger's Journal, xxviii. 1.

We may observe on the above, that it is highly im-

probable that atropia should have a saturating power,

intermediate between potassa and soda.

ATTE'NUANT. (Attenuans; from attenuo, to make thin.) An attenuant or diluent is that which possesses the power of imparting to the blood a more thin and more fluid consistence than it had, previous to its exhibition; such are, water, whey, and all aque-

ATTO'LLENS. (Attollens; from attollo, to lift up. Lifting up: a term applied to some muscles, the office of which is to lift up the parts they are affixed to.

ATTOLLENS AUREM. A common muscle of the ear.

Attollens auriculæ of Albinus and Douglas; Superior auris of Winslow; and Attollens auriculam of Cowper. It arises thin, broad, and tendinous, from the condens of the control from the life from the life. tendon of the occipito-frontalis, from which it is almost inseparable, where it covers the aponeurosis of the temporal muscle: and is inserted into the upper part of the ear, opposite to the antihelex. Its use is to draw the ear upwards, and to make the parts into

Mich it is inserted, tense.

ATTOLLENS OCCULI. One of the muscles which pulls up the eye.—See Rutus superior occuli.

ATTO NITUS MORBUS. (From attono, to surprise;

ATTO'NITUS MORBUS. (From attono, to surprise; so called because the person falls down suddenly.) Attonitus stupor. The apoplexy and epilepsy.

ATTRACTION. (Attractio; from attraho, to attract.) Affinity. The terms attraction, or affinity, and repulsion, in the language of modern philosophers, are employed merely as the expression of the general facts, that the masses or particles of matter have a tendency to approach and unite to, or to recede from one another, under certain circumstances. The term attraction is used synonymously with affinity. See attraction is used synonymously with affinity. See Affinity.

All bodies have a tendency or power to attract each other more or less, and it is this power which is called

Attraction is mutual: it extends to indefinite dis-All bodies whatever, as well as their component elementary particles, are endued with it. It is not annihilated, at how great a distance soever, we suppose them to be placed from each other; neither does it disappear though they be arranged ever so near each other.

The nature of this reciprocal attraction, or at least the cause which produces it, is altogether unknown to us. Whether it be inherent in all matter, or whether it be the consequence of some other agent, are ques-tions beyond the reach of human understanding; but its existence is nevertheless certain.

"The instances of attraction which are exhibited by the phenomena around us, are exceedingly numerous, and continually present themselves to our observation. The effect of gravity, which causes the weight of bo-dies, is so universal, that we can scarcely form an idea

now the universe could subsist without it. Other attractions, such as those of magnetism and electricity, are likewise observable; and every experiment in chemistry tends to show, that bodies are composed of various principles or substances, which adhere to each other with various degrees of force, and may be separated by known methods. It is a question among phi losophers, whether all the attractions which obtain be-tween bodies be referrible to one general cause modi-fied by circumstances, or whether various original and distinct causes act upon the particles of bodies at one and the same time. The philosophers, at the begin-ning of the present century were disposed to see the ning of the present century, were disposed to consider the several attractions as essentially different, because the laws of their action differ from each other; but the moderns appear disposed to generalize this subject, and to consider all the attractions which exist between bodies, or at least those which are permanent, as dejending upon one and the same cause, whatever it may be, which regulates at once the motions of the immense bodies that circulate through the celestial spaces, and those minute particles that are transferred from one combination to another in the operations of chemistry. The earlier philosophers observed, for example, that the attraction of gravitation acts upon bodies with a force which is inversely as the squares of the distances; and from mathematical deduction they have inferred, that the law of attraction between the particles themselves follows the same ratio; but when their observa-tions were applied to bodies very near each other, or in contact, an adhesion took place, which is found to be much greater than could be deduced from that law applied to the centres of gravity. Hence they con-cluded, that the cohesive attraction is governed by a much higher ratio, and probably the cubes of the distances. The moderns, on the contrary, have remarked, that these deductions are too general, because, for the most part, drawn from the consideration of spheri-cal bodies, which admit of no contact but such as is indefinitely small, and exert the same powers on each other, whichever side may be obverted. They remark, likewise, that the consequence depending on the sum of the attractions in bodies not spherical, and at minute distances from each other, will not follow the inverted ratio of the square of the distance taken from any point assumed as the centre of gravity, admitting the particles to be governed by that law; but that it will greatly differ, according to the sides of the solid which are presented to each other, and their respective distances; insomuch that the attractions of certain particles indefinitely near each other will be indefi-nitely increased, though the ratio of the powers acting upon the remoter particles may continue nearly the That the parts of bodies do attract each other, is

evident from that adhesion which produces solidity, and requires a certain force to overcome it. For the sake of perspicuity, the various effects of attraction have been considered as different kinds of affinity or powers. That power which physical writers call the powers. That power which physical writers call the attraction of cohesion, is generally called the attraction of aggregation by chemists. Aggregation is considered as the adhesion of parts of the same kind. Thus a number of pieces of brimstone, united by fusion, form an aggregate, the parts of which may be separated again by mechanical means. These parts have been called integrant parts; that is to say, the minutest parts into which a body can be divided, either really or by the imagination so as not to charge its really or by the imagination, so as not to change its nature, are called integrant parts Thus, if sulphur and an alkali be combined together, and form liver of sulphur, we may conceive the mass to be divided and subdivided to an extreme degree, until at length the mass consists of merely a particle of brimstone and a particle of alkali. This then is an integrant part; and particle of alkali. This then is an integrant part; and if it be divided further, the effect which chemists call decomposition will take place; and the particles, consisting no longer of liver of sulphur, but of sulphur alone, and of alkali aione, will be what chemists call component parts or principles.

The union of bodies in a gross way is called mixture. Thus sand and alkali may be mixed together. But when the very minute parts of a body unite with

But when the very minute parts of a body unite with those of another so intimately as to form a body which has properties different from those of either of them, the union is called combination or composition. Thus, if sand and an alkali be exposed to a strong heat,

If two solid bodies, disposed to combine together, be brought into contact with each other, the particles which touch will combine, and form a compound; and if the temperature at which this new compound assumes the fluid form be higher than the temperature assumes the fluid form be higher than the temperature of the experiment, the process will go no farther, because this new compound, being interposed between the two bodies, will prevent their farther access to each other; but if, on the contrary, the freezing point of the compound be lower than this temperature, ilquefaction will ensue; and the fluid particles being at liberty to arrange themselves according to the law of their attractions, the process will go on, and the whole their attractions, the process will go on, and the whole mass, will gradually be converted into a new compound, in the fluid state. An instance of this may be pound, in the faint state. An instance of this may be exhibited by mixing common salt and perfectly dry pounded lee together. The crystals of the salt alone will not liquefy unless very much heated; the crystals of the water, that is to say, the ice, will not liquefy unless heated as high as thirty-two degrees of Fahrenhett; and we have, of course, supposed the temperature of the experiment to be lower than this, because our water is in the solid state. Now it is a well-known fact that brine or the saturated solution of known fact, that brine, or the saturated solution of sea-salt in water, cannot be frozen unless it be cooled thirty-eight degrees lower than the freezing point of pure water. It follows then, that if the temperature of the experiment be higher than this, the first combinations of salt and ice will produce a fluid brine, and the combination will proceed until the temperature of the mass has gradually sunk as low as the freezing point of brine; after which it would cease if it were not that surrounding bodies continually tend to raise the temperature. And accordingly it is found by ex-periment, that if the ice and the salt be previously cooled below the temperature of freezing brine, the combination and liquefaction will not take place.

The instances in which solid bodies thus combine together not being very numerous, and the fluidity which ensues immediately after the commencement of this kind of experiment, have induced several chemists to consider fluidity in one or both of the bodies applied to each other, to be a necessary circumstance, in order that they may produce chemical action upon

action upon cach order. Corpora non agant misi sint fluida.

If one of two bodies applied to each other be fluidat the temperature of the experiment, its parts will successively unite with the parts of the solid, which will by that means be suspended in the fluid, and disappear. Such a fluid is called a solvent or menstruum;

and the solid body is said to be dissolved.

Some substances unite together in all proportions. In this way the acids unite with water. But there are likewise many substances which cannot be dissolved in a fluid, at a settled temperature, in any quantity beyond a certain portion. Thus, water will dissolve only about one-third of its weight of common salt; and if more salt be added, it will remain solid. A fluid which holds in solution as much of any substance as it can dissolve, is said to be saturated with it. But saturation with one substance is so far from preventing a fluid from dissolving another body, that it very frequently happens, that the solvent power of the compound exceeds that of the original fluid itself. Chemists likewise use the word saturation in another sense; in which it denotes such a union of two bodies as produces a compound th: most remote in its properties from the properties of the component parts themselves. In combinations where one of the principles predomi-

In combinations where one of the principles predominate, the one is said to be supersaturated, and the other principle is said to be supersaturated, and the other principle is said to be subsaturated.

Heat in general increases the solvent power of fluids, probably by preventing part of the dissolved substance from congealing or assuming the solid form.

It often happens, that bodies which have no !cndency to unite are made to combine together by means of a third, which is then called the medium. Thus water and fat this are made to unite by the medium of an alkali, in the combination called soap. Some writers, who seem desirous of multiplying terms, call this tendency to unite the affinity of intermedium. This case has likewise been called disposing affinity; but Berthollet more properly styles it reciprocal affinity. He likewise distinguishes affinity into elementary, when it is between the elementary parts of bodies;

the minute parts of the mixture combine and form and resulting, when it is a compound only, and would not take place with the elements of that compound.

It very frequently happens, on the contrary, that the tendency of two bodies to unite, or remain in combination together, is weakened or destroyed by the addition of a third. Thus alkohol unites with water in such a manner as to separate most salts from it. A striking instance of this is seen in a saturated or strong solution of nitre in water. If to this there be added an equal measure of alkohol, the greater part of the nitre instantly falls down. Thus magnesia is separated from a solution of Epsom salt, by the addition of an alkali, which combines with the sulphuric acid, and separates the earth. The principle which falls down is said to be precipitated, and in many instances is called a precipitate. Some modern chemists use the term precipitation in a more extended, and rather forced sense; for they apply it to all substances thus separated. In this enunciation, therefore, they would say, that potassa precipitates soda from a solution of common salt, though no visible separation or precipi-tation takes place; for the soda, when disengaged from its acid, is still suspended in the water by reason of its solubility.

From a great number of facts of this nature, it is clearly ascertained, not as a probable hypothesis, but as simple matter of fact, that some bodies have a stronger tendency to unite than others; and that the union of any substance with another will exclude, or separate, a third substance, which might have been previously united with one of them; excepting only in those cases wherein the new compound has a tendency to unite with that third substance, and form a triple compound. This preference of uniting, which a given compound. This preference of uniting, which a given substance is found to exhibit with regard to other bodies, is by an easy metaphor called elective attraction, and is subject to a variety of cases, according to the number and the powers of the principles which are respectively presented to each other. The cases which have been most frequently observed by chemists, are those called simple elective attractions, and

double elective attractions.

When a simple substance is presented or applied to another substance compounded of two principles, and unites with one of these two principles so as to separate or exclude the other, this effect is said to be produced by simple elective attraction.

It may be doubted whether any of our operations have a provided to this degree of simplicity.

have been carried to this degree of simplicity. the chemical principles we are acquainted with are the chemical principles we are acquainted with are simple only with respect to our power of decomposing them; and the daily discoveries of our contemporaries tend to decompose those substances, which chemists a few years ago considered as simple. Without insisting, however, upon this difficulty, we may observe, that water is concerned in all the operations which are called humid, and beyond a doubt modifies all the effects of such bodies as are suspended in it; and the variations of temperature, whether arising from an actual igneous fluid, or from a mere modification of the parts of bodies, also tend greatly to disturb the effects of elective attraction. These causes render it difficult to point out an example of simple elective attraction, which may in strictness be reckoned as such.

Double elective attraction takes place when two bodies, each consisting of two principles, are presented to each other, and mutually exchange a principle of each; by which means two new bodies, or compounds, are produced of a different nature from the original compounds.

Under the same limitations as were pointed out in speaking of simple elective attraction, we may offer instances of double elective attraction. Let oxyde of mercury be dissolved to saturation in the nitric acid, the water will then contain nitrate of mercury. Again, let potassa be dissolved to saturation in the sulphuric acid, and the result will be a solution of sulphate or potassa. If mercury were added to the latter solution, it would indeed tend to unite with the acid, but, would it would indeed tend to unite with the acid, but, would produce no decomposition; because the elective attraction of the acid to the alkali is the strongest. So likewise, if the nitric acid alone be added to it, its tendency to unite with the alkali, strong as it is, will not effect any change, because the alkali is already in combination with a stronger acid. But if the nitrate of mercury be added to the solution of sulphate of poATT

tassa, a change of principles will take place; the sulphuric acid will quit the alkali, and unite with the mercury, while the nitric acid combines with the alkali; and these two new salts, namely, nitrate of potassa, and sulphate of mercury, may be obtained separately by crystallization. The most remarkable circumstance in this process, is that the joint effects of the attractions of the sulphuric acid to mercury, and the nitric acid to alkali process to be attractions than the the nitric acid to alkali, prove to be stronger than the sum of the attractions between the sulphuric acid and the alkali, and between the nitrous acid and the mer-cury; for if the sum of these two last had not been weaker, the original combinations would not have been broken.

Mr. Kirwan, who first, in the year 1782, considered this subject with that attention it deserves, called the affinities which tend to preserve the original combina-tions, the quiescent affinities. He distinguished the affinities or attractions which tend to produce a change of principles, by the name of the diviellent affinities.

some eminent chemists are disposed to consider as Some eminent chemists are disposed to consider as effects of double affinities, those changes of principles only which would not have taken place without the assistance of a fourth principle. Thus, the mutual decomposition of sulphate of soda and nitrate of potassa, in which the alkalies are changed, and sulphate of potassa and nitrate of soda are produced, is not considered by them as an instance of double decomposition, because the nitra would have been decomposition. position; because the nitre would have been decomposed by simple elective attraction, upon the addition

of the acid only.

There are various circumstances which modify the effects of elective attraction, and have from time to time misled chemists in their deductions. The chief of these is the temperature, which, acting differently upon the several parts of compounded bodies, seldom fails to alter, and frequently reverses the effects of the affinities. Thus, if alkohol be added to a solution of nitrate of potassa, it unites with the water, and precipitates the salt at a common temperature. But if the temperature be raised, the alkohol rises on account of its volatility, and the salt is again dissolved. Thus again, if sulphuric acid be added, in a common temperature, to a combination of phosphoric acid and lime, it will decompose the salt, and disengage the phosphoric acid; but if this same mixture of these principles be exposed to a considerable heat, the sulphuric acid will have its attraction to the lime so much time misled chemists in their deductions. phuric acid will have its attraction to the lime so much diminished, that it will rise, and give place again to the phosphoric, which will combine with the lime. Again, mercury kept in a degree of heat very nearly equal to volatilizing it will absorb oxygen, and become converted into the red oxyde formerly called precipitate per se; but if the heat be augmented still more, the oxygen will assume the elastic state, and fly off, leaving the mercury in its original state. Numberless leaving the mercury in its original state. Numberless instances of the like nature continually present themselves to the observation of chemists, which are suffi-cient to establish the conclusion, that the elective attractions are not constant but at one and the same

Many philosophers are of opinion, that the variations produced by change of temperature arise from the elective attraction of the matter of heat itself. But

there are no decisive experiments either in confirma-tion or refutation of this hypothesis.

If we except the operation of heat, which really produces a change in the elective attractions, we shall find, that most of the other difficulties attending this find, that most of the other difficulties attending this subject arise from the imperfect state of chemical science. If to a compound of two principles a third be added, the effect of this must necessarily be different according to its quality, and likewise according to the state of saturation of the two principles of the compounded body. If the third principle which is added be in excess, it may dissolve and suspend the compound which may be newly formed, and likewise that which might have been precipitated. The metallic/solutions. might have been precipitated. The metallic solutions, decomposed by the addition of an alkali, afford no precipitate in various cases when the alkali is in exprecipitate in various cases when the alkan is in ex-cess; because this excess dissolves the precipitate, which would else have fallen down. If, on the other hand, one of the two principles of the compound body be in excess, the addition of a third substance may combine with that excess, and leave a neutral sub-stance, exhibiting very different properties from the former. Thus, if cream of tartar, which is a salt of

difficult solubility, consisting of potassa united to an excess of the acid of tartar, be dissolved in water, and chalk be added, the excess unites with part of the lime of the chalk, and forms a scarcely soluble salt; and the neutral compound, which remains after the privation of this excess of acid, is a very soluble salt, greatly differing in taste and properties from the cream of tartar. The metals and the acids likewise afford various phenomena, according to their degree of oxydation. A determinate oxydation is in general necessary for the solution of metals in acids; and the acids themselves act very differently, accordingly as they are more or less acidified. Thus, the nitrous acid gives the solution of metals in acids, and the acids themselves acid gives more or less acidified. Thus, the nitrous acid gives the solution acids which are weaker than the pittic acid. place to acids which are weaker than the nitric acid the sulphurous acid gives place to acids greatly inferior in attractive power or affinity to the sulphuric acid. The deception arising from effects of this nature is in a great measure produced by the want of discrimination on the part of chemical philosophers; it being evident that the properties of any compound substance depend as much upon the proportion of its ingredients, as upon their respective nature.

The presence and quantity of water is probably of more consequence than is yet supposed. Thus, bis-muth is dissolved in nitrous acid, but falls when the

water is much in quantity.

The power of double elective attractions, too, is disturbed by this circumstance: If muriate of lime be added to a solution of carbonate of soda, they are both decomposed, and the results are muriate of soda and carbonate of lime. But if lime and muriate of soda be mixed with just water sufficient to make them into a paste, and this be exposed to the action of carmto a paste, and this be exposed to the action of car-bonic acid gas, a saline efflorescence, consisting of carbonate of soda, will be formed on the surface, and the bottom of the vessel will be occupied by muriate of lime in a state of deliquescence.

Berthollet made a great number of experiments, from which he deduced the following law:—that in elective attractions the power exerted is not in the ratio of the affinity simple, but in a ratio companyeded of the

affinity simple, but in a ratio compounded of the force of affinity and the quantity of the agent; so that quantity may compensate for weaker affinity. Thus an acid which has a weaker affinity than another for a given base, if it be employed in a certain quantity, is capable of taking part of that base from the acid which has a stronger affinity for it; so that the base will be divided between them in the compound stice. which has a stronger amount for it; so that the base will be divided between them in the compound ratio of their affinity and quantity. This division of one substance between two others, for which it has different affinities, always takes place, according to him, when three such are present under circumstances in which they can mutually act on each other. And hence it is, that the force of affinity acts most power-first come into contact and fully when two substances first come into contact, and continues to decrease in power as either approaches the point of saturation. For the same reason it is so difficult to separate the last portions of any substance adhering to another. Hence, if the doctrine laid down by M. Berthollet be true, to its utmost extent, it must be impossible ever to free a compound completely from any one of its constituent parts by the agency of elective attraction; so that all our best established analyses are more or less inaccurate.

The solubility or insolubility of principles, at the temperature of any experiment, has likewise tended to mislead chemists, who have deduced consequences from the first effects of their experiments. It is evident, that many separations may ensue without precipitation; because this circumstance does not take place unless the separated principle be insoluble, or nearly so. The soda cannot be precipitated from a solution of sulphate of soda, by the addition of potassa, because of its great solubility; but, on the contrary, the new compound itself, or sulphate of potassa, which is much less soluble, may fall down, if there be not enough of water present to suspend it. knowledge can therefore be derived from the appearance or the want of precipitation, unless the products be carefully examined. In some instances all the products remain suspended; and in others, they all fall down, as may be instanced in the decomposition of sulphate of iron by lime. Here the acid unites with the lime, and forms sulphate of lime, which is scarcely at all soluble; and the still less soluble oxyde of iron, which was disengaged, falls down along with it.

Many instances present themselves, in which decom

position does not take place, but a sort of equilibrium of affinity is perceived. Thus, soda, added to the supertartrate of potassa, forms a triple salt by combining with its excess of acid. So likewise ammonia combines with a portion of the acid of muriate of mercury, and forms the triple compound formerly dis-tinguished by the barbarous name of "sal alembroth."

Attraction, double elective. See Affinity, double.

Aua'nte. (From avairw, to dry.) A dry disease, proceeding from a fermentation in the stomach, described by Hippocrates de Morbis.

Aua'rse. The same.

Au'chen. (From avaiw, to be proud.) The neck, which in the posture of pride, is made stiff and erect. AUDITORY. (Auditorius; from audio, to hear.) Belonging to the organ of hearing: as auditory nerve.

Belonging to the organ of hearing; as auditory nerve,

Auditory nerve. See Portio mollis.

Auditory passage. See Ear, and Meatus auditorius internu

AUGITE. Pyroxene of Hauy. A green, brown, or black mineral, found crystallized, and in grains in volcanic rocks in basaltes. It consists of silica, lime, oxyde of iron, magnesia, alumina, and manganese.

oxyde of iron, magnesia, alumina, and manganese. [It occurs in crystals, amorphous, in rounded fragments, or in grains. The Augite has a foliated structure in two directions, parallel to the sides of the primitive form. It is harder than hornblende or olivine, scratches glass, and gives sparks with steel. Its specific gravity varies from 3.10 to 3.47.

It is fuscd with difficulty by the blow-pipe; but in small fragments melts into an enamel, which, in the coloured varieties, is black. Its greater hardness, the results of mechanical division, and its difficult fusibility, will in general be sufficient to distinguish it from hornblende, which it often resembles. It cannot easily be confounded with schorl. It has two varieties. I. Common Augite. 2. Coccolite.—Cl. Min. A.]

Augu'stum. An epithet formerly given to several compound medicines.

compound medicines.

Auli'scos. (From aulos, a pipe.) A catheter, or

AU'LOS.

clyster-pipe. AU'RA. (Aura, x. f.; from aw, to breathe.) Any subtile vapour or exhaltation.

(Aulos, a pipe.) A catheter, canula, or

AURA EPILEPTICA. A sensation which is felt by epileptic patients, as if a blast of cold air ascended from

the lower parts towards the heart and head.

AURA SEMINIS. The extremely subtile and vivifying portion of the semen virile, that ascends through the Fallopian tubes, to impregnate the ovum in the ovarium.

AURA VITALIS: So Van Helmont calls the vital

heat

AURA'NTIUM. (Aurantium, i. n.; so called, ab

aureo colore, from its golden colour, or from Arantium, a town of Achaia.) Theorange. See Citrus aurantium.
AURANTIUM CURASSAVENTE. The Curassoa, or Curassao apple, or orange. The fruit so called seems to be the immature oranges, that by some accident have been checked in their growth. They are a grateful aronatic bility of a dargurery different for the ful aromatic bitter, of a flavour very different from that of the peel of the ripe fruit, and without any acid; what little tartness they have when fresh, is lost in drying. Infused in wine, or brandy, they afford a good nitter for the stomach. They are used to promote the discharge in issues, whence their name of issue peas, and to give the flavour of hops to beer.

AURANTH CORTEX. See Citrus aurantium.

AURANTH CORTEX. See Citrus aurantium.

AURICHALCUM. Brass.
AURI'CULA. (Auricula, &. f. dim. of auris, the ar.)
1. An auricle or little ear.

ear.) 1. An auricle or little ear.
2. The external ear, upon which are several eminences and depressions; as the heliz, antiheliz, tragus, antitragus, conchæ auriculæ, scapha, and lobulus. See

3. Applied to some parts which resemble a little car,

as the auricles of the heart.

4. In botany, applied to parts of plants, which resemble an ear in figure, as Auricula juda, and Auricula

AURICULA JUDÆ. See Petiza auricula. Auricula muris. See Hieracium.

AURICULE CORDIS. The auricles of the heart. See Heart.

AURICULA'RIS. (Auricularis; from auris, the ear.) Pertaining to the ear.
AURICULARIS DIGITUS. The little finger; so called

because people generally put it into the ear, when the

hearing is obstructed. AURICULATUS. Auricled. A leaf is said to be so, when furnished at its base with a pair of leaflets, pro-perly distinct, but occasionally liable to be joined to it, as in Citrus aurantium.

Auri'ga. (Auriga, a wagoner.) A bandage for the sides is so called because it is made like the traces of a

wagon-horse.—Galen.
AURI'GO. (Ab aureo colore; from its yellow colour.) The jaundice. See Ieterus
AURIPI'GMENTUM. (From aurum, gold, and pigmentum, paint; so called from its colour and its use to painters.) Yellow orpiment. See Arsenic.

AU'RIS. (Auris, is. I.; from aura, air, as being the medium of hearing.) The ear, or organ of hearing

scalpo, to scrape.) An instrument for cleansing the car.
Auru'go. The jaundice. See Aurigo.
AU'RUM. 1. Gold.
2. This term was

alchemists and chemists, which resembled gold in colour or virtues.

AURUM FULMINANS. The precipitate formed by putting ammonia into a solution of gold.

AURUM GRAPHICUM. An ore of gold.

AURUM HORIZONTALE. Oil of cinnamon and sugar.

AURUM LEPROSUM. Antimony.
AURUM MUSIVUM. Mosaic gold. "A combination of tin and sulphur, which is thus made; Melt twelve ounces of tin, and add to it three ounces of mercury; ounces of tin, and add to it three ounces of mercury; triturate this amalgam with seven ounces of sulphur, and three of muriate of ammonia. Put the powder into a mattress, bedded rather deep in sand, and keep it for several hours in a gentle heat; which is afterward to be raised, and continued for several hours longer. If the heat have been moderate, and not continued too long, the golden-coloured scaly porous mass, called aurum musicum, will be found at the bottom of the vessel; but if it have been too strong, the aurum musicum fuses to a black mass of a striated texture. This process is thus explained: as the heat increases This process is thus explained: as the heat increases, the tin, by stronger affinity, seizes and combines with the muriatic acid of the muriate of ammonia; while the alkali of that salt, combining with a portion of the sulphur, flies off in the form of a sulphuret. The combination of tin and muriatic acid sublimes; and is found adhering to the sides of the mattress. The mercury, which, served to divide the tin, combines with part of the sulphur, and forms cinnabar, which also sublimes; and the remaining sulphur, with the remaining tin, forms the aurum musicum which occupies the lower part of the vessel. It must be admitted, however, that this explanation does not indicate the reasons why such an indirect and complicated process should be required to form a simple combination of tin and sulphur. This process is thus explained: as the heat increases

and supplur.

Aurum musivum has no taste, though some specimens exhibit a sulphureous smell. It is not soluble in water, acids, or alkaline solutions. But in the dry way it forms a yellow sulphuret, soluble in water. It deflagrates with nitre. Bergman mentions a native aurum musivum from Siberia, containing tin, sulphur,

and a small proportion of copper.

This substance is used as a pigment for giving a golden colour to small statue or plaster figures. It is likewise said to be mixed with melted glass to imi-

tate lapis lazulii.

tate lapis lamin.

AURUM POTABILE. Gold dissolved and mixed with oil of rosemary, to be drunk.

AUTHE MERON. (From αυτος, the same, and ημερα, a day.) A medicine which gives relief, or is to be administered the same day.

AUTOCRATE IA. The healing power of nature.

Hippocrates.
[AUTOMALITE. This mineral substance is otherwise called Gahnite. It is always crystallized in octaedrons, which are some-[AUTOMALITE. This inner al substance is otherwise called Gahnite. It is always crystallized in small, but very regular octaedrons, which are sometimes double, like those of spinelle. Its colour is deep green, or greenish black, and its fragments are translucent. It scratches quartz, and has an uneven or conchoidal fracture. Its specific gravity varies from the to 4.60. It is not a conductor of electricity. 4.26 to 4.69. It is not a conductor of electricity.

Before the blow-pipe it is infusible; but with borax, according to Eckeberg, it gives a green glass, while hot, which becomes colourless when cold. It contains Alumine 60., oxide of zinc 24.25, oxide of iron 9.25, silex, 4.75=98.25. According to Vauquelin, Alumine 42., oxide of zinc 28., oxide of iron 5., silex 4., sulphur 17., insoluble residue 4. It has been found at a mine of Fahlun, in Sweden, in a rock abounding in tale.—Cl. Min. A.1 -Cl. Min. A.] AUTO'PSIA.

(From auros, himself, and on 70 µat,

AUTO PSIA. (From autos, himself, and on Jopan, to see.) Ocular evidence.

AUTO PYROS. (From autos, itself, and whoos, wheat.) Bread made with the meal of wheat, from which the bran has not been removed.—Galen.

AUXILIARY. Assisting. This term is applied to the means which co-operate in curing diseases, and to parts which assist, others in performing certain functions. The pyramidales were called auxiliary muscles.

AVANTURINE. A variety of quartz rock containing mica spangles. It is found in Spain and Scot-

AVELLA'NA. (From Abella, or Avella, a town in Campania, where they grow.) The specific name of

the hazel-nut. See Corylus avellana.

AVELLANA CATHARTICA. A purgative seed or nut, from Barbadoes, the produce of the Jatropha curcas.

from Barbadoes, the produce of the Jatropha curcas. See Jatropha curcas.

AVELLANA MEXICANA. Cocoa and chocolate nut.

AVELLANA PURGATRIX. Garden spurge.

AVE'NA. (Avena, a. f.; from aveo, to covet; because cattle are so fond of it.) The oat. 1. The name of a genus of plants in the Linnwan system. Class, Triandria; Order, Digynia.

2. The pharmacopæial name of the oat.

AVENA SATIVA. The systematic name for the avena of the pharmacopæias. It is the seed which is commonly used, and called the oat. There are two kinds of oats: the black and the white. They have similar virtues, but the black are chiefly sown for horses. They are less farinaceous, and less nourishing, than rice, or wheat; yet afford sufficient nourishment, of easy digestion, to such as feed constantly on them. In They are less farinaceous, and less nourishing, than rice, or wheat; yet afford sufficient nourishment, of easy digestion, to such as feed constantly on them. In Scotland, and some of the northern counties of England, oats form the chief bread of the inhabitants. They are much used in Germany; but, in Norway, oat bread is a luxury among the common people, Gruels, made with the flour, or meal, called oatmeal, digest easily, have a soft mucilaginous quality, by which they obtund acrimony, and are used for common drink and food in fevers, inflammatory disorders, coughs, hoarseness, roughness, and exulceration of the fauces; and water gruels answer all the purposes of Hippocrates's ptisan. Externally, poultices, with oatmeal, vinegar, and a very little oil, are good for sprains and bruises. Stimulant poultices, with the grounds of strong beer, mixed up with oatmeal, are made for tumours, &c. of a gangrenous tendency.

AVENS. (Avens, entis; from aves, to desire.) 1. The specific name of a species of dipsosis in Good's Nosology: immoderate thirst.

2. The name of a plant. See Geum.

AVENIUS. Veinless. Without a vein. A term applied by botanists to a leaf which is without what they call a vein; as in Clusia alba.

AVENZOAR. A native of Seville, in Spain, who flourished about the beginning of the twelfth century; he was made physician to the king, and is said, but on imperfect evidence, to have attained the uncommon

he was made physician to the king, and is said, but on imperfect evidence, to have attained the uncommon age of 135. He prepared his own medicines, and practised surgery, as well as physic. His principal work was a compendium of the practice of medicine, called, "Al-Theiser," containing some diseases not elsewhere described, and numerobs cases candidly related. He was called the Experimenter, from his careful investi-gation of the powers of medicines by actual trial. AVERROES. An eminent philosopher and physi-cian, born about the middle of the 12th century, at

Corduba, in Spain. He studied medicine under Avenzoar, but does not appear to have been much engaged in the practice of it, his life exhibiting the most extraordinary vicissitudes of honours bestowed upon him as a magistrate, and persecutions, which he underwent for religion. He appears to have first observed, that the small-pox occurs but once in the same person. His principal medical work, called the "Universal," is

a compendium of physic, mostly collected from other authors. He died about the year 1206.

AVICENNA. A celebrated philosopher and physician, born in Chorasan, in the year 980. He studied at Bagdat, obtained a degree, and began to practise at 18: and he soon attained great wealth and honour in the court of the caliph. But during the latter part of his life, residing at Ispahan, after several years spent in travelling, he impaired his constitution by intemperance, and died of a dysentery in his 58th year. His chief work on medicine, called "Canon Medicine," though mostly borrowed from the Greek or other preceding writers, and in a very diffuse style, acquired great reputation, and was taught in the European colleges till near the middle of the 17th century.

AVICE'NNIA. (Named after the celebrated physician)

AVICENNIA. (Named after the celebrated physician of that name.) The name of a genus of plants in the Linnwan system. Class, Didynamia; Order,

Angiospermia.

Avicennia Tomentosa. The systematic name for the Avicennia—foliis cordato ovatis, subtus tomentosis, of Linnaus, which affords the Malacca bean, or Anacardium orientale of the pharmacopeias. The fruit, or nut, so called, is of a shining black colour, heart-shaped, compressed, and about the size of the thumbnail. It is now deservedly forgot in this country.

nail. It is now deservedly forgot in this country.

Avigato pear. See Laurus persea.

Awl-shaped. See Leaf.

AWN. See Arista.

AXE-STONE. A species of nephrite, and a subspecies of jade, from which it differs in not being of so light a green, and in having a somewhat slaty texture.

[The fracture of this mineral is more or less splintery and glimmering. The structure of large specimens is a little slaty. Its hardness is less than that of nephrite; it is more easily broken, and often falls into tabular. a little staty. Its hardness is less than that of nephrite; it is more easily broken, and often falls into tabular fragments. It is usually translucent, sometimes at the edges only. Its colour varies from a dark or leek green, to grass and olive green, or even greenish gray. It occurs amorphous, sometimes in rolled fragments. It is less easily fusible than nephrite or Saussurite, and melts with efferverscence into a black enamel. It often appears to be nearly allied to sementine.

and mets with enerverscence into a black challenger of the form appears to be nearly allied to serpentine. This mineral has been found chiefly in South America, New Zealand, and the islands of the South sea. It receives a tolerable polish; and is employed by the natives of the aforesaid islands for making hatchets. and other instruments; and hence its name.-Cleav.

Min. A.)

AXI'LLA. (Axilla, a. f. Atzil, Heb. Scaliger deduces it from ago, to act; in this manner, ago, axo, axa, axula, axilla.)

1. In anatomy, the cavity under the upper part of the arm, called the arm-pit.

2. In botany, the angle formed by the branch and stem of a plant, or by the leaf with either.

AXILLARIS. (From axilla, the arm-pit.) Axillary.

1. Of, or belonging to the axilla, or arm-pit.

2. In botany, leaves, &c. are said to be axillary which proceed from the angles formed by the stem and branch.

branch

AXILLARIS. See Axillary.

AXILLARIS GEMMA. Axillary gem. The gem which comes out of the axilla of a plant. It is this which bears the fruit. AXILLARY.

(Azillaris; from axilla, the arm-

AXILLARY. (Azillaris; from azilla, the armpit.) Of or belonging to the axilla, or arm-pit.

AXILLARY ARTERIES. Arteriæ azillares. The axillary arteries are continuations of the subclavians, and give off, each of them, in the axilla, four mammary arteries, the subscapular, and the posterior and anterior circumflex arteries, which ramify about the

Nervis axillares. Articular AXILLARY NERVES. nerve. A branch of the brachial plexus, and some-times of the radial nerve. It runs outwards and back-wards, around the neck of the humerus, and is lost in

the muscles of the scapula.

the muscles of the scapula.

AXILLARY VEINS. Venæ axillares. The axillary veins receive the blood from the veins of the arm, and evacuate it into the subclavian vein.

AXINITE. Thumerstone. A massive or crystallized mineral, the crystals of which resemble an axe in the form and sharpness of their edges. It is found in beds at Thum, in Saxony, and in Cornwall.

[This mineral is sometimes in tabular masses, but most commonly in crystals, which are easily recognised. The general form of these crystals is a very

oblique romb, or rather four-sided prism, so flattened, that some of its edges become thin and sharp, like the edge of an axe. The primitive form is a four-sided prism, whose bases are parallelograms with angles of 1019 30' and 78° 30". The integrant particles are oblique triangular prisms. M. Haûy has described five second-

triangular prisms. M. Hauy has described five secondary forms.

Before the blow-pipe it easily melts with ebullition, into a dark gray enamel, which with borax becomes olive green. It contains, according to Vanquelin, silex 44, alumine 18, lime 19, iron 14, manganese 4,=99.

Aximite is a rare mineral. It is found in primitive rocks, more particularly in fissures or veins which traverse them. In Dauphiny, it is associated with quartz, feldspar, epidote, and asbestus. In the Pyrenees with quartz and limestone. In Norway, near Arendal, with feldspar and epidote; and near Konsberg it exists in limestone with mica, quartz, &c. In occurs in lamellar masses near Thum in Saxony, whence the name Thumerstone.—Cl. Min. A.]

A'XIS. (From ago, to act.) The second vertebra. See Dentatus.

See Dentatus,
AXU'NGIA. (Azungia, a. f.; from axis, an axletree, and unguo, to anoint.) Hog's lard.
AXUNGIA CURATA. Purified hog's lard.

Marrow

AXUNGIA DE MUMMIA. Marrow.
A'ZAC. (Arabian.) Gum ammoniac.
AZA'GOR. Verdigris.
AZALÆA. (From aξαλεος, dry, from its growing in a dry soil.) The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Mono-

AZALEA PONTICA. The Pontic azalea.

AZAMAR. Native cinnabar. Vermilion.

AZAD. A fine kind of camphire.

AZOTE. (From a, priv. and ζω, to live; because is unfit for respiration.) Azot. See Nitrogen.

Azotane. The chloride of azote. Azote, chloride of. See Nitrogen. Azote, deutozyde of. See Nitrogen Bzote, naseous oxyde of. See Nitrogen. Atote, gaseous oxyde of. See Nitrogen.
Atote, iodide of. See Nitrogen.
Atote, iodide of. See Nitrogen.
Atote, protoxyde of. See Nitrogen.
A'zorh. An imaginary universal remedy.
A'zus. Alum.
Azurestone. See Levis levis desired.

Azurestone. See Lapis lazuli.

Azure spar, prismatic. See Azurite
AZURITE. Prismatic azure spar. Lazulite of
Werner. A mineral of a fine blue colour, composed
of alumina, magnesia, silica, oxyde of iron, and lime. It occurs in Vorau, in Stiria, and the bishopric of

Azu'RIUM. Quicksilver, sulphur, and sal-ammoniac.

A'zygks. (From a, priv. and ζυγος, a yoke.) The os sphenoides was so called, because it has no fellow. A'ZYGOS. (From a, priv. and ζυγος, a yoke; because it has no fellow.) Several single muscles, veins, bones, &c. are so called.

Azygos Processus. A process of the os sphenoides.
Azygos UVULE. A muscle of the uvula. Palatostaphilinus of Douglas. Staphilinus, or Epistaphilinus of Winslow. It arises at one extremity of the
suture which joins the palate bones, runs down the
whole length of the velum and uvula, resembling an
earth-worm, and adhering to the tendons of the circumfleyi. It is inserted into the tim of the uvula. Its cumflexi. It is inserted into the tip of the uvula. Its use is to raise the uvula upwards and forwards, and to shorten it.

Azygos vena. Azygos vein. Vena sine pari. This vein is situated in the right cavity of the thorax, upon the dorsal vertebra. It receives the blood from the vertebral, intercostal, bronchial, pericardiac, and diaphragmatic veins, and evacuates it into the vena cava superior.

BABUZICA'RIUS. (Βαδουζικαριος; "vom βαδαζω, to speak inarticulately.) The incubus, or night-mare: so called, because, in it, the person is apt to make an inarticulate or confused noise.

BA'CCA. (Bacca, & f., a berry.) A pulpy peri-carpium, or seed-vessel, enclosing several naked seeds, connected by a slender membrane, and dispersed through the pulp. It is distinguished by its figure into,

Bacca rotunda, round; as in Ribes rubrum, the current, and Grossularia, the gooseberry.

2. Bacca oblonga, oblong; as in Barbaria vulgaris,

common barberry.

3. Bacca dicocca, double, as in Jasminum.

4. Bacca recutita, circumcised like the prominent glans penis, without the prepuce; as in Taxus

From the substances it is denominated,

Bacca succosa, juicy; as in Ribes rubrum.
 Bacca corticosa, covered with a hard bark; as in

Garcinia mangostana. 3. Bacca exsicea, dry; as in Hedera helix. From the number of loculaments into,

Bacca unilocularis, with one; as in the Actea and Cactus.

2. Bacca bilocularis, with two; as in Lonicera.

Bacca trilocularis, with three; as in Asparagus

4. Bacca quadrilocularis, with four; as Caris qua-

5. Bacca guinquelocularis, with five; as in Me-

6. Bacca multilocularis, with many; as in Nymphwa.

From the number of the seeds into,

1. Bacca monosperma, with one only; as in Daphne, Viscum, and Viburnum.

2. Bacca disperma, with two seeds; as Barbarca valgaris, and Coffea arabica

Bacca trisperma, with three; as in Sambucus, and Juniperis.

4. Bacca quadrisperma, with four; as in Ligus-trum, and Ilex.
5. Bacca polysperma, with many seeds; as in Ar-butus unedo, Ribes, and Gardenia.
The Bacca is also distinguished into simple and

compound, when it is composed of several berries, which are called acini; as in Rubus fruticosus.

BACCA BERMUDENSIS. The Bermuda berry. See

Sopindus saponaria.
*Bacca Juniperi. The juniper berry. See Juniperus communis.

BACCA LAURI. The laurel berry. See Laurus nobilis.

BACCA MONSPELIENSIS. See Inula dysenterica.
BACCA NORLANDICA. The shrubby strawberry. See Rubus arcticus.

BACCA PISCATORIA. So named because fish are caught with them. See Menispormum cocculus.

BACCA'LIA. (From baccharum copia, because it abounds in berries.) The bay, or laurel-tree. See

BA'CCHARIS. (From bacchus, wine; from its fragrance resembling that liquor.) See Inula dysen-

to bear.) Berry bearing.

The plants are so called which BACCIFERUS. (From bacco, a berry, and fero,

BACCHER PLANTE. Plans are so called which have a berry or pulpy pericarpium.

BA'CCHIA. (From bacchus, wine; because it generally proceeds from hard drinking and intemperance.) A name given by Linnaus to the pimpled face, which results from free living.

BACCILLUM. A little berry.

BACCIUS, ANDREW, a native of Ancona, practised medicine at Rome towards the end of the 16th century, and became physician to Pope Sixtus V. He appears to have had great industry and learning from his nu-merous publications; of which the chief, "De Ther-mis," gives an extensive examination of natural waters.

Ba'ccult. 1. Is used, by some writers, for a parti-cular kind of lozenges, shaped into little short rolls. 2. Hildanus likewise uses it for an instrument in

Bacher's Pills. Pilulæ tonicæ Bacheri. A celebrated medicine in France, employed for the cure of dropsies. Their principal ingredient is the extract of melampodium, or black hellebore.

Ba'cora. The Banana.

BACTISHUA, George, was a celebrated physician of Chorasan, distinguished also for his literary attainments. He was successful in curing the reigning calliph of a complaint of the stomach, which brought him into great honour; he translated several of the ancient medical authors into the Arabian language; and many of his observations are recorded by Rhazes and medical authors into the Arabian language; and many of his observations are recorded by Rhazes and other succeeding physicians. His son, Gabriel, was in equal estimation with the famous Haroun Al Raschid, whom he cured of apoplexy by blood-letting, in opposition to the opinion of the other physicians.

Badia'ga. A kind of sponge usually sold in Russia, the powder of which is said to take away the livid marks of blows and bruisse within a few hours. It is only described by Ranybaum, and its nature is not

only described by Bauxbaum, and its nature is not

properly understood.

BADIAN SEMEN. The seed of a tree which grows in China, and smells like anisced. The Chinese, and Dutch, in imitation of them, sometimes use the badian

to give their tea an aromatic taste.

Badi'za aqua. See Balk waters.

Badranum semen. Indian aniseed.

Badu'cca. The Indian name for a species of cap-

BA'DZCHER. An antidote.

BA'DZCHER. An antidote,

BA'OS. Batos. In Hippocrates it means few; but in P. Ægineta, it is an epithet for a poultice.

BAGLIVI, GEORGE, born at Ragusa in 1668, after graduating at Padua, and improving himself greatly by travelling throughout Italy, was made professor of medicine and anatomy at Rome. In 1696, he published an excellent work on the practice of physic, condemning the exclusive attachment to theory, and earnestly recommending the Hippocratic method of observation; which, he maintained, assisted by the modern improvements in anatomy and physiology, would tend greatly to the advancement of medicine. He has left also several other tracts, though he died at the early age of thirty-eight.

the early age of thirty-eight.

BAGNIGGE WELLS. A saline mineral spring, near Clerkenwell, in London, resembling the Epsom water. In most constitutions, three half-pints is con-

sidered a full dose for purging.

BA'GNIO. (From bagno, Italian.) A bathing or

sweating-house.

BA'HEI COYOLLI. Ray takes it to be the Areca, or

Fanfel.
BA'HEL SCHULLI. An Indian tree. See Genistaspinosa indica.

BAHOBAL. See Adansonia.

BAIKALITE. The asbestiform species of tremolite.

[It is a variety of tremolite which Kirwan named Baikalite, because it was first found near lake Baikal in Siberia, in foliated limestone.—In Chinese Tartary it occurs in delemite. it occurs in dolomite.

It is found in groups of acicular prisms, sometimes very long, and sometimes radiating from a centre. Its colour is greenish, often with a shade of yellow; and colour is greenish, often with a shade of yellow; and its lustre sometimes silky. According to Kirwan, its spec. grav. is only 2.90, and it melts into a dark green glass. It contains silex 44, lime 20, magnesia 30, oxyde of iron 6.—See Cl. Min. A.]

BAILLIE, MATTIEW, born in Scotland, in the year 1760. His mother was sister of the two celebrated languages.

Hunters, Dr. William and Mr. John; his father, a clergyman. In the early part of his education he enjoyed great advantages. After studying at Glasgow, where his father was Professor of Divinity, he was sent to one of the exhibitions of that university at Baliol Colone of the exhibitions of that university at Ballot College, Oxford, where he took his degrees in physic, by which he became a Fellow of the College of Physicians in London, and was soon after elected Fellow of the Royal Society. At an early period he came to London and was an inmate with his uncle, Dr. William Hunter, at that time lecturing to a numerous class of pupils, and who had the superintendence of his education. After demonstrating in the dissecting room with the celebrated and learned Mr. Cruick-H shanks, he became, on the death of his uncle, lecturer with him, and continued to lecture until 1799

Dr. Baillie's practice as a physician was for several years extremely small, and he often complained of the little he had to do; indeed, at one time, he thought of leaving the metropolis. In the year 1787, he was elected physician to St. George's Hospital; and he now began to find his practice increase. About this partied he married.

period he married.

Dr. Denman, the celebrated accoucheur of the day, had two daughters; Mr. Croft, afterward Sir Richard, married one, Dr. Baillie, the other. The confidence which the two first obtained in the higher circles of which the two first obtained in the higher circles of society, was great and extensive; and they lost no opportunity of requiring the opinion and attendance of their relation. Dr. Baillie's pupils had now gone yearly to every part of England, and the Indies, and were not merely enforcing the principles and doctrines of their master, whose lectures they had heard delivered with such lucid order, and clearness of expression, as to convey information in the most simple and intelligible manner; but were sending their patients from the most distant parts to profit by his advice and experience. Two other circumstances soon occurred, which at once placed Dr. Baillie in a practice before unheard of. His uncle's, and his own great friend, Dr. Pitcairn, who was in great practice, was, from ill health, obliged to leave England for a more temperate climate, and he previously introduced him from ill health, obliged to leave England for a more temperate climate, and he previously introduced him to all his patients; and Dr. Warren, who had enjoyed the greater part of the practice of the nobility, was suddenly cut off. There was no practitioner left whose opportunities had fitted him to take the lead, and thus a field was opened for aspiring genius, ability, skill, and perseverance, which Dr. Baillie soon occupied, and from which he reaped an abundant harvest for more than twenty years. vest for more than twenty years.

Before he discontinued his lectures in 1799, he pub-

Before he discontinued his fectures in 1799, he published an octavo volume, on Morbid Anatomy, in which is compressed more accurate and more useful information than is to be found in the elaborate works of Bonetus, Morgagni, and Lieutaud. This was followed by a large work, consisting of a series of splendid engravings to illustrate Morbid Anatomy. He also gave a description of the gravid uterus, and many important contributions to the transactions and medical portant contributions to the transactions and medical

collections of the time.

Dr. Baillie presented his collection of specimens of

morbid parts to the college of physicians, with a sum of money-to be expended in keeping them in order.

The professional and moral character of this great physician cannot be too highly appreciated. To his brethren, among whom he might, from his extensive and peculiar practice, have exercised a high and reserved deportment, he was humble, attentive, commu-nicative, and kind; and he never permitted the caprice of a patient or friends to interfere with the conduct of, or injure a practitioner, when unjustly censured.

conduct of, or injure a practitioner, when unjustly censured.

In the exercise of his practice, he displayed a discriminating and profound knowledge; happy in the conception of the cause of symptoms, he distinguished diseases from those with which they might have been confounded, and pointed out their probable progress and termination; and in delivering his opinion, he expressed himself with clearness, decision, and candour. His moral character was adorned by the strictest virtues, and amplest charities. He died in the year 1823, in the sixty-third year of his age, from a gradual decay of the powers of nature, continuing to practice until about a year before his death, leaving a wife, a son, a daughter, and a sister, Miss Joanna Baillie, who has acquired a degree of eminence surpassed by none of her sex in any age. A few of his private professional friends have directed a simple tablet and bust from the chisel of Chantry, to be placed in Westminster Abbey, to perpetuate his high and honourable professional character, and his many private virtues.

BAHLLOF, GUILLAUME pe, commonly called Ballonius, was born in 1538 at Paris, where he graduated, and attained considerable eminence. He was very active in the contest for precedence between the physicians and surgeons, which was at length decided in favour of the former. His writings are numerous, though not now much esteemed; but he appears to have been the first, who properly discriminated between gout and rheumatism.

have been the first, who properly discriminated be-

tween gout and rheumatism.

BALA. The plaintam-tree.

BALÆNA. (Βαλαινα; from βαλλω; to cast, from its power in casting up water.) The name of a genus of animals. Class, Mammalia; Order, Cete.

[BALÆNA MYSTICKTUS. The systematic and Linnaran name for the common or right whale, which is pursued in the icy and Greenland seas, on the coast of Brazil, and in the Pacific Ocean, supplying, when taken, blubber and whalebone. The blubber is the fat cut from the body of the whale, and being afterward tried, produces common whale or lamp oil. The tried, produces common whale or lamp oil. The whalebone is a horny substance projecting from the jaws, and does not partake of the nature of bone. The ends are split into numerous fibres, and the animal uses them as a filtering machine. The right-whale lives upon the small worms and molluscous animals which abound in the ocean. When it feeds, it opens which abound in the ocean. When it feeds, it opens the mouth, and swims forward, and when it has collected a large quantity of these vermes, the mouth is closed, and the water is forced through the fibrous ends of the whalebone, while the small animals are retained within and swallowed.—See Scoresby's North. Whale Fishery. A.]

BALENA MACROCEPHALA. The systematic name of a species of whale

cies of whale.

[This is the cacholet or large-headed whale, the true spermaceti-whale, principally taken in the Pacific ocean. It is called macrocephalus, from μακρος, large, and κεφαλη, the head, because the head constitutes two-thirds of the animal. The blubber or fat is stripped off this as it is from the right-whale, and affords abundant oil. There is however a cavity in the skull of the macrocephalus containing a large quantity of pure oil called head-matter, which affords the best of spermaceti. In the natural state it is so liquid that it can be dipped out with a bucket. A.]

Balais ruby. See Spinelle.

BALANCE. "The beginning and end of every exact chemical process consists in weighing. With imported, instruments this operation will be tedious This is the cacholet or large-headed whale, the true

exact chemical process consists in weighing. With imperfect instruments this operation will be tedious and inaccurate; but with a good balance, the result will be satisfactory; and much time, which is so precious in experimental researches, will be saved.

The balance is a lever, the axis of motion of which is formed with an edge like that of a knife; and the two dishes at its extremities are hung upon edges of

two dishes at its extremities are hung upon edges of the same kind. These edges are first made sharp, and then rounded with a fine hone, or a piece of bull leather. The excellence of the instrument depends, in a great measure, on the regular form of this rounded part. When the lever is considered as a mere line, the two outer edges are called points of suspension, and the inner the fulcrum. The points of suspension are supposed to be at equal distances from the fulcrum,

are supposed to be at equal distances from the fulcrum, and to be pressed with equal weights when loaded.

1. If the fulcrum be placed in the centre of gravity of the beam, and the three edges lie all in the same right line, the balance will have no tendency to one position more than another, but will rest in any position it may be placed in, whether the scales be on or off, empty or loaded.

2. If the centre of gravity of the beam, when level, be immediately above the fulcrum, it will overset by the smallest action; that is, the end which is lowest will descend: and it will do this with more swiftness, the higher the centre of gravity, and the less the points of suspension are loaded.

3. But if the centre of gravity of the beam be immediately below the fulcrum, the beam will not rest in

diately below the fulcrum, the beam will not rest in any position but when level; and, if disturbed from this position, and then left at liberty, it will vibrate, and at last come to rest on the level. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, and the less the weights were the points of suspension.

centre of gravity of the beam be nearly in the fulcrum, all the vibrations of the loaded beam will be made in times nearly equal, unless the weights be very small, when they will be slower. The vibrations of balances are quicker, and the horizontal tendency stronger, the higher the fulcrum.

6. If the arms of a balance be unequal, the weights in equipoise will be unequal in the same proportion. It is a severe check upon a workman to keep the arms equal, while he is making the other adjustments in a

equal, while he is making the other adjustments in a strong and inflexible beam.

7. The equality of the arms of a balance is of use, in scientific pursuits, chiefly in making weights by bisection. A balance with unequal arms will weigh as accurately as another of the same workmanship with equal arms, provided the standard weight itself be first counterpoised, then taken out of the scale, and the thing to be weighed be put into the scale, and adjusted against the counterpoise; or when proportional justed against the counterpoise; or when proportional quantities only are considered, as in chemical and in other philosophical experiments, the bodies and products under examination may be weighed against the weights, taking care always to put the weights into the same scale. For then, though the bodies may not be really equal to the weights, yet their proportions among each other may be the same as if they had been accurately so. accurately so.

8. But though the quality of the arms may be well dispensed with, yet it is indispensably necessary that their relative lengths, whatever they may be, should continue invariable. For this purpose, it is necessary, either that the three edges be all truly parallel, or that the points of suspension and support should be always in the same part of the edge. This last requisite is

in the same part of the edge. This last requisite is the most easily obtained.

The balances made in London are usually constructed in such a manner, that the bearing parts form notches in the other parts of the edges; so that the scales being set to vibrate, all the parts naturally fall into the same bearing. The balances made in the country have the fulcrum edge straight, and confined to one constant bearing by two side plates. But the points of suspension are referred to notches in the edges, like the London balances. The balances here mentioned, which come from the country, are enclosed in a small iron japanned box; and are to be met with at Birmingham and Sheffield ware-houses, though less-frequently than some years ago; because a pocket contrivance for weighing guineas and half-guineas has got possession of the market. They are, in general, well made and adjusted, turn with the twentieth of a grain when empty, and will sensibly show the fenth of a grain, with an ounce in each scale. Their price is from five shillings to half a guinea; but those which are under seven shillings, have not their edges hardened, and consequently are not durable. This may be ascertained by the purchaser, by passing the point to one constant bearing by two side plates. But the be ascertained by the purchaser, by passing the point of a penknife across the small piece which goes through one of the end boxes: if it make any mark or impres-

sion, the part is soft.

9. If a beam be adjusted so as to have no tendency to any one position, and the scales be equally loaded; then, if a small weight be added in one of the scales, that balance will turn, and the points of suspension will move with an accelerated motion, similar to that of falling bodies, but as much slower, in proportion, very nearly, as the added weight is less than the whole weight borne by the following.

10. The stronger the tendency to a horizontal posi-tion in any balance, or the quicker its vibrations, the greater additional weight will be required to cause it to turn, or incline to any given angle. No balance, therefore, can turn so quick as the motion deduced. Such a balance as is there described, if it were to turn lower the centre of gravity, and the less the weights upon the points of suspension.

4. If the fulcrum be below the line joining the points of suspension, and these be loaded, the beam will overset, unless prevented by the weight of the beam tending to produce a horizontal position. In this last case, small weights will equilibrate; a certain exact weight will rest in any position of the beam; and all greater weights will cause the beam to overset. Many scales are often made this way, and will overset with any considerable load.

5. If the fulcrum be above the line joining the points of suspension, the beam will come to the horizontal position, unless prevented by its own weight. If the

nice experiments, but are likewise much more expeditious than others in common weighing. If a pair of scales with a certain load be barely sensible to onetenth of a grain, it will require a considerable time to ascertain the weight to that degree of accuracy, because the turn must be observed several times over, and is very small. But if no greater accuracy were required, and scales were used which would turn with the hundredth of a grain, a tenth of a grain, more or less, would make so great a difference in the turn, that it would be seen immediately.

12. If a balance be found to turn with a certain 12. If a balance be found to turn with a certain addition, and is not moved by any smaller weight, a greater sensibility may be given to that balance, by producing a tremulous motion in its parts. Thus, if the edge of a blunt saw, a file, or other similar instrument, be drawn along any part of the case or support of a balance, it will produce a jarring, which will diminish the friction on the moving parts so much, that the turn will be evident with one-third or onethat the turn will be evident with one-third or one fourth of the addition that would else have been required. In this way, a beam which would barely turn by the addition of one-tenth of a grain, will turn with one-thirtieth or fortieth of a grain.

13. A balance, the horizontal tendency of which depends only on its own weight, will turn with the

same addition, whatever may be the load; except so far as a greater load will produce a greater friction.

14. But a balance, the horizontal tendency of which depends only on the elevation of the fulcrum, will be less sensible the greater the load; and the addition requisite to produce an equal turn will be in propor-

tion to the load itself. 15. In order to regulate the horizontal tendency in some beams, the fulcrum is placed below the points of suspension, and a sliding weight is put upon the cock or index, by means of which the centre of gravity may be raised or depressed. This is a useful con-

trivance

16. Weights are made by a subdivision of a standard weight. If the weight be continually halved, it will produce the common pile, which is the smallest num-ber for weighing between its extremes, without placing any weight in the scale with the body under examination. Granulated lead is a very convenient substance to be used in this operation of halving, which, however, is very tedious. The readlest way to subdivide small weights, consists in weighing a certain quantity small weights, consists in weighing a certain quantity of small wire, and afterward cutting it into such parts, by measure, as are desired; or the wire may be wrapped close round two pins, and then cut asunder with a knife. By this means it will be divided into a great number of equal lengths, or small rings. The wire ought to be so thin, as that one of these rings may barely produce a sensible effect on the beam. If any quantity (as, for example, a grain) of these rings be weighed, and the number then reckoned, the grain may be subdivided in any proportion, by dividing that may be subdivided in any proportion, by dividing that number, and making the weights equal to as many of the rings as the quotient of the division denotes. Then, if 750 of the rings amounted to a grain, and it were required to divide the grain decimalty, downwards, 9-10ths would be equal to 675 rings, 8-10ths would be equal to 600 rings, 7-10ths to 525 rings, &c. Small weights may be made of thin leaf brass. Jewellers' foil is a good material for weights below 1-10th of a foil is a good material for weights below 1-10th of a grain, as low as to 1-100th of a grain; and all lower quantities may be either estimated by the position of the index, or shown by actually counting the rings of

wire, the value of which has been determined.

17. In philosophical experiments, it will be found very convenient to admit no more than one dimension of weight. The grain is of that magnitude as to de-serve the preference. With regard to the number of weights the chemists ought to be provided with, wri-ters have differed according to their habits and views. Mathematicians have computed the least possible number, with which all weights within certain limits might be ascertained; but their determination is of little use. Because, with so small a number, it must often happen, that the scales will be heavily loaded with weights on each side, put in with a view only to with weights on each side, put in with a view only to determine the difference between them. It is not the least possible number of weights which it is necessary H 2

greater strength, and less weight of a short balance, an operator should buy to effect his purpose, that we are certainly advantages. for ascertaining his inquiries with accuracy and expe-The error of adjustment is the least possible when only one weight is in the scale; that is, a single weight of five grains is twice as likely to be true, as two weights, one of three, and the other of two grains, but into the dish to supply the place of the sin-gle five; because each of these last has its own proba-bility of error in adjustment. But since it is as inconsistent with convenience to provide a single weight, as it would be to have a single character for every number ; and as we have nine characters, which we use inrotation, to express higher values according to their rotation, to express higher values according to their position, it will be found very serviceable to make the set of weights correspond with our numerical system. This directs us to the set of weights as follows: 1000 grains, 900 g. 800 g. 700 g. 600 g. 500 g. 400 g. 300. 200 g. 100 g. 90 g. 80 g. 70 g. 60 g. 50 g. 40 g. 30 g. 20 g. 10 g. 9 g. 8 g. 7 g. 6 g. 5 g. 4 g. 3 g. 2 g. 1 g. 9-10 g. 8-10 g. 7-10 g. 6-10 g. 5-10 g. 4-10 g. 3-10 g. 2-10 g. 1-10 g. 9-100 g. 8-100 g. 7-100 g. 6-100 g. 5-100 g. 4-100 g. 3-100 g. 3-100 g. 1-100 g. 3-100 g. 3-10 1-10 g. \ scales as there are figures in the number expressing the weights in grains. Thus 742.5 grains will be weighed by the weights 700, 40,2, and 5-10ths."—Ure's Chemical Dictionary.

BALANI'NUM GLEUM. Oil of the ben-nut.

BALANOCA'STANUM. (From βαλανος, a nut, and καςανογ, a chesnut, so called from its tuberous root.)
The earth-nut. See Bunium bulbocastanum.
BA'LANOS. (From βαλλω, to cast; because it sheds its fruit upon the ground.) Balanus. I. An

The oak-tree. See Quercus robur.
 Theophrastus uses it sometimes to express any

glandiferous tree.

4. From the similitude of form, this word is used to express suppositories and pessaries, βαλανος signify-

 A name of the glans penis.
 Balas ruby. See Spinelle.
 BALAU'STIUM. (From βαλιος, various, and αυω, to dry; so called from the variety of its colours, and avw, to dry; so called from the variety of its colours, and its becoming soon dry; or from $\beta \lambda a \varphi a \nu \omega$, to germinate.) Ralaustia. A large rose-like flower, of a red colour, the property of the plant from which we obtain

the granate. See Punica granatum.

BALBUTIES. (From βαδαζω, to stammer; or from balbel, Heb. to stammer.) A defect of speech; properly, that sort of stammering where the patient sometimes hesitates, and immediately after, speaks preci-pitately. It is the Psellismus balbutiens of Cullen.

Baldmoney. See Æthusa meum.

Baldwin's phosphorus. Ignited nitrate of lime.
BALISMUS. (Βαλλισμος; from βαλλιζω, tripudio, pedibus plando.) The specific name of a disease in Good's genus Synclonus for shaking palsy. See Chorea

BALI'STA. (From $\beta a \lambda \lambda \omega$, to cast.) The astragulus, a bone of the foot, was formerly called os balista,

because the ancients used to cast it from their slings.

BALLOO'N. (Ballon, or balon, French.) I. A
large glass receiver in the form of a hollow globe. For certain chemical operations balloons are made with two necks, placed opposite to each other; one to receive the neck of a retort, and the other to enter the neck of a second balloon: this apparatus is called cnfi-laded balloons. Their use is to increase the whole space of the receiver, because any number of these may be adjusted to each other. The only one of these vessels which is generally used, is a small obloon bal-loon with two necks, which is to be luted to the retort, and to the receiver, or great balloon; it serves to reto hinder it from being too much heated.

2. A spherical bag filled with a gas of a small spe-

2. A spherical bag filled with a gas of a small specific gravity, or with heated air, by the buoyancy of which it is raised into the atmosphere.

BALLO'TE. (From βαλλω, to send forth, and our wros the ear; because it sends forth flowers like ears.) Ballota. The name of a genus of plants. Class, Didynamia; Order, Gymnospermia.

BALLOTE NIGEA. Stinking horehound. A nettle-like plant, used, when boiled, by the country people received security and cutaneous cruptions.

against scurvy and cutaneous cruptions.

BALM. See Melissa.

BALM. See Melissa.

Balm of Gilead. See Dracocephalum.

Balm of Mecca. See Amyris gileadensis.

Balm, Turkey. See Dracocephalum.

BA'LNEUM. (Balneum, ci. n. βαλανειον, a bath.)

A bath, or bathing-house. See Bath.

BALNEUM ANIMALE. The wrapping any part of an animal just killed, round the body, or a limb.

BALNEUM ARENE. A sand-bath for chemical purposes. See Bath.

BALNEUM CALIDUM. A hot-bath. See Bath.

BALNEUM FRIGIDUM. A cold-bath. See Bath.

BALNEUM MARIE. Balneum maris. A warm-water bath. See Bath. BALNEUM MARIA. ter bath. See Bath.

BALNEUM MEDICATUM. A bath impregnated with

drugs.

Balneum siccum. Balneum cinereum. A dry bath, either with ashes, sand, or iron filings.

Balneum sulphureum. A sulphurous bath.
Balneum tepidum. A tepid bath. See Bath.
Balneum vaporis. A vapour bath.

Ba'LSAM. (Balsamum; from baal samen, Hebrew.) The term balsam was anciently applied to any strong-secuted, natural vegetable resin of about the fluidity of treacle, inflammable, not miscible with water, without addition, and supposed to be possessed of many medical virtues. All the turpentines, the Peruvian balsam, copaiba balsam, &c. are examples of natural balsams. Besides, many medicines compounded of various resins, or oils, and brought to this consistence, obtained the name of balsam. Latterly, however, chemists have restricted this term to vegetable juices, either liquid, or which spontaneously beble juices, either liquid, or which spontaneously be-come concrete, consisting of a substance of a resinous nature, combined with benzoic acid, or which are capable of affording benzoic acid, by being heated alone, or with water. They are insoluble in water, but readily dissolve in alkohol and ather. The liquid balsams are copaiva, opo-balsam, Peru, styrax, Tolu; the concrete are benzoin, dragon's blood, and storax. Balsam apple, male. The fruit of the elaterium.

Balsam apple, male. The fruit of the elaterium. See Momordica elaterium. Balsam, artificial. Compound medicines are thus termed which are made of a balsamic consistence and fragrance. They are generally composed of expressed or ethereal oils, resins, and other solid bodies, which give them the consistence of butter. The basis, or body of them, is expressed oil of nutmeg, and frequently wax, butter, &c. They are usually tinged with cinnabar and saffron.

Balsam of Canada. See Pinus Balsamca.

Balsam, Canary. See Dracocephalum.

Balsam of Copaiba. See Copaifera officinalis.

Balsam, natural. A resin which has not yet assumed the concrete form, but still continues in a fluid state, is so called, as common turpentine, balsamum consists permissionem toleranum see

fluid state, is so called, as common turpentine, balsamum copaiva, peruvianum, tolutanum, &c.

Balsam, Peruvian. See Myroxylon Peruiferum.

Balsam of sulphur. See Balsamum sulphuris.

Balsam of Tolu. See Toluifera balsamum.

Balsam, Turkey. See Dracocephalum.

BALSAMA'TIO. (From balsamum, a balsam.)

The embalming of dead bodies.

BALSA'MEA. (From balsamum, balsam.) The balm of Gilead fir; so called from its odour. See Pinus balsamea.

BALSAMELE'ON. (From balsamum, balsam, and thatov, oil.) Balm of Gilead, or true balsamum Ju-

BA'LSAMI OLEUM. Balm of Gilead.

BALSA'MIC. (Balsamica, sc. medicamenta; from βαλσαμον, balsam.) A term generally applied to substances of a smooth and oily consistence, which possess emollient, sweet, and generally aromatic qualities. Hoffman calls those medicines by this name, which are hot and acrid, and also the natural balsams, stimulating gums. So by which the vital heat is increased. lating gums, &c. by which the vital heat is increased. Dr. Cullen speaks of them under the joint title of balsamica et resinosa, considering that turpentine is the basis of all bassams.

basis of all bassams.

BALSAMIFERA. (From balsamum, balsam, and fero, to bear.) Balsam berry.

BALSAMIFERA BRAZILIENSIS. The copaiba tree.

See Copaifera officinalis.

BALSAMIFERA INDICANA: Peruvian balsam tree.

See Margardon peruiferam.

See Myroxylon peruiferum:
Balsamita væminea. See Achillea ageratum.
116

Balsamita Lutea. See Polygonum persicaria.
Balsamita major. See Tanacetum balsamita.
Balsamita mas. See Tanacetum balsamita.
Balsamita minor. Sweet maudiin.
BA'LSAMUM. (From baal samen, the Hebrew for the prince of oils.) A Balsam. See Balsam.
Balsamum ægyptiacum. See Amyris gileadensis.
Balsamum alpinum. See Amyris gileadensis.
Balsamum americanum. See Myroxylon peruiferum.

Balsanum anodynum. A preparation made from tacamahacca, distilled with turpentine and soap lini-ment; and tincture of opium, but there were a great number of balsams sold under this name formerly. Balsamum archi. A preparation composed of gum-elemi and suet.

BALSAMUM ERAZILIENSE. See Amyris gileadensis.
BALSAMUM ERAZILIENSE. See Pinus balsamea.
BALSAMUM CANADENSE. See Pinus balsamea.
BALSAMUM CEPHALICUM. A distillation from oils, nutnegs, cloves, amber, &c.

RALSAMUM COMMENDATORIS. A composition of

BALSAMUM COMMENDATORIS. A composition of

Storax, benzoe, myrrh, aloes.

Balsamum copaibe. See Copaifera efficinalis.

Balsamum embryonum. A preparation of anisced, fallen into disuse.

BALSAMUM GENUINUM ANTIQUORUM. See Amyris gileadensis.

BALSAMUM GUALACINUM. Balsam of Peru and

BALSAMUM GUIDONIS. The same as balsamum

anodynum.

Balsamum hungaricum. A balsam prepared from

BALSAMUM HUNGARICUM. A baisam prepared from a coniferous tree on the Carpathian mountains.

BALSAMUM JUDAICUM. See Amyris gileadensis.

BALSAMUM LUCATELLI. (Lucatelli; so called from its inventor Lucatellus.) A preparation made of oil, turpentine, wax, and red saunders; now disused; formerly exhibited in coughs of long standing.

BALSAMUM MAS. The herb costmary. See Tanacetum halsamita.

cetum balsamita.

BALSAMUM E MECCA. See Amyris gileadensis. BALSAMUM MEXICANUM. See Myroxylon perui-

BALSAMUM NOVUM. A new balsam from a red fruit in the West Indies.

BALSAMUM ODORIFERUM. A preparation of oil, wax, and any essential oil.

BALSAMUM PERSICUM.

Storax, benzoe, myrrh, and aloes.

storax, benzoe, myrrh, and aloes.

See Myrozylon perui-

BALSAMUM RACKASIRA. This balsam, which is inodorous when cold, but of a smell approaching to that
of Tolu balsam when heated, is brought from India in
gourd-shells. It is slightly bitter to the taste, and adheres to the teeth, on chewing. It is supposed to be one of the factitious balsams, and is scarcely ever prescribed in this country.

Balsamum samech. A factitious balsam, composed of tartar, and spirits of wine.

Balsamum saponaceum. A name given to the preparation very similar to the compound soap liniment.

Balsamum saturni. The remedy so named is prepared by dissolving the acetate of lead in oil of turpentine, by digesting the mixture till it acquires a red colour. This is found to be a good remedy for cleansing foul ulcers; but it is not acknowledged in our dispensatories. our dispensatories.

BALSAMUM STYRACIS BENZOINI. See Styrax benzoin. BALSAMUM SUCCINI. Oil of amber.

BALSAMUM SULPHURIS. A solution of sulphur in oil. BALSAMUM SULPHURIS ANISATUM. Terebinthinated balsam of sulphur, and oil of aniseed.

BALSAMUM SULPHURIS BARBADENSE. Sulphur boiled with Barbadoes tar.

BALSAMUM SULPHURIS CRASSUM. Thick balsam of sulphur.

BALSAMUM SULPHURIS SIMPLEX. Sulphur boiled with oil.

BALSAMUM SULPHURIS TEREBINTHINATUM. is made by digesting the sulphur with oil of turpentine; it is now confined to veterinary medicine.

Balsamum syriacum. See Amyris gileadensis.

Balsamum tolutanum. See Toluifera balsamum

Balsamum Traumaticum. Vulnerary balsam. A form of medicine intended to supply the place of the tincture commonly called Friar's balsam, so famous for curing old ulcers. The London College have named it Tinctura Benzoini composita.

Balsamum Universale. The unguentum saturninum of old pharmacopæias. See Ceratum plumbi compositum.

num of Gra procession of the compositum.

Balsamum verum. See Amyris gileadensis.

Ralsamum viride. Linseed-oil, turpentine, and

verdigris mixed together.

Balsamum vite hoffmanni. Beaume de vie. An artificial balsam, so named from its inventor, and composed of a great variety of the warmest and most grateful essential oils, such as nutmegs, cloves, lavender, &c., with balsam of Peru, dissolved in highly rectified spirit of wine; but it is now greatly abridged in the number of ingredients, and but little used.

Balzoi'num. The gum-benjamin.

BAMBA'LIO. (From βαμβαινω, to speak inarticulately.) A person who stammers, or lisps.

Bambo'o. (An Indian root.) See Arundo bambos.

Ba'mia moschata. See Hibiscus.

Bamier. The name of a plant common in Egypt, the husk of which they dress with meat, and, from its agreeable flavour, make great use of it in their ragouts.

Ban a'rbor. The coffee-tree.

Bana'na. An Indian word. See Musa sapientum.

Bananei'ra. See Banana.

BANA'NA. An Indian word. See Musa sapientum.
BANANRI'RA. See Banana.
BA'NCIA. The wild parsnip:
BANDAGE. Deligatio. Fascia. An apparatus consisting of one or several pieces of linen, or flannel, and intended for covering or surrounding parts of the body for surgical purposes. Bandages are either simple or compound. The chief of the simple are the circular, the spiral, the uniting, the retaining, the expellent, and the creeping. The compound bandages used in surgery, are the T bandage, the suspensory one, the capistrum, the eighteen-tail bandage, and others, to be met with in surgical treatises.

BANDU'RA. A plant which grows in Ceylon, the root of which is said to be astringent.

BANGU'E. Bange. A species of opiate in great use throughout the East, for its intoxicating qualities. It is the leaf of a kind of wild hemp, growing in the countries of the Levant, and made into powder, pills, or conserves.

or conserves

or conserves.

Ba'nica. The wild parsnip.

Bani'las. See Epidendrum vanilla.

Bani'las. See Epidendrum vanilla.

Bao'bab. See Adansonia digitata.

Ba'ptica coccus. Kermes berries.

BAPTISTE'RIUM. (From βαπ/ω, to immerge.)

A bath, or repository of water, to wash the body.

Bapti'strum. (From βαπ/ω, to dye.) A species of wild mustard, so called from its reddish colour.

BA'RBA. (From barbarus, because wild nations are usually unshaven.) 1. The beard of man.

2. In botany a species of pubescence, or down, with which the surface of some plants are covered some-

which the surface of some plants are covered some-times in patches; as in the leaves of the Mesembryanthemum barbatum

Some vegetables have the specific name of barba, the ramifications of which are bushy, like a beard, as

the ramifications of which are bushy, like a beard, as Barba, jovis, &c.

Barba Aronis. See Arum maculatum.

Barba Capræ. See Spirea ulmaria.

Barba Hirci. See Tragopogon.

Barba Jovis. Jupiter's beard. This name is given to several plants, as the silver bush; the Sempervivum majus; and of a species of anthyllis.

BARBADOES. The name of an island in the West, from which we obtain a mineral tar, and several medicinal plants.

Barbadoes charry. See Malphigia glabra.

ral medicinal plants.

Barbadoes cherry. See Malphigia glabra.

Barbadoes nut. See Jatropha curcas.

Barbadoes tar. See Petroleum barbadense, the use of which in medicine is limited to its external application, at times, in paralytic cases.

Barbarea. (From St. Barbary, who is said to have found its virtues.) See Erysimum barbarea.

Barbaro'ssæ filula. Barbarossa's pill. An ancient composition of quicksilver, rhubarb, diagridium, musk, amber, &c. It was the first internal mercurial medicine which obtained any real credit.

Barbarum. The name of a plaster in Scribonius Largus.

BARBATINA. A Persian vermifuge seed.
BARBA'TUS. (From barba, a beard.) Bearded; applied to a leaf which has a hairy or beard-like pubescence; as Mesembryanthemum barbatum, and Spa-

nanthe paniculata.

BA'RBEL. Barbo. An oblong fish, resembling the pike, the eating of the roe of which often brings on the cholera.

BARBERRY. See Berberis.
BARBEYRAC, CHARLES. A French physician of the 17th century, who graduated and settled at Montpelier, where he acquired great celebrity. He died in 1699, at the age of about 70, having published little, except a good account of the diseases of the chest and stomach in females. Mr. Lorka has been extended. stomach in females. Mr. Locke, who became intimate with him abroad, considered him very similar in his manners and opinions to Sydenham. His practice is said to have been distinguished for simplicity and

BAREO'TA. The barbut. A small river-fish. It is remarkable for the size of its liver, which is esteemed

remarkable for the size of its liver, which is esteemed the most delicate part of it.

[BARD, Dr. John. Dr. Bard was of French descent. His ancestors preferring their faith to their country, became exiles under the provisions of the revocation of the edict of Nautes. Dr. Bard first settled in his profession in Philadelphia, but after practising in that city about five or six years, he was induced to remove to New-York in the year 1746. By the urbanity of his manners, his professional talents, and the charms of his conversation, which was enlivened by an uncommon flow of cheerfulness, enriched by sound sense. his conversation, which was enlivened by an uncommon flow of cheerfulness, enriched by sound sense, and adorned by a large fund of anecdote, he so effectually recommended himself to the notice and friendship of the most respectable families, that he was almost immediately introduced into a valuable scene of business, and very soon arrived at the first rank of professional eminence, which he retained through a long life of more than fourscore years. He died in March, 1799, leaving a son who afterward eclipsed his father in his professional career.—See Thack. Med. Bios. A.1

Biog. A.]
[BARD, Samuel, M.D. LL.D. was the son of Dr. John Bard, and was born in Philadelphia, April 1, 4742. He acquired his classical education at Kings, in the city of New-York. He 1742. He acquired his classical education at Kings, now Columbia Coilege, in the city of New-York. He spent five years abroad, and acquired his medical education principally in Edinburgh, where he received his degree of Doctor in Medicine in May, 1765. He commenced practice in New-York, but the events of the revolution prevented his success until the close of the war in 1783, after which he rose in professional eminence until he retired from practice in 1798. After his return from Europe, he was instrumental in establishing the medical faculty which was annexed to Colum ing the medical faculty which was annexed to Colum

return from Europe, he was instrumental in establishing the medical faculty which was annexed to Columbia College, his alma mater, and he was appointed the first professor of the practice of physic. The establishment of the New-York hospital was effected principally by his exertions, and he was for many years one of the physicians to the institution. He was author of several medical essays, but the principal work of his is a system of midwifery, published after he retired from practice. Princeton College in New Jersey conferred upon him the degree of (LL.D.) Doctor of Laws, on account of the high reputation of his professional skill, learning, and abilities.—See Thack. Med. Biog. A.]

BARDA'NA> (From bardus, foolish; because silly people are apt to throw them on the garments of passengers, having the property of sticking to whatever they touch.) Burdock. See Arctium lappa.

BARE'GE. The small village of Barege, celebrated for its thermal waters, is situated on the French side of the Pyrenees, about half way between the Mediterranean and the Bay of Biscay. The hot springs are four in number. They have all the same component parts, but differ somewhat in their temperature, and in the quantity of sulphur, the hottest being most strongly penetrated with this active ingredient. The coolest of these waters raises Fahrenheit's thermometer to 73 deg.; the hottest to 120 deg. Barege waters are remarkable for a very smooth, soapy feel; they render the skin very supple and pliable, and dissolve perfectly well soap and animal lymph; and are resorted to as a bath in resolving tumours of various kinds, rigidities, and contractions of the tendons, stiffness of the joints, left by rheumatic and gouty comness of the joints, left by rheumatic and gouty com-

plaints, and are highly serviceable in cutaneous crup-tions. Internally taken, this water gives considerable relief in disorders of the stomach, especially attended with acidity and heart-burn, in obstinate colics, jaundice, and in gravel, and other affections of the urinary

BAR

BARI'LLA. See Barilla.
BARI'LLA. Barillor; Bariglia The term given in commerce to the impure soda imported from Spain and the Levant. It is made by burning to ashes different plants that grow on the sea-shore, chiefly of the genus salsola, and is brought to us in hard porous masses, of a speckled brown colour. Kelp, which is made in this country by burning sea-weeds, and is called British barilla, is much more impure.

[Barilla is much used in the arts on account of the

soda it contains.

"Carbonate of soda is chiefly obtained by the combustion of marine plants, the ashes of which afford, by lixiviation, the impure alkali called soda. Two kinds of rough soda occur in the market; barilla and kelp; besides which some native carbonate of soda is also imported. Barilla is the semifused ashes of the salsola soda, which is largely cultivated upon the salsola soda, which is largely cultivated upon the Mediterranean shores of Spain, in the vicinity of Alicant. Kelp consists of the ashes of sea-weeds which are collected upon the sea coast and burned in kilns, or merely in excavations made in the ground and surrounded by stones. It seldom contains more than five per cent, of carbonated alkali, and about 24 tons of sea-weed are required to produce one ton of kelp. The best produce is from the hardest fuci, such as the serratus, digitatus, nodosus, and restrutosus. The rough alkali is contaminated by common salt, and impurities, from which it may be separated salt, and impurities, from which it may be separated by solution in a small portion of water, filtrating the by solution in a small portion of water, intrating the solution, and evaporating it at a low heat; the common salt may be skimmed off as its crystals form upon the surface."—See Webster's Man. of Chem. A.]

BARIUM. (From barytes, from which it is obtained.) The metallic basis of the earth barytes, so

tained.) The metallic basis of the earth barytes, so named by Sir Humphrey Davy, who discovered it.

"Take pure barytes, make it into a paste with water, and put this on a plate of platinum. Make a cavity in the middle of the barytes, into which a globule of mercury is to be placed. Touch the globule with the negative wire, and the platinum with the positive wire, of a voltaic battery of about 100 pairs of plates in good action. In a short time an amalgam will be formed, consisting of mercury and barium. This amalgam must be introduced into a fittle bent tube, made of glass free from lead, scaled at one end, which made of glass free from lead, scaled at one end, which being filled with the vapour of naphtha, is then to be hermetically scaled at the other end. Heat must be applied to the recurved end of the tube, where the amalgam lies. The mercury will distil over, while the barium will remain.

This metal is of a dark gray colour, with a lustre This metal is of a dark gray colout, with a fusion inferior to that of cast iron. It is fusible at a red heat. Its density is superior to that of sulphuric acid; for though surrounded with globules of gas, it sinks immediately in that liquid. When exposed to air, it instantly becomes covered with a crust of barytes; and when gently heated in air, burns with a deep red light. It effervesces violently in water, converting this

liquid into a solution of barytes."

BARK. A term very frequently employed to signify, by way of eminence, Peruvian bark. See Cin.

Bark, Carribean. See Cinchona Carribe Bark, Jamaica. See Cinchona Carribea. Bark, Peruvian. See Cinchona. Bark, red. See Cinchona oblongifolia. See Cinchona Carribaa. Bark, red. See Cinchona oblongifolia.
Bark, yellow. See Cinchona cordifolia.
BARLEY. See Hordeum.
Barley, caustic. See Cevadilla.
Barley, pearl. See Hordeum.
BARM. See Fermentum cerevisia.
BARNET. A town near London, where there is a mineral water; of a purging kind, of a similar quality to that of Epsom, and about-half its strength.

[BAROLITE. The name given by Kirwan to the carbonate of barytes. A.]

carbonate of barytes. A.]
BARO'METER. (From Bagos, weight, and perpose, measure.) An instrument to determine the weight of the air; it is commonly called a weather-glass.

BAROLYTE. A carbonate of barytes

BARO'NES. Small worms; called also Nepones. BA'ROS. (Bapos.) Gravity. 1. Hippocrates uses this word to express by it, an uneasy weight in any

2. It is also the Indian name for a species of camphire, which is distilled from the roots of the true cinnamon-tree

[BAROSELENITE. Kirwan's name for the sul-

phate of barytes. A.]
BARRAS. Galipot. The resinous incrustation on the wounds made in fir-trees.

Barren Flower. See Flos.

BA'RRENNESS. See Sterility.

BA'RTHOLINE, Thomas, was born at Copenhagen in 1616. After studying in various parts of Europe, particularly Padua, and graduating at Basil, he became professor of anatomy in his native city; in which office he greatly distinguished himself as well which office he greatly distinguished himself, as well which office he greatly distinguished himself, as well as in many other branches of learning. He was the first who described the lymphatics with accuracy; though some of these vessels, as well as the lacteals and thoracic duct, had been before discovered by other anatomists. Besides many learned works which he published, several others were unfortunately destroyed by fire in 1670; and he particularly regretted a dissertation on the ancient practice of midwifery, of which an outline was afterward published by his son Caspar. Of those which remain, the most esteemed are, his epistolary correspondence with the most cele-Caspar. Of those which remain, the most esteemed are, his epistolary correspondence with the most celebrated of his cotemporaries: his collection of cases where focuses have been discharged by preternatural outlets; and the "Medical and Philosophical Transactions of Copenhagen," enriched by the communications of many correspondents. This last work was in four volumes, published within the ten years preceding his death, which happened 1680; and a fifth was afterward added by his son. ward added by his son.

BARTHOLINIA'NÆ GLANDULÆ. See Sublingual

[BARTLETT, Josiah, M. D. Dr. Bartlett was born in Amesbury in Massachusetts in 1729, and after acin Amesbury in Massachusetts in 1729, and after acquiring his profession commenced practice in the town of Kingston in New-Hampshire, where he had acquired considerable reputation before the commencement of the American revolution, in which he took an active and decided part in favour of his country. "From his integrity and decision of character, Dr. Bartlett was soon designated as a magistrate, and sustained various offices from the lowest to the highest. In 1775 he was chosen a delegate to the continental congress. He attended in that honourable assembly, and when the vote for American Independence was taken, Dr. Bartlett's name was first called, as representing the most easterly province, and he boldly answered in the affirmative." After the revolution he was elected governor of the state of New-Hampshire under the new form of government.

"His mind was quick and penetrating, his memory tenacious, his judgment sound and prospective; his natural temper was open, humane, and compassionate. In all his dealings he was scrupulously just, and faithful in the performance of all his engagements. These shining talents accompanied with distinguished probits, early in life recommended him to the estate or

shining talents accompanied with distinguished pro-bity, early in life recommended him to the esteem and confidence of his fellow-citizens. But few persons by their own merit, without the influence of family or party connexions, have risen from one degree of honour to another as he did; and fewer still have been the instances in which a succession of honourable and

the instances in which a succession of honourable and important offices, have been held by any man with less envy, or executed with more general approbation."—See Thach. Med. Biog. A.]

[BARTON, Benjamin Smith, M. D. Dr. Barton was born at Lancaster in Pennsylvania in 1766. In 1786 he went to Great Britain, and prosecuted his medical studies at Edinburgh and London. He afterward visited Gottingen, and there obtained the degree of doctor in medicine. On returning to Philadelphia, in 1789, he established himself as a physician in that city, and his superior talents and education soon procured him competent employment. He was that year city, and his superior talents and education soon pro-cured him competent employment. He was that year appointed Professor of Natural History and Botany in the College of Philadelphia, and continued in the office on the incorporation of the college with the university, in 1791. He was appointed Professor of Materia Me-dica on the resignation of Dr. Griffiths, and on the death of Dr. Rush, succeeded him in the department

of the Theory and Practice of Medicine. He died in December, 1815.

He published, "Elements of Zoology and Botany," "Elements of Botany, or Outlines of the Natural History of Vegetables," "Collections for an Essay towards a Materia Medica of the United States;" besides numerous essays and communications contributed to the "Medical and Physical Journal."—See Thacher's

"Medical and Physical Journal."—See Thacher's Med. Biog. A.]

BARYCOl'A. (From βαρυς, heavy, and ακουω, to hear.) Deafness, or difficulty of hearing.

BARYCOc'ccalon. (From βαρυς, heavy, and κοκκαλος, a nut; because it gives a deep sound.) A name for the stramonium.

BARYPHO'NIA. (From βαρυς, dull, and φωνη, the voice.) A difficulty of speaking.

BARY'TES. (From βαρυς, heavy; so called because it is very ponderous.) Cauk; Calk; Terra ponderosa; Baryta. Ponderous earth; Heavy earth. United with the sulphuric acid, it forms the mineral called sulphate of barytes, or barosclenite. When united to carbonic acid, it is called aĕrated barytes, or carbonate of barytes. See Heavy spar.

Barytes, is a compound of barium and oxygen. Oxygen combines with two portions of barium, forming, 1.

Barytes, is a compound of barium and oxygen. Oxygen combines with two portions of barium, forming, 1.

Barytes. 2. Deutoxyde of barium.

1. Barytes, or protoxyde of barium, "is best obtained by igniting, in a covered crucible, the pure crystallized nitrate of barytes. It is procured in the state of hydrate, by adding caustic potassa or soda to a solution of the muriate of nitrate. And barytes, slightly coloured with charcoal, may be obtained by strongly igniting the carbonate and charcoal mixed together in igniting the carbonate and charcoal mixed together in fine powder. Barytes obtained from the ignited nitrate is of a whitish-gray colour; more caustic than strontites, or perhaps even lime. It renders the syrup of violets green, and the infusion of tumeric red. Its specific gravity by Fourcroy is 4. When water in small quantity is poured on the dry earth, it slakes like micklime, but perhaps with evolution of more best quicklime, but perhaps with evolution of more heat. When swallowed it acts as a violent poison. It is destitute of smell.

When pure barytes is exposed, in a porcelain tube, at a heat verging on ignition, to a stream of dry oxygen gas, it absorbs the gas rapidly, and passes to the state of deutoxyde of barium. But when it is calcined in contact with atmospheric air, we obtain at first this deutoxyde and carbonate of barytes; the former of which passes very slowly into the latter, by absorption

of carbonic acid from the atmosphere.

of carbonic acid from the atmosphere.

2. The deutoxyde of barium is of a greenish-gray colour, it is caustic, renders the syrup of violets green, and is not decomposable by heat or light. The voltaic pife reduces it. Exposed at a moderate heat to carbonic acid, it absorbs it, emitting oxygen, and becoming carbonate of barytes. The deutoxyde is probably decomposed by sulphuretted hydrogen at ordinary temperatures. Aided by heat, almost all combustible bodies, as well as many metals, decompose it. The action of hydrogen is accompanied with remarkable phenomena. phenomena. Water at 50° F. dissolves one-twentieth of its weight

of barytes, and at 212° about one half of its weight. It is colourless, acrid, and caustic. It acts powerfully on the vegetable purples and yellows. Exposed to the air, it attracts carbonic acid, and the dissolved barytes is converted into carbonate, which falls down in inso-

luble crusts.

Sulphur combines with baryles, when they are mixed together, and heated in a crucible. The same compound is more economically obtained by igniting a pound is more economically obtained by igniting a mixture of sulphate of barytes and charcoal in fine powder. This sulphuret is of a reddish yellow colour, and when dry without smell. When this substance is put into hot water, a powerful action is manifested. The water is decomposed, and two new products are formed, namely, hydrosulphuret, and hydroguretted sulphuret of barytes. The first crystallizes as the liquid cools, the second remains dissolved. The hydrosulphuret is a compound of 9.75 of barytes with 2.125 sulphuret is a compound of 9.75 of barytes with 2.125 sulphuretted hydrogen. Its crystals should be quickly separated by filtration, and dried by pressure between the folds of porous paper. They are white scales, have a silky lustre, are soluble in water, and yield a solution having a greenish tinge. Its taste is acrid, sulphureous, and when mixed with the hydroguretted

sulphuret, eminently corrosive. It rapidly attracts oxygen from the atmosphere, and is converted into the sulphate of barytes. The hydroguretted sulphuret is a compound of 9.75 barytes with 4.125 bisulphuretted hydrogen: but contaminated with sulphite and hyposulphite in unknown proportions. The dry sulphuret consists probably of 2 sulphur + 9.75 barytes. The readiest way of obtaining barytes water is to boil the solution of the sulphuret with deutoxyde of copper, which seizes the sulphur, while the hydrogen flies off. which seizes the sulphur, while the hydrogen flies off, and the barytes remains dissolved.

and the barytes remains dissolved.

Phosphuret of barytes may be easily formed by exposing the constituents together to heat in a glass tube. Their reciprocal action is so intense as to cause ignition. Like phosphuret of lime, it decomposes water, and causes the disengagement of phosphuretted hydrogen gas, which spontaneously inflames with contact of air. When sulphur is made to act on the deutoxyde of barytes, sulphuric acid is formed, which unites to a portion of the earth into a sulphate.

The salts of barytes are white, and more or less transparent. All the soluble sulphates cause in the soluble salts of barytes a precipitate insoluble in nitric acid. They are all poisonous except the sulphate; and

acid. They are all poisonous except the sulphate; and hence the proper counter-poison is dilute sulphuric acid for the carbonate, and sulphate of soda for the soluble salts of barytes."

Pure barytes has a much stronger affinity than any other body for sulphuric acid; it turns blue tincture of cabbage green. It is entirely infusible by heat alone, but melts when mixed with various earths. Its specific gravity is 4.000. It changes quickly in the air, swells, becomes soft, and falls into a white powder, with the acquisition of about one-fifth of its weight. This slaking is much more active and speedy than that of lime. It combines with phosphorus, which compound decomposes water rapidly. It unites to sulphur by the dry and humid way. It has a powerful attraction for water, which it absorbs with a hissing noise, and consolidates it strongly. It is soluble in twenty and consolidates it strongly. It is soluble in twenty times its weight of cold, and twice its weight of boiling water. Its crystals are long four-sided prisms of a satin-like appearance. It is a deadly poison to animals

Other Methods of obtaining Barytes.—1. Take native carbonate of barytes; reduce it to a fine powder, and dissolve it in a sufficient quantity of diluted nitric acid; evaporate this solution till a pellicle appears, and then suffer it to crystallize in a shallow basin. The acid; evaporate this solution till a pellicle appears, and then suffer it to crystallize in a shallow basin. The salt obtained is nitrate of barytes; expose this nitrate of barytes to the action of heat in a china-cup, or silver crucible, and keep it in a dull red heat for at least one hour; then suffer the vessel to cool, and transfer the greenish solid contents, which are pure barytes, into a well-stopped bottle. When dissolved in a small quantity of distilled water, and evaporated, it may be obtained in a beautiful crystalline form.

In this process the nitric acid, added to the native carbonate of barytes, unites to the barytes, and expels the carbonic acid, and forms nitrate of barytes; on exposing this nitrate to heat, it parts with its nitric acid, which becomes decomposed into its constituents,

acid, which becomes decomposed into its constituents,

leaving the barytes behind.

2. Pure barytes may likewise be obtained from its sulphate. For this purpose, boil powdered sulphate of barytes in a solution of twice or three times its weight of carbonate of potassa, in a Florence flask, for about two hours; filter the solution, and expose what remains on the filter to the action of a violent

In this case, the sulphuric acid of the barytes unites to the potassa, and the carbonic acid of the latter joins to the barytes; hence sulphate of potassa and carbonate of barytes are obtained. The former is in solution, and passes through the filter; the latter is insoluble, and remains behind. From this artificial carbonate of barytes, the carbonic acid is driven off

by heat. BARYTE MURIAS. Terra ponderosa salita. The muriate of barytes is a very acrid and poisonous preparation. In small doses it proves sudorific, diuretic, deobstruent, and alterative; in an over-dose, emetic, and violently purgative. The late Dr. Crawford found it very serviceable in all diseases connected with scrofula; and the Germans have employed it with great success in some diseases of the skin and viscera, and obstinate ulcers. The dose of the saturated solution in

distilled water, is from five to fifteen drops for children.

distilled water, is from five to fifteen drops for children, and from fifteen to twenty for adults.

Basaal. (Indian.) The name of an Indian tree. A decoction of its leaves, with ginger, in water, is used as a gargle in disorders of the fauces. The kernels of the fruit kill worms.—Ray's Hist.

BASA'LTES. (In the Æthiopic tongue, this word means iron, which is the colour of the stone.) A heavy and hard kind of stone, found standing up in the form of regular angular columns, composed of a number of joints, one placed upon and nicely fitted to another as if formed by the hands of a skilful architect. It is found in beds and veins in granite and mica slate, the old red sandstone, limestone, and coal forslate, the old red sandstone, limestone, and coal for-mations. It is distributed over the whole world; but

mations. It is distributed over the whole world; but nowhere is it met with in greater variety than in Scotland. The German basalt is supposed to be a watery deposite; and that of France to be of volcanic origin. The most remarkable is the columnar basaltes, which forms immense masses, composed of columns thirty, forty, or more feet in height, and of enormous thickness. Nay, those at Fairhead are two hundred and fifty feet high. These constitute some of the most astonishing scenes in nature, for the immensity and regularity of their parts. The coast of Antrim in Ireland, for the space of three miles in length, exhibits a very magnificent variety of columnar cliffs; and the Giant's Causeway consists of a point of that coast very magnificent variety of columnar cliffs: and the Giant's Causeway consists of a point of that coast formed of similar columns, and projecting into the sea upon a descent for several hundred feet. These columns are, for the most part, hexagonal, and fit very accurately together; but most frequently not adherent to each other, though water cannot penetrate between them. And the basaltic appearances on the Hebrides Islands on the coast of Scotland, as described by Sir Joseph Banks, who visited them in 1772, are upon a scale very striking for their vastness and variety.

[Basaltes belongs to a class of rocks now called superincumbent. They are always found in a vertical position, resting upon other strata of rocks which are horizontal. Some of the most remarkable of these are the Pallisado rocks, extending forty miles or more along the Hudson river, on its west bank, partly in New-Jersey and partly in the state of New-York. There are other ridges of the same formation in other parts of New-Jersey, all resting upon sandstone. On the

parts of New-Jersey, all resting upon sandstone. On the south shore of Lake Superior, the basaltic rocks, as they have been described by travellers, particularly by Mr. Schoolcraft, have a grand and imposing appearance. There is a ridge of this kind of rock extending a number of miles north from New-Haven, in the state of Connecticut. A singular formation of basaltic rocks is found in North Carolina, constituting a wall many miles in extent, which has given rise to much controversy; but Dr. Woodhouse, of Philadelphia, settled the question, as to the true nature of this for-

mation.

"Basalt (says professor Eaton) is a hornblende rock, not primitive, probably of volcanic origin. Subdivisions—Amygdaloid, when amorphous, of a compact texture, but containing cellules, empty or filled. Greenstone trap, when of a columnar structure, or in angular blocks, often coarse-grained. Variety—Toadstone, when the amygdaloid has a warty appearance, and resembles slag." A.]

Basaltic hornblende. See Hornblende.

BASANITE. See Flinty slate.

BASANITES. (From δασανίζω, to find out.) A stone said, by Pliny, to contain a bloody juice, and useful in diseases of the liver: also a stone upon which, by some, the purity of gold was formerly said to be tried,

some, the purity of gold was formerly said to be tried, and of which medical mortars were made.

and of which medical mortars were made.

BASE. See Basis.

Base, acidifiable. See Acid.

Base, acidifying. See Acid.

BASIA'TIO. (From basio, to kiss.) Venereal connexion between the sexes.

BASIA'TOR. See Orbicularis oris

BASIL. See Ocimum basilicum.

BASILA'RIS. See Basilary.

BASILA'RIS. See Basilary.

BASILA'RIS. Beasilary.

BASILARIS ARTERIA. Basilary artery. An artery of the brain; so called, because it lies upon the basilary process of the occipital bone. It is formed by the junction of the two vertebral arteries within the skull, and runs forwards to the sella turcica along the pons varous lii, which it supplies as well as the adjacent parts with lii, which it supplies, as well as the adjacent parts, with blood

Basilaris forcessus. See Occipital bone.
Basilaris apophysis. See Occipital bone.
Basilary. (Basilaris; from βασίλεης, a king.)
Several parts of the body, bones, arteries, veins, processes, &c. were so named by the ancients, from their situation being connected with or leading to the liver or brain, which they considered as the seat of the soul or royalty. or royalty.

Basilica mediana. See Basilica vena.
Basilica nux. The walnut.
Basilica vena. The large vein that runs in the internal part of the arm, and evacuates its blood into the axillary vein. The branch which crosses, at the head of the arm, to join this vein, is called the basilic median. They may either of them be opened in the operation of bloodletting.

Basilicon. See Basilicum unguentum.
BASI'LICUM. (From βασιλικος, royal; so called from its great virtues.) See Ocimum basilicum.
BASILICUM UNGUENTUM. Unguentum basilicum βανημη. An ointment popularly so called from its having the ocimum basilicum in its composition. It came afterward to be composed of wax, resin, &c. and is now called ceratum resina.

BASILICUS. (From βασιλευς, a king. See Basi-

lary.) Basilic.
Basilicus pulvis. The royal powder. A preparation formerly composed of calomel, rhubarb, and jalapation formerly composed by the ancients, so called, Many compositions were, by the ancients, so called, from their supposed pre-eminence.

BASILI'DION. An-lichy ointment was formerly so

called by Galen.

BA'SILIS. A name formerly given to collyriums of supposed virtues, by Galen.

BASILI'SCUS. (From $\beta \alpha \sigma i \lambda \epsilon \nu s$, a king.). 1. The basilisk, or cockatrice, a poisonous serpent; so called from a white spot upon its head, which resembles a crown.

2. The philosopher's stone.
3. Corrosive sublimate.
BASIO. Some muscles so have the first part of

their names, because they originate from the basilary process of the occipital bone.

BASIO-CERATO-CHONDRO-GLOSSUS. See Hyoglossus.

Basio-Glossum. See Hyoglossus. Basio-Pharyng &us. See Constrictor pharyngis

meatus.

BA'SIS. (From $\beta_{\alpha\nu\omega}$, to go: the support of any thing, upon which it stands or goes.) Base. I. This word is frequently applied anatomically to the body of any part, or to that part from which the other parts appear, as it were, to proceed, or by which they are appear. supported.

2. In pharmacy it signifies the principal ingredient.
3. In chemistry, usually applied to alkalies, earths, and metallic oxydes, in their relations to the acids and

and metallic oxydes, in their relations to the acids and salts. It is sometimes also applied to the particular constituents of an acid or oxyde, on the supposition that the substance combined with the oxygen, &c. is the basis of the compound to which it owes its particular qualities. This notion seems unphilosophical, as these qualities depend as much on the state of combination as on the nature of the constituent.

Basi collica. The name of a medicine in Scribonius Largus, compounded of aromatics and honey.

BASSORINE. This substance is extracted from the gum resins which contain it, by treating them successively with water, alkohol, and ather. Bassorine being insoluble in these liquids, remains mixed merely with the woody particles, from which it is easy to separate it, by repeated washings and decantations: because one of its characteristic properties is to swell extremely in the water and to become very buoyant. This substance swells up in cold as well as in boiling extremely in the water and to become very buoyant. This substance swells up in cold as well as in boiling water, without any of its parts dissolving. It is soluble however almost completely by the aid of heat, in water sharpened with nitric or muriatic acid. If after concentrating with a gentle heat the nitric solution, we add highly rectified alkohol, there results a white precipitate, flocculent and bulky, which, washed with much alkohol and dried, does not form, at the utmost, the tenth of the quantity of bassorine employed, and which presents all the properties of guestless of gu ployed, and which presents all the properties of gum-arabic. Vauquelin, Bulletin de Pharmacie, iii. 56. BASTARD. A term often employed in medicine, and botany, to designate a disease or plant which has

the appearance of, but is not in reality what it resem-

bles: The name of that which it similates is generally attached to it, as bastard peripneumony, bastard pellitory, &c.

Bastard pellitory. See Achillea ptarmica.
Bastard pleurisy. See Peripneumonia notha.
Bata'Tas. (So the natives of Peru call the root of

a convolvulus falso. The potato, which is a native of that country. See Solanum tuberosum, and Convolvulus batatas.

[The Solanum tuberosum is the common potato, from which all the edible varieties are derived. The Convolvulus batatas is the Carolina or sweet potato of the United States. A.]

of the United States. A.]

A hath.

BATH. Βαλανείον Balneum. A bath.

1. A convenient receptacle of water, for persons to wash or plunge in, either for health or pleasure. These are distinguished into hot and cold; and are either natural or artificial. The natural hot baths are formed of the water of hot springs, of which there are many in different parts of the world; especially in those countries where there are, or have evidently been, volcanoes. The artificial hot baths consist either of water, or of some other fluid, made hot by art. The cold bath consists of water, either fresh or salt, in its natural degree of heat; or it may be made colder by art, as by a mixture of nitre, sal-ammoniac, &c. The chief hot baths in our country are those of Bath and Bristol, and those of Buxton and Matlock; which latter, however, are rather warm, or tepide than hot. The use of baths is found to be beneficial in diseases of the head, as palsies, &c.; in cuticular diseases, as leprosies, &c.; obstructions and constipations of the bowels, the scurvy, and stone; and in many diseases of women and children. The cold bath, though popu-larly esteemed one of the most innocent remedies yet discovered, is not, however, to be adopted indiscrimi-nately. On the contrary, it is liable to do considerable mischief in some cases of diseased viscera, and is not, in any case, proper to be used during the existence of costiveness. As a preventive remedy for the young, and as a general bracer for persons of a relaxed fibre, especially of the female sex, it often proves highly advantageous; and, in general, the popular idea is a correct one, that the glow which succeeds the use of cold or temperate bath, is a test of their utility; while,

on the other hand, their producing chilliness, headache, &c. is a proof of their being pernicious.

1. The Cold Bath. The diseases and morbid symptoms, for which the cold bath, under one form or
another, may be applied with advantage, are very
numerous; and some of them deserve particular attention. One of the most important of its uses is in ardent fever; and, under proper management, it forms a highly valuable remedy in this dangerous disorder. It is highly important, however, to attend to the precau-tions which the use of this vigorous remedial process requires, "Affusion with cold water," Dr. Currie ob-serves, "may be used whenever the heat of the body is steadily above the natural standard, when there is no sense of chilliness, and especially when there is no general nor profuse perspiration. If used during the cold stage of a fever, even though the heat be higher than natural, it brings on interruption of respiration, a fluttering, weak, and extremely quick pulse, and cer-tainly might be carried so far as to extinguish anima-tion entirely." The most salutary consequence which follows the proper use of this powerful remedy, is the production of free and general perspiration. circumstance that appears to give so much advantage to a general affusion of cold water in fevers, in prefer-ence to any partial application. The cold bath is betence to any partial application. ter known, especially in this country, as a general tonic remedy in various chronic diseases. The general cirremedy in various chronic diseases. cumstances of disorder for which cold bathing appears to be of service, according to Dr. Saunders, are a langour and weakness of circulation, accompanied with profuse sweating and fatigue, on very moderate exertion; tremors in the limbs, and many of those symptoms usually called nervous; where the moving pow-ers are weak, and the mind listless and indolent; but, at the same time, where no permanent morbid ob-struction, or visceral disease, is present. Such a state of body is often the consequence of a long and debilitating sickness, or of a sedentary life, without using the exercise requisite to keep up the activity of the bodily powers. In all these cases, the great object to

be fulfilled, is to produce a considerable reaction, from the shock of cold water, at the expense of as little heat as possible; and when cold bathing does harm, it is precisely where the powers of the body are too languid to bring on reaction, and the chilling effects remain unopposed. When the patient feels the shock of immersion very severely, and, from experience of its pain, has acquired an insurerable dread of this its pain, has acquired an insuperable dread of this application; when he has felt little or no friendly glow to succeed the first shock, but on coming out of the bath remains cold, shivering, sick at the stomach, oppressed with headache, languid, drowsy, and listless, and averse to food and exercise during the whole of the day, we may be sure that the bath has been too cold, the shock too severe, and no reaction produced at all adequate to the impression on the surface of the

body.
There is a kind of slow, irregular fever, or rather febricula, in which Dr. Saunders has often found the febricula of singular service. This disorder principles of singular service. pally affects persons naturally of a sound constitution, but who lead a sedentary life, and at the same time are employed in some occupation which strongly engages their attention, requires much exertion of thought, and excites a degree of anxiety. Such persons have constantly a pulse rather quicker than natural, hot hands, restless nights, and an impaired appetite, but without any considerable derangement in the di-gestive organs. This disorder will continue for a long gestive organs. time in an irregular way, never entirely preventing their ordinary occupation, but rendering it more than usually anxious and fatiguing, and often preparing the way for confirmed hypochondriasis. Persons in this situation are remarkably relieved by the cold bath, and, for the most part, bear it well; and its use should also, if possible, be aided by that relaxation from business, and that diversion of the mind from its ordinary train of thinking, which are obtained by attending a watering place. The Doctor also found cold bathing watering place. The Doctor also found cold bathing hurtful in chlorosis, and observes, that it is seldom ad-visable in those cases of disease in the stomach which are brought on by high living, and constitute what may be termed the true dyspepsia.

The topical application of cold water, or of a cold saturnine lotion, in cases of local inflammation, has become an established practice; the efficacy of which is daily experienced. Burns of every description will bear a most liberal use of cold water, or even of ice: and this may be applied to a very extensive inflamed surface, without even producing the ordinary effects of general chilling, which would be brought on from the same application to a sound and healthy skin. Another very distressing symptom, remarkably relieved by cold water, topically applied, is that intolerable itching in the vagina, which women sometimes experience, entirely unconnected with any general cause, and which appears to be a kind of herpes confined to that part. Cold water has also been used topically in the various cases of strains, bruises, and similar injuries, in tentinous and ligamentous parts, with success, also in rigidity of muscles, that have been long kept at rest, in order to favour the union of bone, where there appears to have been no organic injury, but only a de-ficiency of nervous energy, and in mobility of parts, or at most, only slight adhesions, which would give way to regular exercise of the weakened himb. Another very striking instance of the powerful effects of topical cold, in stimulating a part to action, is shown in the use of cold, or even iced water, to the vagina of perturient women, during the dangerous hæmorrhages that take place from the uterus, on the partial separation of the placenta.

2. The Shower Bath. A species of cold bath. A modern invention, in which the water falls through numerous apertures on the body. A proper apparatus for this purpose is to be obtained at the shops. The use of the shower bath applies, in every case, to the same purposes as the cold bath, and is often attended with particular advantages. 1. From the sudden contact of the water, which, in the common cold bath, is only momentary, but which, in the shower bath, may be prolonged, repeated, and modified, at pleasure; and, secondly, from the head and breast, which are exposed to some inconvenience and danger in the and, secondly, from the head and breast, which are exposed to some inconvenience and danger in the common bath, being here effectually secured, by receiving the first shock of the water.

3. The Tepid Bath. The range of temperature,

In general, the heat of water which we should term tepid, is about 90 deg. In a medicinal point of view, it produces the greatest effect in ardent fever, where the temperature is little above that of health, but the powers of the body weak, not able to bear the vigorous application of cold immersion. In cutaneous diseases, a tepid bath is often quite sufficient to produce

a salutary relaxation, and perspirability of the skin.

4. The Hot Bath. From 93 to 96 deg. of Fahrenheit, the hot bath has a peculiar tendency to bring on a state of repose, to alleviate any local irritation, and thereby induce sleep. It is, upon the whole, a safer remedy than the cold bath, and more peculiarly appli-cable to very weak and irritable constitutions, whom the shock produced by cold immersion would over power, and who have not sufficient vigour of circulation for an adequate reaction. In cases of topical inflam-mation, connected with a phlogistic state of body, preceded by rigour and general fever, and where the local formation of mafter is the solution of the general inflammatory symptoms, experience directs us to the use of the warm relaxing applications, rather than those which, by exciting a general reaction, would in-crease the local complaint. This object is particularly to be consulted when the part affected is one that is essential to life. Hence it is that in fever, where there is a great determination to the lungs, and the respiration appears to be locally affected, independently of ration appears to be locally affected, independently of the oppression produced by mere febrile increase of circulation, practitionens have avoided the external use of cold, in order to promote the solution of the fever; and have trusted to the general antiphlogistic treatment, along with the topically relaxing applica-tion of warm vapour, inhaled by the lungs. Warm bathing appears to be peculiarly well calculated to re-lieve those complaints that seem to depend on an irre-rular or diminished action of any part of the alimentgular or diminished action of any part of the aliment-ary canal; and the state of the skin, produced by immersion in warm water, seems highly favourable to the healthy action of the stomach and bowels. ther very important use of the warm bath, is in herpetic eruptions, by relaxing the skin, and rendering it more pervious, and preparing it admirably for receiv-ing the stimulant applications of tar of atment, mercu-rials, and the like, that are intended to restore it to a healthy state. The constitutions of children seem more extensively relieved by the warm bath than those of adults; and this remedy seems more generally applicable to acute fevers in them than in persons of a more advanced age. Where the warm bath produces its salutary operation, it is almost always followed by an easy and profound sleep. Dr. Saunders strongly recommends the use of the tepid bath, or even one of a higher temperature in the true memorylagia of fea higher temperature, in the true menorrhagia of fe-males. In paralytic affections of particular parts, the powerful stimulus of heated water is generally allowed; and in these cases, the effect may be assisted by any thing which will increase the stimulating properties thing which will increase the stimulating properties of the water; as, for instance, by the addition of salt. In these cases, much benefit may be expected from the use of warm sea-baths. The application of the warm bath topically, as in pediluvia, or fomentations to the feet, often produces the most powerful effects in quieting irritations in fever, and bringing on a sound and refreshing repose. The cases in which the warm bath is likely to be attended with danger are particularly is likely to be attended with danger, are particularly those where there exists a strong tendency to a determination of blood to the head; and apoplexy has sometimes been thus brought on. The lowest temper-ature will be required for cutaneous complaints, and to bring on relaxation in the skin, during febrile irritation; the warmer will be necessary in paralysis: more heat should be employed on a deep-seated part than

one that is superficial.

5. The Vapour Bath. The vapour bath, called also Balneum laconicum, though not much employed in England, forms a valuable remedy in a variety of In most of the hot natural waters on the Continent, the vapour bath forms a regular part of the bathing apparatus, and is there highly valued. In no country, however, is this application carried to so great an extent as in Russia, where it forms the principal and almost daily luxury of all the people, in every rank; and it is completed as rank; and it is employed as a sovereign remedy for a great variety of disorders. The Hon. Mr. Basil Coch-

from the lowest degree of the hot bath to the highest rane has lately published a Treatise on the Vapour of the cold bath, forms what may be termed the tepid. Bath, from which, it appears, he has brought the apparatus to such perfection, that he can apply it to all degrees of temperature, partially or generally, by shower, or by steam, with a great force or a small one; according to the particular circumstances under which patients are so variously placed, who require such assistance. See Cochrane on Vapour Baths. Connected with this article, is the air-pump vapour bath; a species of vapour bath, or machine, to which the inventor has given this name. This apparatus has been found efficacious in removing paroxysms of the gout, and preventing their recurrence; in acute and chronic rheumatism, palsy, cutaneous diseases, ulcers, &c. It has also been proposed in chilblains, leprosy, yaws, tetanus, amenorrhea, and dropsy.
[The vapour bath has been introduced and success-

fully applied in many cutaneous and other diseases, in the city of New-York. This bath may be either aqueous or spirituous. Its immediate effect is to produce relaxation of the skin and copious perspiration. It may be made a medicated bath by passing the steam or vapour through a quantity of herbs, before it is ap-

or vapour through a quantity of herbs, before it is applied to the body of the person requiring it. A.]

II. Those applications are called dry baths, which are made of ashes, salt, sand, &c. The ancients had many ways of exciting a sweat, by means of a dry heat, as by the use of hot sand, stove rooms, or artificial bagnios; and even from certain natural hot steams of the earth, received under a proper arch, or the control of the same of the earth, received under a proper arch, or another kind of hath by insolution, where the hady hot house, as we learn from Celsus. They had also another kind of bath by insolation, where the body was exposed to the sun for some time, in order to draw forth the superfluous moisture from the inward parts; and to this day it is a practice, in some nations, to cover the body over with horse-dang, especially in painful chronic diseases. In New-England, they make a kind of stove of turf, wherein the sick are shut up to bathe, or sweat. It was probably from a knowledge of this practice, and of the exploded doctrines of Celestrate the exploded process. sus, that the noted empiric Dr. Graham drew his notions of the salutary effects of what he called carth bathing; a practice which, in the way he used it, consigned some of his patients to a perpetual mansion under the ground. The like name of dry bath, is sometimes also given to another kind of bath, made of kindled coals, or burning spirit of wine. The patient being placed in a convenient close chair, for the reception of the fume, which rises and provokes sweat in a plentiful manner; care being taken to keep the head out, and to secure respiration. This bath

has been said to be very effectual in removing old obstinate pains in the limbs.

III. Medicated baths are such as are saturated with various mineral, vegetable, or sometimes animal substances. Thus we have sulphur and iron baths, aromatic and milk baths. There can be no doubt that such ingredients if duty mixed and a superior such ingredients. such ingredients, if duly mixed, and a proper temperature given to the water, may, in certain complaints, be productive of effects highly beneficial. Water, impregnated with sulphate of iron, will abound with the bracing particles of that inetal, and may be useful for strengthening the part to which it is applied, re-invi-gorating debilitated limbs, stopping various kinds of bleeding, restoring the menstrual and hamorrhoidal discharges when obstructed, and, in short, as a substi-tute for the natural iron bath. There are various other medicated baths, such as those prepared with alum, and quick-lime, sal-ammoniac, &c by boiling them together, or separately, in pure rain water. These have long been reputed as eminently serviceable in paralytic, and all other diseases arising from nervous and muscular debility.

IV. A term in chemistry, when the vessels in which bodies are exposed to the action of heat, are not placed in immediate contact with the fire, but receive the required degree of heat by another intermediate body, such apparatus is termed a bath. These have been variously named, as dry, vapour, &c. Modern chemists distinguish three kinds

 Balneum arcnæ, or the sand bath. This consists merely of an open iron, or baked clay sand-pot, whose bottom is mostly convex, and exposed to the furnace. Finely sifted sea-sand is put into this, and the vessel containing the substance to be heated, &c. in the sand bath, immersed in the middle.

2. Balneum maria, or the water bath. This is very

simple, and requires no particular apparatus. The object is to place the vessel containing the substance to be heated, in another, containing water; which last must be of such a nature as to be fitted for the application of fire, as a common still, or kettle.

3. The vapour bath. When any substance is heated

by the steam, or vapour, of boiling water, chemists say it is done by means of a vapour bath.

BATH WATERS. Bathonia aqua; Solis aqua; Badigua aqua. Bath is the name of a city in Gloucester-shire, that has been celebrated, for a long series of a contract of the suppression of the years, for its sumerous hot springs, which are of a higher temperature than any in this kingdom, (from 1120 to 1160,) and, indeed, are the only natural waters which we possess that are at all hot to the touch; all the other thermal waters being of a heat below the animal temperature, and only deserving that appellation from being invariably warmer than the general average of the heat of common springs. By the erec tion of elegant baths, these waters are particularly adapted to the benefit of invalids, who find here a variety of establishments, contributing equally to health, convenience, and amusement. There are three principal springs in the city of Bath, namely, those called the King. those called the King's Bath, the Cross Bath, and the Hot Bath; all within a short distance of each other, and emptying themselves into the river Avon, after having passed through the several baths. Their supply is so copious, that all the large reservoirs used for bathing are filled every evening with fresh water from their respective fountains. In their sensible and medicinal properties, there is but a slight difference. According to Dr. Falconer, the former are—I. That the water, when newly drawn, appears clear and colourless, remains perfectly inactive, without bubbles, or any sign of briskness, or effervescence. 2. After being exposed to the open air for some hours, it becomes rather turbid, by the separation of a pale yellow, ochery precipitate, which gradually subsides. 3. No odour is perceptible from a glass of the fresh water, but a slight pungency to the taste from a large mass of it, when fresh drawn: which, however, is neither feetid nor sulphureous. 4. When hot from the pump, it affects the mouth with a strong chalybeate impression, without being of a saline or pungent taste. And, fifthly, on growing coul, the chalybeate taste is entirely lost, leaving only a very slight sensation on the tongue, by which it can scarcely be distinguished from common hard spring-water. The temperature of the King's Bath water, which is usually preferred for drinking, is, when fresh drawn in the glass, above 116°; that of the Cross Bath, 112°. But, after flowing into the spacious bathing vessels, it is generally from 1999 to 1069 in the hotter baths and from 989 to from 1000 to 1060 in the hotter baths, and from 920 to 94° in the Cross Bath; a temperature which remains nearly stationary, and is greater than that of any other natural spring in Britain. A small quantity of gas is also disengaged from these waters, which Dr. Priestley first discovered to contain no more than one-twentieth part of its bulk of fixed air, or carbonic acid. The chemical properties of the Bath waters, according to the most accurate analyzers, Doctors Lucas, Falconer, and Gibbs, contain so small a proportion of iron, as to amount only to one-twentieth or one-thirty-eighth of a grain in the pint; and, according to Dr. Gibbs, fifteen grains and a quarter of siliceous earth in the Dr. Saunders estimates a gallon of the King's Bath water to contain about eight cubic inches of carbonic acid, and a similar quantity of air, nearly azotic, about eighty grains of solid ingredients, one-half of which probably consists of sulphate and muriate soda, fifteen grains and a half of siliceous earth, and the remainder is selenite, carbonate of lime, and so small a portion of oxyde of iron as to be scarcely cal-Hence he concludes, that the King's Bath water is the strongest chalybeate; next in order, the Hot Bath water; and, lastly, that of the Cross Bath, which contains the smallest proportions of chalybeate, gaseous and saline, but considerably more of the earthy particles; while its water, in the pump, is also two degrees lower than that of the others. It is likewise now ascertained, that these springs do not exhibit the slightest traces of sulphur, though it was formerly believed, and erroneously supported, on the authority of Dr. Charleton, that the subtile aromatic vapour in the Bath waters, was a sulphureous principle entirely similar to common brimstone.

With regard to the effect of the Bath waters on the human system, independent of their specific properties, as a medicinal remedy not to be imitated completely by any chemical process, Dr. Saunders attributes much of their salubrious influence to the natural degree of warmth peculiar to these springs, which, for ages, have preserved an admirable degree of uniformity of temperature. He thinks too, that one of their most important uses is that of an external application, yet supposes that, in this respect, they differ little from common water, when heated to the same temperature, and applied under similar circumstances.

According to Dr. Falconer, the Bath water, when drunk fresh from the spring, generally raises, or rather accelerates the pulse, increases the heat, and promotes the different secretions. These symptoms in most cases, become perceptible soon after drinking it, and will sometimes continue for a considerable time. It is, however, remarkable, that they are only produced in invalids. Hence we may conclude, that these waters not only possess heating properties, but their internal use is likewise attended with a peculiar stimu-

lus, acting more immediately on the nerves

One of the most salutary effects of the Bath water, consists in its action on the urinary organs, even when taken in moderate doses. Its operation on the bowels varies in different individuals, like that of all other waters, which do not contain any cathartic salt; but, in general, it is productive of costiveness: an effect resulting from the want of an active stimulus to the intestines, and probably also from the determination this water occasions to the skin, more than from any this water occasions to the skin, more than from any astringency which it may possess; for, if perspiration be suddenly checked during the use of it, a diarrhea is sometimes the consequence. Hence it appears that its stimulant powers are primarily, and more particularly exerted in the stomach, where it produces a variety of symptoms, sometimes slight and transient, but, occasionally, so considerable and permanent, as to require it to be discontinued. In those individuals with whom it is likely to agree, and prove beneficial, the Bath waters excite, at first, an agreeable glowing the Bath waters excite, at first, an agreeable glowing sensation in the stomach, which is speedily followed by an increase both of appetite and spirits, as well as a quick secretion of urine. In others, when the use of them is attended with headache, thirst, and constant dryness of the tongue, heaviness, loathing of the sto-mach, and sickness; or if they are not evacuated, either by urine or an increased perspiration, it may be justly inferred that their further continuance is im-

Proper.

The diseases for which these celebrated waters are resorted to, are very numerous, and are some of the most important and difficult to cure of all that come under medical treatment. In most of them, the bath is used along with the waters, as an internal medicine. The general indications, of the propriety of using this medicinal water, are in those cases where a gentle, gradual, and permanent stimulus, is required. Bath water may certainly be considered as a chalybeate, in which the iron is very small in quantity, but in a highly active form; and the degree of temperature is in itself a stimulus, often of considerable powers. These cir-cumstances again point out the necessity of certain cautions, which, from a view of the mere quantity of foreign contents, might be thought superfluous. Although, in estimating the powers of this medicine, allowance must be made for local prejudice in its favour, there can be no doubt but that its employment is hazardous, and might often do considerable mischief, in various cases of active inflammation, especially in in various cases of active inflammation, especially in irritable habits, where there exists a strong tendency to hectic fever; and even in the less inflammatory state of diseased and suppurating viscera; and, in general, wherever a quick pulse and dry tongue indicate a degree of general fever. The cases, therefore, to which this water are peculiarly suited, are mostly of the chronic kind; and by a steady perseverance in this remedy, very obstinate disorders have given way. The following, Dr. Saunders, in his Treatise on Mineral Waters, considers as the principal, viz. 1. Chlorosis, a disease which, at all times, is much relieved by rai waters, considers as the principal, the relieved by a disease which, at all times, is much relieved by steel, and will bear it, even where there is a considerable degree of feverish irritation, receives particular benefit from the bath water; and its use, as a warm bath, excellently contributes to remove that languor of circulation, and obstruction of the natural evacuations,

which constitute the leading features of this common and troublesome disorder. 2. The complicated discases, which are often brought on by a long residence in hot climates, affecting the secretion of bile, the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and alimentary canal, and the functions of the stomach, and the stomach alimentary canal, and the stomach alimentary can which generally produce organic derangement in some part of the hepatic system, often receive much benefit from the bath water, if used at a time when suppurative inflammation is not actually present. 3. Another and less active disease of the biliary organs, the jaundice, which arises from a simple obstruction of the gall-ducts, is still oftener removed by both the internal and external use of these waters. 4. In them. the gall-ducts, is still oftener removed by both the internal and external use of these waters. 4. In rheumatic complaints, the power of this water, as Dr. Charleton well observes, is chiefly confined to that species of rheumatism which is unattended with inflammation, or in which the patient's pains are not increased by the warmth of his bed. A great number of the patients that resort to Bath, especially those that are admitted into the hospital, are affected with rheumatism in all its stages; and it appears, from the most respectable testimony, that a large proportion of them receive a permanent cure. (See Falconer on Bath Water in Rheumatic Cases.) 5. In gout, the greatest benefit is derived from this water, in those cases where it produces anomalous affections of the head, stomach, and bowels; and it is here a principal advantage to be able to bring, by warmth, that active local inflammation in any limb, which relieves all the other troublesome and dangerous symptoms. Hence it is that Bath some and dangerous symptoms. Hence it is that Bath water is commonly said to produce the gout; by which is only meant that, where persons have a gouty affection, shifting from place to place, and thereby much disordering the system, the internal and external use of the bath water will soon bring on a general increase of action, indicated by a flushing in the face, fulness in the circulating vessels, and relief of the fulness in the circulating vessels, and relief of the dyspeptic symptoms; and the whole disorder will terminate in a regular fit of the gout in the extremities, which is the crisis always to be wished for. 6. The colica pictonum, and the paralysis or loss of nervous power in particular limbs, which is one of its most serious consequences, is found to be peculiarly relieved by the use of the Bath waters, more especially when applied externally, either generally, or upon the part applied externally, either generally, or upon the part

The quantity of water taken daily, during a full course, and by adults, is recommended by Dr. Falconer, not to exceed a pint and a half, or two pints; and in chlorosis, with irritable habits, not more than one pint is employed; and when the bath is made use of, it is generally two or three times a week, in the morning. The Bath waters require a considerable time to be personned in heave a full and fair trial can be made. severed in, before a full and fair trial can be made. Chronic rheumatism, habitual gout, dyspepsia, from a long course of high and intemperate living, and the like, are disorders not to be removed by a short course of any mineral water, and many of those who have once received benefit at the fountains, find it necessary to make an annual visit to them, to repair the waste in health during the preceding year.

BATH, CAUTERES. A sulphureous bath near Barege,

which raises the mercury in Fahrenheit's thermometer

BATH, ST. SAVIOUR'S. A sulphureous and alkaline bath, in the valley adjoining Barege, the latter of which raises Fahrenheit's thermometer as high as 131°. It is much resorted to from the South of France, and used chiefly externally, as a simple thermal water.

BATTIE, WILLIAM, was born in Devonshire, in 1704. He graduated at Cambridge, and after practising some years successfully at Uxbridge, settled in London, and became a fellow of the College of Physical Society. The insufficient of the college of the surface of the college of the sicians, as well as of the Royal Society. The insufficiency of Bethlehem bespital to receive all the indigent objects labouring under insanity in this metropolis, naturally led to the establishment of another similar institution; and Dr. Battie having been very active in promoting the subscription for that purpose, he was appointed physician to the new institution, which was called St. Luke's Hospital, then situated on the north-side of Moorfields. In 1757 he published a treatise on madness; and a few years after, having exposed before the House of Commons the abuses often committed in private mad-houses, they became the subject of legislative interference, and were at length placed of legislative interference, and were at length placed under the control of the College of Physicians, and the magistrates in the country. He died at the

BAUHIN, John, was born at Lyons, in 1541. Being greatly attached to botany, he accompanied the cele-brated Gesner in his travels through several countries of Europe, and collected abundant materials for his principal work, the "Historia Plantarum," which contributed greatly to the improvement of his favourite science. He was, at the age of 32, appointed phy-sician to the duke of Wirtemberg, and died in 1613. A Treatise on Mineral Waters, and some other pub-

A Treatise on Mineral Waters, and some other publications by him also remain.

BAUHIN, GASPARD, was brother to the preceding, but younger by 20 years. He graduated at Basle, after studying at several universities, and was chosen Greek professor at the early age of 22; afterward professor of anatomy and botany; then of medicine, with other distinguished honours, which he retained till his death in 1624. Besides the plants collected by himself, he received material assistance from his pupils and friends, and was enabled to add considerably to the knowledge of botany; on which subject, as well as knowledge of botany; on which subject, as well as anatomy, he has left numerous publications. Among other anatomical improvements, he claims the discovery of the valve of the colon. His "Pinax" contains the names of six thousand plants mentioned by the ancients, tolerably well arranged; and being continually referred to by Linnæus, must long retain its value.

BEER. The wine of grain made from malt and hops in the following manner. The grain is steeped for two or three days in water, until it swells, becomes somewhat tender, and tinges the water of a bright reddish brown colour. The water being then drained away, the barley is spread about two feet thick upon a floor, where it heats spontaneously, and begins to grow, by first shooting out the radical. In this state the germination is stopped by spreading it thinner, and the germination is stopped by spreading it thinner, and turning it over for two days; after which it is again made into a heap, and suffered to become sensibly hot, which usually happens in little more than a day. Lastly, it is conveyed to the kiln, where, by a gradual and low heat, it is rendered dry and crisp. This is malt; and its qualities differ according as it is more or less soaked, drained, germinated, dried, and baked. In this, as in other manufactories, the intelligent operators often make a mystery of their processes from views of profit; and others pretend to peculiar secrets who really possess none. who really possess none.

Indian corn, and probably all large grain, requires to be suffered to grow into the blade, as well as root, before it is fit to be made into malt. For this purpose it is buried about two or three inches deep in the ground, and covered with loose earth; and in ten or twelve days it springs up. In this state it is taken up and washed, or fanned, to clear it from its dirt; and then dried in the kiln for use.

then dried in the kiln for use,

Barley, by being converted into mait, becomes one fifth lighter, or 20 per cent.; 12 of which are owing to kiln-drying, 1.5 are carried off by the steep-water, 3 dissipated on the floor, 3 loss in cleaning the roots, and 0.5 waste or loss

The degree of heat to which the malt is exposed in this process, gradually changes its colour from very pale to actual blackness, as it simply dries it, or con-

verts it to charcoal.

The colour of the malt not only affects the colour of the liquor brewed from it; but, in consequence of the chemical operation, of the heat applied, on the principles that are developed in the grain during the process of malting, materially alters the quality of the beer, especially with regard to the properties of becoming fit

especially with regard to the properties of becoming in for drinking and growing fine.

Beer is made from malt previously ground, or cut to pieces by a mill. This is placed in a tun, or tub with a false bottom; hot water is poured upon it, and the whole stirred about with a proper instrument. The temperature of the water in this operation, called mashing, must not be equal to boiling; for, in that case, the malt would be converted into a paste, from which the impregnated water could not be separated. which the impregnated water could not be separated. This is called setting. After the infusion has remained for some time upon the malt, it is drawn off, and is then distinguished by the name of Sweet Wort. By one or more subsequent infusions of water, a quantity of weaker wort is made, which is either added to the of weaker wort is made, which is either added to the foregoing, or kept apart, according to the intention of the operator. The wort is then boiled with hops, which gives it an aromatic bitter taste, and is supposed to render it less liable to be spoiled in keeping; after which it is cooled in shallow vessels, and suffered to ferment, with the addition of a proper quantity of yest. The fermented liquor is beer; and differs greatly in its quality, according to the nature of the grain, the malting, the mashing, the quantity and kind of the hops and the yest, the purity or admixtures of the water made use of, the temperature and vicissitudes of the weather, &c.

Beside the various qualities of malt liquors of a

Beside the various qualities of malt liquors of a similar kind, there are certain leading features by which they are distinguished, and classed under different names, and to produce which, different modes of

management must be pursued. The principal distinctions are into beer, properly so called; ale; table, or small beer; and porter, which is commonly termed beer in London. Beer is a strong, fine, and thin liquor; the greater part of the mucilage having been separated by boiling the wort longer than for ale, and carrying the fermentation farther, so as to convert the saccharine matter into alkohol. Ale is of a more syrupy consistence, and sweeter taste; more of the management. saccharine matter into alkohol. Ale is of a more syrupy consistence, and sweeter taste; more of the mucilage being retained in it, and the fermentation not having been carried so far as to decompose all the sugar. Small beer, as its name implies, is a weaker liquor; and is made, either by adding a large portion of water to the malt, or by mashing with a fresh quantity of water what is left after the beer or ale wort is drawn off. Porter was probably made originally from very high dried malt; but it is said, that its peculiar flavour cannot be imparted by malt and hops alone. liar flavour cannot be imparted by malt and hops alone.

Mr. Brande obtained the following quantities of alkohol from 100 parts of different species of beers. Burton ale, 8.88; Edinburgh ale, 6.2; Dorchester ale, 5.56; the average being = 6.87. Brown stout, 6.8; London porter (average) 4.2; London small beer (average) 1.98

As long ago as the reign of Queen Anne, brewers were forbid to mix sugar, honey, Guinea pepper, essen-tia bina, cocculus indicus, or any other unwholesome tia bina, cocculus indicus, or any other unwholesome ingredient, in beer, under a certain penalty; from which we may infer, that such at least was the practice of some; and writers, who profess to discuss the secrets of the trade, mention most of these, and some other articles, as essentially necessary. The essential bina is sugar boiled down to a dark colour, and empyreumatic flavour. Broom tops, wormwood, and other bitter plants, were formerly used to render beer fit for keeping, before hops were introduced into this country; but are now prohibited to be used in beer made for sale.

By the present law of this country, nothing is allow.

By the present law of this country, nothing is allowed to enter into the composition of beer, except malt and hops. Quassia and wormwood are often frauduand hops. Quassia and wormwood are often fraudulently introduced; both of which are easily discoverable by their nauseous bitter taste. They form a beer which does not preserve so well as hop beer. Sulphate of iron, alum, and salt, are often added by the publicans, under the name of beer heading, to impart a frothing property to beer, when it is poured out of one vessel into another. Molasses and extract of gentian root are added with the same view. Capsicum, grains of paradise, ginger root, coriander seed, and orange, peel, are also employed to give pungency and flavour to weak or bad beer. The following is a list of some of the unlawful substances seized at different breweries, and brewers' druggists' laboratories, in London, as copied from the minutes of the committee of the as copied from the minutes of the committee of the house of commons. Cocculus indicus multum, (an house of commons. Cocculus indicus multum, (an extract of the cocculus) colouring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice, caraway seeds, copperas, capsicum, mixed drugs. Sulphuric acid is very frequently added to bring beer forward, or make it hard, giving new beer instantly the taste of what is 18 months old. According to Mr. Accum, the present entire beer of the London brewer is composed of all the waste and spoiled beer of the publicans, the bottoms of buts, the leavings of the pots, the drippings of the machines for drawing the beer, the remnants of beer that lay in the leaden pipes of the brewery, with beer that lay in the leaden pipes of the brewery, with a portion of brown stout, bottling beer, and mild beer. He says that opium, tobacco, nux vomica, and extract of poppies, have been likewise used to adulterate beer. By evaporating a portion of beer to dryness, and igniting the residuum with chlorate of potassa, the iron of the copperas will be procured in an insoluble oxyde. Muriate of barytes will throw down an abundant precipitate from beer contaminated with sulphuric acid or copperas; which precipitate may be collected, dried, and ignited. It will be insoluble in nitric acid.

Reer appears to have been of ancient use, as Tacitus

Beer appears to have been of ancient use, as Tacitus mentions it among the Germans, and has been usually supposed to have been peculiar to the northern na-tions; but the ancient Egyptians, whose country was not adapted to the culture of the grape, had also contrived this substitute for wine; and Mr. Park has found the art of making malt, and brewing from it very good beer, among the negroes in the interior parts of Africa. form.) See Chrysanthemum.

BELLI'NI, LAURENCE, an ingenious physician, born at Florence in 1643. He was greatly attached to the mathematics, of which he was made professor at Pisa, when only twenty years of age. He was soon after appointed professor of anatomy, which office he filled with credit for nearly thirty years. He was one of the chief supporters of the mathematical theory of medicine, which attempted to explain the functions of the body, the causes of diseases, and the operations of medicines on mechanical principles: and having im-prudently regulated his practice accordingly, he was generally unsuccessful, and lost the confidence of the public, as well as of Cosmo III. of Florence, who had appointed him his physician. In his anatomical re-searches he was more successful, having first accu-rately described the nervous papille of the tongue, and discovered them to be the organ of taste; and also having made better known the structure of the kid-ney. He was author of several other publications, and died in 1704.

[Benne seep. Among the postores in Coordin.

[Benne seed. Among the negroes, in Georgia, a plant is cultivated which appears to be a species of sesamum. They call it benne, which is probably its African name. The seeds are of a brownish-white, African name. The seeds are of a brownish white, and about the size of flaxseed, abounding in oil.

Several barrels of benne seeds were shipped by John

Several barrels of beane seeds were snipped by some Milledge, from Savannah to New-York, in 1807, consigned to Col. Few. By direction of this latter gentleman, they were pressed, and have been found to yield three gallons, at least, to a bushel. The plenty of oil; three gallons, at least, to a bushel. The benne plant is an annual, and may hereafter become of some importance to this country. One difficulty in its cultivation, since ascertained, arises from the facility with which the plant sheds its seeds before the whole are mature.—See Mod. Repos. vol. ii.

[Benne oil. This vegetable oil is clear, mild, and well-flavoured, and excellent for salads. Its qualities are so good and wholesome that it may be employed in lieu of the oil of olives, both in medicine and diet. Instead of importing this article from the south of English

Instead of importing this article from the south of Eu-

structure, and may be crushed under the screw without previous grinding. In addition to all which circumstances it may be added, that the oil separates freely by cold expression; and it may hence be hoped that our tables will, in process of time, be furnished with plentiful supplies of this sweet and nutritious substance.—See Med. Repos. vol. ii, p. 88.

The sesamum orientale is cultivated in Asia, Africa, and the West Indies, principally on account of its oil.

The sesamum orientale is cultivated in Asia, Africa, and the West Indies, principally on account of its oil. Its seeds were used by the ancient Egyptians for food, and are still employed by the negroes and Asiatics for this purpose. The plant is now cultivated in the southern parts of the United States. The seeds afford a copious quantity of oil, amounting, according to some authors, to nearly one half of their weight. This oil is bland, sweet, and is said to keep some years without turning rancid. It is applicable to the same purposes as olive oil, and in sufficient doses proves purgative on the same principle as other animal and purgative on the same principle as other animal and vegetable fixed oils."—See Big. Mat. Med. A.]

BENZO'AS. Abenzoate. A salt formed by the union of benzoic acid with salifiable bases; as benzo-

ate of alumine, &c.
BENZO'E. See Styrax benzoin.

BENZOE AMYGDALOIDES. See Styraz benzoin.
BENZOES FLORES. See Benzoic acid.
BENZOIC ACID. See Acidum benzoicum. acid was first described in 1608, by Blaise de Vigenere, in his Treatise on Fire and Salt, and has been generally known since by the name of flowers of benjamin or benzoin, because it was obtained by sublimation from the resin of this name. As it is still most commonly procured from this substance, it has preserved the epithet of benzoic, though known to be a peculiar acid, obtainable not from benzoin alone, but from different vegetable balsams, venello, cinnamon, ambergris, the urine of children, frequently that of adults, and always, according to Fourcroy and Vauquelin, though Giese denies this, from that of quadrupeds living on grass and hay, particularly the camel, the horse, and the cow. There is reason to conjecture that many vegetables, and among them some of the grasses, contain it, and that it passes from them into the urine. Fourcroy and Vauquelin found it combined with potassa and lime in the liquor of dunghills, as well as in the urine of the quadrupeds above-mentioned; and acid was first described in 1608, by Blaise de Vigenere, the urine of the quadrupeds above-mentioned; and they strongly suspect it to exist in the Anthoxanthum odoratum, or sweet-scented vernal-grass, from which hay principally derives its fragrant smell. Glese, however, could find none either in this grass or in oats.

The usual method of obtaining it affords a very ele gant and pleasing example of the chemical process of gant and pleasing example of the chemical process of sublimation. For this purpose a thin stratum of pow-dered benzoin is spread over the bottom of a glazed earthen pot, to which a tall conical paper covering is fitted: gentle heat is then to be applied to the bottom of the pot, which fuses the benzoin, and fills the apartment with a fragrant smell, arising from a portion of essential oil and acid of benzoin, which are dissipated into the air, at the same time the acid itself rises very suddenly in the paper head, which may be occasionally inspected at the top, though with some little care, because the fumes will excite coughing. This saline sublimate is condensed in the form of long needles, or straight filaments of a white colour, crossing each other in all directions. When the acid ceases to rise, the cover may be changed, a new one applied, and the heat raised: more flowers of a yellowish co-lour will then rise, which will require a second sublimation to deprive them of the empyreumatic oil they

The sublimation of the acid of benzoin may be conveniently performed by substituting an inverted earth-en pan instead of the paper cone. In this case the two pans should be made to fit, by grinding on a stone with sand, and they must be luted together with paper dipped in paste. This method seems preferable to the other, where the presence of the operator is required elsewhere; but the paper head can be more easily in-spected and changed. The heat applied must be gentle, and the vessels ought not to be separated till they have become cool.

The quantity of acid obtained in these methods differs according to the management, and probably differs according to ble also from difference of purity, and in other respects, of 127

BEN BEN

the resin itself. It usually amounts to no more than | about one-eighth part of the whole weight. Indeed Scheele says, not more than a tenth or twelfth. The whole acid of benzoin is obtained with greater cer-tainty in the humid process of Scheele: this consists in boiling the powdered balsam with lime water, and afterward separating the lime by the addition of muriatic acid. Twelve ounces of water are to be poured upon four ounces of slaked lime; and, after the ebullition is over, eight pounds, or ninety-six ounces, more of water are to be added; a pound of finely-powdered benzoin being then put into a tin vessel, six ounces of the lime water are to be added, and mixed well with the powder; and afterward the rest of the lime water in the same gradual manner, because the benzoin would coagulate into a mass, if the whole were added at once. This mixture must be gently boiled for half at once. This mixture must be gently boiled for nair an hour with constant agitation, and afterward suffered to cool and subside during an hour. The supernatant liquor must be decanted, and the residuum boiled with eight pounds more of lime water; after which the same process is to be once more repeated: the remaining powder must be edulcorated on the filter by affusions of hot water. Lastly, all the decoctions, being mixed together, must be evaporated to two pounds, and strained into a glass vessel. This to two pounds, and strained into a glass vessel: This fluid consists of the acid of benzoin combined with lime. After it is become cold, a quantity of muriatic acid must be added, with constant stirring, until the fluid tastes a little sourish. Duirng this time the lastmentioned acid unites with the lime, and forms a so-luble salt, which remains suspended, while the less luble salt, which remains suspended, while the less soluble acid of benzoin being disengaged, falls to the bottom in powder. By repeated affusions of cold water upon the filter, it may be deprived of the muriate of lime and muriatic acid with which it may happen to be mixed. If it be required to have a shining appearance, it may be dissolved in a small quantity of boiling water, from which it will separate in silky filaments by cooling. By this process the benzoic acid may be procured from other substances, in which it exists. exists.

Mr. Hatchell has shown, that, by digesting benzoin

Mr. Hatchell has shown, that, by digesting benzom in hot sulphuric acid, very beautiful crystals are sublimed. This is perhaps the best process for extracting the acid. If we concentrate the urine of horses or cows, and pour muriatic acid into it, a coplous precipitate of benzoic acid takes place. This is the cheapest source of it."—Ure's Chem. Dict.

As an economical mode of obtaining this acid, Four-

croy recommends the extraction of it from the water that drains from dunghills, cowhouses, and stables, by means of the muriatic acid, which decomposes the benzoate of lime contained in them, and separates the benzoic acid, as in Scheele's process. He confesses the smell of the acid thus obtained differs a little from that of the acid extracted from benzoin; but this, he says, may be remedied, by dissolving the acid in boiling water, filtering the solution, letting it cool, and thus suffering the acid to crystallize, and repeating this ope-

ration a second time.

The acid of benzoin is so inflammable, that it burns with a clear yellow flame without the assistance of a wick. The sublimed flowers in their purest state, as which is subdimed Howers in their purest state, as white as ordinary writing paper, were fused into a clear transparent yellowish fluid, at the two hundred-and-thirtieth degree of Fahrenheit's thermometer, and at the same time began to rise in sublimation. It is probable that a heat somewhat greater than this may be required to separate it from the resin. It is strongly disposed to take the crystalline form in cooling. disposed to take the crystalline form in cooling. The concentrated sulphuric and nitric acids dissolve this concentrated sulphuric and intric acids dissolve this concrete acid, and it is again separated without alteration, by adding water. Other acids dissolve it by the assistance of heat, from which it separates by cooling, unchanged. It is plentifully soluble in ardent spirit, from which it may likewise be separated by diluting the spirit with water. It readily dissolves in oils, and in melted tallow. If it be added in a small proportion to this last fluid, part of the tallow congeals before the rest, in the form of white one we clouds. If the quanrest, in the form of white opaque clouds. If the quantity of acid be more considerable, it separates in part by cooling, in the form of needles or feathers. It did not communicate any considerable degree of hardness to the tallow, which was the object of this experiment.

When the tallow was heated nearly to ebullition, it emitted fumes which affected the considerable to the tallow. emitted fumes which affected the respiration, like those | 128

of the acid of benzoin, but did not possess the peculiar and agreeable smell of that substance, being probably the sebacic acid. A stratum of this tallow, about onethe sebacic acid. A stratum of this tallow, about one-twentieth of an inch thick, was fused upon a plate of brass, together with other fat substances, with a view to determine its relative disposition to acquire and retain the solid state. After it had cooled, it was left upon the plate, and, in the course of some weeks, it gradually became tinged throughout of a bluish-green colour. If this circumstance be not supposed to have arisen from a solution of the copper during the fusion, it seems a remarkable instance of the mutual action of two bodies in the solid state, contrary to that axiom of chemistry which affirms, that bodies do not act on each other, unless one or more of them be in the fluid state.

other, unless one or more of them be in the fluid state. Tallow itself, however, has the same effect.

Pure benzoic acid is in the form of a light powder, evidently crystallized in fine needles, the figure of which is difficult to be determined from their smallness. It has a white and shining appearance; but when contaminated by a portion of volatile oil, is yellow or brownish. It is not brittle, as might be expected from its appearance, but has rather a kind of ductility and elasticity, and, on rubbing in a mortar, becomes a sort of paste. Its taste is acrid, hot, acidulous, and bitter. It reddens the infusion of litmus, but not syrup of violets. It has a peculiar aromatic smell, but not strong unless heated. This, however, appears not to belong to the acid; for Mr. Giese informs us, that not to belong to the acid; for Mr. Giese informs us, that on dissolving the benzoic acid in as little alkohol as on dissolving the behazoic acta in as inthe akknow as possible, filtering the solution, and precipitating by water, the acid will be obtained pure, and void of smell, the odorous oil remaining dissolved in the spirit. Its specific gravity is 0.667. It is not perceptibly altered by the air, and has been kept in an open vessel twenty years without losing any of its weight. None of the combustible substances have any effect on it; but it may be refined by mixing it with charcoal powder and subliming, being thus rendered much whiter and better crystallized. It is not very soluble in water: Wenzel and Lichtenstein say four hundred parts of cold water dissolve but one, though the same quantity of boiling water dissolves twenty parts, nineteen of which separate on cooling.

The benzoic acid unites without much difficulty with the earthy and alkaline bases. These com-pounds are called benzoates.

pounds are called benzoates.

The benzoate of barytes is soluble, crystallizes tolerably well, is not affected by exposure to the air, but is decomposable by fire, and by the stronger acids. That of lime is very soluble in water, though much less in cold than in hot, and crystallizes on cooling. It is in like manner decomposable by the acids and by barytes. like manner decomposable by the acids and by barytes. The bestroate of magnesia is soluble, crystallizable, a little deliquescent, and more decomposable than the former. That of alamina is very soluble, crystallizes in dendrites, is deliquescent, has an acerb and bitter taste, and is decomposable by fire, and even by most of the vegetable acids. The benzoate of potassa crystallizes on coolng in little compacted needles. All the acids decompose it, and the solution of barytes and lime form with it a precipitate. The benzoate of soda is very crystallizable, very soluble, and not deliquescent like that of potassa, but it is decomposable by the same means. It is sometimes found native in the urine of graminivorous quadrupéds, but by no means so abungraminivorous quadrupeds, but by no means so abundantly as that of lime. The benzoate of ammonia is volatile, and decomposable by all the acids and all the bases. The solutions of all the benzoates, when drying on the sides of a vessel wetted with them, form dendritical crystallizations.

dendritical crystallizations.

Trommsdorf found in his experiments, that benzoic acid united readily with metallic oxydes.

The benzoates are all decomposable by heat, which, when it is slowly applied, first separates a portion of the acid in a vapour, that condenses in crystals. The soluble benzoates are decomposed by the powerful acids, which separate their acid in a crystalline form.

The benzoic acid is occasionally used in medicine, but not so much as formerly, and enters into the com-

but not so much as formerly; and enters into the com-position of the camphorated tincture of opium of the London college, heretofore called paregoric clixir.

savinage. BETA (So called from the river Batis, in Spain, where it grows naturally; or, according to Blanchard, from the Greek letter $\beta\eta\tau a$, which it is said to resemble when turgid with seed.) The beet.

1. The name of a genus of plants in the Linnaan system. Class, Pentandria; Order, Digynia. The

2. The pharmacoperial name of the common beet. See Beta ruigaris.

BETA HYBRIDA. The plant which affords the root of scarcity. Mangel wursel of the Germans; a large root. It contains much of the saccharine principle, and is very nourishing. Applied externally it is useful in cleaning foul ulcers; and is a better application than the carrot.

BETA VULGARIS. The systematic name for the beet of the pharmacopeaas. Beta:—floribus congestis of Linnæus. The root of this plant is frequently eaten by the French; it may be considered as nutritious and antiscorbutic, and forms a very elegant pickle with vinegar. The root and leaves, although formerly employed as laxatives and emollients, are now forgotten. A considerable quantity of sugar may be obtained from the root of the best. It is likewise said, that if best roots be dried in the same manner as malt, good beer may be made from them. It is occasionally used to improve the colour of claret.

BETELE. Bethle; Betle; Betelle. An oriental plant, like the tail of a lizard. It is chewed by the In-

dians, and makes the teeth black; is cordial and exhibitanting, and in very general use throughout the cast.

It is supposed to be the long pepper.

BETO'NICA. (Corrupted from Vettonica, which is derived from the Vectones, an ancient people of Spain.) Betony.

1. The name of a genus of plants in the Linnaran system. Class, Didynamia; Order, Gymnos-

See Betonica officinalis.

2. The pharmacopoial name of the wood betony, BETONICA AQUATICA. See Scrophularia aquatica, BETONICA OFFICINALIS. The systematic name of the betony of the pharmacopwias. Betonica purpurea; Betonica vulgaris; Cestrum; Vetonica cordi; Betonica—spica interrupta, torollarum labit lacinia inter-media emarginata of Linnaus. The leaves and tops of this plant have an agreeable, but weak smell; and to the taste they discover a slight warmth, accompa-nied with some degree of adstringency and bitterness. The powder of the leaves of betony, snuffed up the nose, provokes sneezing; and hence it is sometimes made an ingredient in sternutatory powders. Its leaves are sometimes smoked like tobacco. The roots differ greatly, in their quality, from the other parts; their taste is very bitter and nauseous; taken in a small dose, they vomit and purge violently, and are supposed to have somewhat in common with the roots of hellebore. Like many other plants, formerly in high medical estimation, betony is now almost entirely neglected. Antonius Musa, physician to the emperor Augustus, filled a whole volume with enumerating its virtues staying it as a recogly for no less than forty. Augustus, filled a whole volume with enumerating its virtues, stating it as a remedy for no less than forty-seven disorders; and hence in Italy the proverbial compliment, You have more virtues than betony.

BETONICA PAULLI. A species of veronica.

BETONY. See Betonica officinalis.

BETONY. See Betonica.

Betony, water. See Scrophularia aquatica BETULA. 1. The name of a genus of plants in the Linnean system. Class, Monacia; Order, Tetrandria, Alder and birch.

2. The pharmacopeial name of the white birch.
See Betula alba.

BETULA ALBA. The systematic name of the betula of the pharmacopaias. Betula:—feliis ovatis, acuminatis, serratis, of Linnaus. The juice, leaves, and

bark have been employed medicinally. If the tree be | proofs of genuine bezoar, and which a vegetable juice bark have been employed medicinally. If the tree be bored early in the spring, there issues, by degrees, a large quantity of limpid, watery, sweetish juice; it is said that one tree will afford from one to two gallons a day. This juice is esteemed as an antiscorbatic, deobstruent, and diuretic. When well fermented, and having a proper addition of raisins in its composition, it is framently a rich and steams. having a proper addition of raisins in its composition, it is frequently a rich and strong liquor; it keeps better than many of the other made-wines, often for a number of years, and was formerly supposed to possess many medical virtues; but these experience does not seem to sanction; and the virtues of the alder, like those of many other simples formerly prized, have sunk into oblivion. The leaves and bark were used externally as resolverts, determine and antisenties.

externally as resolvents, detergents, and antiseptics.

Betula alnus. The systematic name for the alnus of the pharmacopeias. The common alder.

BEX. (From βησσω, to cough.) A cough. Dr. Good, in his Nosology, has applied this term to a genus of diseases, which embraces three species, bex humida, sicca, convulsiva.

BEXAGUI'LLO. A name given to the white ipecacu-anha, which the Spaniards bring from Peru, as the

Portuguese do the brown from Brazil.

BEXU'GO. The root of the Ematitis peruviana of Caspar Bauhin; one drachm of which is sufficient for

BEZAHAN. The fossile bezoar.

BEZETTA CCRULEA. See Croton tinctorium

BEZOAR. (From pa-zahar, Persian, a destroyer of poison.) Lapis bezoardicus. Bezoard. A preternatural or morbid concretion formed in the bodies of land-animals. Several of these kinds of substances were formerly celebrated for their medicinal virtues, and distinguished by the names of the countries from whence they came, or the animal in which they were found. There are eight kinds, according to Fourcroy, Vauquelin, and Berthollet.

1. Superphosphate of lime, which forms concretions in the intestines of many mammalia.

2. Phosphate of magnesia, semitransparent and yel-

lowish, and of sp. grav. 2.160.

3. Phosphate of ammonia and magnesia. 3. Phosphate of ammonia and magnesia. A concretion of a gray or brown colour, composed of radiations from a centre. It is found in the intestines of herbiverous animals, the elephant, horse, &c.

4. Biliary, colour reddish-brown, found frequently in the intestines and gall-bladder of oxen, and used by painters for an orange-yellow pigment. It is inspired.

sated bile.

5. Resinous. The oriental bezoars, procured from unknown animals, belong to this class of concretions.

They consist of concentric layers, are fusible, combustible, smooth, soft, and finely polished. They are composed of bile and resin.

6. Fungous, consisting of pieces of the Boletus igni-

arius, swallowed by the animal.

7. Hairy. 8. Ligniform. Three bezoars sent to Bonaparte by the king of Persia, were found by Berthollet to be no-thing but woody fibre agglomerated.

Bezoars were formerly considered as very powerful Bezoars were formerly considered as very powerful alexipharmics, so much so, indeed, that other medicines, possessed, or supposed to be possessed, of alexipharmic powers, were called bezoardies; and so efficacious were they once thought, that they were bought for ten times their weight in gold. These virtues, however, are in the present day justly denied them, as they produce no other effects than those common to the satine particles which they contain, and which may the saline particles which they contain, and which may be given to greater advantage from other sources. composition of bezoar with absorbent powders, has been much in repute, as a popular remedy for disor-ders in children, by the name of Gascoigne's powder and Gascoigne's ball; but the real bezoar was rarely, if ever, used for these, its price offering such a tempta-tion to counterfeit it. Some have employed for this purpose, a resinous composition, capable of melting in the fire, and soluble in alkohol; but Newmann supposed that those nearest resembling it, were made of gypsum, chalk, or some other earth, to which the proper colour was imparted by some vegetable juice. We understand, bowever, that tobacco-pipe clay, tinged with ox-gall, is commonly employed, at least for the Gascoigne's powder; this giving a yellow tint to paper, rubbed with chalk, and a green to paper rub-bed over with quick-lime; which are considered as

vould not effect.

BEZOAR BOVINUM. Bezoar of the ox.

BEZOAR GERMANICUM. The bezoar from the alpine

BEZOAR HYSTRICIS. Lapis porcinus; Lapis ma-lacensis; Petro del porco. The bezoar of the Indian porcupine; said to be found in the gall-bladder of an Indian porcupine, particularly in the province of Ma-lacca. This concrete differs from others: it has an intensely bitter taste; and on being steeped in water, for a very little time, impregnates the fluid with its bitterness, and with aperient, stomachic, and, as it is supposed, with alexipharmic virtues. How far it differs in virtue from the similar concretions found in the gall-bladder of the ox, and other animals, does not appear.

BEZOAR MICROCOSMICUM. The calculus found in

BEZOAR OCCIDENTALE. Occidental bezoar. This concretion is said to be found in the stomach of an animal of the stag or goat kind, a native of Peru, &c. It is of a larger size than the oriental bezoar, and some-

is of a larger size than the oriental bezoar, and sometimes as large as a hen's egg; its surface is rough, and the colour green, grayish, or brown.

BEZOAR ORIENTALE. Lapis bezoar orientalis.

Oriental bezoar stone. This concretion is said to be found in the pylorus, or fourth stomach of an animal of the goat kind, which inhabits the mountains of Persia. It is generally about the size of a kidney bean, of a roundish or oblong figure, smooth, and of a shining olive or dark greenish colour.

shining olive or dark greenish colour.

BEZOAR PORCINUM. See Bezoar hystricis. BEZOAR SIMLE. The bezoar from the monkey.

BEZOARDICA RADIX. See Dorstenia.

BEZOARDICUM JOVIALE. Bezoar with tin. It differed very little from the Antihecticum Poterii.

BEZOARDICUM LUNALE. A preparation of antimony

and silver.

BEZOARDICUM MARTIALE. A preparation of iron and antimony.

BEZOARDICUM MINERALE. A preparation of antimony, made by adding nitrous acid to butter of anti-

BEZOARDICUM SATURNI. A preparation of antimony and lead.

BEZO'ARDICUS LAPIS. See Bezoar.
BEZOARDICUS PULVIS. The powder of the oriental

BEZOARTICUM MINERALE. A calx of antimony.
BI. (From bis, twice.) In composition signifies twice or double, and is frequently attached to other words in anatomy, chemistry, and botany; as biceps, having two heads; bicuspides, two points, or fangs; bilocular, with two cells; bivalve, with two valves, &c.

BIEON. Wine made from sun-raisins, fermented

in sea water.

BIBITO'RIUS. (Bibitorius, from bibo, to drink, because by drawing the eye inwards towards the nose, it causes those who drink to look into the cup.) See Rectus internus oculi

Rectus internus ocult.

BIBULUS. Bibulous; attracting moisture; charta bibula, biotting paper.

BICAPSULARIS. Having two capsules. Pericarpium bicapsulare. See Capsula.

BICEPS. (From bis, twice, and caput, a head.)

Two heads. Applied to muscles from their having two distinct origins or heads.

BICEPS BRACHII. See Biceps flexor cubiti.
BICEPS CRURIS. See Biceps flexor cruris.
BICEPS CRURIS. See Biceps flexor cubiti.
BICEPS CRURIS. See Biceps flexor cubiti.
BICEPS EXTERNUS. See Triceps extensor cubiti.
BICEPS EXTERNUS. Biceps cruris of Albinus.
Biceps of Winslow, Douglas, and Cowper; and Ischiofemoroperonien of Dumas. A muscle of the leg, situ ated on the hind part of the thigh. It arises by two distinct heads; the first, called longus, arises in common with the semitendinosus, from the upper and posterior part of the tuberosity of the os ischium. The second, called brevis, arises from the linea aspera, a little below the termination of the glutaeus maximus, by a fleshy acute beginning, which soon grows broader, by a fleshy acute beginning, which soon grows broader, as it descends to join with the first head, a little above the external condyle of the os femoris. It is inserted, by a strong tendon, into the upper part of the head of the fibula. Its use is to bend the leg. This muscle

forms what is called the outer hamstring; and, between it and the inner, the nervous popliteus, arteria and

vena poplitea, are situated.

vena poplitea, are situated.

BICEPS FLEXOR CUBITI. Biceps brachii of Albinus.
Coraco-radialis, seu biceps of Winslow. Biceps internus of Douglas. Biceps internus humeri of Cowper. Scapulo coracoradial of Dumas. A muscle of the forearm, situated on the forepart of the os humeri. It arises by two heads. The first and outermost, called longus, begins tendinous from the upper edge of the glenoid cavity of the scapula, passes over the head of the os humeri within the joint, and in its descent without the joint, is enclosed in a groove near the head of the os humeri, by a membraneous ligament that proceeds from the capsular ligament and the head of the os humeri, by a membraneous ligament that proceeds from the capsular ligament and adjacent tendons. The second, or innermost head, called brenis, arises, tendinous and fleshy, from the coracobrachialis muscle. A little below the middle of the forepart of the os humeri, these heads unite. It is inserted by a strong roundish tendon into the tubercle on the upper end of the radius internally. Its use is to turn the hand supine, and to bend the forearm. At the bending of the elbow, where it begins to grow tendinous, it sends off an aponeurosis, which covers all the muscles on the inside of the forearm, and joins with another tendinous membrane, which is sent off from the triceps extensor cubiti, and covers all the from the triceps extensor cubiti, and covers all the muscles on the outside of the forearm, and a number of the fibres, from opposite sides, decussate each other. It serves to strengthen the muscles, by keeping them from swelling too much outwardly when in action, and a number of their fleshy fibres take their origin

BICEPS INTERNUS. See Biceps flexor cubiti.
BICHI'CHLE. An epithet of certain pectorals, or rather troches, described by Rhazes, which were made

of liquorice, &c.

Bi'chos. A Portuguese name for the worms that get under the toe of the people in the Indies, which are destroyed by the oil of cashew nut.

Bici. The Indian name of an intoxicating liquor, made from Turkey wheat in South America. See

wheat, Turkey.

Bl'CORNIS. (From bis, twice, and cornu, a horn.)

1. An epithet sometimes applied to the os hyoides, which has two processes, or horns.

2. In former times, to muscles that had two termi-

nations.

3. A name given to those plants, the antheræ of which have the appearance of two horns.

BICORNES PLANTÆ. The name of an order of plants in the natural method of Linnæus and Gerard. BICUSPIDATUS. Having two points. See Bi-

BICU'SPIS. (From bis, twice, and cuspis, a spear.)

1. The name of those teeth which have double points,

or fangs. See Teeth.

2. Applied to leaves which terminate by two points;

2. Applied to leaves which terminate by two points; folia bicuspida, or bicuspidata.

BI'DENS. (From bis, twice, and dens, a tooth; so called from its being deeply serrated, or indented.)

The name of a genus of plants in the Linnman system.

Class, Syngenesia; Order, Polygamia aqualis.

BIDENS TRIPARTITA. The systematic name of the hemp agrimony, formerly used as a bitter and aperient, but not in the practice of the present day.

hemp agrimony, formerly used as a bitter and aperient, but not in the practice of the present day.

BIDLOO, GODREY, a celebrated anatomist, born at Amsterdam, in 1649. After practising several years as a surgeon, he was appointed physician to William III., and in 1694, made professor of anatomy and surgery at Leyden. He published 105 very splendid, though rather inaccurate anatomical tables, with explanatious; and several minor works. His nephew, Nicholas, was physician to the Czar Peter I.

BIENNIS. Biennial. A biennial plant is one, as the term imports, of two year's duration. Of this tribe there are numerous plants, which being raised one year from the seed, generally attain perfection the same year, or within about twelve months, shooting up stalks, producing flowers, and perfecting seeds in the following spring or summer, and soon after com-

the following spring or summer, and soon after com-

monly perish.

BIFARIAM. In two parts,
BIFER. (From bis, twice, and fero, to bear.) A
plant is so called, which bears twice in the year, in
spring and autumn, as is common between the tropics.

BIFIDUS. Forked. Divided into two; as a bifid seed-vessel in Adoxa moschatellina, petala bifida in the Silene nocturna and Alyssum incanum.

BIFLORUS. Bearing two flowers; as pedunculus

BIFORIUM. Applied to a leaf which points two

BIFORUS. (From bis, twice, and forus, a door.)
Two-doored, or bivalved. A class of plants is so denominated in some natural arrangements, constituted by those which have a pericarp, or seed-vessel, furnished with two valves.

BIFURCATE. (Bifurcus; from bis, twice, and furca, a fork.) A vessel, or nerve, stem, root, &c. is said to bifurcate when it divides into two branches;

thus the bifurcation of the aorta, &c.

fork.) Forked. See Bifurcate and Dichotomus.

BIGA'STER. (Bigaster: from his BIFURCATIO. Bifurcation. BIFURCATUS. (From bis,

yaşno, a belly.) A name given to muscles which have two bellies.

BIGEMINATUS. (From bis, and gemini, twins.) Twice paired. Biconjugatus. A leaf is so called when near the apex of the common petiole there is a single pair of secondary petioles, each of which support a pair of opposite leaflets; as in Mimosa un-

BIH'ERNIUS. (From bis, double, and hernia, a disease so called.) Having a double hernia or one on

each side.

Bihydroguret of carbon. See Carburetted hydrogen.
BilUGUS. A winged leaf is termed folium bijugum, which bears two pairs of leaflets.
BILABIATUS. Two-lipped. Often used in botany; as pericarpium bilabiatum; corolla bilabeata, &c.
BILACINIATUS. Applied to a leaf. Folium bilaciniatum; when cut into two segments.
BILACINIATUS. A name of iron.

BILA'DEN. A name of iron.

BILAMELLATUS. Composed of two lamina.

Bilberry bean. See Arbutus wea wrsi.

BILDSTEIN. See Figurestone.

BILE. (Bilis. Navius derives it from bis, twice, and lis, contention; as being supposed to be the cause of anger and dispute.) The gall. A bitter fluid, secreted in the glandular substance of the liver; in part flowing into the intestines and in rest recognitions. flowing into the intestines, and in part regurgitating into the gall-bladder. The secretory organs of this fluid are the penicilli of the liver, which terminate in very minute canals, called biliary ducts. The biliary ducts pour their bile into the ductus hepaticus, which conveys it into the ductus expression in the ductus hepaticus, which conveys it into the ductus communis choledochus, from whence it is in part carried into the duodenum. The other part of the bile regurgitates through the cystic duct into the gall-bladder: for hepatic bile, except during digestion, cannot flow into the duodenum, which contracts when empty; hence it necessarily regurgi-tates into the gall-bladder. The branches of the vena porta contribute most to the secretion of bile; its peculiar blood, returning from the abdominal viscera, is supposed to be, in some respects, different from other venal blood, and to answer exactly to the nature of venal blood, and to answer exactly to the nature of bile. It is not yet ascertained clearly whether the florid blood in the hepatic artery, merely nourishes the liver, or whether, at the same time, it contributes a certain principle, necessary for the formation of bile. It has been supposed, by physiologists, that cystic bile was secreted by the arterial vessels of the gall-bladder; but the fallacy of this opinion is proved by making a ligature on the cystic duct of a living animal. From what has been said, it appears that there are, as it were, two kinds of bile in the human body:—

1. Henatic bile, which flows from the liver into the

were, two kinds of bile in the human body:—

1. Hepatic bile, which flows from the liver into the diodenum: this is thin, of a faint yellow colour, inodorous, and very slightly bitter, otherwise the liver of animals would not be eatable.

2. Cystic bile, which regurgitates from the hepatic duct into the gall-bladder, and there, from stagnating, becomes thicker, the aqueous part being absorbed by lymphatic vessels, and more acrid from concentration Healthy bile is of a yellow, green colour; of a plastic consistence, like thin oil, and when very much agitated, it froths like soap and water: its smell is fatuous, somewhat like musk, especially the putrefying or evaporating bile of animals: its taste is bitter.

The primary uses of this fluid, so important to the

The primary uses of this fluid, so important to the animal economy, are:

3. It imparts a yellow colour to the excrements: thus we observe the white colour of the faces in jaundice, in which disease the flow of bile into the duode-

dice, in which disease the now of one into the duode-num is entirely prevented.

4. It prevents the abundance of mucus and acidity in the prima viæ; hence acid, pituitous, and vermin-ous saburra are common from deficient or inert bile.

The chemical analysis of bile has been principally illustrated by Mons. Thenard. "Ox bile is usually of a greenish-yellow colour, rarely of a deep green. By its colour it changes the blue of turnsole and violet to a reddish-yellow. At once very bitter, and slightly By its colour it changes the blue of turnsole and violet to a reddish-yellow. At once very bitter, and slightly sweet, its taste is scarcely supportable. Its smell, though feehle, is easy to recognise, and approaches somewhat to the nauscous odour of certain fatty matters, when they are heated. Its specific gravity varies very little. It is about 1.026 at 43° F. It is sometimes limpid, and at others disturbed with a yellow matter, from which it may be easily separated by water: its consistence varies from that of a thin mucilage, to viscidity." Cadet regarded it as a kind of water: its consistence varies from that of a thin mucilage, to viscidity." Cadet regarded it as a kind of soap. This opinion was first refuted by Thenard. According to this able chemist, 800 parts of ox bile are composed of 700 water, 15 resinous matters, 60 picromel, about 4 of a yellow matter, 4 of soda, 2 phosphate of soda, 3.5 muriates of soda and potassa, 0.8 sulphate of soda, 1.2 phosphate of lime, and a trace of oxide of iron. When distilled to dryness, it leaves from 1-8th to 1-6th of solid matter, which, urged with a higher heat, is resolved into the usual igneous with a higher heat, is resolved into the usual igneous products of animal analysis; only with more oil and less carbonate of ammonia.

Exposed for some time in an open vessel, the bile gradually corrupts, and lets fall a small quantity of a yellowish matter; then its mucilage decomposes. Thus the putrefactive process is very mactive, and the odour it exhales is not insupportable, but in some cases has been thought to resemble that of musk.

Water and alkebol combine in all proportions with Water and alkohol combine in all proportions with bile. When a very little acid is poured into bile, it becomes slightly turbid, and reddens litmus; when more is added, the precipitate augments, particularly if sulphuric acid be employed. It is formed of a yellow animal matter, with very little resin. Potassa and soda increase the thinness and transparency of bile. Accords of lead precipitates the yellow matter. bile. Acetate of lead precipitates the yellow matter, and the sulphuric and phosphoric acids of the bile. The solution of the subacetate precipitates not only these bodies, but also the picromel and the muriatic acid, all combined with the oxide of lead. The acetic acid remains in the liquid united to the soda. The greater number of fatty substances are capable of being dissolved by bile. This property, which made it be considered a soap, is owing to the soda, and to the triple compound of soda, resin, and picromel. Scourers sometimes, prefer it to soap, for cleansing weeklen. sometimes prefer it to soap, for cleansing woollen. The bile of the calf, the dog, and the sheep, are similar to that of the ox. The bile of the sow contains no picromel. It is merely a soda-resinous soap. Human bile is peculiar. It varies in colour, sometimes being green, generally yellowish-brown, occasionally almost colourless. Its taste is not very bitter. In the gall-big dies it is seldere limited containing often like that colouriess. Its taste is not very bitter. In the gall-bladder it is seldom limpid, containing often, like that of the ox, a certain quantity of yellow matter in sus-pension. At times this is in such quantity, as to ren-der the bile somewhat grumous. Filtered and boiled, it becomes very turbid, and diffuses the odour of white of egg. When evaporated to dryness, there results a brown extract, equal in weight to 1-11th of the bile. By calcination we obtain the same salts as from ox bile. All the acids decompose human bile, and occasion

By calcination we obtain the same salts as from ox bile.

All the acids decompose human bile, and occasion an abundant precipitate of albumen and resin, which are easily separable by alkohol. One part of nitric acid, sp. grav. 1.210, saturates 100 of bile. On pouring into it a solution of sugar of lead, it is changed into a liquid of a light-yellow colour, in which no picromel can be found, and which contains only acetate of soda and some traces of animal matter. Human bile appears hence to be formed, by Thenard, in 1100 parts; of 1000 water; from 2 to 10 yellow insoluble

1. To separate the chyle from the chyme: thus chyle is never observed in the duodenum before the chyme has been mixed with the bife; and thus it is that oil is extricated from linen by the bife of animals.

2. By its acridity it excites the peristaltic motion of the intestines; hence the bowels are so inactive in people with jaundice.

3. It imparts a yellow colour to the excrements:

BILGUER Jour Ulrack, was born at Coire, in

BILGUER, JOHN-ULRICK, was born at Coire, in Swisserland. He practised surgery at Berlin with such reputation, that he was appointed, by the great Frederick, Surgeon-General to the Prussian army. It was then the general practice to amputate in bad compound fractures; and being struck with the small proportion of those who recovered after the operation, he was led to try more lenient methods; from which meeting with much better success, he published as a thesis, on graduating at Halle, in 1761, a pretty general condemnation of amputation. This work attracted much notice throughout Europe, and materially checked the unnecessary use of the knife. In his "Instruc-tions for Hospital Surgeons," which appeared soon after, he insisted farther on the same subject; and where amputation was unavoidable, he advised leav-ing a portion of the integuments, which is now gene-rally adouted.

(Biliaris; from bilis, the bile.) Of BILIARY.

or belonging to the bile.

BILIARY DUCT. Ductus biliosus. The very vascular glandules, which compose almost the whole substance of the liver, terminate in very small canals, called biliary ducts, which at length form one trunk, the ductus hepaticus. Their use is to convey the bile, secreted by the liver, into the hepatic duct; this uniting with a duct from the gall-bladder, forms one common

canal, called the ductus communis choledochus, which conveys the bile into the intestinal canal.

Biti'mbi. (Indian.) See Malus Indica.

Bl'LIOUS. (Biliosus, from bilis, bile.) A term very generally made use of, to express diseases which arise from too copious a secretion of bile: thus bilious code history dispenses the bilious force for the secretion. colic, bilious diarrhæa, bilious fever, &c.

colic, bilious diarrhœa, bilious fever, &c.

BILIS. See Bile.

BILIS ATRA. Black bile. The supposed cause among the ancients of melancholy.

BILIS CYSTICA. Bilis fellea. Cystic bile. The bile when in the gall-bladder is so called to distinguish it from that which is found in the liver. See Bile.

BILIS HEPATICA. Hepatic bile. Bile that has not entered the gall-bladder. See Bile.

BILOBUS. (From bis, double, and lobus, the end of the ear.) Having two jobes, resembling the tips of ears; applied to a leaf, folium bilobum, when it is deeply divided into rounded segments, as the petals of the Geranium pyrenaicum and striatum which are the Geranium pyrenaicum and striatum which are bilobed.

BILOCULARIS (From bis, twice, and loculus, a little cell.) Two-celled; applied to a capsule which has two cells.

BILOCULARES. Is the name of a natural order of

BIME'STRIS. (From bis, twice, and mensis, month.) Two months old.
BINATUS. Binus. Binate. A term applied to compound leaves, when consisting of a pair of leaflet only, on one footstalk as in the great everlasting pea, and other species of lathyrus.

BINDWEED. See Convolvulus septum.

BINERVIUS. Two-nerved. Having two ribs on nerves very apparent. Hence, folium binerium.

BINGA'LLE. See Casumuniar.

BINGA'LLE. See Casumuniar.

BING'CULUS. (From binus, double, and oculus, the eye.) A bandage for securing the dressings on both eyes.

BINSICA. A disordered mind.—Helmont.

BINSICA MORS. The binsical, or that death which

follows a disordered mind.

BINUS. (From bis, twice.) Two by two; by couplets; applied to leaves when there are only two upon a plant, folia bina; as in Convallaria majalis, &c.

BIOLY'CHNIUM. (From βιος, life, and λυχνιον, a lamp.) Vital heat: also the name of an officinal

BI'OTE. (From βιος, life.) Life. Also light food. BIOTHA'NATI. (From βια, violence, or βιος, life, and βανα/ος, death.) Those who die a violent death, or suddenly, as if there were no space between life and death.

BIPARTITUS. Bipartite. Deeply divided almost

to the basis; as calyx bipartitus; folium bipartitum; perianthium bipartitum; and petala bipartita.

BIPEMU'LLA. See Pimpinella.

BIPINATIFIDUS. Doubly pinnatifid; as in the long rough beaded proper. Paparer arregions. See

long rough-headed poppy, Papaver arzemone.

BIPINNATIFIDUS. Doubly pinnatifid; applied

to a leaf. See Leaf.

BIPINNATUS. Doubly pinnate. A compound leaf is so termed when the secondary petioles are arranged in pairs on the common petiole, and each secondary petiole is pinnate.

Bi'ra. Malt liquor or beer.

Bira'o. Stone Parsley.

BIRCH. See Betula.

BIRCO. Stone Parsiey.

BIRCH. See Betula.

BIRDLIME. The best birdlime is made of the middle bark of the holly, boiled seven or eight hours in water, till it is soft and tender; then laid in heaps in pits in the ground and covered with stones, the water being previously drained from it; and in this state left for two or three weeks to ferment, till it is reduced to a kind of mucilage. This being taken from the pit is pounded in a mortar to a paste, washed in river water, and kneaded, till it is freed from extraneous matters. In this state it is left four or five days in earthen vessels, to ferment and purify itself, when it is fit for use

It may likewise be obtained from the misletoe, the Viburnum lantana, young shoots of elder, and other vegetable substances

It is sometimes adulterated with turpentine, oil, vine-

gar, and other matters.

Good birdlime is of a greenish colour, and sour fla-Good birdlime is of a greenish colour, and sour flavour; gluey, stringy, and tenacious; and in smell resembling linseed oil. By exposure to the air it becomes dry and brittle, so that it may be powdered; but its viscidity is restored by wetting it. It reddens tincture of litmus. Exposed to a gentle heat it liquefies slightly, swells in bubbles, becomes grumous, emits a smell resembling that of animal oils, grows brown, but recovers its properties on cooling, if not heated too much. With a greater heat it burns, giving out a brisk flame and much smoke. The residuum contains sulphate and muriate of potassa, carbonate of lime and alle and muriate of potassa, carbonate of lime and alumina, with a small portion of iron.

BIRDSTONGUE. A name given to the seeds of the Flaxinus excelsior of Linnaus.

BI'RSEN. (Hebrew for an aperture.) A deep ulcer,

or imposthume in the breast.

BIRTHWORT. See Aristolochia.

Birthwort, climbing. See Aristolochia clematitis.

Birthwort, long-rooted. See Aristolochia longa.

Birthwort, snake-killing. See Aristolochia an See Aristolochia an-

Birthwort, three-lobed See Arislolochia trilobata. BISCO CTUS. (From bis, twice, and coque, to boil.) Twice dressed. It is chiefly applied to bread much baked, as biscuit.

BISCUTE'LLA. Mustard. BISE'RMAS. A name formerly given to clary, or

garden clary.

BISHOP'S WEED. See Ammi.

BISHOP'S WEED. from bis, twice, and lingua, a tongue; so called from its appearance of being double-tongued; that is, of having upon each leaf a less leaf.) The Alexandrian laurel.

BISMA'LVA. From vismalva, quasi viscum malva, from its superior viscidity. The water, or marsh-

mallow

(Bismuthum, from Bismut, Germ.) A metal which is found in the earth in very few different states, more generally native or in the metallic state. Native bismuth is met with in solid masses, and also in small particles dispersed in and frequently and also in small particles dispersed in and frequently deposited on different stones, at Schreeberg, in Saxony, Sweden, &c. Sometimes it is crystallized in four sided tables, or indistinct cubes. It exists combined with oxygen in the oxide of bismuth (bismuth hochre,) found in small particles, dispersed, of a bluish or yellowish-gray colour, needle-shaped and capillary; sometimes laminated, forming small cells. It is also, though more seldom, united to sulphur and iron in the form of a sulphuret in the martial sulphuretted bismuth ore. This ore has a vellowish-gray appearance, resembling This ore has a yellowish-gray appearance, resembling somewhat the martial pyrites. And it is sometimes combined with arsenic.

Bismuth is a metal of a yellowish or reddish-white colour, little subject to change in the air. It is somewhat harder than lead, and is scarcely, if at all malleable; being easily broken, and even reduced to powder, by the hammer. The internal face, or place of fracture, exhibits large shining plates, disposed in a variety of positions; thin pieces are considerably sonorous. At a temperature of 480° Fahrenheit, it melts, and its surface becomes covered with a greenish-gray or brown oxide. A stronger heat ignites it, and causes it to burn with a small blue flame; at the same time that a yellowish oxide, known by the name of flowers of bismuth, is driven up. The oxide appears to rise in of bismuth, is driven up. The oxide appears to rise in consequence of the combustion; for it is very fixed, and runs into a greenish glass when exposed to heat

Bismuth urged by a strong heat in a close vessel, sublimes entire, and crystallizes very distinctly when

gradually cooled.

The sulphuric acid has a slight action upon bismuth, when it is concentrated and boiling. Sulphurous acid gas is exhaled, and part of the bismuth is converted into a white oxide. A small portion combines with the sulphuric acid, and affords a deliquescent salt in the form of small needles.

The nitric acid dissolves bismuth with the greatest rapidity and violence; at the same time that much heat is extricated, and a large quantity of nitric oxide escapes. The solution, when saturated, affords crystals as it cools; the salt detonates weakly, and leaves a yellow oxide behind, which effloresces in the air. Upon dissolving this salt in water, it renders that fluid of a milky white, and lets fall an oxide of the same colour.

The nitric solution of bismuth exhibits the same pro perty when diluted with water, most of the metal falling down in the form of a white oxide, called magistery of bismuth. This precipitation of the nitric solution, by the addition of water, is the criterion by which bismuth is distinguished from most other metals. The magistery or oxide is a very white and subtile powder; when prepared by the addition of a large quantity of water, it is used as a paint for the complexion, and is thought gradually to impair the skin. plexion, and is thought gradually to impair the skin. The liberal use of any paint for the skin seems indeed likely to do this; but there is reason to suspect, from the resemblance between the general properties of lead and bismuth, that the oxide of this metal may be attended with effects similar to those which the oxides of lead are known to produce. If a small portion of muriatic acid be mixed with the nitric, and the precipitated oxide he washed with but a small quantity of pitated oxide be washed with but a small quantity of cold water, it will appear in minute scales of a pearly lustre, consisting the pearl powder of perfumers. These paints are liable to be turned black by sulphuretted hydrogen gas.

The muriatic acid does not readily act upon bismuth. When bismuth is exposed to chlorine gas it takes fire, and is converted into a chloride, which, formerly prepared by heating the metal with corrosive sublimate, was called butter of bismuth. The chloride is of a grayish-white colour, a granular texture, and is one gray. It is fixed at a red heat. When juding and opaque. It is fixed at a red heat. When iodine and bismuth are heated together, they readily form an iodide of an orange yellow colour, insoluble in water, but easily dissolved in potassa ley.

Alkalis likewise precipitate its oxide; but not of so beautiful a white colour as that afforded by the affu-

sion of pure water.

The gallic acid precipitates bismuth of a greenishyellow, as ferroprussiate of potassa does of a yellow-

ish colour.
There appears to be two sulphurets, the first a compound of 100 bismuth to 22.34 sulphur; the second of 100 to 46.5: the second is a bisulphuret.

The metal unites with most metallic substances, and renders them in general more fusible. When calcined with the imperfect metals, its glass dissolves them, and produces the same effect as lead in capillation; in which process it is even said to be preferable to lead.

Bismuth is used in the composition of payter in the

Bismuth is used in the composition of pewter, in the Bismuth is used in the composition of pewier, in the fabrication of printers' types, and in various other metallic mixtures. With an equal weight of lead, it forms a brilliant white alloy, much harder than lead, and more malleable than bismuth, though not ductile; and if the proportion of lead be increased, it is rendered still more malleable. Eight parts of bismuth

five of lead, and three of tin, constitute the fusible metal, sometimes called Newton's, from its discoverer, metal, sometimes called Newton's, from its discoverer, which melts at the heat of boiling water, and may be fused over a candle in a piece of stiff paper without burning the paper. One part of bismuth, with five of lead, and three of tin, forms plumbers' solder. It forms the basis of a sympathetic ink. The oxide of bismuth precipitated by potassa from nitric acid, has been recommended in spasmodic disorders of the stomach, and given in doses of four grains, four times a day. A writer in the Jena Journal says he has known the dose carried gradually to one scruple withknown the dose carried gradually to one scruple with-

Bismuth is easily separable, in the dry way, from its ores, on account of its great fusibility. It is usual, in the processes at large, to throw the bismuth ore into a fire of wood; beneath which a hole is made in the ground to receive the metal, and defend it from oxi-dation. The same process may be imitated in the small way, in the examination of the ores of this metal; nothing more being necessary, than to expose it to a moderate heat in a crucible, with a quantity of reducing flux; taking care, at the same time, to perform the operation as speedily as possible, that the bismuth

may be neither oxidized nor volatilized.

["In the United States, native bismuth has been found in Connecticut. The officinal preparation of this metal is the subnitrate. As a small portion of nitric acid remains combined with the oxide of bismuth in its preparation, it is properly called a subnitrate. The precipitation which takes place from hitric solution by adding more water is a criterion by trate. The precipitation which takes place to nitric solution, by adding mere water, is a criterion by which bismuth is distinguished from most other me-Subnitrate of bismuth is a fine, soft powder, of a pearly white colour, and nearly destitute of taste and smell. It changes to a dark colour on the contact of

sulphuretted or carburetted hydrogen.

Under the name of magistery of blsmuth, this substance was formerly regarded as noxious to the human system. But during the last forty years it has been brought into the practice of medicine, and found to be a salutary tonic to the stomach and organs of digestion. Its use commenced in Geneva, and it has since had the testimony of some of the most distinguished physicians in France and England in its favour. It has also in this country generally satisfied the expectations formed of it. In dyspeptic complaints, especially in patients of a nervous temperament, it is found a very useful palliative, and sometimes does much toward promoting a cure. It is an important medicine in the case of persons habitually subject to cramp of the stomach, and does more to fortify that organ against the returns of the disease than perhaps any of the tonics in common use. In habitual vomiting or nausea, both from a primary affection of the stomach, and from sympathy with other parts, it frequently gives great relief. Its tonic effect appears not to be confined to the stomach, since it is found to do good in different spasmodic affections, such as palpitations and chorea. Recently, it has been announced to cure intermittents.

A drachm of the bismuth, with an equal quantity of A drachm of the bismuth, with an equal quantity of liquorice powder, divided into twelve papers, three of which are to be taken during the day, will commonly be sufficient to display the activity of the medicine. Large quantities taken at once are unsafe."—Big. Mat. Med. A.]

BISMU'THUM, (From bismut, German.) See

BISSET, CHARLES, was born about the year 1716. After studying at Edinburgh, and practising some years as an hospital-surgeon in Jamaica, he entered the army; but soon after settled in Yorkshire, and in 1755, published a Treatise on the Scurvy. But his most celebrated work is an "Essay on the Medical Constitution of Great Britain," in 1762. He obtained three years after a diploma from St. Andrew's, and reached his 75th year.

BISTORT. See Bistorta.

BISTORTA. (From bis, twice, and torqueo, to bend; so called from the contortions of its roots.) Bistort. See Polygonum bistorta.

BISTOURY. (Bistoire, French.) Any small knife for surgical purposes.

for surgical purposes.

BISTRE. A brown pigment, consisting of the finer parts of wood soot, separated from the grosser by washing. The soot of the beech is said to make the

A sulphate with an additional BISULPHATE.

quantity of sulphuric acid.

BIT NOBEN. Salt of bitumen. substance has lately been imported from India by this name, which is not a natural production, but a Hindoo preparation of great antiquity. It is called in the country, bit noben, padanoon, and soucherloon, and popularly khala mimuc, or black salt. Mr. Henderson, of Bengal, conjectures it to be the sal asphaltites and sal sodomenus of Pliny and Galen. This salt is far more extensively used in Hindostan than any other modeling whatever. The Hindostan than any other medicine whatever. The Hindoos use it to improve their appetite and digestion. They consider it as a specific for obstructions of the liver and spleen; and it is in high estimation with them in paralytic disorders, particularly those that affect the organs of speech, cutaneous affections, worms, old rheumatisms, and indeed all chronic disorders of man and beast.

BITERNATUS. Twice-ternate. Applied to com-

pound leaves, when the common footstalk supports three secondary petioles on its apex, and each of these support three leaflets; as in **Egopodium*.

BITHI'NICI EMPLASTRUM. A plaster for the spleen.

BITHI NICI EMPLASTRUM. A plaster for the special Bithinos. A Galenical plaster.
BITTER. Amarus.
BITTER APPLE. See Cucumis Colocynthis.
BITTERN. The mother water which remains after the crystallization of common salt in sea-water, or the water of salt springs. It abounds with sulphate and muriate of magnesia, to which its bitterness is

BITTERSPAR. Rhombspar. A mineral of a grayish or yellowish colour, and somewhat pearly lustre, usually found embedded in serpentine, chlorite, or steatite, and found in the Tyrol, Salsburg, Dauphiny, Scotland, and the Isle of Man.

BITU'MEN. (Πιθυμα, πιθυς, pine; because it flows from the pine-tree; or, quod vi tumcat è terra, from its bursting forth from the earth.) This term increased the second of the pine tree in the second of the second of

cludes a considerable range of inflammable mineral substances, burning with flame in the open air. They

substances, burning with flame in the open air. They are of different consistency, from a thin fluid to a solid; but the solids are for the most part liquefiable at a moderate heat. The fluid are,

1. Naphtha; a fine, white, thin, fragrant, colourless, oil, which issues out of white, yellow, or black clays in Persia and Media. This is highly inflammable, and is decomposed by distillation. It dissolves resins, and the assential oils of thome and layender, but is and the essential oils of thyme and lavender; but is not itself soluble either in alkohol or ether. It is the lightest of all the dense fluids, its specific gravity being

o.708. See Naphtha.

2. Petroleum, which is a yellow, reddish, brown, greenish, or blackish oil, found dropping from rocks, or issuing from the earth, in the dutchy of Modena, and in various other parts of Europe and Asia. This likewise is insoluble in alkohol, and seems to consist of naphtha, thickened by exposure to the atmosphere. It contains a portion of the succinic acid. See Petroleum.

3. Barbadoes tar, which is a viscid, brown, or black inflammable substance, insoluble in alkohol, and containing the succinic acid. This appears to be the mineral oil in its third state of alteration.

The solid are, 1. Asphaltum, mineral pitch, of which there are three varieties: the cohesive; the semi-compact, maltha; the compact, or asphaltum. These are smooth, more or less hard or brittle, inflammable substances, which melt easily, and burn with-out leaving any or but little ashes, if they be pure.

They are slightly and partially acted on by alkohol and other. See Asphaltum.

2. Mineral tallow, which is a white substance of the consistence of tallow, and as greasy, although more brittle. It was found in the sea on the coasts of Evolund in the sea on the coasts of Finland, in the year 1736; and is also met with in some rocky parts of Persia. It is near one-fifth lighter than tallow; burns with a blue flame, and a smell of grease, leaving a black viscid matter behind, which is more difficultly consumed.

3. Elastic bitumen, or mineral caoutchouc, of which there are two varieties. Besides these, there are other bituminous substances, as jet and amber, which approach the harder bitumens in their nature; and all the varieties of pit coal, and the bituminous schistus, or shale, which contain more or less of bitumen in their composition.

BITUMEN BARBADENSE. See Petroleum barbadense.

BITUMEN JUDAICUM. Asphaltus. Jews' pitch. A solid, light, bituminous substance; of a dusky colour on the outside, and a deep shining black within; of very little taste, and scarcely any smell, unless heated; when it emits a strong pitchy one. It is said to be found plentifully in the earth in several parts of Egypt, and floating on the surface of the Dead sea. Egypt, and floating on the surface of the Dead sea. It is now wholly expunged from the catalogue of officinals of this country; but was formerly esteemed as a discutient, sudorific, and emmenagogue.

BITUMEN LIQUIDUM. See Petroleum. BITUMINOUS. Of the nature of bitumen.

[BITUMINOUS COAL. In the United States, coal has been explored in several districts, and undoubtedly exfists in great abundance. In Virginia, near Richmond, is a deposite of coal about 20 miles in length, and ten miles in breadth; it is accompanied by a whitish sandstone and shale, with vegetable impressions, as is usual in the independent coal formation, which here lies over, and is surrounded by, primitive rocks. In Pennsylvania, coal is found on the west branch of the Susquehannah; in various places west of that branch; also on the Ju-niata, and on the waters of the Alleghany and Monon-gahela. Indeed, according to Mr. Maclure, the inde-pendent coal formation extends from the head waters of the Ohio, with some interruptions, to the waters of the Tombigbee river, in Alabama.—See Cl. Min. A.]

BITUMINOUS LIMESTONE. Found near Bristol, and in Galway, in Ireland. The Dalmatian is so charged with bitumen, that it may be cut like soap, and is used for building houses. When the walls are reared, fire

is applied to them, and they burn white.

BIVALVIS. Two-valved. Applied to the valves of the absorbents in anatomy, and in botany to capsules.—Capsula bivalvis.

BIVASCULARIS. (From bis, twice, and vasculum, a little vessel.) Having two cells.

BIVENTER. (From bis, twice, and venter, a belly.) A muscle is so termed, which has two bellies.

BIVENTER CERVICIS. A muscle of the lower law.

BIVENTER CERVICIS. A muscle of the lower jaw. BIVENTER MAXILLE INFERIORIS. See Digastricus. BI'XA. The name of a genus of plants. Class,

Polyandria. Order, Monogymia.

BIXA ORELLANA. The systematic name for the plant affording the terra orellana or annotto of the shops and pharmacopæias. The substance so called is a ceraceous mass obtained from the pellicles of the seeds. In Jamaica and other warm climates, it is considered as a useful remedy in dysentery, possessing adstringent and stomachic qualities; but here it is only used to colour cheese, and some other articles.

BLA'CCIÆ. The measles.—Rhazes.

BLA'CKBERRY. The fruit of the common bram-

bles.—See Rubus fruticosus.
[In the United States, there are two species of the blackberry, the fruit of which is eaten, and the roots used as astringents. They are the Rubus trivialis, or Dewberry, or running blackberry, and the Rubus villegus or standing blackberry.

losus, or standing blackberry.

"The bark of the root of the dewberry, or low blackberry, a common native briar, is highly astringent, possessing both tannin and gallic acid in large quantity. It is a popular remedy in cholera infantum, to which disease it appears well suited after liberal evacuations have been made. In the secondary stages of dysentery, and in diarrhea, after the removal of offending causes from the alimentary canal, it has been resorted to with success in controlling the discharges, and giving tone to the bowels. It is usually exhibited in strong decoction.

The Rubus villosus is commonly distinguished from the preceding by the name of high, or tall blackberry. The properties of the two are the same."—See Big.

A jelly made of the fruit is an excellent domestic remedy for young children in cholera infantum, after

proper evacuations. A.]

BLACK CHALK. A mineral of a bluish black colour, and slaty texture, which soils the fingers. It is found in primitive mountains, and occurs in Caer-

naryonshire, and the island of Isla.

[Black prop. "The formula for this preparation in the Pharmacopæia, is essentially the same with the one made public by Dr. Armstrong, and which, under the name of Black Drop, has been known and prized in England for a century and upwards. As the recipe wants the usual precision of pharmaceutical formula, it may be proper to secure a tolerable uniformity of strength, by boiling the first ingredients no longer than is necessary to blend them together, and by afterward exposing them in a warm place, until about one-fourth of their original volume is evaporated. The compound directed in the Pharmacopæia should afford about two pints of strained liquor. As the filtration of so viscid a liquor is difficult, it may be strained without pressure through a double linen bag.

The black drop is a fermented aromatic vinegar of opium. Its taste, when properly prepared, is bitter and acid, the saccharine principle being changed by the fermentation. Its consistence is moderately viscid.

Acetous solutions of opium have been in use since

the days of Van Helmont, and even earlier. Our medical chemists of the present day consider that the peculiarities which attend the operation of these preparations depend upon the formation of an acetate of morphia. The black drop has sustained its popularity for a great length of time on account of its favourable operation. According to Dr. Armstrong, it often stays in the stomach when other preparations will not, and it also affects the head less than laudanum. and other medical writers give their testimony to its usefulness.

About ten or twelve minims form a dose. Notwith-standing the advantages ascribed to this preparation, it is not always uniform in its strength, or in the amount of sediment it deposites. It is probable that a better vinegar of opium might be prepared."-Big. Mat.

BLACK JACK. Blende, or mock lead; an ore

of zinc.

BLACK LEAD. See Plumbago.

BLACK MORE, Sir RICHARD, was born in Wiltshire about the year 1650. After studying at Oxford,
he took his degree in medicine at Padua, then settled
in London, and met with considerable success, insomuch that he was appointed physician to William III. and retained the same office under Queen Anne. He then published several long and dull epic poems, which appear to have materially lessened his reputation; so that his opposition to the inoculation for small-pox had

very little weight. He wrote also several medical tracts, which are little known at present.

RLACK WADD. One of the ores of manganese.

[Black vomit. This is one of the fatal symptoms of yellow fever, it being a very rare case for a patient to recover after its occurrence.

"A memoir on the analysis of black the Cathral, was read before the American Philosophical Cathral, was read before the 20th June, 1800. The experienced and intrepid author has given a description of the black vomit, has analyzed the fluids ejected a few hours before the commencement of black vomiting itself, to which he has added experiments to ascertain the effects of black vomit on the living system of man and other animals, and a synopsis of the opinions of authors concerning its formation and qualities. The experiments show that this singular morbid excretion contains an acid, which is neither carbonic, phospho-ric, nor sulphuric; and, what our readers will hardly expect, that the black vomit may be smelled, tasted, and swallowed, without inducing yellow fever, or even any sickness at all-so little infection or contagion does it seem to contain. He concludes it to be an altered secretion from the liver."—New-York Med. Repos.

vol. iv. p. 75.

"Dr. May, of Philadelphia, dropped the matter of black vomit into his eyes, and never experienced inconvenience or sickness."—Med. Rep. vol. v. p. 131.

"Dr. Ffirth of Salem, in New-Jersey, has published a Dissertation on Malignant Fever, with an attempt to prove that it is not contagious. In this he relates a number of experiments which he has made upon the newtre of black vomit, as discharged by persons labourmatter of black vomit, as discharged by persons labour-ing under that disease. He inoculated himself in the left fore-arm with black vomit just discharged from a moribund patient; a slight inflammation ensued, which subsided in three days, and the wound readily healed, and without the formation of pus. To avoid cavil and deception, he repeated these experiments above twenty times on various parts of his body, with the black matter collected in Philadelphia during the seasons of 1802 and 1803. He put it into his eye, without experiencing more inconvenience than cord water

produces. He exposed himself to the exhalations of it while acted upon by heat in an iron skillet, and experienced no unpleasant sensation. He swallowed the thick extractive matter which remained after evaporation, in the form of pills, without incommoding his stomach. He even went so far as to mix half an ounce of fresh black vomit with an ounce and a half of water, and to drink it. It produced no more effect upon his stomach than so much water. He increased the dose to two ounces, and finally swallowed the black vomit in like quantity without any dilution at all, and without sustaining the least injury. He inoculated himself with saliva and serum, with as little inconvenience!!"—Med. Rep. vol. viii. p. 70. A.]

BLADDER. See Urinary bladder, and Gall-

bladder.

Bladder, inflamed. See Cystitis.
BLADE-BONE. See Scapula.
BLÆ'SITAS. (From blæsus.) A defect in speech,

called stammering.

BLæ'sus. (From βλαπ7ω, to injure.) A stam-

BLA'NCA. (Blane, French.) A purging mixture; so called because it was supposed to evacuate the white phlegmatic humours. Also white lead.

BLANCARD, STEPHEN, was born at Leyden, and graduated at Francker, in 1678. He settled at Amsterdam.

dam, and published many anatomical and medical works; especially one on morbid anatomy, containing 200 cases, and a "Lexicon Medicum," which passed through numerous editions.

BLASIUS, GERARD, son of a physician at Amster-

dam, from whom he derived a great predilection for comparative anatomy. After graduating at Leyden about the year 1646, he returned to his native city, and acquired so much reputation, that he was made pro-fessor of medicine in 1660, and soon after physician to the hospital. Besides publishing new editions of seve-ral useful works, with notes comprehending subsequent improvements, he was author of various original ones, especially relating to comparative and morbid anatomy. He claimed the discovery of the ductus salivaris, asserting he had pointed it out to Steno; to

whom it has been commonly ascribed.

BLASTE'MA. (From βλας ανω, to germinate.) A bud or shoot. Hippocrates uses it to signify a cutane-

ous pimple like a bud.

BLA'STUM MOSYLITUM. Cassia bark kept with the

BLA'TTA. (From βλαττω, 'to hurt.) A sort of beetle, or bookworm; so called from its injuring books or clothes; the kermes insect.

[Blatta is the generic name given by Linnaus to the cock-roach, which infests houses, and preys upon provisions, and not upon clothes. A.]

BLATTA'RIA LUTEA. (From blatta; so called, because, according to Pliny, it engenders the blatta.)
The Verbascum blattaria, or herb yellow mothemulisis.

BLEACHING. The chemical art by which the

BLEACHING. The chemical art by which the various articles used for clothing are deprived of their natural dark colour, and rendered white.

Bleaching powder. The chloride of lime.

Ble'chos. (From βληχαομαι, to bleat; so called according to Pliny, because if sheep taste it they bleat.)

The herb, wild penny-royal. See Mentha pulegium.

BLEEDING. See Blood-letting and Hamorrhage.

BLE'MA. (From δαλλω, to inflict.) A wound.

BLE'NDE. A species of zinc ore, formed of zinc in combination with sulphur, forming a sulphuret of

in combination with sulphur, forming a sulphuret of

BLE'NNA. Βλεννα. Blena. Mucus, a thick excrementitious humour.

BLENNORRHA'GIA. (From βλεννα, mucus, and βεω, to flow.) The discharge of mucus from the urethra.

BLENNORRHŒ'A. (From βλεννα, mucus, and ρεω, to flow.) 1. A gleet; Gonorrhæa mucosa. A discharge of mucus from the urethra, arising from

2 The name of a genus of diseases in Good's Nosology, embracing three species, Blennorrhaa simplez,

fundes, and chronica. BLE PHARA. (Quasi βλεπους φαρος, as being the tover and defence of the sight.) The cyclids.

BLEVRA'RIDES. (From βλεφαρον.) The hair upon the cyclids; also the part of the cyclids where the hair

BLEPHAROPHTHA'LMIA. (From βλεφαρον, the

eyelid, and οφθαλμια, a disease of the eye.) An inflammation of the eyelid.

BLEPHAROPTO'SIS. (From βλεφαρον, the eyelid, and π/ωσις, from πιπ/ω, to fall.) A prolupse, or falling down of the upper eyelid, so as to cover the correct See Persis.

BLEPHARO TIS. (From βλεφαρον, the eyelid.)
An inflammation of the eyelids.

BLEPHARO XYSIS. (From βλεφαρον, the eyelid, and ξω, to scrape off.) 1. The cleansing of the eyelids.

2. Inflammation of the eyelids.

Inflammation of the cyclids.

BLEPHAROXY STON. (From βλεφαρογ, the eyelid, and ξεω, to scrape off.) A brush for the eyes. An instrument for cleansing or scraping off foul substances

from the eyelids.

BLESSED. Benedictus. Applied to remedies and plants from their supposed virtues. See Benedictus.

Blessed Thistle. See Centaurea benedicta.

BLESTRI'SMUS. (From βαλλω, to throw about.)

Phrenitic restlessness

BLE'TA. A word used by Paracelsus to signify white, and applied to urine when it is milky, and pro-

cceds from a disease of the kidneys.

BLETI. (Bletus, from $\beta a \lambda \lambda \omega$, to strike.) Those seized with dyspnæa or suffocation.

BLISTER. Vesicatorium; Epispasticum. 1. The name of a topical application, Emplastrum vesicatorium, which when put on the skin raises the cuticle in the form of a vesicle, filled with a scrous fluid. Variation of the skin raises the cuticle in the form of a vesicle, filled with a scrous fluid. ous substances produce this effect on the skin; but the powder of the cantharis, or blistering fly, is what ope-

rates with most certainty and expedition, and is now invariably made use of for the purpose.

It is a principle sufficiently established with regard to the living system, that where a morbid action exists, it may often be removed by inducing an action of a different kind in the same or neighbouring part. On this principle is explained the utility of blisters in local inflammation and spasmodic action, and it regulates their application in pneumonia, gastritis, hepatitis, phrenitis, angina, rheumatism, colic, and spasmodic phrenius, angina, rhenmatism, colic, and spasmodic affections of the stomach; diseases in which they are employed with the most marked advantage. A similar principle exists with respect to pain; exciting one pain often relieves another. Hence blisters often give relief in toothache, and some other painful affections. Lastly, blisters, by their operation, communicate a stimulus to the whole system, and raise the vigour of the circulation. Hence in part, their utility in fewers the circulation. Hence, in part, their utility in fevers of the typhoid kind, though in such cases they are used with still more advantage to obviate or remove local inflammation.

When it is not wished to maintain a discharge from the blistered part, it is sufficient to make a puncture in the cuticle to let out the fluid; but when the case re-quires keeping up a secretion of pus, the surgeon must remove the whole of the detached cuticle with a pair of scissors, and dress the excoriated surface in a par-ticular manner. Practitioners used formerly to mix powder of cantharides with an ointment, and dress the powder of cantharides with an ointment, and dress the part with this composition. But such a dressing not unirequently occasioned very painful affections of the bladder, a scalding sensation in making of water, and very afflicting stranguries. The treatment of such complaints consists in removing every particle of the fly from the blistered part, making the patient drink abundantly of mucilaginous drinks, giving emulsions and some doses of camphor. and some doses of camphor.

These objections to the employment of salves containing the lytta, for dressing blistered surfaces, led to the use of mezereon, euphorbium, and other firstating substances, which, when incorporated with ointment, form very proper compositions for keeping blisters open, which they do without the inconvenience of irritating the bladder, like the blistering fly. The favourite application, however, for keeping open blisters, is the savine cerate, which was brought into notice by Mr. Crowther in his book on white swellings. (See Ceratum Sabina.) On the use of the savine cerate, immediately after the cuticle raised by the blister is removed, savs Mr. Crowther, it should be observed that taining the lytta, for dressing blistered surfaces, led to moved, says Mr. Crowther, it should be observed that experience has proved the advantage of using the application lowered by a half or two-thirds of the

unguentum ceræ. produce less irritation and more discharge, than if the savine cerate were used in its full strength. Mr. Crowther says also, that he has found fomenting the part with flannel, wrung out of warm water, a more easy and preferable way of keeping the blistered surface clean, and fit for the impression of the cintment, than scraping the part, as has been directed by others. An occasional dressing of unguentum resine flaving, he has found a very useful application for rendering the sore free from an appearance of slough, or rather dense lymph, which has sometimes been so firm in its texture as to be separated by the probe, with as much readiness as the cuticle is detached after blistering. As the discharge diminishes, the strength of the savine dressing should be proportionably increased. The ceratum sabine must be used in a stronger, or weaker degree, in proportion to the excitement produced on the patient's skin.

2. The name of a vesicle on the skin, whether formed by a blistering application, or arising from any

BLONDEL, JAMES AUGUSTUS, was born in England of a French family, and admitted licentiate of the College of Physicians about 1720. He chiefly distinguished himself by controverting, in a very able manner, the opinion then generally received, that marks could be imprinted on the fœtus by the imagination of

the mother, and he has the merit of contributing very largely to the removal of this prejudice, which had prevailed for ages, and often produced much mischief. BLOOD. Sanguis. A red homogeneous fluid, of a saltish taste, and somewhat urinous smell, and glutinous consistence, which circulates in the cavities of the heart, arteries, and veins. The quantity is estimated to be about twenty-eight pounds in an adult; of this four parts are contained in the veins and a fifth this, four parts are contained in the veins, and a fifth in the arteries. The colour of the blood is red; in the arteries it is of a florid hue, in the veins darker; exarteries it is of a florid hue, in the veins darker; except only the pulmonary vessels in which the colour is reversed. The blood is the most important fluid of our body. Some physicians and anatomists have considered it as alive, and have formed many lugeni us hypotheses in support of its vitality. The temperature of this fluid is of considerable importance, and appears to depend upon the circulation and respiration. The blood of man, quadrupeds, and birds is hotter than the medium they inhabit; hence they are termed animals of warm blood; while in fishes and reptiles, animals with cold blood, it is nearly of the temperature of the medium they inhabit. The blood possesses remarkable physical properties. Its colour is of a dark red, it is less deep in certain cases, and perhaps even scarlet. physical properties. Its colour is of a dark red, it is less deep in certain cases, and perhaps even scarlet. Its odour is insipid, and sui generis; its taste is also peculiar; however, it is known to contain salts, and principally the muriate of soda. Its specific gravity is a little more than that of water. Haller found its medium as 1.0527: 1.0000. Its capacity for caloric may be expressed by 934, that of arterial blood being 921. Its mean temperature is 31 degrees of Reaumur, = 100 F 102 F.

Venous blood, being extracted from its proper vessels, and left to itself, in a short time forms a soft mass; this mass separates spontaneously into two parts, the one liquid, yellowish, transparent, called serum: the other soft, almost solid, of a deep brown red, entirely opaque: this is the cruor, or clot. This occupies the bottom of the vessel; the serum is placed above. Sometimes a thin layer forms at the top of the serum, which is soft and reddish, and to which has been very improperly given the name of rind, buff, or crust of

This spontaneous separation of the elements of the blood does not take place quickly, except when it is in repose. If it is agitated it remains liquid, and pre-

serves its homogeneity much longer.

If the venous blood is placed in contact with the atmosphere, or with oxygen gas, it takes a vermition red colour; with ammonia it becomes cherry red; with azote a deeper brown red, &c. In changing colour it absorbs a considerable quantity of these different gases; it exhales a considerable quantity of carbonic acid, when kept some time under a bell upon

The serum sometimes presents a whitish tint, as if

An attention to this direction will milky, which has made it be supposed that it contained on and more discharge, than if the chyle: it appears to be a fatty matter which gives it this appearance.

The cruor, or clot of the blood is essentially formed of fibrin, and colouring matter.

The fibrin, separated from the colouring matter, is whitish, insipid, and inodorous; heavier than water, without action upon vegetable colours, elastic when humid, it becomes brittle by being dried.

In distillation it gives out a great deal of carbonate of ammonia, and a vast quantity of carbon, the ashes of which contain much phosphate of lime, a little phosphate of magnesia, carbonate of lime, and car-bonate of soda. A hundred parts of fibrin are com-

Oxygen 19.685

Total..... 100.000

The colouring matter is soluble in water and in the serum of the blood. Examined with the microscope in solution with these liquids, it appears like most fluids of the animal economy, formed of small glo-bules; dried and calcined in contact with the air, it melts and swells up, burns with flame, and yields a coal that is difficultly reduced to ashes.

It is of importance to remark, that in none of the parts of the blood are any gelatine or phosphate of

iron found, as was at first supposed.

The respective relations in quantity of the serum to the coagulum, and those of the colouring matter to the fibrin, have not yet been carefully examined. It is to

be presumed, as we shall see afterward, that they are variable according to an infinity of circumstances.

The coagulation of the blood has been, by turns, attributed to refrigeration, to the contact of the air, to the state of repose, &c.; but J. Hunter and Hewson have demonstrated by experiments, that this phenome-Have demonstrated by experiments, that this phenomenon cannot be attributed to any of these causes. Hewson took fresh blood, and froze it, by exposing it to a low temperature. He afterward thawed it: the blood appeared fluid at first, and shortly afterward it coagulated as usual. An experiment of the same kind was made by J. Hunter, with a similar result. Thus, blood does not coagulate because it is cooled. It even appears that a temperature a little elevated is favourable to its coagulation. We also know by experience that the blood thickens when it is deprived of the contact of the air, and agitated; its coagulation is, however, generally favoured by repose and the contact of

the air.

The elements of venous blood, such as we have noticed, are known by its analysis; but as all the matters absorbed from the intestinal canal, the serous membranes, the cellular tissue, &c., are immediately mixed with the venous blood, the composition of this liquid must vary in proportion to the matter absorbed. There will be found in it, in different circustances, alkohol, ether, camphor, and salts which it does not usually contain, &c., when these substances have been submitted to absorption in any part of the body

When, by the aid of a strong lens, or a microscope, we observe the transparent parts of cold-blooded animals, we see in the blood-vessels an immense multitude of small, rounded molecules, which swim in the serum, and roll upon each other, while they flow through the arteries and the veins

Similar observations have never been made upon the hot-blooded animals; the membranes and sides of the vessels being opaque. But as, in separating a drop of blood in water, rounded particles are often seen with the microscope, the existence of globules has been admitted for the blood of animais, and con-

Authors have related marvellous things of these globules. According to Leuwenhoeck, a thousand millions of those globules are not larger than a grain of sand. Haller, in speaking of cold-blooded animals, for he never could see those of hot-blooded animals, says, that they are to an inch as one inch is to five thousand. Some will have them of the same form and diameter in all animals: others, on the contrary, assert, that they have a particular form and size for each animal; some declare that they are spherical pierced and solid, others that they are flattened, and

tains a certain number of smaller globules.

Probably many errors of imagination and optical illusions, have slid into these different opinions. Dr. Magendie made a great number of microscopic experiments, in order to satisfy himself in this respect.

He has never seen, in the blood of man diluted in water, any thing but particles of colouring matter, generally rounded, of different sizes, which, according as they are placed exactly or not in the focus of the microscope, appear sometimes subscriptly semetimes. as they are placed exactly or not in the focus of the microscope, appear sometimes spherical, sometimes flat, and, at other times, of the figure of a disc, pierced in the centre. All these appearances, he says, can be produced at pleasure, by varying the position of the particles relatively to the instrument, and he believes that bubbles of air have often been described and drawn for globules of blood; at least, nothing has more resemblance to certain figures of Hewson, than more resemblance to certain figures of Hewson, than very small bubbles of air that are produced by slightly agitating the liquid submitted to the microscope.

The latest and most accurate chemical analysis of

blood is as follows:

The specific gravity of the serum is about 1.029, while that of blood itself is 1.058. It changes syrup of violets to a green, from its containing free soda. At 1560 serum coagulates, and resembles boiled white of egg. When this coagulated albumen is squeezed, a muddy fluid exudes, which has been called the serosity. According to Berzelius, 1000 parts of the serum of bullock's blood consist of 905 water, 79.99 albumen, 6.175 lactate of soda and extractive matter, 2.565 muriates of soda and potassa, 1.52 soda and animal mat-ter, and 4.75 loss. 1000 parts of serum of human blood consist, by the same chemist, of 905 water, 80 albumen, 6 muriates of potassa and soda, 4 lactate of soda with animal matter, and 4.1 of soda, and phos-phate of soda with animal matter. There is no gelatin

The cruor has a specific gravity of about 1.245. By making a stream of water flow upon it till the water runs off colourless, it is separated into insoluble fibrin, and the soluble colouring matter. A little albumen has also been found in cruor. The proportions of the former two are, 64 colouring matter, and 36 fibrin in 100. To obtain the colouring matter pure, we mix the cruor with 4 parts of oil of vitriol previously diluted with 8 parts of water, and expose the mixture to a heat of about 160° for 5 or 6 hours. Filter the liquid while hat and wash the residue with a few ounces. while hot, and wash the residue with a few ounces of hot water. Evaporate the liquid to one-half, and add ammonia, till the acid be almost, but not entirely saturated. The colouring matter falls. Decant the supernatant liquid, filter and wash the residuum from the whole of the sulphate of ammonia. When it is well drained, remove it with a platina blade, and dry

it in a capsule.

When solid, it appears of a black colour, but becomes wine-red by diffusion through water, in which, however, it is not soluble. It has neither taste nor smell. Alkohol and ether convert it into an unpleasant smell-ing kind of adipocire. It is soluble both in alkalies and acids. It approaches to fibrin in its constitution, and contains iron in a peculiar state, \(\frac{1}{2}\) of a per cent, of the oxide of which may be extracted from it by calcination. The incinerated colouring matter weighs 1-80th of the whole; and these ashes consist of 50 oxide of iron, 7.5 subphosphate of iron, 6 phosphate of lime, with traces of magnesia, 20 pure lime, 16.5 carbonic acid and loss; or the two latter ingredients may be reckoned 32 carbonate of lime. Berzelius imagines that none of these bodies existed in the colouring matter, but only their bases, iron, phosphorus. ing matter, but only their bases, iron, phosphorus, calcium, carbon, &c.; and that they were formed during the incineration. From the albumen of blood, the same proportion of ashes may be obtained, but no

The importance of the blood is very considerable; it distends the cavities of the heart and blood vessels, and prevents them from collapsing; it stimulates to contraction the cavities of the heart and vessels, by which means the circulation of the blood is performed; which means the circulation of the choose is the choose is the choose in the choose is the choose it is generates within itself animal heat, which it propagates throughout the body; it nourishes the whole body; and, lastly, it is that source from which every secretion of the body is separated.

Dr. Akerly to Dr. Samuel L. Mitchill, Professor, &c.

Dear Sir.—While speaking on the operation of remedies, it reminds me of an occurrence which took place in 1819, connected with this subject. A man called on me in the summer of that year, stating that he had fallen in the street in a fit, from which having recovered he requested to be bled to relieve his head, as from the distress there he was apprehensive of another. Mr. Knapp having just commenced the study of medi-cine with me, I desired him to take a stick and stir the blood to collect the fibrin, and to show him that the blood would not coagulate after being deprived of it. blood would not coagulate after being deprived of it. His attention as soon as he began to stir the blood was attracted by the strong smell of spirituous liquor arising from it. We both satisfied ourselves that the alkoholic odour actually arose from the blood, and that it was more perceptible when agitated, than when undisturbed. I immediately went out and made inquiries at a neighbouring store of the character and habits of the man, and ascertained that he was a great lover of ardent spirits, and daily drank a quart or more by small glasses. This appeared to me a case in which the fluid taken into the stomach reached the blood vessels without change, and as it may throw some light vessels without change, and as it may throw some light on the operation of remedies upon the human consti-tution, I communicate the fact for your considera-

BLOOD-LETTING. Under this term is compre-

hended every artificial discharge of blood made with a view to cure or prevent a disease. Blood-letting is divided into general and topical. As examples of the former, venæsection and arteriotomy may be mentioned; and of the latter, the application of leeches, cupping-glasses, and scarification.
[Blood-Root. "This is an indigenous article, derived

from the Sanguinaria Canadensis, one of our earliest flowering plants, common in woods in various parts of the United States.

The root is brownish externally; but, when broken, emits a bright vermilion or orange-coloured juice. This root has a bitter taste, leaving a sense of acrimony in the throat when swallowed. Besides fibrous matter, it contains resin, fæcula, bitter extractive, and an acrid

The medicinal properties of blood-root are those of an acrid narcotic. When taken in a large dose, it irritates the fauces, leaving a disagreeable sensation in the throat for some time after it is swallowed. It occasions heartburn, nausea, fainting, and frequently vertigo, and diminished vision. It also vomits; but in this operation it is less certain than many other emetics in common use. When given in smaller doses, such as produce nausea without vomiting, and repeated at frequent intervals, it lessens the frequency of the pulse in a manner somewhat analagous to the operation of digitals. This, however, is a secondary effect, since, in its primary operation, it seems to accelerate the circulation. In still smaller doses, such as do not disturb the stomach, it has required some reputation as a tonic. It has been given in phthisis, both as a preventive in the early symptoms and as a palliative in the con-firmed disease; also in catarrh, typhoid pneumonia, dyspepsia and various other complaints; in which, however, its use should not exclude the employment of more active means. It should be dried a short time before it is to be used, as the virtues are much impaired

From ten to twenty grains ordinarily produce vomit-Many country physicians prefer an infusion made with a drachm of the powder to a gill of water, of which a table-spoonful may be repeated till the effect of the medicine is obtained. As a tonic, the tincture is more frequently used."—See Big. Mat.

BODY. Whatever is capable of acting on our senses may be so denominated.

Bodies in Natural Philosophy are divided into Pon-

derable and Imponderable.

The first are those which may act upon several of our senses, and of which the existence is sufficiently established; of this kind are solids, fluids, and gases. The second are those which, in general, only act on one of our senses, the existence of which is by no marked.

of the size of a common probe, or larger, to inflate vessels and other parts.

The chemical blowpipe is made of brass, is of about one-eighth of an inch diameter at one end, and the Ponderable bodies are endowed with common or calculated.

general properties, and likewise with particular or secondary properties.

secondary properties.

The general properties of bodies are,—extent, divisibility, impenetrability, mobility. A ponderable body, of whatever kind, always presents these four properties combined. Secondary properties are variously distributed among different bodies; as hardness, porosity, elasticity, fluidity, &c. They constitute, by their combination with the general properties, the condition or state of bodies. It is by gaining or losing some of these secondary properties that bodies change their state: for instance, water may appear under the form of ice, of a fluid, or of vapour, although it is always the same body. To present itself successively under these three forms, nothing more is necessary than the addition or abstraction of some of its secondary qualities.

Bodies are simple, or compound.

Simple bodies are rarely met with in nature; they are almost always the product of art, and we even name them simple, only because art has not arrived at their decomposition. At present, the bodies regarded as simple are the following:—Oxygen, chlorine, iodine, described and the control of the control fluorine, sulphur, hydrogen, boracium, carbon, phosphorus, azote, silicium, zirconium, aluminum, yttrium, glucinum, magnesium, calcium, strontium, barium, sodium, potassium, manganese, zinc, iron, tin, arsenic, molybdenum, chromium, tungsten, columbium, antimony, uranium, cerium, cobalt, titanium, bismuth,
copper, tellurium, nickel, lead, mercury, osmium, silver,
rhodium, palladium, gold, platinum, iridium, selenium,
lithium, thorenum, wood, anium, cadmium.
Compound, bodies, occur, compound, bodies,

Compound bodies occur every where; they form the mass of the globe, and that of all the beings which are seen on its surface. Certain bodies have a constant composition; that is to say, a composition that never is changed, at least from accidental circumstances: there are, on the contrary, bodies, the composition of which is changed at every instant.

This diversity of bodies is extremely important; it divides them naturally into two classes; bodies, the composition of which is constant, are named brute, or gross, inert, inorganic; but those, the elements of which continually vary, are called living, organized bodies.

Brute and organized bodies differ from each other in respect, 1st, of form; 2d, of composition; 3d, of the laws which regulate their changes of state. The following table presents the differences which are best

TABLE I.

DIFFERENCES BETWEEN INORGANIC AND LIVING BODIES.

Inorganie Bodies.	Angular form. Indeterminate Volume.	Living Bodies.	Rounded form. Determinate Volume.
	2.	Composition	
	Sometimes simple. Seldom of more than 3 elements.		Never simple. At least 4 elements, off

Body, combustible. This term is given by chemists to all substances which, on account of their affinity for oxygen, are capable of burning.

Body, caseous. See Gas.

Body, inflammable. Chemists give this name to such bodies as burn with facility, and flame in an increased temperature, although, strictly speaking, all combustible bodies are inflammable bodies; such are the diamond, sulphur, bitumens, &c.

the diamond, sulphur, bitumens, &c.

Body, Phosphorescent. Bodies which produce light, though their temperature be not increased.

Bo'E. (From βοαω, to exclaim.) Clamour, or moaning made by a sick person.

BOERHAAVE, HERMAN, was born at Voorhout, in Holland, December 31, 1668. His father, the pastor of the village, having nine children, educated them bimself, and intending Herman for the church, was careful to ground him well in the learned languages; in which he made such rapid progress, that he was sent at 14 to Leyden. His father dying soon after in slender circumstances, he was fortunately supported by the burgomaster, Daniel Van Alphin; which Boerhaave ever remembered with gratitude. Among other studies, he was very partial to the mathematics, and improved so much, as to be able to give private instructions in them, whereby he partly maintained himself. In 1690, he took his degree in philosophy, and in an inaugural thesis refuted the errors of the materialists. But he soon after turned his mind to the study of medicine, and attended dissections under Nuck; he greatly preferred Hippocrates among the ancient, and Sydenham among the modern physi-

In Anatomy. The human body is divided by anatomists into the trunk and extremities: i.e. the head, and inferior and superior extremities, each of which have certain regions before any part is removed, by which the physician is enabled to direct the application of blisters and the like, and the situation of discasse, especially the urine. He was then engaged in forming a new theory of medicine, by a judicious section of blisters and the like, and the situation of discasse, especially the urine. He was then engaged in forming a new theory of medicine at Harderwyck, in 1693; and in his dissertation on that occasion, in sisted on the utility of observing the excretions in disease, especially the urine. He was then engaged in forming a new theory of medicine at Harderwyck, in 1693; and in his dissertation on that occasion, in sisted on the utility of observing the excretions in disease, especially the urine. He was then engaged in forming a new theory of medicine, by a judicious section of blisters and the like, and the situation of disease, especially the urine. was so well arranged, and so ably supported by him, that it became generally adopted, and prevailed throughout Europe for more than half a century. He also gave lectures on chemistry, with considerable re-putation, about the same period. The university of Leyden therefore appointed him, in 1701, professor of the theory of medicine; when he read an oration re-commending the study of Hippocrates; and, as he dcclined some very advantageous offers from other parts, they afterward augmented his salary. About this time, he published another Latin oration, "On the Use of mechanical Reasoning in Medicine," which contributed to extend his fame. In 1709, he was appointed professor of botany, to which study he was ever after eminently attached. On that occasion, he produced another oration, maintaining that medicine would be best improved by observation, and by sim-plicity in prescriptions. His "Aphorisms," had applicity in prescriptions. His "Aphorisms," had appeared the year before, giving a brief account of the history and cure of diseases, a work universally admired; to which his pupil Van Swieten afterward attached a very ample commentary. About the same time he published his "Institutes," treating of physiology. These two works, with successive improveology. These two works, with successive improvements, passed through numerous editions, and were translated into every European, nay, even into the Arabic language. In the year after, he printed a catalogue of the plants in the university garden. In 1714, he was made rector of the university, and at the end of the year for which he held the office, delivered a discourse "On attaining Certainty in Physics." About this period he was made professor of the practice of medicine, and in 1718, of chemistry also. His lectures on these subjects, and on botany, were delivered with such clearness and more ison that were delivered with such clearness and precision, that students thronged from every part to hear him; insomuch that Leyden could scarcely afford accommodations for them. He was also often consulted in diffi-cult cases by physicians even in distant parts of the world. When appointed to the chemical chair, he had published a short work on that subject, but some of his pupils having printed his lectures without authority, and very incorrectly, he was led to prepare them for the press in 1732. In his conversation, Boerbaave was generally familiar, in his demeanour grave, but disposed to occasional pleasantry: he was distinguished for piety, and on his moral character, his disciple Haller has passed a very high eulogium. Having acquired considerable wealth by his exertions, and being plain in his dress, as well as abstemious in his diet, he was by some accused of parsimony: but he spared no reasonable expense in procuring rare books, and foreign plants. Being of a vigorous constitution, and accustomed to much exercise abroad, he met with little interruption from illness; but in 1729, having become corpulent, and incapable of riding, his health began to suffer, and he was induced to resign his botanical and chemical appointments. In an oration then delivered, he recounted the chief events of his life, expressing himself grateful for the patronage which he had received from individuals; as well as to his own profession, for the little opposition shown to his opinions. It perhaps never happened, that so great a revolution in science was so readily brought about. The great reputation acquired by his extensive abilities, and the reputation acquired by his extensive abilities, and the moderation of his character, particularly averse from contention, no doubt contributed materially to this result. In the year following, he was again made rector of the university of Leyden; and also elected a fellow of the Royal Society in London, having been previously admitted to the Royal Academy of Sciences in Paris. The remainder of his life was chiefly occupied in revising his own numerous productions in pied in revising his own numerous productions, in publishing more correct editions of several esteemed authors, and in domestic recreations at his seat near Leyden, with his wife and daughter. Toward the end of 1737, he was attacked with symptoms of disease in the chest, which terminated his existence in the September following His fellow-citizens erected an ele-BOETHE'MA. BOHEA. See Thea.

BOHN, John, was born at Leipsic, in 1640; and after studying in many parts of Europe, graduated there, and was made successively professor of anatomy, and of therapeutics, public physician to the city, &c. Among numerous publications, he chiefly distinguished himself by his "Circulus anatomico physiologicus." and a treatise "De officio medici clinico et logicus," and a treatise "De officio medici clinico et forensi," which latter particularly has great merit. He also well explained the judgment to be formed concerning wounds; and recommended purging with calomel in the beginning of small-pox. He died in 1718.

Bois de coissi. See Quassia. Bolar earths. See Bole.

BOLE, $(\beta\omega\lambda\sigma_5)$, a mass,) in chemistry, is a massive mineral, having a perfectly conchoidal fracture, a glimmering internal lustre, and a shining streak. Its colours are yellow-red, and brownish-black, when it is called mountain soap. It is translucent or opaque. Soft, so as to be easily cut, and to yield to the nail. It adheres to the tongue, has a greasy feel, and falls to pieces in water. Sp. grav. 1.4 to 2. It may be polished. If it be immersed in water after it is dried, it If alls asunder with a crackling noise. It occurs in wacke and basalt, in Silesia, Hessia, and Sienna in Italy, and also in the cliffs of the Giant's Caoseway, Ireland. The black variety is found in the trap rocks of the isle of Sky. Several compounds were formerly used in medicine, particularly the Armenian and French; and in old pharmacoperias mention is made of red boles from Armenia, Lemnos, Strigonium, Portugal Tuscany, and Livonia; vellow boles from Armenia. trigal, Tuscany, and Livonia; yellow boles from Armenia, Tockay, Silesia, Bohemia, and Blois; white boles from Armenia, Lemnos, Nocera, Eretria, Lamos, Chio, Malta, Tuscany, and Goltberg. Several of these earths have been commonly made into fittle cates or flat masses and stamped with certain in cakes or flat masses, and stamped with certain impressions; from which circumstance they received the name of terræ sagillatæ, or sealed earths.

Bolk, Armenian. Bolks Armeniæ.

Bole armenic. A pale but bright red-coloured earth, which is occasionally mixed with honey, and applied to children's mouths when afflicted with aphthse. It forms, like all argillaceous earths, a good tooth-powder, when

mixed with some aromatic.

BOLETIC ACID. Acidum boleticum. An acid extracted from the expressed juice of the Boletus pseudo-igniarius, by M. Braconnot. The juice concentrated to a syrup by a very gentle heat, was acted on by strong alkohol. What remained was dissolved in water. When nitrate of lead was dropped into this solution, a white precipitate fell, which, after being well washed with water, was decomposed by a current of sulphuretted hydrogen gas. Two different acids were found in the liquid after filtration and evaporation. One in permanent crystals was boletic acid; the other was a small proportion of phosphoric acid. The former was purified by a solution in alkohol, and subsequent evaporation.

It consists of irregular four-sided prisms, of a white colour, and permanent in the air. Its taste resembles cream of tartar; at the temperature of 63° it dissolves in 180 times its weight of water, and in 45 of alkohol. Vegetable blues are reddened by it. Red oxide of iron, and the oxides of silver and mercury; are precipitated by it from their solutions in nitric acid; but lime and barytes waters are not affected. It sublimes when heated, in white vapours, and is condensed in a white

powder.—Ann. de Chimie, lxxx.

BOLE TUS. (From βωλος, a mass, or βωλετης, from its globular form.) The name of a genus of plants in the Linnean system. Class, Cryptogamia; Order, Fungi. Boletus; Spunk.
BOLETUS CERVI. The mushroom.

BOLETUS IGNIARIUS. The systematic name for the agaricus of the pharmacopæias. Agaricus chirurgorum; Agaricus quercus; Fungus igniarius. Agaric of the oak; Touchwood boletus; Female agaric. This fungus Boletus:—acaulis pulvinatus levis, poris tenuissimis of Linnæus, has been much used by surgeon as an external styptic. Though still employed on the continue, the surgeons in this country has been on the continent, the surgeons in this country have not much confidence in it.

BOLETUS LARICIS. The systematic name for the officinal aga-icus albus, which is met with on old larch trees, in different parts of Europe. Several preparations, as troches, an extract, and pills, are ordered to be made with it in foreign pharmacopæias, which are administered against phthisical complaints.

BOLETUS PINI LARICIS. A species of agaric which

grows on the larch.

BOLETUS SUAVEOLENS. The systematic name for the fungus salicis of the pharmacopæias. This species of fungus, Boletus—acaulis superne lævis, salicibus, of Linnæus, and the Boletus albus of Hudson, when fresh, has a suburinous smell, and at first an acid taste, followed by a bitter. It is seidom used at present, but was formerly given in phthisical complaints

Boll'smus. A voracious appetite, according to Avicenna, but most probably meant for bulimus. BOLOGNIAN STONE. A mixture of mucilage BOLL'SMUS.

BOLOGNIAN STONE. A mixture of mucilage and powdered sulphate of barytes.

[Bolognian priosphorus. When native sulphate of baryta is heated it decrepitates, and at a high tem perature, fuses into an opaque white enamel: it was employed in the manafacture of Jasper ware by the late Mr. Wedgewood. When heated to redness, it acquires the property of phosphorescence. This was first ascertained by Vincenzo Cascarioll, of Bologna, whence the term Bologna phosphorus is applied to it. This kind of phosphorus, after being exposed for a few minutes to the sun's rays, shines in the dark sufficiently minutes to the sun's rays, shines in the dark sufficiently to render visible the dial of a watch. This prosperty is lost by repeated uses, in consequence of the oxygenation of the sulphur: but it may be restored by a second calcination.—See Webster's Man. of Chem. A.]

BO'LUS. (Βωλος, a bole, or bolus.) Any medicine, rolled round, that is larger than an ordinary sized

pea, and yet not too large to be swallowed.

BOLUS ARMENA. See Bole, Armenian.
BOLUS ARMENA ALBA. The white Armenian bole.
BOLUS ARMONIAC. See Bole, Armenian.
BOLUS BLESSENSIS. Bole of Blois. See Bole.
BOLUS GALLICA. French bole. A pale red-coloured

bolar earth, variegated with irregular specks and veins of white and yellow. It is occasionally administered as an absorbent and antacid.

BOMBAX. See Gossypium.

BOMBIATE. Bombias. A salt formed by the union of the bombic acid with salifiable bases; thus,

bombiate of alumine, &c.

BO'MBIC ACID. Acidum bombicum. Acid of the silkworm. Silkworms contain, especially when in the state of chrysalis, an acid liquor in a reservoir placed near the anus. It is obtained by expressing their juice in a cloth, and precipitating the mucilage by spirit of wine, and likewise by infusing the chrysa-lides in that liquor. This acid is very penetrating, of a yellow amber colour, but its nature and combinations are not yet well known. BO'MBUS. Bo μ 605. 1. A resounding noise, or ringing of the ears.

A sonorous expulsion of flatus from the intestines.
 Dr. Good gives this name to that variety of ima-

3. Dr. Good gives this name to that variety of imaginary sound, parapsis illusoria, which is characterized by a dull, heavy, intermitting sound.

Bon arbor. A name given to the coffee-tree.

Bo'na. Boona. The phaseolus, or kidney-beans.

[BOND, Thomas, M.D. This celebrated physician and surgeon was a native of Maryland, and studied his and surgeon was a native of Maryland, and sudded his profession there under Dr. Hamilton, a very learned practitioner. Afterward he travelled in Europe and spent a considerable time in Paris, where he attended the practice of the Hôtel Dieu. He began the practice of medicine in Philadelphia about the year 1734, and soon attracted the public attention. He was the founder of the College and Academy, and one of the most active managers of the Pennsylvania Hospital, at its commencement. He was a contributor to some of most active managers of the Pennsylvania Hospital, at its commencement. He was a contributor to some of the Medical Journals of Great Britain before the establishment of one in this country. In 1782 he delivered the annual address before the American Philosophical Society. The subject was, "The rank and dignity of man in the scale of being, and the conveniences and advantages he derives from the Arts and veniences and advantages he derives from the Arts and Sciences, and the prognostic of the unceasing grandeur and glory of America, founded on the nature of its climate." He was for half a century in the first practice in Philadelphia, and remarkable for attention to the

cases under his care, and his sound judgment. He died in the year 1781, aged 72.—See Thach. Med.

cases under his care, and his sound judgment. He died in the year 1784, aged 72.—See Thach. Med. Biog. A.]

Bo'NDUCH INDORUM. See Guilandina.

BONE. Os. Bones are hard, dry, and insensible parts of the body, of a whitish colour, and composed of a spongy, compact, or recticular substance. They vary much in their appearances, some being long and hollow, others flat and compact, &c. The greater number of bones have several processes and cavities, which are distinguished from their figure, situation, use, &c. Thus, processes extended from the end of a bone, if smooth and round, are called heads; and condyles, when flattened either above or laterally. That part which is beneath the head, and which exceeds the rest of the bone in smallness and levity, is called the neck. Rough, unequal processes are called tuberosities, or tubercles: but the longer and more acute, spinous, or styloid processes, from their resemblance to a thorn. Thin broad processes, with sharp extremities, are known by the name of crista, or sharp edges. Other processes are distinguished by their form, and called alar, or ptergoid; mamillary, or mastoid; dentiform, or odontoid, &c. Others, from their situation, are called superior, inferior, exterior, and interior. Some have their name from their direction; as oblique, straight, transverse, &c.; and some from their use, as trochanters, rotators, &c. Furrows, depressions, and cavities, are destined either for the reception of configuous bones, to form an articulation with them, when they are called articular cavities, which are sometimes deeper, sometimes shallower; or they receive hard parts, but do not constitute a joint with them. Cavities serve also for the cavities, which are sometimes deeper, sometimes shallower; or they receive hard parts, but do not constitute a joint with them. Cavities serve also for the transmission and attachment of soft parts. Various names are given to them, according to the magnitude and figure of bones. If they be broad and large at the beginning, and not deep, but contracted at their ends, they are called force, or pits. Furrows are open canals, extending longitudinally in the surface of bones. A hollow, circular tube, for the most part of the same diameter from beginning to end, and more or the same diameter from beginning to end, and more or less crooked or straight, long or short, is named a canal. Foramina are the apertures of canals, or they are formed of the excavated margins of two bones, placed against each other. If such be the form of the margin a bone, as if a portion were taken out of it, it is called a notch.

With respect to the formation of bone, there have been various opinions. Physiologists of the present day assert, that it is from a specific action of small arteries, by which ossific matter is separated from the blood, and deposited where it is required. The first thing observable in the embryo, where bone is to be formed, is a transparent jelly, which becomes gradually firmer, and is formed into cartilage. The cartilage gradually increases to a certain size, and when the process of ossification commences, vanishes as it the process of ossification commences, vanishes as it advances. Cartilages, previous to the ossific action, are solid, and without any cavity; but when the ossific action of the arteries is about to commence, the absorbents become very active, and form a small cavity in which the bony matter is deposited; bone continues to be separated, and the absorbents model the mass into its required shape. The process of ossification is extremely rapid in utero: it advances slowly after birth, and is not completed in the human body till about the twentieth year. Ossification in the flat bones, as the twentieth year. Ossification in the flat bones, as those of the skull, always begin from central points, Ossification in the flat bones, as and the radiated fibres meet the radii of other ossifying points, or the edges of the adjoining bone. In long bones, as those of the arm and leg, the clavical, metacarpal, and metatarsal bones, a central ring is formed in the body of the bone, the head and extremities being cartilage, in the centre of which ossification afterward begins. The central ring of the body shoots its bony fibres towards the head and extremities, which extend towards the body of the bone. The head and extre-mities at length come so close to the body as to be merely separated by a cartilage, which becomes gra-dually thinner until the twentieth year. Thick and round bones, as those of the tarsus, carpus, sternum, and patella, are, at first, all cartilage: ossification begins in the centre of each. When the bones are deprived of their soft parts, and are hung together in their natural interests. their natural situation, by means of wire, the whole is termed an artificial skeleton; but when they are kept

together by means of their ligaments, it is called a natural skeleton.—The uses of the bones are various, and are to be found in the account of each bone; it is therefore, only necessary to observe, in this place, that they give shape to the body, contain and defend the vital viscera, and afford an attachment to 'all the muscles.

Calcined human bones, according to Berzelius, are composed, in 100 parts, of 81.9 phosphate of lime, 3 fluate of lime, 10 lime, 1.1 phosphate of magnesia, 2 soda, and 2 carbonic acid. 100 parts of bones by calcination are reduced to 63. Four croy and Vauquelin found the following to be the composition of 100 parts of ox bones: 51 solid gelatin, 37.7 phosphate of lime, 10 carbonate of lime, and 1.3 phosphate of magnesia; but Berzelius gives the following as their constituents: 33.3 cartilage, 55.35 phosphate of lime, 3 fluate of lime, 3.85 carbonate of lime, 2.05 phosphate of magnesia, and 2.45 soda, with a little common salt.

About 1-30th of phosphate of magnesia was obtained

About 1-30th of phosphate of magnesia was obtained from the calcined bones of fowls, by Fourcroy and

Vauquelin. When the enamel of teeth, rasped down, is dissolved in muriatic acid, it leaves no albumen, like that that of boiling water, but not equal to that of Papin's digester, which would give it an empyreuma. the other bones. Fourcroy and Vauquelin state its components to be, 27.1 gelatin and water, 72.9 phoscomponents to be, 27.1 gelatin and water, 72.9 phosphate of lime. Messrs. Hatchett and Fepys rate its composition at 78 phosphate of lime, 6 carbonate of lime, and 16 water and loss. Berzelius, on the other hand, found only 2 per cent. of combustible matter in teeth. The teeth of adults, by Mr. Pepys, consist of 64 phosphate of lime, 6 carbonate of lime, 20 cartilage, and 10 water or loss. The fossil bones of Gibraltar are composed of phosphate of lime and carbonate, like burnt bones. Much difference of conjugar exists with burnt bones. Much difference of opinion exists with regard to the existence of fluoric acid in the teeth of animals; some of the most eminent chemists taking opposite sides of the question. It appears that bones buried for many centuries still retain their albumen, with very little diminution of its quantity.

Fourcroy and Vauquelin discovered phosphate of magnesia in all the bones they examined, except human bones. The bones of the horse and sheep afford about 1-36th of phosphate of magnesia; those of fish nearly the same quantity as those of the ox. They account for this by observing, that phosphate of mag-nesia is found in the urine of man, but not in that of animals, though both equally take in a portion of mag-

nesia with their food.

The experiments of Mr. Hatchett show, that the membranous or cartilaginous substance, which retains the earthy salts within its interstices, and appears to determine the shape of the bone, is albumen. Mr. Hatchett observes, that the enamel of tooth is analogous to the porcellaneous shells, while mother of pearl approaches in its nature to true bone.

A curious phenomenon with respect to bones is the circumstance of their acquiring a red tinge, when mad-der is given to animals with their food. The bones of young pigeons will thus be tinged of a rose colour in twenty-four hours, and of a deep scarlet in three days; but the bones of adult animals will be a fortnight in acquiring a rose colour. The bones most remote from the heart are the longest in acquiring this tinge. Mr. Gibson informs us, that extract of logwood too, in considerable quantity, will tinge the bones of young pigeons purple. On desisting from the use of this food, however, the colouring matter is again taken up into the circulation, and carried off, the bones regaining their natural hue in a short time. It was said by Du Hamel, that the bones would become coloured and colourless in concentric layers, if an animal were fed alternately one week with madder, and one week without; and hence he inferred, that the bones were formed in the same manner as the woody parts of trees. But he was mistaken in the fact; and indeed had it been true, with the inference he naturally draws from it, the bones of animals must have been out of all proportion larger than they are at present.

Bones are of extensive use in the arts. In their natural state, or dyed of various colours, they are made into handles of knives and forks, and numerous articles of turnery. We have already noticed the articles of turnery. We have already noticed the manufacture of volatile alkali from bones, the coal of which forms bone-black; or, if they be afterward caltined to whiteness in the open air, they constitute the bone ashes of which cupels are made, and which, finely levigated, are used for cleaning articles of paste, and some other trinkets, by the name of burnt hartshorn. The shavings of hartshorn, which is a species of home afford an elegant inhome and the latest trinkets and trinkets trinkets and trinkets trinkets trinkets. of bone, afford an elegant jelly; and the shavings of other bones, of which those of the calf are the best, are

often employed in their stead.

On this principle, Mr. Proust has recommended an economical use of bones, particularly with a view to improve the subsistence of the soldier. He first chops them into small pieces, throws them into a kettle of boiling water, and lets them boil about a quarter of an When this has stood till it is cold, a quantity of fat, excellent for culinary purposes when fresh, and at any time fit for making candles, may be taken off the liquor. This, in some instances, amounted to an eighth, and in others even to a fourth, of the weight of the bones. After this the bones may be ground, and boiled in eight or ten times their weight of water, of which that already used may form a part, till about half is wasted, when a very nutritious jelly will be obtained. The boiler should not be of copper, as this metal is easily dissolved by the jelly; and the cover

The bones of meat that have been boiled are nearly as productive as fresh bones; but Dr. Young found those of meat that had been roasted afforded no jelly, at least by simmering, or gentle boiling.

Bones, growth of. See Ostcogeny. BONEBINDER. See Ostcocolla.

[Boneset. Thoroughwort. Eupatorium perfoliatum. This is an indigenous vegetable, growing in wet meadows throughout the United States. The whole plant is medicinal, but the leaves and flowers are most

etive. See Eupatorium perfoliatum. A.] BONET, THEOPHILUS, was born at Geneva in 1620, and graduated at Bologna. He had considerable practice, and was extremely zealous in the pursuit of mor-bid anatomy, as well as in extracting valuable obser-vations from authors. His hearing becoming impaired, he devoted the latter part of his life to the arrangement of the materials which he had prepared. His princi-pal work, entitled "Sepulchretum," published 1679, was highly approved; and laid the foundation of Morgagni's excellent treatise, "De Sedibus et Causis Mor-borum." Another publication of his, "Mercurius comborum." Another publication of his, "Mercurius com-pilatitius," is an index of medical literature to the time of its appearance, 1632. His death occurred seven years after.

BONONIE'NSIS LAPIS. The Bononian stone. Called also phosphorus bononiensis, phosphorus kircheri, the light carrier, or Bononian phosphorus. As a medicine,

the stone is caustic and emetic.

BONTIUS, JAMES, was born at Leyden, where he studied medicine, and then went to practice in India. After his return, he wrote several valuable works on the diseases and practice of that country, as well as on its natural productions, animal and vegetable. The most esteemed is entitled "De Medicina Indorum," and appeared in 1642.

BO'NUS. Good. A term applied to plants, and

remedies from their supposed efficacy.

Bonus henricus. (Henricus; so called, because its virtues were detected by some one whose name was Henry.) See Chenopodium bonus Henricus BONY. Osseus. Of, or belonging to, or resembling

BORACIC ACID. Acidum boracicum. Sedative salt of Homberg. Acid of Borax. Boracine acid. "The salt composed of this acid and soda had long been used both in medicine and the arts under the name of borax, when Homberg first obtained the acid separate in 1702, by distilling a mixture of borax and sulphate of iron. He supposed, however, that it was a product of the latter; and gave it the name of vola-tile narcotic salt of vitriol, or schative salt. Lemery the younger, soon after discovered that it could be obtained from borax equally by means of the nitric or muriatic acid; Geoffroy detected soda in borax: and at length Baron proved, by a number of experiments, that borax is a compound of soda and a peculiar acid. Cadet has disputed this; but he has merely shown, that the borax of the shops is frequently contaminated with copper; and Struve and Exchaquet have endeavoured to prove that the boracic and phosphoric acids are the same; yet their experiments only show, that they resemble each other in certain respects, not in all.

To procure the acid, dissolve borax in hot water, and filter the solution, then add sulphuric acid by little and little, till the liquid has a sensibly acid taste. Lay it aside to cool, and a great number of small shining laminated crystals will form. These are the boracic They are to be washed with cold water, and

drained upon brown paper.

Boracic acid thus procured is in the form of thin irregular hexagonal scales, of a silvery whiteness, having some resemblance to spermaceti, and the same kind of greasy feel. It has a sourish taste at first, then makes a bitterish cooling impression, and at last leaves makes a bitterish cooling impression, and at last leaves an agreeable sweetness. Pressed between the teeth, it is not brittle but ductile. It has no smell; but, when sulphuric acid is poured on it, a transient odour of musk is produced. Its specific gravity in the form of scales is 1.479; after it has been fused, 1.803. It is not altered by light. Exposed to the fire it swells up, from losing its water of crystallization, and in this state is called calcined boracic acid. It makes the state is called calcined boracic acid. It melts a little before it is red-hot, without perceptibly losing any

BOR BOR

water, but it does not flow freely till it is red, and then less than the borate of soda. After this fusion it is a hard transparent glass, becoming a little opaque on exposure to the air, without abstracting moisture from it, and unaltered in its properties, for on being dissolved in boiling water it crystallizes as before. This glass is used in the composition of false gems.

Bolling water scarcely dissolves one-fiftieth part, and cold water much less. When this solution is distilled in close vessels, part of the acid rises with the water, and crystallizes in the receiver. It is more soluble in aikohol, and alkohol containing it burns with a green flame, as does paper dipped in a solution of

green flame, as does paper dipped in a solution of

boracic acid.

Neither oxygen gas, nor the simple combustibles, nor the common metals, produce any change upon boracic acid, as far as is at present known. If mixed with finely powdered charcoal, it is nevertheless capable of vitrification; and with soot it melts into a black bitumen-like mass, which however is soluble in water, and cannot easily be burned to askes, but subjumes in part. With the assistance of a distilling heat limes in part. With the assistance of a distilling heat it dissolves in oils, especially mineral oils; and with these it yields fluid and solid products, which impart a green colour to spirit of wine. When rubbed with phosphorus it does not prevent its inflammation, but an earthy yellow matter is left behind. It is hardly capable of oxiding or dissolving any of the metals expect its and previous corporate but it comcapanie of oxiding of dissorving any of the metals ex-cept iron and zinc, and perhaps copper; but it com-bines with most of the metallic oxides, as it does with the alkalies, and probably with all the earths, though the greater part of its combinations have hitherto been little examined. It is of great use in analyzing stones that contain a fixed alkali.

stones that contain a fixed alkali.

Crystallized boracic acid is a compound of 57 parts of acid and 43 of water. The honour of discovering the radical of boracic acid, is divided between Sir H. Davy and Gay Lussac and Thenard. The first, on applying his powerful voltaic battery to it, obtained a chocolate-coloured body in small quantity; but the two latter chemists, by acting on it with potassium in equal quantities, at a low red-heat, formed boron and sub-borate of potass. For a small experiment, a glass tube will serve, but on a greater scale a copper tube is to be preferred. The potassium and boracic acid, perfectly dry, should be intimately mixed before exposing them to heat. On withdrawing the tube from the fire, to be preferred. The potassium and boracic acid, perfectly dry, should be intimately mixed before exposing them to heat. On withdrawing the tube from the fire, allowing it to cool, and removing the cork which loosely closed its mouth, we then pour successive portions of water into it, till we detach or dissolve the whole matter. The water ought to be heated each time. The whole collected liquids are allowed to settle; when, after washing the precipitate till the liquid ceases to affect syrup of violets, we dry the boron in a capsule, and then put it into a phial out of contact of air. Boron is solid, tasteless, inodorous, and of a greenish-brown colour. Its specific gravity is somewhat greater than water. The prime equivalent of boracic acid has been inferred from the borate of ammonia, to be about 2.7 or 2.8; oxygen being 1.0; and it probably consists of 2.0 of oxygen + 0.8 of boron. But by Gay Lussac and Thenard, the proportions would be 2 of boron to 1 of oxygen.

The boracic acid has a more powerful attraction for lime than for any other of the bases, though it does not readily form borate of lime by adding a solution of it to lime water, or decomposing by lime water the soluble alkaline borates. In either case an insipid white powder, nearly insoluble, which is the borate of lime, is, however, precipitated. The borate of barytes is likewise an insoluble, tasteless, white powder.

Bergman has observed, that magnesia, thrown by little and little into a solution of boracic acid, dissolved slowly, and the liquor on evaporation afforded granulated crystals, without any regular form: that these

slowly, and the liquor on evaporation afforded granuslowly, and the liquor on evaporation afforded granulated crystals, without any regular form: that these crystals were fusible in the fire without being decomposed; but that alkohol was sufficient to separate the boracic acid from the magnesia. If, however, some of the soluble magnesian salts be decomposed by alkaline borates in a state of solution, an insipid and insoluble borate of magnesia is thrown down. It is probable, therefore, that Bergman's salt was a borate of magnesia dissolved in an excess of boracic acid; which acid being taken up by the alkohol, the true borate of magnesia was precipitated in a white powder, and mistaken by him for magnesia.

One of the best known combinations of this acid is

water, but it does not flow freely till it is red, and then the native magnesio-calcareous borate of Kalkberg, less than the borate of soda. After this fusion it is a hard transparent glass, becoming a little opaque on cubic quartz of various mineralogists, and boracite of

The borate of potessa is but little known, though it is said to be capable of supplying the place of that of soda in the arts; but more direct experiments are required to establish this effect. Like that, it is capable of existing in two states, neutral and with excess of base, but it is not so crystallizable, and assumes the form of parallelobleeds.

With soda the boracic acid forms two different salts. With soda the boracic acid forms two different sairs. One, in which the alkali is more than triple the quantity necessary to saturate the acid, is of considerable use in the arts, and has long been known by the name of borax; under which its history and an account of its properties will be given. The other is a neutral salt, not changing the syrup of violets reen like the borate with excess of base; differing from it in taste and solubility; crystallizing neither so readily, nor in the same manner; not efflorescent like it; but, like it. and sombifity; crystalizing neither so readily, nor in the same manner; not efflorescent like it; but, like it, fusible into a glass, and capable of being employed for the same purposes. This salt may be formed by saturating the superabundant soda in borax with some other acid, and then separating the two salts; but it is obviously more eligible to saturate the excess of soda with the same part of solar salt in the same salts. with an additional portion of the boracic acid itself.

Borate of ammonia forms in small rhomboidal crystals, easily decomposed by fire; or in scales, of a pungent urinous taste, which lose the crystalline form, and grow brown on exposure to the air.

It is very difficult to combine the boracic acid with

alumina, at least in the direct way

The boracic acid unites with silex by fusion, and forms with it a solid and permanent vitreous com-pound. This borate of silex, however, is neither sa-pid, nor soluble, nor perceptibly alterable in the air; and cannot be formed without the assistance of a violent heat. In the same manner, triple compounds may be formed with silex and borates already saturated with other bases.

The boracic acid has been found in a disengaged state in several lakes of hot mineral waters near Monte. Rotondo, Berchiajo, and Castellonuovo, in Tuscany, in the proportion of nearly nine grains in a hundred of water, by Hoeffer. Mascagni also found it adhering to schistus, on the borders of lakes, of an obscure white, yellow, or greenish colour, and crystallized in the form of needles. He has likewise found it in combination with ammonia.

BORACITE. Borate of magnesia. A crystallized

combination with ammonia.

BORACITE. Borate of magnesia. A crystallized mineral found in gypsum in the Kalberg, in Brunswick, and at Segeberg, in Holland. It is translucent, and of a shining greasy lustre, yellowish, grayish, or of a greenish-white colour. Vanquelin's Analysis gives 33.4 boracle acid, and 16.6 magnesia.

BO'RAGE. See Borago.

BORA'GO. (Formerly written Corago; from cor, the heart, and ago, to affect; because it was supposed to comfort the heart and spirits.) Borage. 1. The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Monogynia.

2. The pharmacopeial name of the officinal borage. See Borago officinalis.

See Borago officinalis.

See Borago officinalis.

Borago officinalis. The systematic name for the borage of the shops. Corrago; Buglossum verum; Buglossum latifolium; Borago hortensis. The leaves and flowers of this plant, Borago—foliis omnibus alternis, calycibus patentibus of Linnæus, are esteemed in some countries as refrigerant and cordial. A syrup is prepared from the leaves in France, and used in pleurisies and inflammatory fevers. Their principal use in this island is in that grateful summer beverage, known by the name of cool tankard.

BO'RAS. See Borate.

BO'RATE. Boras. A salt formed of boracic acid with an earthy, alkaline, or metallic base; as borate of soda, &c.

of soda, &c.

BORAX. (Borak, Arabian.) Boras sodæ; Subboras sodæ. The obsolete synonyms are, Chrysocolla;
Capistrum auri; Ancinar; Boraz-trion; Acestis
anucar; Antinçar; Tincal; Amphitane; Baurach;
Nitrum factitium; Santerna, and Nitrum nativum.

"It does not appear that borax was known to the
ancients; their chrysocolla being a very different subcases, companyed of the run; of corpor, Liturated with stance, composed of the rust of copper, triturated with

tirine. The word borax occurs for the list time in the works of Geber.

Borax is found in the East, and likewise in South America.

The purification of borax by the Venetians and the Hollanders, was, for a long time, kepf secret. Chaptal finds, after trying all the processes in the large way, that the simplest method consists in boiling the borax strongly, and for a long time, with water. This solution being filtered, affords by evaporation crystals, which are somewhat first large way be carrifed by rewhich are somewhat foul, but may be purified by re-

peating the operation.

peating the operation.

Purified borax is white, transparent, rather greasy in its fracture, affecting the form of six-sided prisms, terminating in three-sided or six-sided pyramids. Its taste is styptic; it converts syrup of violets to a green; and when exposed to heat, it swells up, boils, loses its water of crystallization, and becomes converted into a porous, white, opaque mass, commonly called Calcined Borax. A stronger heat brings it into a state of quiet fusion; but the glassy substance thus afforded, which is transparent, and of a greenish vellow colour. which is transparent, and of a greenish yellow colour, is soluble in water, and effloresces in the air. It requires about eighteen times its weight of water to dissolve it at the temperature of sixty degrees of Fahrenheit; but water at the boiling heat dissolves three times this quantity. Its component parts, according to Kirwan, are, boracic acid 34, soda 17, water 47.

Borax is rarely used internally in modern practice;

and according to Murray, it does not appear to possess any activity, although it is supposed by some to be, in doses of half a drachm or two scruples, diuretic and emmenagogue. It is occasionally given in cardialgia as an antacid. Its solution is in common use as a cooling gargle, and to detach mucus, &c. from the mouth in putrid fever; and mixed with an equal quan-tity of sugar, it is used in the form of powder to remove the aphthous crust from the tongue in children. The

salts formed by the union of the acid of borax with different bases are called borates.

BORBORY'GMUS. (From βορθοροζω, to make a noise.) The rumbling noise occasioned by flatus in the intestines. It frequently precedes hysterical affec-tions. Dr. Good gives this name to that variety of his Limotis flatus, which is known by frequent rumbling

of the bowels.

BORDEU, Theophilus de, a French physician, born in 1722. He graduated at Montpelier, and was soon after appointed inspector of the mineral waters at Bareges, and professor of anatomy. Subsequently, he went to Paris, and was admitted to the faculty there in 1754. He died of apoplexy in his 55th year. His most esteemed work is on the cellular membrane; his distinctions of the pulse appear too nice for prac-

tical utility

BORELLI, John Alphonsus, was born at Castel-nuovo, in 1608. He first taught the mathematics in Sicily, then as professor at Pisa; and being soon after admitted to the celebrated academy del Cimento, he formed the design of explaining the functions of animal bodies, on mathematical principles. For this purpose he applied himself diagently to dissection. His grand work, "De Motu Animalium," was published after his death, which happened in 1679, at the expense of Christina, queen of Sweden. The imposing appearance of his opinions gained them many converts at first but they have been found very describe on many first, but they have been found very defective on ina-turer examination. He was author of many other publications on different subjects.

BORON. The combustible basis of boracic acid.

See Boracic acid.

Boro'zail. An Ethiopian word for an epidemic disease, in appearance similar to the lues venerea.

Boraa'go. See Borago.

Bo'rat. (Indian.) Borri-borri. Boberri. The Indian name for turmeric; also an ointment used there, in which the roots of turmeric are a chief in-

A name formerly applied to BOTA LE FORAMEN.

the foramen ovale of the heart.

BOTALLUS, LEGNARD, an eminent physician of Piedmont, flourished about the middle of the 16th century. He graduated at Padua; and attained considerable reputation, as well in surgery as in medicine; having the honour of attending two of the French kings, and the Prince of Orange; the latter of whom he cured of a wound, in which the carotid artery had depends.

been injured. He published a treatise on gun-snot wounds, which long remained in high estimation. But that which chiefly gained him celebrity, was a work on bleeding, general and local, which he recommended to be freely practised in a great variety of diseases, both acute and chronic. His opinions were adopted by many, and carried to an extravagant length, particularly in France; but more enlarged experience has tended greatly to lessen their prevalence.

Bota Nicon. (From βστανη, an herb.) A plaster made of herbs, and described by Paulus Ægineta.

BOTANIST. Botanicus. One who understands

BOTANIST. Botanicus. One who understands the nature, history, and distinction of vegetables, on settled and certain principles, and can call every plant by a distinct, proper, and intelligible name.

BOTANY. (Botanica. Boγανικη; from βογανη, an herb or grass, which is derived from βοω, or βοσκω, to feed, because grass is the chief food of the animals which are most useful to man.) That branch of natural history which relates to the vegetable kinedom natural history which relates to the vegetable kingdom the second of the three grand assemblages into which all terrestrial objects are divided. It is a science not confined to the description and classification of plants, as has often been represented, but it comprehends many other important particulars. Its various objects may be conveniently arranged under the following general heads :-

1. The terminology, or description and nomenclature of the several parts of a plant, which are externally

visible.

If all natural objects were simple in their form, it would not be easy to distinguish one from another, nor would it be possible to describe them so as to give nor would it be possible to describe them so as to give a clear and precise idea of them. Hence a boundless variety, connected with general resemblances, is wisely and benevolently made their universal character. Every plant is composed of several parts, which differ from each other in their outward appearance, and which cannot fail to strike the most careless spectator. Many of them also are themselves compound, and are obviously capable of being divided into subordinate obviously capable of being divided into subordinate

2. The classification or arrangement. A knowledge of the different parts of a plant must necessarily be gained before it is described. But amidst the numerous vegetable productions of even a single country, this of itself would avail but little. To give a peculiar name to every individual would be a labour which no invention or diligence can perform; and, if performed, would produce a burden which no memory can sustain. would produce a burden which no memory can sustain. It is necessary, therefore, to pursue resemblances and differences through a number of gradations, and to found on them primary and subordinate divisions, either ascending from particulars to generals, or descending from generals to particulars. The former is the method in which science of every kind is slowly formed and extended; the latter that in which it is most easily taught. The number of stages through which these subdivisions should be carried is either not pointed out by nature, or enough of nature is not not pointed out by nature, or enough of nature is not known to fix them with precision. They differ, there-fore, in different systems; and, unfortunately, corresponding ones have not always been called by the same

3. The synonymes of plants; or the names by which they are distinguished in the writings of professed botanists and others, from the earliest times to the

4. The sensible qualities of plants, or the different manner in which they severally affect the organs of sight, smell, taste, and touch.
5. The anatomy of plants, or description of the different visible parts of which their substance is

6. The physiology of plants. A plant, like an animal, is a very compound, organized, living being, in which various operations, both chemical and mechawhich various operations, both chemical and mechanical, are continually carrying on, from its first production to its final dissolution. It springs from a seed fertilized by the pollen of its parent plant. It takes in foreign substances by its inhaling and absorbent vessels. It elaborates and assimilates to its own substance those parts of them that are nutritious, and throws off the rest. It secretes a variety of fluids by the means of glands, and other unknown organs. It gives that motion to its sap on which a continuance of its life. motion to its sap on which a continuance of its life

7. The purposes to which different plants are applied, either as articles of food, ingredients in the composieither as articles of root, ingretients in the composi-tion of medicine, or materials and instruments in the useful and elegant arts; the soil and situation in which they are generally found, and which are most favour-able to their growth, the time of year in which they open their flowers, and ripen their fruit, with many other incidental particulars, are properly within the province of the botanist. But as a botanist he is concerned with nothing more than the simple facts. The first methods of cultivating such as are raised in considerable quantities for the special use or amusement of man; the theory of their nutritious or medicinal properties; and the manner in which they are to be prepared, so as to effect the intended purposes; are the province either of the gardener, farmer, physician, chemist, or the artist.

chemist, or the artist.

8. The history of botany.

BOTANY BAY. An English settlement in New Holland, so called because it afforded the botanist numerous plants. A yellow resin goes by the name of Botany Bay gum, which exudes spontaneously from the trunk of the tree called Acarois resinifera, and also from the wounded bark. All the information that has been hitherto collected respecting the history of the yellow gum is the following:—The plant that produces it is low and small, with long grassy leaves; but the fructification of it shoots out in a singular manner from the centre of the leaves, on a single straight stem, to the height of twelve or fourteen feet. Of this stem, which is strong and light, like some of Of this stem, which is strong and light, like some of the reed class, the natives usually make their spears. the reed class, the natives usually make their spears. The resin is generally dug up out of the soil under the tree, not collected from it, and may, perhaps, be that which Tasman calls "gum lac of the ground." Mr. Boles, surgeon of the Lady Penrhyn, gives a somewhat different account; and as this gentleman appears to have paid considerable attention to the subject, his account may certainly be relied upon. After describing the tree in precisely the same manner as above, he observes, that at the top of the trunk of the tree, long grassy leaves grow in great abundance. The gum is found under these leaves in considerable quantities: it commonly exudes in round tears, or drops, tities: it commonly exudes in round tears, or drops, from the size of a large pea to that of a marble, and sometimes much larger. These are, by the heat of the sun, frequently so much softened, that they fall on the ground, and in this soft state adhere to whatever they fall upon: hence the gum is frequently found mixed with dirt, wood, the bark of the tree, and various other substances; so that one lump has been seen composed of many small pure pieces of various sizes, united together, which weighed nearly half a hundredweight. It is produced in such abundance, that one man may collect thirty or forty pounds in the space of a few hours. The convicts have another method of collecting it; they dig round the tree, and break off pieces of the roots, which always have some, and frequently considerable quantities of the gum in them. This gum appears nearly, but not entirely, the same as that which exudes from the trunk of the tree; the former is often mixed with a strong-smelling resinous tities: it commonly exudes in round tears, or drops former is often mixed with a strong-smelling resinous substance of a black nature, and is so interwoven in the wood itself, that it is with difficulty separated.

The latter appears a pure, unmixed, resinous substance.
Several experiments have been made, principally with the view of determining what menstruum would dissolve the gum the most readily, and in the greatest quantity, from which it appears alkohol and ather dissolve the most.

The diseases in which this resin is administered are

those of the primæ viæ, and principally such as arise from spasm, a debility, a loss of tone, or a diminished action in the muscular fibres of the stomach and bowaction in the muscular fibres of the stomach and bowels, such as loss of appetite, sickness, vomiting, flatulency, heart-hurn, pains in the stomach, &c. when they were really idiopathic complaints, and not dependent upon any disease in the stomach, or affections of other parts of the body communicated to the stomach. In debilities and relaxations of the bowels, and the symptoms from thence arising, such as purging and flatulency, it has been found of good effect. In certain cases of diarrhæa, however, (and it seemed those in which an unusual degree of irritability prevailed) it did not answer so well, unless given in small doses, and combined with opiates, when the patient second to gain greater advantage than when opiates

only were had recourse to. In cases of amenorrhos, depending on (what most of those cases do depend upon) a sluggishness, a debility, and flaccidity of the system, this medicine, when assisted by proper exercise and diet, has, by removing the symptoms of dys-pepsia, and by restoring the tone and action of the muscular fibres, been found very serviceable. This muscular fibres, been found very serviceable. medicine does not, in the dose of about half a drachm, appear to possess any remarkably sensible operation. It neither vomits, purges, nor binds the belly, nor does it materially increase the secretion of urine or perspiration. It has, indeed, sometimes been said to purge and at others to occasion sweating; but they are not constant effects, and, when they do occur, it generally depends on some accidental circumstance. It should depends on some accidental circumstance. It should seem to possess, in a very extensive degree, the property of allaying morbid irritability, and of restoring tone, strength, and action, to the debilitated and relaxed fibre. When the gum itself is given, it should always be the pure unmixed part; if given in the form of a draught, it should be mixed in water with muci lage of gum-arabic; if made into pills, a small portion of Castile soap may be employed; it was found the lixiv. sapon. dissolved it entirely. It is commonly, however, made into a tincture by mixing equal parts however, made into a tincture by mixing equal parts of the gum and rectified spirit; one drachm of this tincture, (containing half a drachm of the pure gum) made into a draught with water and syrup, by the assistance of fifteen grains of gum-arabic in mucilage forms an elegant medicine, and at the same time very palatable. It soon solidifies by the sun, into pieces of a yellow colour of various sizes. It pulverizes easily without caking; nor does it adhere to the teeth when chewed. It has a slightly sweet astringent taste. It melts at a moderate heat. When kindled, it emits a white fragrant smoke. It is insoluble in water, but imparts to it the flavour of storax. Out of nine parts, six are soluble in water, and astringent to the taste; and two parts are woody fibre.

Bo'THRION. (From βοθριον, a little pit.) Botrium

1. The socket for the tooth.

2: An ulceration of the cornea.

BOTRY'TIS. (From βοτρυς, a bunch of grapes.) Botryites. A sort of burnt cadmia, collected in the top of the furnace, and resembling a bunch of grapes.

BOTRYOLITE. A brittle and moderately hard mineral, which occurs in mamillary concretions of a pearly or grayish-white colour, composed of silica, boracic acid, lime, oxide of iron and water. It comes frem Norway.

BO TRYS. (Bolows, a cluster of grapes: so called because its seeds hang down like a bunch of grapes.,

The oak of Jerusalem.

BOTRYS MEXICANA. See Chenopodium ambro sioides.

BOTRYS VULGARIS. See Chenopodium botrys. BOUBA'LIOS. See Momordica Elaterium, and Pu dendum muliebre.

Bou'Bon. See Bubo.

BOUGI'E. (French for wax candle.) Candel cerea; Candela medicata; Catheteres of Swediaur Cerei medicati of Le Dran; Cercolus Chirurgorum A term applied by surgeons to a long, slender instru A term applied by suggest through the urethra into the bladder. Bougies made of the elastic gum are prefera ble to those made of wax. The caustic bougie differs from the ordinary one in having a thin roll of caustic in its middle, which destroys the stricture, or any part it comes in contact with. Those made of catgut are very seldom used, but are deserving of the attention very seldom used, but are deserving of the attention of the surgeon. Bougies are chiefly used to overcome strictures in the urethra, and the introduction of them requires a good deal of address and caution. They should not be kept in the urethra so long at one time as to excite much pain or irritation. Before their use is discontinued, they should, if practicable, be carried the length of the bladder, in order to ascertain the extent of the strictures, taking care that this be performed not at once, but in a gradual manner, and after repeat ed trials, for much injury might arise from any hasty or violent efforts to remove the resistance that may present itself. There are bougies also for the geophapresent itself. There are bougies also for the œsophagus and rectum. BOU'LIMUS.

BOU'LIMUS. (From βου, greatly, and λιμος, hunger; or from βουλομαι, to desire.) A canine or voracious appetite.

BOURNONITE. An antimonial sulphuret of lead.

Bovey coal. Of a brownish-black colour and lamel-lar texture, formed of wood, penetrated with petro-leum or bitumen, and found in England, France,

Boyl'LLE. (From bos, an ox, because cattle were supposed subject to it.) The measles.

Boyl'NA FAMES. The same as bulimia.

Boyl'STA. See Lycoperdon.

BOWEN, PARDON, M.D. This accomplished physician and excellent man was born in Providence, Rhode Island, 22d of March, in the year 1757.

The incidents of Dr. Bowen's early life, we have been unable to collect with sufficient accuracy to warrant us

During the prevalence of the yellow fever in Provi-dence, when dejection and dismay sat upon many a brow, and the sense of personal danger threatened to absorb the sympathies of our common nature, and death mocked at the expedients of human science to avert his blow, Dr. Bowen shrunk not from the perils in his way. More than once was his life endangered by an attack of that fearful malady, but God preserved him from thus becoming a victim to his noble intre-

pidity in the service of humanity.

Dr. Bowen confined his attention to no particular department of his profession, but aimed at excellence in all. For his skill in operative surgery he was highly respected, and during many years most of the surgical operations, in and around Providence, were performed by him. In medical surgery he was thought extremely judicious; and his uncommon science, experience, and success in obstetrics, left him without a superior in that

difficult branch of his profession.

Dr. Bowen contributed occasionally to the medical journals of the day; and in the fourth volume of Hosack and Francis's Medical and Philosophical Register may be found an elaborate account from his pen of the yellow fever, as it prevailed in Providence in the year 1805. He died in October 1826, aged 69 years. His life, in all its stages, was a beautiful exhibition of the virtues, and at its close, an example of Christian holiness.—See *Thach. Med. Biog.* A.]

BOX-TREE. See *Buxus*.

BOYLE'S FUMING LIQUOR. The hydroguret-

ted sulphuret of ammonia.
[BOYLSTON, Dr. Zabdiel, was born in Massachusetts in 1680, and was the eldest son of an English physician of the same name, one of the early settlers of that province under the British government. Dr. Boylston is represented as a skilful physician, bold, persevering, courageous and benevolent. "In the year persevering, courageous and penevoient. In the year 1721 the small-pox appeared in Boston, and pursued its usual desolating career, carrying with it the utmost terror and confusion. On this alarming occasion Dr. Cotton Mather, the learned and distinguished divine, communicated to Dr. Boylston a publication in the Transactions of the Royal Society, announcing the discovery of a new method of mitigating the virulence of this fatal disease. Dr. Boylston was forcibly im-pressed with the benefit of the discovery, and accordingly after deliberating on the most safe and expeditious mode of thus artificially introducing the disease into the system, he communicated to the medical gentlemen in Boston the plan he proposed to adopt, and the source whence he derived the first hints of the operation, desiring their concurrence in the undertaking." In this measure he was opposed by the physicians and clergy, some of whom denounced him from the pulpit; and the inhabitants became enraged, and were excited to commit atrocious acts of outrage on the person of Dr. Boylston, extending their rancour even to his family.

"Undismayed, however, by all this violence, and unsupported by the friendship of any but Dr. Mather, he commenced, on the 27th June 1721, while the smallpox was in its most destructive progress through the town, this untried experiment of inoculation on his own son, a child of thirteen years of age, and two blacks in his family, one of thirty-six, and the other of two years of age, and on all with complete success. This rekindled the fury of the populace, and induced the authorities of the town to summon him before them to answer for his practice. He underwent repeated examinations; and although he invited all the practitioners in Boston to visit his patients and judge for themselves, he received only insults and threats in reply The facts we have thought worthy of notice, K 2

as remarkable in themselves, and as in some degree characteristic of the excitable spirit of the times. thus encountering obloquy and reproach, however, Dr. Boylston but experienced the fortune of most of those who have attempted to innovate on long established usages, or to take the lead in the career of public improvement. The small-pox ceased its ravages in May 1722; and during its prevalence Dr. Boylston continued the practice of inoculation to all who could be induced to submit to it. He increased with his care induced to submit to it. He inoculated with his own hand two hundred and forty-seven of both sexes from name two hundred and torty seven of both seves from nine months to sixty-seven years of age in Boston and in the neighbouring towns; thirty-nine were inoculated by other physicians, after the tumult had in some measure subsided, making in the whole two hundred and eighty-six, of whom only six died; and of these, these were supposed to have taken the disease the name of the party three were supposed to have taken the disease the natural way, some days previous to their being inoculated; three of those who died were his oldest patients. It appears, by the account published by the select men, that during the same period five thousand seven hundred and fifty-nine had taken the natural small-pox, eight hundred and forty-four of whom fell victims to the disease, being more than one in six. In the vicinity of Boston it had been still more malignant and fatal. The utility of the practice was now established without dispute; and its success encouraged its more general practice in England, in which country it had been tried upon but few persons, most of whom were condemned convicts and charity children. The daughter of Lady Mary W. Montague was inoculated in London, in April 1721, being the first instance in Europe, and the convicts were made the subjects of the experiment in August of the same year. Dr. Boylston therefore is justly entitled to the honour of being the first inoculator in America; and this, even before the single instance of the experiment in Europe had come to his knowledge

Dr. Boylston, during his unjust persecution, held a correspondence with Sir Hans Sloane, of London, the court physician; who, being apprised of his very eminent services in first introducing inoculation into America, honoured him with an invitation to visit London. He accordingly embarked for that city and He accordingly embarked for that city, and on his arrival was greeted with the most cordial affec-tion and respect. He was elected a member of the Royal Society, the first American, we believe, ever admitted to that honour. He was moreover honoured by being introduced to the royal family, and received the most flattering attentions and friendship of some of the most distinguished characters of the nation. After his return to his native country, Dr. Boylston continued at the head of his profession, and engaged in literary pursuits, making many ingenious and useful communications to the Royal Society, and corresponding with his numerous friends, among whom he used to mention with great respect and affection the Rev, Dr. Watts, who appears by his letters to have been a

warm advocate for inoculation.

Dr. Boylston possessed a strong and reflecting mind and acute discernment. His character through life was one of unimpeached integrity. He was charitable in his opinions of others, patient under the severest persecution, and forgiving of his bitterest enemies. These qualities, added to the natural case and suavity of his manners, which had been increased. of his manners, which had been improved by inter-course with the world, caused his society to be much sought, and to his family and his friends rendered him a most interesting and instructive companion. a most interesting and instructive companion. His health was often interrupted by severe attacks of asthma, to which he was subject for the last forty years of his life. He met death with calmness and perfect resignation in the eighty-seventh year of his age, saying to his friends, 'my work in this world is done, and my hopes of futurity are brightening.' He was buried in the family tomb at Brooklyn, on which is inscribed the following appropriate and just language: was buried in the family tomb at Brooklyn, on which is inscribed the following appropriate and just language: 'Sacred to the memory of Dr. Zabdiel Boylston, Esq., physician and F.R.S., who first introduced the practice of inoculation into America. Through a life of extensive benevolence, he was always faithful to his word, just in his dealings, affable in his manners; and after a long sickness, in which he was exemplary for his patience and resignation to his Maker, he quitted this mortal life in a just expectation of a happy immortality, March 1st, 1766.' His wife died a few years before him."—See Thack Med. Biog. A.]

BRACHE'RIUM. (From brachiale, a bracelet.) A truss or bandage for hernia; a term used by the bar-

barous Latin writers.

BRACHLE'US. Brachial; belonging to the arm.
BRACHLEUS EXTERNUS. See Triceps extensor

cubits.

BRACHIEUS INTERNUS. See Brachialus internus. BRACHIEUS MUSCULUS. See Brachialis internus. BRACHIAL. Brachialis. Of or belonging to the arm.

BRACHIAL ARTERY. Arteria brachialis. The brachial artery is the continuation of the axillary artery, which, as it passes behind the tendon of the pectoralis major, receives the name of brachial. It runs down on the inside of the arm, over the musculus coracobrachialis, and anconœus internus, and along the inner edge of the biceps, behind the vena basilica, giving out small branches as it goes along. Below the bend of the arm it divides into the cubitalis and radialis. Sometimes, though rarely, the brackial artery is divided from its origin into two large branches, which run down on the arm, and afterward on the fore-arm, where they are called cubitalis and radialis.

Brackia'le. The word means a bracelet; but the

ancient anatomical writers apply this term to the carpus, the part on which the bracelet was worn.
BRACHIA'LIS. See Brachial.

BRACHIALIS EXTERNUS. See Triceps extensor

Brachiaus internus. Brachiaus of Winslow. Brachiaus internus of Cowper; and Humero-cubital of Dumas. A muscle of the fore-arm, situated on the fore-part of the os humeri. It arises fleshy from the middle of the os humeri, at each side of the insertion of the deltoid muscle, covering all the inferior and fore-part of this bone, runs over the joint, and adheres firmly to the ligament; is inserted, by a strong short tendon, into the coronoid process of the ulna. Its use

is to bend the fore-arm, and to prevent the capsular ligament of the joint from being pinched.

BRACHIATUS. Brachiate. Applied to branches, panicles, &c. spread in four directions, crossing each other alternately in pairs; a common mode of growth in the branches of shrubs that have opposite leaves, as

the lilac, syringa, &c.
BRA'CHII OS. See Humeri os.

BRACHIO-CUBITAL LIGAMENT. Ligamentum brachio-bitale. The expansion of the lateral ligament, which is fixed in the inner condyle of the os humeri, runs over the capsular, to which it closely adheres, and is inserted like radii on the side of the great sigmoid cavity of the ulna; it is covered on the inside by several tendons, which adhere closely to it, and seem to strengthen it very considerably.

BRACHIO-RADIAL LIGAMENT. Ligamentum brachio-radiale. The expansion of the lateral ligament, which runs over the external condyle of the os humeri, is inserted round the coronary ligament from thence all the way down to the neck of the radius, and also in the neighbouring parts of the ulua. Through all this passage it covers the capsular ligament, and is covered by several tendons adhering closely to both.

BRACHIUM. (Recovery, the arm.) The arm.

BRA'CHIUM. (Beaxtor, the arm.) from the shoulder to the wrist. The arm,

BRACHIUM MOVENS QUARTUS. See Latissimus

BRACHU'NA. According to Avicenna, a species of

furor uterinus. BRACHYCHRO'NIUS. (From βραχυς, short, and χοονος, time.) A disease which continues but a short

Brachypke'a. (From βραχυς, short, and ωνεω, to breathe.) Shortness and difficulty of breathing.

Bra'chys. (From βραχυς, short.) A muscle of

BRACTEA. (Bractea, a thin leaf or plate of metal.) A floral leaf. One of the seven fulcra or props of plants, according to Linnæus. A bractea is a little leaf-like appendage to some flowers, lying under or interspersed in the flower, but generally different in colour from the true leaves of the plant.

1. It is green in some; as in Ocymum basilicum

majus.
2. Coloured in others; as in Salvia horminum, &c.
3. In some it is caducous, falling off before the

4. In others in remains; as in Tibia europæa.

Coma bracteata is, when the flower-stem is terminated with a number of very large bractex, resembling a bush of hair.

BRACTEATÆ. (From bractea, here meaning a corolla.) The name of a class of Boerhaave's method of plants, consisting of herbaceous vegetables, which have petals, and the seeds of which are furnished with a single lobe or cotyledon.

BRACTEATUS. (From bractea, a floral leaf.)

Having a floral leaf; as pedunculus bracteatus.

BRACTEIFORMIS Resembling a bractea or

floral leaf.

Bradype Psia. (From $\beta \rho \alpha \delta v_S$, slow, and $\varpi \epsilon \pi \gamma \omega$, to concoct.) Weak digestion.

BRA'GGAT. A name formerly applied to a ptisan of

BRAIN. See Cerebrum

BRAN. Furfur. The husks or shells of wheat, which remain in the bolting machine. It contains a portion of the farinaceous matter, and is said to have

portion of the farinaceous matter, and is said to have a laxative quality. Decoctions of bran, sweetened with sugar, are used by the common people, and sometimes with success, against coughs, hoarseness, &c. BRA'NCA. (Branca, the Spanish for a foot, or branch.) A term applied to some herbs, which are supposed to resemble a particular foot; as branca leonis, lion's foot; branca ursina, beat's foot.

BRANCA LEONIS. See Alchemilla.

BRANCA URSINA. See Alchemilla.

BRANCA URSINA. See Acanthus and Heracleum
BRA'NCHE. (From Boryo, to make noist.) Branch.

BRA'NCH E. (From βρεχω, to make moist.) Branchi. Swelled tonsils, or glandulous tumours, of the fauces, which secrete saliva.

BRA κchus. (From βρεχω, to moisten.) A defluxion of humours from the fauces.

of humours from the fauces.

BRANDY. Spiritus Gallicus. A colourless, slightly opaque, and milky fluid, of a hot and penetrating taste, and a strong and agreeable smell, obtained by distilling from wine. It consists of water, ardent spirit, and a small portion of oil, which renders it milky at first, and, after a certain time, colours it yellow. It is the fluid from which rectified or ardent spirit is obtained. Its peculiar flavour depends on the nature of the volatile principles, or essential oil, which come over along with it in the distillation, and likewise, in some measure, upon the management of the wise, in some measure, upon the management of the fire, the wood of the cask in which it is kept, &c. It is said, that our rectifiers imitate the flavour of brandy, is said, that our rectifiers imitate the flavour of brandy, by adding a small proportion of nitrous ather to the spirit of malt, or molasses. The utility of brandy is very considerable, but, from its pleasant taste and exhilarating property, it is two often taken to excess. It gives energy to the animal functions; it is a powerful tonic, cordial, and antispasmodic; and its utility with camphire, in gangrenous affections, is very great.

BRANKS. The name in Scotland for the mumps. See Cynanche parotidea.

BRANKURSINE. See Acanthus.

BRANKURSINE. See Acanthus.

BRASI'LIA. Brazil wood.

Brasiliense lignum. See Hamatoxylum campe-

Brasiliensis Radix. The ipecacuanha root is sometimes so called.

(From βρασσω, to boil.) Malt, or ger-BRA'SIUM. minated barley

minated barley.

Bra sma. (From βρασσω, to boil.) The unripe black pepper. Fermentation.

Bra'smos. The same.

BRASS. Æs. A combination of copper and zinc.

Brassade Lla. Brassatella. The Ophioglossum, or herb, adder's tongue.

BRA'SSICA. (Varro says, quasi præsica; from præseco, to cut off; because it is cut from the stalk for use; or from πρασια, a bed in a garden where they are cultivated, or from βρασσω, to devour, because it is eagerly eaten by cattle.) The name of a genus of plants in the Linnæau system. Class, Tetradynamia; Order, Siliquosa. Crambe. Cabbage. Colewort.

Brassica alba. The white cabbage.

Brassica alba. The white cabbage.

Brassica arbana. Jagged or crimpled colewort.

Brassica canina. Mercurialis sylvestris. Sec

Mercurialis sylvestris. BRASSICA CANINA.

Mercurialis annua.

Cabbage. There are several BRASSICA CAPITATA. varieties of cabbage, all of which are generally hard of digestion, producing flatulencies, and afford very lit-tle nourishment. These inconveniences are not expo-

rienced by those whose stomachs are strong and accustomed to them. Few vegetables run into a state of putrefaction so quickly as cabbages; they ought, therefore, always to be used immediately after cutting. In Holland and Germany there is a method of preserving them, by cutting them into pieces, and sprinkling salt and some aromatic herbs among them; this mass is put into a tub, where it is pressed close, and left to ferment, when it is called sour crout, of sauer kraut. These, and all pickles of cabbage, are considered as wholesome and antiscorbutic, from the vinegar and wholesome and antiscorbutic, from the vinegar and spices they contain.

Brassica congylodes, Turnip cabbage.
Brassica cumana. Red colewort.
Brassica eruca. Brassica erucastrum. Eruca sylvestris. The systematic name for the plant which sylvestris. The systematic name for the plant which affords the semen eruca. Garden rocket. Roman rocket. Rocket gentle. Brassica—foliis lyartis, caule hirsuto siliquis glabris, of Linnœus. The seeds of this plant, and of the wild rocket, have an acrid taste, and are eaten by the Italians in their pickles, &c. They are said to be good aperients and antiscorbutics, but are esteemed by the above-mentioned people for

their supposed aphrodisiac qualities.

Brassica erucastrum. See Brassica eruca.

Brassica florida. The cauliflower.

Brassica gonylicodes. The turnip cabbage.

Brassica Lacuturria. Brassica lacuturris. The Savoy plant.

BRASSICA MARINA. See Convolvulus soldanella. BRASSICA NAPUS. The systematic name for the plant from which the semen napi is obtained. Napus sylvestris. Bunias. Wild navew, or rape. The seeds yield, upon expression, a large quantity of oil called rape oil, which is sometimes ordered in stimulating liniments.

BRASSICA OLERACEA. The systematic name for the brassica capitata of the shops. See Brassica

the brassica capitata of the shops. See Brassica capitata.

Brassica rapa. The systematic name for the plant whose root is called turnip. Rapum. Rapus. Napus. Napus dulcis. The turnip. Turnips are accounted a salubrious food, demulcent, detergent, somewhat laxative and diuretic, but liable, in weak stomachs, to produce flatulencies, and prove difficult of digestion. The liquor pressed out of them, after boiling, is sometimes taken medicinally in coughs and disorders of the breast. The seeds are greasionally taken as diuretics: breast. The seeds are occasionally taken as diuretics; they have no smell, but a mild acrid taste.

Brassica Rubra. Red cabbage, A very excellent

test both for acids and alkalies in which it is superior

to litmus, being naturally blue, turning green with alkalies, and red with acids.

Brassica sabauda. The Savoy plant.

Brassica sativa. The common garden cabbage.

Brasside Llica ars. A way of curing wounds, mentioned by Paracelsus, by applying the herb Brassidelle to them. della to them.

Bra'thu. Boαθυ. An old name for savine.
BrAZIL WOOD. See Casalpina crista.
["Brazil wood is the produce of the Casalpina crista, growing in Brazil, in the Isle of France, Japan, and other countries. The wood is hard and heavy; and though pale when recent, it acquires a deep red colour by exposure. Digested in water, it affords a fine red infusion, of a sweetish flavour; the residue, which appears nearly black, imparts much of its colour to alkaline liquors. With alkohol it gives a deep red tincture: alkalies and soap convert its red colour to a fine purple; hence, paper tinged with Brazil wood is sometimes used as a test for alkalies; Brazil wood is sometimes used as a test for alkalies; acids render it yellow: alum produces a fine crimson lake, with infusion of Brazil wood: muriate of tin forms with it a crimson precipitate, bordering on purple: the salts of iron give a dingy purple colour. Sulphuretted hydrogen destroys the colour of infusion of Brazil wood, but it reappears on expelling the gas."—See Webster's Man. of Chem. A.]

BREAD. Panis. "Farinaccous vegetables are converted into meal by trituration, or grinding in a mill; and when the husk or bran has been separated by sifting or holling, the powder is called flour. This

by sifting or bolting, the powder is called flour. This is composed of a small quantity of mucilaginous saccharine matter, soluble in cold water; much starch, which is scarcely soluble in cold water, but combines with that fluid by heat; and an adhesive gray substance insoluble in water, alkohol, oil, or ather, and

resembling an animal substance in many of its pro-

When flour is kneaded together with water, it forms a tough paste, containing these principles very little altered, and not easily digested by the stomach. The action of heat produces a considerable change in the gluten, and probably in the starch, rendering the com-pound more easy to masticate, as well as to digest. Hence the first approaches towards the making of bread consisted in parching the corn, either for immediate use as food, or previous to its trituration into meal; or else in baking the flour into unleavened bread, or boiling it into masses more or less consistent; of all which we have sufficient indications in the histories of the earlier nations, as well as in the various prac-tices of the moderns. It appears likewise from the Scriptures, that the practice of making leavened bread is of very considerable antiquity; but the additions of yest, or the vinous ferment, now so generally used, seems to be of modern date.

Unleavened bread in the form of small cakes, or bis-cuit, is made for the use of shipping in large quanti-ties; but most of the bread used on shore is made to undergo, previous to baking, a kind of fermentation, which appears to be of the same nature as the fermentation of saccharine substances; but is checked and modified by so many circumstances, as to render it not a little difficult to speak with certainty and pre-

cision respecting it.

When dough or paste is left to undergo a spontaneous decomposition in an open vessel, the various parts of the mass are differently affected, according to the humidity, the thickness or thinness of the part, the vicinity or remoteness of fire, and other circumstances less easily investigated. The saccharine part is disposed to become converted into alkohol, the mucilage has a tendency to become sour and mouldy, while the gluten in all probability verges towards the putrid state. An entire change in the chemical attractions of the several component parts must then take place in a progressive manner, not altogether the same in the internal and more humid parts as in the external parts, which not only become dry by simple evaporation, but are acted upon by the surrounding air. The outside may therefore become mouldy or putrid, while the inner part may be only advanced to an acid state. Occasional admixture of the mass would of course not only produce some change in the rapidity of course not only produce some change in the rapidity of this alteration, but likewise render it more uniform throughout the whole. The effect of this commencing fermentation is found to be, that the mass is rendered more digestible and light; by which last expression it is understood, that it is rendered much more porous by the disengagement of elastic fluid, that separates its parts from each other, and greatly increases its bulk. The operation of baking puts a stop to this process, by evaporating great part of the moisture which is requisite to favour the chemical attraction, and probably also by still farther changing the nature of the bably also by still farther changing the nature of the

bably also by still farther changing the nature of the component parts. It is then bread.

Bread made according to the preceding method will not possess the uniformity which is requisite, because some parts may be mouldy, while others are not yet sufficiently changed from the state of dough. The same means are used in this case as have been found effectual in promoting the uniform fermentation of large masses. This consists in the use of a leaven or ferment, which is a small portion of some matter of the same kind, but in a more advanced stage of the the same kind, but in a more advanced stage of the fermentation. After the leaven has been well incorporated by kneading into fresh dough, it not only brings on the fermentation with greater speed, but causes it to take place in the whole of the mass at the same time; and as seen as the dough has by this means acquired a due increase of bulk from the carbonic acid, which endeavours to escape, it. is judged to be sufficiently fermented, and ready for the oven.

The fermentation by means of leaven or sour dough it is generally so managed, that the bread has a sour flavour.

is thought to be of the accious kind, because it is generally so managed, that the bread has a sour flavour and taste. But it has been ascertained that this acidity proceeds from true vinegar. Bread raised by leaven is usually made of a mixture of wheat and rye, not very accurately cleared of the bran. It is distinguished by the name of rye-bread; and the mixture of these two kinds of grain is called bread-corn, or meslin, in many parts of the kingdom, where it is raised on one

Yest or barm is used as the ferment for the finer kinds of bread. This is the mucilaginous froth which rises to the surface of beer in its first stage of fermentation. When it is mixed with dough, it produces a much more speedy and effectual fermentation than that obtained by leaven, and the bread is accordingly much lighter, and scarcely ever sour. The fermentation by yest seems to be almost certainly of the vinous or spirituous kind.

Bread is much more uniformly miscible with water than dough; and on this circumstance its good quali-

ties most probably do in a great measure depend.

A very great number of processes are used by cooks, A very great number of processes are used by cooks, confectioners, and others, to make cakes, puddings, and other kinds of bread, in which different qualities are required. Some cakes are rendered brittle, or as it is called *short*, by an admixture of sugar or of starch. Another kind of brittleness is given by the addition of butter or fat. White of egg, gum-water, isinglass, and other adhesive substances, are used, when it is intended that the effect of fermentation shall expand the dough into an exceedingly porous mass. Dr. Percival has recommended the addition of salep, or the nutritious powder of the orchis root. He says, that nutritious powder of the orchis root. He says, that an ounce of salep, dissolved in a quart of water, and mixed with two pounds of flour, two ounces of yest, and eighty grains of salt, produced a remarkably good loaf, weighing three pounds two ounces; while a loaf made of an equal quantity of the other ingredients, without the salep, weighed but two pounds and twelve ounces. If the salep be in too large quantity, how-ever, its peculiar taste will be distinguishable in the bread. The farina of potatoes, likewise, mixed with wheaten flour, makes very good bread. The reflecting chemist will receive considerable information on this subject from an attentive inspection of the receipts to be met with in treatises of cooking and confectionary. Mr. Accum, in his late Treatise on Culinary Poisons,

states, that the inferior kind of flour which the London bakers generally use for making loaves, requires the addition of alum to give them the white appear-ance of bread made from fine flour. 'The baker's flour is very often made of the worst kinds of damaged foreign wheat, and other cereal grains mixed with them in grinding the wheat into flour. In this capital, no fewer than six distinct kinds of wheaten flour are brought into the market. They are called fine flour, seconds, middlings, fine middlings, coarse middlings, and twenty-penny flour. Common garden beans and pease are also frequently ground up among the Lon-

don bread flour.

'The smallest quantity of alum that can be employed with effect to produce a white, light, and porous bread from an inferior kind of flour, I have my own baker's

authority to state, is from three to four ounces to a sack of flour weighing 240 pounds.'

'The following account of making a sack of five bushels of flour into bread, is taken from Dr. P. Markham's Considerations on the Ingredients used in the Adulteration of Flour and Bread, p. 21.

Five bushels flour,

Eight ounces of alum.

Eight ounces of alum,

Four lbs. salt, Half a gallon of yest, mixed with about Three gallons of water.

Three gallons of water.

'Another substance employed by fraudulent bakers is subcarbonate of ammonia. With this salt they realize the important consideration of producing light and porous bread from spoiled, or what is technically called sour flour. This salt, which becomes wholly converted into a gaseous substance during the operation of baking, causes the dough to swell up into air-bubbles, which carry before them the stiff dough, and thus it renders the dough porous; the salt itself is at the same time totally volatilized during the operation of baking.'—'Potatoes are likewise largely, and, perhaps, constantly used by fraudulent bakers, as a cheap ingredient to enhance their profit.'—'There are instances of convictions on record, of bakers havare instances of convictions on record, of bakers having used gypsum, chalk, and pipe-clay, in the manufacture of bread.'

Mr. E. Davy, Prof. of Chemistry at the Cork Insti-tution, has made experiments, showing that from twinty to forty grains of common carbonate of mag-

and the same piece of ground, and passes through all nesia, well mixed with a pound of the worst new settle processes of reaping, threshing, grinding, &c. in this mixed state.

The habitual and daily introduction of a portion of alum into the human stomach, however small, must be prejudicial to the exercise of its functions, and parbe prejudicial to the exercise of its functions, and particularly in persons of a bilious and costive habit. And, besides, as the best sweet flour never stands in need of alum, the presence of this salt indicates an inferior and highly acescent food; which cannot fail to aggravate dyspepsia, and which may generate a calculous diathesis in the urinary organs. Every precaution of science and law ought, therefore, to be employed to detect and stop such deleterious adulteration if Bread may be analyzed for alum by crumbling it down when somewhat stale in distilled water, squeezpassing the liquid through a paper filter. A limpid infusion will thus be obtained. It is difficult to procure it clear if we use new bread or hot water. A dilute solution of muriate of barytes dropped into the filtered infusion, will indicate by a white cloud, more or the presence and quantity of alum. I find ing the pasty mass through a piece of cloth, and then less heavy, the presence and quantity of alum. I find that genuine bread gives no precipitate by this treat-ment. The earthy adulterations are easily discovered by incinerating the bread at a red heat in a shallow earthen vessel, and treating the residuary ashes with a little nitrate of ammonia. The earths themselves will then remain, characterized by their whiteness and

insolubility.

The latest chemical treatise on the art of making bread, except the account given by Mr. Accum in his work on the Adulterations of Food, is the article Baking, in the Supplement to the Encyclopædia Bri-

Under Process of Baking, we have the following statement: 'An ounce of alum is then dissolved over the fire in a tin pot, and the solution poured into a large tub, called by the bakers the seasoning-tub. Four pounds and a half of salt are likewise put into the tub, and a pailful of hot water.' Note on this passage.—'In London, where the goodness of bread is estimated entirely by its whiteness, it is usual with those bakers who employ flour of an inferior quality, to add as much alum as common salt to the dough. to add as much alum as common salt to the dough. Or, in other words, the quantity of salt added is dimior, in other words, and the deficiency supplied by an equal weight of alum. This improves the look of the bread very much, rendering it much whiter and firmer.'"—Ure's Chem. Dict.

BREAD-FRUIT. The tree which affords this,

BREAD-FRUIT. The use trade grows in all the Ladrone islands in the South sea, in the West Indies. The breadfruit grows upon a tree the size of a middling oak. fruit is about the size of a child's head, and the surface is reticulated, not much unlike the surface of a truffle. It is covered with a thin skin, and has a core about the size of a small knife. The eatable part is between the skin and the core: it is as white as snow, and somewhat of the consistence of new bread. It must be toasted before it is eaten, being first divided into three or four parts. Its taste is insipid, with a slight sweetness, nearly like that of wheaten bread and artichoke together. This fruit is the constant food of the inhabitants all the year, it being in season eight months.

See Brosimum alicastrum. Mamma. The two globular projec-Bread-nut. BREAST. tions, composed of common integuments, adipose substance, and lacteal glands and vessels, and adhering to the anterior and lateral regions of the thorax of females. On the middle of each breast is a projecting

females. On the middle of each breast is a projecting portion, termed the papilla, or nipple, in which the excretory ducts of the glands terminate, and around which is a coloured orb, or disc, called the arcola. The use of the breasts is to suckle new-born infants.

BREAST-BONE. See Sternum.

BRECCIA. An Italian term, frequently used by our mineralogical writers to denote such compound stones as are composed of agglutinated fragments of considerable size. When the agglutinated parts are rounded, the stone is called pudding-stone. Breccias are denominated according to the nature of their component parts. Thus we have calcareous breccias, or marbles; and siliceous breccias, which are still more minutely classed, according to their varieties.

BRE'GMA. (From 6ρεχω, to moisten; formerly so

BRE'GMA. (From 600xw, to moisten; formerly 80

called, because, in infants, and sometimes even in adults, they are tender and moist.) An old name for the parietal bones.

BREVIS. Short. Applied to distinguish parts dif-fering only in length, and to some parts, the termina-tion of which is not far from their origin; as brevia vasa, the branches of the splenic vein.

Brey'sia. (An American plant named in honour of Dr. Brennius.) A species of capparis.

BRIAR. See Rosa.

BRI CUMUM. A name which the Gauls gave to the herb artemisia.

BRIMSTONE. See Sulphur.

BRISTLE. See Seta.

BRISTOL HOT-WELL. Bristoliensis aqua. A

pure, thermal or warm, slightly acidulated, mineral spring, situated about a mile below Bristol. The fresh spring, situated about a mile below Bristol. The fresh water is inodorous, perfectly limpid and sparkling, and sends forth numerous air-bubbles when poured into a glass. It is very agreeable to the palate, but without having any very decided taste, at least none that can be distinguished by a common observer. Its specific gravity is only 1.00077, which approaches so mar to that of distilled water, that this circumstance alone would show that it contained but a very small admixture of foreign ingredients. The temperature of these waters, taking the average of the most accurate observations, may be reckoned at 74 deg.; and this does not very sensibly vary during winter or summer. Bristol water contains both solid and gaseous matter, and the distinction between the two requires to be and the distinction between the two requires to be attended to, as it is owing to the very small quantity of solid matter that it deserves the character of a very fine natural spring; and to an excess in gaseous contents that it seems to be principally indebted for its medical properties, whatever they may be, independent of those of mere water, with an increase of tempera-ture. From the different investigations of chemists, it appears that the principal component parts of the Hot-Well water are, a large proportion of carbonic acid gas, or fixed air, and a certain portion of magnesia and lime, in various combinations, with the muriatic, vitriolic, and carbonic acids. The general inference is, that it is considerably pure for a natural fountain, as it contains no other solid matter than is found in

as it contains no other solid matter than is jound in almost all common spring water, and in less quantity.

On account of these ingredients, especially the carbonic acid gas, the Hot-Weil water is efficacious in promoting salutary discharges, in green-sickness, as well as in the blind hamorrhoids. It may be taken with advantage in obstructions, and weakness of the bowels, arising from habitual costiveness; and, from the purity of its aqueous part, it has justly been con-sidered as a specific in diabetes, rendering the urinary organs more fitted to receive benefit from those medicines which are generally prescribed, and sometimes

But the high reputation which this spring has ac-But the high reputation which this spring has acquired, is chiefly in the cure of pulmonary consumption. From the number of unsuccessful cases among those who frequent this place, many have denied any peculiar efficacy in this spring, superior to that of common water. It is not easy to determine how much may be owing to the favourable situation and mild, temperate climate which Bristol enjoys; but it cannot be doubted that the Hot-Well water, though by no means a cure for consumption, alleviates some of the most harassing symptoms of this formidable disease. It is particularly efficacious in moderating the thirst, the dry, burning heat of the hands and feet, the partial night sweats, and the symptoms that are peculiarly hectical; and thus, in the earlier stages of phthisis, it may materially contribute to a complete re-establishment of health; and even in the latter periods, mitigate the discase when the cure is doubtful, if not hopeless.

The sensible effects of this water, when drunk

warm and fresh from the spring, are a gentle glow of the stomach, succeeded sometimes by a slight and transient degree of headach and giddiness. By a con-tinued use, in most cases it is diuretic, keeps the skin timed use, in most cases it is diuretic, keeps the skin moist and perspirable, and improves the appetite and health. Its effects on the bowels are variable. On the whole, a tendency to costiveness seems to be the more general consequence of a long course of this medicinal spring, and therefore the use of a mild aperient is requisite. These effects, however, are applicable only to invalids; for healthy persons who taste the water at

The season for the Hot-Well is generally from the middle of May to October: but as the medicinal pro-perties of the water continue the same throughout the year, the summer months are preferred merely on account of the concomitant benefits of air and exercise.

It should be mentioned, that another spring, nearly resembling the Hot-Well, has been discovered at Clifton, which is situated on the summit of the same hill, from the bottom of which the Hot-Well issues. The water of Ston-Spring, as it is called, is one or two degrees colder than the Hot-Well; but in other respects it sufficiently resembles it to be employed for all similar

BRITANNICA HERBA. See Rumex hydrolapathum,

and Arctium lappa.
BRITA'NNICUS. British. Applied to plants which

grow in this country, and to some remedies.

BRITISH GUM. When starch is exposed to a temperature between 6000 and 7000 it swells, and exhales peculiar smell; it becomes of a brown colour, and in that state is employed by calico-printers. It is so-luble in cold water, and does not form a blue compound with iodine. Vauquelin found it to differ from gum in affording oxalic instead of mucous acid, when treated with nitric acid.—Brande's Manuel, iii. 34.

British Oil. A variety of the black species of pe-

troleum, to which this name has been given as an

empirical remedy

BROCATELLO. A calcareous stone or marble, composed of fragments of four colours, white, gray,

yellow, and red. BRO'CCOLL

composed of fragments of four colours, white, gray, yellow, and red.

BRO'CCOLL Brassica Italica. As an article of diet, this may be considered as more delicious than cauliflower and cabbage. Sound stomachs digest broccoli without any inconvenience; but in dyspeptic stomachs, even when combined with pepper, &c. it always produces flatulency, and nauseous eructations. Brochos. (Βροχος, a snare.) A bandage.

Bro'Chthus. (From βρεχω, to pour.) The throat; also a small kind of drinking vessel.

Bro'Chtes. Βροκος. One with a prominent upperlip, or one with a full mouth and prominent teeth.

BROCKLESBY, Richard, was born in Somersetshire, though of an Irish family, in 1722. After studying at Edinburgh, he graduated at Leyden; then settled in London, but did not advance very rapidly in practice. About 1757, he was appointed physician to the army in Germany, and on his return after six years, published the result of his experience, in a work entitled "Economical and Medical Observations." His success now became more decided, and being prudent in his affairs, and without a family, he realized a considerable fortune. He proved himself however sufficiently liberal by presenting 1000l. to Mr. Edmund Burke, who had been his school-fellow; and by offering an annuity of 100l. to Dr. Johnson, to enable him to travel, which was not however accepted. He was author of several other works, and died in 1797.

ing an annuity of 10w. to Dr. Johnson, to enable him to travel, which was not however accepted. He was author of several other works, and died in 1797.

Bro'Dium. A term in pharmacy, signifying the same with jusculum, broth, or the liquor in which any thing is boiled. Thus, we sometimes read of brodium salis, or a decoction of salt.

BRO'MA. (From βρωσκω, to eat.) Food of any kind that is masticated, and not drank.

BROMA-THEON. (From βρωσκω, to eat.) Mushrooms. BROMATO LOGY. (Bromatologia; from βρωμα, food, and λογος, a discourse.) A discourse or treatise

BROME'LIA. (So named in honour of Olaus Bromel, a Swede, author of Lupologia, &c. in 1687.) The name of a genus of plants. Class, Hexandria.

The name of a genus of plants. Class, Hexandria. Order, Monogynia.

Bromelia ananas. The systematic name of the plant which affords the pine-apple, Bromelia:—foliis eiltato spinosis, mucronatis, spica comosa of Linnæus It is used principally as a delicacy for the table, and is also given with advantage as a refrigerant in fevers.

Bromelia karatas. The systematic name of the plant from which we obtain the fruit called penguin, which is given in the Spanish West Indies to cool and quench thirst in fevers, dysenteries, &c. It grows in a cluster, there being several of the size of one's finger together. Each portion is clothed with husk containing a white pulpy substance, which is the eatable part; and if

it be not perfectly ripe, its flavour resembles that of the | which detonates by percussion. The acid of the bropine-apple. The juice of the ripe fruit is very austere, and is made use of to acidulate punch. The inhabitants of the West Indies make a wine of the penguin,

which is very intoxicating, and has a good flavour.

BROMFIELD, WILLIAM, was born in London,
1712; and attained considerable reputation as a surgeon. At the age of twenty-nine he began to give anatomical lectures, which were very well attended.

About three years after, in conjunction with the Rev.

Mr. Madan, he formed the plan of the Lock Hospital;

and so ably enforced the advantages of such an institution, that a sufficient fund was raised for erecting the present building; and it has been since maintained by voluntary contributions. He was appointed surgeon, and held that office for many years: he was also surgeon to St. George's Hospital, and to Her Majesty's household. He wrote many works; the most con-siderable was entitled "Chirurgical Cases and Observations," in 1773, but reckoned not to answer the expectations entertained of him. He attained his eightieth year. [BROMINE.

In 1826, M. Balard of Montpelier discovered in sea-water a new substance, to which he gave the name muride; but it has since been changed to bromine, a word derived from the Greek βεωμος

(graveolentia) signifying a strong or rank odour.

Bromine exists in sea-water in the form of hydro bromic acid. It is present, however, in very small quantity; and even the uncrystallizable residue called bittern, left after the muriate of soda has been separated from sea-water by evaporation, contains but little of it. On adding chlorine to this liquid, an orange yellow tint appears; and on heating the solution to the boiling point, the red vapours of bromine are expelled, which may be condensed by a freezing mixture. A better process is to transmit a current of chlorine gas through the bittern, and then to agitate a portion of wther with the liquid. The wther dissolves the whole of the bromine, from which it receives a beautiful hyacinth red tint, and on standing, rises to the surface. When the ethereal solution is agitated with caustic potassa, its colour entirely disappears, and on evaporation, cubic crystals of the hydro-bromate of potassa are deposited. On mixing these crystals, reduced to powder, with pure peroxide of manganese, and adding sulphuric acid diluted with its volume of water, the bromine is disengaged in a gaseous state. A small receiver, nearly filled with water, is attached to the retort, the beak of which and the receiver are kept cool by a frigorific mixture. The bromine condenses in the beak, runs into the receiver, and falls to the bottom on account of its great specific gravity. It is slightly soluble, but the water in its immediate vicinity soon becomes saturated. The water is decanted, and the remainder distilled with chloride of calcium, by which the bromine is obtained in a liquid state.

M. Balard has also detected bromine in marine

plants which grow on the shores of the Mediterranean, and has procured it from the ashes of the sea weeds that furnish iodine. He has likewise found it in the

ashes of some animals, especially in those of the janthina violacea, one of the testaceous mollusca.

Bromine at common temperature is a liquid, the colour of which is blackish red, when viewed in mass and by reflected light, but appears hyacinth red when a thin stratum is interposed between the light and the observer. Its odour, which somewhat resembles that of chlorine, is very disagreeable; and its taste powerof chlorine, is very disagreeable; and its taste powerful. It acts with energy on organic matters, such as wood or cork, and corrodes the animal texture; but if applied to the skin for a short time only, it communicates a yellow stain less intense than that from iodine, and which soon disappears. It is highly destructive to animals: one drop of it placed on the beak of a bird proves fatal.—Webster's Man. of Chem. A.]

[Bronic actd. Bromine unites with oxygen and forms Bromic acid, which may be obtained in a separate state by decomposing a dilute solution of the bromate of baryta with sulphuric acid. From the analy-

mate of baryta with sulphuric acid. From the analy-

mate of baryta with sulphuric acid. From the analysis of the bromate of potassa, it appears to consist of 1 atom of bromine +5 atoms oxygen.

The bromates are analogous to the chlorates and iodates. Thus the bromate of potassa is converted by heat into the bromuret of potassium, with discussion of pure oxygen, deflagrates when thrown on burning coals, and forms with sulphur a mixture 152

"Bronchocele is said to have been cured by iodine; for which see that article. A.]

BRONCHOS. (Βρογχος, the windpipe.) A catarrh; a suppression of the voice from a catarrh.

BRONCHOTOMY. (Bronchotomia; from βρογχος, the windpipe, and τεμίνω, to cut.) Tracheotomy; Laryngotomy. This is an operation in which an

mates is decomposed by hydro-bromic and muriatic acids.—Webst. Man. of Chem. A.]

Bro'Mion. (From βρωμος, the oat.) The name of a plaster, made with oaten flour, mentioned by Paulus

BRO'MUS. (From βρωμα, food.) The name of a genus of plants in the Linnwan system. Class, Triandria; Order, Digynia. Brome-grass.

BROMUS STERILIS. (From βρωσκω, to eat.) The

Appertaining to the windpipe, or bronchia; as bronchial gland, antery, &c.
BRONCHIA'LIS. See Bronchial.

Bronchial arteries,-BRONCHIALES ARTERIE. Branches of the aorta given off in the chest.

Branches of the aorta given off in the chest.

Branches Glanbulz. Bronchial glands.—

Large blackish glands, situated about the bronchia and trachea

and trachea.

BRONCHOCE LE. (From βρογχος, the windpipe, and κηλη, a tumour.) Botium; Hernia gutturis; Guttur tumidum; Trachelophyma; Gossum; Exechebronchos; Gongrona; Hernia bronchialis; Tracheocele. Derbyshire neck. This disease is marked by a tumour on the fore-part of the neck, and seated between the trachea and skin. In general, it has been supposed principally to occupy the typoria gland. We are given to understand that it is a very common disgiven to understand that it is a very common disorder in Derbyshire; but its occurrence is by no means frequent in other parts of Great Britain, or in Ireland. Among the inhabitants of the Alps, and other mountainous countries bordering thereon, it is a disease very often met with, and is there known by the name of goitre. The cause which gives rise to it, is by no means certain, and the observations of different writers are of very little practical utility. Dr. Saunders controverts the general idea of the bronchocele being produced by the use of snow water. The swelling is at first without pain, or any evident fluctuation; when the disease is of long standing, and the swelling considerable, we find it in general a very difficult matter to effect a cure by medicine, or any external applica-tion; and it might be unsafe to attempt its removal with a knife, on account of the enlarged state of its arteries, and its vicinity to the carotids; but in an early stage of the disease, by the aid of medicine, a cure may be effected.

Although some relief has been obtained at times, and the disease probably somewhat retarded by external applications, such as blisters, discutient embrocations, and saponaceous and mercurial plasters, still a com-plete cure has seldom been effected without an in replete cure has seldom been effected without an in urnal use of medicine; and that which has always proved the most efficacious, is burnt sponge. The form ander which this is most usually exhibited, is that of a lozenge. R. spongiæ ustæ 3 ss. mucilag. Arab tam. q. s. fiat trochiscus. When the tumour appears about the age of puberty, and before its structure has been the age of puberty, and before its structure has been too morbidly deranged, a pill consisting of a grain or two of calomel, must be given for three successive nights; and, on the fourth morning, a saline purge. Every night afterward, for three weeks, one of the troches should, when the patient is in bed, be put under the tongue, suffered to dissolve gradually, and the solution swallowed. The disgust at first arising from this remedy soon wears off. The pills and the purge are to be repeated at the end of three weeks, and the troches had recourse to as before; and this plan is to be pursued till the tumour is entirely dispersed. Some recommend the burnt sponge to be administered in larger doses. Sulphuretted potassa dissolved in water, in the proportion of 30 grains to a quart daily, is a in the proportion of 30 grains to a quart daily, is a remedy which has been employed by Dr Richter with success, in some cases, where calcined sponge failed. The sode subcarbonas being the basis of burnt sponge, is now frequently employed instead of it, and, indeed. it is a more active medicine.

BRO BRO

opening is made into the larynx, or trachea, either for the purpose of making a passage for the air into and out of the lungs, when any disease prevents the patient from breathing through the mouth and nostrils, of his fellow-citizens have retained his valuable seror of extracting foreign bodies, which have accidentally fallen into the trachea; or, lastly, in order to be able to inflate the lungs, in cases of sudden suffocation, drowning, &c. Its practicableness, and little danger, are founded on the facility with which certain wounds of the windpipe, even of the most complicated kind, have been healed, without leaving any ill effects whatever, and on the nature of the parts cut, which

kind, have been healed, without leaving any ill effects whatever, and on the nature of the parts cut, which are not furnished with any vessel of consequence.
BRO'NCHUS. (From βρεχω, to pour.) The ancients believed that the solids were conveyed into the stomach by the asophagus, and the fluids by the bronchia; whence its name.
1. The windpipe.
2. A defluxion from the fauces. See Catarrhus.
BRONZE. A mixed metal consisting chiefly of copper, with a small portion of tin, and sometimes other metals.

BRONZITE. A massive metal-like mineral, fre-quently resembling bronze, found in large masses in

quently resembling bronze, found in large masses in beds of serpentine in Upper Stiria, and in Perthshire. BROOKLIME. See Veronica beccabunga.

[BROOKS, John, M.D. LL.D. The honourable John Brooks was born in Medford, Massachusetts, in the year 1752. His father, Captain Caleb Brooks, was a respectable independent farmer, and the son spent his earliest years in the usual occupations of a farm. He received no education preparatory to his professional studies, but that of the town school; at which, however, he was able to acquire sufficient of the learned languages to qualify him for the profession. the learned languages to qualify him for the profession of medicine. At the age of fourteen, he was placed under the tuition of Dr. Simon Tufts, of Medford, by a written indenture as an apprentice for seven years;

this being the usual custom of that day.

Having finished his studies, he chose the neighbouring town of Reading as his residence, and commenced his practice there. But by this time, the storm of the revolutionary war was gathering; and, as its distant thunders rolled towards our shores, the hearts of the gallant youth of our country responded to the sound, and preparations for the field superceded the minor

concerns of life.

Dr. Brooks accordingly entered into the military service of his country. As a Captain, he first exhibited his bravery in his attack upon the British at Lexington, in the neighbourhood of Boston. He shortly after received the commission of Major in the Continental army, as it was then called. In 1777, he was promoted to the rank of Colonel, and was a very efficient officer in the battles of Saratoga, which resulted in the capture of Burgoyne. In the battle of Monmouth, in New-Jersey, he was acting Adjutant-General, and on this, as on all occasions, conducted with great coolness and bravery, through the whole of the great coolness and bravery, through the whole of the

revolutionary war.

After the war, he recommenced the practice of After the war, he recommenced the practice of physic, and continued for many years in high estimation as a practitioner. It is said of him, that, "As a physician, he ranked in the first class of practitioners. He possessed in an eminent degree those qualities which were calculated to render him the most useful in his professional labours, and the delight of those to whom he administered relief. His manners were dignified, courteous, and benign. He was kind, patient, and attentive. His kind offices were peculiarly acceptable from the felicitous manner in which he performed them. His mind was well furnished with formed them. His mind was well furnished with scientific and practical knowledge. He was accurate in his investigations, and clear in his discernment. He therefore rarely failed in forming a true diagnosis. If he were not so bold and daring as some, in the administration of remedies, it was because his judgment and good sense led him to prefer erring on the side of prudence, rather than on that of rashness. He

of his fellow-citizens have retained his valuable services; but they forbore urging him to any farther sacrifices for the good of his country. He retired to private life with dignity, and with the love and blessings of a grateful people." He died in March, 1825, in the 73d year of his age.—See Thack. Med. Biog. A.] BROOM. See Spartrum scoparium.

BROSIMUM. (From βρωσιμος, eatable.) The name of a genus of plants in the Linnæan system. Class, Diæcia; Order, Monandria.

BROSIMUM ALICASTRUM The specific name of the tree, which affords the bread-nut.

BROWN, JOHN, born in the county of Perwick in

BROWN, John, born in the county of Berwick, in EROWN, John, both in the county of Berwick, in 1735. He made very rapid progress in his youth in the learned languages, and at the age of twenty went to Edinburgh to study theology; but before he could be ordained, became attached to free living and free thinking. About 1759, having translated the inaugural thesis of a medical candidate into Latin, and the performance being highly appliauded, he was led to the study of medicine. The professors at Edinburgh allowed him to attend their lectures gratuitously; and he maintained himself by instructing the students in Latin, and composing or translating their dissertations. Dr. Cullen particularly encouraged him, notwithstanding his irregularities, employing him as tutor to his sons, and allowing him to repeat and enlarge upon his lectures in the evening, to those pupils who chose to attend. In 1765 he married, and his house was soon filled with boarders; but his imprudence brought on bankruptcy within four years after. About this period he was an unsuccessful candidate for one of the medical chairs; and attributing his failure to Dr. Cullen, became his declared enemy. This probably determined him to form his new system of medicine, afterward published under the title of "Elementa Medicine:" in which certainly much genius is displayed, cine:" in which certainly much genius is displayed, but little acquaintance with practice, or with what had been written before on the subject. His chief object seems to have been to reduce the medical art to the utmost simplicity: whence he arranged all diseases under the two divisions of sthenic and asthenic, and maintained that all agents operate on the body as stimuli; so that we had only to increase or diminish the force of these according to circumstances. At the head of his stimulant remedies, he places wine, brandy, and opium, in the recommendation of which he is very liberal; and especially betrays his partiality to them by asserting, contrary to universal experience, that he found them in his own person the best pre-servatives against the gout. He is said to have pre-pared himself for his lectures by a large dose of laudanum in whiskey; and thus roused himself to a de-gree of enthusiasm bordering on frenzy. After completing his work, he procured a degree from St. Andrew's, and commenced public teacher. The novelty and imposing simplicity of his doctrines procured him at first a pretty numerous class; but being irregular in his attendance, and his habits of intemperance increasing, they fell off by degrees; and he was at length so embarrassed, as to be obliged to quit Edinburgh in 1788. He they satisfied in London har real with little. 1786. He then settled in London, but met with little success, and in about two years after died. His opisuccess, and in about two years after died. His optimions at first found many supporters, as well in this as in other countries; but they appear now nearly fallen into deserved oblivion.

BROWN SPAR. Pearl spar. Sideroculcite. A white, red, or brown, or black spar; harder than the calcargous but yields to the knife.

white, red, or brown, or black spar; harder than the calcareous, but yields to the knife.

BROWNE, Sta Thomas, was born in Cheapside, 1605. After studying and practising for a short time at Oxford, he spent about three years in travelling, graduating at length at Leyden. He then came to London, and published his "Religio Medici;" which excited great attention as a work of genius, though blemished by a few of the popular superstitions then prevailing. He soon after settled at Norwich, and got into very good practice; and was admitted an honorary member of the London College of physicians. In 1646 appeared his most popular work "On Vulgar Errors," which added greatly to his fame; though he injudiciously ranked the Copernican system among side of prudence, rather than on that of rashness. He watched the operations of nature, and never interfered unless it was obvious he could aid and support her. He was truly the 'Hierophant of Nature,' studying her mysteries, and obeying her oracles."

Dr. Brooks became so great a favourite of his countrymen, that he was finally elected Governor of the state of Massachusetts. Dr. Thacher says of him:—
"Having faithfully and ably discharged the duties of chief magistrate for seven successive years, he

was also a physician, and attained considerable emi-nence, having had the honour of attending Charles II. and William III., and being for three years president

of the college.

(BRUCE, ARCHIBALD, M.D. A native of New-York, born in 1777, during the revolutionary war. He studied physic under Dr. Hosack, visited Europe, and graduated at Edinburgh in the year 1800. During and graduated at Edinburgh in the year 1800. During a tour of two years in France, Switzerland, and Italy, Dr. Bruce collected a mineralogical cabinet of great value and extent. Upon his return to England, he married in London, and came out to New-York in the summer of 1803, to enter upon the duties of a practitioner of medicine. In 1807, he was appointed professor of Materia Medica and Mineralogy, in the College of Physicians and Surgeons of New-York. In 1810, he commenced the editorship of a Journal of American Mineralogy, after the manner of the well-American Mineralogy, after the manner of the well known work issued by the School of Mines, at Paris. It met with becoming success, and had many valuable contributors to its pages; but owing to various causes, was never carried beyond the completion of the first volume. The Mineralogical Journal contributed materially to extend the fame of Dr. Bruce, as well as his discovery of the hydrate of magnesia, at Hoboken.
He died in February, 1818, in the 41st year of his age.
—See Thach. Med. Biog. A.]
BRU CEA. (So named by Sir Joseph Banks, in

honour of Mr. Bruce, the traveller in Abyssinia, who first brought the seeds thence into England.) The name of a genus of plants in the Linnæan system. Class, Diæcia: Order, Tetrandria.

BRUCEA ANTIDYSENTERICA. The systematic name

of the plant from which it was erroneously supposed we obtained the Angustura bark. See Cusparia.

BRUCEA FERRUGINEA. This plant was also sup-

posed to afford the Angustura bark.

BRUCIA. Brucine. A new vegetable alkali, lately extracted from the bark of the false Angustura, or Brucia antidysenterica, by Pelletier and Caventou. After being treated with sulphuric ather, to get rid of a fatty matter, it was subjected to the action of alkohol. The dry residuum, from the evaporated alkoholic solution, was treated with Goulard's extract, or setate of lead to threat days the colour. solution of acetate of lead, to throw down the colouring matter, and the excess of lead was separated by a current of sulphuretted hydrogen. The nearly colour-less alkaline liquid was saturated with oxalic acid, and evaporated to dryness. The saline mass being freed from its remaining colouring particles by absolute alkohol, was then decomposed by lime or magnesia, when the brucia was disengaged. It was dissolved in when the brucia was disengaged. It was this product was boiling alkohol, and obtained in crystals, by the slow evaporation of the liquid. These crystals, when obtained by very slow evaporation, are oblique prisms, the bases of which are parallelograms. When depothe bases of which are parallelograms. When desited from a saturated solution in boiling water, cooling, it is in bulky plates, somewhat similar to bo-racic acid in appearance. It is soluble in 500 times its weight of boiling water, and in 850 of cold. Its solu-bility is much increased by the colouring matter of the

Its taste is exceedingly bitter, acrid, and durable in the mouth. When administered in doses of a few grains, it is poisonous, acting on animals like strychnia, but much less violently. It is not affected by the air. The dry crystals fuse at a temperature a little above that of boiling water, and assume the appearance of wax. At a strong heat it is resolved into car-bon, hydrogen, and oxygen; without any trace of azote. It combines with the acids, and forms both

neutral and super-salts.

BRUCINE. See Brucia.

BRUISEWORT. See Saponaria.

BRUMALIS. (From Bruma, winter.) Hyemalis.

Belonging to winter. Plants which flower in our BRUMALLES PLANTE.

winter, common about the cape.

BRUNE'LLA. See Pranella. BRUNNER, JOHN CONRAD, was born in Switzerland BRUNNER, JOHN CONRAD, Was born in Switzerland in 1653. He obtained his degree in medicine at Strasburg when only nineteen. He afterward spent several years in improving bimself at different universities, particularly at Paris; where he made many experiments on the pancreas, and found that it might be removed from a dog with impunity. On his return he was made professor of medicine at Heidelburg; and

gained great reputation, so as to be consulted by most of the princes of Germany. He discovered the mucous glands in the duodenum; and was author of several inconsiderable works. He died in 1727.

Brunner's glands. Brunneri glandulæ. Peyer's glands. The muciparous glands, situated between the villous and cellular coat of the intestinal canal; so

named after Brunner, who discovered them.
BRUNSWICK GREEN. An ammoniaco-muriate

of copper.

BRUNTKUP FERZ. Purple copper ore.

BRU'NUS. An erysipelatous eruption.
BRU'SCUS. See Ruscus.
BRUT'A. An Arabian word which means instinct,

and is also applied to Savine.

BRU'TIA. An epithet for the most resinous kind of BRU'TIA. An epithet for the most resinous kind of pitch, and therefore used to make the Oleum Picinum. The Piz Brucia was so called from Brutia, a country in the extreme parts of Italy, where it was produced.

BRUTI'NO. Turpentine.

BRUTOBON. The name of an ointment used by the

BRUTUA. See Cissampelos Pareira.
BRUXANZ'LI. (Indian.) A tall tree in Malabar, the
bark of which is diuretic.

BRY'SMUS. (From βρυχω, to make a noise.) A peculiar kind of noise, such as is made by gnashing or grating the teeth; or, according to some, a certain kind of convulsion affecting the lower jaw, and striking the teeth together, most trequently observed in such children as have worms.

BRYO'NIA. (From βρυω, to abound, from its abundance.) Bryony. 1. The name of a genus of plants in the Linnæan system. Class, Diacia; Order,

Syngenesia.
2. The pharmacopœial name of the white bryony.

See Bryonia alba.

Bryonia Alba. The systematic name of the white bryony plant. Vitis alba sylvestris; Agrostis; Anpelo sagria; Archeostris; Echetrosis of Hippocrates. peto sagria; Archeostris; Echetrosis of Hippociates.
Bryonia aspera; Cedrostis; Chelidonium; Labrusca;
Melothrum; Ophrostaphylon; Psilothrum. Bryonia
—foliis palmatis utrinque calloso-scabris of Linnæus.
This plant is very common in woods and hedges. The root has a very nauseous biting taste, and disagreeable smell. Bergius states the virtues of this root to be purgative, hydragogue, emmenagogue, and diuretic; the fresh root emetic. This powerful and irritating cathartic, though now seldom prescribed by physicians, is said to be of great efficacy in evacuating serous humours, and has been chiefly employed in hydropical cases. Instances of its good effects in other chronic diseases are also mentioned; as asthma, mania, and epilepsy. In small doses, it is reported to operate as a diuretic, and to be resolvent and deobstruent. In powder, from Dj. to a drachm, it proves strongly purgative, and the juice, which issues spontaneously, in doses of a spoonful or more, has similar effects, but is doses of a spoonful or more, has similar effects, but is more gentle in its operation. An extract prepared by water, acts more mildly, and with greater safety, than the root in substance, given from half a drachm to a drachm. It is said to prove a gentle purgative, and likewise to operate powerfully by urine. Of the expressed juice, a spoonful acts violently both upwards and downwards; but cream of tartar is said to take off its virulence. Externally, the fresh root has been employed in cataplasms, as are solvent and discutient: also in ischiadic and other rheumatic affections.

BRYONIA MECHOACHANA NIGRICANS. A name given

BRYONIA MECHOACHANA NIGRICANS. A name given

to the jalap root.

BRYONIA NIGRA. See Tamus communis. BRYONIA NIGRA. See Tamus communis.
BRYONY. See Bryonia nigra.
Bryony, black. See Tamus.
Bryony, white. See Bryonia alba.
BRY'THION. Βρυθιον. A malagma; so called and described by Paulus Ægineta.
BRY'TON. (From βρυω, to pour out.) A kind of ale, or wine, made of barley.

or wine, made of barley.

BUBASTECO'RDIUM. (From bubastus and cor, the heart.) A name formerly given to artemisia, or mug-

BU BO. (From βουδων, the groin; because they most frequently happen in that part.) Modern surgeous mean, by this term, a swelling of the lymphatic glands, particularly of those of the groin and axilla. The disease may drise from the mere irritation of sums

local disorder, when it is called sympathetic bubo; from

local disorder, when it is called sympathetic bubo; from the absorption of some irritating matter, such as the venereal poison; or from constitutional causes, as in the pestilential bubo, and scrophulous swellings, of the inguinal and axillary gland.

BUBON. (Prom βουδων, the groin, or a tumour to which that part is liable, and which it was supposed to cure.) The name of a genus of plants in the Linnaan system. Class, Pentandria; Order, Digynia.

BUBON GALBANUM. The systematic name of the plant which affords the officinal galbanum. Albetad; Chalbane; Gesor. The plant is also named Ferula Africana; Orcoselinum Africanum; Anisum fruticosum galbaniferum; Anisum Africanum fruticescens; Ayborzat. The lovage-leaved bubon. Bubon;—foliis rhombeis dentatis striatis glabris, umbellis paucis, of rhombets dentatis striatis glabris, umbellis paucis, of Linnæus. Galbanum is the gummi-resinous juice, obtained partly by its spontaneous exudation from the joints of the stem, but more generally, and in greater abundance, by making an incision in the stalk, a few inches above the root, from which it immediately issues, and soon becomes sufficiently concrete to be gathered. It is imported into England from Turkey, and the East Indies, in large, softish, ductile, pale-coloured masses, which, by age, acquire a brownish-yellow appearance; these are intermixed with distinct whitish tears. whitish tears, that are the most pure part of the mass. Galbanum has a strong unpleasant smell, and a warm, bitterish, acrid taste. Like the other gummy resins, it unites with water, by trituration into a milky liquor, but does not perfectly dissolve, as some have reported, in water, vinegar, or wine. Rectified spirit takes up much more than either of these menstrua, but not the whole; the tincture is of a bright golden colour. A mixture of two parts of rectified spirit, and one of water, dissolves all but the impurities, which are commonly in considerable quantity. In distillation with water, the oil separates and rises to the surface, in colour yellowish, in quantity one-twentieth of the whitish tears, that are the most pure part of the mass. colour yellowish, in quantity one-twentieth of the weight of the galbanum. Galbanum, medicinally con-sidered, may be said to hold a middle rank between assafætida and ammoniacum; but its fætidness is very inconsiderable, especially when compared with the former: it is therefore accounted less antispasmodic, nor are its expectorant qualities equal to those of the latter: it however is esteemed more efficacious than either in hysterical disorders. Externally, it is often applied, by surgeons, to expedite the suppuration of inflammatory and indolent tumours, and, by physicians, as a warm stimulating plaster. It is an ingredient in the pilula galbani composite, the emplastrum galbani compositum of the London Pharmacoposia, and in the malastrum garmmasum of the Edinburgh.

emplastrum gummosum of the Edinburgh.

Bubon Macenonicum. The systematic name of the plant which affords the semen petroselini Macedonici of the shops. Apium petraum; Petrapium. Macedonian parsley. This plant is similar in quality to the common parsley, but weaker and less grateful. The seeds enter the celebrated compounds mithridate and

theriaca.

Bubo'nium. (From βουβων, the groin.) A name of the golden starwort; so called because it was supposed to be efficacious in diseases of the groin.

BUBONOCE LE. (From $\beta o \nu \delta \omega \nu$, the groin, and $\kappa \eta \lambda \eta$, a tumour.) Hernia inguinalis. Inguinal hernia, or rupture of the groin. A species of hernia, in which the bowels protrude, at the abdominal ring. See Hernia inguinalis. BU'CCA. (Hebrew.)

The cheek. The hollow inner part of the cheek, that is inflated by the act of

Buccacka' τον. (From bucca, or buccella, and κραω, to mix.) A morsel of bread sopped in wine, which served in old times for a breakfast.

BU'CCAL. (From bucca, the cheek.) Belonging

Buccinales Glandulæ. The small glands of the mouth, under the cheek, which assist in secreting saliva into that cavity.

Buccea. (From bucca, the cheek; as much as can be contained at one time within the checks.) 1. A

mouthful; a morsel.

2. A polypus of the nose.

Buccela Ton. (From buccella, a morsel.) A purging medicine, made up in the form of a loaf; consisting medicine, made up in the form of a loaf; consisting medicine, made up in the form of a loaf; consisting form and then of scammony, &c. put into fermented flour, and then baked in an oven,

Bucce'lla. Paracelsus calls the polypus in the nose by this name, because he supposes it to be a portion of flesh parting from the bucca, and insinuating itself into

Buccella'rio. (From bucellatus, cut into small pieces.) Baccellatio. A method of stopping an hæmorrhage, by applying small pieces of lint to the vein,

or artery.

BUCCINA'TOR. (From βουκανον, a trumpet; so named from its use in forcing the breath to sound the trumpet.) Retractor anguli oris of Albinus, and alveolo-maxillaire of Dumas. The trumpeter's muscle. The buccinator was long thought to be a muscle of the buccinator was long the buccinator w of the lower jaw, arising from the upper alveoli, and inserted into the lower alveoli, to pull the jaw upwards; but its origin and insertion, and the direction of its fibres, are quite the reverse of this. For this large flat muscle, which forms in a manner the walls of the flat muscle, which forms in a manner the walls of the cheek, arises chiefly from the coronoid process of the lower jaw-bone, and partly also from the end of the alveoli, or socket process of the upper-jaw, close by the pterygoid process of the sphenoid bone: it goes forward, with direct fibres, to be implanted into the corner of the mouth; it is thin and flat, covers in the mouth, and forms the walls of the cheek, and is perforated in the middle of the cheek by the duct of the parotid gland. These are its principal uses:—it flattens the cheek, and so assists in swallowing liquids: it turns or helps to so assists in swallowing liquids; it turns, or helps to turn, the morsel in the mouth while chewing, and prevents it from getting without the line of the teeth; in blowing wind instruments, it both receives and expels the wind; it dilates like a bag, so as to receive the wind in the checks; and it contracts upon the wind, so as to expel the wind, and to swell the note. In blowing the strong wind-instruments, we cannot blow from the lungs, for it distresses the breathing, we reserve the air in the mouth, which we keep continually full; and from this circumstance, as mentioned above, it is named buccinator, from blowing the trumpet.

Bu'ccula. (Diminutive of bucca, the cheek.) The fleshy part under the chin.

fleshy part under the chin.

Bucephalon, red-fruited. See Trophis Americana.

Bu'ceras. (From βovs, an ox, and κερας, a horn; so called from the horn-like appearance of its seed.)

Buceros. See Trigonella Fanumgracum.

BUCHAN, WILLIAM, was born at Ancram, in 1729. After studying at Edinburgh, he settled in Sheffield, and was soon appointed physician to the Foundling Hospital at Ackworth: but that establishment being afterward given up, he went to practise at Edinburgh, where he remained several years. During that burgh, where he remained several years. During that period he composed his celebrated work, called "Do-mestic Medicine," on the plan of Tissot's "Avis aux Peuples;" which has been very extensively circulated, translated into other languages, and obtained the author a gold medal, with a commendatory letter, from the Empress of Russia. It has been objected, that such publications tend to degrade and injure the medical profession; but it does not appear, that those who are properly qualified can suffer permanently thereby. There seems more foundation for the opinion, that imaginary diseases will be multiplied, and patients sometimes fall victims to their complaints, being

sometimes fall victims to their complaints, being treated by those who do not properly understand them. Dr. Buchan afterward practised in London, and published some other works; and died in 1805 BUCK-BEAN. See Menyanthes trifoliata. BUCK-THORN. See Rhamnus catharticus. BUCK-WHEAT. See Polygonum fagopyrum. Buck-wheat, eastern. See Polygonum divaricatum. BUCNEMIA. (Bucnemia; from 600, a Greek augment, and κνημη, the leg.) A name in Good's Nosology for a genus of disease characterized by a tense, diffuse, inflammatory swelling of the lower extremity; usually commencing at the inguinal glands, and exusually commencing at the inguinal glands, and extending in the course of the lymphatics, it embraces two speces; 1. Bucnemia sparganosis, the puerperal tumid leg.

Bucnemia tropica, the tumid leg of hot climates.
 Bucra'NION. (From βους, an οχ, and κρανιον, the head; so called from its supposed resemblance to a calf's snout.) The Snap-dragon plant. See Antir

Bu'cron. The hymen, according to Pirgus.

BUGLE. See Pranella.
[Bugle weed. This plant is the Lycopus Vir-

pinica. It has of late been popular as a remedy in bleeding from the lungs, taken freely in the form of decoction. It is not, however, introduced as a medicinal plant into the American Pharmacopæia, nor in Bigelow's Materia Medica. Physicians in general place little confidence in its efficacy. A.]

BUGLOSS. See Anchusa officinalis.
BUGLO'SSA. See Anchusa officinalis.
BUGLO'SSUM. (Buglossum, i. n.; from βους, an ox, and γλωσσα, a tongue: so called from the shape and roughness of its leaf.) See Anchusa officinalis.

BUGLOSSUM ANGUSTIFOLIUM. See Anchusa offici-

Buglossum majus. See Anchusa officinalis. BUGLOSSUM SATIVUM. See Anchusa officinalis. BUGLOSSUM SYLVESTRE. The stone bugloss.

BU GULA. (A diminutive of buglossa.) See Ajuga

[BUHRSTONE. Millstone. "The exterior aspect of this mineral is somewhat peculiar. It occurs in amorphous masses, partly compact, but always containing a greater or less number of irregular cavities. Sometimes the mass is comparatively compact, and the cavities small and less frequent, but they always exist even in specimens of a moderate size. These cavities are sometimes crossed by siliceous threads or membranes, much resembling the interior structure of certain bones; and are sometimes lined by siliceous incrustations, or crystals of quartz.

Its fracture is nearly even, sometimes dull, and sometimes smooth, like that of flint. Its colour is gray or whitish, sometimes with a tinge of blue, and sometimes yellowish or reddish. Near Paris, the Buhrstone occurs in beds, unusually horizontal, and seldom more than 9 or 10 feet thick. It contains no organic remains. Its cayities are often crossed by threads, and filled with argillaceous marl or sand; but are very seldom lined by crystals of quartz.

In Georgia, (United States,) the Buhrstone is found near the boundary of South Carolina, about 40 miles from the sea. It is said to cover shell limestone. Some of its cavities are those of shells in a siliceous state, and lined by siliceous incrustations, or crystals of quartz. Others are traversed by minute threads, or contain a friable substance somewhat argillaceous. its hardness and cavities, when not too numerous, render it peculiarly useful for making millstones. Hence also it is sometimes known by the name of Millstone."—See Cleav. Min. A.]

BULBIFERUS. (From bulbus, and fero, to bear.)

Bulb-bearing. Having one or more bulbs; applied to dems. Caulis bulbiferus.

Bulk DOCA STANLIM. (From Solfer a bulb and

BULBOCA'STANUM. (From βολδος, a bulb, and ταςανων, a chesnut: so called from its bulbous appearance.) See Bunium bulbocastanam.
BULBOCAVERNO'SUS. (So called from its ori-

BULBOCAVERNO SCS. (So cancel from its off-gin and insertion.) See Accelerator urina. BULBOSUS. (From bulba, a bulb.) Bulbous: applied in anatomy to soft parts which are naturally enlarged, as the bulbous part of the urethra. In bota-

ny, to roots which have a built; as tulip, onion, lily, &c.

Bulbos &. (From bulbus.) The name of a class of Casalpinus's systematic method, consisting of heroaccous vegetables, which have a bulbous root, and a pericarpium, divided into three cells; also, the name of one of the natural orders of plants.

BULLIUS A little built.

BULBULUS. A little bulb.

BUL'BUS. (Βολδος, a bulb, or somewhat rounded reot.) A globular, or pyriform coated body, solid, or formed of fleshy scales or layers, constituting the lower part of some plants, and giving off radicals from the circumference of the flattened basis. A bulb difference of the flattened basis. fers from a tuber, which is a farinaceous root, and sends off radicles in every direction.

Bulbs are divided into, 1. The solid, which consists of a solid fleshy nutritious substance; as in Crocus sativus, Colchicum au-

tumnale, Tulipa gesneriana.
2. The scaly, which consists of fleshy concentrical scales attached to a radical plate; as in Allium cepa.

3. The squamose, consisting of concave, overlapping

scales: as in Lilium candidum, and Lilium bulbiferum.

4. The compounded, consisting of several lesser bulbs, lying close to each other: as in Allium satirum.

The bulbs of the orchis tribe differ from the common bulbs in not sending off radicles from the lower part, but from between the stem and basis. These are distinguished into,

The testiculate, having two bulbs of a round-oblong form; as in Orchis morio, and Orchis mascula.
6. Palmate, a compressed bulb, hand-like, divided below into finger-like lobes; as in Orchis maculata.
BULBUS ESCULENTUS. Such bulbous roots as are

commonly eaten are so called.

Bulbus vomitorius. See Hyacinthus muscari.

Bulge-Water-Tree. The Geoffroya jamai-

BULI'MIA. (From βov, a particle of excess, and λιμος, hunger.) Bulimiasis; Boulimos; Bulimus; Bolismos of Avicenna. Fames canina; Appetitus caninus; Phagedæna; Adephagia; Bupcina; Cynorexia. Insatiable hunger, or canine appetite.

Dr. Cullen places this genus of disease in the class Locales, and order Dysorexio; and distinguishes three species. 1. Bulimia hellunum; in which there is no other disorder of the stomach, than an excessive craving of food. 2. Bulimia syncopalis; in which there is a frequent desire of food, and the sense of hunger is preceded by swooning. 3. Bulimia emetica, also cynorexia; in which an extraordinary appetite for food is followed by vomiting. The real causes of this disease are, perhaps, not properly understood. In some cases, it has been supposed to proceed from an acid in the stomach, and in others, from a superabundance of acid in the gastric juice, and from indigested sordes, or worms. Some consider it as depending more frequently on monstrosity than disease. An extraordinary and well attested case of this disease, is Dr. Cullen places this genus of disease in the class more frequently on monstrosity than disease. An extraordinary and well attested case of this disease, is related in the third volume of the Medical and Physical Journal, of a French prisoner, who, in one day, consumed of raw cow's utder 4 lbs., raw beef 10 lbs., candles 2 ibs.; total, 16 lbs.; besides 5 bottles of porter.

BULIMIA ADEPHAGIA. A voracious appetite.

BULIMIA CANINA. A voracious appetite, with sub-

sequent vomiting.

BULINIA CARDIALGICA. A voracious appetite, with heartburn.

BULIMIA CONVULSORUM. A voracious appetite, which attends some convulsive diseases.

BULIMIA EMETICA. A voracious appetite, with vomiting.

BULIMIA ESURIGIO. Gluttony.

BULIMIA BELLUONUM. Gluttony.

BULIMIA SYNCOPALIS. A voracious appetite, with fainting from hunger.

BULIMIA VERMINOSA. A voracious appetite from

BULIMI'ASIS. See Bulimia.

BULIMI ASIS. See Butimia.
BULI THUM. (From βους, an ox, and λιθος, a stone.) A bezoar, or stone found in the kidneys, or gall, or urinary bladder, of an ox, or cow.
BULLA. A bubble. A clear vesicle, which arises from burns, or scalds; or other causes.
[This word is also applied by Linnæus to a genus character shells. A.]

of univalve shells. A.]

BU'LLACE. The English name of the fruit of the Prunus insitia of Linnæus, which grows wild in our hedges. There are two varieties of bullace, the red hedges. There are two varieties of bullace, the red and the white, which are used with the same inten-

and the white, which are used with the same intention as the common damsons.

BULLATUS. (From bulla, a bubble, or blister.)

Blistery. Applied to a leaf which has its veins so tight, that the intermediate space appears blistered. This appearance is frequent in the garden cabbage.

BULLO'SA FEBRIS. An epithet applied to the vesicular fever, because the skin is covered with little vericles or blisters. See Percepture.

sicles, or blisters. See Pemphigus.

Buni'tes vinum. (From bunium, wild parsley.)

Wine made of bunium and must.

BU'NIUM. (From βουνος, a little hill; so called from the tuberosity of its root.) I. The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Digynia.

2. The name of the wild parsley.

2. The name of the wind parsiey.

Bunium Bulbocastanum. The systematic name of a plant, the root of which is called the pig-nut.

Agricastanum; Nucula terrestris; Bulbocastaneum; Bulbocastanum majus et minus. Earth-nut; Hawknut; Kipper-nut; and Pig-nut. The root is as large as a nutmeg; hard, tuberous, and whitish; which is eaten raw, or roasted. It is sweetish to the taste, nourishing, and supposed to be of use against strangury

and bloody urine. The roots, which are frequently ploughed up by the peasants of Burgundy, and called by them arnotta; and those found in Scotland, and ing out the power of the part. If any extraneous subcalled arnots, are most probably the roots of this species of bunium. They are rousted, and thus acquire the flavour of chesnuts.

Bu'nus. A species of turnip.
Bu'PEINA. (From βου, a particle of magnitude, and πεινα, hunger.) A voracious appetite.
Bu'PHAGOS. (From βου, a particle of excess, and φεγω, to eat.) The name of an antidote which created

Paracious appetite in Marcellus Empericus.

BUPHTHA LMUM. (From βους, an ox, an οφθαλμος, an eye; so called from its flowers, which are supposed to resemble an eye.) The herb, ox-eye daisy. See Chrysanthemum leucanthemum.

BUPHTHALMUM CRETICUM. Pellitory of Spain. See

Anthemis pyrethrum.

BUPHTHALMUM GERMANICUM. The common ox-eye

BUPHTHALMUM MAJUS. Great, or ox-eye daisy.

See Chrysanthemum teucanthemum.
BUPHTHALMUS. (From βους, an ox, and οφθαλμος, an eye; so named from its large appearance like an ox's eye.)

1. Houseleek.

 Houseleek.
 Diseased enlargement of the eye.
 BUBLEU'RUM. (From βον, large, and ωλευρον, a rib; so named from its having large rib-like filaments upon its leaves.)
 The name of a genus of plants in the Linnaun system. Class, Syngenesia; Order, Polygamia superflue.

2. The pharmacopoial name of the herb hare's ear.

See Bupleurum rotundifolium.

BUPLEURUM ROTUNDIFOLIUM. The systematic name of the plant called perfoliata, in some pharmacopeias.

Bupleuron; Bupleuroides. Round-leaved hare's ear, or thorow wax. This plant was formerly celebrated for curing ruptures, mixed into a poultice with wine and oatmeal.

BU'RDOCK.

BU'RDOCK. See Arctium lappa. BU'RGUNDY PITCH. See Pinus abies. Bu'Ris. According to Avicenna, a scirrhous hernia,

or hard abscess.

BURN. Ambustio. A burn, or scald, is a lesion of the animal body, occasioned by the application of heat, but the latter term is applicable only where this is conveyed through the medium of some fluid. The conveyed through the medium of some fluid. The consequences are more or less serious according to the extent of the injury, or the particular part affected: sometimes even proving fatal, particularly in irritable constitutions. The life of the part may be at once destroyed by those accidents, or mortification speedily follow the violent inflammation excited; but when slighter, it usually produces an effusion of serum under the cuticle, like a blister. When the injury is extensive, considerable fever is apt to supervene, sometimes a comatose state; and a remarkable difficulty of times a comatose state; and a remarkable difficulty of breathing often precedes death. In the treatment of these accidents, two very different methods have been pursued. The more accient plan consists in antiphlogistic means, giving cooling purgatives, &c. and even taking blood, where the irritation is great; employing at the same time cold applications, and where the skin is destroyed, emollient dressings; opium was also recommended to relieve the pain, notwithstanding stupor might attend.

Mr. Cleghorn, a brewer at Edinburgh, was very successful in these cases by a treatment materially different; first bathing the part with vinegar, usually a little warmed, till the pain abated; then, if there were any destruction of the parts, applying poultices, and finely powdered chalk immediately on the sore, to absorb the discharge: in the meantime allowing the patient to live pretty well, and abstaining from active purgatives, &c. More recently, a surgeon at Newcastle, of the name of Kentish, has deviated still more from the ancient practice; applying first oil of turpentine, alkohol, &c. practice; applying first oil of turpentine, alkohol, &c. heated as much as the sound parts could bear, and gradually lessening the stimulus; in the mean time supporting the patient by a cordial diet, ether, &c. and giving opium largely to lessen the irritation. Now, the cases chiefly under his care were of persons scorched very extensively by the explosion of carburetted hydrogen in mines; and probably where the injury is over a large part of the surface, or where the constitution is weakly, it may be hazardous to pursue constitution is weakly, it may be hazardous to pursue

ing out the power of the part. If any extraneous sub-stance be forced into the burnt part, it should be of course removed: and sometimes where a limb is irrecoverably injured, amputation may be necessary.

BU'RNEA. Pitch.

BURNEA. PHEN.

Burnet saxifrage. See Pimpinella.

BURNING. Brenning. An ancient medical term, denoting an infectious disease, got in the stews by conversing with lewd women, and supposed to be the version what wa now call the venereal disease. same with what we now call the venereal disease.

Burnt hartshorn. See Cornu ustum.

Burnt sponge. See Spongia usta.

Bu'rrhus's spirit, for disorders of the womb. A compound of myrrh, olibanum, amber, and spirit of wine.

BU'RSA. From βυρσα, a bag.) A bag. 1. The

scrotum.

An herb called Thlaspi bursæ pastoris, from the re-semblance of its seminal follicles to a triangular purse.

BURSA MUCOSA. A mucous bag, composed of pro-per membranes, containing a kind of mucous fat, formed by the exhaling arteries of the internal coat. The bursæ mucosæ are of different sizes and firmness, and are connected by the cellular membrane with articular cavities, tendons, ligaments, or the periosteum. Their use is to secrete and contain a substance to lubricate tendons, muscles, and bones, in order to render their motions easy.

A Table of all the Bursa Mucosa.

In the Head.

A bursa of the superior oblique muscle of the eye, situated behind its trochlea in the orbit.

2. The bursa of the digastricus, situated in the internal surface of its tendon.

3. A bursa of the circumflexus, or tensor palati, situated between the hook-like process of the sphenoid bone and the tendon of that muscle.

4. A bursa of the sterno-hyoideus muscle, situated

between the os hyoides and larynx.

About the Shoulder-joint.

1. The external acromial, situated under the acromion, between the coracoid process, deltoid muscle, and capsular ligament.

2. The internal acromial, situated above the tendon of the infra-spinatus and teres major: it often com-

municates with the former.

3. The coracvid bursa, situated near the root of the coracoid process; it is sometimes double and sometimes triple.

4. The clavicula bursa, found where the clavicle touches the coracoid process.

5. The subclavian bursa, between the tendon of the subclavius muscle and the first rib.

6. The coraco-brachial, placed between the common origin of this muscle and the biceps, and the capsular ligament.

7. The bursa of the pectoralis major, situated under the head of the humerus, between the internal surface of the tendon of that muscle, and another bursa placed

on the long head of the biceps.

8. An external bursa of the teres major, under the head of the os humeri, between it and the tendon of

the teres major.

9. An internal bursa of the teres major, found within the muscle where the fibres of its tendons diverge. A bursa of the latissimus dorsi, between the

tendoh of this muscle and the os humeri.

11. The humero-bicipital bursa, in the vagina of the tendon of the biceps.

There are other bursæ mucosæ about the humerus, but their situation is uncertain.

Near the Elbow-joint.

The radio-bicipital is situated between the tendon of the biceps, brachialis, and anterior tubercle of the

2. The cubito-radial between the tendon of the biceps, supinator brevis, and the ligament common to the radius and ulna.

The anconeal bursa, between the olecranon and

tendon of the anconous muscle.

157

common to the extensor carpi radialis brevis, and extensor communis digitorum, and round head of the radius. There are occasionally other bursæ; but as their situation varies, they are omitted.

About the inferior part of the Fore-arm and Hand.

On the inside of the Wrist and Hand.

1. A very large bursa, for the tendon of the flexor pollicis longus.

2. Four short burge on the forepart of the tendons of the flexor sublimis.

A large bursa behind the tendon of the flexor pollicis longus, between it and the forepart of the ra-dius, capsular ligament of the wrist and os trapezium.

A large bursa behind the tendons of the flexer digitorum profundus, and on the forepart of the end of the radius, and forepart of the capsular ligament of the wrist. In some subjects it communicates with the former.

5. An oblong bursa between the tendon of the flexor

carpi radialis and os trapezium.

6. A very small bursa between the tendon of the flexor carpi ulnaris and os pisitorme.

On the back part of the Wrist and Hand.

7. A bursa between the tendon of the abductor pollicis longus and the radius.

8. A large bursa between the two extensores carpi

radiales.

9. Another below it, common to the extensores carpi radiales.

10. A bursa, at the insertion of the tendon of the

extensor carpi radialis.

11. An oblong bursa, for the tendon of the extensor pollicis longus, and which communicates with 9.

12. A bursa, for the tendon of the extensor pollicis longus, between it and the metacarpal bone of the thumb.

13. A bursa between the tendons of the extensor of the fore, middle, and ring fingers.

14. A bursa for the extensors of the little finger.

15. A bursa between the tendon of the extensor carpi ulnaris and ligament of the wrist.

here are also bursæ mucosæ between the musculi

lumbricales and interossei.

Near the Hip-joint.

On the forepart of the joint.

1. The ileo-puberal, situated between the iliacus internus, psoas magnus, and the capsular ligament of the

2. The pectineal, between the tendon of the pectineus and the thigh-bone.

3. A small bursa of the gluteus mediu muscle, situated between it and the great trochanter, before the insertion of the pyriformis.

4. A bursa of the gluteus minimus muscle between its tendon and the great trochanter.

The gluteo-fascial, between the gluteu maximus and vastus externus.

On the posterior part of the Hip-joint.

6. The tubero-ischiatic bursa, situated between the obturator internus muscle, the posterior spine of the ischium, and its tuberosity.

7. The obturatory bursa, which is oblong and found between the obturator internu and gemini muscles,

and the capsular ligament.

8. A bursa of the semi-membranosu under its origin

and the long head of the biceps femoris.

9. The gleuteo trochanteral bursa, situated between the tendon of the psoas muscle and the root of the great trochanter.

10. Two gluteo-femoral bursæ, situated between the tendon of the gluteus maximus and os femoris.

11. A bursæ of the quadratus femoris, situated between it and the little trochanter.

The iliac bursa, situated between the tendon of the iliacus internus and the little trochanter.

Near the Knee-joint.

1. The supra-genual, which adheres to the tendons of the vastus and cruralis and the forepart of the thigh-bone. 158

4. The capitulo-radial bursa, between the tendon | 2. The infra-genual bursa, situated under the ligament of the patella, and often communicating with the

3. The anterior genual, placed between the tendon of the sartorius, gracilis, and semitendinosus, and the

internal and lateral ligament of the knee.

4. The posterior genual, which is sometimes double, and is situated between the tendons of the semi-membranosus, the internal head of the gastrocnemius, the

capsular ligament, and internal condyle.

5. The popliteal, conspicuous between the tendon of that muscle, the external condyle of the femur, the

semilunar cartilage, and external condyle of the tibia.

6. The bursa of the biceps cruris, between the external part of the tendon, the biceps cruris, and the external lateral ligament of the knee.

In the Foot.

On the back side, and hind part of the Foot,

1. A bursa of the tibialis anticus, between its ten-don, the lower part of the tibia, and capsular ligament of the ankle.

2. A bursa between the tendon of the extensor pollicis pedis longus, the tibia, and capsular ligament of

the ankle.

3. A bursa of the extensor digitorum communis, between its tendons, the tibia, and ligament of the

4. A large bursa, common to the tendons of the peronei muscles.

5. A bursa of the peroneus brevis, proper to its tendon.

6. The calcaneal bursa, between the tendo Achillis and os calcis.

In the Sole of the Foot.

1. A bursa for the tendon of the peroneus longus.
2. A bursa common to the tendon of the flexor pollicis pedia longus, and the tendon of the flexor digitorum pedis communis longus profundus.

3. A bursa of the tibialis posticus, between its tendon, the tibia, and astragalus.

4. Five bursæ for the flexor tendons, which begin a little above the first joint of each toe, and extend to the root of the third phalanx, or insertion of the

BUTTER. (Butyrum; from \(\beta\)ovs, a cow, and \(\tau\)ovs, coagulum, or cream.) "The oily, inflammable part of milk, which is prepared in many countries as an article of food. The common mode of preserving it is by the addition of salt, which will keep it good a considerable time, if in sufficient quantity. Mr. Eaton informs us, in his Survey of the Turkish Empire, that most of the butter used at Constantinople is brought from the Crimea and Kirban, and that it is kept sweet from the Crimea and Kirban, and that it is kept sweet by melting it while fresh over a very slow fire, and removing the scum as it rises. He adds, that by melt-ing butter in the Tartarian manner, and then salting it in ours, he kept it good and fine-tasted for two years; and that this melting, if carefully done, injures neither the taste nor colour. Thenard, too, recommends the Tartarian method. He directs the melting to be done on a water-bath, or at a heat not exceeding I80° F.; and to be continued until all the caseous matter has subsided to the bottom, and the butter is transparent. It is then to be decanted, or strained through a cloth, and cooled in a mixture of pounded ice and salt, or at least in cold spring water, otherwise it will become lumpy by crystallizing, and likewise not resist the action of the air so well. Kept in a close vessel, and in a cool place, it will thus remain, six months or more,

melting and cooling in this manuer.

Dr. Anderson has recommended another mode of curing butter, which is as follows: Take one part of sugar, one of nitre, and two of the best Spanish great the powder. This sait, and rub them together into a fine powder. This composition is to be mixed thoroughly with the butter, as soon as it is completely freed from the milk, in the as soon as it is completely freed from the milk, in the proportion of one ounce to sixteen; and the butter thus prepared is to be pressed tight into the vessel prepared for it, so as to leave no vacuities. This butter does not taste well till it has stood at least a fortnight; it then has a rich marrow flavour, that no other butter ever acquires; and with proper care may be kept for years in this climate, or carried to the East Indies, if nacked so as not to melt. if packed so as not to melt.
In the interior parts of Africa, Mr. Parc informs us,

there is a tree much resembling the American oak, producing a nut in appearance somewhat like an olive. The kernel of this nut, by boiling in water, affords a kind of butter, which is whiter, firmer, and of a richer flavour, than any he ever tasted made from

cow's milk, and will keep without salt the whole year. The natives call it shea toulou, or tree butter. Large quantities of it are made every season."

Fresh butter is nourishing and relaxing, but it readily becomes sour, and, in general, agrees with few stomachs. Rancid butter is one of the most unwhole-

Butter of antimony. See Murias antimonii.

Butter of cacao. An oily concrete white matter, of a firmer consistence than suet, obtained from the cacao nut, of which chocolate is made. The method of separating it consists in bruising the cacao and boil-ing it in water. The greater part of the superabun-dant and uncombined oil contained in the nut is by this means liquefied, and rises to the surface, where it swims, and is left to congeal, that it may be the more easily taken off. It is generally mixed with small pieces of the nut, from which it may be purified, by keeping it in fusion without water in a pretty deep vessel, until the several matters have arranged themselves according to their specific gravities. By this treatment it becomes very pure and white.

Butter of cacao is without smell, and has a very

mild taste, when fresh; and in all its general proper-ties and habitudes it resembles fat oils, among which it must therefore be classed. It is used as an ingredi-

ent in pomatums. BUTTER-BUR. BUTTER-BUR. See Tussilago petasites. BUTTER-FLOWER. See Ranunculus.

Butter-milk. The thin and sour milk which is separated from the cream by churning it into butter. BUTTERWORT. See Pinguicula.

BUTTON SNARE BOOK

CRIM. A.]

BUTYRIC ACID. We owe the discovery of this acid to M. Chevreul. Butter, he says, is composed of two fat bodies, analogous to those of hog's lard, of a colouring principle, and a remarkably odorous one, to which it owes the properties that distinguish it from which he which it owes the properties that distinguish it from the fats, properly so called. This principle, which he has called butyric acid, forms well characterized salts with barytes, strontian, lime, the oxides of copper, lead, &c.; 100 parts of it neutralize a quantity of base which contains about 10 of oxygen. M. Chevreul has not explained his method of separating this acid from the other constituents of butter. See Journ. de Phar-

BUTY'RUM. See Butter.
BUTY'RUM ANTIMONIL See Murias antimonii.
BUXTON. A village in Derbyshire in which there are warm mineral springs. Buttonienses aqua. They have been long celebrated for their medicinal properties. With respect to sensible properties, the Buxton water cannot be distinguished from common spring water when heated to the same temperature. spring water, when heated to the same temperature.

Its temperature, in the gentleman's bath, is invariably throngingly 82°. The principal peculiarity in the appearance of this spring, is a large quantity of elastic vapour, that

nearly as good as at first, particularly after the top is taken off. If beaten up with one sixth of its weight of the cheesy matter when used, it will in some degree resemble fresh butter in appearance. The taste of rancid butter, he adds, may be much corrected by melting and cooling in this manner.

The Anderson has recommended another mode of these subbles was ascertained, by Dr. Pearson, to consist of azotic gas, mixed with a small proportion of atmospheric air. Buxton water is frequently employed both internally and externally: one of which methods after a powerful proposed. and break as soon as they reach the surface. The air of these bubbles was ascertained, by Dr. Pearson, to consist of azotic gas, mixed with a small proportion of atmospheric air. Buxton water is frequently employed both internally and externally: one of which methods often proves beneficial when the other would be injurious; but as a light alone its fittenance may not be thous often proves beneficial when the other would be injurious: but, as a bath alone, its virtues may not be superior to those of tepid common water. As the temperature of 82° is several degrees below that of the human body, a slight shock of cold is felt on the first immersion into the bath; but this is almost immediately succeeded by a pleasing glow over the whole system. It is therefore proper for very delicate and irritable habits. The cases which derive most benefit from the systemal use of Buylon waters are those in from the external use of Buxton waters, are those in which a loss of action, and sometimes of sensation, affects particular limbs, in consequence of long-continued or violent inflammation, or external injury. Hence the chronic rheumatism succeeding the acute, and where the inflammation has been seated in particular limbs, is often wonderfully relieved by this bath. The internal use of the water has been found to be of considerable service in symptoms of defective diges-tion and derangement of the alimentary organs. A judicious use of this simple remedy will often relieve the heartburn, flatulency, and sickness; it will in-crease the appetite, animate the spirits, and improve the health. At first, however, it sometimes occasions a diarrhœa, which is rather salutary than detrimental; but costiveness is a more usual effect, especially in sluggish habits. It also affords great relief when taken internally, in painful disorders of the bladders and kid neys; and has likewise been recommended in cases of gout; but when taken for these complaints, the addition of some aromatic tincture is recommended. In all cases of active inflammation, the use of these waall cases of active inflammation, the use of these waters should be carefully avoided, on account of their supposed heating properties. A full course consists of two glasses, each containing one-third of a pint, before breakfast; which quantity should be repeated between breakfast and dinner. In chronic cases, a long residence on the spot is requisite to insure the desired effect. BU XUS. (From \(\pi\)\epsilon\(\pi\)\epsi

sempervirens.

BUXUS SEMPERVIRENS. The systematic name of the buxus of the pharmacopoias. The leaves possess a very strong, nauseous, bitter taste, and aperient vir-tues. They are occasionally exhibited, in form of decoction, among the lower orders of people, in cases of dropsy, and asthma, and worms. As much as will lie upon a shilling, of the common dwarf box, dried and powdered, may be given at bed-time, every night, to an infant.

By'ARUS. A plexus of blood vessels in the brain.
Byng. A Chinese name for green tea.
Byrer'thrum (Beretta, Ital. or barette, Fr. a cap.)
Byrethrus. An odoriferous cap, filled with cephalic drugs, for the head.

(Bupoa, leather.) A leather skin, to By'RSA. spread plasters upon.

Bysau'chen. (From βυω, to hide, and αυχην, the neck.) Morbid stiffness of the neck.
BYSSOLITE. A massive mineral of an olive green colour, found at the foot of Mount Blanc and near Oisans in gneiss

By'ssus. (Hebrew.) 1. A woolly kind of moss. 2. The Pudendum muliebre.

3. A kind of fine linen.
[4. The fine silky threads by which the Mytilus and Pinna, both bivalve shells, fasten themselves, and thereby remain attached to logs or stones in the water.

thereby remain attached to logs or stones in the water. The Pinna affords the most and finest quantity of this byssus; and, in the Mediterranean, it has been collected and spun into silk, of which various ornamental articles have been made. A.]

By'thos. (Bubos, deep.) An epithet used by Hippocrates for the bottom of the stomach.

By'zen. (From Buo, to rush together.) In a heap; throngingly. Hippocrates uses this word to express the hurry in which the menses flow in an excessive discharge.

CABALUSTICA ARS. (It is derived from the Hebrew word signifying to receive by tradition.)
Cabala; Cabala; Kabala. The cabalistic art. A term that hath been anciently used, in a very mysterious sense, among divines; and since, some enthusiastic philosophers and chemists transplanted it into medicine, importing by it somewhat magical; but such unmeaning terms are now justly rejected.

Cabalistic art. See Cabalistica ars.
CABALLINE. (Caballinus; from καδαλλος, a horse.) Of, or belonging to, a horse; applied to the coarsest aloes, because it is so drastic as to be fit only for horses.

Cabulline aloes. See Aloe.

CABBAGE. See Brassica.

Cabbage tree. See Geoffraya jamaicensis.

CACAGO'GA. (From κακκη, excrement, and αγω, to

expel.) 1. Cathartics.
2. Ointments which, being rubbed on the funda-

ment, procure stools.—Paulus Ægineta.

Caca'lla. (From κακον, bad, and λιαν, exceedingly; because it is mischievous to the soil on which it grows.) Cacamum. The herb wild chervil, or wild carraways.

CA'CANUM. See Cacalia. CA'CAO. See Theobroma cacao. CACAPHO'NIA. (From κακος, bad, and φωνη, the

voice.) Defective articulation.

Cacato Ria. (From caco, to go to stool.) thet given by Sylvius to a kind of intermittent fever, attended with copious stools.

attended with copious stools.

CACCIO'NDE. A pill recommended by Baglivi against dysenteries; its basis is catechu.

CACHE'XIA. (Prom κακος, bad, and έξες, a habit.)

A bad habit of body, known by a deprayed or vitiated state of the solids and fluids.

CACHE'XIÆ. (The plural of cachexia.) A class of diseases in Culien's Nosology, embracing three orders; viz. Marcores, Intumescentiae, and Impetigines.

CACHINNA'TIO. (From cachinno, to laugh about.) A tendency to immoderate laughter, as in some hysteric and maniacal affections.

some hysteric and maniacal affections.

A little stone, or pebble. Galen says, that the cachleces, heated in the fire and quenched in whey, become astringents, and useful in dysenteries. CACHOLONG. A variety of quartz.

CACHO'RE. A name of catechu.
CA'CHRYS. (Kaxovs: which is used in various enses.)
1. Galen says, it sometimes means parched senses.)

2. The name of a genus of plants in the Linnaan

system. Class, Pentandria; Order, Digynia.

Cacherys onontalgica. Aplant, the root of which
may be substituted for that of the pyrethrum against

toothache.

CACHU. See Acacia catechu.
CACHU'NDE. A medicine highly celebrated among the Chinese and Indians, made of several aroamong the Chinese and Indians, made of several aromatic ingredients, perfumes, medicinal earths, and precious stones. They make the whole into a stiff paste, and form out of it several figures, according to their fancy, which are dried for use. These are principally used in the East Indiës, but are sometimes brought over to Portugal. In China, the principal persons usually carry a small piece in their mouths, which is a continued cordial, and gives their breath a very sweet smell. It is highly esteemed as a medicine in nervous complaints; and it is reckoned a prolonger of life and a provocative to venery; the two great intentions of most of the medicines used in the East.

Cachy'ma. Kakuma. An imperfect metal, or an immature metalline ore, according to Paracelsus.

Immature metalline ore, according to Paracelsus.

Cacoalexite Rium. (From kakos, bad, and alexi-

7ηοεω, to preserve.) An antidote to poison or against infectious diseases.

CACOCHO LIA. (From κακος, and χολη, bile.)
A vitiated or unhealthy condition of the bile.
CACOCHY'LIA. (From κακος, bad, and χυλη, the chyle.) Indigestion, or deprayed chylification.
CACOCHY'MIA. (From κακος, bad, and χυμος, juice, or humour.)
A diseased or deprayed state of the humours. the humours.

CACOCNE'MUS. (From kakes, bad, and kvnun, the leg.) Having a natural defect in the tibia.

CACOCORE'MA. (From κακος, bad, and κορτω, to purge, or cleanse.) A medicine which purges off the

vitiated humours

CACODÆMON. (From κακος, bad, and δαιμων, a spirit.) An evil spirit, or genius, which was supposed to preside over the bodies of men, and afflict them with certain disorders. The nightmare.

CACODIA. (From κακος, bad, and ωξω, to smell.) A defect in the sense of smelling.

CACOE THES. (From $\kappa a \kappa o s$, ill, and $\eta \theta o s$, a word which, when applied to diseases, signifies a quality, or a disposition.) Hippocrates applied this word to malignant and difficult distempers. Galen, and some others, express by it an incurable ulcer, that is rendered so thereafth the action of the humans flowing. dered so through the acrimony of the humours flowing to it. Linnaus and Vogel use this term much in the to it. Linnaus and Vogel use this term much in the same sense with Galen, and describe the ulcer as superficial, spreading, weeping, and with callous edges.

CACOPA'THIA. (From κακος, bad, and ωαθος, affection.) An ill affection of the body, or part.

CACOPHO'NIA. (From κακος, bad, and φωνη, the voice.) 1. A defect in the organs of speech.

2. A bad pronunciation.

CACOPRA'GIA. (From rarce, bad, and σου 3.

CACOPRA'GIA. (From Kakos, bad, and mpar76, to perform.) Diseased viscera.

CACORRY THMUS. (From κακος, bad, and ρυθμος, der.) A disordered pulse. CACO'SIS. (From κακος, bad.) A bad disposition

CACOSITIA. (From Kakos, and oi/lov, food.)

CACOSPTIA. (From κακος, and σι/ιον, 100d.)
An aversion to food, or nausea.
CACOSPHY XIA. (From κακος, bad, and σφυχις, pulse.) A disorder of the pulse.
CACOSTO MACHUS. (From κακος, bad, and σομαχος, the stomach.) A bad or disordered stomach; applied also to food which the stomach rejects.

YSTOMUS. (From κακος, bad, and ςομα, a Having a bad formed, or disordered mouth. CACO'STOMUS. CACOTHY'MIA. (From Kakos, ill, and Svuos, the

mind.) Any vicious disposition of the mind; or a diseased mind.

CACOTRO PHIA. (From Kakos, ill, and τροφη,

CACOTRO PHIA. (From κακος, 10, and 1947), nutriment.) 1. A vitiated nourishment.
2. A wasting of the body, from want of nutrition.
CA'CTUS: (From κακτος, the Greek name of a plant described by Theophrasta.) The name of a genus of plants in the Linnæan system. Class, Icosandria; Order, Monogynia. The melon-thistle, or prickly-pear.

CACTUS OPUNTIA. The systematic name of the opuntia of the pharmacopæias. The prickly leaves this plant abound with a mucilaginous matter, which is esteemed in its native countries an emollient,

in the form of poultice.

CACU'BALUS. (From κακος, evil, and βαλλω, to cast out; so named because it was thought to be efficacious in expelling poisons.) See Cucubalus baeciforum.

CACULE. The Arabian for cardamous. CACU'MEN. (Cacumen, minis. neut.) The top or

CADA'VER. (Cadaver, veris. neut., from cade, to fall: because the body, when deprived of life, falls to the ground.) A carcass, or body deprived of life.

CA'DMIA. (Hebrew.) The lapis calaminaris.

See Zinc.

CADMIA METALLICA. A name given, by the Ger

mans, to cohalt.

CADMIUM. "A new metal, first discovered by M.
Stromeyer, in the autumn of 1817, in some carbonate of zinc which he was examining in Hanover. It has

been since found in the Derbyshire silicates of zinc.

The following is Dr. Wollaston's process for procuring cadmium. From the solution of the salt of zinc supposed to contain cadmium, precipitate all the other metallic impurities by iron; filter and immerse a cylinder of zinc into the clear solution. If cadmium be present, it will be thrown down in the metallic state, and when redissolved in muriatic acid, will exhibit its peculiar character on the application of the proper tests.

M. Stromeyer's process consists in dissolving the substance which contains cadmium in sulphuric acid, and passing through the acidulous solution a current of sulphuretted hydrogen gas. He washes this precipitate, dissolves it in concentrated muriatic acid, and
expels the excess of acid by evaporation. The residue
is then dissolved in water, and precipitated by carbonate of ammonia, of which an excess is added, to
redissolve the zinc and the copper that may have been
precipitated by the sulphuretted hydrogen gas. The
carbonate of cadmium being well washed, is heated,
to drive off the carbonic acid, and the remaining oxide
is reduced by mixing it with lamp-black, and exposing
it to a moderate red heat in a glass or earthen retort. of sulphuretted hydrogen gas. He washes this preit to a moderate red heat in a glass or earthen retort.

The colour of cadmium is a fine white, with a slight The colour of cadmium is a line white, with a slight shade of bluish-gray, approaching much to that of tin; which metal it resembles in lustre and susceptibility of polish. Its texture is compact, and its fracture hackly. It crystallizes easily in octohedrons, and presents on its surface, when cooling, the appearance of leaves of fern. It is flexible, and yields readily to of leaves of tern. It is nextue, and yields readily to the knife. It is harder and more tenacious than tin; and, like it, stains paper, or the fingers. It is ductile and maileable, but when long hammered, it scales off in different places. Its sp. grav. before hammering, is 8.6040; and when hammered, it is 8.6944. It melts, and is volatilized under a red heat. Its vapour, which has no smell may be condensed in drops like mercury. has no smell, may be condensed in drops like mercury, which, on congealing, present distinct traces of crystallization.

Cadmium is as little altered by exposure to the air as tin. When heated in the open air, it burns like that metal, passing into a smoke, which falls and forms a very fixed oxide, of a brownish-yellow colour. Nitric acid readily dissolves it cold; dilute sulphuric, muriatic, and even acetic acids, act feebly on it with the disengagement of hydrogen. The solutions are Cadmium forms a single oxide, in which 100 parts

of the metal are combined with 14,352 of oxygen.
The prime equivalent of cadmium deduced from this
compound seems to be very nearly 7, and that of the
oxide 8. This oxide varies in its appearance according to circumstances, from a brownish-yellow to a dark brown, and even a blackish colour. With char-coal it is reduced with rapidity below a red heat. It gives a transparent colourless glass bead with borax. It is insoluble in water, but in some circumstances forms

It is insoluble in water, but in some circumstances forms a white hydrate, which speedily attracts carbonic acid from the air, and gives out its water when exposed to heat."—Ure's Chem. Dict.

CADOGAN, WILLIAM, graduated at Oxford in 1755. Five years before, he had published a small treatise on the management of children, which was very much approved. In 1764, his "Dissertation on the Gout and all Chronic Diseases" appeared, which attracted considerable attention, being written in a attracted considerable attention, being written in a popular style. He referred the gout principally to indolence, vexation, and intemperance; and his plan of treatment is generally judicious. He was a fellow of the London College of Physicians, and died in 1797,

at an advanced age.

CADTCHU. See Acacia catechu.

CADU'CA. (From cado, to fall down.) See De-

The name of a class in Linnaus's Metho-CADUCI.

dus calycina. CADU'CUS. CADU'CUS. (From cado, to fall.) 1. In Botany, The falling off before the unfolding of the flower or leaf; as the perianthium of Papaver, the stipular of Prunus avium. This term is expressive of the shortest period of duration, and has different acceptations, according to the different parts of the plant to which it is applied. A calyx is said to be caducous, which drops at the first opening of the petals, or even before, as in the poppy. Petals are caducous, which are scarcely unfolded before they fall off, as in Thalictrum; and such leaves as fall off before the end of summer, have obtained this denomination. See Deciduus and Parasiticus

2. The epilepsy or falling sickness is called morbus

CÆ'CITAS. (From cacus, blind.)

See Coligo and Amaurosis.

CÆCUM. (From excus, blind: so called from its being perforated at one end only.) The excum, or blind gut. The first portion of the large intestines,

placed in the right iliac region, about four fingers' breadth in length It is in this intestine that the ileum terminates by a valve, called the valve of the cacum. The appendicula caci vermiformis is also attached to it. See Intestines.

CÆ'LIUS, AURELIANUS, is supposed to have been born at Sicca, in Africa, and is referred by Le Clerc to the fifteenth century, from the harshness of his style. He has left a Latin translation of the writings of Soranus, with additional observations, partly col-lected from others, partly from his own experience. The work is in eight books, three on acute, the rest on chronic disorders. He treats of several diseases not mentioned by any earlier writers, and has some observations in surgery peculiar to himself; he appears, too, generally correct in his remarks on the opinions

Ca'ros. Katoos. Hippocrates, by this word, means the opportunity or moment in which whatever is to be effected should be done.

CAESALPINA. (Named in honour of Casalpinus, chief physician to Pope Clement VIII.) The name of a genus of plants in the Linnaran system. Class,

of a genus of plants in the Linnman system. Class, Decandria; Order, Monogynia.

Cæsalpina crista. The systematic name of the tree that affords the Brazil wood. It is of the growth of the Brazils in South America, and also of the Isle of France, Japan, and elsewhere. It is chiefly used as a red dye. See Brazil wood.

CÆSALPINUS, Andrew, was born in Tuscany, in 1519. He graduated at Pisa, and became professor in anatomy and medicine there; and was afterward

in anatomy and medicine there; and was afterward made physician to Pope Clement VIII. He died in made physician to Pope Clement VIII. He died in 1603. His works are numerous, and evince much genius and Jearning. In 1571, he published a work, defending the philosophy of Aristotle against the doctrines of Galen, from some passages in which he appears to have approached very near to a knowledge of the circulation of the blood; having explained the use of the valves of the heart, and pointed out the course which these compelled the blood to take on both sides during the contraction and dilatation of that both sides during the contraction and dilatation of that organ. In a treatise "De Plantis," he justly compared the seeds to the eggs of animals; and formed an arrangement of them according to the parts of fructification. On medical subjects also he offered many judicious remarks.

CÆ'SARES. Casones. Children who are brought into the world as Julius Casar is said to have been.

See Casarian operation.

CÆSA'RIAN OPERATION. (So called because Julius Cæsar is said to have been extracted in this manner.) Hysterotomia. Hysterotomatocia. The operation for extracting the fætus from the uterus, by dividing the integuments of the abdomen and the

There are three cases in which this operation may be necessary.—1. When the foctus is perceived to be alive, and the mother dies, either in labour or in the last two months. 2. When the foctus is dead, but cannot be delivered in the usual way, from the deformity of the mother, or the disproportionate size of the child. 3. When both the mother and the child are living, but delivery cannot take place, from the same causes as in the second instance. Both the mother and the child if accounts can be credited have mother and the child, if accounts can be credited, have often lived after the Cæsarian operation, and the mother even borne children afterward. Heister gives a relation of such success, in his Institutes of Surgery; and there are some others. In England, the Casarian operation has almost always failed. Mr. James Barlow, of Chorley, Lancashire, succeeded, however, in taking a factus out of the uterus by this bold proceeding, and the mother was perfectly restored to health Car'TCHU. See Acaoia catechu. Car; Cafa; Caffa. Names given by the Arabians

to camphire.

to camphire.

CAFFEIN. The name of a bitter principle procured from coffee by Chenevix, by adding muriate of tin to an infusion of unroasted coffee. From this he obtained a precipitate, which he washed and decomposed by sulphuretted hydrogen. The supernatant liquid contained this principle, which occasioned a green precipitate in concentrated solutions of iron. When the liquid was evaporated to dryness, it was yellow and transparent, like horn. It did not attract moisture from the air, but was soluble in water and

almost as delicate a test of Iron as infusion of galls is; yet gelantine occasions no precipitate with it.

["Caffein is a new principle, which was discovered in coffee by Robiquet. It is white, volatile, and crystallizable; and is particularly distinguished by the large quantity of nitrogen which it contains, being greater than that in almost any other vegetable. According to Dumas and Pelletier, it consists of 27 14 oxygen, 4.81 hydrogen, 46.51 carbon, and 21.54 nitrogen.—Webster's Man. of Chem. A.]

CAGA STRUM. A barbarous term used by Paracelsus, to express the morbific matter which generates diseases.

to express the morbific matter which generates diseases.

CAITCHU. See Acacia catechu. CAIUS, John, was born at Norwich, in 1510. studying at Cambridge, and in different parts of Italy, and distinguishing himself by his interpretations of Hippocrates, Galen, and other ancient authors, he graduated at Bologna. In 1544, he returned to this country, and for some time read lectures in anatomy to the corporation of surgeons in London. He afterward practised at Shrewsbury, having been admitted a fellow of the College of Physicians; and published a popular account of the memorable sweating sickness, which prevailed in 1551, subsequently reprinted, much improved, in Latin. He was made physician to Edward VI., to Mary, and to Elizabeth. On the death of Linacre, he was chosen President of the College of Physicians, and during the seven years for which he Physicians, and during the seven years for which he held that office, performed many important services. He was also a signal benefactor to Gonvil Hall, where he studied at Cambridge, having obtained permission to erect it into a college, considerably enlarging the building, and assigning provision for three fellows and twenty scholars. He was chosen master on the completion of the improvements, and retained that office till near the period of his death, which happened in 1573. He published a dissertation "De Cambus Britannicis," which Mr. Pennant has entirely followed in his British Zoology and some other learned works besides those already mentioned.

CA'JAN. See Phaseolus creticus. Ca'jeput oil. See Melaleuca.

Calagrature. See Metaleuca.
Calagrature. See Catophyllum inophyllum.
Calagrature radix. Calagrature radix. The root so called is knotty, and somewhat like that of the polypody tribe. It has been exhibited internally at Rome, with success, in dropsy; and it is said to be efficacious in pleurisy, contusions, abscesses, &c. It was first used in America, where it is obtained; and Italian physicians have since written concerning it, in terms of approbation.
Calama'corus. Indian reed.
CALAMAGRO'STIS. (From καλαμος, a reed, and αγρωςις, a sort of grass.) Reed grass. Gramen Arundinacum. The Arundo calamagrostis of Linnæus: the root of which is said to be diuretic and emmenagogue.

gogue. CALAMARIÆ. (From calamus, a reed.) The name of an order of Linnaus's fragments of a natural

method, which embraces the reed-plants. CALA MBAC. An Indian name for agallochum. See

Lignum Aloes. Calamine Juoes.

Calame Joos. (From καλαμος, a feed.) A sort of fracture which runs along the bone, in a straight line, like a reed, but is lunated in the extremity.

CA'LAMINA. See Calamine.

Calamina PREPARATA. Prepared calamine. Burn the calamine and reduce it to provide the late.

the calamine, and reduce it to powder; then let it be brought into the state of a very fine powder, in the same manner that chalk is directed to be prepared.

See Calamin

See Calamine.

CA'LAMINE. (Calamina; from calamus, a reed: so called from its reed-like appearance.) Cadmia; Cathmia; Cadmia lapidosa arosa; Cadmia fossilis; Calamina; Lapis calaminaris. A native carbonate of zinc. A mineral, containing oxide of zinc and carbonic acid, united with a portion of iron, and sometimes other substances. It is very heavy, moderately hard and brittle, of a gray, yellowish, red, or blackish times other substances. It is very heavy, moderately hard and brittle, of a gray, yellowish, red, or blackish brown; found in quarries of considerable extent, in brown; found in quarries of considerable extent, in several parts of Europe, and particularly in this country, in Derbyshire, Gloucestershire, Nottinghamshire, and Somersetshire; as also in Wales. The calamine of England is by the best judges, allowed to be superior in quality to that of most other countries. It selfor in quality to that of most other countries. It selfor in the properties of the calamine of the calamine of the calamine of England is by the best judges, allowed to be superior in quality to that of most other countries. It selfor in the calamine of t

alkohol. The solution had a pleasant bitter taste, and assumed with alkalies a garnet-red colour. It is almost as delicate a test of iron as infusion of galls is; yet gelantine occasions no precipitate with it.

["Caffeth is a new principle, which was discovered in coffee by Robiquet. It is white, volatile, and crystallizable, and it provides a state, and it provides a it is supposed to contain, and in order to render it more easily reducible into a fine powder. In this state, it is employed in collyria, for weak eyes, for promoting the cicatrization of ulcers, and healing ex-coriations of the skin. It is the basis of an officinal cerate, called Ceratum calamine by the London College, formerly called ceratum lapidis caliminaris, ceratum epuloticum; and ceratum carbonatis zinci impuri tum epuloticum; and ceratum carbonatis zinci impuri by the Edinburgh College. These compositions form the cerate which Turner strongly recommends for healing ulcerations and excoriations, and which have been popularly distinguished by his name. The collyria in which the prepared calamine has been employed, have consisted simply of that substance added to rose-water, or elder-flower water.

CALAMINT. See Melissa celamintha.

Calamint, mountain. See Melissa grandiflora.

CALAMINTHA. (From καλος, beautiful, or καλαμος, a reed, and μενθη, mint.) Common calamint. See Melissa.

CALAMINTHA ANGLICA. See Melissa nepeta.

CALAMINTHA ANGLICA. See Melissa nepeta. CALAMINTHA HUMILIOR. The ground-ivy. Glecoma hederacea.

CALAMINTHA MAGNA FLORE. See Melissa grandi-

CALAMINTHA MONTANA. See Melissa Calamintha.
CA'LAMUS. (From Kalam, an Arabian word.)

1. A general name denoting the stalk of any plant.
2. The name of a genus of plants in the Linnwan system. Class, Hexandria; Order, Monogynia.
CALAMUS AROMATICUS. See Meorus calamus.

[CALAMUS. Sweet flag-root. Acorus calamus, or calamus aromaticus. "The Acorus calamus is found in Europe, Asia, and North America. With us it grows in wet meadows, commonly in beds or bunches. The root has a strong aromatic odour, and a bitter spicy taste. Its properties depend upon a volatile oil, and a bitter matter soluble in water. Medicinally considered, it is stimulant, heating and tonic; and is given in flatulent colic, cramp of the stomach, &c., in the dose of a scruple and upwards."—Big. Mat. Med. A.]

CALAMUS AROMATICUS ASIATICUS. See Acorus ca-

lamus.

CALAMUS ODORATUS. The sweet-scented rush.

Sec Acorus calamus. CALAMUS ROTANG. The systematic name of the plant from which we obtain the Dragon's blood. Cin-

plant from which we obtain the Dragon's blood. Cinnabaris gracorum; Draconthæma; Asegen; Asegon. Dragon's blood. The red resinous juice which is obtained by wounding the bark of the Calamus rotang;—caudice densissime aculeata, aculeis erectis, spadice crecto. The Petrocarpus draco and Dracana draco also afford this resin. It is chiefly obtained from the Molucca islands, Java, and other parts of the East Indies. It is generally much adulterated, and varied in goodness and purity. The best kind is of a dark red colour, which, when powdered, changes to crimson: it is insoluble in water, but soluble in a great measure in alkohol; it readily melts and catches flame, has no smell, but to the taste discovers some degree of warmth and pungency. The ancient Greeks were well acquainted with the adstringent power of this drug; in which character it has since oven much this drug; in which character it has since ocen much employed in hæmorrhages, and in alvine fluxes. At present, however, it is not used internally, being superseded by more certain and effectual remedies of this

numerous class. CALAMUS SCRIPTORIUS. A furrow or kind of canal at the bottom of the fourth ventricle of the brain, so called from its resemblance to a writing pen.

CALATHIANA. (From καλαθος, a twig basket; so called from the shape of its flowers.) The herb marsh-gentian. See Gentiana pneumonanthe.

Calbu'anum. The name of a plaster in Myrepsus.

Calca'dinum. Vitriol.

the astragalus, is very regular, and divided into a body and processes. It has a large tuberosity or knob, pro-jecting behind to form the heel. A sinuous cavity, as its fore-part, which, in the fresh subject, is filled with fat, and gives origin to several ligaments. prominences, at the inner and fore-part of the bone, with a pit between them, for the articulation of the under and fore-part of the astragalus. A depression, in the external surface of the bone near its fore-part, where the tendon of the perongus longus runs, A large cavity, at the inner side of the bone, for lodging the long flexors of the toes, together with the vessels and nerves of the sole. There are two prominences, at the under and back part of this bone, that give origin to the aponeurosis, and several muscles of the sole. The anterior surface of the os calcis is concave, for its to the astragalus by ligaments.

Calcan'thum. (From χαλκος, brass, and ανθος, a flower; i. e. flowers of brass.) Calcanthos. Copperas; Vitriol. articulation with the os cuboides, and it is articulated

CALCAR. (Calcar, aris. n. From calx, the heel; also from calco, to heat.) 1. The heel-bone.

2. The furnace of a laboratory.

 A spur. In botany, applied to a part of the ringent and personate corolla of plants. It is a tube forming an obtuse or acute sac, at the side of the receptacle. It is of rare occurrence.

CALCARATUS. Spurred; applied to the corols and nectaries of plants; as Calcarata corolla, Nectarium calcaratum; as in Aquilegia and Antirrhinum

Linaria.

CALCAREOUS. (Calcarius; from calx, lime.) That which partakes somewhat of the nature and qualities of calx.

Calcareous earth. See Calx and Lime.
Calcareous spar. Crystallized carbonate of lime, which occurs in more than 600 different forms. It is found in veins in all rocks from granite to alluvial strata. The rarest and most beautiful crystals are found in Derbyshire, but it exists in every part of the world.

CALCA'RIS FLOS. The larkspur. CALCA'RIUS. See Calcarcous. CALCARIUS LAPIS. Limestone. CA'LCATAR. A name of vitriol.

CALCATRI'PPA. See Jjuga pyramidalis.
CALCEDONY. A mineral, so called from Calcedon, in Asia Minor, where it was found in ancient times. There are several sub-species, common calcedony, heliotrope, crysoprase, plasma, onyx, sand, and sardonyx.

Common calcedony occurs of various colours; it is regarded as pure silica with a little water. Very fine stalactical specimens have been found in Cornwall

and Scotland.

and Scotland.

Ca'lceum equinum. (From calccus, a shoe, and equus, a horse; so called from the figure of its leaf.)
The herb colt's-foot. See Tussilago farfara.

Calchantrum. Pliny's name for copperas.

Calchi'theos. (From calx, a stone, and frango, to break; so named from its supposed property of breaking the human calculus.) Breakstone. In Scribenius Largus, it means, the herb spleenwort, or scolopendrium; others mean by it the Pimpinella saxifraga of Linneus.

fraga of Linneus, CALCINA TION, Oxidation. The fixed residues of such matters as have undergone combustion are called cinders, in common language, and calces, but now more commonly oxides, by chemists; and the operation, when considered with regard to these residues, is termed calcination. In this general way, it has likewise been applied to bodies not really combustible, but only deprived of some of their principles by heat. Thus we hear of the calcination of chalk, to convert it into lime by driving off its carbonic acid and water; of gypsum, or plaster-stone, of alum, of borax, and other saline bodies, by which they are deprived of their water of crystallization; of bones which lose their volatile parts by this treatment, and of various other bodies

CALCINA'TUS. Calcined.

CALCINA'TUS. Whatever is dulcified by the chemical art, which was not so by nature; such as dulcified mercury, lead, and the like substances, which are very speedily consolidated.

CALCINATUM MAJUS POTERIT. Mercury dissolved in aqua fortis, and precipitated with salt water. Poterius used it in the cure of ulcers.

CALCINATUM MINUS. Any thing which is sweet by nature, and speedily cures, as sugar, manna, tama-

rinds, &c.

rinds, &c.

Calcino'nia. See Calcena.

Ca'lcis aqua. See Calcis liquor.

Ca'lcis liquor. Solution of lime, formerly called aqua calcis. Lime-water. Take of lime, half a pound; boiling distilled water, twelve pints. Pour the water upon the lime, and stir them together; next cover the vessel immediately, and let it stand for three hours; then keep the solution upon the remaining lime in stopped glass bottles, and pour off the clear liquor when it is wanted for use.

Lime is soluble in about 450 times its weight of

Lime is soluble in about 450 times its weight of water, or little more than one grain in one fluid ounce. It is given internally, in doses of two ounces and upwards, in cardialgia, spasms, diarrhoa, &c. and in proportionate doses in convulsions of children, arising from acidity, or ulcerated intestines, intermittent fevers, &c. Externally it is applied to burns and

CALCIS MURIAS. Calx solita; Sal ammoniacus fixus. Muriate of lime. Take of the salt remaining after the sublimation of subcarbonate of ammonia two pounds, water a pint; mix and fliter through paper. Evaporate the salt to dryness; and preserve it in a closely-stopped vessel. This preparation is exhibited with the same views as the muriate of barytes. It possesses deobstruent, diuretic, and cathartic virtues, and is much used by the celebrated Fourcroy against scrophula, and other analogous diseases. Six, twelve, and twenty grains, are given to children, three times a day, and a drachm to adults.

Calcis Muriatis Liquor. Take of muriate of lime two ounces, distilled water three fluid ounces; dissolve the salt in the water, and filter it through

CALCIS OS. See Calcaneum. CALCIS VIVI FLORES. The pellicle on the surface of lime water

CALCITRA'PA. (An old botanical term of similar meaning to tribulus, compounded of calco, to tread or kick, and τρεπω, to turn, because the caltrops are continually kicked over, if they fail of their intended mischief. See Trapa.) See Centaurea calcitrapa.

CALCITRAPA OFFICINALIS. See Centaurea solsti-

CALCIUM. The metallic basis of lime. Davy, the discoverer of this metal, procured it by the process which he used for obtaining barium. It was in such small quantities, that little could be said concerning its nature. It appeared brighter and whiter than either barium or strontium; and burned when gently heated, producing dry lime.

There is only one known combination of calcium and oxygen, which is the important substance called lime. The nature of this substance is proved by the phenomena of the combustion of calcium; the metal changing into the earth with the absorption of oxygen changing into the earth with the absorption of oxygen gas. When the amalgam of calcium is thrown into water, hydrogen gas is disengaged, and the water becomes a solution of lime. From the quantity of hydrogen evolved, compared with the quantity of lime formed in experiments of this kind, M. Berzelius endeavoured to ascertain the proportion of oxygen in The nature of lime may also be proved by ana-When potassium in vapour is sent through the earth ignited to whiteness, the potassium was found by Sir H. Davy to become potassa, while a dark gray substance of metallic splendour, which is calcium, either wholly or partially deprived of oxygen, is found imbedded in the potassa; for it effervesces violently, and forms a solution of lime by the action of water.

CALCSINTER. Stalactical carbonate of lime, which is continually forming by the infiltration of carbonated lime water through the crevices of the roofs of caverns. The irregular masses on the bottoms of caves have been called stalagmites.

CALCTUFF. An alluvial formation of carbonate of lime, probably deposited from calcareous springs of a yellowish dull gray colour, containing impressions of vegetable matter. earth ignited to whiteness, the potassium was found

of vegetable matter. CALCULI FRAGUS.

(From calculus, a stone, Stone-breaker, having the and frango, to break.)

power to break stone in the human body. 1. A synonym of lithontriptic. See Lithontriptic.
2. The scolopendrium, and pimpernel. See Calci-

CALCULUS. (Diminutive of calx, a lime-stone. Calculus humanus; Betoar microcosmicum. Gravel; Stone. In English we understand by gravel, small sand-like concretions, or stones, which pass from the kidneys through the ureters in a few days; and by stone, a calculous concretion in the kidneys, or bladder, of too large a size to pass, without great difficulty. Similar concretions are found occasionally in other cavities or passages. When a disposition to form minute calculi or gravel exists, we often find nephritic paroxysms, as they are called, (see Nephritis) which consist of pain in the back, shooting down through the pelvis to the thighs; sometimes a numbness in one leg, and a retraction of either testicle in men, symptoms arising from the irritation of a stone passing through the ureters, as these cross the spermatic cord, on the nerves passing to the lower extremities. These pains, often violent, are terminated by the painful discharge of small stones through the urethra, and the patient is for a time easy. What, however, is CA'LCULUS. (Diminutive of calx, a lime-stone. the patient is for a time easy. What, however, is meant by the stone is a more serious and violent dis-It is singular that these discharges of small gra-not usually terminate in stone. Many have exvel do not usually terminate in stone. Many have experienced them during a long life, without any more serious inconvenience: while the latter is a disease chiefly of the young, and depending on circumstances not easily explained. If the stone attacks persons more advanced in age, it is often the consequence of paroxysms of gout, long protracted, and terminating imperfective. imperfectly.

When once a stone has acquired a moderate size, it usually occasions the following symptoms:—frequent inclination to make water, excessive pain in voiding it drop by drop, and sometimes a sudden stoppage of it, if discharged in a stream; after making water, great torture in the glans penis, which lasts one, two, or three minutes; and, in most constitutions, the violent straining makes the rectum contract and expelite excrements; or, if it be empty, occasions a tenestwo, or three minutes; and, in most constitutions, the violent straining makes the rectum contract and expelits excrements; or, if it be empty, occasions a tenesmus, which is sometimes accompanied with a prolapsus ani. The urine is often tinctured with blood, from a rupture of the vessels, and sometimes pure blood itself is discharged. Sometimes the urine is very clear, but frequently there are great quantities of slimy sediment deposited at the bottom of it, which is only a preternatural separation of the mucilage of the bladder, but has often been mistaken for pus. The stone is a disease to which both sexes and all ages are liable; and calculi have even been found in the bladders of very young children, nay, of infants only six months old.

Women seem less subject to this complaint than men, either owing to constitutional causes, or to the capaciousness, shortness, and straightness of their urethræ, allowing the calculi to be discharged while small, together with the urine.

The Scat and Physical Properties of Urinary Calculi.

Calculi are found in different parts of the urinary system, in the pelvis of the kidney, in the ureters, in the bladder and urethra; but as they, for the most part, originate in the kidney, the calculi renales make the nucleus of the greatest number of urinary stones. The calculi renales differ greatly with respect to their external conalities: for the most part, however, they

part, originate in the kidney, the calculi renales make the nucleus of the greatest number of urinary stones. The calculi renales differ greatly with respect to their external qualities; for the most part, however, they consist of small, concrete, roundish, smooth, glossy, and crystalline bodies, of a red-yellow colour, like that of wood, and so hard as to admit of polishing. On account of their minuteness, they easily pass through the urinary passages in form of gravel, which being sometimes of a rough surface, cause several complaints on their passage. But in some instances they are of too great a size to be able to pass along the ureters; in which case they increase in the kidneys, sometimes to a great size. Calculi renales of this kind are generally of a brown, dark red, or black colour, and surrounded with several strata of coagulated blood and pus; they have also been observed of a yellow, reddish, and lighter colour; and some consisting of a homogeneous stony mass, but white or gray calculi renales are very rarely to be met with. Among the great number that were examined, one or two only were found of a gray or blackish colour, and of a composition similar to those which generally bear the name of mulberry-like stones.

The stones in the ureters, which, on passing into tho ureters, are prevented by their size from descending into the bladder, frequently increase very much: they,

into the bladder, frequently increase very much: they, however, rarely occur; their colour is white, and they consist of phosphate of lime.

The stones in the bladder are the most frequent urinary concrements that have been principally examined; they draw their first origin from the kidneys, whence they descend into the bladder, where they increase; or they immediately originate and increase in the bladder; or they arise from a foreign body that by chance has got into the bladder, which not unfrequently happens, particularly in the female sex. Concretions of this kind differ greatly in their respective physical qualities and external form, which, however, is generally spherical, oval, or compressed on both sides; and sometimes, when there are several stones in the bladder, they have a polyhedrous or cubical form; their extremities are frequently pointed or roundish, but they are very seldom found cylindrical, and more rarely with cylindrical ends.

There is a great variety in the size of the calculi, and likewise in their selective their extensitive differences.

and more rarely with cylindrical ends.

There is a great variety in the size of the calculi, and likewise in their colour, which is materially different, according to their respective nature and composition. They occur, 1. of a yellowish colour, approaching nearly to red, or brown; such stones consist of lithic acid. 2. Gray, or more or less white; these stones always contain phosphates of earths. 3. Dark gray, or blackish; stones of this colour have oxalates of earths. Many stones show brown or gray spots, on a yellow or white ground, generally raised on the surface, and consisting of oxalate of lime; which is enclosed in lithic acid, when the ground colour of the stone is of a wood colour, or in phosphate of lime, when it is white. These spots are, in general, only to be observed in the middle of the stone, or at one of its extremities.

its extremities.

All that is here stated, is the result of observations on more than 600 calculi; and different other colours, that are said to have been observed, either arise from that are said to have been observed, either arise from heterogeneous substances, or are merely variations of the above colours. Their surface is smooth and polished in some; in others, only smooth; and in others uneven, and covered with rough or smooth corpuscles, which are always of a yellow colour; in some, the surface is partly smooth and partly rough. The white ones are frequently even and smooth, half transparent, and covered with shining crystals, that generally indicate phosphate of ammonia, with magnesia; or they are faint, and consist of minute grains; or rough, in which case they consist of phosphate of lime. The which case they consist of phosphate of lime. The brown and dark gray stones are, from their simi-larity to mulberries, called mulberry-stones, and being frequently very rugged, they cause the most pain

of all.

On examining the specific weight of urinary calculi in more than 500 specimens, it was found to be, in the lightest, as 1213.1000, in the heaviest, as 1976.1000. Their smell is partly strong, like urine or ammonia, partly insipid, and terreous; especially the white ones, which are like sawed ivory, or rasped bone.

The internal texture of calculi is but seldom guessed from their external appearance, particularly when they exceed the size of a pigeon's egg. On breaking them, they generally separate into two or three strata, more or less thick and even, which prove that they are formed by different precipitations, at different times. In the middle, a nucleus is generally seen, of the same mass as the rest. When the place they are broken at is finely streaked, and of a yellow or reddish colour, the lithic acid predominates; but when they are half transparent, luminous like spar, they have are half transparent, luminous like spar, they have ammoniacal phosphate of magnesia in them, and phosphate of lime, and then they are brittle and friaphosphate of lime, and then they are brittle and fria-ble; but when they are so hard as to resist the instru-ment, of a smooth surface, and a smell like ivory, they contain oxalate of lime. It frequently happens, that the exterior stratum consists of white phosphate of earth, while the nucleus is yellow lithic acid, or oxalate of lime, covered sometimes with a yellow stratum of lithic acid, in which case the nucleus ap-nears radiant; but when it consists of lithic acid, and stratum of ithic acid, in which case the nucleus ap-pears radiant; but when it consists of lithic acid, and is covered with white phosphate of earth, it is round-ish, oval, and somewhat crooked. These concretions have very seldom three strata; namely, on the outside a phosphate, towards the inside lithic acid, and quite withinside an oxalate of lime; but still rarer these

substances occur in more strata, or in another order, as before-mentioned.

Stones of the urethra are seldom generated in the urethra itself; however, there are instances of their having been formed in the fossa navicularis, by means of foreign bodies that have got into the urethra. We also very frequently observe stony concrements deposited between the glans and prepuce. All the concretions produced in the inside and outside the urethra consist of phosphate of earths, which are easily precipitated from the urine. There are likewise stones in the urethra which have come out of the bladder, having been produced there, or in the kidneys; and they generally possess the properties of stones of the

The different constituents of Urinary Calculi.
"If we except Scheele's original observation concerning the uric or lithic acid, all the discoveries relating to urinary concretions are due to Dr. Wollaston; discoveries so curious and important, as alone are sufficient to entitle him to the admiration and gratitude of mankind. They have been fully verified by the subsequent researches of Fourcroy, Vauquelin, and Brande, Drs. Henry, Marcet, and Prout. Dr. Marcet, in his late valuable essay on the chemical history and medical treatment of calculous disorders, arranges the representations into nine species. concretions into nine species.

1. The lithic acid calculus.

2. The ammonia-magnesian phosphate calculus.

The bone earth calculus, or phosphate of lime.
 The fusible calculus, a mixture of the 2d and 3d

5. The mulberry calculus, or oxalate of lime.
6. The cystic calculus; cystic oxide of Dr. Wol-

laston.

7. The alternating calculus, composed of alternate layers of different species.

8. The compound calculus, whose ingredients are so

intimately mixed, as to be separable only by chemical

Calculus from the prostate gland, which, by Dr. Wollaston's researches, is proved to be phosphate of lime, not distinctly stratified, and tinged by the secre-

tion of the prostate gland.

To the above Dr. Marcet has added two new subspecies. The first seems to have some resemblance to the cystic oxide, but it possesses also some marks of distinction. It forms a bright lemon yellow residuum on evaporating its nitric acid solution, and is comon evaporating its intric acid solution, and is composed of laminæ. But the cystic oxide is not laminated, and it leaves a white residuum from the nitric acid solution. Though they are both soluble in acids as well as alkalies, yet the oxide is more so in acids than the new calculus, which has been called by Dr. Marcet, from its yellow residuum, xanthic oxide. Dr. Marcet's other new calculus was found to research. other new calculus was found to possess the properties of the fibrin of the blood, of which it seems to be a

deposite. He terms it fibrinous calculus.

Species 1. Uric acid calculi. Dr. Henry says, in his instructive paper on urinary and other morbid concretions, read before the Medical Society of London, March 2, 1819, that it has never yet occurred to him to examine calculi composed of this acid in a state of absorbate partice. They contain about 9-10ths of the pure examine calcult composed of this acid in a state of absolute purity. They contain about 9-10ths of the pure acid, along with urea, and an animal matter which is not gelatin, but of an albuminous nature. This must not, however, be regarded as a cement. The calculus is aggregated by the cohesive attraction of the lithic acid itself. The colour of lithic acid calculi is yellowish or reddish-brown, resembling the appearance of wood. They have commonly a smooth, polished surface, a lamellar or radiated structure, and consist of fine particles well compacted. Their specific gravity varies from 1.3 to 1.8. They dissolve in alkaline lixivia, without evolving an ammoniacal odour, and exhale the smell of horn before the blowpipe. The relative frequency of lithic acid calculi will be seen relative frequency of lithic acid calculi will be seen from the following statement. Of 150 examined by Mr. Brande, 16 were composed wholly of this acid, and almost all contained more or less of it. Fourcroy and Vauquelin found it in the greater number of 500 which they analyzed. All those examined by Scheele consisted of it alone; and 300 analyzed by Dr. Pearson, contained it in greater or smaller proportion. According to Dr. Henry's experience, it constitutes 10 urinary concretions out of 26, exclusive of the alternating calculi. And Mr. Brande lately states; that out of 58

cases of kidney calculi, 51 were lithic acid, 6 oxalic

and 1 cystic.

Species 2. Ammonia-magnesian phosphate. This calculus is white like chalk, is friable between the fingers, is often covered with dog-tooth crystals, and contains semi-crystalline layers. It is insoluble in contains semi-crystalline layers. It is insoluble in alkalies, but soluble in nitric, muriatic, and acetic acids. According to Dr. Henry, the earthy phosphates, comprehending the 2d and 3d species, were to the whole number of concretions, in the ratio of 10 to 85. Mr. Brande justly observes, in the 16th number of his Journal, that the urine has at all times a tendency to deposite the triple phosphate upon any body over which it passes. Hence drains by which urine is carried off, are often incrusted with its regular crystals; and in cases where extraneous bodies have got into the and in cases where extraneous bodies have got into the bladder, they have often in a very short time become considerably enlarged by deposition of the same sub-stance. When this calculus, or those incrusted with its semi-crystalline particles, are strongly heated before the blowpipe, ammonia is evolved, and an imperfect fusion takes place. When a little of the calcaroous phosphate is present, however, the concretion readily phosphate is present, however, the concretion readily fuses. Calculi composed entirely of the ammoniamagnesian phosphate are very rare. Mr. Brande has seen only two. They were crystallized upon the surface, and their fracture was somewhat foliated. In its pure state, it is even rare as an incrustation. The powder of the ammonia-phosphate calculus has a brilliant white colour, a faint sweetish taste, and is somewhat soluble in water. Fourcroy and Vauquelin suppose the above deposites to result from incipient putrefaction of urine in the bladder. It is certain that putrefaction of urine in the bladder. It is certain that

the triple phosphate is copiously precipitated from urine in such circumstances out of the body.

Species 3. The bone earth calculus. Its surface, according to Dr. Wollaston, is generally pale brown, smooth, and when sawed through it appears of a laminated texture, easily separable into concentric crusts.

Sometimes, also, each lamina is striated in a direction perpendicular to the surface as from an assemblage of sometimes, also, each lamina is striated in a direction perpendicular to the surface, as from an assemblage of crystalline needles. It is difficult to fuse this calculus by the blowpipe, but it dissolves readily in dilute mu riatic acid, from which it is precipitable by ammonia. This species, as described by Fourcroy and Vauquelin, was white, without lustre, friable, staining the hands, paper, and cloth. It had much of a chaiky appearance, and broke under the forcess, and was intimately ance, and broke under the forceps, and was intimately mixed with a gelatinous matter, which is left in a membraneous form, when the earthy salt is withdrawn by dilute muriatic acid. Dr. Henry says, that he has never been able to recognise a calculus of pure phosphate of lime in any of the collections which he has examined; nor did he ever find the preceding species in a pure state, though a calculus in Mr. White's collections contained more than 90 per cent of ammorphisms. tion contained more than 90 per cent. of ammonia-

magnesian phosphate.

Species 4. The fusible calculus. This is a very friable concretion, of a white colour, resembling chalk in appearance and texture; it often breaks into layers, and pearance and texture; it often breaks into layers, and exhibits a glittering appearance internally, from intermixture of the crystals of triple phosphate. Sp. grav. from 1.14 to 1.47. Soluble in dilute muriatic and nitric acids, but not in alkaline lixivia. The nucleus is generally lithic acid. In 4 instances only out of 187, did Dr. Henry find the calculus composed throughout of the earthy phosphates. The analysis of fusible calcu-lus is easily performed by distilled vinegar, which at a gentle heat dissolves the ammonia-magnesian phosphate, but not the phosphate of lime; the latter may be taken up by dilute muriatic acid. The lithic acid present will remain, and may be recognised by its solubility in the water of pure potassa or soda. Or the lithic acid may, in the first instance, be removed by the alkali, which expels the ammonia, and leaves the

the alkali, which expels the ammonia, and leaves the phosphate of magnesia and lime.

Species 5. The mulberry calculus. Its surface is rough and tuberculated; colour deep reddish-brown. Sometimes it is pale brown, of a crystalline texture, and covered with flat octohedral crystals. This calculus has commonly the density and hardness of ivory, a sp. grav. from 1.4 to 1.98, and exhales the odour of semen when sawed. A moderate red heat converts it into carbonate of lime. It does not dissolve in alkaline lixivia, but slowly and with difficulty in acids. When the oxalate of lime is voided directly after leaving the kidney, it is of a grayish-brown colour.

composed of small cohering spherules, sometimes with a polished surface resembling hempseed. They are easily recognised by their insolubility in muriant. are easily recognised by their insolubility in muriatic acid, and their swelling up and passing into pure lime before the blowpipe. Mulberry calculi contain always an admixture of other substances besides oxalate of lime. These are, uric acid, phosphate of lime, and animal matter in dark flocculi. The colouring matter of these calculi is probably effused blood. Dr. Henry rates the frequency of this species at 1 in 17 of the whole which he has compared; and out of 187 calculi, he found that 17 were formed round nuclei of oxalate of lime.

Species 6. The cystic-oxide calculus. bles a little the triple phosphate, or more exactly mag-nesian limestone. It is somewhat tough when cut, and has a peculiar greasy lustre. Its usual colour is pale has a pecuniar greasy itsue. As usual colour is pane brown, bordering on straw yellow; and its texture is irregularly crystalline. It unites in solution with acids and alkalies, crystallizing with both. Alkohol precipitates it with nitric acid. It does not become red with nitric acid; and it has no effect upon vegetable blues. Neither water, alkohol, nor ether dissolves it. It is decomposed by heat into carbonate of ammonia and oil, leaving a minute residuum of phosphate of lime. This concretion is of very rare occurrence. Dr. Henry states its frequency to the whole as le to 985. In two which he examined, the nucleus was the same substance with the rest of the concretion; and in a third, the nucleus of a uric acid calculus was a small spherule of cystic oxide. Hence, as Dr. Marcet has remarked this oxide appears to he in reality the has remarked, this oxide appears to be in reality the production of the kidneys, and not, as its name would import, to be generated in the bladder. It might be called with propriety reaal oxide, if its eminent discoverer should think fit.

Species 7. The alternating calculus. The surface of this calculus is usually white like chalk, and friable or semicrystalline, according as the exterior coat is the calcareous or ammonia-magnesian phosphate. They are frequently of a large size, and contain a nu-cleus of lithic acid. Sometimes the two phosphates form alternate layers round the nucleus. The above form alternate layers round the nucleus. The above are the most common alternating calculi; next are those of oxalate of lime with phosphates; then oxalate of lime with lithic acid; and lastly, those in which the three substances alternate. The alternating, taken all together, occur in 10 out of 25, in Dr. Henry's list; lithic acid with phosphates, as 10 to 48; the oxalate of lime with phosphates, as 10 to 116; the oxalate of lime with lithic acid, as 10 to 170; the oxalate of lime with lithic acid and phosphates, as 10 to 255.

Species 8. The compound calculus. This consists of a mixture of lithic acid with the phosphates in variable proportions, and is consequently variable in

variable proportions, and is consequently variable in its appearance. Sometimes the alternating layers are so thin as to be undistinguishable by the eye, when their nature can be determined only by chemical analysis. This species, in Dr. Henry's l'st, forms 10 in 235. About 1-40th of the calculi examined by Fourcroy and Vauquelin were compound.

Species 9 has been already described.

In almost all calculi, a central nucleus may be disthe ureters into the bladder. The disease of stene is to be considered, therefore, essentially and originally as belonging to the kidneys. Its increase in the bladder may be occasioned, either by exposure to urine that contains an excess of the same ingredient as that composing the nucleus, in which case it will be uniformly assertionally the machine and the machine and the machine as the mach formly constituted throughout; or if the morbid nu-cleus deposite should cease, the concretion will then acquire a coating of the earthy phosphates. It becomes,

position to secrete an excess of lithic acid has been the essential cause of the origin of stone. Hence it becomes a matter of great importance to inquire, what are the circumstances which contribute to its excessive production, and to ascertain by what plan of diet and medicine this morbid action of the kidney may best be obviated or removed. A calculus in Mr. White's collection had for its nucleus a fragment of a bougie, that had slipped into the bladder. It belonged to the foreible spreads a consisting of fusible species, consisting of,

20 phosphate of lime, 60 ammonia-magnesian phosphate, 10 lithic acid,

10 animal matter.

In some instances, though these are comparatively very few, a morbid secretion of the earthy phosphates in excess, is the cause of the formation of stone. Dr. m excess, is the cause of the formation of stone. Dr. Henry relates the case of a gentleman, who, during paroxysms of gravel, preceded by severe sickness and voniting, voided urine as opaque as milk, which deposited a great quantity of an impalpable powder, consisting of the calcareous and triple phosphate in nearly equal proportions. The weight of the body was rapidly equal from 188 to 100 pounds, apparently by the chemical properties of the properties of t reduced from 188 to 100 pounds, apparently by the ab-struction of the earth of his bones; for there was no emaciation of the muscles corresponding to the above diminution.

diminution.

The first rational views on the treatment of calculous disorders, were given by Dr. Wollaston. These have been followed up lately by some very judicious observations of Mr. Brande, in the 12th, 15th, and 16th numbers of his Journal; and also by Dr. Marcet, in his excellent treatise already referred to. Of the many substances contained in human urine, there are rarely more than three which constitute gravel; viz. calcareous phosphate, ammonia-magnesian phosphate, and lithic acld. The former two form a white sediment; the latter, a red or brown. The urine is always an acidulous secretion. Since by this excess of acid, the earthy salts, or white matter, are held in solution, whatever disorder of the system, or improprictly of food and medicine, diminishes that acid excess, favours the formation of the white deposite. The internal use of acids was shown by Dr. Wollaston to be the appropriate remedy in this case.

the appropriate remedy in this case.

White gravel is frequently symptomatic of disordered digestion, arising from excess in eating or drinking; and it is often produced by too farinaceous a diet. It is also occasioned by the indiscreet use of magnesia, soda water, or alkaline medicines in general. Medical practitioners, as well as their patients, ignorant of chemistry, have often committed fatal mistakes, by considering the white gravel, passed on the administration of alkaline medicines, as the dissolution of the calculus itself; and have hence pushed a practice, which has rapidly increased the size of the stone. Magnesia, in many-cases, acts more injuriously than alkaii, in precipitating insoluble phosphate from the urine. The acids of urine, which, by their excess, hold the carths in solution, are the phosphoric, lithic, and carbonic. Mr. Brande has uniformly obtained the

and carbonic. Mr. Brande has uniformly obtained the latter acid, by placing urine under an exhausted receiver; and he has formed carbonate of barytes, by dropping barytes water into urine recently voided.

The appearance of white sand does not seem deserving of much attention, where it is merely occasional, following indigestion brought on by an accidental excess. But if it invariably follows meals, and if it be observed in the urine, not as a mere deposite, but at the time the last drops are voided, it becomes a acquire a coating of the earthy phosphates. It becomes, the most predominate nucleus. Out of 137 calculi examined by Dr. Henry, 17 were formed round nuclei of cystic oxide; 4 round nuclei of the earthy phosphates; 2 round extraneous substances; and in 3 the nucleus was replaced by a small cavity, occasioned, probably, by the shrinking of some animal matter, round which the ingredients of the calculi (fusible) had been deposited. Rau has shown by experiment, that pus may form the nucleus of a urinary concretion. The remaining 153 calculi of Dr. Henry's list, had central nuclei composed chiefly of lithic acid. It appears also, that in a very great majority of the cases referred to by him, the dismall liquor, madeira, and port; to cat salads, with acid but at the time the last drops are voided, it becomes a matter of importance, as the forerunner of other and serious forms of the disorder. It has been sometimes viewed as the effect of irritable bladder, where it was in reality the cause. Acids are the proper remedy, and unless some peculiar tonic effect be sought for in sulphuric acid, the vegetable acids ought to be preferred. Tartar, or its acid, may be prescribed with advantage, but the best medicine is citric acid, in daily doses from 5 to 30 grains. Persons returning from warm climates, with dyspeptic and hepatic disorders, often void this white gravel, for which they have re-

fruits; and if habit requires it, a glass of cider, champagne, or claret, but the less of these fermented liquors | A large quantity of mucus streaked with blood, or of the better. An effervescing draught is often very bencha purulent aspect, and hamorrhagy, are frequent ficial, made by dissolving 30 grains of bicarbonate of potassa, and 20 of citric acid, in separate teacups of water, mixing the solution in a large tumbler, and drinking the whole during the effervescence. This dose may be repeated 3 or 4 times a-day. The carbonic acid of the above medicine enters the circulation, and passing off by the bladder, is useful in retaining, particularly, the triple phosphate in solution, as was first pointed out by Dr. Wollaston. The bowels should be kept regular by medicine and moderate exercise. The febrile affections of children are frequently attended by an apparently formidable deposite of white sand in the urine. A dose of calomel will generally carry off both the fever and the sand. Air, exercise, bark, bitters, mineral tonics, are in like manner often successful in removing the urinary complaints of grown-up

In considering the red gravel, it is necessary to dis-tinguish between those cases in which the sand is actually voided, and those in which it is deposited, after some hours, from originally limpid urine. In the first, the sabulous appearance is an alarming indi-cation of a tendency to form calculi; in the second, it is often merely a ficeting symptom of indigestion. Should it frequently recur, however, it is not to be dis-

regarded.

Bicarbonate of potassa or soda is the proper remedy for the red sand, or Ifthic acid deposite. The alkali may often be beneficially combined with opium. Ammonia, or its crystallized carbonate, may be resorted to with advantage, where symptoms of indigestion are brought on by the other alkalies; and particularly in red gravel connected with gout, in which the joints and kidneys are affected by turns. Where potassa and soda have been so long employed as to disagree with the stomach to create nausea, flatulency a sense of the stomach, to create nausea, flatulency, a sense of weight, pain, and other symptoms of indigestion, magnesia may be prescribed with the best effects. The tendency which it has to accumulate in dangerous quantities in the intestines, and to form a white sedi-ment in urine, calls on the practitioner to look minutely after its administration. It should be occasionally alternated with other laxative medicines. Magnesia dissolved in carbonic acid, as Mr. Scheweppe used to prepare it many years ago, by the direction of Mr. Brande, is an elegant form of exhibiting this

Care must be had not to push the alkaline medicines too far, lest they give rise to the deposition of earthy phosphates in the urine.

Cases occur in which the sabulous deposite consists of a mixture of lithic acid with the phosphates. The sediment of urine in inflammatory disorders is sometimes of this nature; and of those persons who habitually indulge in excess of wine; as also of those who, labouring under hepatic affections, secrete much albumen in their urine. Purges, tonics, and nitric acid, which is the solvent of both the above sabulous matters, are the appropriate remedies. The best diet for patients labouring under the lithic deposite, is a vege-table. Dr. Wollaston's fine observation, that the ex-crement of birds fed solely upon animal matter, is in a great measure lithic acid, and the curious fact since ascertained, that the excrement of the boa constrictor, fed also entirely on animals, is pure lithic acid, concur in giving force to the above dietetic prescription. A week's abstinence from animal food has been known to relieve a fit of lithic acid gravel, where the aikalies were of little avail. But we must not carry the vegetable system so far as to produce flatulency and indi-

Such are the principal circumstances connected with the disease of gravel in its incipient or sabulous state. The calculi formed in the kidneys are, as we have said above, either lithic, oxalic, or cystic; and very rarely indeed of the phosphate species. An aqueous regimen, moderate exercise on horseback, when not accompanied with much irritation, cold bathing, and mid aperients, along with the appropriate ch mical medicines, must be prescribed in kidney cases. These are particularly requisite immediately after acute pain in the region of the ureter, and indiamatory symptoms have led to the belief that a nucleus has descended into the bladder. Purges, kim-

a purulent aspect, and hæmorrhagy, are frequent symptoms of the passage of the stone into the bladder. When a stone has once lodged in the bladder, and

increased there to such a size as no longer to be capa-ble of passing through the urethra, it is generally allowed by all who have candidly considered the subject, and who are qualified by experience to be judges, that the stone can never again be dissolved; and although it is possible that it may become so loosened in its texture as to be voided piecemeal, or gradually to crumble away, the event is so rare as to be barely

By examining collections of calculi we learn, that in by far the greater number of cases, a nucleus of lithic acid is enveloped in a crust of the phosphates. Our endeavours must therefore be directed towards reducing the excess of lithic acid in the urine to its natural standard; or, on the other hand, to lessen the tendency to the deposition of the phosphates. The urine must be submitted to chemical examination, and a suitable course of diet and medicines prescribed. But the chemical remedies must be regulated nicely, so as to hit the happy equilibrium, in which no deposite will be formed. Here is a powerful call on the physi-cians and surgeons to make themselves thoroughly versant in chemical science; for they will otherwise commit the most dangerous blunders in calculous complaints.

'The idea of dissolving a calculus of uric acid in "The idea of dissolving a calculus of uric acid in the bladder, by the internal use of the caustic alkalies,' says Mr. Brande, 'appears too absurd to merit serious refutation.' In respect to the phosphates, it seems possible, by keeping up an unusual acidity in the urine, so far to soften a crust of the calculus, as to make it crumble down, or admit of being abraded by the sound; but this is the utmost that cau be looked for; and the lithic nucleus will still remain. 'These considerations,' adds Mr. Brande, 'independent of more urgent reasons, show the futility of attempting the velocity of a stone of the bladder by the injection the solution of a stone of the bladder by the injection of acid and alkaline solutions. In respect to the alka-lies, if sufficiently strong to act upon the uric crust of the calculus, they would certainly injure the coats of the biadder; they would otherwise become inactive by combination with the acids of the urine, and they would form a dangerous precipitate from the same cause.'—'It therefore appears to me, that Fourcroy and others, who have advised the plan of injection, have thought little of all these obstacles to success, and have regarded the bladder as a lifeless receptacle, and have regarded the bladder as a meress receptacie, into which, as into an India rubber bottle, almost any solvent might be injected with impunity."—Journal of Science, vol. viii. pr 216.

It does not appear that the peculiarities of water in different districts, have any influence upon the production of calculous disorders. Dr. Wollaston's discrete

covery of the analogy between urinary and gouty concretions has led to the trial in gravel of the visuam col-chici, the specific for gout. By a note to Mr. Brande's, dissertation we learn, that benefit-has been derived from it in a case of red gravel.

Dr. Henry confirms the above precepts in the follow-ing decided language. 'These cases, and others of the same kind, which I think it unnecessary to mention, tend to discourage all attempts to dissolve a stone supposed to consist of uric acid, after it has attained considerable size in the bladder; all that can be effected under such circumstances by alkaline medicines appears, as Mr. Brande has remarked, to be the precipitating upon it a coating of the earthy phosphates from the urine, a sort of concretion which, as has been observed by various practical writers, increases much more rapidly than that consisting of uric acid only. The same unfavourable inference may be drawn also from the dissections of those persons in drawn also from the dissections of those persons in whom a stone was supposed to be dissolved by alkaline medicines; for in these instances it has been found either encysted, or placed out of the reach of the sound by an enlargement of the prostate gland.' The urinary calculus of a dog, examined by Dr. Pearson, was found to consist principally of the phosphates of lime and ammonia, with animal matter. Several taken from horses, were of a similar composition. One of a rabbit consisted chiefly of carbonate.

CAL CAL

phoric acid. A quantity of sabulous matter, neither crystallized nor concrete, is sometimes found in the bladder of the horse: in one instance there were nearly 45 pounds. These appear to consist of carbonate of 45 pounds. These appear to consist of carbonate of lime and animal matter. A calculus of a cat gave Fourcroy three parts of carbonate, and one of the phosphate of lime. That of a pig, according to Berthollet, was phosphate of lime.

The renal calculus in man appears to be of the same nature as the urinary. In that of the horse, Fourcroy found 3 parts of carbonate, and one of phosphate of lime. Dr. Pearson, in one instance, carbonate of lime, and animal matter; in two others, phosphates of lime

and animal matter; in two others, phosphates of lime and ammonia, with animal matter.

Arthritic calculi, or those formed in the joints of arthritic caiculi, or those formed in the joints of lime, whence they were once supposed to be carbonate of lime, whence they were called chalkstones; afterward it was supposed that they were phosphate of lime; but Dr. Wollaston has shown that they are lithate of soda. The calculi found sometimes in the pineal, prostate, salivary, and bronchial glands, in the pancreas, in the corpora cavernosa penis, and between the muscles, as well as the tartar, as it is called, that incrusts the teeth, appear to be phosphate of lime. Dr. Crompton, however, examined a calculus taken from the lungs of a deceased soldier, which consisted of lime 45, carof a deceased soldier, which consisted of lime 45, carbonic acid 37, albumen and water 18. It was very hard, irregularly spheroidal, and measured about 6½ inches in circumference.

It has been observed, that the lithic acid, which constitutes the chief part of most human urinary calculi, and abounds in the arthritic, has been found in no phytivorous animal; and hence has been deduced a practical inference, that abstinence from animal food would prevent their formation. But we are inclined to think this conclusion too hasty. The cat is carnivorous; but it appeared above, that the calculus of that animal is equally destitute of lithic acid. If, therefore, we would form any deduction with respect to regimen, we must look for something used by man, exclusively of all other animals; and this is obviously found in fermented liquors, but apparently in nothing else: and this practical inference is sanctioned by the most respectable medical authorities.

The following valuable criteria of the different kinds of urinary calculi, have been given by M. Berzelius in his treatise on the use of the blowpipe:

1. We may recognise calculi formed of uric acid, from their being carbonized and smoking with an animal odour, when heated by themselves on charcoal or platinum-foil. They dwindle away at the blowpipe flame. Towards the end, they burn with an increase of light; and leave a small quantity of very white alkaline ashes. It has been observed, that the lithic acid, which

alkaline ashes.

'To distinguish these concretions from other sub-To distinguish these concretions from other substances, which comport themselves in the above manner, we must try a portion of the calculus by the humid way. Thus a tenth of a grain of this calculus being put on a thin plate of glass or platinum, along with a drop of nitric acid, we must heat it at the flame of the lamp. The uric acid dissolves with effervescence. The matter, when dried with precaution to prevent it from charring, is obtained in a fine red colour. If the calculus contains but little uric acid, the substance sometimes blackens by this process. We must then calculus contains but little uric acid, the substance sometimes blackens by this process. We must then take a new portion of the concretion, and after having dissolved it in nitric acid, remove it from the heat: the solution, when nearly dry, is to be allowed to cool and become dry. We then expose it, sticking to its support, to the warm vapour of caustic ammonia. (From water of ammonia heated in a tea-spoon.) This ammoniacal vapour developes a beautiful red colour in it. We may also moisten the dried matter with a little weak water of ammonia. weak water of ammonia.

'If the concretions are a mixture of uric acid and earthy phosphate, they carbonize and consume like the above, but their residuum is more bulky; it is not alkaline, nor soluble in water. They exhibit with nitric acid and ammonia, the fine red colour of uric acid. Their ashes contain phosphate of lime, or of lime and magnesia.

When there are earthy salts (phosphates) in these concretions, they afford a whitish or opaque gray glass.

'3. The calculi of wrate of ammonia comport themselves at the blowpipe like those of uric acid. A drop of caustic potassa makes them exhale, at a moderate heat, much ammonia. We must not confound this odour with the slight ammoniaco-lixivial smell, which potassa disengages from the greater part of animal substances. Urate of soda is likewise found in these

'4. Calculi of phosphate of lime. They blacked, with the exhalation of an empyreumatic animal odour, with the exhalation of an empyreumanic animal odour, without meiting of themselves at the blowpipe, but whiten into an evident calcareous phosphate. With soda they swell up without vitrifying. Dissolved in boracic acid, and fused along with a little iron, they yield a bead of phosphuret of iron.

'5. Calculi of ammoniaco-magnesian phosphate, heated alone on a plate of platinum, exhale the empy reumatic animal odour, at the same time blackening, swelling up, and becoming finally grayish white. A

reumatic animal odour, at the same time blackening, swelling up, and becoming finally grayish white. A kind of grayish-white enamel is in this manner obtained. With borax they melt into a glass, which is transparent, or which becomes of a milky-white on cooling Soda in small quantity causes them to fuse into a frothy white slag; a larger quantity of soda makes them infusible. They yield, with iron and boracic acid, a bead of phosphuret of iron; with nitrate of cobalt, a glass of a deep red or brown. If salts of lime exist in these concretions, the mixture of them is less fusible.

is less fusible.

'6. Calculi of oxalate of lime, exposed to the blow-pipe, exhale at first the urinous smell; they become first of a dull colour at the flame, and afterward their cotour brightens. What remains after a moderate ignition, effervesces with nitric acid. After a smart ignition, effervesces with nitric acid. After a smart jet of the flame, there remains quicklime on the charcoal, which reacts like an alkali on the colour of litmus, wild mallow flower, or cabbage, and slakes with water. But this does not happen when the residuum consists of calcareous phosphate.

47. The siliceous calculus, heated alone, leaves subcoriaceous or infusible ashes. Treated with a little soda, these dissolve with effervescence, but slowly, "leaving a bead of glass of a gray colour, or of little transparency."

'8. Lastly, the cystic oxyde calculi afford nearly the same results as uric acid at the blowpipe. They reasame results as uric acid at the blowpipe. They readily take fire, burning with a bluish green flame, with out melting, with the disengagement of a lively and very peculiar acid odour, which has some affinity to that of cyanogen. Their ashes, which are not alkaline, redissolve by a jet of the flame, into a grayish-white mass. They do not yield a red colour in their treatment with nitric acid, like the uric acid concretions?"

The Causes of the Generation of Urinary Calculi.

To inquire into the causes by which urinary concretions are produced, is both interesting and useful, however attended with the greatest difficulties. The writings of medical authors are full of conjectures and hypotheses with regard to this subject, on which nothing could be ascertained before we had acquired an accurate knowledge of the nature of urinary concretions. It is owing to this circumstance that the most enlightened physicians acquiesced in ascribing the imenlightened physicians acquiesced in ascribing the im-mediate cause of them to a superabundance of terre-ous matter in the urine; and Boerhaave, as well as, particularly, Van Swieten, imagined that the urine of all men contained calculous matter in the natural state, and that, for the generation of stones, a nucleus was only required, to attract it. That this may be the was only required, to attract it. That this may be the case, in some instances, is proved by frequent experience; but stones produced by foreign bodies, that have accidentally got into the urethra or bladder, are always white, and composed of phosphates of earths, and seldom or never covered with lithic acid, a suband seldom or never covered with lithic acid, a substance and magnesia.

'2. The calculi of wrate of soda are hardly met with except in the concretions round the articulations of gouty patients. When heated alone upon charcoal, they blacken, exhaling an empyreumatic animal odour; they are with difficulty reduced into ashes, which are strongly alkaline, and are capable of vitrifying silica.

from the urine, but not why it unites in strata. A coagulating substance is required for separating, attracting, and, as it were, agglutinating the condensible particles that are precipitated. This substance is undoubtedly the animal matter which we have constantly found in all calculous masses, and which seems to constitute the basis of stones, like the membraneous gelatina that of bones. It is known that the urine of calculous patients is generally muddy, ductile, in threads, slimy, and as if mixed with albumen, which quality it obtains at the moment when the ammonia to dispense and or on the addition of rotages a that separated. is disengaged, or on the addition of potassa that separates it from the acid in which it was dissolved; and in all cases of superabundance of lithic acid the urine contains a great quantity of that animal matter, which promotes the precipitation of it, and attracts, and unites the particles thus separated. Hence it appears, that every thing capable of increasing the quantity of that pituitous gluten in the urine, may be considered as the remote cause of the formation of calculi. And the old ideas on pituitous temperaments, or superathe old ideas on pituitous temperaments, or supera-bundant pituita, &c. which were thought to dispose people to a calculus, seem to be connected with the late discoveries on the nature of urinary stones. Though the animal matter appears to be different in different calculi, yet it is certain, that every calculous substance contains an animal gluten, from which its concrete and solid state arises; whence we may fairly state the superabundance of that substance as the chief and principal cause of the formation of calculi and principal cause of the formation of calculi.

There are, however, other causes which seem to have a particular influence on the nature of urinary stones, and the strata in which they are formed; but it is extremely difficult to penetrate and to explain them. We are, for instance, entirely ignorant of the manner in which urinary stones are formed from the oxalate of lime; though, from their occurring more frequently in children than in adults, we might be entired to the property of the control of the strategy of titled to ascribe them to a disposition to acor, a cause considered by Boerhaave as the general source of a great number of diseases incident to the infantile age. This opinion seems to be proved by the ideas of Bonhomme, physician at Avignon, on the oxalic or saccharic acid, as the cause of mollities ossium in the rickets; by this acid being discovered in a species of saliva by Brugnatelli; and, lastly, by an observation of Turgais, who found this acid in the urine of a child diseased with worms. We but rarely observe saccharic acid in the human body, which appears to be mostly adventitious, and by which the animal matter is rendered coagulable, and deposited, or precipitated, with the oxalate of lime; or the oxalic acid decomposes the phosphate of lime, and forms an insoluble combination, incapable of being any longer kept dissolved in the urine. It is, however, extremely difficult to determine how far the constitution of the body is connected with that particular disposition in the urine, of precipitating sometimes phosphate of lime mixed with oxalate of lime, sometimes phosphate of ammoniacal magnesia, either by itself or mixed with lithic acid, &c. &c. Who can explain the reason why, of 600 stones, there were only two in which siliceous earth could be traced? Still more difficult is it to explain the causes why the above substances precipitate either at once or in differ-ent strata; but it may suffice to have shown how many observations and experiments are required, and what accurate attention and perseverance are neces-sary, in order to throw light on so difficult a subject.

The means to be employed in calculous comptaints must vary according to circumstances. Permanent relief can be obtained only by the removal of the morbid concretion: and where this is of too large a size to be passed by the natural outlet, the operation of lithotomy becomes necessary. Various remedies indeed have been proposed as capable of dissolving urinary calculi; and some of them are certainly useful in palliating the symptoms, and perhaps preventing the formation of fresh calculous mauer: but experience has not sanctioned their efficacy as actual lithontrip-tics; and by delaying the operation, we not only incur the risk of organic disease being produced, but the concretion may also become friable externally, so as to be with more difficulty removed. Sometimes, however, the advanced age of the patient, the complication with organic disease, or the exhausted state of the system, may render an operation inexpedient; or he may not be willing to submit to it; we shall then find some ad-

vantage from the use of chemical remedies, according to the morbid quality of the urine; that is generally from alkaline or earthy preparations, where a red de-posite appears, and from acids where there is a white some of the mild astringents, especially uva ursi, and occasional narcotics, where violent pain attends: sometimes an inflammatory tendency may require fomentations, the local abstraction of blood, and other antiable girls measures. The most likely place of effects antiphlogistic measures. The most likely plan of effecting a solution of the calculus must certainly be that proposed by Fourcroy, namely, injecting suitable liquids into the bladder. The most common calculi, containing uric acid, are readily soluble in a solution of potassa, or soda, weak enough to be held in the mouth, or even swallowed without inconvenience; mouth, or even swallowed without inconvenience; those which consist of phosphoric acid neutralized by lime, or other base, the next in frequency, dissolve in nitric or muriatic acid of no greater strength; the most rare variety, made up mostly of oxalate of lime, may be dissolved, but very slowly, in nitric acid, or solutions of the fixed alkaline carbonates, weak enough not to irritate the bladder. However, it is not easy to ascertain which of these solvents is proper in a particular case, for most calculi, are not uniform throughcular case, for most calculi are not uniform throughout, owing probably to the urine having varied during their formation, so that the examination of this secretion will not certainly indicate the injection required. The plan recommended, therefore, is, the bladder having been evacuated, and washed out with tepid water, to inject first the alkaline solution, heated to the temperature of the body, and direct it to be retained for half an hour, or longer, if the person can bear it; then, to the liquor voided and filtered, add a little muriatic acid, which will cause a white precipitate, if there be any uric acid dissolved; and so long as this happens, the same injection should be used, otherwise diluted muriatic acid is to be thrown in, and ammonia added to it when discharged; whereby phosphate of lime, if there be any, is precipitated: and when nei-ther of these succeeds, diluted nitric acid is to be tried; in each case varying the injection from time to time, as that previously used loses its efficacy. However, there appears one source of error in this method; namely, that the urine secreted, while the liquid is retained, may give rise to a precipitate, though none of the calculus may have been dissolved; it would therefore be proper to examine the urine previously, as well as occasionally during the use of injections, and, if necessary, correct its quality by the exhibition of proper internal medicines. See Lithontriptics and Lithotomy.

CALCULUS BILIARIS. See Gall-stone.
CALDA'RIUM. (From caleo, to make hot.) A
vessel in the baths of the ancients, to hold hot water.
CALEFA'CIENT. (Calefaciens; from calidus,
warm, and facio, to make.) A medicine, or other
substance, which excites a degree of warmth in the

substance, which excues a degree of warmth in the parts to which it is applied: as piper, spiritus vini, &c. They belong to the class of stimulants.

CALE NDULA. (Quad singulis calendis, i. e, mensibus, florescat; so called because it flowers every month.)

1. The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia

2. The pharmacopæial name of the single marigold.

See Calendula officinalis.

CALENDULA ALPINA. The mountain arnica. See Arnica montana.

CALENDULA ARVENSIS. The wild marigold. See

Caltha palustris.

CALENDULA OFFICINALIS. The garden marigold. Calendula sativa; Chrysanthemum; Sponsa solis; Caltha vulgaris. The flowers and leaves of this Caltha vulgaris. Caltha vulgaris. The flowers and leaves of this plant, Calendula:—seminibus cymbiformibus, muricatis, incurvatis omnibus, of Linnæus, have been exhibited medicinally: the former, as aperients in uterine obstructions and icteric disorders, and as diaphoretics in exanthematous fevers; the latter, as gentle aperients, and to promote the secretions in general.

aperients, and to promote the secretions in general.

CALENDULA PALUSTRIS. Common single marshmarigold. See Caltha palustris.

CA'LENTURE. A febrile delirium, said to be peculiar to sailors, wherein they imagine the sea to be green fields, and will throw themselves into it if not restrained. Bonetus, Dr. Oliver, and Dr. Stubbs, give an account of it.

149

The Indian name of a tree which ; CALR'SIUM. grows in Malabar, the bark of which made into an ointment with butter, cures convulsions from wounds, and heals ulcers. The juice of the bark cures the aphthæ, and, taken inwardiy, the dysentery .-- Ray.

Calf's snout. See Antirrhinum. Calt. (Arabian.) The same as kali.

CALICHA'PA. The white-thorn. CA'LIDUS. In medical language, it is commonly used for animal heat, or the vis vitæ thus, calidum animale innatum.

CALIDÆ PLANTÆ. (From calor, heat.)

that are natives of warm climates.

CALIE'TA. (From καλιης, a nest, which it somewhat resembles.) Calliette. A fungus growing on

the juniper-tree.

CALI'GO. (Caligo, ginis. fcm.) A disease of the eye, known by diminished or destroyed sight; and by the interposition of a dark body between the object and the retine. It is arranged by Collen in the class Locales, and order dysasthesic. The species of caligo are distinguished according to the situation of the interposed body: thus caligo lentis, caligo corna, caligo pupilla, caligo humorum, and caligo palpe-

CALIHA'CHA. The cassia-lignea, or cassia-tree of

Malabar.

CALIMA. The lapis calaminaris. CA'LIX. (Calix, icis. m.; from καλυπ7ω, to cover.)

See Calyz. Calle UM. (From καλλυνω, to adorn.) Calleon. The gills of a cock, which Galen says, is food not to be praised or condemned.

CALLE'NA. A kind of saltpetre. CA'LLI. Nodes in the gout.—Galen.

(From Ralos, beautiful.) A name of the CA'LLIA. chamomile.

Callible Phara. (From καλος, good, and βλέφα-ρον, the eyelid.) Medicines, or compositions, appro-priated to the eyelids.

CALLICO CCA. The name of a genus of plants in the Linnean system. Class, Pentandria, Order,

Monogynia.

Callicocca ipecacuanna. The plant from which ipecacuan root is obtained was long unknown; it was said by some writers to be the Psychotria emetica. Class, Pentandria; Order, Monogynia; by others, the Viola ipecacuanha, a syngenesious plant of the order Monogynia. It is now ascertained to be neither, but a small plant called Callicocca ipecacuanha. There are three sorts of ipecacuan to be met with in our shots, viz. the ash-coloured or gray, the brown and sho; s, viz. the ash-coloured or gray, the brown, and the white.

The ash-coloured is brought from Peru, and is a small wrinkled root, bent and contorted into a great variety of figures, brought over in short pieces, full of wrinkles, and deep circular fissures, down to a small white woody fibre that runs in the middle of each piece the cortical part is compact, brittle, looks smooth and resinous upon breaking: it has very little snell; the taste is bitterish and subacrid, covering the tongue, as it were, with a kind of mucilage.

The brown is small, somewhat more wrinkled than the foregoing; of a brown or blackish colour without, and white within this brown or blackish colour without,

and white within; this is brought from Brazil.

The white sort is woody, and has no wrinkles, nor any perceptible bitterness in taste. The first, the ash-coloured or gray ipecacuan, is that usually preferred for medicinal use. The brown has been sometimes observed, even in a small dose, to produce violent effects. The white, though taken in a large one, has scarcely any effect at all. Experience has proved that this medicine is the safest emetic with which we are accurated baying this peculiar advantage, that if it acquainted, having this peculiar advantage, that, if it does not operate by vomit, it readily passes off by the other emunctories. Ipecacuan was first introduced as an infallible remedy against dysenteries, and other inveterate fluxes, as diarrhea, menorrhagia, leucorrhea, &c. and also in disorders proceeding from obstructions of long standing; nor has it lost much of its reputation by time: its utility in these cases is thought to depend upon its restoring perspiration. It has also been successfully employed in spasmodic asthma, catarrhal and consumptive cases. Nevertheless, its chief use is as a vomit, and in small doses, joined with opium, as a diaphoretic. The officinal preparations are the pulvis ipecacuanha compositus, and the vinum ipecacuanha.

Calli'creas. (From salos, good, and speas, meat; so named from its delicacy as food.) Sweet-bread-See Pancreas.

Callional Rehus. (From kales, beautiful, and youn, a knot, or joint; so named from its being handsomely jointed, like a cane.) The polygonum, or knot-grass. Callional Rehus. The Gaullic name, in Marcellus

Empiricus, of colt's-foot.

Empiricus, of coit's-foot.

Ca'llion. A kind of night-shade

Calliphy'llum. From καλλος, beauty, and φυλλον, a leaf.) See Adianthum.

Callistrit'thia. (From καλος, good, and ςρυθος, a
sparrow; because it was said to fatten sparrows.) A
fig mentioned by Pliny, of a good taste.

Callitri'che. (From καλλος, beauty, and
βρίξ, hair; so named because it has the appearance of
long, beautiful hair; or, according to Littleton, because it nourishes the hair, and makes it beautiful.)

The name of a genus of plants in the Linnæan system. Class, Monandria; Order, Digynia. Water
starwort. Water chickweed.

2. The herb maidenhair. See Adianthum.

 The herb maidenbair. See Adianthum.
 CALLO'NE. (From καλος, fair.) Hippocrates used this word, to signify that decency and gravity of character and deportment which it is necessary that all medical men should be possessed of. CALLO'SITAS. Callosity, or preternatural hard-

CALLOSITY. Callositas. Hardness.
CALLOSUS. Hard. Applied in surgery to parts which are morbidly hard; and, in botany, to seeds which are hard; as those of the Citrus medica.
CA'LLOUS. Callosus. Hardened or indurated;

as the callous edges of ulcers.

CA'LLUS. (Callus, i.m.; and Callum, i. n.) 1. The bony matter deposited between the divided ends of broken bones, about the fourteenth day after the fracture. It is in reality nothing more than the new ossific substance formed by a process of nature, very similar to the growth of any other part of the body.

2. A preternatural hardness, or induration, of any

fleshy part.

3. This term is applied in Good's Nosology to that species of ecphyma, which is characterized by callous extuberant thickening of the cuticle; insensible to the

touch.

Caloca'Tanus. (From καλος, beautiful, and καλανον, a cup; so called from the beauty of its flower and
shape.) The wild poppy. See Papaver rhwas.

CALO'MELAS. (From καλος, good, and μελας,
black; from its virtues and colour.) 1. The preparation called Æthiops mineral, or hydrargyrus cum
sulphure, was formerly so named.

2. The chloride of mercury. See Hydrargyri sub-

CALO'RIC. (Caloricum; from calor, heat.) Heat; Igneous fluid.

Heat and cold are perceptions of which we acquire the ideas from the senses; they indicate only a certain state in which we find ourselves, independent of any exterior object. But as these sensations are for the most part produced by bodies around us, we consider them as causes, and judging by appearances, we apply the terms hot, or cold, to the substances themselves; calling those bodies hot, which produce in us the sensation of heat, and those cold, which communicate the contrary sensation.

This ambiguity, though of little consequence in the common affairs of human life, has led unavoidably to confusion and perplexity in philosophical discussions. It was to prevent this, that the tramers of the new nomenclature adopted the word caloric, which denotes that which produces the sensation of heat.

Theories of Heat,
Two opinions have long divided the philosophical

world concerning the nature of heat.

1. The one is; that the cause which produces the sensation of heat, is a real, or distinct substance, universally pervading nature, penetrating the particles or pores of all bodies, with more or less facility, and in different quantities.

This substance, if applied to our system in a greater proportion than it already contains, warms it, as we call it, or produces the sensation of heat; and hence it

has been called caloric or calorific.

2. The other theory concerning heat is; that the cause which produces that sensation is not a separate

or self-existing substance; but that it is merely like gravity, a property of malter; and that it consists in a specific or peculiar motion, or vibration of the particles of bodies.

The arguments in favour of the first theory have The arguments in favour of the first theory have been principally deduced from the evolution and absorption of heat during chemical combinations; those of the latter are chiefly founded on the production of heat by friction. For it has been observed, that whatever is capable of producing motion in the particles of any mass of matter, excites heat. Count Rumford and Professor Davy have paid uncommon attention to this fact, and proved, that heat continues to be evolved from a body subjected to friction, so long at it is applied, and the texture or form of the body as it is applied, and the texture or form of the body not altered.

All the effects of heat, according to this theory, depend therefore entirely upon the vibratory motion of the particles of bodies. According as this is more or less intense, a higher or lower temperature is produced; and as it predominates over, is nearly equal or inferior to the attraction of cohesion, bodies exist in the gaseous, fluid, or solid state.

Different bodies are susceptible of it in different degrees, and receive and communicate it with different celerity. From the generation, communication, and attraction of this repulsive motion, under these laws, all the phenomena ascribed to heat are explicable. Each of these theories has been supported by the

most able philosophers, and given occasion to the most important disputes in which chemists have been engaged: which has contributed in a very particular manner to the advancement of the science. The obscurity of the subject, however, is such, that both parties have been able to advance most plausible arguments.

Setting aside all inquiries concerning the merits of these different doctrines, we shall confine ourselves to the general effects which heat produces on different bodies. For the phenomena which heat presents, and their relation to each other, may be investigated with sufficient precision, though the materiality, or imma-

teriality of it, may remain unknown to us. Nature of Heat.

Those who consider heat as matter, assert that caloric

In the first state it is not sensible to our organs, nor indicated by the thermometer; it forms a constituent part of the body; but it may be brought back to the state of sensible heat. In this state it affects animals with the sensation of heat. It therefore has been called sensible or free heat, or fire; and is synonymous with uncombined caloric, thermometrical caloric, caloric of temperature, interposed caloric, &c. expressions now pretty generally superseded.

From the diversity of opinions among chemists respecting the nature of caloric, several other expressions have been introduced, which it is proper to notice. For instance, by specific heat is understood, the relatitive quantities of caloric contained in equal weights of different bodies at the same temperature. Latent heat is the expression used to denote that quantity of caloric which a body absorbs when changing its form. It is, however, more properly called caloric of fluidity. The disposition, or property, by which different bodies contain certain quantities of caloric, at any temperature, is termed their capacity for heat. By the expression of absolute heat, is understood the

whole quantity of caloric which any body contains.

Methods of exciting and collecting Heat.

Of the different methods of exciting heat, the fol-

towing are the most usual: I. Percussion or Collision. This method of producing heat is the simplest, and therefore it is generally made use of in the common purposes of life for

obtaining fire. When a piece of hardened steel is struck with a flint, some particles of the metal are scraped away from the mass, and so violent is the heat which follows the stroke, that it melts and vitrilies them. If the fragments of steel are caught upon paper, and viewed with a microscope, most of them will be found perfect spherules, and very highly polished. Their sphericity demonstrates that they have been in a fluid state, and the polish upon their surface, shows them to be vitrified.

No heat, however, has been observed to follow the

percussion of liquids, nor of the softer kind of bodies

percussion of liquids, nor of the softer kind of bodies which yield to a slight impulse.

2. Friction. Heat may likewise be excited by mere friction. This practice is still retained in some parts of the world. The natives of New Holland are said to produce fire in this manner, with great facility, and spread it in a wonderful manner. For that purpose, they take two pieces of dry wood; one is a stick, about eight or nine inches long, and the other piece is flat; the stick they bring to an obtuse point at one end, and pressing it upon the other piece, they turn it very and pressing it upon the other piece, they turn it very nimbly, by holding it between both hands, as we do a chocolate-mill, often shifting their hands up, and then moving down upon it, in order to increase the pressure as much as possible. By this method they get fire in a few minutes, and from the smallest spark they increase it with great speed and devicety. increase it with great speed and dexterity.

If the irons at the axis of a coach-wheel are applied to each other, without the interposition of some unc-tuous matter to keep them from immediate contact, they will become so hot when the carriage runs swiftly along, as to set the wood on fire; and the fore-wheels, being smallest, and making most revolutions in a given

time, will be most in danger.

The same will happen to mill-work, or to any other

machinery.

It is no uncommon practice in this country, for blacksmiths to use a plate of iron as an extemporane-ous substitute for a tinder-box; for it may be ham-mered on an anvil till it becomes red-hot, and will fire a brimstone match. A strong man who strikes quick, and keeps turning the iron so that both sides may be equally exposed to the force of the hammer, will perform this in less time than would be expected.

If, in the coldest season, one dense iron plate be laid on another, and pressed together by a weight, and then rubbed upon each other by reciprocal motions, they will gradually grow so hot as, in a short time, to emit sparks, and at last become ignited.

It is not necessary that the substances should be very hard; a cord rubbed backwards and forwards swiftly

against a post or a tree will take fire.

Count Rumford and Professor Pictet have made some very ingenious and valuable experiments con-

cerning the heat evolved by friction.

3. Chemical Action. To this belongs the heat produced by combustion. There are, besides this, many chemical processes wherein rapid chemical action takes place, accompanied with a development of heat, or fire, and flame.

4. Solar heat. It is well known that the solar rays, when collected by a mirror, or leas, into a focus, pro-

duce the most astonishing effects.

Dr. Herschel has discovered that there are rays emitted from the sun, which have not the power of illuminating or producing vision: and that these are the rays which produce the heat of the solar light.

Consequently, heat is emitted from the sun in rays, but these rays are not the same with the rays of light.

5. The Electric Spark, and Galvanism. The effects

5. The Electric Spark, and Galvanism. The effects of electricity are two well known in this point of view to need any description.

Galvanism has of late become a powerful instrument for the purpose of exciting heat. Not only easily inflammable substances, such as phosphorus, sulphur, &c. have been fired, but likewise, gold, silver, copper, tin, and the rest of the metals, have been burnt by means of calvanism. means of galvanism.

General Effects of Heat.

The first and most obvious effect which heat produces on bodies, is its expansive property. Experience bods taught us that, at all times, when bodies become hot, they increase in bulk. The bodies experience a ditatation which is greater in proportion to the accumulation of coloric, or in other words, to the intensity of the heat. This is a general law, which holds good as long as the bodies have suffered no change either in their combination or in the quantity of their chemical principles.

This power, which heat possesses, consists, there This power, which heat possesses, consists there fore, in a constant tendency to separate the particles of bodies. Hence philosophers consider heat as the repulsive power which acts upon all bodies whatever, and which is in constant opposition to the power of

The phenomena which result from these mutual actions, seem, as it were, the secret springs of natura

der to be more visible, and then immerse the globe of the instrument in a vessel of hot water; the included fluid will instantly begin to mount into the neck. If it be taken out of the water and brought near the fire, it will ascend more and more, in proportion as it be-comes heated; but, upon removing it from the source of heat, it will sink again: a clear proof that caloric dilates it, so as to make it occupy more space when hot than when cold. These experiments may, there-fore, serve as a demonstration that heat expands fluid

2. Expansion of Aëriform Bodies. Take a bladder 2. Expansion of Aeriform Bodies. Take a biadder partly filled with air, the neck of which is closely tied, so as to prevent the enclosed air from escaping, and let it be held near a fire. The air will soon begin to occupy more space, and the bladder will become gradually distended; on continuing the expansion of the air, by increasing the heat, the bladder will burst with

a loud report.

3. Expansion of Solid Bodies. If we take a bar of tron, six inches long, and put it into a fire till it becomes red-hot; and then measure it in this state accurately, it will be found I-20th of an inch longer than it was before; that is, about 120th part of the whole. That the metal is proportionally expanded in breadth, will be seen by trying to pass it through an aperture which is fitted exactly when cold, but which will not admit it when red-hot. The bar is, therefore, increased in length and diameter. length and diameter.

To discover the minutest changes of expansion by heat, and the relative proportions thereof, instruments have been contrived, called *Pyrometers*, the sensibility of which is so delicate as to show an expansion

of 1-100,000th of an inch.

It is owing to this expansion of metals, that the motion of time-pieces is rendered erroneous; but the ingenuity of artists has discovered methods of obviating this inaccuracy, by employing the greater expansion of one metal, to counteract the expansion of another; this is effected in what is called the grid-iron pendulum. Upon the same principle, a particular construction of watches has been contrived.

The expansion of metals is likewise one of the principal reasons that clocks and watches vary in winter cipal reasons that clocks and watches vary in winter and summer, when worn in the pocket, or exposed to the open air, or when carried into a hotter or a colder climate. For the number of the vibrations of the pendulum is always in the sub-duplicate ratio of its length, and as the length is changed by heat and cold, the times of vibration will be also changed. The quantity of alteration, when considered in a single vibration, is exceedingly small, but when they are often repeated, it will be very sensible. An alteration of one-thousandth part in the time of a single vibration of a pendulum which beats seconds, will make a change of eighty-six whole vibrations in twenty-four

As different metals expand differently with the same degree of heat; those musical instruments, whose parts are to maintain a constant true proportion, should never be strung with different metals. It is on this account that harpsichords, &c. are out of tune by

a change of temperature.

Bodies which are brittle, or which want flexibility, crack or break, if suddenly heated. This likewise depends upon the expansive force of heat, stretching the surface to which it is applied, while the other parts, not being equally heated, do not expand in the same ratio, and are therefore torn asunder or break. Hence thin vessels stand heat better than thick ones.

thin vessels stand heat better than thick ones. The same holds, when they are suddenly cooled.

Measurement of Heat.

Upon the expansive property of heat, which we have considered before, is founded its artificial measurement. Various means have been employed to assist the imperfection of our sensations in judging of the different degrees of heat; for our feelings, unaided, afford but very inaccurate information concerning this matter; they indicate the presence of heat, only when the bodies presented to them are hotter than the actual the bodies presented to them are hotter than the actual temperature of our organs of feeling. When these

Heat, however, does not expand all bodies equally, and we are still ignorant of the laws which it follows.

1. Expansion of Fluid Bodies. Take a glass globe, with a long slender neck (called a bold heat); fill it up to the neck with water, ardeat spirit, or any other fluid which may be coloured with red or black ink, in order to be more visible, and then improve the globes.

The effects of heat upon material bodies in general.

The effects of heat upon material bodies in general, which are easily visible to us, afford more precise and determinate indications of the intensity, than can be derived from our feelings alone. The ingenuity of the philosopher and artist has therefore furnished us with instruments of measuring the relative heat or temperature of bodies. These instruments are called Thermometers and Pyrometers. By these, all degrees are measurable, from the slightest to that of the most intense heat. See Thermometer and Pyrometer.

Exceptions to the Expansion by Heat.

Philosophers have noticed a few exceptions to the law of heat expanding bodies. For instance; water, The effects of heat upon material bodies in general,

law of heat expanding bodies. For instance; water, when cooled down within about 7° of the freezing point, instead of contracting on the farther deprivation of heat, actually expands.

Another seeming exception is manifested in alumine, or clay; others occur in the case of cast-iron, and a or clay; others occur in the case of cast-fron, and a few other metals. Alumine contracts on being heated, and cast-iron, bismuth, &c. when fully fused, are more dense than when solid; for, as soon as they become so, they decrease in density, they expand in the act of cooling, and hence the sharpness of figures upon iron which has been cast in moulds, compared to that of

many other metals.

Some philosophers have persuaded themselves that these exceptions are only apparent, but not really true. They say, when water freezes, it assumes a crystalline They say, when water freezes, it assumes a crystaline form, the crystals cross each other and cause numerous vacuities, and thus the ice occupies more space. The same is the case with fused iron, bismuth, and antimony. The contraction of clay is considered owing to the loss of water, of which it loses a part at every increased degree of temperature hitherto tried; there is, therefore, a loss of matter; and a reduction of volume must follow: but others assert, that this only happens to a certain extent. only happens to a certain extent.

Mr. Tilloch has published a brief examination of the received doctrines respecting heat and caloric, in which these truths are more fully considered, together with many other interesting facts relative to the re-

ceived notions of heat.

Equal Distribution of Heat.

If a number of bodies of different temperatures are placed in contact with each other, they will all at a certain time acquire a temperature, which is intermediate; the caloric of the hottest body will diffuse itself among those which are heated in a less degree, till they have all acquired a certain mean temperature. Thus, if a bar of iron, which has been made red hot, be kept in the open air, it does not retain the heat which it had received, but becomes gradually colder and colder, till it arrives at the temperature of the bo dies in its neighbourhood. On the other hand, if we cool down the iron bar by keeping it for some time covered with snow, and then carry it into a warm room, it does not retain its low temperature, but becomes gradually hotter, till it acquires the temperature of the room. It is therefore obvious, that in the one instance the temperature is lowered, and in the other it is

These changes of temperature occupy a longer or a shorter time, according to the nature of the body, but they always take place at last. This law itself is, in deed, familiar to every one: when we wish to heat a body, we carry it towards the fire: when we wish to

cool it, we surround it by cold bodies.

Propagation of Heat.
We have seen, that when bodies of higher temperature than others are brought into contact with each other, the heat is propagated from the first to the second, or the colder body deprives the warmer of its excess of heat. We shall now see that some bodies do so much more quickly than others. Through some bodies caloric passes with undiminished velocity, through others its passage is prodigiously retarded.

This disposition of bodies, of admitting, under equal circumstances, the refrigeration of a heated body within a shorter or a longer time, is called the power of conducting heat; and a body is said to be a better or worse conductor of heat, as it allows the refrigerature than others are brought into contact with each

tion to go on quicker or slower. Those bodies, therefore, which possess the property of letting heat pass with facility, are called good conductors, those through which it passes with difficulty are called bad conductors, and those through which it is supposed not to pass at all, are called non-conductors; thus we say, in common language, some bodies are warm, or capable of preserving warmth, and from this arises the great difference in the sensation excited by different bodies, when applied at the same temperature to our organs when applied at the same temperature to our organs of feeling. Hence, if we immerse our hand in mer-cury, we feel a greater sensation of cold than when we immerse it in water, and a piece of metal appears to be much colder than a piece of wood, though their temperatures, when examined by means of the thermometer, are precisely the same

It is probable that all solids conduct heat in some degree, though they differ very much in their conducting power. Metals are the best conductors of heat; ing power. Metals are the best conductors of heat; but the conducting powers of these substances are by no means equal. Stones seem to be the next best conductors. Glass conducts heat very slowly; wood and charcoal still slower; and feathers, silk, wool, and hair, are still worse conductors than any of the sub-

stances yet mentioned.

The best conductors of electricity and galvanism are

also the best conductors of heat.

Experiment.-Take a number of straight wires, of equal diameters and lengths, but of different metals; for instance, gold, silver, copper, iron, &c.; cover each of them with a thin coat of wax, or tallow, and plunge their extremities into water, kept boiling, or into melted lead. The melting of the coat of wax will show that caloric is more quickly transmitted through some metals than others.

It is on this account also, that the end of a glass rod may be kept red-hot for a long time, or even melted, without any inconvenience to the hand which holds the other extremity; though a similar metallic rod, heated in the same manner, would very soon become

too hot to be held.

Liquid and Aëriform Bodies convey Heat by an actual Change in the Situation of their Particles. Count Rumford was the first who proved that fluids

in general, and aeriform bodies, convey heat on a dif-ferent principle from that observed in the solids. This opinion is pretty generally admitted, though various ingenious experiments have been made, by different philosophers, to prove the contrary. In water, for in-stance, the count has proved that caloric is propagated principally in consequence of the motion which is oc-casioned in the particles of that fluid.

All fluids are considered by him, strictly speaking, in a similar respect as non-conductors of caloric. They can receive it, indeed, from other substances, and can give it to other substances, but no particle can either receive it from or give it to another particle of the same kind. Before a fluid, therefore, can be heated or cooled, every particle must go individually to the substance from which it receives or to which it gives out caloric. Heat being, therefore, only propagated in fluids, in consequence of the internal motion of their particles, which transport the heat; the more rapid these motions are, the more rapid is the communication of heat. The cause of these motions is the change in the specific gravity of the fluid, occasioned by the change of temperature, and the rapidity is in proportion to the change of the specific gravity of the liquid by any given change of temperature. The following experiment may serve to illustrate this theory: Take a thin glass tube, eight or ten inches long, and

about an inch in diameter. Pour into the bottom part, for about the depth of one inch, a little water coloured with Brazil-wood, or litmus, and then fill up the tube with common water, extremely gently, so as to keep the two strata quite distinct from each other. Having done this, heat the bottom part of the tube over a lamp; the coloured infusion will then ascend, and gradually tinge the whole fluid; on the contrary, if the heat be applied above, the water in the upper part of the tube may be made to boil, but the colouring matter will remain at the bottom undisturbed. The heat cannot get downwards to make it seems.

not act downwards to make it ascend.

By thus being able to make the upper part of a fluid boil without heating the bottom part, water may be kept boiling for a considerable time in a glass tube over ice, without melting it.

Other experiments, filustrating the same principle, may be found in count Rumford's excellent essays,

especially in Essay the 7th; 1797.

To this indefatigable philosopher we are wholly indebted for the above facts; he was the first who taught us that air and water were nearly non-conductors. The results of his experiments, which are contained in the above essay, are highly interesting; they also show that the conducting power of fluids is impaired by the admixture of fibrous and glutinous matter.

Count Rumford proved that ice melted more than 80 times slower, when boiling hot water stood on its surface, than when the ice was placed to swim on the surface of the hot water. Other experiments showed that water, only eight degrees of Fahrenheit above the freezing point, or at the temperature of forty degrees, melts as much ice, in any given time, as an equal vo-lume of that fluid at any higher temperature, provided the water stands on the surface of the ice. Water, at the water stands on the surface of the ice. Water, at the temperature of 41°, is found to melt more ice, when standing on its surface, than boiling water. It appears, however, that liquids are not, as he supposes, complete non-conductors of caloric; because, if heat be applied at top, it is capable of making its way downwards, through water, for example, though very innerfectly and slowly.

imperfectly and slowly.

Imperfectly and slowly.

It becomes farther evident, from the Count's ingenious experiments, that of the different substances used in clothing, hares' fur and eider-down are the warmest; next to these, beavers' fur, raw silk, sheep's wool, cotton wool, and lastly, lint, or the scrapings of fine linen. In fur, the air interposed among its particles is so engaged as not to be driven away by the set communicated thereto by the animal lady, not heat communicated thereto by the animal body; not being easily displaced, it becomes a barrier to defend the animal body from the external cold. Hence it is obvious that those skins are warmest which have the finest, longest, and thickest fur; and that the furs of the beaver, otter, and other like quadrupeds, which live much in the water, and the feathers of water-fowl, are capable of confining the heat of those animals in winter potentials and the said of the said animals in the said of the said animals in the said of the sa winter, notwithstanding the coldness of the water which they frequent. Bears, and various other animals, inhabitants of cold climates, which do not often take the water, have their fur much thicker on their backs than on their bellies.

The snow which covers the surface of the earth in winter, in high latitudes, is doubtless designed as a garment to defend it against the piercing winds from the polar regions, which prevail during the cold season. Without dwelling farther upon the philosophy of this truth, we must briefly remark that the happy

application of this law, satisfactorily elucidates some of the most interesting facts of the economy of nature.

Theory of Caloric of Fluidity, or Latent Heat.

There are some bodies which, when submitted to the action of caloric, dilate to such a degree, and the power of aggregation subsisting among their particles is so much destroyed and removed to such a distance by the interposition of caloric, that they slide over each other in every direction, and therefore appear in a fluid state. This phenomenon is called fusion. Bodies thus rendered fluid by means of caloric, are said to be fused, or melted; and those that are subject to it, are called fusible.

The greater number of solid bodies may by the

The greater number of solid bodies may, by the application of heat, be converted into fluids. Thus metals may be fused; sulphur, resin, phosphorus, may be melted; ice may be converted into water, &c.

Those bodies which cannot be rendered fluid by any

degree of heat hitherto known, are called infusible.

degree of heat hitherto known, are called hypostole. If the effects of heat, under certain circumstances, be carried still farther than is necessary to render bodies fluid, vaporization begins; the bodies then become converted into the vaporous or gascous state. Vaporization, however, does not always require a previous fusion. Some bodies are capable of being converted into the vaporous state, without previously converted into the vaporous state, without previously becoming fluid, and others cannot be volatilized at any temperature hitherto known: the latter are termed

any temperature increases.

Fluidity is, therefore, by no means essential to any species of matter, but always depends on the presence of a quantity of caloric. Solidity is the natural state of all bodies, and there can be no doubt that every fluid is capable of being rendered solid by a due reduction of temperature; and every solid may be fused by 173

the agency of caloric, if the latter does not decompose | given out by steam on its being condensed by cold. them at a temperature inferior to that which would be necessary for their fusion.

Caloric of Fluidity.

Dr. Black was the first who proved that, whenever caloric combines with a solid body, the body becomes heated only, until it is rendered fluid: and that, while it is acquiring the fluid state, its temperature remains stationary, though caloric is continued to be added to The same is the case when fluids are converted into the aëriform or vaporous state.

From these facts, the laws of latent heat have been inferred. The theory may be illustrated by means of

the following experiments

If a lump of ice, at a low temperature, suppose at 17 a limit of ice, at a low temperature, suppose at 22°, be brought into a warm room, it will become gradually less cold, as may be discovered by means of the thermometer. After a very short time, it will reach the temperature of 32° (the freezing point); but there it stops. The ice then begins to mett; but the process goes on very slowly. During the whole of that time its temperature continues at 32°; and as it is constantly surrounded by warm air, we have it is constantly surrounded by warm air, we have reason to believe that caloric is constantly entering into it; yet it does not become hotter till it is changed into water. Ice, therefore, is converted into water by

a quantity of caloric uniting with it.

It has been found by calculation, that ice in melting absorbs 140° of caloric, the temperature of the water

produced still remaining at 320

This fact may be proved in a direct manner.

Take one pound of ice, at 32°, reduced to a coarse powder; put it into a wooden bowl, and pour over it one pound of water, heated to 172°; all the ice will become melted, and the temperature of the whole fluid, if examined by a thermometer, will be 320; 1400 of caloric are therefore lost, and it is this quantity which was requisite to convert the ice into water. This experiment succeeds better, if, instead of ice, fresh-fallen snow be employed.

This caloric has been called latent caloric, because

its presence is not measurable by the thermometer

also more properly caloric of fluidity.

Dr. Black has also ascertained by experiment, that the fluidity of melted wax, tallow, spermaceti, metals, &c. is owing to the same cause; and Landriani proved, that this is the case with sulphur, alum, nitrate of

We consider it therefore as a general law, that whenever a solid is converted into a fluid, it combines with caloric, and that is the cause of fluidity.

Conversion of Solids and Fluids into the Aëriform or

Gascous State.

We have seen before, that, in order to render solids fluid, a certain quantity of caloric is necessary, which combines with the body, and therefore cannot be measured by the thermometer; we shall now endeavour to prove that the same holds good in respect to the conversion of solids or fluids into the vaporous or gaseous state.

Take a small quantity of carbonate of ammonia, introduce it into a retort, the neck of which is directed under a cylinder filled with mercury, and inverted in a basin of the same fluid. On applying heat to the body of the retort, the carbonate of ammonia will be volatilized, it will expel the mercury out of the cylinder, and become an invisible gas, and would remain so, if its temperature was not lowered.

The same is the case with benzoic acid, camphire,

and various other substances.

All fluids may, by the application of heat, be converted into an aeriform elastic state.

When we consider water in a boiling state, we find that this fluid, when examined by the thermometer, is not hotter after boiling several hours, than when it began to boil, though to maintain it boiling a brisk fire must necessarily be kept up. What then, we may ask, becomes of the wasted caloric? It is not perceptible in the water, nor is it manifested by the steam; for the steam, if not compressed, upon examination, is found not to be hotter than boiling water. The caloric is therefore absorbed by the steam, and although what is so absorbed, is absolutely necessary for the conversion of water into the form of steam; it does not increase its temperature, and is therefore not appreciable by the thermometer.

This is particularly manifested in the condensation of this fluid in the process of distilling, where, upon examining the refrigeratory, it will be found that a much greater quantity of caloric is communicated to it, than could possibly have been transmitted by the caloric which was sensibly acting before the condensation. This may be easily ascertained by observing the quantity of caloric communicated to the water in the refrigeratory of a still, by any given quantity of liquid that passes over.

1. The boiling point, or the temperature at which the conversion of fluids into gases takes place, is different in different fluids, but constant in each, provided

the pressure of the atmosphere be the same.

Put any quantity of sulphuric æther into a Florence flask, suspend a thermometer in it, and hold the flask over an Argand's lamp, the ather will immediately begin to boil, and the thermometer will indicate 980 if the ather has been highly rectified.

If highly rectified ardent spirit is heated in a similar manner, the thermometer will rise to 1760, and there

remain stationary.

If water is substituted, it will rise to 2120.

If strong nitrous acid of commerce be made use of, it will be found to boil at 248°; sulphuric acid and linseed-oil at 600°; mercury at 656°, &c.

2. The boiling point of fluids is raised by pressure.

Mr. Watt heated water under a strong pressure to 400°. Yet still, when the pressure was removed, only part of the water was converted into vapour, and the temperature of this vapour, as well as that of the remaining fluid, was no more than 2120. There was, therefore, 1880 of caloric suddenly lost. This caloric was carried off by the steam. Now as only about one-fifth of the water was converted into steam, that steam must contain not only its own 1880, but also the 188° lost by each of the other four parts; that is to say, it must contain 188°×5, or about 940°. Steam, therefore, is water combined with at least 940° of calorie, the presence of which is not indicated by the thermometer.

3. When pressure is removed from the surface of bodies, their conversion into the gaseous state is greatly

facilitated, or their boiling point is lowered.

In proof of this the following experiments may serve:

Let a small bottle be filled with highly rectified sulphuric wher, and a piece of wetted bladder be tied over its orifice around its neck. Transfer it under the receiver of an air-pump, and take away the super-incumbent pressure of the air in the receiver. When the exhaustion is complete, pierce the bladder by means of a pointed sliding wire, passing through a collar of leather which covers the upper opening of the receiver. Having done this, the ather will instantly begin to boil, and become converted into an invisible gaseous fluid.

Take a small retort or Florence flask, fill it one half or less with water, and make it boil over a lamp; when kept briskly boiling for about five minutes, cork the mouth of the retort as expeditiously as possible,

and remove it from the lamp.

The water, on being removed from the source of heat, will keep boiling for a few minutes, and when the ebullition begins to slacken, it may be renewed by dipping the retort into cold water, or pouring cold water upon it.

The water, during boiling, becomes converted into vapour; this vapour expels the air of the vessel, and occupies its place; on diminishing the heat, it condenses; when the retort is stopped, a partial vacuum is formed; the pressure becomes diminished, and a less degree of heat is sufficient to cause an chullition.

For the same reason, water may be made to boil under the exhausted receiver at 94°. Fahr., or even at a lower degree; alkohol at 56°; and ather at -20°. On the conversion of fluids into gases is founded the

following experiment, by which water is frozen by means of sulphuric ather.

Take a thin glass tube four or five inches long and about two or three-eighths of an inch in diameter, and a two-ounce bottle furnished with a capillary tube fitted to its neck. In order to make ice, pour a little water into the tube, taking care not to wet the outside, nor to leave it moist. Having done this, let a stream of sulphuric other fall through the capillary The conclusion is farther strengthened by the heat | tube upon that part of it containing the water, which

If the glass tube, containing the water, be exposed to the brisk thorough air, or free draught of an open window, a large quantity of water may be frozen in a shorter time; and if a thin spire of wire be introduced previous to the congelation of the water, the ice will adhere to it, and may thus be drawn out conveadhere to it, and may thus be drawn out conve-

A person might be easily frozen to death during very warm weather, by merely pouring upon his body for some time sulphuric æther, and keeping him exposed to a thorough draught of air.

Artificial Refrigeration.

The cooling or refrigeration of rooms in the summer season by sprinkling them with water, is on the prin-

ciple of evaporation.

The method of making ice artificially in the East Indies depends on the same principle. The ice-makers at Benares dig pits in large open plains, the bottom of which they strew with sugar-canes or dried stems of maize or Indian-corn. Upon this bed they place a major of an array made of a parrows an earth number of unglazed pans, made of so porous an earth that the water penetrates through their whole sub-stance. These pans are filled toward evening in the winter season with water that has boiled, and left in that situation till morning, when more or less ice is found in them, according to the temperature and other qualities of the air; there being more formed in dry and warm weather, than in that which is cloudy, though it may be colder to the human body.

Every thing in this process is calculated to produce cold by evaporation; the beds on which the pans are placed, suffer the air to have a free passage to their bottoms; and the pans constantly oozing out water to their external surface, are cooled by the evaporation

of it.

In Spain, they use a kind of earthen jars, called buxaros, which are only half-baked, the earth of which is so porous, that the outside is kept moist by the water which filters through it, and though placed in

It is a common practice in China to cool wine or other liquors by wrapping the bottle in a wet cloth, and hanging it up in the sun. The water in the cloth becomes converted into vapour, and thus cold is pro-

The blacks in Senegambia have a similar method of cooling water by filling tanned leather bags with it, which they hang up in the sun; the water oozes, more or less through the leather so as to keep the outer surface wet, which by its quick and continued evapo-

ration cools the water remarkably.

The winds on the borders of the Persian gulf are often so scorching, that travellers are suddenly suffo-cated unless they cover their heads with a wet cloth; if this be too wet, they immediately feel an intolerable cold, which would prove fatal if the moisture was not speedily dissipated by the heat.

Condensation of Vapour.

If a cold vessel is brought into a warm room, particularly where many people are assembled, the outside of it will soon become covered with a sort of dew.

Before some changes of weather, the stone pavements, the walls of a house, the balustrades of staircases, and other solid objects, feel clammy and damp.

In frosty nights, when the air abroad is colder than the air within, the dampness of this air, for the same

reason, settles on the glass panes of the windows, and is there frozen into curious and beautiful figures

Thus fogs and dews take place, and in the higher regions clouds are formed from the condensed vapour. The still greater condensation produces mists and rain.

Capacity of Bodies for containing Heat.

The property which different bodies possess, of containing at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, is called their capacity for heat. The capacities of bodies for heat are therefore considered as great or small in proportion as their temperatures are either raised by the addition, or diminished by the depriva-tion, of equal quantities of heat, in a less or greater

In homogeneous bodies, the quantities of caloric which they contain are in the ratio of their temperature and mass: when, therefore, equal quantities of

by this means will be converted into ice in a few minutes, and this it will do even near a fire, or in the midst of summer. | water, of oil, or of mercury, of unequal temperatures, are mingled together, the temperature of the whole will be the arithmetical mean between the temperatures of the two quantities that had been mixed together. It is a self-evident truth that this should be the case, for the particles of different portions of the same substance being alike, their effects must be equal-

Mix a pound of water at 172° with a pound at 32°, half the excess of heat in hot water will quit it to go over into the colder portion; thus the hot water will be cooled 70°, and the cold will receive 70° of temperature; therefore 172-70, or 32 + 70 = 102, will give the heat of the mixture. To attain the arithmetical mean very exactly, several precautions, however,

When heterogeneous bodies of different temperatures are mixed together, the temperature produced is never the arithmetical mean of the two original tem-

peratures.

In order to ascertain the comparative quantities of heat of different bodies, equal weights of them are mingled together; the experiments for this purpose being in general more easily executed than those by which they are compared from equal bulks.

Thus, if one pound of mercury heated to 410° Fahr., be added to one pound of water of 44°, the temperature of the blended fluids will not be changed to 77°, as it would be if the surplus of heat were divided among those fluids in the proportion of their quantities. It will be found, on examination, to be only 47°.

On the contrary, if the pound of mercury be heated to 44°, and the water to 110°, then, on stirring them together, the common temperature will be 107°.

Hence, if the quicksilver loses by this distribution 63° of caloric, an equal weight of water gains only 3° from this loss of 63° of heat. And, on the contrary, if the water loses 3°, the mercury gains 63°.

When, instead of comparing the quantities of caloric which equal weights of different bodies contain, we compare the quantities contained in equal volumes, we still find that an obvious difference takes place. Thus Thus, if one pound of mercury heated to 410° Fahr.,

still find that an obvious difference takes place. it is found by experiment, that the quantity of caloric necessary to raise the temperature of a given volume of water any number of degrees, is, to that necessary to raise an equal volume of mercury, the same number of degrees as 2 to 1. This is, therefore, the proportion between the comparative quantities of caloric which these two bodies contain, estimated by their volumes and similar differences exist with respect to every other kind of matter.

From the nature of the experiments by which the quantities of caloric which bodies contain are ascertained, it is evident that we discover merely the com-parative, not the absolute quantities. Hence water has been chosen as a standard, to which other bodies may be referred; its capacity is stated as the arbitrary term of 1000, and with this the capacities of other bodies are compared.

It need not be told that puns have been taken to estimate on these experiments that portion of heat which diffuses itself into the air, or into the vessels where the mercury and water are blended together. As however such valuations cannot be made with complete accuracy, the numbers stated above are only an approximation to truth.

Radiation of Caloric.

Caloric is thrown off or radiates from heated bodies in right lines, and moves through space with incon-ceivable velocity. It is retarded in its passage by at-mospheric air, by colouriess fluids, glass, and other transparent bodies.

transparent bodies.

If a glass mirror be placed before a fire, the mirror transmits the rays of light, but not the rays of heat.

If a plate of glass, taic, or a glass vessel filled with water, be suddenly interposed between the fire and the eye, the rays of light pass through it, but the rays of caloric are considerably retarded in its passage; for no heat is perceived until the interposed substance is saturated with heat, or has reached its maximum. It then ceases to intercept the rays of caloric, and allows them to pass as freely as the rays of light.

It has been lately shown by Dr. Herschel, that the rays of caloric are refrangible, but less so than the rays of light; and the same philosopher has also proved by experiment, that it is not only the rays of caloric emitted by the sun, which are refrangible, but likewise.

the rays emitted by common fires, by candles, by heat-ed iron, and even by hot water.

Whether the rays of caloric are differently refracted. in different mediums, has not yet been ascertained. We are certain, however, that they are refracted by all transparent bodies which have been employed as burning glasses.

burning glasses.

The rays of caloric are also reflected by polished surfaces in the same manner as the rays of light.

This was long ago noticed by Lambert, Saussure, Scheele, Pictet, and lately by Dr. Herschel.

Professor Pictet placed two concave metallic mirrors opposite to each other, at the distance of about twelve feet. When a hot body, an iron bullet for instance, was placed in the focus of the one, and a mercurial thermometer in that of the other, a substance radiated from the bullet; it passed with incalculable velocity through the air, it was reflected from the mirrors, it bethrough the air, it was reflected from the mirrors, it became concentrated, and influenced the thermometer placed in the focus, according to the degree of its concentration.

An iron ball two inches in diameter, heated so that it was not luminous in the dark, raised the thermome-ter not less than ten and a half degrees of Reaumur's scale, in six minutes.

A lighted candle occasioned a rise in the thermome-

A Florence flask containing two ounces and three drachms of boiling water, raised Fahrenheit's thermometer three degrees. He blackened the bulb of his thermometer, and found that it was more speedily influenced by the radiation than before, and that it rose

M. Pictet discovered another very singular fact; namely, the apparent radiation of cold. When, instead of a heated body, a Florence flask full of ice or snow is placed in the focus of one of the mirrors, the thermometer placed in the focus of the other immediately descends, and accords again, whenever the diately descends, and ascends again whenever the

cold body is removed. This phenomenon may be explained on the supposition, that from every body at every temperature caloric radiates, but in less quantity as the temperature is low; so that in the above experiment, the thermometer gives out more caloric by radiation, than it receives from the body in the opposite focus, and therefore its temperature is lowered. Or, as Pictet has supposed, when a number of bodies near to each other have the same temperature, there is no radiation of caloric, because in all of them it exists in a state of equal tension; but as soon as a body at an inferior temperature is introduced, the balance of tension is broken, and caloric begins to radiate from all of them, till the temperature of that body is raised to an equality with their. In the above experience, therefore the with theirs. In the above experiment, therefore, the placing the snow or ice in the focus of the mirror causes the radiation of caloric from the thermometer, and hence the diminution of temperature which it

These experiments have been since repeated by Dr. Young and Professor Davy, at the theatre of the Royal Institution. These gentlemen inflamed phosphorus by reflected caloric; and proved that the heat thus excited, was very sensible to the organs of feeling.

It is therefore evident, that caloric is thrown off from bodies in rays, which are invisible, or incapable of exciting vision, but which are capable of exciting

These invisible rays of caloric are propagated in right lines, with extreme velocity; and are capable of the laws of reflection and refraction.

The heating agency however is different in the different coloured rays of the prismatic spectrum. According to Dr. Herschel's experiments, it follows inversely the order of the refrangibility of the rays of light. The least refrangible, possessing it in the greatest degree.

greatest degree.

Sir Henry Englefield has lately made a series of experiments on the same subject, from which we learn, that a thermometer having its ball blackened, rose when placed in the blue ray of the prismatic spectrum in 3' from 55° to 56°; in the green, in 3' from 54° to 58°; in the yellow, in 3' from 56° to 62°; in the full red, in 2 1-2' from 56° to 72°; in the confines of the red, in 2 1-2' from 58° to 73 1-2°; and quite out of the visible light, in 2 1-2' from 61° to 79°.

Between each of the observations the thermometer

Between each of the observations, the thermometer was placed in the shade so long as to sink it below the heat to which it had risen in the preceding observation; of course, its rise above that point could only be the effect of the ray to which it was exposed. It was continued in the focus long after it had ceased to rise; therefore the heats given are the greatest effects of the several rays on the thermometer in each observation. A thermometer placed constantly in the shade near the apparatus, was found scarcely to vary during the experiments,

Sir Henry made other experiments with thermometers with naked balls, and with others whose balls were painted white, for which we refer the reader to the interesting paper of the Baronet, from which the

above experiments are transcribed.

Production of Artificial Cold, by means of Frigorific Mixtures.

A number of experiments have been lately made by different philosophers, especially by Pepys, Walker, and Lowitz, in order to produce artificial cold. And as these methods are often employed in chemistry, with a view to expose bodies to the influence of very low temperatures, we shall enumerate in a tabular form the different substances which may be made use of for that purpose, and the degrees of cold which they are capable of producing.

To produce the effects stated in the table, the salts must be reduced to powder, and contain their full quantity of water of crystallization. The vessel in which the freezing mixture is made, should be very thin, and just large enough to hold it, and the materials should be mixed together as expeditiously as possible very the produce of the salts. sible, taking care to stir the mixture at the same time

with a rod of glass or wood.

In order to obtain the full effect, the materials ought to be first cooled to the temperature marked in the to be first cooled to the temperature marked in the table, by introducing them into some of the other frigorific mixtures, and then mingling them together in a similar mixture. If, for instance, we wish to produce —46°, the snow and diluted nitric acid ought to be cooled down to 0°, by putting the vessel which contains each of them into the fifth freezing mixture in the above table, before they are mingled together. If a more intense cold be required, the materials to produce it are to be brought to the proper temperature by being previously placed in the second freezing mixture. This process is to be continued till the required degree of cold has been procured,

gree of cold has been procured.

A TABLE OF FREEZING MIXTURES.

Miztures.	Thermometer sinks
Muriate of ammonia 5 parts Nitrate of potassa 5 Water 16	From 50° to 10°.
Muriate of ammonia 5 parts Nitrate of potassa 5 Sulphate of soda 8 Water 16	From 50° to 4°.
Sulphate of soda	From 50° to —3°.
Sulphate of soda 8 parts Muriatic acid	From 50° to 0°.
Snow 1 part Muriate of soda	From 32° to 0°.
Snow, or pounded ice	From 0° to —5°.
Snow, or pounded ice	From -5° to -18°.
Snow, or pounded ice	From —18° to —25°.
Snow	From 0° to -46°.
Muriate of lime	From 32° —50°.
Potassa	From 32° to51°.
Snow	From —10° to —56°
Snow	From 20° to60°.
Muriate of lime	From 0° to —66°.
Muriate of lime	From -40° to -73°.
Diluted sulphuric acid	Prom -68° to -91°.
Nitrate of ammonia	From 50° to 4°.
Nitrate of ammonia	From 50° to —7°.
Sulphate of soda 6 parts Muriate of ammonia 4 Nitrate of potassa 2 Diluted nitric acid 4	From 50° to —10°.
Snlphate of soda	From 50° to —14°.
Phosphate of soda	From 50° to —12°.
Phosphate of soda	From 50° to —21°.
Sulphate of soda	From 50° to 3°.

CALORI METER. An instrument by which the whole quantity of absolute heat existing in a body in chemical union can be ascertained.

CALP. An argillo-ferruginous limestone.
CA'LTHA. (Καλθα, corrupted from χαλχα, yellow; from whence, says Vossius, come calthula, caldula, calcula, calcula, calcula.) The marigold. I. The name of a genus of plants in the Linnæan system. Class, Polyandria; Order, Polygynia.

2. The pharmacopælal name of the herb wild marigold, so called from its colour.

M

CALTHA ARVENSIS. Calendula arvensis: Caltha vulgaris. The wild marigold. Its juice is given, from one to the garden marigold.

The caltha is so called. CALTHA VULGARIS.

CALTRULA. The caltha is so called.
CALTROPS. See Trapa natans.
CALU'MBA. The name now adopted by the London college of physicians for the root of the Cocculus palmatus of De Candolles, in his Systema natura. It was formerly called Colombo; Calomba; and Colamba. This root is imported from Colomba, in Ceylon, in circular, brown knobs, wrinkled on their outer the called the colomba and colomba. surface, yellowish within, and consisting of cortical, woody, and medullary lamina. Its smell is aromatic; its taste pungent, and very bitter. From Dr. Percival's experiments on the root, it appears that rectified spirit of wine extracts its virtues in the greatest perfection. The watery infusion is more perishable than that of other bitters. An ounce of the powdered root, half an other bitters. An ounce of the powdered root, half an ounce of orange-peel, two ounces of brandy, and four teen ounces of water, macerated twelve h urs without heat, and then filtered through paper, aford a sufficiently strong and tolerably pleasant infusion. The extract made first by spirit and then with water, and reduced by evaporation to a pillular consistence, is found to be equal, if not superior in efficacy, to the powder. As an antiseptic, Calumba root is inferior to the bark; but, as a corrector of putrid bile, it is much superior to the bark; whence also it is probable, that it would be of service in the West-India yellow fever. It-also restrains alimentary fermentation, without im-It also restrains alimentary fermentation, without im-It also restrains alimentary fermentation, without impairing digestion; in which property it resembles mustard. It does not appear to have the least heating quality, and therefore may be used in phthisis pulmonalis, and in hectic cases, to strengthen digestion. It occasions no disturbance, and agrees very well with a milk diet, as it abates flatulence, and is indisposed to acidity. The London, Edinburgh, and Dublin colleges, direct a tincture of Calumba root. The dose of the powdered root is as far as half a drachm, which, in urgent cases, may be repeated every third or fourth hour.

[CALUMBO. See American Columbo. A.] CA'LVA. (From calvus, bald.) The scalp or up-ter part of the cranium or top of the head; so called

because it often grows bald first.

CALVA'RIA. (From calvus, bald.) The upper part or the cranium which becomes soon bald. It comprehends all above the orbits, temples, ears, and occipital eminence.

CALVITIES. (From calvus, bald.) Calvitium. Baldness; want or loss of hair, particularly upon the sinciput.

This name is applied by Dr. Good to a species of his

trichosis athrix, or baldness.

CALX. (Calz, cis. feem; from kalah, to burn. Arabian.) 1. Chalk. Limestone.

2. Lime. Calz viva. The London College directs it to be prepared thus:—Take of limestone one pound: break it into small pieces, and heat it in a crucible, in a strong fire, for an hour, or until the carbonic acid is entirely driven off, so that on the addition of acctic entirely driven on, so that on the addition of accent acid, no bubbles of gas shall be extricated. Lime may be made by the same process from oyster-shells previously washed in boiling water, and cleared from extraneous matters. See Lime.

Calx antimonii. See Antimonii oxydum.

Calx cum kali puro. See Potassa cum calce.

Calx hydrargyrii alba. See Hydrargyrum præ-

cipitatum album.

CALX METALLIC. A metal which has undergone the process of calcination, or combustion, or any other equivalent operation.

CALX VIVA. See Calz.

CALYCANTHEME. (From calyz, the flower-cup, and aνθος, the flower.) The name of an order in Linnæus's fragments of a natural method, consisting of plants, which, among other characteristics, have the corolla and stamina inserted into the calyx.

CALYCIFLOR A. (From calyz, and flos, a flower.) The name of an order in Linnaus's fragments of a

natural method, consisting of plants which have the stamina inserted into the Calyx.

CALYCINUS. (From calyx, the flower-cup.) Calycinalis. Belonging to the calyx of a flower; applied to the nectary, nectarium calycinum, it being a production of the calyx; as in Tropaolum majus, the garden nacturium. den nasturtium.

CALYCULATUS. (From calyculus, a small calyx.)
Calyculate. Applied to a perianthium when there are 178

less ones, like scales, about its base; as in Dianthus caryophyllus. Semina calyculata are those which are enclosed in a hard bone-like calyx, as those of the Coix lachryma, or Job's tears.

CALYCULUS. (Diminutive of calyx.) A little

A botanical term for

calyx. A botanical term for
I. The membranaceous margin surrounding the apex of a seed. The varieties are,

Calyculus integer, the margin perfect not incised; as in Tanacetum vulgare, and Dipsacus laciniatus.
 Calyculus palyaceus, with chaffy scales; as in

Helianthus annuus

3. Calyculus aristatus, having two or three awns at the top; as in Tagetes patula, and Bidens tripartita.

4. Calyculus rostratus, the style of the germ remaining; as in Sinapis, and Scandiz cerefolium.

5. Calyculus cornutas, horned, the rostrum bent; as

in Nigella damascena.
6. Calyculus cristatus, a dentate, or incised membrane on the top of the seed; as in Hedysarum crista

galli.

H. A little calyx exterior to another proper one.

CALY PTER. (From καλυπτω, to hide.) A carneous excrescence covering the hæmorrhoidal vein.

CALYPTRA. (From καλυπτω, to cover.) I. The veil, or covering of mosses. A kind of membraneous hood placed, on their capsule or fructification, like an extinguisher on a candle, well seen in Bryum caspitosum. Linnæus considered it as a calyx, but other botanists, especially Schreber and Smith, reckon it to be a sort of corolla. It is either,

1. Acuminate, pointed; as in Minium and Bryum.

2. Caducous, falling off yearly; as in Bauxbaumia.

3. Conical; as in most mosses.

3. Conical; as in most mosses
4. Smooth; as in Hypnum.

5. Lavis, without any inequalities; as in Splanchnum.

6. Oblong; as in Minium.
7. Villous; as in Polytrichum.
8. Complete, surrounding the whole of the top of the capsule.

9. Dimidiate, covering only half the capsule; as in Bryum androgynum.
10. Dentate, toothed in the margin; as in Eucalypta

ciliata.

In many genera it is wanting.

II. The name in Tournefort, and writings of former botanists, for the proper exterior covering or coat of the seed, which falls off spontaneously.

CALYPTRATUS. (From calyptra, the veil, or covering of mosses.) Calyptrate: having a covering like the calvates of mosses.

like the calyptra of mosses.

CALYX. (Calyr, icis. f.; καλυξ; from καλυπτω, to cover.) Caliz. I. The flower-cup, or, more correctly, the external covering of the flower, for the most part green, and surrounding the corolla, or gaudy

There are five genera of calyces, or flower-cups.

1. Perianthium:

2. Involucrum.

3. Amentum. 5. Gluma.

4. Spatha. 6. Perichætium

Volva.

II. The membrane which covers the papillæ in the

pelvis of the human kidney.

CA'MARA. (From καμαρα, a vault.) Camarium.

1. The fornix of the brain.

The vaulted part of the auricle of the heart. CAMA'RIUM.

CAMARO'MA. (From καμαρα, a vault.) Camarosis; Camaratio. A fracture of the skull, in the shape of an arch or vault.

CAMBIREA. So Paracelsus calls the venereal bubo. CA'MBIUM. The gelatinous substance, or matter of organization which Du Hamel and Mirbel suppose

produces the young bark, and new wood of plants.

CAMBIUM. (From cambio, to exchange.) The nutritious humour which is changed into the materials of which the body is composed.

Cambo'dia. See Stalagmitis

CAMBO DIA. See Stalagmitis,
CAMBO GIA. (From the province of Cambaya, in
the East Indies;) Cambodja and Cambogia; Cambodia; Cambogium; Gambogia; Gambogium. See Sta-CAMBOGIA GUTTA. See Stalagmitis.
CAMBO GIUM. See Cambogia and Stalagmitis.

Cambro-Britannica. See Rubus Chamamorus.
Cambu'ca. Cambuta membrata. So Paraceisus calls the venereal cancer. By some it is described as a bubo, an ulcer, an abscess on the pudenda; also a boil

CAMBUT. The wild American myrtle of Piso and Margrave, which is said to be astringent.

Camel's hay. See Andropogon Schwnanthus.
CAMELEON MINERAL. When pure potassa
and black oxide of manganese are fused together in a crucible, a compound is formed, whose solution in water, at first green, passes spontaneously through the whole series of coloured rays to the red. From this latter tint, the solution may be made to retrograde in colour to the original green, by the addition of potassa; or it may be rendered altogether colourless, by adding either sulphureous acid or chlorine to the solution, in which case there may or may not be a precipitate, ac-CA'MERA. A chamber or cavity. The chambers of the eye are termed camera.

CA'MERA. See Camaroma.

CA'MER. Camet. Silver.

CAM'NGA. See Canella alba.

CA'MINUS. A furnace and its chimney. In Rulan-

dus it signifies a bell.

Cami'sia retus. (From the Arabic term kamisah, an under garment.) The shirt of the fectus. See Chorion.

Camomile. See Chamomile.

CAMOMI'LLA. Corrupted from chamomelum.

CA'MMORUM. (Καμμορον, quia homines, κακφ μορφ, perimat; because if eaten, it brings men to a miscrable end.) A species of monkshood. See Aco-

CAMPA'NA. A bell. In chemistry, a receptacle like a bell, for making sulphuric acid; thus the oleum

CAMPANACEÆ. Bell-shaped flowers. The name of an order of Linnæus's natural method.

CAMPANIFORMIS. Campanaceus; Campanula-Bell-shaped; applied to the corolla and nectaries

CAMPA'NULA. (From campana, a bell; named from its shape.) The name of a genus of plants in the Linnwan system. Class, Pentandria; Order, Monogynia. The Bell flower.

CAMPANULA TRACHELEUM. Cervicaria. The Great

Throat-wort: by some recommended against inflammatory affections of the throat and mouth.

CAMPAN'ULATUS. (From Campanula, a little bell.) Bell-shaped: applied to the corolla and nectary of plants, as in Campanula. See Corolla and Necta-

CA'MPE. (From καμπτω, to bend.) A flexure or bending. It is also used for the ham, and a joint, or

articulation.

Campeachy wood. See Hamatoxylon Campechianum. Campechense, Lignum. See Hamatoxylon Cam-

pechianum, or Logwood.

CAMPER, PETER, was born at Leyden in 1722, where he studied under Boerhaave, and took his degree in medicine. He then travelled for some years, and was afterward appointed a professor successively at Francker, Amsterdam, and Groningen. He was subsequently occupied in prosecuting his favourite studies, in visiting various parts of Europe, by the differ-ent societies of which he was honourably distinguishent societies of which he was honourably distinguished, and in performing many public duties in his own country, being at length chosen one of the council of state. He died in 1789 of a pleurisy. He published some improvements in midwifery and surgery, but anatomy appears to have been his favourite pursuit. He finished two parts of a work of considerable magnitude and improvements in which the health madnitude and importance, in which the healthy and morbid structure of the arm, and of the pelvis, are exhibited in very accurate plates, from drawings made by himself: which he appears to have purposed ex-tending to the other parts of the body. There are also tending to the other parts of the body. There are also some posthumous works of Camper possessing great merit, partly on subjects of natural history, partly evincing the connexion between anatomy and painting; in which latter judicious rules are laid down for exhibiting the diversity of features in persons of various countries and ages, and representing the different emotions of the mind in the countenance; also for delineating the general forms of other animals, which he shows to be modified according to their economy.

CAMPESTRIS. Of or belonging to the field; applied as a trivial name to many plants, which are com-

mon in the fields.

CAMPHIRE. See Laurus camphora.

CAMPHORA. (Camphura. Arabian. The ancients meant by camphor what now is called asphalaints and the company of the camphora.

tuin, or Jews' pitch; καφουρα.) See Laurus camphora.
CA'MPHORE FLORES. The subtle substance which first ascends in subliming camphor. It is nothing more than the camphor.

CAMPHOR & FLORES COMPOSITI. Camphor sublimed with benzoin.

CA'MPHORAS. A camphorate. A salt formed by the union of the camphoric acid with a salifiable base; thus, camphorate of alumine, camphorate of ammonia,

CAMPHORA'SMA. (From camphora; so called from its camphor-like smell.) Turkey balsam. See

CAMPHORA'TA. See Camphorosma.
CAMPHORA'TA. See Linimentum camphora.
CAMPHORIC ACID. Acidum camphoricum. An acid with peculiar properties is obtained, by distilling nitric acid eight times following from camphor; and the following is the account Bouillon Lagrange gives

of its preparation and properties

One part of camphor being introduced into a glass retort, four parts of nitric acid of the strength of 36 degrees are to be poured on it, a receiver adapted to the retort, and all the joints well luted. The retort is then retort, and all the joints well luted. The retort is then to be placed on a sand-heat, and gradually heated. During the process a considerable quantity of nitrous gas, and of carbonic acid gas, is evolved; and part of the camphor is volatilized, while another part seizes the oxygen of the nitric acid. When no more vapours are extricated, the vessels are to be separated, and the sublimed camphor added to the acid that remains in the retort. A like quantity of nitric acid is again to the retort. A like quantity of nitric acid is again to be poured on this, and the distillation repeated. This operation must be reiterated till the camphor is com-pletely acidified. Twenty parts of nitric acid at 36 are sufficient to acidify one of camphor.

When the whole of the camphor is acidified, it crystallizes in the remaining liquor. The whole is then to be poured out upon a filter, and washed with distilled water, to carry off the nitric acid it may have retained. The most certain indication of the acidification of the camphor is its crystallizing on the cooling of the liquor remaining in the retort. To purify this acid it must be dissolved in hot distilled water, and the solution, after being filtered, evaporated nearly to half, or till a slight pellicle forms; when the camphoric acid will be ob-

tained in crystals on cooling.

The camphoric acid has a slightly acid, bitter taste, and reddens infusion of litmus.

It crystallizes; and the crystals upon the whole resemble those of muriate of ammonia. It effloresces on exposure to the atmosphere; is not very soluble in cold water; when placed on burning coals, it gives out a thick aromatic smoke, and is entirely dissipated; and with a gentle heat melts, and is sublimed. The mineral acids dissolve it entirely. It decomposes the sul-phate and muriate of iron. The fixed and volatile oils dissolve it. It is likewise soluble in alkohol, and is not precipitated from it by water; a property that distinguishes it from the benzoic acid. It unites easily with

the earths and alkalies, and forms camphoratis.

To prepare the camphorates of lime, magnesia, and alumina, these earths must be diffused in water, and crystallized camphoric acid added. The mixture must then be boiled, filtered while hot, and the solution con-

centrated by evaporation.

The camphorate of barytes is prepared by dissolving the pure earth in water, and then adding crystallized

camphoric acid.

Those of potassa, soda, and ammonia, should be pre-pared with their carbonates dissolved in water; these solutions are to be saturated with crystallized campho ric acid, heated, filtered, evaporated, and cooled; by which means the camphorates will be obtained.

If the camphoric acid be very pure, they have no smell; if it be not, they have always a slight smell of

camphor.

The camphorates of alumina and barytes leave a little acidity on the tongue; the rest have a slightly bitterish taste.

They are all decomposed by heat; the acld being disappearing after birth, that conveys the maternal separated and sublimed, and the base remaining pure; blood from the porta of the liver to the ascending venation. that of ammonia excepted, which is entirely volatilized.

If they be exposed to the blowpipe, the acid burns with a blue flame: that of ammonia gives first a blue flame; but toward the end it becomes red.

The camphorates of lime and magnesia are little so-luble, the others dissolve more easily.

The mineral acids decompose them all. The alka-lies and earths act in the order of their affinity for the camphoric acid; which is, lime, potassa, soda, barytes, ammonia, alumina, magnesia.

Several metallic solutions, and several neutral salts, decompose the camphorates; such as the nitrate of

decompose the camphorates; such as the nitrate of barytes, most of the calcareous salts, &c.

The camphorates of lime, magnesia, and barytes, part with their acid to alkohol.—Lagrange's Manuel d'un Cours de Chimie.

d'un Cours de Chimie.

CAMPHORO'SMA. (From camphora, and οσμη, smell; so called from its smelling of camphire.) The camphor-smelling plant.

1. The name of a genus of plants in the Linnæan system. Class, Tetrandria; Order, Monogynia.

2. The pharmacopæial name of the camphorata. See Camphorosma Monspeliensis.

CAMPHOROSMA MONSPELLENSIS. The systematic name of the plant called camphorata in the pharmacopæias. Chamapeuce—Camphorata hirsuta—Camphorosma Monspeliaca. Stinking ground-pine. This plant, Camphorosma—foliis hirsutis linearibus, of Linnæus, took its name from its smell resembling so strongly that of camphor: it has been exhibited internally, in form of decoction, in dropsical and asthmatic nally, in form of decoction, in dropsical and asthmatic complaints, and by some is esteemed in fomentations against pain. It is rarely, if ever, used in modern practice.

CA'MPTER. (From καμπ 7ω, to bend.) An inflexion

or incurvation.

CA'MPULUM. (From καμπτω, to twist about.) A distortion of the eyelids or other parts.

CAMPYLO'TIS. (From καμπυλος, bent.) A pre-CAMPY LOTTIS. (From Kamerolos, bent.) A preternatural incurvation, or recurvation of a part; also
a distortion of the eyelids.
CA'MPY LUM. See Campylotis.
CA'NABIL. A sort of medicinal earth.
CANABI'NA AQUATICA. See Bidens.
CA'NABIS INDICA. See Bangue and Cannabis.
CANABIS PEREGRINA. See Caunabis.
Canada balsam. See Pinus balsamea.
Canada maidenbay. See Pinus balsamea.
Canada maidenbay. See Adjanthym medatum.

Canada maidenhair. See Adianthum pedatum.
CANADE'NSIS. (Brought from Canada.) Canadian. A name of a balsam. See Pinus balsamea.
CANALICULATUS. Channelled; having a long furrow; applied to leaves, pods, &c. See Leaf and

Legumen.
CANALI'CULUS. (Diminutive of canalis, a channel.) A little canal. See Canalis arteriosus.
CANA'LIS. (From xavos, an aperture, or rather from canna, a reed.) A canal.
Secologically applied to many parts of the body; as

1. Specifically applied to many parts of the body; as

canalis nasalis, &c.

2. The hollow of the spine.

3. A hollow round instrument like a reed, for embracing and holding a broken limb.

CANALIS ARTERIOSUS. Canaliculus arteriosus; Canalis botalii. A blood-vessel peculiar to the fœtus, disappearing after birth; through which the blood pass-

es from the pulmonary artery into the aorta.

Canalis Nasalis. A canal going from the internal canthus of the eye downwards into the nose; it is situated in the superior maxillary bone, and is lined with the pituitary membrane, continued from the

Canalis petitianus. A triangular cavity, haturally containing a moisture between the two laminæ of the hyaloid membrane of the eye, in the anterior part, formed by the separation of the anterior lamina from the posterior. It is named after its discoverer, M. Perir. M. Petit.

Canalis semicircularis. Semicircular canal. There are three in each ear placed in the posterior part of the labyrinth. They open by five orifices into the vestibulum. See Ear.

Canalis semispetros. The half bony canal of the Semicircular canal.

CANALIS VENOSUS. A canal peculiar to the fætus,

Cana'ry balm. See Dracocephalum. Ca'ncamum Græcorum. See Hymenesa courbaril. CANCELLATUS. Having the reticulated appearance of the cancelli of bones.

CANCE'LLI. Lattice-work; applied to the reti-

cular substance in bones.

CANCE LLUS. (From cancer, a crab.) A species of cray-fish, called Bernard the hermit and the wrong heir; the Cancer cancellus of Linnaus; supposed to cure rheumatism, if rubbed on the part.

CA'NCER. 1. The common name of the crab-fish. See Cancer Astacus.

2. The name of a disease, from καρκινος, a crab; so called by the apprients because it exhibited large blue.

called by the ancients, because it exhibited large blue veins like crab's claws: likewise called Carcinoma, veins like crab's claws: likewise called Carcinoma, Carcinos, by the Greeks, Lupus by the Romans, because it eats away the flesh like a wolf. Dr. Cullen places this genus of disease in the class Locales, and order Tumores. He defines it a painful scirrhous tumour, terminating in a fatal ulcer. Any part of the body may be the seat of cancer, though the glands are most subject to it. It is distinguished according to its stages, into occult and open; by the former is meant its scirrhous state, which is a hard tumour that sometimes remains in a quiet state for many years. When its scirrhous state, which is a hard tumour that some-times remains in a quiet state for many years. When the cancerous action commences in it, it is attended with frequent shooting pains; the skin that covers it becomes discoloured, and ulceration sooner or later takes place: when the disease is denominated open cancer. Mr. Pearson says, "When a malignant scir-rhus or a watery excrescence hath proceeded to a period of ulceration, attended with a constant sense of ardent and occasionally shooting pains, is irregular in period of ulceration, attended with a constant sense of ardent and occasionally shooting pains, is irregular in its figure, and presents an unequal surface; if it discharges sordid, sanious, or fætid matter; if the edges of the sore be thick, indurated, and often exquisitely painful, sometimes inverted, at other times retorted, and exhibit a serrated appearance; and should the ulcer in its progress be frequently attended with hamorrhage, in consequence of the erosion of blood-vessels; there will be little hazard of mistake in calling it a cancerous ulcer." In men, a cancer most frequently seizes the tongue, mouth, or penis; in women, the seizes the tongue, mouth, or penis; in women, the breasts or the uterus, particularly about the cessation of their periodical discharges; and in children, the eyes. The following description of Scirrhus and Cancer, from the above writer, will serve to elucidate the subject. A hard unequal tumour that is indolent, and without any discoloration in the skin, is called a scir-rhus; but when an itching is perceived in it, which is followed by a pricking, shooting, or lancinating pain, and a change of colour in the skin, it is usually denominated a cancer. It generally is small in the beginning, and increases gradually; but though the skin changes to a red or livid appearance, and the state of changes to a red or livid appearance, and the state of the tumour from an indolent to a painful one, it is sometimes very difficult to say when the scirrhus really becomes a cancer, the progress being quick or slow according to concurring causes. When the tumour is attended with a peculiar kind of burning, shooting pains, and the skin hath acquired the dusky purple or livid hue, it may then be deemed the malignant scirrhus or confirmed cancer. When thus far advanced in women's breasts, the tumour sometimes increases speedily to a great size, having a knotty unequal surface, more glands becoming obstructed, the nipple sinks in, turgid veins are conspicuous, ramifying around, and resembling a crab's claws. These are the characteristics of an occult cancer on the external the characteristics of an occult cancer on the external the characteristics of an occult cancer on the external parts; and we may suspect the existence of one internally, when such pain and heat as has been described, succeed in parts where the patient hath before been sensible of a weight and pressure, attended with obtuse pain. A cancerous tumour never melts down in suppuration like an inflammatory one; but when it is ready to break open, especially in the breast, it generally becomes prominent in some minute point, attended with an increase of the peculiar kind of hurn tended with an increase of the peculiar kind of burn-ing, shooting pain, felt before at intervals, in a less de-gree and deeper in the body of the gland. In the prominent part of the tumour, in this state, a corroding ichor sometimes transudes through the skin, soon forming an ulcer: at other times a considerable quantity of a thin lymphatic fluid tinged with blood from

eroded vessels is found on it. Ulcers of the cancerous nature discharge a thin, fætid, acrid sanies, which corrodes the parts, having thick, dark-coloured retorted lips; and fungous excrescences frequently rise from these ulcers, notwithstanding the corrosiveness of the discharge. In this state they are often attended with excruciating, pungent, lancinating, burning pains, and sometimes with bleeding.

Though a scirrbus may truly be deemed a cancer.

Though a scirrhus may truly be deemed a cancer, as soon as pain is perceived in it, yet every painful tumour is not a cancer; nor is it always easy to say whether a cancer is the disorder or not. Irregular hard lumps may be perceived in the breast; but on ex-amining the other breast, where no uncasiness is perceived, the same kind of tumours are sometimes found, which renders the diagnostic uncertain. Yet in every case after the cessation of the catamenia, hard, unequal tumours in the breast are suspicious; nor, though without pain, are they to be supposed indolent or in-

In the treatment of this disease, our chief reliance must be on extirpating the part affected. Some have attempted to dispet the scirrhous tumour by leeches and various discutient applications, to destroy it by caustics, or to check its progress by narcotics; but without material success. Certainly before the disease is confirmed, should any inflammatory tendency appear, antiphlogistic means may be employed with propriety; but afterward the operation should not be de-layed; nay, where the nature of the tumour is doubt-ful, it will be better to remove it, than incur the risk of this dreadful disease. Some surgeons, indeed, have contested the utility of the operation; and no doubt the disease will sometimes appear again; from constitutional tendency, or from the whole not having been removed; but the balance of evidence is in favour of the operation being successful, if performed early, and to an adequate extent. The plan of destroying the part by caustic is much more tedious, painful, and uncertain. When the disease has arisen from some accident, not spontaneously, when the patient is otherwise healthy, when no symptoms of malignancy in the can-cer have appeared, and the adjacent glands and absorbents seem unaffected, we have stronger expectation of success: but unless all the morbid parts can be removed success: but unless all the morbid parts can be removed without the risk of dividing important nerves or arteries, it should scarcely be attempted. In operating it is advisable, 1. To make the external wound sufficiently large, and nearly in the direction of the subjacent muscular fibres. 2. To save skin enough to cover it, unless diseased. 3. To tie every vessel which might endanger subsequent harmorrhage. 4. To keep the lips of the wound in contact, not interposing any dressing &c. 5. To preserve the parts in an easy and steady ing, &c. 5. To preserve the parts in an easy and steady position for some days, before they are inspected. 6. To use only mild and cooling applications during the cure. Supposing, however, the patient will not con-sent to an operation, or circumstances render it inadmissible, the uterus, for example, being affected, in-ternal remedies may somewhat retard its progress, or alleviate the sufferings of the patient; those, which have appeared most beneficial, are, I. Arsenic, in very small doses long continued. 2. Conium, in doses progressively increased to a considerable extent. 3. Opium. gressively increased to a considerable extent. 3. Opium.

4. Belladonna. 5. Solanum. 6. Ferrum ammoniatum. 7. Hydrargyri oxymurias. 8. The juice of the galium aparine. When the part is external, topical applications may be useful to alleviate pain, cleanse the sore, or correct the fætor; especially, 1. Freshbruised hemlock leaves. 2. Scraped young carrots.

3. The fermenting poultice. 4. Finely levigated chalk.

5. Powdered charcoal. 6. Carbonic acid gas, introtroduced into a bladder confined round the part. 7. A watery solution of opium. 8. Liquid tar, or tarwater. But none of these means can be relied upon for effecting a cure. for effecting a cure. 3. See Carcinus.

CANCER ASTACUS. The systematic name of the crab-fish, from which the claws are selected for medical use. Crab's claws and crab's eyes, as they are called, which are concretions found in the stomach, are of a calcareous quality, and possess antacid virtues.
They are exhibited with their compounds in pyrosis,
diarrhea, and infantile convulsions from acidity.

Cancer cancellus. See Cancellus.
Cancer gammarus. The systematic name of the

lobster

CANCER MUNDITORIUM. A peculiar ulceration of

the scrotum of chimney-sweepers.

CA'NCHRYS. Parched barley.—Galen.

CANCER'NA. Paracelsus uses this word instead of gangræna.

CANCRO'RUM CHELE. Crab's claws. See Carbonas calcis, and Cancer astacus.

CANCRORUM OCULI. See Carbonas calcis, and Can-

CA'NCRUM. (From cancer, a spreading ulcer.) The canker.

CANCRUM ORIS. Canker of the mouth; a fretted

ulceration of the gums.

CANDE'LA. (From candeo, to shine.) A candle.

CANDELA FUMALIS. A candle made of odoriferous powders and resinous matters, to purify the air and excite the spirits.

CANDELA REGIA. See Verbascum.

CANDELA'RIA. (From candela, a candle; so called from the resemblance of its stalks to a candle.) Mul-

lein. See Verbascum.

Candy carrot. See Athamanta cretensis.

Cane La. Sometimes used by the ancients for cin-

namon, or rather cassia.

CANE'LLA. (Canella, diminutive of canna, a reed; so named because the pieces of bark are rolled up in the form of a reed.) The name of a genus of plants in the Linnæan system. Class, Dodecandria; Order, Monogynia. The canella-tree.

CANELLA ALBA. The pharmacopæial name of the laurel-leaved canella. See Winteria aromatica.

CANELLA CUBANA. See Canella alba.

CANELLE MALABARICE CORTEX. See Laurus cas-

CANELLI'FERA MALABARICA. See Laurus cassia.

Caneon. (From καννη, because it was made of split cane.)- A sort of tube or instrument, mentioned by Hippocrates, for conveying the fumes of antihysteric drugs into the womb.

drugs into the womb.

CA'NICÆ. (From canis, a dog, so called by the ancients, because it was food for dogs.) Coarse meal.

Hence panis caniccus means very coarse bread.

CANICI'DA. (From canis, a dog, and cædo, to kill; so called because dogs are destroyed by eating it.)

Dog's bane. See Aconitum.

CANICI'DIUM. (From canis, a dog, and cædo, to kill.) The anatomical dissection of living dogs; for the purpose of illustrating the physiology of parts.

the purpose of illustrating the physiology of parts.

CANINA LINGUA. See Cynoglossum.
CANINA MALUS. The mandragora.
CANINA RABIES. See Hydrophobia.
CANINE. Whatever partakes of, or has any rela-

CANINE. Whatever partakes of, or has any relation to, the nature of a dog.

Canine appetite. See Bulimia.

Canine madness. See Hydrophobia.

Canine madness. See Hydrophobia.

Canine Teeth. Dentes canini; Cynodontes; Cuspidati of Mr. John Hunter; because they have the two sides of their edge sloped off to a point, and this point is very sharp or cuspidated; columellares of Varo and Pliny. The four eye-teeth are so called from their resemblance to those of the dog. See Teeth.

CANI'NUS. (From canis, a dog.) 1. a tooth is so called, because it resembles that of a dog. See Teeth.

2. The name of a muscle, because it is near the canine tooth. See Levator anguli oris.

3. A disease to which dogs are subject is called Rabies canina. See Hydrophobia.

Caninus sentis. See Rosa canina.

Caninu'bus. (From canis, and rubus, a bramble.) See Rosa canina. is very sharp or cuspidated; columellares of Varo and

See Rosa canina.
CA'NIS. 1. A dog. The white dung of this animal, called album gracum, was formerly in esteem, but now disused.

2. The framum of the penis. Canus interfector. Indian barley. See Veratrum sabadilla.

CANNA. (Hebrew.) 1. A reed or hollow cane.
2. The fibula, from its resemblance to a reed.
CANNA FISTULA. See Cassia fistula.
CANNA INDICA. See Sagittaria alexipharmica.
CANNA MAJOR. The tibia.
CANNA MAJOR. The tibia.

CANNA MINOR CRURIS. The fibula.
CANNABI'NA. (From canna, a reed, named from its reed-like stalk.) So Tournefort named his datisea.
CA'NNABIS. (From kanna, a reed. Kannabot are foul springs, wherein hemp, &c. grow naturally. Or

from kanaba, from kanah, to mow. Arabian.) Hemp 1. The name of a genus of plants in the Linnwan sys-tem. Class, Diacia; Order, Pentandria. tem. Class, Diacia; Orner, remanare.

2. The pharmacopæial name of the hemp-plant. See

CANNABIS SATIVA. The systematic name of the hemp-plant. It has a rank smell of a narcotic kind. The effluvia from the fresh herb are said to affect the The effluria from the fresh herb are said to affect the eyes and head, and that the water in which it has been long steeped is a sudden poison. Hemp-seeds, when fresh, afford a considerable quantity of oil. Decoctions and emulsions of them have been recommended against coughs, ardor uring, &c. Their use, in general, depends on their emollient and demulcent qualities. The leaves of an oriental hemp, called bang or bangue, and by the Egyptians assis, are said to be used in eastern countries, as a narcotic and aphrodisiac. See Bangue. siac. See Bangue.

CA'NNULA. (Diminutive of canna, a reed.) The name of a surgical instrument. See Canula.

CA'NON. Κανων. A rule or canon, by which

medicines are compounded.

Cano'NIAL. Κανονιαι. Hippocrates in his book De Aëre, &c. calls those persons thus, who have straight, and not prominent bellies. He would intimate that they are disposed, as it were, by a straight rule.

Cano'Picon. (From κανωπον, the flower of the elder.) 1. A sort of spurge, so named from its resemblance.

2. A collyrium, of which the chief ingredient was

CANOPI'TE. The name of a collyrium mentioned by Celsus.

CANO'PUM. Κανωπον. The flower or bark of the elder-tree, in Paulus Ægineta.

CANTA'BRICA. See Convolvulus.

CANTA'BRUM. (From kanta, Hebrew.) In Cœlius Aurelianus it signifies brañ.

CA'NTACON. Garden saffron. CA'NTARA. The plant which bears the St. Ignatius's CA'NTARA.

bean. See Ignaria amara.

CANTERBURY. The name in history of a much celebrated town in Kent, in which there is a mineral

water, Cantuariensis aqua, strongly impregnated with iron, sulphur, and carbonic acid gas; it is recommended in disorders of the stomach, in gouty complaints, jaundice, diseases of the skin, and chlorosis.

CA'NTHARI FIGULINI. Earthen cucurbits.

CA'NTHARIS. (Cantharis, pl. cantharides: from κανθαρος, a beetle, to which tribe it belongs.) Musca Hispanica; Lytta vesicatoria; The blistering fly: Spanish fly. These flies have a green shining gold body, and are common in Spain. Italy, France, and body, and are common in Spain, Italy, France, and Germany. The largest come from Italy, France, and Spanish cantharides are generally preferred. The importance of these flies, by their stimulant, corrosive, and epispastic qualities, in the practice of physic and surgery, is very considerable; indeed, so much so, as to induce many to consider them as the most powerful restriction in the practice of them. to induce many to consider them as the most powerful medicine in the materia medica. When applied on the skin, in the form of a plaster, it soon raises a blister full of serous matter, and thus relieves inflammatory diseases, as phrenitis, pleuritis, hepatitis, phlegmon, bubo, myositis, arthritis, &c. The tincture of these flies is also of great utility in several cutaneous diseases, rheumatic affections, sciatic pains, &c. but ought to be used with much caution. See Blister, and Tinctura cantharidis. This insect is two-thirds of an inch in length, one-fourth in breadth, oblong, and of a inch in length, one-fourth in breadth, oblong, and of a gold shining colour, with soft elytera or wing sheaths, marked with three longitudinal raised stripes, and covering brown membrateous wings. An insect of a square form, with black feet, but possessed of no vesicating property, is sometimes mixed with the cantharides. They have a heavy disagreeable odour, and

According to Robiquet, who first discovered them, these plates form the true blistering principle. They might be called *Vesicatoria*. Besides the above pecumight be catled Vesicatoria. Besides the above peculiar body, cantharides contain, according to Robiquet, a green bland oil, insoluble in water, soluble in alkohol; a black matter, soluble in water, insoluble in alkohol, without blistering properties; a yellow viscid matter, mild, soluble in water and alkohol; the crystalline plates; a fatty bland matter; phosphates of lime and magnesia; a little acetic acid, and much lithic or uric acid. The blistering fly taken into the stomach in doses of a few grains, acts as a poison, occasioning horrible satyriasis, delirium, convulsions, and death. Some frightful cases are related by Orfila, vol. i. part second. Oils, milk, syrups, frictions on the spine, with volatile liniment and laudanum, and draughts containing musk, opium, and camphorated draughts containing musk, opium, and camphorated emulsion, are the best antidotes

emulsion, are the best antidotes.

["Cantharides Vittata. Potato flies. The Cantharis rittata of Olivier, called Lytta vittata by Fabricius, inhabits the United States and South America. It is also given by Pallas among his insects of Siberia. It feeds on different plants, but chiefly on the potato vine, and is easify caught in the morning and towards night. It agrees with the Spanish fly in its generic character, but is a smaller insect, having its elytra or wing cases black with a vellow string and margin, its character, but is a smaller insect, having its elytra or wing cases black with a yellow stripe and margin, its head reddish yellow, and its abdomen and legs black. This fly is found by abundant experience to possess all the vesicating powers of the European cantharis, and to exert the same effect, when internally administered, upon the bladder and urethra. The potato fly might well supersede the Spanish, were it not that its visits in different years vary greatly as to certainty and numbers. It is probable that many insects of the coleouterous class possess vesicating powers. Reand numbers. It is probable that many insects of the coleopterous class possess vesicating powers. Recently a fly possessing this quality was sent from the country to a physician in Boston. It proved to be the meloe proscarabeus of Linnæus. The discovery of the epispastic property in any native insect, is an object of interest. But that such insects may become extensively useful, they must be abundant and easy of collection."—Big. Mat. Med. A.}

CA'NTHUN. Sugar-candy.

CA'NTHUS. (Kardos, the tire or iron binding of a cart-wheel. Dr. Turton, in his glossary, supposes from its etymology, that it originally signified the circular extremity of the eyelid.) The angle or corner of the eye, where the upper and under eyelids meet. That next the nose is termed the internal or greater canthus; and the other, the external or less canthus.

next the nose is termed the internal or greater canthus; and the other, the external or less canthus.

Cantion. Sugar.

Ca'NULA. (Diminutive of canna, a reed.) Cannula. A small tube. The term is generally applied to a tube adapted to a sharp instrument, with which it is thrust into a cavity or tumour, containing a fluid; the perforation being made, the sharp instrument is withdrawn, and the canula left, in order that the fluid may pass through it. may pass through it.

CANUSA. Crystal. CAOUTCHOU'C. The substance so called is obtained from the vegetable kingdom, and exists also in the mineral.

the mineral.

1. The first, known by the names Indian rubber, Elastic gum, Cayenne resin, Cautchuc, and Caoutchuc, is prepared principally from the juice of the Siphonia clastica;—foliis ternatis ellipticis integerrimis subtis canis longe petiolatis, (Suppl. Plant.) and also from the Jatropha elastica and Unceola clastica. The manner of obtaining this juice is by making incisions through the bark of the lower part of the trunk of the tree, from which the fluid resin issues in great abundance, appearing of a milky whiteness as it flows abundance, appearing of a milky whiteness as it flows into the vessel placed to receive it, and into which it into the vessel placed to receive it, and into which it is conducted by means of a tube or leaf fixed in the incision, and supported with clay. On exposure to the air, this milky juice gradually inspissates into a soft, reddish, clastic, resin. It is formed by the Indians in South America into various figures, but is commonly brought to Europe in that of pear-shaped bottles, which are said to be formed by spreading the juice of the Siphonia over a proper mould of clay; as soon as one layer is dry, another is added, until the bottle be of the thickness desired. It is then exposed to a thick dense smoke, or to a fire, until it becomes so If the inspissated watery decoction of these insects be treated with pure alkohol, a solution of a resinous matter is obtained, which being separated by gentle evaporation to dryness, and submitted for some time to the action of sulphuric æther, forms a yellow solution. By spontaneous evaporation, crystalline plates are deposited, which may be freed from some adhering colouring matter by alkohol. Their appearance is like spermaceti. They are soluble in boiling alkohol, but precipitate as it cools. They do not dissolve in water.

effected by softening it with water.
"The elasticity of this substance is its most remark-"The elasticity of this substance is its most remarkable property: when warmed, as by immersion in hot water, slips of it may be drawn out to seven or eight times their original length, and will return to their former dimensions nearly. Cold renders it stiff and rigid, but warmth restores its original elasticity. Exposed to the fire it softens, swells up, and burns with a bright flame. In Cayenne it is used to give light as a candle. Its solvents are æther, volatile oils, and petroleum. The æther, however, requires to be washed with water repeatedly, and in this state it dissolves it completely. Pelletier recommends to boil the caoutchour pletely. Pelletier recommends to boil the caoutchouc in water for an hour; then to cut it into slender threads; to boil it again about an hour; and then to put it into rectified sulphuric æther in a vessel close stopped. In this way he says it will be totally dissolved in a few days, without heat, except the impurities, which will fall to the bottom if where enough be employed. Berniard says, the nitrous where dissolves it better than the sulphuric. If this solution be spread on any substance, the where evaporates very quickly, and leaves a coating of caoutchout unaltered in its properties. Narhtha or catalogue restified into a and leaves a coating of caoutchout unaltered in its properties. Naphtha, or petroleum, rectified into a colourless liquid, dissolves it, and likewise leaves it unchanged by evaporation. Oil of turpentine softens it, and forms a pasty mass, that may be spread as a varnish, but is very long in drying. A solution of caoutchout in five times its weight of oil of turpentine, and this solution dissolved in eight times its weight of different properties. ing linseed oil by boiling, is said to form the varnish of air-balloons. Alkalies act upon it so as in time to destroy its elasticity. Sulphuric acid is decomposed by it; sulphurous acid being evolved, and the caoutchouc converted into charcoal. Nitric acid a 1s upon it with heat; nitrous gas being given out, and oxalic acid crystallizing from the residuum. On distillation it crystallizing from the residuum. On distill gives out ammonia, and carburetted hydrogen.

Caoutchouc may be formed into various articles without undergoing the process of solution. If it be cut into a uniform slip of a proper thickness, and wound spirally round a glass or metal rod, so that the edges shall be in close contact, and in this state be boiled for some time, the edges will adhere so as to form a tube. Pieces of it may be readily joined by touching the edges with the solution in ather; but this is not absolutely necessary, for, if they be merely softened by heat, and then pressed together, they will unite very firmly.

very firmly.

If linseed oil be rendered very drying by digesting it armseed off be rendered very drying by digesting it upon an oxide of lead, and afterward applied with a small brush on any surface, and dried by the sun or in the smoke, it will afford a pellicle of considerable firmness, transparent, burning like caoutchouc, and wonderfully elastic. A pound of this oil, spread upon a stone, and exposed to the air for six or seven months, according almost all the properties of caoutchouc, it acquired almost all the properties of caoutchouc; it was used to make catheters and bougies, to varnish

balloons, and for other purposes.

Of the mineral caoutchout there are several varie ties:-1. Of a blackish-brown, inclining to olive, soft, exceedingly compressible, unctnous, with a slightly aromatic smell. It burns with a bright flame, leaving a black oily residuum, which does not become dry. 2. Black, dry, and cracked on the surface, but, when cut into, of a yellowish-white. A fluid resembling pyrolignic acid exudes from it when recently cut. It is pellucid on the edges, and nearly of a hyacinthine red colour. 3. Similar to the preceding, but of a somewhat firmer texture, and ligneous appearance, from having acquired consistency in repeated layers. 4. Resembling the first variety, but of a darker colour, and adhering to gray calcureous spar, with some grains of galæna. 5. Of a liver-brown colour, having the aspect of the vegetable caoutchouc, but passing by gradual transition into a brittle bitumen, of vitreous lustre, and a yellowish colour. 6. Dull reddish-brown, of a spongy or cork-like texture, containing blackish-gray nuclei of impure caoutchouc. Many more varieties are enumerated.

One specimen of this caoutchouc has been found in a petrified marine shell enclosed in a rock, and another eaclosed in a crystallized fluor spar.

The mineral caoutchouc resists the action of solvents

certain instruments of iron, or wood, it is ornamented on the outside with various figures. This being done, it remains only to pick out the mould, which is easily burning it is resolved into a pitchy viscous substance. petroleum affects it most, particularly when by partial burning it is resolved into a pitchy viscous substance. A hundred grains of a specimen analyzed in the dry way by Klaproth, afforded carburetted hydrogen gas 38 cubic inches, carbonic acid gas 4, bituminous oil 73 grains, acidulous phlegm 1.5, charcoal 6.25, lime 2, silex 1.5, oxide of iron .75, sulphate of lime .5, alumina .25

CAPAIBA. See Copaifera officinalis.
CAPAIVA. See Copaifera officinalis.
CAPELI'NA. (From capeline, French, a woman's hat, or bandage.) A double-headed roller, put round

the head.

CAPE'LLA. A cupel or test. Also a name for a goat.

CAPER. See Capparis.

Caper-bush. See Capparis.

CA'PETUS. (Καπεῖος, per aphæresin, pro σκαπεῖος; from σκαπτῶο, to dig.) Hippocrates means by this word a foramen, which is impervious, and needs the use of a chirurgical instrument to make an opening; as the anus of some new-born infants.

CA'PHORA. (Arabian.) Camphire.

CA'PHURA BAROS INDORUM. A name for camphire. CAPHURÆ OLEUM. An aromatic oil distilled from the root of the cinnamon-tree.

CAPILLACEUS. Capillary.
CAPILLARIS. See Capillary.
CAPILLARES PLANTE. Capillary, or hair-shaped

Capillaris vermiculus. See Crinones and Dra-

CAPI'LLARY. (Capillaris; from capillus, a little hair: so called from the resemblance to hair or fine thread.) 1. Capillary vessels. The very small ramifications of the arteries, which terminate upon the external surface of the body, or on the surface of internal cavities, are called capillary.

2. Capillary attraction. See fittraction.

2. Capillary attraction. See Attraction.
3. Applied to parts of plants, which are, or resemble, hairs: thus, a capillary root is one which consists of many very fine fibres, as that of Festuca ovina, and most grasses.

CAPILLA'TIO. (From fracture of the cranium. (From capillus, a hair.) A capillary

CAPI'LLUS. (Quasi capitis pilus, the hair of the head.) The hair. Small, cylindrical, transparent, insensible, and elastic filaments, which arise from the skin, and are fastened in it by means of small roots. The human hair is composed of a spongy, cellular texture, containing a coloured liquid, and a proper covering. Hair is divided into two kinds; long, which arises on the scalp, cheek, chin, breasts of men, the anterior parts of the arms and legs, the arm-pits, groins, and pelvis: and short, which is softer than the long, and is present over the whole body, except only the paim of the hand and sole of the foot. The hair originates in the adiroge membrane from an oblong mem nates in the adipose membrane from an oblong mem braneous bulb, which has vessels peculiar to it. The hair is distinguished by different names in certain parts; as, capillus, on the top of the head: crinis, on the back of the head; circrinnus, on the temples; cilium, on the eyelids; supercilium, on the eyebrows; vibrissa, in the nostrils; barba, on the chin; pappus, on the middle of the chin; mystax, on the upper lip; pilus, on the body.

From numerous experiments Vauquelin infers, that black hair is formed of nine different substances,

namely:

 An animal matter, which constitutes the greater part.
 A white concrete oil, in small quantity.
 Another oil of a grayish-green colour, more abundant than the former. 4. Iron, the state of which in the hair is uncertain. 5. A few particles of oxide of man ganese. 6. Phosphate of lime. 7. Carbonate of lime, in very small quantity. 8. Silex, in a conspicuous quantity. 9. Lastly, a considerable quantity of sul-

The same experiments show, that red hair differs from black only in containing a red oil instead of a blackish-green oil; and that white hair differs from both these only in the oil being nearly colourless, and in containing phosphate of magnesia, which is not found in them.

found in them.

CAPILLUS VENERIS. See Adianthum. CAPILLUS VENERIS CANADENSIS. See Adianthunt

canadense.

CAPIPLE'NIUM. (From caput, the head, and plenus, full; a barbarous word: but Baglivi uses it to signify that continual heaviness or disorder in the head, which

that continual heaviness or disorder in the head, which the Greeks call καρηβαρία.) A catarrh.

Capistra'rio. (From capistrum; a bridle: so called because the præpuce is restrained as it were with a bridle.) See Phimosis.

CAPI'STRUM. (From caput, the head.)

I. A bandage for the head is so called.

2. In Vogel's Nosology it is the same as Trismus.

CAPITAL. Capitalis. 1. Belonging to the caput, or head. or head.

2. The head or upper part of an alembic.

CAPITA'LIA. (From caput, the head.) Medicines which relieve pains of the head.

CAPITATUS. (From caput, the head.) Headed.

CAPITE'LLUM. The head or seed vessels, fre-

quently applied to mosses, &c. CAPITILU'VIUM. (From caput, the head, and lave, to wash.) A lotion for the head.

CA'PITIS OBLIQUUS INFERIOR ET MAJOR. See Obli-

quus inferior capitis.

CAPITIS PAR TERTIUM FALLOPII. See Trachelomastoideus.

CAPITIS POSTICUS. See Rectus capitis posticus

CAPITIS RECTUS. See Rectus capitis posticus minor. CAPITULUM. (Diminutive of caput, the head.) 1. A small head.

A protuberance of a bone, received into the concavity of another bone.

3. An alembic.

In botany, the term for a species of inflorescence, called a head or tuft, formed of many flowers, in a globular form, upon a common peduncle.

From the insertion of the flowers, it is called, 1. Pedunculated; as in Astragalus syriacus, and

Eryngium maritimum. 2. Sessile: as in Tri

Sessile; as in Trifolium tomentosum. 3. Terminal; as in Annarda fistulosa.
4. Axillary; as in Gomphrena sessilis.
From the figure, it is said to be,
1. Globose; as in Gomphrena globosa.
2. Subrotund; as in Trifolium pratense.
3. Conic; as in Trifolium wontanum.
4. Dimidiate, flat on one side, round on the other; as in Trifolium lupinaster.
From its covering

From its covering,

1. Naked; as in Illecebrum polygonoides.

2. Foliose; as in Plantago indico.

A capitulum that is very small, and is mostly in the

axilla, is called Glomeridius.

CAPI'VI. See Copaifera officinalis.

CAPNELÆ'UM. (From καπνος, smoke, and ελαιον, oil; so named from its smoky exhalations when exposed to heat.) In Galen's works it means a resin.

Ca'pnias. (From καπνος, a smoke.) 1. A jasp

of a smoky colour.

A vine which bears white and part black grapes. Capni's Ton. (From καπνος, smoke.) A prepara-tion of spice and oil, made by kindling the spices, and fumigating the oil.

CAPNOTIS. (From καπνος, smoke; so called from its smoky colour.) Tutty.

CAPNOT DES. (From καπνος, fumitory, and ειδος,

CAPNOl'DES. (From καπνος, fumitory, and ειδος, likeness.) Resembling fumitory.

CA'PNOS. (Καπνος, smoke; so called, says Blanchard, because its juice, if applied to the eyes, produces the same effect and sensations as smoke.) Capnus. The herb fumitory. See Fumaria.

CAPNUS. See Capnos.

CA'PPA. (Â capite, from the head: so called from its supposed resemblance.) The herb monkshood. See Aconitum.

CA'PPARIS. (From cabar, Arab. or ωαρα το καππανειν αραν, from its curing madness and melancholy.) The caper plant.

1. The name of a genus of plants in the Linnæan system. Class, Polyandria; Order, Monogynia.

2. The pharmacopeial name of the caper plant. See Cannaria spinger.

See Capparis spinosa.

Capparis spinosa. The systematic name of the caper plant. Capparis:—pendunculis solitariis uniforis, stipulis spinosis, foliis annuis, capsulis ovalibus of Linnæus. The buds, or unexpanded flowers of this plant are in coramon use as a pickle, which is said to plant are in common use as a pickle, which is said to

possess antiscorbutic virtues. The bark of the root was formerly in high esteem as a deobstruent.

CAPREOLA'RIS. (From capreolus, a tendril.) apreolatus. Resembling in its contortions, or other Capreolatus. appearance, the tendrils of a vine; applied to the spermatic vessels.
CAPREOLATUS.

See Capreolaris.

CAPRE OLUS. (Dim. of caprea, a tendril. Dr. Turton suggests its derivation from caper, a goat, the horn of which its contortions somewhat resemble.) 1. The helix or circle of the ear, from its tendril-like

2. A Tendril. See Cirrus.

CAPRICO'RNUS. Lead. CAPRIFICATION. (Caprificatio; from caprificus,

a wild fig.) The very singular husbandry, or management of fig-trees.

CAPRIFI'CUS. (From caper, a goat, and ficus, a fig; because they are a chief food of goats.) The wild fig-tree. See Ficus.

CAPRIMULOUS. A species of bird, the goat-sucker, to which belong the night-hawk and the whip-

CAPRI'ZANS. Galen and others used this word to

express an inequality in the pulse, when it leaps, and, as it were, dances in uncertain strokes and periods. Carse Lla. (Diminutive of capsa, a chest, from its resemblance.) A name in Marcellus Empiricus for viper's bugloss; the Echium Italicum, of Linnæus. CA'PSICUM. (From καπ/ω, to bite; on account of its effect on the mouth.)

 The name of a genus of plants in the Linnman stem. Class, Pentandria; Order, Monogynia. system. Class, Pentandria; Order, Monogyma. See 2. The pharmacopæial name of the capsicum. See

Capsicum annuum.

Capsicum annuum.

Capsicum annuum. The systematic name of the plant from which we obtain Cayenne pepper. Guinea pepper. Piper indicum; Lada chilli; Capo Molago; Solanum urens; Siliquastrum Plinii; Piper Brazilianum; Piper Guincense; Piper Calecuticum; Piper Hispauicum; Piper Lusitanicum. Cayenne pepper. This species of pepper is obtained from the Capsicum; caule herbaceo, pedunculus solitariis of Linnæus. What is generally used under the name of Cayenne pepper, however, is an indiscriminate mix-Cayenne pepper, however, is an indiscriminate mix-ture of the powder of the dried pods of many species of capsicum, but especially of the capsicum minimum, or bird pepper, which is the hottest of all. These pep-pers have been chiefly used as condiments. They prevent flatulence from vegetable food, and give warmth to the stomach, possessing all the virtues of the oriental spices, without producing those complaints of the head which the latter are apt to occasion. An abuse of them, however, gives rise to visceral obstructions, especially of the liver. In the practice of medicine, there can be little doubt that they furnish us with one of the purest and strongest stimulants which can be introduced into the care by introduced into the stomach, and may be very useful in roduced into the stomach, and may be very useful in some paralytic and gouty cases. Dr. Adair, who first introduced them into practice, found them useful in the cachexia Africana, which he considers as a most frequent and fatal predisposition to disease among the slaves. Dr. Wright says, that in dropsical and other complaints where chalybeates are indicated, a minute portion of powdered exists. a minute portion of powdered capsicum forms an ex-cellent addition, and recommends its use in lethargic affections. This pepper has also been successfully employed in a species of cynanche maligna, which proved very fatal in the West Indies, resisting the use of Peruvian bark, wine, and other remedies com-monly employed. In tropical fevers, coma and delirium are common attendants; and, in such cases, cataplasms of capsicum have a speedy and happy effect. They redden the parts, but seldom blister unless when kept on too long. In ophthalmia from relaxation, the diluted juice of capsicum is found to be a valuable remedy. Dr. Adair gave six or eight grains for a dose, made into pills; or else he prepared a tincture by digesting half an ounce of the pepper in a pound of alkohol, the dose of which was one or two drachms, diluted with a sufficient quantity of water. A tinctura capsici is now for the first time introduced into the

London pharmacopæia. [" This article is well known for its excessively pungent and biting acrimony, exceeding that of any other article used with food. The principle on which its article used with food. The principle on which its pungency depends is soluble in both water and alko-

hol, and is not dissipated by boiling. Its solutions are disturbed by various reagents, which, however, are of no consequence in practical use. It is found to contain cinchonin, resin, mucilage, and an acrid principle said to be alkaline. It is sometimes adulterated with

red-lead to increase its weight.

Capsicum is a warm, powerful stimulant, promoting digestion, and obviating flatutence. Its abuse, however, produces visceral obstructions, and an inflamma-tory disposition in the system. It is never of service to the healthy. In disease it is administered to stimulate the stomach when in a torpid state, and to excite the nerves of the paralytic and lethargic. In the West Indies it has been employed both externally and internally in ulcerated sore throat. It is applied as a gargle in this disease, and in paralysis of the tongue. Its chief use, however, is as a rubefacient to the skin, upon which it acts with great power. The dose inter-nally is from five to ten grains. The rubefacient cataplasm is made of meal and vinegar heated, and its surface covered with pulverized capsicum."-Big. Mat. Med. A.] CA'PSULA.

(Diminutive of capsa, a chest or case.) A capsule. 1. A membraneous production enclosing a part of the body like a bag; as the capsular ligaments, the capsule of the crystalline lens, &c.

2. In botany, a dry, woody, coriaceous, or membra-neous pericarpium, or seed-vessel, generally splitting into several valves.

The parts of a capsule, are,

1. The valves, or external shell, into which the cap-

sule splits.

2. The sutures, or the external surface in which the

valves are joined.

3. The dissepimenta, or partitions by which the capsule is divided into several cells.

4. The loculamenta, or cells, the spaces between the partitions and valves.

5. The columella, or central column, or filament, which unites the partitions, and to which the seeds are usually attached.

From the number of the valves, a capsule is said to be,

Bivalved; as in Magnolia, and Caprarta. Three-valved; as in Canna indica. Four-valved; as in Datura stramonium and Enothera biennis.

4. Five-valved; as in Illecebrum, and Coris.

- Manyvalved; as in Hura crepitans.
 Operculate, or circumcised, the operculum splitting horizontally; as in Hyosciamus niger, and Lecythis ollaria.
- From the number of cells, 1. Unilocular, when there is no partition; as in Parnassia palustris, and Agrostema.

 2. Bilocular, two-celled; as Hyosciamus niger, and

Datura stramonium.

3. Trilocular, three-celled; as in Æsculus hypocastanum, and Iris germanica. 4. Quinquelocular, five-celled; as in Hibiscus syri-

acus, and Azalea procumbens 5. Novembocular, nine-celled; as in Punica gra-

 Submultilocular, when there are many cells, and the partitions do not reach the middle of the capsule; as in Papaver somniferum.

From the appearance of the external surface, a cap-

sule is called.

Glabrous; as in Papaver somniferum.
 Aculeate; as in Datura stramonium.
 Muricate; as in Canna indica.

From the number of tubercles on the external 1. Capsula dicocca, or didyma; as in Spigelia.

2. C. tricocca; as in Euphorbia lathyrus, and Cne-

3. C. tetracocca; as in Paururus cernuus, and Evonymus curopeus

From the number of contiguous capsules,

1. C. simplex, if solitary.

2. C. duplex, two aggregated; as in Paonia officinalis.

3. C. triplex; as in Veratrum album.
4. C. quintuplex; as in Aquilegia vulgaris, and Nigella.

5. C. multiplez; as in Sempervivum tectorum. From the substance, a capsule is called,

1. Membranaceous; as in Datura stramonium.

2. Corticated, the external fungous membrane re-

ceding from the capsule; as in Ricinus communis.

3. Woody, very hard, yet splitting; as in Hura crepitans

4. Baccated, when the seed is surrounded by a pulp;

as Evonymus europeus, and Samyda.
5. Spurious, if the calyx, capsule-like, surrounding the seed, splits; as in Fagus sylvatica.
The number of seeds contained in the capsule, given

rise to the following distinctions.

Capsula monosperma, one-seeded; as in Gom-phrenia, Herniaria, and Salsola.

2. C. disperma, two-seeded; as in Hebenstratia,

and Buffonia.

3. C. Trisperma, three-seeded; as in Glaux, and Hudsonia.

4. C. polysperma, many-seeded; as in Papaver somniferum.

CAPSULA ATRABILARIS. See Renal Glands.

CAPSULA RENALIS. See Renal Glands.
CA'PSULAR. (Capsularis; from capsa, a bag.)
Surrounding a part, like a bag: applied to a ligament which surrounds every moveable articulation, and contains the synovia like a bag.

CA'PSULE. See Capsula.

Capsule of Glisson. Capsula Glissonii. Vagina porta; Vagina Glissonii. A strong tunic, formed of cellular texture, which accompanies the vena porta, and its most minute ramifications, throughout the whole liver.

(From καμπτω, to bend.) A contor-CA'PULUM.

tion of the eyelids, or other parts

CA'PUR. (Arabian.) Camphire. CA'PUT. (Caput, itis, neut.; fr CA'PUR. (Arabian.) Camphire.
CA'PUT. (Caput, itis. neut.; from capio, to take; because from it, according to Varro, the senses take their origin.) 1. The head, cranium, or skull. It is situated above or upon the trunk, and united to the cervical vertebræ. It is distinguished into skull and face. On the skull are observed vertez, or crown; sinciput, or foreparts; occiput, or hinder part; and the temples. The parts distinguished on the face are well known; as the forehead, nose, eyes, &c. The arteries of the head are branches of the carotids; and the veins empty themselves into the jugulars. See the veins empty themselves into the jugulars. Skull and Face

2. The upper extremity of a bone; as the head of the humerus or femur.

3. The origin of a muscle; as the long head of the biceps.

4. A protuberance like the head of any thing; as caput gallinaginis.

5. The beginning of a part; as caput cœci.

6. The remains of any thing after its destruction by fire, or other means: hence caput mortuum, or ashes.

Caput Galbinagins. Verumentanum. A cuta-neous eminence in the urethra of men, before the neck of the bladder, somewhat like the head of a woodcock in miniature, around which the seminal ducts, and the

ducts of the prostate gland, open.

CAPUT MORTUUM. A fanciful term, much used by the old chemists, but now entirely rejected. noted the fixed residue of operations. As the As the earlier chemists did not examine these, they did not find any inconvenience in one general term to denote them: but the most slender acquaintance with modern chemistry must show, that it is utterly impracticable to denote, by one general term, all the various matters that remain fixed in certain degrees of heat. The term is obsolete, but spoken of fancifully.

CAPUT OBSTIPUM. The wry neck. Mostly a spas-

modic complaint.

(A barbar sus word, from caput, the to purge.) Medicines which, by Caput purgia. (A barbar us word, from caput, the head, and purgo, to purge.) Medicines which, by causing a defluxion from the nose, purge, as it were, CAPYRI'DION. (From καπυρος, burnt.) Capyrion.

A medicated cake, much baked.

CAPY RION. See Capyridion.

CA'RABUS. A genus of insects of the capyrion of the capyridion.

CAPYRION. See Capyriaton.

CA'RABUS. A genus of insects of the beetle kind.

Two species, the chrysocephalus and ferrugineus, have been recommended for the toothache. They must be pressed between the fingers, and then rubbed on the gum and tooth affected.

CAROCO'SMOS. A name of the sour mare's milk, so much admired by the Tartars.

CARAGUA'TA. The aloe of Brazil.

CARA'NNA. (Spanish.) Caragna. Caranna

A concrete resinous juice, that tree, of which we have no partise brought from New Spain and dissolves easily in water. When heated it fuses, and dissolves easily in water. When heated it fuses, and dissolves easily in water. When heated it fuses, and is decomposed with very powerful explosion, producing a vivid yellow flame: 100 parts lose at 2120 F. 125 parts of water; 100 parts of the anhydrous salt contain, 75.72 acid, and 24.28 baryta.

**Carbazotate of Lime obtained like the salt of baryta, forms flattened, quadrangular prisms, very soluble in water, and detonating like the salt of potassa.

Carbazotate of Maynesia forms very long indistinct. gummi. Bresilis. A concrete resinous julce, tha exudes from a large tree, of which we have no particular account. It is brought from New Spain and America, in little masses, rolled up in leaves of flags; externally and internally it is of a brownish colour, variegated with irregular white streaks. When fresh, it is soft and tenacious; but becomes dry and friable by keeping. Pure caranna has an agreeable aromatic smell, especially when heated, and a bitterish slightly pungent taste. It was formerly employed as an ingredient in vulnerary balsams, strengthening, discutient, and suppurating plasters; but its scarcity has CARAWAY. See Co

CARAWAY. See Carum.
CA'RBASUS. Kapbagos. Scribonius Largus uses
this word for lint.

this word for fint.

["CARBAZOTIC ACID. By the action of nitric acid upon indigo, a substance is obtained in yellow brilliant crystalline plates, which exhibits acid properties, and has been called by Dr. Liebig, carbazotic acid, a name derived from its composition, which is as follows:

Azote,16.167 or 3 — Oxygen,48.790 or 15 —

To obtain carbazotic acid, the following process has

To obtain carbazotic acid, the following process has been given by Dr. Liebig:

A portion of the best indigo is to be broken into small fragments, and moderately heated with eight or ten times its weight of nitric acid, of moderate strength. It will dissolve, evolving nitrous vapours and swelling up in the vessel; after the scum has fallen, the liquid is to be boiled, and nitric acid is added as long as any red vapours are disenguged. When the liquid has become cold, a large quantity of semi-transparent yellow crystals will be formed, and if the operation has been well conducted, no artificial tannin or resin will be obtained. The crystals are to be washed with cold water, and then boiled in water sufficient to dissolve them. If any oily drops of tannin form on the surface of the solution, they must be careform on the surface of the solution, they must be carefully removed by touching them with filtering paper. Then filtering the fluid, and allowing it to cool, yellow brilliant crystalline plates will be obtained, which will not lose their lustre by washing. To obtain the substance perfectly pure, the crystals must be redissolved in boiling water, and neutralized by carbonate of potassa. Upon cooling, a salt of potassa will crystallize, which should be purified by repeated crystallizations. When the substance is heated, it fuses, and is volatifized without decomposition; when subjected to a strong heat, it inflames without explosion, its vaccure.

strong heat, it inflames without explosion, its vapours burning with a yellow fiame, and a carbonaccous residue remaining. It is but little soluble in cold water, due remaining. It is but little soluble in cold water, but much more so in boiling water; the solution has a bright yellow colour, reddens litmus, has an extremely bitter taste, and acts like a strong acid on metallic oxides, dissolving them, and forming peculiar crystal-lizable salts. Ether and alkohol dissolve it readily. Carbazotic acid combines with bases, and forms

(Of which the following salts called carbazotates."

have been determined :)

Carbazotate of Potassa, crystallizes in long, yellow, semi-transparent, and very brilliant needles; it dissolves in 260 parts of water at 599 Fah. Strong acids decompose it. When a little is gradually heated in a glass tube, it first fuses, and then suddenly explodes, breaking the tube to atoms; traces of charcoal are observed on the fragments. The slight solubility of this salt supplies an easy method of testing and separating potassa in a fluid. Even the potassa in tincture of litmus may be discovered by it; on the addition of a few drops of carbazotic acid dissolved in alkohol, to infusion of litmus, crystals of the salt gradually separate. The salt contains no prater of annually separate. rate. The salt contains no water of crystallization.

Its composition is potassa 16.21, acid 83.79.

Carbazotate of Soda crystallizes in fine silky yellow needles, having the general properties of the salt of potassa, but soluble in from 20 to 24 parts of water at 59° F.

Carbazotate of Ammonia forms very long, flattened, brilliant, yellow crystals, very soluble in water. Heated carefully in a glass tube, it fuses, and is volatilized without decomposition; heated suddenly, it inflames without explosion, and leaves much carbonaceous residue.

Carbazotate of Baryta, obtained by heating carbo-nate of baryta, and carbazotic acid with water, crys-

Carbazotate of Magnesia forms very long indistinct needles, of a clear yellow colour, is very soluble and

detones violently.

Carbazotate of Copper, prepared by decomposing sulphate of copper by carbazotate of baryta: it crystallizes with difficulty, the crystals being of a fine green colour: it is deliquescent; when heated it is decomposed without explosion.

Carbazotate of Silver. Carbazotic acid readily dis-solves oxide of silver, when heated with it and water and the solution, gradually evaporated, yields starry groups of fine accular crystals of the colour and lustre of gold; the salt dissolves readily in water; when heated to a certain degree; it does not detonate, but fuses like gunpowder.

Proto-carbazotate of Mercury, obtained in small yellow triangular crystals, by mixing boiling solutions of the carbazotate of potassa or soda, and protonitrate of mercury. It requires more than 1200 parts of water for its solution; it consists of 53,79 acid, and

46.21 protoxide of mercury per cent.

Carbazotate of Lead may be formed by decomposing a salt of lead by carbazotate of potassa or soda: it is a yellow powder, but slightly soluble, and detonating by heat.

All these salts detonate much more powerfully when All these saits detonate much more powerfully when heated in close vessels, than when heated in the air, and what is remarkable, those bases yielding oxygen most readily are those which explode with least force."—From Webster, as taken from Ann. de Chim. xxv. 72, and Quart. Jour. N. S. iii. A.]

CA'RBO. (Charbah, Hebrew, burnt or dried.) Coal.

1. In medicine and chemistry, it is commonly understood to mean chargoal, and receives its name from

derstood to mean charcoal, and receives its name from

its mode of preparation, which is by burning pieces of light wood into a dry, black coal.

2. A carbuncle. See Anthrax.

CARBO LIGNA. Charcoal. As an external application, powdered charcoal has been recommended in the cure of gangrene, from external causes, and all descriptions of feetid ulcers. Meat which has acquired a mawkish or even putrid smell, is found to be rendered perfectly sweet, by rubbing it with powdered

charcoal. It is also used as tooth-powder.

CA'RBON. (From carbo, coal.) Chemists apply this term to the diamond, and what is commonly called charcoal. The diamond is the purest form of it.

1. When vegetable matter, particularly the more solid, as wood, is exposed to heat in close vessels, the volatile parts fly off, and leave behind a black porous substance, which is charcoal. If this be suffered to undergo combustion in contact with oxygen, or with atmospheric air, much the greater part of it will com-bine with the oxygen, and escape in the form of gas; leaving about a two-hundredth part, which consists chiefly of different saline and metallic substances.

This pure inflammable part of the charcoal is what is commonly called carbon; and if the gas be received into proper vessels, the carbon will be found to have been converted by the oxygen into an acid, called the carbonic. See Carbonic acid.

From the circumstance, that inflammable sub-stances refract light in a ratio greater than that of their densities. Newton inferred, that the diamond was in flammable. The quantity of the inflammable part of charcoal, requisite to form a hundred parts of carbonic charcoal, requisite to form a hilhdred parts of carbonic acid, was calculated by Lavoisier to be twenty-eight parts. From a careful experiment of Mr. Tennant, 27.6 parts of diamond, and 72.4 of oxygen, formed 100 of carbonic acid; and hence he inferred the identity of diamond and the inflammable part of charcoal.

Well-burned charcoal is a conductor of electricity, though wood simply deprived of its moisture by baking is a non-conductor; but it is a very bad conductor of caloric, a property of considerable use on many occasions, as in lining crucibles.

It is insoluble in water, and hence the utility of charring the surface of wood exposed to that liquid, in

order to preserve it, a circumstance not unknown to the ancients. This preparation of timber has been proposed as an effectual preventive of what is commonly called the dry rot. It has an attraction, however, for a certain portion of water, which it retains very forcibly. Heated red-hot, or nearly so, it decomposes water; forming with its oxygen carbonic acid, or carbonic oxide, according to the quantity present; and with the hydrogen a gaseous carburet, called carburetted hydrogen, or heavy inflammable air.

Charcoal is infusible by any heat. If exposed to a very high temperature in close vessels, it loses little or nothing of its weight, but shrinks, becomes more com-

nothing of its weight, but shrinks, becomes more com-

pact, and acquires a deeper black colour.

Recently prepared charcoal has a remarkable property of absorbing different gases, and condensing them in its pores, without any alteration of their pro-

perties or its own.

Very light charcoal, such as that of cork, absorbs scarcely any air; while the pit-coal of Rastiberg, sp. gr. 1.326, absorbs ten times and a half its volume. The absorption was always completed in 24 hours. This absorption was always completed in 24 hours. This curious faculty, which is common to all porous bodies, resembles the action of capillary tubes on liquids. When a piece of charcoal, charged with one gas, is transferred into another, it absorbs some of it, and parts with a portion of that first condensed. In the experiments of Messrs. Allen and Pepys, charcoal was found to imbibe from the atmosphere in a day about one-eighth of its weight in water. For a general view one-eighth of its weight in water. For a general view

of absorption, see Gas

When oxygen is condensed by charcoal, carbonic acid is observed to form at the end of several months. But the most remarkable property displayed by charcoals impregnated with gas, is that with sulphuretted hydrogen when exposed to the air or oxygen gas. The sulphuretted hydrogen is speedily destroyed, and water and sulphur result, with the disengagement of considerable heat. Hydrogen alone has no such effects. When charcoal was exposed by Sir Humphrey Davy to intense ignition in vacuo, and in condensed azot, by means of Mr. Children's magnificent voltaic battery, it slowly volatilized, and gave out a little hydrogen. The remaining part was always much harder than before; and in one case so hard as to scratch glass, while its lustre was increased. This fine experiment may be regarded as a near approach to the production of dia-

Charcoal has a powerful affinity for oxygen; whence its use in disoxygenating metallic oxides, and restoring their base to its original metallic state, or reviving the the metal. Thus too it decomposes several of the acids, as the phosphoric and sulphuric, from which it abstracts their oxygen, and leaves the phosphorus and sulphur free.

Carbon is capable of combining with sulphur, and With iron it forms steel; and it with hydrogen. unites with copper into a carburet, as observed by Dr.

Priestley.

A singular and important property of charcoal is that of destroying the smell, colour, and taste of various substances : for the first accurate experiments on which we are chiefly indebted to Mr. Lowitz, of Petersburgh, though it had been long before recommended to correct the fætor of foul ulcers, and as an unti-septic. On this account it is certainly the best dentiseptic. On this account it is certainly the best dentifrice. Water that has become putrid by long keeping in wooden casks, is rendered sweet by filtering through charcoal powder, or by agitation with it; particularly if a few drops of sulphuric acid be added. Common vinegar boiled with charcoal powder becomes perfectly limpid. Saline solutions, that are tinged yellow or brown, are rendered colourless in the same way, so as to afford perfectly white crystals. same way, so as to afford perfectly white crystals. The impure carbonate of ammonia obtained from bones, is deprived both of its colour and fætid smell by sublimation with an equal weight of charcoal Malt spirit is freed from its disagreeable flavour by distillation from charcoal; but if too much be vour by distillation from charcoal; but if too much be used, part of the spirit is decomposed. Simple maceration, for eight or ten days, in the proportion of about 1-150th of the weight of the spirit, improves the flavour much. It is necessary that the charcoal be well burned, brought to a red heat before it is used, and used as soon as may be, or at least be carefully excluded from the air. The proper proportion too should be ascertained by experiment on a small scale. excluded from the air. The proper proportion too should be ascertained by experiment on a small scale. | gen gas. | CA'RBONIC ACID. Acidum carbonicum. | air; Carbonaceous acid; Calcareous acid;

The charcoal may be used repeatedly, by exposing it for some time to a red heat before it is again employed.

Charcoal is used on particular occasions as fuel, on account of its giving a strong and steady heat without smoke. It is employed to convert iron into steel by cementation. It enters into the composition of gunpowder. In its finer states, as in ivory-black, lamp-black, &c. it forms the basis of black paints, Indian ink, and printers' ink.

The purest carbon for chemical purposes is obtained by strongly igniting lamp-black in a covered crucible. This yields, like the diamond, unmixed carbonic acid

by combustion in oxygen.

Carbon unites with all the common simple combustibles, and with azot, forming a series of most impor-tant compounds. With sulphur it forms a curious limpid liquid, called carburet of sulphur, or sulphuret of carbon. With phosphorus it forms a species of compound, whose properties are imperfectly ascer-tained. It unites with hydrogen in two definite proportions, constituting subcarburetted and carburetted hydrogen gases. With azot it forms prussic gas, the cyanogen of Gay Lussac. Steel and plumbago are two different compounds of carbon with iron. In black chalk we find this combustible intimately associated with either and plumbago. ciated with silica and alumina. The primitive com-bining proportion, or prime equivalent of carbon, is 0.75 on the oxygen scale.

2. Carbon mineral. This is of a gray blackish co-It is charcoal with various proportions of earth and iron, without bitumen. It has a silky lustre, and the fibrous texture of wood. It is found in small quantities, stratified with brown coal, slate coal, and

pitch coal

Carbon, gaseous oxide of. Gaseous oxide of carbon was first described by Dr. Priestley, who mistook it for a hydrocarbonate. With the true nature of it, we have been only lately acquainted. It was first proved to be a peculiar gas, by Mr. Cruikshank, of Woolwich, who made it known to us as such, in April, 1801, through the medium of Nicholson's Journal for that month. Several additional properties of this gas were soon afterward noticed by Desormes, Clement, and others. Gaseous oxide of carbon forms an intermediate substance between the pure hydrocarbonates and carbonic acid gas; but not being possessed of acid properties, Mr. Cruikshank called it, conformably to the rules of the chemical nomenclature, gaseous oxide of carbon, for it consists of oxygen and carbon rendered gaseous by caloric. See Carbonic oxide. Carbonaceous acid. See Carbonic acid.

CARBO'NAS. (Carbonas, atis. m.; from carbonic acid being one of its constituents.) A carbonate. A salt formed by the union of carbonic acid with a salifiable basis. The carbonates employed in medicine

Carbonic acid is dilated by heat, but not otherwise

acid. "This acid, being a compound of carbon and oxygen, may be formed by burning charcoal; but as it exists in great abundance ready formed, it is not necessary to have recourse to this expedient. All that is necessary is to pour sulphuric acid, diluted with five or six times its weight of water, on common chalk, which is a compound of carbonic acid and lime. An effervescence ensues; carbonic acid is evolved in the state of gas, and may be received in the usual manner.

Carbonic acid abounds in great quantities in nature, and appears to be produced in a variety of circumstances. It composes 44-100th of the weight of limestone, marble, calcareous spar, and other natural spe-cimens of calcareous earth, from which it may be extricated, either by the simple application of heat, or by the superior affinity of some other acid; most acids having a stronger action on bodies than this. This last process does not require heat, because fixed air is strongly disposed to assume the elastic state. Water, under the common pressure of the atmosphere, and at a low temperature, absorbs somewhat more than its bulk of fixed air, and then constitutes a weak acid. If the pressure be greater, the absorption is augmented. It is to be observed, likewise, that more gas than water will absorb should be present. Heated water absorbs less; and if water impregnated with this acid be exposed on a brisk fire, the rapid escape of the aërial bubbles affords an appearance as if the water were at bubbles affords an appearance as if the water were at the point of boiling, when the heat is not greater than the hand can bear. Congelation separates it readily and completely from water; but no degree of cold or pressure has yet exhibited this acid in a dense or concentrated state of fluidity.

Carbonic acid gas is much denser than common air, and for this reason occupies the lower parts of such mines or caverns as contain materials which afford it by decomposition. The miners call it choke-damp. The Grotto del Cano, in the kingdom of Naples, has been famous for ages on account of the effects of a stratum of fixed air which covers its bottom. It is a cave or hole in the side of a mountain, near the lake Agnano, measuring not more than eighteen feet from its entrance to the inner extremity; where if a dog or other animal that holds down its head be thrust, it is immediately killed by inhaling this noxious fluid

Carbonic acid gas is emitted in large quantities by bodies in the state of the vinous fermentation, and on account of its great weight, it occupies the apparently empty space or upper part of the vessels in which the empty space or upper part of the vessels in which the fermenting process is going on. A variety of striking experiments may be made in this stratum of elastic fluid. Lighted paper, of a candle dipped into it, is immediately extinguished; and the smoke remaining in the carbonic acid gas renders its surface visible, which may be thrown into waves by agitation like water. If a dish of water be immersed in this gas, and briskly agitated, it soon becomes impregnated, and obtains the pungent taste of Pyrmont water. In consequence of the weight of the carbonic acid gas, it may be lifted out in a pitcher, or bottle, which, if well corked, may be used to convey it to great distances, or it may be drawn out of a vessel by a cock like a liquid. The effects produced by pouring this invisible fluid from one vessel to another, have a very singular appearance: if a candle or small animal be placed in a deep vessel, the former becomes extinct, and the latter expires in a few seconds, after the carbonic acid gas is poured upon them, though the eye is incapable of distinguishing any thing that is poured. If, however, it be poured into a vessel full of air, in the sunshine, its density being so much greater than that of the air, renders it slightly visible by the undulations and streaks it forms in this fluid, as it descends through it.

Carbonic acid reddens infusion of litmus; but the redness vanishes by exposure to the air, as the acid flies off. It has a peculiar sharp taste, which may be perceived over vats in which wine or beer is fermenting, as also in sparkling Champaign, and the brisker kinds of cider. Light passing through it is refracted by it, but does not effect any sensible alteration in it, though it appears, from experiment, that it favours the separation of its principles by other substances. It will not unite with an overdose of oxygen, of which it contains 72 parts in 100, the other 28 being pure carhon. It not only destroys life, but the heart and muscle of animals killed by it lose all their irritability, so as to be insensible to the stimulus of galvanism.

altered by it. It is not acted upon by oxygen, or any of the simple combustibles. Charcoal absorbs it, but gives it out again unchanged, at ordinary temperatures; but when this gaseous acid is made to traverse charcoal ignited in a tube, it is converted into carbonic oxide. Phosphorus is insoluble in carbonic acid gas; but, as already observed, is capable of decomposing it by compound affinity, when assisted by sufficient heat; and Priestley and Cruikshank have shown that iron, zinc, and several other metals, are capable of producing the same effect. If carbonic acid be mixed with sul-phuretted, phosphuretted, or carburetted gas, it renders them less combustible, or destroys their combustibility entirely, but produces no other sensible change. Such mixtures occur in various analyses, and particularly in the products of the decomposition of vegetable and animal substances. The inflammable air of marshes is frequently carburetted hydrogen intimately mixed with carbonic acid gas, and the sulphuretted hydrogen gas obtained from mineral waters is very often mixed Carbonic acid appears from various experiments of

Ingenhuosz to be of considerable utility in promoting vegetation. It is probably decomposed by the organs of plants, its base furnishing part at least of the carbon that is so abundant in the vegetable kingdom, and its oxygen contributing to replenish the atmosphere with that necessary support of life, which is continually diminished by the respiration of animals and other

The most exact experiments on the neutral carbonates concur to prove, that the prime equivalent of carbonic acid is 2.75; and that it consists of one prime of carbon=0.75+2.0 oxygen.

Water absorbs about its volume of this acid gas, and

thereby acquires a specific gravity of 1,0015. On freezing it, the gas is as completely expelled as by boiling. By artificial pressure with forcing pumps, water may be made to absorb two or three times its bulk of carbonic acid. When there is also added a little potassa or soda, it becomes the aërated or carbonic allo little potassa. nated alkaline water, a pleasant beverage, and a not inactive remedy in several complaints, particularly dyspepsia, hiccup, and disorders of the kidneys. Alkohol condenses twice its volume of carbonic acid. The most beautiful analytical experiment with carbonic acid, is the combustion of potassium in it, the

formation of potassa, and the deposition of charcoal.

In point of affinity for the earths and alkalies, carbonic acid stands apparently low in the scale. Before its true nature was known, its compounds with them were not considered as salts, but as the earths and alkalies themselves, only distinguished by the names of mild, or effervescent, from their qualities of effer-

vescing with acids, and wanting causticity.

The carbonates are characterized by effervescing with almost all the acids, even the acctic, when they evolve their gaseous acid, which, passed into lime water by a tube, deprives it of its taste, and converts it into chalk and pure water.

The carbonate of barytes, found native in Cumber-land, by Dr. Withering. From this circumstance it has been termed Witherite. It has been likewise

has been termed Witherite. It has been likewise called aërated heavy spar, aërated barosclenite, aërated heavy earth or barytes, barolite, &c.

Carbonate of strontian, found native in Scotland, at Strontian in Argylishire, and at Leadhills.

Carbonate of lime exists in great abundance in nature, variously mixed with other bodies, under the names of marble, chalk, limostone, stalactites, &c. in which it is of more important and extensive use than appropriate of the salls, except perhaps the muriate of any other of the salts, except perhaps the muriate of

The carbonate, or rather sub-carbonate of potassa, was long known by the name of vegetable alkali. It was also called fixed nitre, salt of tartar, salt of wormwood, &c. according to the different modes in which it was procured; and was supposed to retain something of the virtues of the substance from which it was extracted. This error has been sometime ex-ploded, but the knowledge of its true nature is of more

As water at the usual temperature of the air dissolves rather more than its weight of this salt, we have thus a ready mode of detecting its adulterations in general; and as it is often of consequence to know how

much alkali a particular specimen contains, this may

much alkan a particular specimen contains, this may be ascertained by the quantity of sulphuric acid it will saturate. This salt is deliquescent. It consists of 6 potassa +2.75 carbonic acid=8.75.

The bi-carbonate of potassa crystallizes in square prisms, the apices of which are quadrangular pyramids. It has a urinous but not caustic taste; changes the strength of violets are not build a water disaster. mids. It has a urinous but not caustic taste; changes the syrup of violets green: boiling water dissolves five-sixths of its weight, and cold water one-fourth; alkohol, even when hot, will not dissolve more than 1-1200th. Its specific gravity is 2.012. When it is very pure and well crystallized it efforesces on exposure to a dry atmosphere, though it was formerly considered as deliquescent. It was thought that the common salt of tartar of the shops was a compound of this carbonate and pure potassa; the latter of which, being very deliquescent, attracts the moisture of the air till the whole is dissolved. From its smooth feel, and the the whole is dissolved. From its smooth feel, and the manner in which it was prepared, the old chemists

called this solution oil of tartar per deliquium.

The bi-carbonate of potassa melts with a gentle heat, loses its water of crystallization, amounting to near, loses its water of crystalization, amounting to 9-100th, and gives out a portion of its carbonic acid; though no degree of heat will expel the whole of the acid. Thus, as the carbonate of potassa is always prepared by incineration of vegetable substances, and lixiviation, it must be in the intermediate state; or that of a carbonate with excess of alkali; and to obtain the true carbonate we must saturate this salt with carbonic acid, which is best done by passing the acid in the state of gas through a solution of the salt in twice its weight of water; or, if we want the potassa pure, we must have recourse to lime, to separate that portion of acid which fire will not expel.

The bi-carbonate, usually called super-carbonate by the apothecaries, consists of 2 primes of carbonic acid =5.500, 1 of potassa=6, and 1 of water=1.125, in all 12.625.

12.625.

The carbonate of soda has likewise been long known, and distinguished from the preceding by the name of mineral alkali. In commerce it is usually name of mineral alkali. In commerce it is usually called barilla, or soda; in which state, however, it always contains a mixture of earthy bodies, and usually common salt. It may be purified by dissolving it in a small portion of water, filtering the solution, evaporating at a low heat, and skimming off the crystals of muriate of soda as they form on its surface. When these cease to form, the solution may be suffered to cool, and the carbonate of soda will crystallize. cool, and the carbonate of soda will crystallize.

It is found abundantly in nature. In Egypt, where it is collected from the surface of the earth, particularly after the desiccation of temporary lakes, it has been known from time immemorial by the name of in Spain by incinerating the maritime plant of salsola; and it is manufactured in this country, as well as in France, from different species of sea-weeds. It is likewise found in mineral water, and also in some

It crystallizes in irregular or rhomboidal decaedrons, formed by two quadrangular pyramids, truncated very near their bases. Frequently it exhibits only rhomboidal laminæ. Its specific gravity is 1.3591. Its taste is urinous, and slightly acrid, without being caustic. It changes blue vegetable colours to a green. It is soluble in less than its weight of boiling water, and twice its weight of cold. It is one of the most efflorescent salts known, falling completely to powder in no long time. On the application of heat it is soon rendered fluid from the great quantity of its water of crystallization; but is dried by a continuance of the heat, It crystallizes in irregular or rhomboidal decaedrons, lization; but is dried by a continuance of the heat, and then melts. It is somewhat more fusible than the carbonate of potassa, promotes the fusion of earths in a greater degree, and forms a glass of better quality. Like that, it is very tenacious of a certain portion of its carbonic acid. It consists in its dry state of 4 soda, +2.75 acid, =6.75.

But the crystals contain 10 prime proportions of water. They are composed of 22 soda, +15.3 carbonic acid, +62.7 water in 100 parts, or of 1 prime of soda =4.1 of carbonic acid =2.75, and 10 of water

=11.25, in whole 18.

The bi-carbonate of soda may be prepared by saturating the solution of the preceding salt with carturating the solution of the preceding with a very genbonic acid gas, and then evaporating with a very gen-tle heat to dryness, when a white irregular saline mass is obtained. The salt is not crystallizable. Its

constituents are 4 soda, +5.50 carb. acid, +1.125 water, =10.625; or in 100 parts 37.4 soda, +52 acid, +10.6 water.

The carbonate of magnesia, in a state of imperfect saturation with the acid, has been used in medicine for some time under the simple name of magnesia. It is prepared by precipitation from the sulphate of It is prepared by precipitation from the sulphate of magnesia by means of carbonate of potassa. Equal parts of sulphate of magnesia and carbonate of potassa, each dissolved in its own weight of boiling water, are filtered and mixed together hot; the sulphate of potassa is separated by copious washing with water; and the carbonate of magnesia is then left to drain, and afterward spread thin on paper, and carried to the drying stove. When once dried it will be in friable white cakes, or a fine powder.

To obtain carbonate of magnesia saturated with

To obtain carbonate of magnesia saturated with acid, a solution of sulphate of magnesia may be mixed cold with a solution of carbonate of potassa; and at the expiration of a few hours, as the superflu-ous carbonic acid that held it in solution flies off, the carbonate of magnesia will crystallize in very regular transparent prisms of six equal sides. It may be equally obtained by dissolving magnesia in water impregnated with carbonic acid, and exposing the solu-

tion to the open air.

These crystals soon lose their transparency, and become covered with a white powder. Exposed to the fire in a crucible, they decrepitate slightly, lose their water and acid, fall to powder, and are reduced to one-fourth of the original weight. When the common carbonate is calcined in the grate, it appears as if boiling, from the extrication of carbonic acid; a small portion ascended like a various and is decessived. portion ascends like a vapour, and is deposited in a white powder on the cold bodies with which it comes into contact; and in a dark place, toward the end of the operation, it shines with a bluish phosphoric light. It thus loses half its weight, and the magnesia is left quite pure.

As the magnesia of the shops is sometimes adulte-rated with chalk, this may be detected by the addition of a little sulphuric acid diluted with eight or ten times its weight of water, as this will form with the magnesia a very soluble salt, while the sulphate of lime will remain undissolved. Calcined magnesia should dissolve in this dilute acid without any effer-

vescence.

The crystallized carbonate dissolves in forty-eight times its weight of cold water; the common carbonate requires at least ten times as much, and first forms a paste with a small quantity of the fluid.

The carbonate of ammonia, once vulgarly known by the name of volatile sal ammoniae, and abroad by that of English volatile salt, because it was first prepared in this country, was commonly called mild volatile alkali, before its true nature was known.

When very pure it is in a crystalline form, but seldom very regular. Its crystals are so small, that it is difficult to determine their figure. The taste and smell of this salt are the same with those of pure ammonia, but much weaker. It turns the colour of violets green, and that of tumeric brown. It is soluble in rather more than twice its weight of cold water, and in its own weight of hot water; but a boiling heat volatilizes it. When pure, and thoroughly saturated, it is not perceptibly alterable in the air; but when it has an excess of ammonia, it softens and grows moist. It cannot be doubted however that it is soluble in air. cannot be doubted, however, that it is soluble in air; for if left in an open vessel, it gradually diminishes in weight, and its peculiar smell is diffused to a certain distance. Heat readily sublimes, but does not decom-

It has been prepared by the destructive distillation of animal substances, and some others, in large iron pots, with a fire increased by degrees to a strong redpots, with a fire increased by degrees to a strong red-heat, the aqueous liquor that first comes over being removed, that the salt might not be dissolved in it. Thus we had the salt of hartshorn, salt of soot, essen-tial salt of vipers, &c. If the salt were dissolved in the water, it was called spirit of the substance from which it was obtained. Thus, however, it was much contaminated by a feetid animal oil, from which it re-quired to be subsequently purified, and is much better quired to be subsequently purified, and is much better fabricated by mixing one part of muriate of ammonia and two of carbonate of lime, both as dry as possible, and subliming in an earthen retort.

Sir H. Davy has shown that its component parts

than fifty per cent. of alkali; if at 60°, not more than twenty per cent.

There are three or four definite compounds of carbo-

nic acid and ammonia.

The first is the solid sub-carbonate of the shops. It consists of 55 carbonic acid, 30 ammonia, and 15 was a sub-carbonic acid, 5 ammonia, acid, 5 ammonia, acid, 5 ammonia, acid, 5 ammonia, acid, 5 ammonia. ter; or probably of 3 primes carbonic acid, 5 ammo-nia, and 2 water; in all 14.7 for its equivalent. 2d, Gay Lüssac has shown that when 100 volumes

of ammoniacal gas are mixed with 50 of carbonic acid, the two gases precipitate in a solid salt, which must consist by weight of 56 1-3 acid +43 2-3 alkali, being in the ratio of a prime equivalent of each.

3d, When the pungent sub-carbonate is exposed in powder to the air, it becomes scentless by the evaporation of a definite portion of this ammonia. It is then a compound of about 55 or 56 carbonic acid, 21.5 ammonia, and 22.5 water. It may be represented by 2

primes of acid, 1 of ammonia, and 2 of water, =9.875.

Another compound, it has been supposed, may be prepared by passing carbonic acid through a solution of the sub-carbonate till it be saturated. This, however, may be supposed to yield the same product as the last salt. Lussac infers the neutral carbonate to consist of equal volumes of the two gases, though they will not directly combine in these proportions. This would give 18.1 to 46.5; the very proportions in the scentless salt. For 46.5: 18.1; : 55: 21.42.

It is well known as a stimulant usually put into smelling-bottles, frequently with the addition of some oderiforms of

odoriferous oil.

Fourcroy has found, that an ammoniaco-magnesian carbonate is formed on some occasions. Thus, if car-bonate of ammonia be decomposed by magnesia in the moist way, leaving these two substances in contact with each other in a bottle closely stopped, a complete decomposition will not take place, but a portion of this trisalt will be formed. The same will take place if a solution of carbonate of magnesia in water, impregnated with carbonic acid, be precipitated by pure ammonia; or if ammoniaco-magnesian sulphate, nitrate, or muriate, be precipitated by carbonate of potassa or of soda.

The properties of this triple salt are not much known, but it crystallizes differently from the carbonate of either of its bases, and has its own laws of so-

lubility and decomposition.

The carbonate of glucine is in a white, dull, clotty powder, never dry, but greasy, and soft to the feel. It is not sweet, like the other salts of glucine, but insipid. It is very light, insoluble in water, perfectly unaltera-ble by the air, but very readily decomposed by fire. A saturated solution of carbonate of ammonia takes up a certain portion of this carbonate, and forms with it a

Carbonic acid does not appear to be much disposed to unite with argillaccous earth. Most clays, how-ever, afford a small quantity of this acid by heat. The snowy white substance, resembling chalk, and known by the name of lac luna, is found to consist almost wholly of alumina, saturated with carbonic acid. A saline substance, consisting of two six-sided pyramids, joined at one common base, weighing five or six grains, and of a taste somewhat resembling alum, was produced by leaving an ounce phial of water impregnated with carbonic acid, and a redundancy of alumina, ex-

with carbonic acid, and a redundancy of alumina, exposed to spontaneous evaporation for some months.

Vauquelin has found, that carbonate of zircone may be formed by evaporating muriate of zircone, redissolving it in water, and precipitating by the alkaline carbonate. He also adds, that it very readily combines, so as to form a triple salt, with either of the three alkaline carbonates."—Ure's Chem. Diet.

This gas is much esteemed in the cure of tenhance.

This gas is much esteemed in the cure of typhus fevers, and of irritability and weakness of stomach, producing vomiting. Against the former diseases it is given by administering yest, bottled porter, and the like; and for the latter it is disengaged from the carbonated alkali by lemon juice, in a draught given while effervescing.

CARBONIC OXIDE. Gaseous oxide of carbon.

A gaseous compound of one prime equivalent of carbon.

vary, according to the manner of preparing it. The lower the temperature at which it is formed, the greater the proportion of acid and water. Thus, if formed at the temperature of 300°, it contains more combination of its constituents; for at the temperature of 300°, it contains more ture requisite for effecting a union, the carbon attracts its full dose of oxygen, and thus generates carbonic acid. It may be procured by exposing charcoal to a long continued heat. The last products consist chiefly of carbonic oxide.

To obtain it pure, however, our only plan is to abstract one proportion of oxygen from carbonic acid, either in its gaseous state, or as condensed in the car-

If we subject to a strong heat, in a gun barrel or re tort, a mixture of any dry earthy carbonate, such as chalk, or carbonate of strontites, with metallic filings or charcoal, the combined acid is resolved into the gaseous oxide of carbon. The most convenient mixture is equal parts of dried chalk and iron, or zinc filings

The specific gravity of this gas is stated by Gay Lussac and Thenard, from theoretical considerations, to be 0.96782, though Mr. Cruikshanks's experimental

estimate was 0.9569.

This gas burns with a dark blue flame. Sir H Davy has shown, that though carbonic oxide, in its combustion, produces less heat than other inflammable gases, it may be kindled at a much lower temperature. It inflames in the atmosphere, when brought into contact with an iron wire heated to dull redness, whereas carburetted hydrogen is not inflammable by a similar wire, unless it is heated to whiteness, so as to burn with sparks. It requires, for its combustion, half its volume of oxygen gas, producing one volume of carbonic acid. It is not decomposable by any of the caroonic acid. It is not decomposable by any of the simple combustibles, except potassium and sodium. When potassium is heated in a portion of the gas, potassa is formed with the precipitation of charcoal, and the disengagement of heat and light. Perhaps iron, at a high temperature, would condense the oxygen and carbon by its strong affinity for these substances. Water condenses 1-50th of its bulk of the gas. The above processes are those usually prescribed in our systematic works, for procuring the oxide of carbon. In some of them, a portion of carbonic acid is evolved, which may be withdrawn by washing the gaseous product with weak solution of potassa, or milk of lime. We avoid the chance of this impurity by extricating the gas from a mixture of dry carbon ate of barytes and iron filings, or of oxide of zinc, and previously calcined charcoal. The gaseous product from the first mixture, is pure oxide of carbon. Oxide of iron, and pure barytes, remain in the retort. Carbonic oxide, when respired, is fatal to animal life. Sir H. Davy took three inspirations of it, mixed with about one-fourth of common air; the effect was a temporary loss of sensation, which was succeeded by giddiness, sickness, acute pains in different parts of the body, and extreme debility. Some days clapsed be-fore he entirely recovered. Since then, Mr. Witter of Dublin was struck down in an apoplectic condition, by breathing this gas; but he was speedily restored by the inhalation of oxygen. See an interesting account of this experiment, by Mr. Witter, in the Phil. Mag-

When a mixture of it and chlorine is exposed to John Davy, is formed, to which he gave the name of phosgene gas. It has been called chlorocarbonic acid, though chlorocarbonous acid seems a more appropriate

carbuncle. 1. The name of a gem highly prized by the ancients, probably the alamandine, a va

riety of noble garnet.

2. The name of a disease. See Anthraz.

CARBU'NCULUS. (Diminutive of carbo, a burn ing coal.) A carbuncle. See Anthraz.

CARBURET. Carburctum. A combination of charcoal with any other substance: thus carburetted hydrogen is hydrogen holding carbon in solution; carburetted iron is steel, &c.

CARBURET OF SULPHUR. Sulphuret of carbon Alkohol of sulphur. "This interesting liquid was ori ginally obtained by Lampadius in distilling a mixture CARBONIC OXIDE. Gaseous oxide of carbon. of pulverized pyrites and charcoal in an earthen re tort, and was considered by him as a peculiar compound of oxygen, consisting by weight of 0.75

Desormes first ascertained its true constitution to be carburetted sulphur; and they invented a process of great simplicity, for at once preparing it, and proving its nature. Thoroughly calcined charcoal is to be put into a porcelain tube, that traverses a furnace at a slight angle of inclination. To the higher end of the tube, a retort of glass containing materials. tube, a retort of glass, containing sulphur, is luted; and to the lower end is attached an a lopter tube, which enters into a bottle with two tubulures, half full which enters into a bottle with two tubulures, half full of water, and surrounded with very cold water or ice. From the other aperture of the bottle, a bent tube proceeds into the pneumatic trough. When the porcelain tube is brought into a state of ignition, heat is applied to the sulphur, which subliming into the tube, combines with the charcoal, forming the liquid carburet.

The carburet of sulphur dissolves camphor. It does not unite with water; but very readily with alkohol and wther. With chloride of azot it forms a nondetonating compound. The waters of potassa, bary-tes, and lime, slowly decompose it, with the evolution of carbonic acid gas. It combines with ammonia and lime, forming carbo-sulphurets. The carburet, satulime, forming carbo-sulphurets. The carburet, saturated with ammoniacal gas, forms a yellow pulverulent substance, which sublimes unaltered in close vessels, but is so deliquescent that it cannot be passed from one vessel to another without absorbing moisture. When heated in that state, crystals of hydrosulphuret of ammonia form. The compound with lime is made by heating some quicklime in a tube, and causing the vapour of carburet to pass through it. The time becomes incandescent at the instant of combaniation.

When the carburet is left for some weeks in contract

When the carburet is left for some weeks in contact with nitro-muriatic acid, it is converted into a subwith intro-mariane acid, it is converted into a sun-stance having very much the appearance and physical properties of camphor; being soluble in alkohol and oil, and insoluble in water. This substance is, ac-cording to Berzelius, a triple acid, composed of two atoms of muriatic acid, one atom of sulphurous acid, and one atom of carbonic acid. He calls it, muriatico-

sulphurous-carbonic acid.

When potassium is heated in the vapour of the carwhen potassium is heated in the vapour of the car-buret, it burns with a reddish flame, and a black film appears on the surface. On admitting water, a green-ish solution of sulphuret of potassa is obtained, con-taining a mixture of charcoal. From its vapour pass-ing through ignited muriate of silver, without occa-sioning any reduction of the metal, it is demonstrated that the grahurat is destinated by that this carburet is destitute of hydrogen.

When the compound of potassa, water, and carbu-ret of sulphur, is added to metallic solutions, precipi-tates of a peculiar kind, called carbo-sulphurets, are

Carburet of sulphur was found by Dr. Brewster to exceed all fluid bodies in refractive power, and even the solids, flint-glass, topaz, and tourmaline. In dis-persive power it exceeds every fluid substance except oil of cassia, holding an intermediate place between phosphorus and balsam of Tolu."—Ure.

CARBURETTED HYDROGEN GAS. Carbonated hydrogen gas; Heavy inflammable air; Hydro-carbonate. Olejant gas. Hydroguret of carbon. "Of this compound gas we have two species, differing in the proportions of the constituents. The first, consisting of 1 prime equivalent of each, is carburetted hydrogen; the second, of 1 prime of carbon, and 2 of hydrogen, is subcarburetted hydrogen.

 Curburetted hydrogen, the percarburetted of the French chemists, is, according to Mr. Brande, the only definite compound of these two elements. To prepare it, we mix, in a glass retort, 1 part of alkohol and 4 of sulphuric acid, and expose the retort to a moderate heat. The gas is usually received over water; though De Saussure states, that this liquid absorbs more than De Saussure statés, that this liquid absorbs more than 1-7th of its volume of the gas. It is destructive of animal life. Its specific gravity is 0.978, according to Saussure. 100 cubic inches weigh 28.80 gr. It possesses all the mechanical properties of air. It is invisible, and void of taste and smell, when it has been washed from a little athereous vapour. The effect of heat on this gas is curious. When passed through a porcelain tube, heated to a cherry-red, it lets fall a portion of charcoal, and nearly doubles its volume. At a higher temperature it deposites more charcoal, and augments in bulk; till finally, at the greatest heat to which we can expose it, it lets fall almost the whole of its carbon, and assumes a volume 3½ times greater than it had at first. These remarkable results, observed it had at first.

with great care, have induced the illustrious Ferthollet to conclude, with much plausibility, that hydrogen and carbon combine in many successive propostions. The transmission of a series of electric sparks through this gas, produces a similar effect with that of simple

Carburetted hydrogen burns with a splendid white une. When mixed with three times its bulk of exygen, and kindled by a taper or the electric spark, it ex-

plodes with great violence.

When this gas is mixed with its own bulk of thlowhen this gas is mixed with its own bulk of chlorine, the gaseous mixture is condensed over water into a peculiar oily-looking compound. Hence this carburetted hydrogen was called by its discoverers, the as sociated Dutch chemists, olefant gas. Robiquet and Colin formed this liquid in considerable quantities, by making two currents of its constituent gases meet in a class clobe. The olefant gas should be in rather larger. glass globe. The olefiant gas should be in rather larger glass globe. The olefiant gas should be in rather larger quantity than the chlorine, otherwise the liquid becomes of a green colour, and acquires acid properties. When it is washed with water, and distilled off dry muriate of lime, it may be regarded as pure. It is then a limpid colourless essence of a pleasant flavour, and a sharp, sweet, and not disagreeable taste. At 45° its specific gravity is 2.2201. Dr. Thompson calls this fluid chloric ather, and it may with propriety, Mr. Brande thinks, be termed hydro-chloride of carbon.

Olefiant gas is elegantly analyzed by heating sulphur in it over mercury. One cubic inch of it, with 2 grains

Olefant gas is elegantly analyzed by heating sulphur in it over mercury. One cubic inch of it, with 2 grains of sulphur, yields 2 cubic inches of sulphuretted hydrogen, and charcoal is deposited. Now we know that the latter gas contains just its own volume of hydrogen.

2. Subcarburetted hydrogen. This gas is supposed to be procured in a state of definite composition, from the mud or stagnant pools or ditches. We have only to fill a wide-mouthed goblet with water, and inverting it in the ditch-water, stir the bottom with a stick. Gas rises into the goblet.

Gas rises into the goblet.

The fire-damp of mines is a similar gas to that of ditches. There is in both cases an admixture of car-bonic acid, which lime or potassa-water will remove. A proportion of air is also present, the quantity of which can be ascertained by analysis. By igniting acetate of potassa in a gun-barrel, an analogous species of gas is obtained.

Subcarburetted hydrogen is destitute of colour, taste, and smell. It burns with a yellow flame, like that of

a candle.

As the gas of ditches and the choke-damp of mines is evidently derived from the action of water on de-caying vegetable or carbonaceous matter, we can understand that a similar product will be obtained by passing water over ignited charcoal, or by heating moistened charcoal or vegetable matter in retorts. The gases are here, however, a somewhat complex mix-ture, as well as what we obtain by igniting pit coal and wood in iron retorts. The combustion of subcar-buretted hydrogen with common air takes place only when they are mixed in certain proportions. If from 6 to 12 parts of air be mixed with one of carburetted hydrogen, we have explosive mixtures. Proportions beyond these limits will not explode. In like manner, from 1 to 24 of oxygen must be mixed with one of the combustible gas, otherwise we have no explosion. Sir H. Davy says, that this gas has a disagreeable empyreumatic smell, and that water absorbs 1-30th of its volume of it."—Ure.
CA'RCARUS. (From καρκαιρω, to resound.) Carcaros. A fever in which the patient has a continual horror and trembling, with an unceasing sounding in his care.

his ears.

CA'RCAX. (From καρα, a head.) A species of poppy, with a very large head.

CA'RCER. A remedy, according to Paracelsus, for restraining the motions of body, the extravagant and libidinous conversation in some disorders; as in Chorea Sancti Viti, &c.

CARCHE'SIUS. (Καρχησιος. The openings at the top of a ship's mast through which the rope passes.) A name of some bandages noticed by Galen, and described by Oribasius.

CARCINO'MA. (Carcinoma, atis. n. From Kap-KIPOS, a cancer.) See Cancer. CARCINUS. (Kapkivos, a cancer.) Carcinos. See

CARDAMA'NTICA. (From καρδαμον, the nasturtium) A species of sciatica cresses.

by Gilen.

CARDAMI'NE. (Cardamine es. f.; from καρότα, theheart; because it acts as a cordial and strengthener, or from its having the taste of cardamum, that is, nasturtium, or cress.) Cuckoo-flower. 1. The name of a genus of plants in the Linnean system. Class, Tetredynamia; Order, Siliquosa.
2. The pharmacopeial name of the cuckoo-flower.

See Cardamine pratensis.

CARDAMINE PRATENSIS. The systematic name of the common ladies' smock, or cuckoo-flower, called the common ladies' smock, or cuckoo-flower, called cariamine in the pharmacopæias. Cardamantica; Nasturtium; aquaticum; Culi flos; Iberis sophia; Cardamine:—foliis pinnatis, foliolis, radicalibus sub-rotundis, caulinis lanceolatis of Linnæus. The flower has a place in the materia medica, upon the authority of Sir George Baker, who has published five cases, two of Chorea Sancti Viti, one of spasmodic asthma, one of hemiplegia, and a case of spasmodic affections of the lower limbs, wherein the flores cardamines were supposed to have been successfully used. A variety of virtues have been given to this plant, but it does not deserve the attention of practitioners.

CARDAMO'MUM. (From καρδάμον and αμωμον: because it partakes of the nature, and is like both the cardamum and amomum.) The cardamom. See Amomum, Elettaria, and Illicium.

cardamum and amomum.) The cardamom. See Amomum, Elettaria, and Illicium. CARDAMOMUM MAJUS. See Amomum granum para-

CARDAMOMUM MEDIUM. The seeds correspond, in every respect, with the less, except in being twice as long, but no thicker than the Cardamomum minus.

See Elettaria cardamo-CARDAMOMUM MINUS.

CARDAMOMUM SIBERIENSE. See Illicium stella-

CA'RDAMUM. (From καρδια, the heart; because it comforts and strengthens the heart.) The cardamum. See Amomum, Electraria, and Illicium. CA'RDIA. (From κταρ, the heart.) 1. This term was applied by the Greeks to the heart.

2. The superior opening of the stomach. CARDIAC. (Cardiacus; from καρδια, the heart.) A cordial. See Cordial.

CARDIAC. CONFECTIO. See Canfectic gramatics.

CARDIACA CONFECTIO. See Confectio aromatica.
CARDIACA HERBA. So named from the supposed relief it gives in faintings and disorders of the stomach.

The pharmacopæial name of the plant called Mother-The pharmacoporial name of the plant canel atomet wort. See Leonurus cardiaca.

Cardiaca passio. The cardiac passion. Ancient writers frequently mention a disorder under this name, which consists of that oppression and distress which often accompanies fainting.

Cardiacus morbus. A name by which the an-

CARDIACUS MORBUS. A name by which the ancients called the typus fever.

CARDIA'LGIA. (From καρδια, the cardia, and αλγος, pain.) Pain at the stomach. The heartburn. Dr. Cullen ranks it as a symptom of dyspepsia. Heartburn is an uneasy sensation in the stomach, with anxiety, a heat more or less violent, and sometimes attended with oppression, faintness, an inclination to womit, or a plentiful discharge of clear lymph, like saliva. This pain may arise from various and different causes: such as flatus; from sharp humours, either saliva. This pain may arise from various and different causes; such as flatus; from sharp humours, either acid, bilicus, or rancid; from worms gnawing and vellicating the coats of the stomach; from acrid and pungent food, such as spices, aromatics, &c.; as also from rheumatic and gouty humours, or surfeits; from too free a use of tea, or watery fluids relaxing the stomach, &c.; from the natural mucus being abraded, particularly in the upper orifice of the stomach.

Captilists SPUTATORIA. See Pyrosis.

CARDILIGIA SPUTATORIA. See Pyrosis.

CARDILIGIA SPUTATORIA. See Pyrosis.

CARDINE'LECH. (From καρδια, the heart, and moleck, Heb. a governor.) A fictitious term in Dolæus's Encyclopedia, by which he would express a particular active principle in the heart, appointed to what we call the vital functions.

CARDIMO'NA. Pain at the stomach.
Cardinal flowers. See Lobelia.
CARDINAME'NTUM. (From cardo, a hinge.) An articulation like a hinge.
CARDIO GMUS. (From καρδιωσσω, to have a pain in the stomach.) 1. A distressing pain at the pracordia or stomach.

CALDAMELE'UM. A modicine of no note, mentioned | 2. An aneurism in or near the heart, which occa-

sions pain in the præcordia.

3. A variety of the Ezangia ancurisma of Good's nosological arrangement.

CARDIO NCHUS. (From καρδια, the heart, and ογκος, a tumour.) An ancurism in the heart, or in the neart near the heart.

aorta near the heart.

CARDIOTRO'TUS. (From καρδια, the heart, and τετρωσκω, to wound.) One who hath a wound in his

heart.

CARDITIS. (From kapóla, the heart.) Empresma carditis of Good. Inflammation of the heart. It is a genus of disease arranged by Cullen in the class Pyrexia, and order Phlegmasia. It is known by pyrexia, pain in the region of the heart, great anxiety, difficulty of breathing, cough, irregular pulse, palpitation, and fainting, and the other symptoms of inflammation. The treatment of carditis is, in a great measure, similar to that of pneumonia. It is necessary to take blood freely, as well generally as locally, and apply a blister near the part. Purging may be carried to a greater extent than in pneumonia; and the use of digitalis is more important, to lessen the irritability of the heart. It is equally desirable to promote diaphoresis, but expectoration is not so much to be looked for, unless indeed, as very often happens, the inflammation should have extended, in some degree, to the lungs. lungs

CARDITE. See organic relics.
CA'RDO. A hinge. 1. The articulation called

Ginglymus.

2. The second vertebra of the neck.

CARDO'NIUM. Wine medicated with herbs.—Para-

CARDOPA'TIUM. The low carline thistle. Most pro-bably the Carlina acaulis of Linnaus, said to be diaphoretic

phoretic.

CA'RDUUS. (À carere, quasi aptus carenda lana, being fit to tease wool; or from κειρω, to abrade; so named from its roughness, which abrades and tears whatever it meets with.) The thistle or teasel. The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Polygamia æqualis.

CARDUUS ACANTHUS. The bear's breech.

CARDUUS ALTILIS. The artichoke.

CARDUUS ALTILIS. The way-thistle. See Serratula arrensis.

tula arvensis.

CARDUUS LACTEUS. See Carduus marianus
CARDUUS MARIANUS. The systematic name of the

CARDUUS MARIANUS. The systematic name of the officinal Carduas maria. Common milk-thistle, or Lady's thistle. Carduus: foliis amplexicaulibus, hastato-pinnatifidis, spinosis; calycibus aphyllis; spinis caliculatis, duplicato-spinosis, of Linnæus. The seeds of this plant, and the herb, have been employed medicinally. The former contain a bitter oil, and are recommended as relaxants. The juice of the latter is said to be salutary in dropsies, in the dose of four ounces; and, according to Miller, to be efficacious against pungent pains. The leaves when young surpass, when boiled, the finest cabbage, and in that state are diuretic.

CARDUUS SATIVUS. The articloke.

CARDUUS SATIVUS. The artichoke. CARDUUS SOLSTITIALIS. The Calcitrapa officinalis of Linnæus.

CARDUUS TOMENTOSUS. The woolly thistle. See

One pordium acanthium.

CAREBA'RIA. (From καρη, the head, and βαρος, weight.) A painful and uneasy heaviness of the head.

CARE'NUM. (From καρη, the head.) Galen uses this word for the head.

this word for the head.

CARENUM VINUM. Strong wine.

CAREUM. (From Caria, the country whence they were brought.) The caraway.

CA'REX. (Carez, icis, fam. from careo, not quia viribus careat, but because, from its roughness, it is fit ad carendum, to card, tease, or pull.) Sedge. The name of a genus of plants in the Linnaan system Class, Monacia; Order, Triandria.

CAREX ARENARIA. The systematic name of the officinal sarsaparilla germanica, which grows plentifully on the sea coast. The root has been found serviceable in some mucal affections of the trachea, in rheumatic

in some mucal affections of the trachea, in rheumatic pains, and gouty affections. These roots, and those of

the carex hirta, are mixed with the true sarsaparilla, which they much resemble.

CA'RICA. (From Caria, the place where they were cultivated.) The fig. See Ficus carica.

CARICA PATAYA. Papaw-tree. This is a native of both Indies, and the Guinea coast of Africa. When the roundish fruit are nearly ripe, the inhabitants of India boil and eat them with their means a wedo turnies. They have somewhat the flavour of a pomption. India boil and eat them with their meat, as we do turnips. They have somewhat the flavour of a pompion. Previous to boiling, they soak them for some time in salt and water, to extract the corrosive juice, unless the meat they are to be boiled with should be very salt and old, and then this juice being in them, will make them as tender as a chicken. But they mostly pickle the long fruit, and thus they make no bad succedaneum for mango. The buds of the female flowers are gathered, and made into a sweetmeat; and the inhabitants are such good husbands of the produce of this tree, that they boil the shells of the ripe fruit into a repast, and the insides are eaten with sugar in the manner of melons. Every part of the papaw-tree, except the ripe fruit, affords a milky juice, which is used, in the Isle of France, as an effectual remedy for the tape-worm. In Europe, however, whither it has been sent in the concrete state, it has not answered, perhaps from some change it had undergone, or not having been given in a sufficient dose.

A very remarkable circumstance regarding the pa-paw-tree, is the extraction from its juice of a matter exactly resembling the flesh or fibre of animals, and

paw-tree, is the extraction from its juice of a matter exactly resembling the flesh or fibre of animals, and hence called vegetable fibrin.

Caricum. (From Caricus, its inventor.) Carycum. An ointment for cleansing ulcers, composed of hellebore, lead, and cantharides.

CA'RIES. (From carah, Chald.) Gangrena Caries of Good. Rottenness, mortification of the bones [Cooper derives caries from kerow, to abrade. "It is a disease of the bones, supposed to be very analogous to ulceration of the soft parts; and this comparison is one of great antiquity, having been made by Galen. However, by the generality of the ancients, caries was not discriminated from necrosis.

"It was from the surgeons of the eighteenth century that more correct opinions were derived respecting caries. Until this period, writers had done little more than mentioning the complaint, and the methods of treating it. Some new light was thrown upon the subject by J. L. Petit, in his remarks upon exostosis and caries. But, as he only spoke of the disorder as one of the terminations of exostosis, he has not entered far into the consideration of it. The best observations on caries were first made by Dr. A. Monro, primus. This memoir contains the earliest correct ideas of dry caries, or necrosis, which is rightly compared to more tification of the soft parts, and named gangrenous caries, or necrosis, which is rightly compared to mor-tification of the soft parts, and named gangrenous

"The bones, like other parts of the body, are composed of arteries, veins, absorbent vessels, nerves, and a cellular texture; they are endued with vitality; they a cellular texture; they are endued with vitality; they are nourished, they grow, waste, are repaired, and undergo various mutations, according to the age of the individual; and they are subject to diseases analogous to those of the soft parts. To the phosphate of lime, which is more or less distributed in their texture, they owe all their solidity; and, perhaps, it is to the same earthy substance that the difference in their vital properties, and in their diseases, from those of the rest of the body, is to be referred. In fact, this particular organization, and inferior vitality of the bones, are generally supposed to account for the small number, peculiar character, and general slow progress of their diseases,"—Cooper's Surg. Dict. A.]

CARI'MA. The cassada bread.

CARI'NA. The keel of a ship. 1. A name formerly applied to the back bone.

CARI'NA. The keel of a ship. 1. A name formerly applied to the back bone.

2. In botany, the keel, or that part of the petals which compose a papilionaceous flower, consisting of two, united or separate, which embrace the internal or genital organs. See Corolla.

CARINATUS. Keel-shaped; applied to leaves and petals when the back is longitudinally prominent like the keel of a boat; as in the leaf of the Allium carinatum, and the petals of the Allium ampellprasum Carum carui.

CARINTHINE. A subspecies of mineral augite found in Carinthia.

showed it to him, and that, by the use of it, his army was preserved from the plague.) Carline thistle. The name of a genus of plants in the Linnxan system. Class, Syngenesia; Order, Polygamia aqualis. The officinal name of two kinds of plants.

Carlina Acaulis. The systematic name of the chamaleon album. Carlina; Cardopatium. Carline thistle. Star thistle. Carlina—caule unifloro, flore breviore, of Linnxeus. The root of this plant is bitter, and said to possess diaphoretic and anthelmintic virtues. It is also extolled by foreign physicians in the cure of acute, malignant, and chronic disorders, particularly gravel and jaundice.

Carlina gummifera. Carduus pinea; Ixine. Pine thistle. This plant is the Atractylis gummifera of Linnxeus. The root, when wounded, yields a milky, viscous juice, which concretes into tenaceous masses,

viscous juice, which concretes into tenaceous masses, at first whitish, resembling wax, when much handled growing black; it is said to be chewed with the same

views as mastich.

Carline thistle. See Carlina acaulis.

CA'RLO SANCTO RADIX. St. Charles's root, so called by the Spaniards, on account of its great virtues. It is found in Mechoathan, a province in America. Its bark hath an aromatic flavour, with a bitter acrid taste. The root itself consists of slender fibres. The bark is sudorific, and strengthens the gums and stomach

CA'RMEN. (Carmen, inis. neut. A verse; be-cause charms usually consisted of a verse.) A charm;

an amulet.

CARMES. (The Carmelite friars, Fr.) Carmelite water; so named from its inventors; composed of Carmelite

water; so named from its inventors; composed of baum, lemon-peel, &c.

CARMINA'NTIA. See Carminative.

CARMINATIVE. (Carminativus; from carmen, a verse, or charm; because practitioners, in ancient times, ascribed their operation to a charm or enchantment.) That which allays pain and dispels flatulencies of the prima viæ. The principal carminatives are the semina cardamomi, anisi et carui; olea essentialia carui, anisi et jumperi; confectio aromatica; pulvis aromaticus; tinctura cardamomi composita; zingiber; stimulants; tonics; bitters; and astringents.

CARMINE. A red pigment prepared from cochineal.

CARMINIUM. The name given by the French chemists to the colouring matter of cochineal. See Coccus cacti.

Coccus cacti.

CARNABA'DIUM. Caraway-seed.

CA'RNEA COLUMNA. A fleshy pillar or column.

The name of some fleshy fasciculi in the ventricles of the heart. See Heart.

CARNELIAN. A subspecies of calcedony.

CARNICULA. (Diminutive of caro, carnis, flesh.)

A small fleshy substance; applied to the substance which surrounds the gums.

CARNIFO'RMIS. (From caro, flesh, and forma, likeness.) Having the appearance of flesh. It is commonly applied to an abscess, where the flesh surrounding the orifice is hardened, and of a firm consistence.

CARNOSUS. Fleshy; applied to loaves, pods, &c. of a thick pulpy substance; as in the leaves of all those plants called succulent, especially cedum crassula, &c.

cA'RO. CA'RO. (Caro, carnis. fem.) 1. Flesh. The red part or belly of a muscle.

2. The pulp of fruit.

CAROLINA. See Carlina.

CAROMEL. The smell exhaled from sugar at the CARO'RI. The Amomum verum.

CARO'RA. A chemical vessel that resembles a

urinal.

tals when the back is longitudinally prominent like e keel of a boat; as in the leaf of the Allium caritum, and the petals of the Allium ampellprasum caruni.

CAROTTA. See Daucus.

CAROTTD. (From καροω, to cause to sleep; because, if tied with a ligature, the animal becomes comatose, and has the appearance of being asleep.)

CARIOUS. When a part of a bone is deprived of N

CAROTID ARTERY. Arteria carotidea. The carotids are two considerable arteries that proceed, one on The carotids are two considerable arteries that proceed, one on each side of the cervical vertebre, to the head, to supply it with blood. The right carotid does not arise immediately from the arch of the aorta, but is given off from the arteria innominata. The left arises from the arch of the aorta. Each carotid is divided into external and internal, or that portion without and that within the cranium. The external gives off eight branches, to the neck and face, viz. anteriorly, the superior thyroideal, the sublingual, the inferior maxiliary, the external maxillary; posteriorly, the internal maxillary, the occipital, the external auditory, and the temporal. The internal carotid or cerebral artery, gives off four branches within the cavity of the cranigives off four branches within the cavity of the cranium; the anterior cerebral, the posterior, the central

The central artery of the optic nerve, and the internal orbital.

CARO'UM. The caraway-seed.

CA'RPASUS. (So named παρα το καρον ποιησαι: because it makes the person who eats it appear as if he was asleep.) An herb, the juice of which was formerly called opocarpason, opocarpathon, or opocalpason; according to Galen, it resembles myrrh; but is esteemed highly poisonous.

esteemed highly poisonous.

CARPA'THICUM BALSAMUM. See Pinus Cembra CARPENTA'RIA. (From carpentarius, a carpenter; and so named from its virtues in healing cuts and wounds made by a tool.) A vulnerary herb; not properly known what it is, but believed to be the common milfoil or yarrow, the Achillaa millifolium of Linnaus. CARPHA'LEUS. (From καρφω, to exsiccate.) Hippocrates uses this word to mean dry, opposed to

CARPHOLO'GIA. (From $\kappa a \rho \phi o s$, the nap of clothes, and $\lambda \varepsilon_{I'} \omega$, to pluck.) Carpologia. A delirious picking of the bed-clothes, a symptom of great danger in diseases. See Floccilatio.

CA'RPHUS. (From $\kappa a \rho \phi \eta$, a straw.) 1. In Hippocrates it signifies a mote, or any small substance.

A pustule of the smallest kind.
 The herb fenugreek.

3. The herb fenugreek.

CA'RPIA. (From carpo, to pluck, as lint is made from linen cloth.) Lint.

CARPI'SMUS. The wrist.

CARPOBA'LSAMUM. (From καρπος, fruit, and βαλσαμον, balsam.) See Amyris gileadensis.

CARPOLO'GIA. See Carphologia.

CARPOTICA. (Carpoticus; from καρπωσις, fruitio, from καρπως, fructus.) The name of an order of diseases in the class Genetica of Good's Nosology; diseases afflicting the impregnation. It embraces four diseases afflicting the impregnation. It embraces four genera. 1. Paracyesis, morbid pregnancy. 2. Paradynia, morbid labour. 3. Eccyesis, extra uterine fce-

tation. 4. Pseudocyesis, spurious pregnancy.
CA'RPUS. (Καρπος, the wrist.) The wrist, or carpus. It is situated between the forearm and hand.

CARROT. See Daucus carota.

CARROT. See Daucus carota.
Carrot, candy. See Athamanta Cretensis.
Carrot poultice. See Cataplasma dauci.
CA'RTHAMUS. (From καθαιρω, to purge.) 1. The name of a genus of plants in the Linnaran system.
Class, Syngenesia; Order, Polygamia æqualis.
2. The pharmacopaial name of the saffron flower.

See Carthamus tinctorius.

CARTHAMUS TINCTORIUS. The systematic name CARTHAMUS TINCTORIUS. The systematic name of the saffron flower, or bastard saffron, called also Cnicus; Crocus saracenicus; Carthamum officinarum; Carduus sativus. Carthamus—folius ovatis, integris, serrato-aculeatis of Linnæus. The seeds, freed from their shells, have been celebrated as a gentle cathartic, in the dose of one or two drachms. They are also in the dose of one or two drachms. They are also supposed to be diuretic and expectorant; particularly useful in humoral asthma, and similar complaints. The carthamus lanatus is considered in France as a febrifuge and sudorific. The dried flowers are frequently mixed with saffron, to adulterate it. The plant is cultivated in many places on account of its flowers, which are used as a dye.

"In some of the deep reddish, yellow, or orange-coloured flowers, the yellow matter seems to be of the same kind with that of the pure yellow flowers; but the red to be of a different kind from the pure red ones. Watery menstrua take up only the yellow, and leave the red, which may afterward be extracted by alkohol, or by a weak solution of alkali. Such particularly are the saffron-coloured flowers of carthamus.

leave the red, which may afterward be extracted by alkohol, or by a weak solution of alkali. Such particularly are the saffron-coloured flowers of carthamus.

CARTILAGO ARYTENOIDEA. See Carthago cricoidea.

CARTILAGO CRICOIDEA. The cricoid cartilage belongs to the larynx, and is situated between the thyroid

These, after the yellow matter has been extracted by water, are said to give a tincture to ley; from which, on standing at rest for some time, a deep red fecula subsides called safflower, and from the countrid whence it is commonly brought to us, Spanish red and China lake. This pigment impregnates alkohol with beautiful red tincture; but communicates no colour. a beautiful red tincture; but communicates no colour

to water.

Rouge is prepared from carthamus. For this purpose the red colour is extracted by a solution of the subcarbonate of soda, and precipitated by lemon juice previously depurated by standing. This precipitate is dried on earthen plates, mixed with talc, or French chalk, reduced to a powder by means of the leaves of shave-grass, triturated with it till they are both very fine, and then sifted. The fineness of the powder and proportion of the precipitate constitute the difference between the finer and cheaper rouge. It is fikewise suread very thin on saucers, and sold in this state for spread very thin on saucers, and sold in this state for

Carthamus is used for dying silk of a poppy, cherry, rose, or bright orange-red. After the yellow matter is extracted as above, and the cakes opened, it is put into a deal trough, and sprinkled at different times with pearl ashes, or rather soda, well powdered and sifted, in the proportion of six pounds to a hundred, mixing the alkali well as it is put in. The alkali should be saturated with carbonic acid. The carthamus is then put on a cloth in a trough with a grated bottom, placed on a larger trough, and cold water poured on, till the large trough is filled. And this is repeated, with the addition of a little more alkali toward the end, till the carthamus is exhausted and become yellow. Lemon juice is then poured into the bath, till it is turned of a fine cherry colour, and after it is well stirred, the silk is immersed in it. The silk is wrung, drained, and passed through fresh baths, washing and drying after every operation, till it is of a proper colour; when it is brightened in not water, and lemon juice. For a poppy or fire colour a slight annotto ground is first given; but the silk should not be alumed. For a pale carnation a little soap should be put into the bath. All these baths must be used as soon as

the bath. An these baths must be used as ston as they are made; and cold, because heat destroys the colour of the red fecule."

CARTHEUSER, John Frederick, a professor of medicine at Francfort, on the Oder, acquired considerable reputation about the middle of the last century, by several luminous works on botany and pharmacy; especially his "Rudimenta Materiæ Medicæ Rationa-lis," and "De Genericis quibusdam Plantarum Principiis." He had two sons, Frederick Augustus and William, also of the medical profession, and authors

of some less important works.

CARTHUSIA'NUS. (From the monks of that order, who first invented it.) A name of the precipitated

sulphur of antimony.

CARTILAGE. See Cartilago.

CARTILAGINEUS. Cartilaginous. 1. Applied, in anatomy, to parts which naturally, or from disease, have a cartilaginous consistence.

have a cartilaginous consistence.

2. In botany, to leaves which have a hard or horny leaf-edge, as in several species of saxifrage. See Leaf. CARTILA'GO. (Cartilago, inis. feem. Quasi carnilago; from caro, carnis, flesh.) A white elastic, glistening substance, growing to bones, and commonly called gristle. Cartilages are divided, by anatomists, into obducent, which cover the moveable articulations of hones, into articular, which are situated between of bones; inter-articular, which are situated between the articulations, and uniting cartilages, which unite one bone with another. Their use is to facilitate the motions of bones, or to connect them together.

The chemical analysis of cartilage affords one-third the weight of the bones when the selections.

the weight of the bones, when the calcareous salts are removed by digestion in dilute muriatic acid. It re-sembles coagulated albumen. Nitric acid converts it into gelatin. With alkalies it forms an animal soap. Cartilage is the primitive paste, into which the calcareous salts are deposited in the young animal. In the disease rickets, the earthy matter is withdrawn by morbid absorption, and the bones return into the state nearly of flexible cartilage. Hence arise the distor tions characteristic of this disease.

CARTILAGO ANNULARIS. See Cartilago cricoidea.

and arytenoid cartilages and the trachea; it constitutes, as it were, the basis of the many annular cartilages of the trachea.

lages of the trachea.

CARTILAGO ENSIFORMIS. Cartilago xiphoidea. Ensiform cartilage. A cartilage shaped somewhat like a sword or dagger, attached to the lowermost part of the sternum, just at the pit of the stomach.

CARTILAGO SCUTIFORMIS. See Thyroid cartilage.

CARTILAGO THYROIDEA. See Thyroid cartilage.

CARTILAGO XIPHOIDEA. See Cartilago ensiformis.

CA'RUI. (Caruia. Arabian.) The caraway. See

CA'RUM. (Kaoos; so named from Caria, a province of Asia.) The Caraway. 1. The name of a genus of plants in the Linuxan system. Class, Pentandria; Order, Monogynia.

2. The pharmacopæial name of the caraway plant.

See Carum carui.

CARUM CARUI. The systematic name for the plant, the seeds of which are called caraways. It is also called Carvi; Cuminum pratense; Carus; Caruon. The seeds are well known to have a pleasant spicy smell, and a warm aromatic taste; and, on this account, are used for various economical purposes. They
are esteemed to be carminative, cordial, and stomachic,
and recommended in dyspepsia, flatulencies, and other
symptoms attending hysterical and hypochondriacal
disorders. An essential oil and distilled water are directed to be prepared from them by the London

CARUNCLE. (Carncula; diminutive of caro, flesh.) Ecphynia caruncula of Good. A little fleshy excrescence; as the carunculæ myrtiformes, carunculæ lachrymales, &c.

CARUNCULA. See Caruncle.

CARUNCULA LACHRYMALIS. A long conoidal gland, red externally, situated in the internal canthus of each eye, before the union of the eyelids. It appears to be formed of numerous sebaceous glands, from which many small hairs grow. The hardened smegma observable in this part of the eye in the morning, is separated by this caruncle.

CARUNCULE MAMILLARES. The extremities of the

tubes in the nipple.

CARUNCULÆ MYRTIFORMES. When the hymen has been lacerated by attrition, there remain in its place two, three, or four caruncles, which have received the name of myrtiform.

CARUNCULE PAPILLARES. The protuberances within the pelvis of the kidney, formed by the papillous sub-

stance of the kidney.

Carun. See Carum.
CA'RUS. (Kapos; from kapa, the head, as being the part affected.) Caros; Carosis, 1. Insensibility and sleepiness, as in apoplexy, attended with quiet respiration.

2. A lethargy, or a profound sleep, without fever.
3. Dr. Good gives this name to a genus in his Nosology, embracing those diseases characterized by muscular immobility; mental or corporeal torpitude, or both. It has six species; Carus asphyxia; cestasis;

catalepsia; lethargus; apoplexia; paralysis.
4. The caraway seed.
Ca'ava. The cassia lignea.

CARY DON. See Caryedon.
CARYEDON. (From kapva, a nut.) Carydon. A sort of fracture, where the bone is broken into small pieces, like the shell of a cracked nut.

preces, fixe the shell of a cracked hot.

CARYOCOSTI'NUM. An electuary; so named from two of its ingredients, the clove and costus.

CARYOPHYLLA'TA. (From καρεοφυλλον, the caryophyllus; so named, because it smells like the caryophyllus, or clove July flower.) See Geum ur-

CARYOPHY LLUM. (Καρυοφυλλον; from καρυον, a nut, and φυλλον, a leaf; so named because it was supposed to be the leaf of the Indian nut.) The clove. Eugenia caryophyllata.

CARVOPHYLLUM AROMATICUM. See Eugenia caryo-

phyllata.
Caryophyllus.
Caryophyllus.
CARYOPHY'LLUS. The clove-tree. The name of a genus of plants in the Linnman system. Class, Polyandria; Order, Monogynia. See Eugenia carohyllata.

CARYOPHYLLUS AROMATICUS AMERICANUS.

Myrtus pimenta. Carvorhyllus hortensis. See Dianthus caryo-

CARYOPHYLLUS VULGARIS. See Geum urbanum. CARYO'TIS. (From καρυον, a nut.) Caryota. Galen gives this name to a superior sort of date, of the shape

CASCARI'LLA. (Diminutive of cascara, the bark, or shell. Spanish.) A name given originally to small specimens of cinchona; but now applied to another back. See Croton cascarilla.

Cas'chu. See Acacia catechu.

Cashew-nut. See Anacardium occidentale.

Cashow. See Acacia catechu.

CASEIC ACID. Acidum cascicum. The name given by Proust to an acid formed in cheeses, to which he ascribes their flavour.

he ascribes their flavour.

CA'SIA. See Cassia.
CASMINA'RIS. See Cassumuniar.
CA'SSA. (Arabian.) The breast.
CASSA'DA. See Jatropha manihot.
CA'SSAMUM. The fruit of the balsam of Gilèad-tree,

or Amyrus opobalsamum.

CA'SSAVA. See Jatropha manihot.

CA'SSAVA. See Jatropha manihot.

CASSEBOHM, FREDERIC, a professor of anatomy at Halle in Saxony, published, in 1730, a treatise on the difference between the Fœtus and Adult, in which he notices the descent of the testicle from the abdomen; and, four years after, a very minute and exact descrip-tion of the ear. He likewise explained, in subsequent publications, the manner of dissecting the muscles and the viscera; but an early death prevented his com-pleting his design of elucidating the anatomy of the

pleting his design of elucidating the anatomy of the whole body in the same way.

CASSERIUS, JULIUS, was born of humble parents at Placentia, in 1545. He became servant to Fabricius at Padua, who, observing his talent, first taught him anatomy, then made him his assistant, and finally coadjutor in the professorship in 1609. He pursued the study with uncommon zeal, expending almost all his profits in procuring subjects, and in having drawings and prints made of the parts, which he discovered, or traced more accurately than his predecessors. He employed comparative anatomy, not as a substitute employed comparative anatomy, not as a substitute for, but only as a clue to that of the human subject. He published an account of the organs of voice and hearing, which he afterward extended to the other senses, explaining also the uses of these parts. Some years after his death, in 1616, the rest of his plates,

years after his dean, in 1010, the rest of his places, amounting to 78, with the explanations, were published with the works of Spigelius.

CA'SSIA. (From the Arabic katsia, which is from katsa, to tear off; so called from the act of stripping the bark from the tree.) The name of a genus of plants in the Linnæan system. Class, Decandria;

Order, Monogynia.
Cassia bark. See Laurus cassia.
Cassia carrophyllata. The clove bark tree

See Myrtus caryophyllata.

Cassia ristula. Cassia nigra; Cassia fistularis;
Alexandrina; Chaiarxambar; Canna; Cassia solutiva; Tlai Xiem. The purging cassia. This tree, tiva; Tlai Xiem. The purging cassia. This tree, Cassia—foliis quinquejugis ovatis acuminatis glabris, petiolis eglandulatis of Linnaus, is a native of both Indies. The pods of the East India cassia are of a less diameter, smoother, and afford a blacker, sweetet, and more grateful pulp, than those which are brought from the West Indies. Those pods which are the heaviest, and in which the seeds do not rattle on being shaken, are commonly the best, and contain the most pulp, which is the part medicinally employed, and to be obtained in the manner described in the pharmacopæias. The best pulp is of a bright shining black colour, and of a sweet taste, with a slight degree of acidity. It has been long used as a laxative medicine, and being gentle in its operation, and seldom disor actuity. It has been long used as a laxative medi-cine, and being gentle in its operation, and seldom dis-turbing the bowels, is well adapted to children, and to delicate or pregnant women. Adults, however, find it of little effect, unless taken in a very large dose, as an ounce or more; and, therefore, to them this pulp is rarely given, but usually conjoined with some of the brisker purgatives. The officinal preparation of this drug is the confectio cassiæ; it is also an ingredient in the confectio senne. the confectio sennæ.

Cassia pistularis. See Cassia fistula-Cassia Latinorum. See Osyris.

CASSIA LIGNEA. See Laurus cassia. CASSIA MONSPELIENSIUM. See Osyris.

Cassia Nigra. See Cassia fistula.

Cassia Poetica. Poet's rosemary; a plant which grows in the south of Europe, and is said to be astringent. See Osyris.

Cassia, purging. See Cassia fistula.

Cassia Senna. The systematic name of the plant Cassia senna. The systematic name of the plant which affords senna. Senna alexandrina; Senna ttalica. Senna, or Egyptian cassia. Cassia—foliis sejugis subovatis, petiolis eglandulatis of Linnæus. The leaves of senna, which are imported here from Alexandria, for medicinal use, have rather a disagreeable smell, and a subacrid, bitterish, nauseous taste. They are in common use as a pureative. The formula They are in common use as a purgative. The formulæ given of the senna by the colleges, are in infusion, a compound powder, a tincture, and an electuary. See Infusum sennæ, &c.

Cassia solutiva. See Cassia fistula.

Cassia Marviandica. See American senna.

Cassiæ aramentum. The pulp of cassia.

Cassiæ flores. What are called cassia flowers in the shops, are the flowers of the true cinnamontree, Laurus cinnamonum of Linnæus. They possess aromatic and adstringent virtues, and may be successfully employed in decoctions, &c. in all cases where cinnamon is recommended. See Laurus cinnamo-

Cassia Pulpa. See Cassia fistula.

Cassius's Precipitate. The purple powder, which forms on a plate of tin immersed in a solution of gold. It is used to paint in enamel.

Ca'ssob. An obsolete term for kali. Cassoleta. Warm fumigations described by Marcellus.

CASSUMMU'NIAR. (Of uncertain derivation; perhaps Indian.) Casamunar; Casmina; Risagon; Bengale Indorum. The root, occasionally exhibited under one of these names, is brought from the East Indies. It comes over in irregular slices of various forms, some cut transversely, others longitudinally. The cortical part is marked with circles of a dusky brown colour: the internal part is paler, and unequally yellow. It possesses moderately warm, bitter, and aromatic qualities, and a smell like ginger. It is recommended in hysterical, epilectic, and paralytic

CASTA'NEA. (Καζανον; from Castana, a city in Thessaly, whence they were brought.) See Fagus

CASTANEA EQUINA. The horse-chesnut. See . Escu-

CASTARKA EQUINA. THE HOISE-CHESHUL SECTASCA-lus hippocastanum.

CASTELLANUS, PETER, or Du CHATEL, was born at Grammont, in Flanders, in 1585. His rapid improvement in the Greek language procured him the professorship, at Lovain, in 1609; but he did not graduate in medicine till nine years after. At the same period, he published the lives of eminent physicians in Latin, written in a concise but very entertaining manner, with useful references to the original authori-

manner, with useful references to the original authorities. He died in 1632.

CASTELLUS, BARTHOLOMEW, an Italian physician, who practised at Messina about the end of the 16th century. He was author of two works, both for a long time extremely popular, a Synopsis of Medi-cine, and "Lexicon Medicum Graco-Latinum," in which great learning and judgment are conspicuous.

CASTLE-LEOD. The name of a place in Rossshire, in Scotland, where there is a sulphureous spring, celebrated for the cure of cutaneous diseases and foul ulcer

CASTOR. (Castor: from καςωρ, the beaver, quasi γαςωρ; from γαςηρ, the belly: because of the largeness of its belly; or a castrando, because he was said to castrate himself in order to escape the hunters.)

1. The name of a genus of animals.
2. The English name of the Castorcum of the pharmacopæias, a peculiar concrete substance obtained from the Castor fiber of Linnaus. See Castor fiber.

Castor fiber. The systematic name of the beaver, an amphibious quadruped inhabiting some parts of Prussia, Russia, Germany, &c.; but the greatest number of these animals is met with in Canada. The name of castoreum, or castor, is given to two bags, situated in the inguinal regions of the beaver, which

contain a very odorous substance, soft, and almost fluid when recently cut from the animal, but which dries, and assumes a resinous consistence in process of time. The best comes from Russia. It is of a grayish yellow, or light brown colour. It consists of a mucilage, a bitter extract, a resin, an essential oil, in which the peculiar smell appears to reside, and a flaky crystalline matter, much resembling the adipocire of biary calculi. Castor has an acrid, bitter, and nauseous laste; its smell is strong and aromatic, yet at the same taste; its smell is strong and aromatic, yet at the same time fœtid. It is used medicinally, as a powerful antispasmodic in hysterica and hypochondriacal affections. grains. It has also been successfully administered in epilepsy and tetanus. It is occasionally adulterated with dried blood, gum-ammoniacum, or galbanum, mixed with a little of the powder of castor, and some quantity of the fat of the beaver.

Castor oil. See Ricinus.

Castor, Russian. See Castor fiber. CASTOREUM. See Castor fiber. CASTORI'UM. See Castoreum.

CASTRATION. (Castratio, onis. f.; from castro, to emasculate, quia castrando vis libidinis extinguitur.) 1. A chirurgical operation, by which a testicle

is removed from the body.

2. Botanists apply this term to the removal of the anthera of a flower, and to a plant naturally wanting

CASTRE'NSIS. (From castra, a camp.) Belong-ing to a camp: applied to those diseases with which soldiers, encamped in marshy places, are afflicted. CATA'BASIS. (From καπαδαινω, to descend.)

An operation downwards.

CATABI'BASIS. (From καταδιδαζω, to cause to descend.) An expulsion of the humours downwards.

CATABLACEU'SIS. (From καταδλακευω, to be useless.) Hippocrates uses this word to signify carelessness and negligence in the attendance on and ad-

ministration to the sick.

CATABLE'MA. (From καταβαλλω, to throw round.)

The outermost fillet, which secures the rest of the bandage

CATABRONCHE SIS. (From κα/α, and βρογχος, the throat; or κα/αδρογχιζω, to swallow.) The act

of swallewing. CATACAU'MA. (From κα/ακαιω, to burn.) Α burn or scald.

CATACAU'SIS. (From καζακαιω, to burn.) 1. The

act of combustion, or burning.

2. The name of a genus of diseases in Dr. Good's Nosology: general combustibility of the body. It has

only one species, Catacausis ebriosa.

CATACECLI MENUS. (From καζακλινομαι, to lie down.) Keeping the bed, from the violence of a

CATACECRA'MENUS. (From καζακτραννομι, to reduce to small particles.) Broken into small CATACECRA'MENUS. pieces: applied to fractures.

pieces: applied to fractures.

CATACERA'STICA. (From κατακιραννυμι, to mix together.) Medicines which obtund the acrimony of humours, by mixing with them and reducing them.

CATACLHDE'SIS. (From κα/αχλιδαω, to indulge in delicacies.) A gluttonous indulgence in sloth and delicacies, to the generation of diseases.

CATACHRI'SMA. An ointment.

CATACHRI'STON. (From κα/αχριω, to anoint.) An ointment.

An ointment.

CATA CLASIS. (From $\kappa a / a \kappa \lambda a \omega$, to break, or distort.) Distorted eyelids.

CA"TACLEIS. (From $\kappa a / a$, beneath, and $\kappa \lambda \varepsilon \iota s$, the clavicle.) Catacleis. The subclavicle, or first rib, which is placed immediately under the clavicle.

Which is placed infinediately under the clavicle.

CATACLI'NES. (From κα/ακλινω, to lie down.)

One who, by disease, is fixed to his bed.

CATA'CLISIS. (From κα/ακλινω, to lie down.) A
lying down. Also incurvation.

CATACLY'SMA. (From κα/ακλυζω, to wash.) A

clyster. CATACLY'SMUS. (From καζακλυζω, to wash.)

An embrocation.
 A dashing of water upon any part.
 CATACRE'MNOS. (From κα/a, and κρημνος, a precipice.) Hippocrates means, by this word, a swoln and inflamed throat, from the exuberance of the parts.
 CATACRU'SIS. (From κα/ακρουω, to drive back.)

A revulsion of humours.

CATADOULE'SIS. (From κα/αδουλοω, to enslave.)
The subduing of passions, as in a phrensy, or fever.
CATÆGIZE'SIS. (From κα/αιγιζω, to repel.) A

revulsion or rushing back of humours, or wind in the

CATÆONE'SIS. (From κα/αιονεω, to irrigate.) Irrigation by a plentiful affusion of liquor on some part of the body.

CATA'GMA. (From $\kappa a/a$, and $ay\omega$, to break.) A fracture. Galen says a solution of the bone is called catagma, and closs is a solution of the continuity of the flesh: that when it happens to a cartilage, it has

no name, though Hippocrates calls it catagma.

CATAGMA'TICA. (From κα/αγμα, a fracture.) Catagmatics. Remedies which promote the formation of

CATAGO'GE. (From κα/αγομαι, to abide.) The seat or region of a disease or part.

CATAGY10'SIS. (From κα/αγνιοω, to debilitate.)

An imbecility and enervation of the strength and

CATALE PSIS. (From κα 7 αλαμβανω, to seize, to hold.) Catoche; Catochus; Congelatio; Detentio; Encatalepsis; by Hippocrates, Aphonia; by Antigenes, Anaudia; by Calius Aurelianus, Apprehensio, Oppressio; Comprehensio; Carus catalepsia of Good; Apoplexia cataleptica of Cullen. Catalepsy. A sudden suppression of motion and sensation, the body remaining in the same posture that it was in when seized.

ing in the same posture that it was in when seized.

Dr. Cullen says, he has never seen the catalepsy ex-Dr. Cullen says, he has never seen the catalepsy except when counterfeited; and is of opinion, that many of those cases related by other authors, have also been counterfeited. It is said to come on suddenly, being only preceded by some languor of body and mind, and to return by paroxysms. The patients are said to be for some minutes; sometimes (though rarely) for some hours, deprived of their senses, and all power of voluntary motion; but constantly retaining the position in which they were first seized, whether lying or sitting; and if the limbs be put into any other posture during the fit, they will keep the posture in which they are placed. When they recover from the paroxysm, they remember nothing of what passed during the time of it, but are like persons awakened out of a sleep.

of it, but are like persons awakened out of a sleep.

Catalo'τιca. (From κα/αλοαω, to grind down.)

Medicines to soften and make smooth the rough edges

and crust of cicatrices.

and crust of cicatrices.

CATA'LYSIS. (Καταλυσις: from καταλυω, to dissolve or destroy.) It signifies a palsy, or such a resolution as happens before the death of the patient; also that dissolution which constitutes death.

CATAMARA'SMUS. (From κα/αμαρακυω, to grow thin.) 1. An emaciation of the body.

2. The resolution of tumours.

7 CATAMASSE'SIS. (From κα/αμασσομαι, to manducate.) The grinding of the teeth, and biting of the tongue; common in epilepsy.

CATAME'NIA. (Catamenia, orum, neut. pleur.; from κα/α, according to, and μην, the month.) Monses. The monthly discharge from the uterus of females, between the ages of 14 and 45. Many have questioned whether this discharge arose from a mere rupture of vessels, or whether it was owing to a secretory action. vessels, or whether it was owing to a secretory action. There can be little doubt of the truth of the latter. The secretory organ is composed of the arterial ves-sels situated in the fundus of the uterus. The dissection of women, who have died during the time of their tion of women, who have died during the time of their menstruating, proves this. Sometimes, though very rarely, women, during pregnancy, menstruate; and when this happens, the discharge takes place from the arterial vessels of the vagina. During pregnancy and lactation, when the person is in good health, the catamenia, for the most part, cease to flow. The quantity a female menstruates at each time is very various; depending on climate, and a variety of other circumstances. It is commonly in England from five to six ounces: it rarely exceeds eight. Its duration is from ounces; it rarely exceeds eight. Its duration is from three to four, and sometimes, though rarely, five days. With respect to the nature of the discharge, it differs very much from pure blood; it never coagulates; but is sometimes grumons, and membranes like the decidua are formed in difficult menstruations: in some women it always smalls rank and neculiar, in others it is income. it always smells rank and peculiar; in others it is ino-dorous. The use of this monthly secretion is said to be to render the uterus fit for the conception and nutri-tion of the fœtus; therefore girls rarely conceive before the catamenia appear, and women rarely after their

entire cessation; but very easily soon after menstrua-

CATANA'NCE. Succory.

CATANI PHTHIS. (From καζανιπζω, to wash. Washed, or scoured. Used by Hippocrates of a diarrhœa washed and cleansed by boiled milk.

CATANTLE MA. (From κα/αν/λαω, to pour upon.) A

CATANTLE MA. (From κα/aν/λαω, to pour upon.) A lotion by infusion of water, or medicated fluids.

CATANTLE'SIS. A medicated fluid.

CATAPA'SMA. (Erom καταπασσω, to sprinkle.)

Catapastum; Conspersio; Epipaston; Pasma; Sympasma; Aspersio; Aspergo. The ancient Greek physicians meant by this, any dry medicine reduced to powder, to be sprinkled on the body. Their various forms and uses may be seen in Paul of Egina, lib. vii.

cap. xiii. CATAPAU'SIS. (From $\kappa \alpha / \pi \pi a v \omega$, to rest, or cease.) That rest or cessation from pain which proceeds from

the resolution of uneasy tumours.

CATAPE'LTES. (From κα7α, against, and ωελτη, a shield.) 1. This word means a sling, a granado, or

2. It was formerly used to signify the medicine which heals the wounds and bruises made by such an

CATA'PHORA. (From καταφερω, to make sleepy.) A preternatural propensity to sleep; a mild apoplexy; a species of Dr. Good's Carus Lethargus; remissive lethargy.

CATAPHRA'CTA. (From κα ζαφρασσω, to fortify.) A

bandage on the thorax.

CATAPLA'SMA. (Cataplasma, matis. neut.; from κα/απλασσω, to spread like a plaster.) A poultice. The following are among the most useful:-

CATAPLASMA ACETOS E. Sorrel poultice. The leaves are to be beaten in a mortar into a pulp. A good appli-

cation to scorbutic ulcers.

CATAPLASMA AERATUM. See Cataplasma fermenti.
CATAPLASMA AERATUM. See Cataplasma fermenti.
CATAPLASMA ALUMINIS. This application was formerly used to inflammation of the eyes, which was kept up from weakness of the vessels; it is now seldom used, a solution of alum being mostly substituted.
CATAPLASMA CONII. Hemlock poultice. B. Conji foliorum exsiccatorum 3 j. Aquæ fontanæ, ibij. To be boiled till only a pint remains, when as much linseed-meal as necessary is to be added. This is an excellent application to many cancerous and scrofulous ulcers, and other malignant ones; frequently producing great diminution of the pain of such diseases, and improving their appearance. Justamond preferred the fresh herb bruised. fresh herb bruised.

CATAPLASMA CUMINI. Take of cumin seeds, one pound; bay-berries, the leaves of water germander dried, Virginia snake-root, of each three ounces; cloves, dried, Virginia snake-root, of each three ounces; cloves, one ounce; with honey equal to thrice the weight of the powder formed: of these make a cataplasm. It was formerly called Theriaca Londinensis. This is a warm and stimulating poultice, and was formerly much used as an irritating antiseptic application to gangrenous ulcers, and the like. It is now seldom ordered.

CATAPLASMA DADCI. Carrot poultice. R. Radicis dauci receptis, bj. Bruise it in a mortar into a pulp. Some, perhaps, with reason, recommend the carrots to be first boiled. The carrot poultice is employed as an application to ulcerated cancers, scrofulous sores of an irritable kind, and various inveterate malignant

of an irritable kind, and various inveterate malignant

CATAPLASMA FERMENTI. Yest cataplasm. Take of flour a pound; yest half a pint. Mix and expose to a gentle heat, until the mixture begins to rise. This is a celebrated application in cases of sloughing and mortification.

CATAPLASMA FUCI. This is prepared by bruising a quantity of the marine plant, commonly called sea-tang, which is afterward to be applied by way of a poultice. Its chief use is in cases of scrofula, white swellings, and glandular tumours more especially. When this vegetable cannot be obtained in its recent state, a common poultice of sea-water and oatmeal has been subtituted by the late Mr. Hunter, and other surgeons of eminence. surgeons of eminence.

CATAPLASMA LINE Linseed poultice. R. Farinæ lini, lbss. Aquæ ferventis, lbjss. The powder is to be gradually sprinkled into the water, while they are quickly blended together with a spoon. This is the best and most convenient of all emollient poultices for common cases, and has, in a great measure, super-

CATAPLASMA PLUMBI ACETATIS. B. Liquoris plumbi acetatis, 3 j. Aquæ distili. Ibj. Micæ panis, q. s. Misce. Practitioners, who place much confidence in the virtues of lead, often use this poultice in cases of inflammation.

CATAPLASMA SINAPSOS. See Cataplasma sinapis.
CATAPLASMA SINAPSOS. Mustard cataplasm. Take of mustard-seed, linseed, of each powdered half a pound; boiling vinegar, as much as is sufficient. Mix until it acquires the consistence of a cataplasm.
CATAPLE'XIS. (From κατα, and ωγησσω, to strike.) Any sudden stupefaction, or deprivation of sensation, in any of the members, or organs.
CATAPO'SIS. (From καταπινω, to swallow down.) According to Aretœus, it signifies the instruments of deglutition.

deglutition.

deglutition.

CATAPO'TIUM. (Καταποτιον; from καταπινω, to swallow down.) A pill.

CATAPSY'XIS. (From ψυχω, to refrigerate.) A coldness, or chillness, without shivering, either universal, or of some particular part.

CATAPTO'SIS. (From καταπιπτω, to fall down.) A falling down. 1. Such as happens in apoplexy.

2. The falling down of a limb from palsy.

CATAPU'TIA. (From κα]απυθω, to have an ill savour; or from the Italian, εαεαρκιτα, which has the same meaning; so named from its fætid smell.) Spurge.

CATAPUTIA MAJOR. See Ricinus. CATAPUTIA MINOR. See Euphorbia Lathyris. CA'TARACTA. (From καταρασσω, to confound or disturb: because the sense of vision is confounded, if not destroyed.) A cataract; a disease of the eye. Paropsis cataracta of Good. The Caligo lentis of Cullen. Hippocrates calls it γλανκωμα. Galen, υποχυμα. The Arabians, gutta opaca. Celsus, suffasio. It is a species of blindness, arising almost always from an opacity of the crystalline lens, or its capsule, preventing the rays of light passing to the optic nerve. It commonly begins with a dimness of sight: and this venting the rays of light passing to the optic nerve. It commonly begins with a dimness of sight; and this generally continues a considerable time before any opacity can be observed in the lens. As the disease advances, the opacity becomes sensible, and the patient imagines there are particles of dust, or motes, upon the eye, or in the air, which are called musca volitantes. This opacity gradually increases till the person either becomes entirely blind, or can merely distinguish light from darkness. The disease commonly comes on rapidly, though sometimes its progress is slow and gradual. From a transparent state, it changes to a gradual. From a transparent state, it changes to a perfectly white, or light gray colour. In some very rare instances, a black cataract is found. The con-sistence also varies, being at one time hard, at another entirely dissolved. When the opaque lens is either entirely dissolved. When the opaque lens is either more indurated than in the natural state, or retains a tolerable degree of firmness, the case is termed a firm or hard cataract. When the substance of the lens seems to be converted into a whitish or other kind of fluid, lodged in the capsule, the case is denominated a milky or fluid cataract. When the substance is of a middling consistence, neither hard nor fluid, but about as consistent as a thick jelly, or curds, the case is named a soft or caseous cataract. When the anterior or posterior layer of the crystalline capsule becomes or posterior layer of the crystalline capsule becomes opaque, after the lens itself has been removed from this little membraneous sac, by a previous operation, the affection is named a secondary membraneous cataract. There are many other distinctions made by authors. Cataract is seldom attended with pain; sometimes, however, every exposure to light creates uneasiness, owing probably to the inflammation at the bottom of the eye. The real cause of cataract is not yet well understood. Numbers of authors consider it as proceeding from a preternatural contraction of the vessels ceeding from a preternatural contraction of the vessels of the lens, arising from some external violence, though more commonly from some internal and occult cause. The cataracta is distinguished from gutta serena, by the pupils in the latter being never affected with light, and from no opacity being observed in the lens. It is distinguished from hypopyon, staphyloma, or any other disease in the forepart of the eye, by the evident marks which these affections produce, as well as by the pain attending their beginning. But it is difficult to determine when the opacity is in the lens, or in its capsule. If the retina (which is an expansion or in its capsule. If the retina (which is an expansion 198

seded the bread and milk one, so much in use for-merly.

CATAPLASMA PLUMBI ACETATIS. B. Liquoris plumbi depressing the diseased lens, which is termed couch-

ing, or extracting it.

CATARRHEU'MA. (From κα/αρρεω, to flow from.) A defluxion of humours from the air-pas-

sages.

CATARRHE'XIS. (From κα/αρρηγνυω, to burst out.) A violent and copious eruption or effusion; joined with κοιλιας, it is a copious evacuation from the belly, and sometimes alone it is of the same signification. Vogel applies it to a discharge of pure blood from the intestines such as takes place in dysentery.

the belly, and sometimes it to a discharge of pure blood fication. Vogel applies it to a discharge of pure blood from the intestines, such as takes place in dysentery.

CATARRHŒCUS. (From κα]αρρεω, to flow from.)

A disease proceeding from a discharge of phlegm.

CATA'RRHOPA. (From κα]αρρεω, to flow down.)

Tubercles tending downward; or, as Galen states, those that have their apex on a depending part have

received this appellation.

CATA'RRHOPOS. (Καταρροπος νουσος.) A remission of the disease, or its decline, opposed to the

sion of the disease, or its decline, opposed to the paroxysm.

CATA'RRHUS. (From \(\kat{ra} \) appear, to flow down.)

Coryza. A catarrh. An increased secretion of mucus from the membranes of the nose, fauces, and bronchia, with fever, and attended with sneezing, cough, thirst, lassitude, and want of appetite. It is a genus of disease in the class \(Pyrezia \), and order \(Profuvia \) of Cullen. There are two species of catarrh viz. \(catarrhus \(\alpha \) frigore, which is very common, and is called a cold in the head; and \(catarrhus \(\alpha \) contagio, the influenza, or epidemic catarrh, which sometimes seizes \(\alpha \) whole city. Catarrh is also symptomatic of several other diseases. Hence we have the \(catarrhus \) attended the several other diseases. Hence we have the \(catarrhus \) attended the several other diseases, werninosa, calculosa, \(phthisica, hysterica, \(\alpha \) dentitione, \(gravidarum, metallicolarum, \(\kappa \).

Colarum, &c.

Catarrh is seldom fatal, except in scrofulous habits, by laying the foundation of phthisis; or where it is aggravated by improper treatment, or repeated expoby laying the foundation of phthisis; or where it is aggravated by improper treatment, or repeated exposure to cold, into some degree of peripneumony; when there is hazard of the patient, particularly if advanced in life, being suffocated by the copious effusion of viscid matter into the air-passages. The epidemic is generally, but not invariably, more severe than the common form of the disease. The latter is usually left to subside spontaneously, which will commonly happen in a few days, by observing the antiphlogistic regimen. If there should be fixed pain of the chest, with any hardness of the pulse, a little blood may be taken from the arm, or topically, followed by a blister: the bowels must be kept regular, and diaphoretics exhibited, with demulcents and mild opiates to quiet the cough. When the disease hangs about the patient in a chronic form, gentle tonics and expectorants are required, as myrrh, squill, &c. In the epidemic catarrh more active evacuations are often required, the lungs being more seriously affected; but though these should be promptly employed, they must not be carried too far, the disease being apt to assume the typhoid character in its progress; and as the chief danger appears to be of suffocation happening from the cause abovementioned, it is especially important to promote expectoration, first by antimonials, afterward by squill, the inhalation of steam, &c. not neglecting to support the strength of the patient as the disease advances.

CATARRHUS A FRIGORE. The common defluxion from the head from cold.

CATARRHUS A CONTAGIO. The influenza.

CATARRHUS A CONTAGIO. The influenza. CATARRHUS BELLINSULANUS. Mumps. nanche parotidæa.

CATARRHUS SUFFOCATIVUS. The croup. See Cynanche trachealis.

CATARRHUS VESICE. A discharge of mucus from

CATARRTI'SMUS. (From κα/αο/λίζω, to make perfect. According to Galen, it is a translation of a bone from a preternatural to its natural situation.

CATASA'RCA. (From κα7α and σαρξ, flesh.) See

CATASBE'STIS. (From κα7α and σδεννυμι, to extinguish.) The resolution of tumours without sup-CATASBE'STIS. puration.

CATASCHA'SMUS. (From καζασχαζω, to sca-

rify.) Scarification. CATASEI'SIS. (From κα7α, and σειω, to shake.)

CATASPA'SMA. (From κα/ασπαω, to draw backwards.) A revulsion or retraction of humours, or parts. CATASTA'GMOS. (From κα/α, and σαζω, to distil.) The name which the Greeks, in the time of Celsus, had for distillation.

CATASTA'LTICUS. (From καταστελλω, to restrain, or contract.) Styptic, astringent, repressing. CATA'STASIS. Καταστασις. The constitution, state, or condition of any thing.

CATA TASIS. (From κα / artive, to extend.) In Hippocrates it means the extension of a fractured limb, or a discolated one, in order to replace it. Also

the actual replacing it in a proper situation.

CATA'XIS. (From κα/αγω, to break.) A fracture. Also a division of parts by an instrument.

CATECHO'MENUS. (From κα/τχω, to resist.)

Resisting and making ineffectual the remedies which beauthour applied or given. have been applied or given.
CA TECHU. (It is said, that, in the Japanese lan-

guage, kate signifies a tree, and chu, juice.) See Aca-

CATEIA DION. (From kara, and ua, a blade of grass.) An instrument mentioned by Areteus, having at the end a blade of grass, or made like a blade of grass, which was thrust into the nostrils to provoke a hæmorrhage when the head ached. CATE LLUS. (Dim. of catulus, a whelp.) 1. A

voung whelp.

2. Also a chemical instrument called a cupel, which was formerly in the shape of a dog's head.

CATHÆ RESIS. (From καθαιρω, to take away.)

1. The subtraction or taking away any part or thing from the body.

2. Sometimes it means an evacuation, and Hippo-

crates uses it for such.

3. A consumption of the body, as happens without

manifest evacuation.

CATHERE'TICA. (From καθαιρω, to take away.)
Medicines which consume or remove superfluous flesh.
CATHA'RMA. (From καθαιρω, to remove.) The excrements, or humours, purged off from the body.

CATHA'RMUS. (From καθαιρω, to remove.) purgation of the excrements, or humours.

2 A cure by incantation, or the royal touch.

CATHA'RSIA. (From καθαιρω, to purge.) Medicines which have a purging property.

CATHA'RSIS. (From καθαιρω, to take away.)

Purgation of the excrements, or humours, either me-

dically or naturally. CATHA'RTIC. (Catharticus; from καθαιρω, to purge.) That which, taken internally, increases the number of alvine evacuations. These medicines have received many appellations: purgantia; catocathar-tica; catoretica; catoteretica; dejectoria; alviduca. The different articles referred to this class are divided into five orders.

Stimulating cathartics, as jalap, aloes, bitter apple, and croton oil, which are well calculated to discharge accumulations of serum, and are mostly selected for indolent and phlegmatic habits, and those who

are hard to purge.

2. Refrigerating cathartics, as sulphate of soda, supertartrate of potassa, &c. These are better adapted for plethoric habits, and those with an inflamma-

tory diathesis.

3. Adstringent cathartics, as rhubarb and damask roses, which are mostly given to those whose bowels are weak and irritable, and subject to diarrhea.

Emollient cathartics, as manna, malva, castor oil, and olive oil, which may be given in preference to other cathartics, to infants and the very aged.

Narcotic cathartics, as tobacco, hyoscyamus, and digitalis. This order is never given but to the very strong and indolent, and to maniacal patients, as their

nia alba, Cacumis colocynthis, Momordica elaterium, Rhammus catharticus, Aloe perfoliata, Convolvulus scammonia, Gambogia, Submurias hydrargyri, Sul phas magnesia, Sulphas sodæ, Sulphas potassæ, Supertartras potassæ, Tartras potassæ et sodæ, Phosphas sodæ, Murias sodæ, Terebinthina veneta, Nicotiana tabacum.

Cathartic Glaubers salt. See Soda sulphas.

Cathartic Glaubers salt. See Sodæ sulphas. Cathartic Salt. See Sulphas magnesia, and Sul-

CATHARTINE. A substance of a reddish colour, a peculiar smell, and a bitter nauseous taste, soluble in water and alkohol, but insoluble in æther; obtained

by Lassaigne and Fenuelle from the leaves of senna.

CATHE DRA. (From καθεζομαι, to sit.) The anus, or rather, the whole of the buttocks, as being the part on which we sit.

CATHERE TICA. (From καθαιρω, to remove.) Corrosives. Applications which, by corrosion, remove superfluous flesh.

CA'THETER. (Catheter, teris. m. Καθετρο: from

CA'THETER. (Catheter, teris. m. Καθετηφ; from καθιημε, to thrust into.) A long and hollow tube, that is introduced by surgeons into the urinary bladder, to remove the urine, when the person is unable to pass it. Catheters are either made of silver or of the elasit. Catheters are either made of silver of of the elastic gum. That for the male urethra is much longer than that for the female, and so curved, if made of silver, as to adapt itself to the urethra.
CATHETERI'SMUS. (From καθετηρ, a catheter.)

The operation of introducing the catheter.

CATHI DRYSIS. (From καθιόρυω, to place to-ther.) The reduction of a fracture, or operation of gether.) The reduction setting a broken bone.

CATHMA. A name for litharge.

CA'THODOS. (From Kara, and odos.) A descent of

CATHO LCEUS. (From κατα, and ολκτω, to draw over.) An oblong fillet, made to draw over and cover the whole bandage of the head.
 CATHO LICON. (From κατα, and ολικος, uni-

CATHO'LICON. (From κατα, and ολικος, universal.) A universal medicine: formerly applied to a medicine, that was supposed to purge all the humours.

["CATHRAL, ISAAC, M. D., was a native of Philadelphia, and studied medicine under the direction of the late Dr. John Redman, the preceptor of Rush and Wistar. After acquiring all the instruction in his profession, which the opportunities of Philadelphia offer. Wistar. After acquiring all the instruction in his profession, which the opportunities of Philadelphia offered, aided by a diligent attention on his part, he visited Europe, and attended the practice of the London hospitals, and the lectures of the most distinguished professors in that city. During the prevalence of the widely destroying epidemic fevers of 1793, '97, '98, and '99, he remained in the city, instead of seeking safety by flying, and was a severe sufferer by the disease of the first of those years. Previously to his illness, and after his recovery, besides attending to practice, he lost no opportunity of investigating every phenomenon connected with that pestilential epidemic, which could in any manner tend to illustrate its pathology, or the peculiarities it exhibited. In the year 1794, he published his remarks thereon, and the mode of treatment he pursued. In conjunction with Dr. of treatment he pursued. In conjunction with Dr. Physick, he dissected the bodies of some subjects of the fever of 1793, in order to discover the morbid effects produced by it on the system, and in particular reference to the nature of that singular and generally fatal symptom, the dark-coloured ejection from the stomach, in some cases of the disease. The result of their joint labours was published by them, with their individual labours was published by them, with their individual signatures, and he afterward continued his dissections alone, with unabating zeal, whenever opportunity offered, during the subsequent epidemics and occasional appearance of the disease, which more or less occurred for several years, until he obtained all the light which he thought dissection and experiment could throw them its production and nature. In the year operation is very powerful.

Murray, in his Materia Medica, considers the different cathartics under the two divisions of taxatives and purgatives; the former being mild in their operation, and merely evacuating the contents of the intestines; the latter being more powerful, and even extending their stimulant operation to the neighbouring parts. The following he enumerates among the principal laxatives:—manna, Cassia fistula, Tamarindus indica, Ricinus communis. Sulphur, Magnesia. Under the head of purgatives, he names Cassia senna, Rheum palmatum, Convolvulus jalapa, Helleborus niger, BryoFebruary, 1819, in the 56th year of his age, by a stroke [

of the apoplexy.
"Dr. Cathrall was educated in the religious principles of the Society of Friends, and naturally possessed a grave turn of mind, and a serious deportment. Re-tired in his habits, he was shy in making acquaintances, but firm in his friendships, and a well-bred gen-ances, but firm in his friendships, and a well-bred gen-tleman in his manners. In the important and endear-ing relations of a son, husband, and father, he was truly estimable. As a member of society, he set an example of rigid morality and inflexible integrity, attri-butes which every medical man ought to be proud to have annexed to his character, however distinguished his literary acquirements may be."—Thacher's Med. Biog. A.1 Biog. A.J CATHY PNIA.

(From κατα, and υπνος, sleep.) A

profound but unhealthy sleep.

Ca'τιαs. (From καθιημι, to place in.) An incision knife, formerly used for opening an abscess in the uterus, and for extracting a dead fœtus.

CATI'LLUS. See Catellus.

CA'TINUM ALUMEN. A name given to potassa.

CA'TINUS. Karavov. A crucible.
CAT-KIN. See Amentum.
CA'TMINT. (So called, because cats are very fond

of it.) See Nepeta. CATOCATHA'RTICA. (From κατω, downward, and καθαιρω, to purge.) Medicines that operate by stool.

CATO'CHE. (From Katexw, to detain.) See Cata-

CATOCHEI'LUM. (From κατω, beneath, and

χειλος, the lip.) The lower lip.

CA TOCHUS. (From κατεχω, to detain.) A spasmodic disease in which the body is rigidly held in

an upright posture.

an upright posture.

CATOMI'SMUS. (From κατω, below, and ωμος, the shoulder.) By this word, P. Ægineta expresses a method of reducing a luxated shoulder, by raising the patient over the shoulder of a strong man, that by the weight of the body, the dislocation may be reduced.

CATOPSIS. (From κατοπτομαι, to see clearly.)

An acute and quick perception. The acuteness of the first time which accompanies the latter stages of con-

faculties which accompanies the latter stages of con-

CATOPHYLLUM INOPHYLLUM. Calaba. The Indian mastich-tree. A native of America, where the whole plant is considered as a resolvent and anodyne.

CATO'PTER. (From κατα, and οπτομάι, to see; by metaphor, a probe.) An instrument called a specu-

CATORCHI'TES. (From κατα, and ορχις, the orchis.) A wine in which the orchis root has been infused. CATORE'TICA. (From κατω, downwards, and ρεω, to flow.) Catoteretica; Catoterica. Medicines which purge by stool.

CATOTERE'TICA. See Catoretica.
CATOTICA. (Catoticus; from κατω, below; whence κατωτερος, and κατωτατος, inferior, and infernus.) The name of an order of the class Eccritica, in Good's Nosology; diseases affecting internal surfaces; defined, pravity of the fluids, or emunctories that open into the internal surfaces of organs. It embraces hy-It embraces hyinto the internal surfaces of organs. It embraces hydropsis, emphysema, paruria, and lithia.

CATS-EYE. A mineral, much valued as a precious stone, brought from Ceylon.

CATULO'TICA. (From κατουλοω, to cicatrize.) Me-

dicines that cicatrize wounds.

CATUTRI'PALI. A name of the Piper longum.

See Amentum.

CAU'CALIS. (From καυκιον, a cup; or from δαν-καλις, the daucus.) 1. The name of a family, or genus of plants. Class Pentandria; Order, Monogynia. 2. Bastard parsley; so named from the shape of its

3. The wild carrot.
CAUCALOTDES. (From caucalis, and 22005, a likeness, from its likeness to the flower of the caucalis.) Like unto the caucalis. The patella is sometimes so called.

CAU'DA. (From cado, to fall; because it hangs or falls down behind.) A tail.

The tail of animals.
 A name formerly given to the os coccygis, that being in tailed animals the beginning of the tail.
 A fleshy substance, projecting from the lips of the

vagina, and resembling a tail, according to Actius.

4. Many herbs are called cauda, with the affixed name of some animal, the tail of which the herb is name of some animal, the tail of which the held is supposed to be like; as cauda equina, horse-tail; cauda muris, mouse-tail; and in many other instances.

CAUDA EQUINA. 1. The spinal marrow, at its termination about the second lumbar vertebra, gives off a

large number of nerves, which, when unravelled, re-semble the horse's tail; hence the name. See Medulla spinalis.

2. See Hippuris vulgaris. Cauda seminis. The tail, or elongated, generally feathery appendage to a seed, formed of the permanent style. It is simple, in Geranium zonale; hairy, in Clematis and Pulsatilla; and geniculate in Tormen-

CAUDA'TIO. (From cauda, a tail.) An elongation

of the clitoris

CAUDATUS. (From cauda, a tail.) Tailed: applied to seeds which have a tail-like appendage; as those of the Clematis vitalba, and Anemone sulphurea. CAUDEX. (Caudex, icis. m.) The body of the root of a plant. See Radix.

CAUL. 1. The English name for the omentum.

See Omentum.

2. The amnion, which is sometimes torn by the child's head, passing from the uterus, and comes away

with it wholly separated from the placenta.

CAULE DON. (From καυλος, a stalk.) A transverse fracture, when the bone is broken, like the stump of a

CAU'LIFLOWER. A species of brassica, the flower of which is cut before the fructification expands. The observations which have been made concerning cabbages are applicable here. Cauliflower is because of the concerning cabbages. is, however, a far more délicious vegetable. Sec Brassica capitata.

CAULINUS. Cauline. Belonging to the stem. Leaves and peduncles are so called, which grow on

or come immediately from, the stem.

CAU'LIS. (Caulis, is. m. Καυλος; from kalab, a
Chaldean word.) The stalk or stem of herbaceous
plants. The characters of the stalk are, that it is rarely ligneous, and lives but one or two years in the natural state of the plant.

A plant is said to be

Caulescent, when furnished with a stem. Acauline, when without a stem; as in Caulina

acaulis.

From its duration, the stem is distinguished into, 1. Caulus herbaceus, which perishes every year; as

Melissa officinalis.

2. Caulis suffruticosus, which perishes half way down every year; as Cheiranthus incanus.
3. Caulis fruticosus, shrubby, having many stems, which do not perish in the winter; as Melissa fruticosa.

4. Caulis arboreus; as the trunk of trees. From the substance, it is distinguished into,

5. Caulis fistulosus, hollow internally; as in Anethum graveolens, and Allium fistulosum.
6. Caulis loculamentosus, hollow and divided into cells; as in Angelica, Archangelica, and Phellandrum aquaticum.

Caulis inanis, or medullosus, empty or pithy; as

in Sambucus nigra.

8. Caulis solidus, solid; as in Mentha and Melissa.
9. Caulis ligneus, woody; as Prunus spinosa.
10. Caulis carnosus, fleshy; as in Sodum arboreum,

and Stapelia hirsuta.

Caulis pulposus, pulpy; as in Mesembryanthemum crystallinum.

Caulis fibrosus, separable into long fibres; as Cocos nucifera.

13. Caulis succesus, full of a juice; as in the Euphorbias, and Chelidonium majus.

From the difference of the surface, the caulis is said to be

14. Glaber, or lavis, smooth, without any hairiness, or roughness, or inequality; as Lepedium latifolium.

15. Scaber, or asper, when it has hard inequalities; as in Galium aperine, and Lithospermum arvense.

16. Suberosus, corky; as Passiflora suberosa, and

Quercus suber.

 Rimosus, cracky; as in Ulmus campestris,
 Tuberculatus, with rough nobs; as in Cissus tuberculata.

19. Tunicatus, the cuticle peeling off spontaneously

in large portions; as in Betula alba, and some of the

Spiræas.

20. Striatus, having superficial longitudinal lines; as in Chærophyllum sylvestre, Aster sibiricus, and Daphne mezereon.

21. Sulcatus, furrowed, fluted, when longitudinally indented with long and deep hollows; as in Celosia coccynea, Selinum carvifolia, Pimpinella sanguisarba, Doronicum pardalianches.
22. Perfoliatus, perfoliate; as in Bupleurum perfo-

liatum.

The figure affords the following distinctions:

23. Caulis teres, or cylindricus, round, without angles; as Sinapis arvensis.

24. Semiteres, half-rounded, flat on one side; as Hy-

acinthus orientalis, Allium descendens.

25. Caulis compressus, which implies that two sides of the stem are flat, and approach each other; as in Poa compressa, Lathyrus latifolius, Pancratium decli-

26. Caulis anceps, two-edged; as Iris graminea, Hy-

pericum androsemum.

27. Caulis angulatus, presenting several acute angles in its circumference.

a. Triangulatus, three-cornered; as in Cactus triangularis.

- b. Quadrangulatus, four-cornered; as Cactus teragonus.
- c. Quinqueangulatus; as in Cactus pentagonus.
 d. Sexangulatus, six-cornered; as Cactus hexagonus.

e. Multangulatus, many cornered; as Cactus cereus. 28. Caulis obtusangulatus, obtuse-angled; as in

Scrophularia nodosa. 29. Caulis acutangulatus, acute-angled; as in Scro-

phularia aquatica.

30. Caulis triquetrus, three-sided, when there are three flat sides, forming acute angles; as Hedysarum triquetrum, Viola mirabilis, Carex acuta.

31. Caulis tetraquetrus, four-sided; as in Hypericum quadrangulare, Monarda fistulosa, Mentha officialis.

cinalis.

32. Caulis membranaceus, leaf-like; as in Cactus

physianthus.

33. Caulis alatus, when the edges or angles expand into leaf-like borders; as in Onopordium acanthium, and Lathyrus latifolius.

34. Caulus articulates, jointed; as Cactus flagelli-formis, and Lathyrus sylvestris.
35. Caulis nodosus, knotty, divided at intervals by swellings; as in Scandix nodosa, Geranium nodosum.

36. Caulis enodus, without knot.

- From the directions, a stem is called 37. Rectus, erect, when it ascends almost perpendicularly; as the firs, Chenopodium scoparium, &c.
- 38. Strictus, straight, perfectly perpendicular; as Alcea Rosea.
- 39. Obliquus, oblique; as the Solidago Mexicana. 40. Ascendens, ascending, when its lower portion forms a curve, the convexity of which is towards the earth, or rests upon it, and the summit rises; as exemplified in many grasses, Trifolium pratense, Hedysarum onobrychis.

41. Descendens, or Declinatus, the reverse of the former, forming an arch, towards the ground; as in Pancratium declinatum, Ficus carica.

42. Nutans, or cernuus, nodding, when bent towards the summit; as Polygonatum multiflora.

43. Procumbens, or Prostatus, lying on the earth;

as Veronica officinalis. 44. Decumbens, rising a little, and returning to the

earth; as Thymus serphyllum.

45. Repens, creeping and sending radicles into the ground; as Trifolium repens, Gnaphalium repens.

46. Flexuosis, zigzag; as in Celestrus buxifolius, and solidago flexicaulis.

47. Radicans, sending fibres which take root in the earth; as Ficus Indica.
48. Sarmentosus, trailing, or sending off a runner, which fixes on neighbouring bodies; as the Hedera

49. Stoloniferus, sending off radicating stolos; as

Agrostis stolonifera, and Fragaria vesca.

50. Scandens, climbing, furnished with tendrils; as Solanum dulcamara, Cobœa scandens.

51. Volubits, twining, winding itself spirally round any other plant or body. any other plant or body.

a. Dextrorsum, when from right to left; as Phaseo-lus multiflorus, and Convolvalus.

b. Sinistrorsum, in the opposite direction, or following the apparent motion of the sun; as the Lonicera pericleminum, and Humulus lupulus.

52. Lazus, bent by the lightest wind; as Secale sereale, and Juncus bufonius.

53. Rigidus, breaking when lightly bent; as Boerhaavia scandens.

When clothed with any kind of appendage, the stem is designated by a term expressive of this; thus, 54. Caulis foliosus, when leafy; as Melissa offici-

nalis.

55. Caulus aphyllus, when without leaves; as Asphodelus fistulesus.

56. Caulus squamosus, scaly; as the Orobranche

57. Caulis stipulatus, when furnished with stipulæ; as Cystus helianthemum, and Geranium terebinthina ceum.

58. Caulis imbricatus, tiled or covered with little leaves or scales; as Crassula imbricata, Aloe viscosa.

- 59. Caulus vaginatus, sheathed, embraced by the base of a leaf as by a sheath; as Canna indica, Arundo donax.
- 60. Caulis bulbiferus, bulb-bearing, when studded with bulbs in the axilla of the leaves; as Lilium bulbiferum.

61. Caulis nudus, naked, without leaf, scale, or other covering; as Cuscuta europea.

From its mode of branching, into 62. Caulis simplex, having few branches; as Campanula perfoliata, Verbascum thapsus.

63. Caulis simplicissimus, without branches; as

Orobanche americana and major, Campanula barbata.
64. Caulis prolifer, giving off branches only from the tops of the former; as the Dracena draco.

65. Caulis dichotomus, forked, always divided into pairs; as in Horanthus europæus and Valeriana locusta.

66. Caulis ramosus, branched; as Rosmarinus officinalis.

67. Caulis ramossissimus, having many branches; as Chenopodium scoparia, Ulmus, Grossularia, &c. 68. Caulis paniculatus, paniculate; as in Crambe

tataria.

From the pubescence and armature, or defences, into 69. Caulis spinosus, when furnished with sharp spines; as Prunus spinosa, and Mespilus oxyacantha.
70. Caulis aculeatus, prickly, when covered with sharp-pointed bodies; as Rosa centifolia and elegan-

71. Caulis cetaceus, bristly, when the armature consists of brushes of minute bristles; as Cactus flagelliformis.

72. Caulis ramentaceus, ramentaceous; as in Erica ramentacea.

73. Caulis pilosus, hairy, the pubescence consisting of long hairs; as Hieraceum pilocella, Salvia pratensis.

74. Caulis muricatus, or hispidus, when the hairs are stiff or bristly; as Borago officinalis, and Echium vulgare.

75. Caulis tomentosus, downy, soft to the touch, like down; as Verbascum thapsus, and Geranium rotundifolium.

76. Caulis villosus, shaggy; as Stachys germanica, and Veronica villosa.

77. Caulis lanatus, woolly, when the hairs are long and matted; as in Stachys lanata, and Ballota lanata.

78. Caulis sericus, silky, when the hairs are shining

and silky.

Instead of pubescence, the covering is in some instances either a dry powdery, or a moist, excretion; and hence, the stem is denominated either

79. Ineanus, or pruinosus, when covered with a fine white dust; as the Artiplex portulacoidis.
80. Farinosus, mealy; as the Primula farinosa.
81. Glaucus, of a sea-green colour; as Ricinus officialistics. cinalis.

82. Viscidus, viscid, covered with a resinous exuda-tion; as Siline viscosa.
83. Glutinosus, giutinous, when the exudation is adhesive and soluble in water; as in Primula glu-

The primary division of a stem is into lateral stem-or branches. These are variously denominated

From their situation, into 84. Opposite, when one branch stands on the opposite side of the stem to another, and their bases are nearly on the same plane; as in Mentha arvensis.

85. Alternate, one opposite to another, alternately;

as Althæa officinalis.

86. Verticillated, when more than two proceed from a centre, like the spokes of a wheel; as Pinus

87. Scattered, when given off from the stem in any indeterminate manner.

From their direction, the branches, or rami, are

88. Patentes, spreading, when the angle formed by the branch and the upper part of the stem is obtuse; as in Galium mollugo, and Cestus italicus.

89. Patentissimi, proceeding at a right angle from the stem, or horizontally; as Ammania ramosior, and Asparagus officinalis.

Asparagus officinalis.

90. Brachiati, brachiate, spread in four directions, crossing each other alternately in pairs; as Syringa vulgaris, and Panisteria brachiata.

91. Deflexi, bending downward from the stem, in an arched or curved direction; as Pinus larix.

92. Reflexi, hanging almost perpendicularly from the

stem; as Salix babylonica.

93. Retroflezi, turned backward; as in Solanum dulcamara.

94. Introflezi, bent inward, when the tops bend towards the stem; as Populus dilatata.

95. Fastigiati, when the tops of the branches, from whatever part of the stem they spring, rise nearly to the same height; as Chrysanthemum corymbosum, and Dianthus barbatus.

and Dianthus barbatus.

96. Vigati, weak and long; as Salix viminalis.

97. Appressi, approximated, when nearly parallel and close to the stem; as Genista tinctoria.

98. Fulcrate, supported, when they project nearly horizontally, and give out root-like shoots from the under side, which, extending until they reach the ground, take root, and serve as props to the branches; as in the hanyan-tree, or Figus religiosus. as in the banyan-tree, or Ficus religiosus.

CAULIS FLORIDA. Cauliflower.

CAULO'DES. (From καυλος, a stem.) The white or green cabbage.

CAULO TOM. (From καυλος, a stem; because it grows upon a stalk.) A name given to the beet.

CAU'MA. (Καυμα, heat; from καιω, to burn.) The heat of the body in a fever.

2. The heat of the atmosphere, in a fever.

3. The name given by Good and Young, to an inflammatory fever.

CAU'NGA. A name of the areca.

CAU'SIS. (From καιω, to burn.) A burn; or rather, the act of combustion, or burning.

CAUSO'DES. (From καιω, to burn.) A term applied by Colors of burn.

plied by Celsus to a burning fever.

CAUSO MA. (From καιω, to burn.) An ardent or burning heat and inflammation. A term used by Hip-

CAUSTIC. See Causticum.
Caustic alkali. The pure alkalies are so called. See Alkali.

Caustic barley. See Cevadilla.
Caustic lunar. See Argenti nitras.
Caustic volatile alkali. See Ammonia.
CAU'STICUM. (From καιω, to burn; because it always produces a burning sensation.) A caustic. A substance which has so strong a tendency to combine with organized substances, as to destroy their texture. See Escharotic.

CAUSTICUM AMERICANUM. The cevadilla. See Veratrum sabadilla.

CAUSTICUM ANTIMONIALE. Muriate of antimony. CAUSTICUM ARSENICALE. See Arsenical caustic. CAUSTICUM COMMUNE FORTIUS. See Potassa cum

CAUSTICUM LUNARE. See Argenti nitras.
CAUSUS. (From καιω, to burn.) A highly ardent fever. According to Hippocrates, a fiery heat, insatiable thirst, a rough and black tongue, complexion yellowish, and the saliva bilious, are its pecular characteristics. Others also are particular in describing it; but, whether ancients or moderns, from what they relate, this fever is no other than a continued ardent fever in a bilious constitution. In it the heat of the body is intense; the breath is particularly fiery; the by a burn.

extremities are cold; the pulse is frequent and small; the heat is more violent internally than externally, and the whole soon ends in recovery or death.

and the whole soon ends in recovery or death.

CAUTERY. (Cauterium, from καιω, to burn.)
Cauteries were divided, by the ancients, into actual and potential; but the term is now given only to the red-hot iron, or actual cautery. This was formerly the only means of preventing homorrhages from divided arteries, till the invention of the ligature. It was also used in discarge, with the approximate a way and the cautery. arteries, till the invention of the ligature. It was also used in diseases, with the same view as we employ a blister. Potential cautery was the name by which kali purum, or potassa, was distinguished in former dispensatories. Surgeons of the present day understand, by this term, any caustic application.

CAVA. See Cavus.

CAVE'RNA. (From cavus, hollow.) A cavern. The pudendum mulichte.

The pudendum muliebre.

CAVIARE. Caviarium. A food made of the hard roes of sturgeon, formed into a soft mass, or into cakes, and much esteemed by the Russians.

CAVI CULA. (Diminutive of cavilla.) See Cavilla. CAVI LLA. (From cavus.) The ankle, or hollow of the foot.

CAVITY. (Cavitas, from cavus, hollow.) 1. Any cavity, or hollowness.

2. The auricle of the heart was formerly called cavitas innominata, the hollow without a name.

CAVUS. Hollow. 1. The name of a vein, vena cava.

See Veins.

2. Applied to the roots of plants; as that of the Fumaria cava.

CAWK. A term by which the miners distinguish the opaque specimens of sulphate of barytes.

Cayenne pepper. See Capsicum.
CAZABI. See Jatropha.
CEANO'THUS. (From κεανωθος, quia κεει ανωθεν, because it pricks at the extreme part.) A genus of plants in the Linnæan system. Class, Pentandria; Order, Monogynia.

CEANOTHUS AMERICANUS. Celastrus; Celastus. Some noted Indians depend more on this plant, than on the lobelia, for the cure of syphilis, and use it in the same manner as lobelia.

CEA'SMA. (From κεω, to split, or divide.) Ceasmus. A fissure, or fragment.

CE'BER. (Arabian.) The Lignum aloes. Also the

capparis.

CERIPI'RA. (Indian.) A tree which grows in Brazil, decoctions of the bark of which are used in baths and fomentations, to relieve pains in the limbs, and cutaneous diseases

CE'DAR. See Pinus cedrus.

CE'DAR. (From κεδαω, to disperse.) A defluxion, or rheumatic affection, of the parts about the hips.

CE'DRINUM LIGNUM. See Pinus cedrus.

CEDRITES. (From κεδρος, the cedar-tree.) Wine in which the resin which distils from the cedar-tree has been steeped.

The which distriss from the cedar-tree has been steeped.

CE'DRIUM. 1. Cedar, or cedar-tree

2. Common tar, in old writings.

CEDROME'LA. The fruit of the citron-tree.

CEDRONE'LA. Turkey baum.

CEDRO'STIS. (From κεδρος, the cedar-tree.) A name of the white bryony, which smells like the cedar.

See Bryonia alla.

See Bryonia alba.

CE'DRUS. (From Kedron, a valley where this tree grows abundantly.) See Pinus cedrus.

CEDRUS AMERICANA. The arbor vitæ.

CEDRUS BACCIFERA. The savine.

CETRIA. (From κειρω, to abrade.) The tapeworm; so called from its excoriating and abrading the intestines. the intestines

the intestines.

CE'LANDINE. See Chelidonium majus.

CELA'STRUS. (From κελα, a dart, which it represents. See Ceanothus americanus.

CELASTUS. See Ceanothus americanus.

CE'LE. (From κηλη.) A tumour caused by the protrusion of any soft part. Hence the compound terms hydrocele, bubonocele, &c.

CE'LERY. The English name for a variety of the anium graveolems.

CE'LERY. The English name for a variety of the apium graveolens.
CELESTINE. So called from its occasional delicate blue colour. A native sulphate of strontites. See Heavy spar.

Ce'lis. (From καιω, to burn.) A spot or blemish upon the skin, particularly that which is occasioned

CE'LLULA. (Diminutive of cella, a cell.) A little cell, or cavity.

cell, or cavity.

Cellula Mastoid E. See Temporal bones.

Ce'Llular. Cellularis. Having little cells.

Cellular Membrane. Membrana cellulosa: Tela cellulosa; Panniculus adiposus; Membrana adiposa, pinguedinosa et reticularis. Cellular tissue. The cellular tissue of the body, composed of laminæ and fibres variously joined together, which is the connecting medium of every part of the body. It is by means of the communication of the cells of this membrane, that the butchers blow up their veal. The cellular than the butchers blow up their veal. that the butchers blow up their veal. The cellular membrane is, by some anatomists, distinguished into the reticular and adipose membrane. The former is evidently dispersed throughout the whole body, except the substance of the brain. It makes a bed for the other solids of the body, covers them all, and unites them one to another. The adipose membrane consists of the reticular substance, and a particular apparatus for the secretion of oil, and is mostly found immediately under the skin of many parts, and about the kidne

CELOTO'MIA. (From κηλη, hernia, and τεμνω, to

CELOTO'MIA. (From κηλη, hernia, and τεμνω, to cut.) The operation for hernia.

CE'LSA. A term of Paracelsus, to signify what is called the live blood in any particular part.

CE'LSUS, Aurelius Cornelius. It is commonly supposed, that this esteemed ancient author was a Roman of the Cornelian family, born towards the end of the reign of Augustus, and still living in the time of Caligula. But these points are not established upon certain testimony, and it is even disputed whether he practised medicine; though his perfect acquaintance with the doctrines of his predecessors, his accurate descriptions of diseases, and his judicious rules of treatment, appear to leave little room for doubt on that head. At any rate, his eight books, "De Medicina," have gained him deserved celebrity in modern times, containing a large fund of valuable information; detailed in remarkably elegant and concise language. In surgery particularly he has been greatly admired, for the methods of practice laid down, and for describing accurate accurations as they are still preference. for the methods of practice laid down, and for de-scribing several operations as they are still performed. There have been numerous editions of his work, and translations of it into the several modern languages.

CEMENT. Chemists call by this name whatever they employ to unite or cement things together; as lutes, glues, solders of every kind.

CEMENTATION. A chemical process, which consists in surrounding a body in the solid state with the powder of some other bodies, and exposing the whole for a time in a closed vessel, to a degree of heat not sufficient to fuse the contents. Thus iron is converted into steel by compentation with chargonic converted into steel by cementation with charcoal; green bottle glass is converted into porcelain by ce-mentation with sand, &c.

A crucible. CEME'NTERIUM.

CE'NCHRAMIS. (From KEYXOOS, millet.) A grain or seed of the fig.

CE'NCHRIUS. A species of herpes that resembles

κεγχοος, or millet. CENEANGEI'A. (From κενος, empty, and αγγος, a vessel.) A deficiency of blood, or other fluids in the vessels; so that they have not their proper quantity.

CENT'ODAM. Ceniplam; Cenigotam; Cenipolam. An instrument anciently used for opening the head in

CENIOTE'MIUM. A purging remedy, formerly of use in the venereal disease, supposed to be mercurial.

CENO'SIS. (From xevos, empty.) Evacuation. It imports a general evacuation. Catharsis was applied to the evacuation of a particular humour, which

plied to the evacuation of a particular humour, which offends with respect to quality.

CENOTICA. (Cenoticus; from κενωςις, evacuatio, exinanitio, emptiness.) The name of an order in the class Genetica of Good's Nosology: diseases affecting the fluids, and embracing paramenia, leucorrhwa, blenorrhwa, spermorrhwa, and galectea.

CENTAU'REA. (So called from Chiron, the centaur, who is said to have employed one of its species to cure himself of a wound accidentally received, by letting one of the arrows of Hercules fall upon his foot.) The name of a genus of plants in the Linnean system, of the Order, Polygamia frustanea; Class, Syngenssia.

CENTAUREA BEHEN. The systematic name of the

CENTAUREA BEHEN. The systematic name of the

officinal behen album; Jacea orientalis patula; Raphonticoides lutea. The true white behen of the ancients. The root possesses astringent virtues.

Centaurea benedicta. The systematic name of the blessed or holy thistle. Carduus benedictus; Cnicus sylvestris; Centaurea benedicta—calycibus duplicato-spinosis lanatis involucratis, foliis semi-decurrentibus denticulato-spinosis of Linnaus. This exotic plant, a native of Spain, and some of the Archipelago islands, obtained the name of Benedictus, from its being supposed to possess extraordinary Archipelago Islands, obtained the name of Benedicius, from its being supposed to possess extraordinary medicinal virtues. In loss of appetite, where the stomach was injured by irregularities, its good effects have been frequently experienced. It is a powerful bitter tonic and adstringent. Bergius considers it as antacid, corroborant, stomachic, sudorific, diuretic, and accorratic. Chamomile flowers are now generally Chamomile flowers are now generally eccoprotic. substituted for the Carduus benedictus, and are thought to be of at least equal value.

CENTAUREA CALCITRAPA. The systematic name of the common star-thistie. Star-knapweed. Calcitrapa; Carduus stellatus; Jacea ramosissima, stellatu, rupina. The plant thus called in the pharmacoposias, is the Centaurea—calycibus subduplicato-spinosis, sessilibus; foliis pinnatifidis, linearibus dentatis; caule piloso, of Linnæus, every part of which is bitter. The juice, or extract, or infusion, is said to cure intermittents; and the bark of the root, and the seeds,

have been recommended in nephritic disorders, and in suppression of urine. It scarcely differs, in its effects, from other bitters, and is now little used.

Centaurea centaurium. Rhaponticum vulgare: Centaurium magnum; Centaurium majus. Greater centaury. The root of this plant was formerly used as an aperient and corroborant in alvine fluxes. It is now totally discarded from the Materia Medica of this

CENTAUREA CYANUS. The systematic name of the blue-bottle, or corn-flower plant. Cyani. Cyanus. The flowers of this plant, Centaurea—calycibus serratis : foliis linearibus, integerrimis, infimis dentatis, of Linnaus, were formerly in frequent use; but their antiphlogistic, antispasmodic, cordial, aperient, diuretic, and other properties, are now, with great propriety, forgotten.

Centaurea solstitialis. Calcitrapa officinalis; Carduus stellatus luteus; Carduus solstitialis; Jacea stellata; Jacea lutea capite spinoso minori; Leucanthe veterum. St. Barnaby's thistle. It is commended as an anticteric, anticachectic, and lithontriptic, but is, in reality, only a weak tonic.

Centaurio'des. The gratiola.

CENTAU'RIUM. (From κεν/αυρος, a centaur: so called, because it was feigned that Chiron cured Hercules's foot, which he had wounded with a poisonous

cules's foot, which he had wounded with a poisonous arrow, with it.) Centaury. See Chironia centaurium, CENTAURIUM MAGNUM. See Centaurea Centau-

CENTAURIUM MAJUS. See Centaurea Centaurium.
CENTAURIUM MINUS. See Chironia centaurium.
CENTAU'RY. See Chironia.
CENTIMOR'BIA. (From centum, a hundred, and morbus, a disease.) The Lysimachia nummularia, or moneywort, was so named, from its supposed efficacy in the cure of a multitude of disorders.

CENTINO'DIA. See Centum nodia.
CENTI'PES. (From centum, a hundred, and pes, a foot.) The woodlouse, so named from the multitude of its feet.

(From centrum, a centre.) The con-CENTRA'TIO. centration and affinity of certain substances to each other. Paracelsus expresses by it the degenerating of a saline principle, and contracting a corrosive and exulcerating quality. Hence Centrum salis is said to be the principle and cause of ulcers.

CE'NTRIUM. (From κεντέω, to prick.) A plaster recommended by Galen against stitches and pains in the side.

CE'NTRUM. (From κεντεω, to point or prick.) 1. The middle point of a circle.

2. In chemistry, it is the residence or foundation of

3. In medicine, it is the point in which its virtue resides.

4. In anatomy, the middle point of some parts is so named, as centrum nerveum, the middle or tendinous part of the diaphragm

CENTRUM OVALE. When the two hemispheres of the brain are removed on a line with a level of the corpus callosum, the internal medullary part presents a somewhat oval centre, which is called centrum ovale. Vieussenius supposed all the medullary fibres met at

the diaphragm. See Diapragm.

CENTUMNO'DIA. (From centum, a hundred, and nodus, a knot; so called from its many knots or joints.)

Centinodia. Common knot-grass. See Polygonum

CEPA. (From κηπος, a wool-card, from the likeness of its roots.) The onion. See Allium cepa.

CEPA. (From κηπος, a wool-card, from the likeness of its roots.) The onion. See Allium cepa.

CEPALA A species of onion.

CEPHALÆA. (From κεφαλη, the head.) 1. The flesh of the head which covers the skull.

2. A headache. Dr. Good makes this a genus of disease in his Order, Systatica; Class, Neurotica. It has five species, Cephalaa graverus, intensa, hemicrania, pulsatilis, nauscosa.

CEPHA'LALGIA. (From κεφαλη, the head, and αλγος, pain.) Cephalaa. The headache. It is symptomatic of very many diseases, but is rarely an original disease itself. When mild, it is called cephalalgia; when inveterate, cephalaea. When one side of the head only is affected, it takes the names of hemicrania, migrana, hemipagia, and megrim; in one of the temmigrana, hemipagia, and megrim; in one of the temples only, crotaphos; and that which is fixed to a point, generally in the crown of the head, is distinguished by the name of clavus.

CEPHALA'RTICA. (From κεφαλη, the head, and αρ-τίζω, to make pure.) Medicines which purge the head.

CE'PHALE.

CEPHALE. Κεφαλη. The head.
CEPHALIC. (From κεφαλη, the head.) Pertaining to the head. 1. A variety of external and internal medicines are so called, as being adapted for the cure of disorders of the head. Of this class are the snuffs, which produce a discharge from the mucous membrane of the nose, &c.

2. Nerves, arteries, veins, muscles, &c. are so called, which are situated on the head.

3. The name of a vein of the arm, which it was sup-

posed went to the head.

CEPHALIC VEIN. (Vena cephalica; so called be-cause the head was supposed to be relieved by opening it.) The anterior or outermost vein of the arm, that receives the cephalic of the thumb.

CEPHALICUS PULVIS. A powder prepared from asa-

CEPHALI'TIS. (From κεφαλη, the head.) Inflammation of the head. Empresma cephalitis of Good. See Phrenitis. CEPHALO.

This term is joined to others to denote the connexion of the muscle, artery, nerve, &c. to the

CEPHALONO'SUS. (From κεφαλη, the head and νόσος, a disease.) Any disease of the head. Applied to the febris hungarica, in which the head is principally affected.

CEPHALO-PHARYNGEUS. (From κεφαλη, the head, and φαρογξ, the throat.) A muscle of the pharynx. See Constrictor pharyngis inferior.

CEPHALOPONIA. (From κεφαλη, the head, and

CEPHALOPONIA. (From κεφαλη, the head, and συνος, pain.) Headache.
CEPI'NI. Vinegar.
CEPULA. Large myrobalans.
CERA. Wax. Bees' wax. A solid concrete substance, collected from vegetables by bees, and extracted from their combs after the honey is got out, by heating

from their combs after the honey is got out, by heating and pressing them.

It was long considered as a resin, from some properties common to it with resins. Like them it furnishes an oil and an acid by distillation, and is soluble in all oils; but in several respects it differs sensibly from resins. Like these, wax has not a strong aromatic taste and smell, but a very weak smell, and when pure, no taste. With the heat of boiling water, no principles are distilled from it; whereas, with that heat, some essential oil, or at least a spiritus rector, is obtained from every resin. Farther, wax is less soluble in alkohol. If wax be distilled with a heat greater than that of boiling water, it may be decomposed, but

CENTRUM NERVEUM. The centre of the diaphragm.

ce Diaphragm.

Centrum ovale. When the two hemispheres of the brain are removed on a line with a level of the propus callosum, the internal medullary part presents somewhat oval centre, which is called centrum ovale. The medullary fibres met at his place.

Centrum tendinosum. The tendinous centre of the diaphragm. See Diapragm.

The centre of the diaphragm.

not so easily as resins can. By this distillation, a small quantity of water is first separated from the wax, and then some very volatile and very penetrating acid, accompanied with a small quantity of a very fluid and very odoriferous oil. As the distillation advances, the acid becomes more and more strong, and the oil more and more thick, till its consistence is such that it becomes solid in the receiver, and is then called butter of wax. When the distillation is finished, nothing remains but a small quantity of coal, which is almost mains but a small quantity of coal, which is almost incombustible.

Wax cannot be kindled, unless it is previously heated and reduced into vapours; in which respect it resembles fat oils. The oil of butter of wax may, by repeated distillations, be attenuated and rendered more and more fluid, because some portion of acid is there-by separated from these substances; which effect is similar to what happens in the distillation of other oils and oily concretes: but this remarkable effect attends the repeated distillation of oil and butter of wax, that they become more and more soluble in alkohol; and they become more and more soluble in alkohol; and that they never acquire greater consistence by evaporation of their more fluid parts. Boerhaave kept butter of wax in a glass vessel, open, or carelessly closed, during twenty years, without acquiring a more solid consistence. It may be remarked, that wax, its butter, and its oil, differ entirely from essential oils and resins in all the above-mentioned properties, and that in all these they perfectly resemble sweet oils. Hence Maquer concludes, that wax resembles resins only in being an oil rendered concrete by an acid; but that it differs essentially from these in the kind of the oil, which in resins is of the nature of essential oils, while which in resins is of the nature of essential oils, while in wax and in other analogous oily concretions (as in wax and in other analogous only concretions (as butter of milk, butter of cocoa, fat of animals, spermaceti, and myrtle-wax) it is of the nature of mild unctuous oils, that are not aromatic, and not volatile, and are obtained from vegetables by expression. It seems probable, that the acidifying principle, or oxygen, and not an actual acid, may be the leading cause of the solidity, or low fusibility of wax.

In the state in which it is obtained from the combs, it is called vellow wax. cera flang; and this when

it is called yellow wax, cera flava; and this, when new, is of a lively yellow colour, somewhat tough, yet easy to break: by age, it loses its fine colour, and becomes harder and more brittle. Yellow wax, after being reduced into thin cakes, and bleached by a long exposure to the sun and open air, is again melted, and formed into round cakes, called virgin wax, or white wax, cera alba. The chief medicinal use of wax, is in plasters, unguents, and other like external applica-tions, partly for giving the requisite consistence to other ingredients, and partly on account of its own

emollient quality.

CERA ALBA. See, Cera.

CERA DICARDO. The carduus pinea.
CERA FLAVA. Yellow wax. See Cera.
[CERA VEGETABILIS. Vegetable wax, or natural wax. Wax seems to abound in some plants more than in others, and is easily collected from them. The bayberry (Myrica cerifera) abounds on the sandy shores of the United States, and in the autumn the wax is scraped from the plants, and, when melted and run into cakes, forms a beautiful green vegetable wax, which is made into wax tapers, or sometimes melted with a portion of tallow, and made into candles, which partake of the green colour of the wax, and are called barberry candles, the vegetable correction barberry candles. partake of the green colour of the wax, and are called bayberry candles, the vegetable cera giving hardness and consistence to the candles, and therefore more useful in the heat of summer. We recollect seeing a large specimen of white vegetable wax in the possession of Dr. S. L. Mitchill, received by him from South America, and exhibited to his class when he lectured on Materia Medica, in the College of Physicians and Surgeons of New-York. On inquiry, since, he informs us, that he never could ascertain the botanical name of the plant, though it was said to be a tree. A.]

of the plant, though it was said to be a tree. A.]

Cer π' π. (From κερας, a horn.) So Rufus Ephesius calls the cornua or appendages of the uterus.

CERANI'TES. (From κεραννυμι, to temper together.) name formerly applied to a pastil, or troch, by

CE'RAS. (Kepas, a horn.) A wild sort of parsnip is so named from its shape.

CE'RASA. (Κερασος, the cherry-tree; from Κερασος), a town in Pontus, whence Lucullus first brought than that of boiling water, it may be decomposed, but I them to Rome: or from knp, the heart; from the fruit

because cherries are an ingredient.) A purging medicine in Libavius.

CE'RASIN. The name given by Dr. John of Berlin, to those gummy substances which swell in cold water, but do not readily dissolve in it. Cerasin is soluble in boiling water, but separates in a jelly when the water cools. Water, acidulated with sulphuric, nitric, or muriatic acid, by the aid of a gentle heat, forms a permanent solution of cerasin. Gum tragacanth is the best example of this species of vegetable product.

CERA'SIUS. (From cerasus, a cherry.)
The name of two ointments in Mesue. Crasios.

Cera's Ma. (From κεραννυμι, to mix.) A mixture of cold and warm water, when the warm is poured into the cold.

CE'RASUS. The cherry and cherry-tree. See

Prunus cerasus.

CE'RATE. Ceratum. A composition of wax, oil, or lard, with or without other ingredients. The obsolete synonymes are, ceretaum, ceroma, ceronium, cerotum, ceratomalagma. Cerates take their name from the wax which enters into their composition, and to which they owe their consistence, which is intermediate between that of plasters and that of ointments; though no very definite rule for this consistence is, in

fact, either given or observed.

Cera'tia. (From κερας, a horn, which its fruit resembles.) See Ceratonia siliqua.

Ceraticum. See Ceratonia siliqua.

Cera'ticum. See Ceratonia siliqua.

CERA'Ticum. See Ceratonia siliqua.

CERA'Ticum. See Teratonia siliqua.

CERA'Ticum. See Teratonia siliqua.

Cera'ticum. See Teratonia siliqua.

Cera'ticum. See Teratonia siliqua.

shape.
 Cerato-glossus. (From κερας, a horn, and γλωσσα, a tonghe.) A muscle, so named from its shape and insertion into the tongue. See Hyoglossus.
 Cerato-hyoideus. See Stylo-hyoideus.
 Cerato malagma. A cerate.
 Cerato malagma. A cerate.
 Cerato malagma. A cerate.
 Cerato malagma. See Stylo-hyoideus.
 Cerato malagma. A cerate.
 Cerato malagma. A cerate.
 Cerato malagma. A cerate.
 Cerato malagma. Gerato malagma. See Cornea.
 Cerato malagma. (Κερατωνία of Galen and Paulus Ægineta; so cailed from its horn-like pod.) The name of a genus of plants. Class, Polygamia; Order, Triggia.

Triacia.

Ceratonia siliqua. The systematic name of the plant which affords the sweet pod. Ceratium; Coratia; Siliqua dulcis. The pods are about four inches in length, and as thick as one's finger, compressed and unequal, and mostly bent; they contain a sweet brown pulp, which is given in the form of decoction, as a pectoral in asthmatic complaints and coughs.

CERATUM. (Ceratum; i. m.; from cera, wax, because its principal ingredient is wax.) See Cerate.

Ceratum album. See Ceratum cetacci.

Ceratum calamine. Ceratum lapidis calaminaris; Ceratum epuloticum. Calamine cerate. Take of prepared calamine, yellow wax, of each half a pound; olive oil, a pint. Mix the oil with the melted wax; then remove it from the fire, and, as soon as it begins to thicken, add the calamine, and stir it con-

begins to thicken, add the calamine, and stir it constantly until the mixture becomes cold. A composi-tion of this kind was first introduced under the name of Turner's cerate. It is well calculated to promote the cicatrization of ulcers.

CERATUM CANTHARIDIS. Ceratum Lyttæ. Cerate of blistering fly. Take of spermaceti cerate, six drachms; blistering flies, in very fine powder, a drachm. Having softened the cerate by heat, add the flies, and

mik them together.

CERATUM CETACEI. Cratum spermatis ceti. Ceratum album. Spermaceti cerate. Take of spermaceti, half an ounce; white wax, two ounces; olive
oil, 4 fluid-ounces. Add the oil to the spermaceti and on, 4 fund-ounces. And the off to the spermaceu and wax, previously melted together, and stir them until the mixture becomes cold. This cerate is cooling and emollient, and applied to excoriations, &c.: it may be used with advantage in all ulcers, where no stimulating substance can be applied, being extremely mild and unctuous.

having a resemblance to it in shape and colour.) The cherry. See Prunus.

Cerasa Nigra. See Prunus avium.

Cerasa Rubra. See Prunus cerasus.

Cerasia Tum. (From cerasus, a cherry; so called because cherries are an ingredient.) A purging medical section of the formulæ of St. Bartholomew's hospital, occasionally applied to cancerous, scrofulous, phage-denic, herpetic, and other inveterate sores.

Ceratum epuloticum. See Ceratum calamina.

Ceratum Lapidis Calamina. See Ceratum

CERATUM LITHARGYRI ACETATI COMPOSITUM. See

Ceratum plumbi compositum. CERATUM PLUMBI ACETATIS. CERATUM PLUMBI ACETATIS. Unguentum cerussæ acetatæ Cerate of acetate of lead. Take of acetate of lead, powdered, two drachms; white wax, two ounces; olive oil, half a pint. Dissolve the wax in seven fluid-ounces of oil; then gradually add thereto the acetate of lead, separately rubbed down with the remaining oil, and stir the mixture with a wooden slice, until the whole has united. This cerate is cooling and desiceative.

ing and desiccative.

CERATUM PLUMBI COMPOSITUM. Ceratum lithargyri acctati compositum. Compound cerate of lead. Take of solution of acetate of lead, two fluid-ounces and a compound cerate of lead, two fluid-ounces and a compound cerate of lead. of solution of acetate of lead, two hald ounces and a half; yellow wax, four ounces; olive oil, nine fluid-ounces; camphor, half a drachm. Mix the wax pre-viously melted, with eight fluid-ounces of oil; then remove it from the fire, and, when it begins to thicken, add gradually the solution of acetate of lead, and constantly stir the mixture with a wooden slice until it gets cold. Lastly, mix in the camphor, previously dissolved in the remainder of the oil. Its virtues are cooling, desiccative, resolvent against chronic rheumatism for the cold and a proper application to

gets cold. Lastly, mix in the camphor, previously dissolved in the remainder of the oil. Its virtues are cooling, desiccative, resolvent against chronic rheumatism, &c. &c.; and as a proper application to superficial ulcers, which are inflamed.

Ceratum resinæ. Ceratum resinæ flavæ; Ceratum citrinum. Resin cerate. Take of yellow resin, yellow wax, of each a pound; olive oil, a pint. Melt the resin and wax together, over a slow fire; then add the oil, and strain the cerate, while hot, through a linen cloth. Digestive.

Ceratum sabinæ. Savine cerate. Take of fresh leaves of savine, bruised, a pound; yellow wax, half a pound; prepared lard, two pounds. Having melted together the wax and lard, boil therein the savine leaves, and strain through a linen cloth. This article is of late introduction, for the purpose of keeping up a discharge from blistered surfaces. It was first described by Mr. Crowther, and has since been received into extensive use, because it does not produce the inconveniences that follow the constant application of the common blistering cerate. A thick white layer forms daily upon the part, which requires to be removed, that the cerate may be applied immediately to the surface from which the discharge is to be made.

Ceratum saponis. Soap cerate. Take of hard soap, eight ounces: yellow wax, ten ounces; semi-vitreous oxide of lead, powdered, a pound; olive oil, a pint; vinegar, a gallon. Boil the vinegar, with the oxide of lead, over a slow fire, constantly stirring, until the union is complete; then add the soap, and boil it again in a similar manner, until the moisture is entirely evaporated; then mix in the wax, previously melted with the oil. Resolvent; against scrofulous tumoures: having melted the wax, mix the oil with it. Ceratum sepanatis ceri. See Ceratum cetacei. Ce'rberus, it has three heads, or principal ingredients, each of which is eminently active.) A fanciful name given to the compound powder of scammony.

of which is eminently active.) A functiful name given to the compound powder of scammony.

CERCHNA'LEUM. (From κερχω, to make a noise.)

A wheezing, or bubbling noise, made by the trachea,

A wheezing, or bubbling noise, made by the trachea, in breathing.

CE'RCHNOS. (From κερχω, to wheeze.) Cerchnus. Wheezing. Dr. Good applies it to a species of his genus Rhonchus, to designate a primary evil or disease; rhonchus cerchnus, or wheezing.

CERCHNO'DES. (From κερχω, to wheeze.) Cerchodes. One who labours under a dense breathing, accompanied with a wheezing noise.

CERCHO'DES. See Cerchnodes.

CE'RCIS. (Κερκις literally means the spoke of a wheel, and has its name from the noise which wheels often make; from κρεκω, to shriek.) The radial bone of the fore-arm was formerly so called from its shape, like a spoke Also a pestle from its shape. CERATUM CITRINUM. See Ceratum resine.

Of the fore-arm was formerly so called from CERATUM CONIL. Hemlock cerate. B. unguenti like a spoke. Also a pestle from its shape.

CERCO'SIS. (From KEPKOS, a tail.) 1. A polypus [of the uterus

of the uterus.

2. An enlargement of the clitoris.

CE'REA. (From cera, wax.) The cerumen aurium, or wax of the ear.

CEREA'LIA. (Solemn feasts to the goddess Ceres.)

All sorts of corn, of which bread or any nutritious substance is made, come under the head of cerealia, which term is applied by bromatologists as a genus.

CEREBE'LLA URINA. Paracelsus thus distinguishes urine which is whitish, of the colour of the brain, and from which he pretended to judge of some of its dis-

from which he pretended to judge of some of its dis-

CEREBE'LLUM. (Diminutive of cerebrum.) The little brain. A somewhat round viscus, of the same use as the brain; composed, like the brain, of a cortical and meduliary substance, divided by a septum into a right and left lobe, and situated under the tentorium, in the inferior occipital fossæ. In the cerebellum are to be observed the crura cerebelli, the fourth ventricle, the valvula magna cerebri, and the protuberantic vermiformes.

fourth ventricle, the valvula magna cerebri, and the protuberantic vermiformes.

CE'REBRUM. (Quasi cerebrum; from kapa, the head.) The brain. A large round viscus, divided superiorly into a right and left hemisphere, and inferiorly into six lobes, two anterior, two middle, and two posterior; situated within the cranium, and surrounded by the dura and pia mater, and tunica arachnoides. It is composed of a cortical substance, which is external; and a medullary, which is internal. It has three cavities, called ventricles; two anterior, or lateral, which are divided from each other by the septum lucidum, and in each of which is the choroid plexus, formed of blood-vessels; the third ventricle is a space between the thalami nervorum opticorum. a space between the thalami nervorum opticorum. The principal prominences of the brain are, the corpus callosum, a medullary eminence, conspicuous upon laying aside the hemispheres of the brain; the corpora striata, two striated protuberances, one in the anterior part of each lateral ventricle; the thalami nervorum opticorum, two whitish eminences behind the former, opticorum, two whitish eminences behind the former, which terminate in the optic nerves; the corpora quadrigemina, four medullary projections, called by the ancients nates and testes; a little cerebrine tubercle lying upon the nates, called the pineal gland; and, lastly, the crura cerebri, two medullary columns, which proceed from the basis of the brain to the medulla oblongata. The cerebral arteries are branches of the carotid and vertebral arteries. The veins terminate which return their blood into minate in sinuses, which return their blood into the internal jugulars. The use of the brain is to give off nine pairs of nerves, and the spinal marrow, from which thirty-one more pairs proceed, through whose means the various senses are performed, and muscular motion excited. It is also considered as the organ of the intellectual functions.

Vauquelin's analysis of the brain is in 100 parts; 80 water, 4.53 white fatty matter, 0.7 reddish fatty matter, 7 albumen, 1.12 osmazome, 1.5 phosphorus, 5.15 acids,

salts, and sulphur.

CEREBRUM ELONGATUM. The medulla oblongata, and medulla spinalis.

CEREFO LIUM. A corruption of charophyllum.

See Scandiz cerefolium. CEREFOLIUM HISPANICUM. Sweet-cicely. See Scan-

CEREFOLIUM SYLVESTRE. See Charophyllum syl-

CERELÆ'UM. (From κηρος, wax, and ελαιον, oil.) A cerate, or liniment, composed of wax and oil. Also the oil of tar.

CEREOLUS. A wax bougle.
CEREUS MEDICATUS. See Bougle.
CEREVI'SIA. (From ceres, corn, of which it is made.) Any liquor made from corn, especially ale and strong beer.

CEREVISIE CATAPLASMA. Into the grounds of strong beer, stir as much oatmeal as will make it of a suitable consistence. This is sometimes employed as a stimulant and an antiseptic to mortified parts.

CEREVISIÆ FERMENTUM. See Fermentum Cere-

CE BIA. (From cercus, soft, pliant.) The flat worms which breed in the intestines. See Ταπία. CERIN. 1. Subercerin. A peculiar substance

which precipitates on evaporation from alkohol, which has been digested on cork.

2. The name given by Dr. John to the part of com-mon wax which dissolves in alkohol.

mon wax which dissolves in alkohol.

3. The name of a variety of the mineral allanite.

Ce Rion. (From κηριον, a honey-comb.) An eruptive disorder of the head. See Actor.

CERITE. The sillciferous oxide of cerium. A rare mineral of a rose-red colour, found only in the copper mine of Bastnacs, in Sweden. It consists of silica, oxide of cerium, and oxide of iron, lime, and carbonic acid.

CERIUM. The name of the metal, the oxide of which exists in the mineral cerite.

To obtain the oxide of the new metal, the cerite is To obtain the exide of the new metal, the ceffic is calcined, pulverized, and dissolved in nitromuriatic acid. The filtered solution being neutralized with pure potassa, is to be precipitated by tartrate of potassa; and the precipitate, well washed, and afterwards calcined, is oxide of cerium.

Cerium is susceptible of two stages of oxidation; in the first it is white, and this by calcination becomes of a fullow-red.

The white oxide exposed to the blowpipe soon becomes red, but does not melt, or even agglutinate.
With a large proportion of borax it fuses into a transparent globule

The white oxide becomes yellowish in the open air, but never so red as by calcination, because it absorbs carbonic acid, which prevents its saturating itself with oxygen, and retains a portion of water, which dimi-

nishes its colour. Alkalies do not act on it; but caustic potassa in the dry way, takes part of the oxygen from the red oxide so

as to convert it into the white without altering its nature.

The protoxide of cerium is composed by Hisinger of 85.17 metal + 14.83 oxygen, and the peroxide of 79.3 metal + 20.7. The protoxide has been supposed a binary compound of cerium 5.75 + oxygen 1, and the peroxide a compound of 5.75 × 2 of cerium + 3 oxygen 2 oxygen 2 oxygen 2 oxygen 2 oxygen 3 oxygen 4 oxygen 3 oxygen 3 oxygen 4 oxygen 3 oxygen 4 oxygen 3 oxygen 4 oxygen

gen. An alloy or this inc.
by Vauquelin.
The salts of cerium are white or yellow-coloured,
The salts of cerium are white precipitate with hy-The salts of cerium are white or yellow-coloured, have a sweet taste, yield a white precipitate with hydrosulphuret of potassa, but none with sulpheretted hydrogen; a milk-white precipitate, soluble in nitric and muriatic acids, with ferroprussiate of potassa, and oxalate of ammonia; none with infusion of galls, and a white one with arseniate of potassa.

CERO'MA. (From κηρος, wax.) Ceronium. Terms used by the ancient physicians for an unquent, or cerate, though originally applied to a particular composition which the wrestlers used in their exercises.

CEROPI'SSUS. (From κηρος, wax., and ωίσσα, pltch.) A plaster composed of pitch and wax.

CEROTUM. Κερωτον. A cerate.

[CERULIN. "By the action of sulphuric acid on indigo, two new substances are obtained, termed, by Mr. Crum, Cerulin and Phenicin. To prepare the former, the indigo is digested in the acid, the mixture is dissolved in a large quantity of sulphuric acid, and the

the indigo is digested in the acid, the mixture is dissolved in a large quantity of sulphuric acid, and the filtered solution is precipitated by potassa. The precipitate consists of cerulin, in combination with the sulphate of potassa, and has been called Cerulco-sulphate of potassa. It requires about 120 parts of water for its solution, and forms a very deep blue-coloured liquid. In its property of forming insoluble compounds with neutral salts, cerulin is analogous to tan. From its ultimate analysis, it appears to consist of 1 atom of indigo + 4 atoms of water."—Webster's Man. of Chem. A.]

CERU'MEN. (Cerumen ; diminutive of cera, wax.) Wax. See Cera.

CERUMEN AURIUM. Cerea; Aurium sordes; Mar-morata aurium; Cypsele; Cypselis; Fugile. The waxy secretion of the car, situated in the meatus audi-

wary secretion of the ear, situated in the include adultorius externus.

["Cerumen auris. A degree of deafness is frequently produced by the lodgment of hard dry pellets of this substance in the meatur auditorius. The best plan, in such cases, is to syringe the ear with warm water, which should be injected with moderate force. In some instances, deafness seems to depend on a defective secretion of the cerumen, and a consequent dryness of the meatur. Here, a drop or two of sweet oil. ness of the meatus. Here, a drop or two of sweet oil may now and then be introduced into the ear, and fomentations applied."—Cooper's Surg. Dict. A.] CERU'SSA. (Arabian.) Cerusee. See Plumbi sub-

carbonas.

CERUSSA ACETATA. See Plumbi acetas.

CERVI SPINA. See Rhamnus catharticus. CERVI CAL. (Cervicalis; from cerviz, the neck.) Belonging to the neck; as cervical nerves, cervical

Cervical artery. Arteria cervicalis. A branch of

the subclavian.

Cervical vertebra. The seven uppermost of the vertebre, which form the spine. - See Vertebra.

CERVICA'RIA. (From cervic, the neck; so named hecause it was supposed to be efficacious in disorders and ailments of the throat and neck.) The herb throat-

CE'RVIX. (Cervix, vicis. f.; quasi cerebri via; as being the channel of the spinal marrow.) 1. The neck. That part of the body which is between the head and shoulders.

Applied also to organs, or parts which have some extent, to distinguish their parts; as the cervix uteri, neck of the uterus; cervix vesica, neck of the bladder,

neck of a bone, &c.

CESPITITIE PLANTE. (From cespes, a sod, or turf.)
The name of a class of plants in Sauvages' Methodus Foliorum, consisting of plants which have only radical

leaves; as primrose, &c.

CESPITOSUS. (From cespes, a sod, or turf.) A
plant is so called which produces many stems from one
root, thereby forming a close thick carpet on the surface of the earth.

CESTRI'TES. (From κεςρον, betony.) Wine im-

pregnated with betony.

CE'STRUM. (From κεςρα, a dart; so called from the shape of its flowers, which resemble a dart; or because it was used to extract the broken ends of darts from wounds.) See Betonica oficinalis. CETA'CEUM. Spermaceti. See Physeter macro-

cephalus.
CE'TERACH. (Blanchard says this word is cor-

rupted from Pteryga, \$\pi/\eta\pi\pi\sigma\text{, q. v. as peteryga, ceteryga, and ceterach.}\ See Asplenium ceterach.

CETIC ACID. Acidum ceticum. The name given by Chevreuil to a supposed peculiar principle of spermaceti, which he has lately found to be the substance be basefulled manufacture combined with a fatte parties.

maceti, which he has lately found to be the substance he has called margarine, combined with a fatty matter.

CETINE. The name given by Chevreuit to spermaceti. See Fat.

CEVADIC ACID. By the action of potassa on the fat matter of the cevadilla, a plant that comes from Senegal, called by the French petite orge, there is obtained in the same way as the delphinic acid, an acid which is called the cevadic.

CEVADATE. A salt formed by the combination of the cevadic acid, with earthy, alkaline, and metallic bases.

CEVADILLA. (Dim. of ceveda, barley. Spanish.) See Veratrum sabatilla.

Covenne pepper. See Capsicum. CEYLANITE. The name of the mineral called pleonaste, by Hady, which comes from Ceylon, com-monly in round pieces, but occasionally in crystals. It is of an indigo blue colour, and splendent internally.

CHARASITE. The name of a mineral found in the quarry of Alteberg, near Oberstein, in crystals, the primitive form of which is nearly a cube. It is white, or with a tinge of rose colour, and sometimes transparent.

with a tinge of rose colour, and sometimes transparent.

CHACARI'LLE CORTEX. See Croton Cascarilla.

CHEROFO'LIUM. See Scandix.

CHEROPHY'LLUM. (Χαιροφυλλον; from χαιρος, to rejoice, and φυλλον, a leaf; so called from the abundance of its leaves.) Chervil. 1. The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Digynia.

2. The pharmacopæial name of some plants. See Scandix, and Chærophyllum sylvestre.

Chærophyllum sylvestre. The systematic name of the Cicutaria, or bastard hemlock. Chærophyllum:

of the Cicutaria, or bastard hemlock. Charophyllum; caule lavi striato; geniculis tumidiusculis, of Linnaus. It is often mistaken for the true hemlock. It may with great propriety be banished from the list of officinals, as it possesses no remarkable property.

CHA'TA. (From χεω, to be diffused.) An obsolete name of the human bair.

CHA'TA (From χεω, to relay.) Relaya-

CHALA'SIS. (From xalaw, to relax.) Relaxa-

CHALA'STICA. (From χαλαω, to relax.) Medicines which relax.

CHALA'ZION. (From χαλαζα, a hailstone.) Chalaza; Chalazium; Granado. An indolent moveable tubercle on the margin of the eyelid, like a hail-stone. A species of hordeolum. It is that well-known affection of the eye, called a stye, or stian. It is white, hard, and encysted, and differs from the crithe, another species, only in being moveable. Writers mention a division of Chalazion into scirrhous, cancerous, cystic, and earthy.

CHA'LBANE. Καλβανη. Galbanum.
CHALCA'NTHUM. (From χαλκος, brass, and ανθος, a flower.) Vitriol; or rather, vitriol calcined red. The flowers of brass.

CHALCELON. A species of pimpinella. CHALCOLOUM OS. The OS cunciforme of the tar

CHALLOS DELM OS. THE OS CUMENTOME OF the tar-sus. See Cunciform bone. CHALLITIS. See Colcothar. CHALLICRATUM. (From χαλις, an old word that sig-nifies pure wine, and κεραννυμι, to mix.) Wine mixed with water.

CHALI'NOS. Chalinus. That part of the cheeks, which, on each side, is contiguous to the angles of the mouth.

CHALK. A very common species of calcareous earth, or carbonate of lime, of a white colour. See Creta.

CHALK, BLACK. Drawing slate, found in primitive mountains, and used in crayon drawing, whence its

CHALK, RED. A clay coloured with oxide of iron. CHALK-STONE. A name given to the concretions in the hands and feet of people violently afflicted with the gout, from their resembling chalk, though chemi-cally different. Dr. Wollaston first demonstrated their true composition to be uric acid combined with ammonia, and thus explained the mysterious pathological relation between gout and gravel.

Gouty concretions are soft and friable. They are insoluble in cold, but slightly in boiling water. An acid being added to this solution, seizes the soda, and the uric acid is deposited in small crystals. These concretions dissolve readily in water of potassa. An artificial compound may be made by triturating uric acid and soda with warm water, which exactly resembles gouty concretions in its chemical constitution.

CHALY'BEATE. (Chalybeatus; chalybs, from iron, or steel.) Of or belonging to iron. A term given to any medicine into which iron enters; as chalybeate

mixture, pills, waters, &cc.

CHALYBEATE WATER. Any mineral water which abounds with iron; such as the water of Tunbridge, Spa, Prymont, Cheltenham, Scarborough, and Hartfel;

and many others. [Chalybeate waters are so numerous in the United States as to attract little or no attention unless connected with some peculiarity of circumstance, besides the mere solution of iron. The Ballston and Saratoga waters, of New-York, although they contain iron, are not ranked among the chalybeates, having other and more powerful ingredients in their composition. Of the pure chalybeate waters, containing nothing but iron in solution, those most resorted to for health and pleasure are the Stafford Springs, in Connecticut, and Orange, and Schooley's Mountain Springs in New-Jersey. The Stafford Springs are at the foot of a sand-stone ridge, (old red sand-stone formation of Werner.) Orange Springs are in the same sand-stone formation, in the beautiful town of Orange, in New-Jersey, about 20 miles from New-York. There is an excellent house of entertainment at the springs, and there is a salubrious and well-cultivated country surrounding it. Adjacent to the springs is a considerable elevation, from which an extensive prospect is obtained. The city and bay of New-York are plainly visible, with other and more distant prospects. The water of the springs is strongly impregnated, is not very palatable, and is only drunk by invalids, whose physicians recommend

Schooley's Mountain Spring is about 60 miles from New-York, and about the same distance from Phila-delphia, and is resorted to in summer by the inhabitants of both cities, and other places. It is on the side of a mountain nearly 1500 feet above tide water. The water runs in a constant stream from the crack of a rock by the side of the road leading down a ravine of the mountain, which from its elevation is cool and salubrious. On the top of the mountain is an extensive

plain, crossed by good roads. There are several public houses in the neighbourhood of the spring. The water is a simple chalybeate, without being acrated. The iron is deposited in an ochreous sediment as the water passes over the rock. The mountain appears to be a vast deposite of iron ore, much of which is magnetic, affecting the surveyor's compass. Loose specimens of magnet are occasionally picked up on the

CHALYBIS RUBIGO PREPARATA. See Ferri subcar-

CHA'LYBS. (From Chalybes, a people in Pontus, who dug iron out of the earth.) Acies. Steel. The best, hardest, finest, and the closest-grained forged iron. As a medicine, steel differs not from iron. See

CHALYBS TARTARIZATUS. See Ferrum tartariza-

CHAMÆBA'LANUS. (From χαμαι, on the ground, and βαλανος, a nut.) Wood pea; Earth nut. CHAMÆBU'XUS. (From χαμαι, on the ground, and πυξος, the box-tree.) The dwarf box-tree. CHAMÆCE'DRUS. (From χαμαι, on the ground, and makes the sadar-tree) Chamæcederus. A species and kzopos, the cedar-tree.) Chamacedrys. A species of dwarf abrotanum.

CHAMÆCI'SSUS. (From χαμαι, on the ground, and κισσος, ivy.) Ground-ivy.

CHAMÆCI'SSUS. (From χαμαι, on the ground, and κισσος, ivy.) Ground-ivy.

CHAMÆCLE'MA. (From χαμαι, on the ground, and κλημα, ivy.) The ground-ivy.

CHAMÆCRISTA. The Cassia chamæcrista of Linnæus, a decoction of which drank liberally is said to be serviceable against the poison of the night-shade.

CHAMÆ'DRYS. (From χαμαι, on the ground, and έρυς, the oak; so called from its leaves resembling those of the oak.) See Teucrium chamædrys.

CHAMÆDRYS FRUTESCENS. A name for teucrium.

CHAMÆDRYS INCANA MARITIMA. See Teucrium

CHAMÆDRYS INCANA MARITIMA. See Teucrium

CHAMEDRYS PALUSTRIS. See Teucrium scordium. CHAMEDRYS SPURIA. See Veronica officinalis. CHAMEDRYS SYLVESTRIS. Wild germander. The

CHAMÆLE'A. (From χαμα:, on the ground, and ελαια, the olive-tree.) See Daphne alpina.

CHAMÆLÆA GNUS. (From χαμαι, on the ground, and ελαιαγνος, the wild olive.) See Myrica

gale.

CHAMÆ'LEON. (From χαμαι, on the ground, and λεων, a lion, i. c. dwarf lion.) 1. The chamæleon, an animal supposed to be able to change his colour at

2. The name of many thistles, so named from the

variety and uncertainty of their colours.

CHAMÆLEON ALBUM. See Carlina acaulis.

CHAMÆLEON VERUM. See Cnicus.

CHAMÆLEU'CE. (From χαμαι, on the ground, and λευκη, the herb colt's-foot.) See Tussilago far-

Chamæli'num. (From xaµai, on the ground, and pop, flax.) Purging flax. See Linum catharticum.

λινον, flax.) Purging flax. See Linum catharticum. CHAMÆME LUM. (From χαμαι, on the ground, and μηλον, an apple; because it grows upon the ground, and has the smell of an apple.) See Anthemis

CHAMEMELUM CANARIENSE. The Chrysanthemum frutescens of Linnaus,

CHAMEMELUM CHRYSANTHEMUM. The Bupthalmum germanicum of Littuens.
CHAMENELUM PETIDUM. The Anthemis cotule of

Linnæus.

CHAM EMBLUM NOBILE. See Anthemis nobilis. CHAMEMELUM VULGARE. See Matricario chamo-

CHAMÆ MORUS. (Χαμαιμορία; from χαμαι, on the ground, and μορία, the mulberry-tree.) See Rubus

CHAMÆPEU'CE. (From χαμαι, on the ground, and πευκη, the pine-tree.) See Camphorosma Mons-

CHAMÆ PITYS. (Chamæpitys, yos. f.; from χαμαι, the ground, and ωιτυς, the pine-tree.) See Ten-

crium chamæpitys. CHAMEPITYS MOSCHATA. The French ground pine.

CHAMÆ'PLION. See Erysimum alliaria.

CHAMERA PHANUS. (From xanat, on the ground, and pandavos, the radish.) 1. The upper part of the

root of apinm, according to P. Ægineta. The smallage, or parsley.

2. The dwarf radish.

CHAM & RIPHES. The Chamerops humilis, or dwarf

CHAM & RODODE'NDRON. (From xapat, on the ground, and pococcipor, the rose laurel.) The Azalwa pontica and počočerepov, the rose laurel.)

of Linneus.

Chamerubus. (From χαμαι, on the ground, and rubus, the bramble.) See Rubus chamemorus.

Chamerubus. (From χαμαι, on the ground, and σπαρτιον, Spanish broom.) See Genista tinctoria.

Chamerubus. Camara. The space between the capsule of the crystalline lens and the corner of the eye, is divided by the iris into two spaces, called chambers; the space before the iris is termed the anterior chamber; and that behind it, the posterior. They are filled with an aqueous fluid.

Chamerubus. Chamerubus. Chamerubus. Chamber in the same profession. They invented among them an instrument, the obstetric forceps, which greatly facilitated delivery in many cases, and often saved the them an instrument, the obstetric forceps, which greatly facilitated delivery in many cases, and often saved the child: but to him alone, as most distinguished, the merit has been usually ascribed. In 1683, he published a translation of Mauriceau's Observations, which was much sought after. The instrument procured him great celebrity in this, as well as other countries; and, with successive improvements by Smellie, &c. still continues to be esteemed one of the most valuable adjuvants in the obstetric art. The period of his death adjuvants in the obstetric art. The period of his death is not ascertained.

CHA RABE. (From χαρασσω, to excavate.) The bowels, or sink of the body.

bowels, or sink of the body.

Charamais. The purging hazel-nut.

Charamais. See Momordica elaterium.

CHARGOAL. When vegetable substances are exposed to a strong heat in the apparatus for distillation, the fixed residue is called charcoal. For general purposes, wood is converted into charcoal by building it up in a pyramidal form, covering the pile with clay or earth, and leaving a few air holes, which are closed as soon as the mass is well lighted; and by this means the combustion is carried on in an imperfect manner. the combustion is carried on in an imperfect manner.

In charring wood it has been conjectured, that a portion of it is sometimes converted into a pyrophorus, and that the explosions that happen in powder-mills

are sometimes owing to this.

Charcoal is made on the great scale, by igniting wood in iron cylinders. When the resulting charcoal

CHE CHA

crude vapours be prevented, by cutting off the commu-nication between the interior of the cylinders and the apparatus for condensing the pyrolignous acid, when-ever the fire is withdrawn from the furnace. If this

precaution be not observed, the gunpowder made with the charcoal would be of inferior quality.

In the third volume of Tilloch's magazine, we have some valuable facts on charcoal, by Mr. Mushet. He justly observes, that the produce of charcoal in the small way, differs from that on the large scale, in which the quantity of char depends more upon the hardness and compactness of the texture of wood, and the skill of the workman in magazing the pyramid the skill of the workman in managing the pyramid of fagots, than on the absolute quantity of carbon it

Clement and Desormes say, that wood contains one-half its weight of charcoal. Proust says, that good pit-coals afford 70, 75, or 80 per cent. of charcoal or coke; from which only two or three parts in the hundred of ashes remain after combustion .- Tilloch's Mag. vol.

viii.

Charcoal is black, sonorous, and brittle, and in general retains the figure of the vegetable it was obtained from. If, however, the vegetable consist for the most part of water or other fluids, these in their extrication will destroy the connexion of the more fixed parts. In this case the quantity of charcoal is much less than in the former. The charcoal of oily or bituminous substances is of a light pulverulent form, and rises in soot. This charcoal of oils is called lamp-black. A very fine kind is obtained from burning alkohol. See

CHA'RDONE. The artichoke.

CHARISTOLO CHIA. (From $\chi a \rho i s$, joy, and $\lambda o \chi i a$, the lochia; so named from its supposed usefulness to women in childbirth.) The plant mogwort. See Ar-

CHARLTON, WALTER, was born in Somerset-shire, 1619. After graduating at Oxford, where he distinguished himself by his learning, he was appointed physician to Charles L, and admitted a fellow of the Royal College of Physicians, in London. He had afterward the honour of attending Charles IL, and was one of the first members of the Royal Society. He was author of several publications, on medical and other subjects; the former of which contained little original matter, but had the merit of spreading the knowledge of the many improvements made about knowledge of the many improvements made about that period, particularly in anatomy and physiology; the principal of them are his "Exercitationes Pathologicas," and his "Natural History of Nutrition, Life, and Voluntary Motion." In 1689, he was chosen president of the College, and held that office two years He afterward retired to Jersey, and died in 1707.

Cha'rme. (From xaips, to rejoice.) Charmis. A cordial mentioned by Gaien.

Cha'rpie. The French. For scraped linen, or lint. CHA'rpie. The French. For scraped linen, or lint. CHA'rpie. The annios, or interior fortal membrane, was called the charta virginea, from its likeness to a piece of fine paper.

CHARTREUX, POUDRE DE. (So called because it was said to have been invented by some friars of the Carthusian order.) A name of the kermes mineral, or hydrosulphuret of antimony.

CHA'SME. (From xaivw, to gape.) Chasmus. Os-

citation, or gaping.

CHASTE TREE. See Agrus castus.

CHA'TE. The Cucumus agyptia.

["CHAUNCEY, CHARLES, M.D. second President of Harvard College, was born in England in 1589. He had his grammar education at Westminster, and was at the school when the gunpowder plot was to have taken effect, and must have perished if the parliament-house had been blown up. At the university of Cambridge he commenced Bachelor of Divinity, and took the degree of M.D. Being intimately acquainted with Archbishop Usher, one of the finest scholars in Europe, he had more than common advantages to expand his mind and marks in the common advantages. his mind, and make improvements in literature. A more learned man than Mr. Chauncey was not to be found among the fathers of New-England. He had been chosen Hebrew professor at Cambridge, by the heads of both houses, and exchanged this branch of

is to be used in the manufacture of gunpowder, it is instruction to oblige Dr. Williams, Vice-Chancellor of essential that the last portion of vinegar and tar be suffered to escape, and that the reabsorption of the languages, but especially the Hebrew, which he knew by very close study, and by conversing with a Jew, who resided in the same house. He was also an accurate Greek scholar, and was made professor of this language when he left the other professorship. This uncommon scholar became a preacher, and was settled at Ware. He displeased archbishop Land, by opposing the book of sports, and reflecting upon the discipline of the church, which caused him to emigrate to Plymouth, in Massachusetts in 1638 to Plymouth, in Massachusetts, in 1638.

President Channesy is said to have been an eminent physician; but we are not informed to what extent he devoted himself to the practice. He left six sons, all of whom were educated at Harvard college, and were preachers. Some of them were learned divines. Dr. Mather says they were all eminent physicians, as their father was before them."—Thach. Med. Biog. A.]

Chay. See Oldenlandia umbellata. See Oldenlandia umbellata.

CHEEK-BONE. See Jugale os. CHEESE. Caseus. The coagulum of milk. When prepared from rich milk, and well made, it is very nutritious in small quantities; but mostly indigestible when hard and ill prepared, especially to weak sto-machs. If any vegetable or mineral acid be mixed with milk, the cheese separates, and, if assisted by heat, coagulates into a mass. The quantity of cheese is less when a mineral acid is used. Neutral salts, is less when a mineral acid is used. Neutral salts, and likewise all earthy and metallic salts, separate the cheese from the whey. Sugar and gum-arabic produce the same effect. Caustic alkalies will dissolve the curd by the assistance of a boiling heat, and acids occasion a precipitation again. Vegetable acid by occasion a precipitation again. Vegetable acids have very little solvent power upon curd. This accounts for a greater quantity of curd being obtained when a vegetable acid is used. But what answers best is reanet, which is made by macerating in water a piece of the last stomach of a calf, salted and dried for this

Scheele observed, that cheese has a considerable analogy to albumen, which it resembles in being coagulable by fire and acids, soluble in ammonia, and affording the same products by distillation or treatment with nitric acid. There are, however, certain differences between them. Rouelle observed, likewise, a striking analogy between cheese and the gluten of wheat, and that found in the feculæ of green vegetables. By kneading the gluten of wheat with a little salt and a small portion of a solution of starch, he gave it the small portion of a solution of starch, he gave it the taste, smell, and unctuosity of cheese; so that after it had been kept a certain time, it was not to be distinguished from the celebrated Rochefort cheese, of which it had all the pungency. This caseous substance from glutch, as well as the cheese of milk, appears to contain acetate of ammonia, after it has been kept long enough to have undergone the requisite fermentation, as may be proved by examining it with sulphuric acid, and with potassa. The pungency of strong cheese, too, is destroyed by alkohol.

In the 11th volume of Tilloch's Magazine, there is an excellent account of the mode of making Cheshire cheese, taken from the Agricultural Report of the county. "If the milk," says the reporter, "be set together very warm, the curd will be firm; in this case, the usual mode is to take a common case-knife, and make incisions across it, to the full depth of the knife's blade, at the distance of about one inch; and again crossways in the same manner, the incisions intersecting each other at right angles. The whey rising through these incisions is of a fine pale-green colour. The cheese-maker and two assistants then proceed to break the curd: this is performed by their repeatedly putting their hands down into the tub; the cheese-maker, with the skimming-dish in one hand, breaking every part of it as they catch it, raising the curd from the bottom, and still breaking it. This part of the bu-siness is continued till the whole is broken uniformly small; it generally takes up about forty minutes, and the curd is then left covered over with a cloth for about half an hour, to subside. If the milk has been set cool together, the curd will be much more tender, the whey will not be so green, but rather of a milky appearance. CHEILOCA'CE. (From χειλος, a lip, and κακον, an evil.) A swelling of the lips, or canker in the

mouth.

CHEIME'LTON. (From XELUA, winter.) A chilblain. I line and chalybeate principle. When first drawn, it is

CHEIRA'NTHUS. (From $\chi u\rho$, a hand, and $\alpha \nu \theta o \rho$, a flower; so named from the likeness of its blossoms to the fingers of the hand.) The name of a genus of plants in the Linnwan system. Class, Tetradynamia; Order, Siliquosa. The wall-flower.

CHEIRASTHUS CHEIRI. The systematic name of

the wall-flower. Leucoium luteum: Viola lutea. Common yellow wall-flower. 'The flowers of this plant, Cheranthus; foliis lanceolatis, acutis, glabris; ramis angulatis; caule fruticoso, of Linnaus, are recommended as possessing nervine and deobstruent virtues. They have a moderately strong, pleasant smell, and a nauseous, bitter, somewhat pungent

[CHEIRANTHODENDRON. A tree growing in Mexico, called from the appearance of the flower representing the human hand and fingers. (From χειρ, a hand, ανθος, a flower, and ἐενδρον, a tree.) It is a large tree, bearing a flower resembling a human hand. The part producing this resemblance is the pistillum, which rises above the calyx, and is divided into five parts, and except to the though and fingers. The resemblance analogous to the thumb and fingers. The resemblance is very striking, but the digits are sharp and pointed; more like claws. We have seen preserved specimens of the flowers in very good order. A.]

CHEIRA'PSIA. (From χιρ, the hand, and απτομαι, to touch.) The act of scratching; particularly the scratching one hand with another, as in the itch. CHEI'RI. (Cheiri, Arabian.) See Cheiranthus Cheiri.

CHEIRIA TER. (From χειρ, the hand, and ια γρος, a physician.) A surgeon whose office it is to remove maladies by operations of the hand.

CHEIRISMA. (From χειρίζομαι, to labour with the hand.) Handling. Also a manual operation.

CHEIRIXIS. (From χειρέζομαι, to labour with the hand.) The art of surgery.

CHEIRIXIS. (From χειρεξομαι, to labour with the hand.) The art of surgery.

CHEIRONO'MIA. (From χειρονομεω, to exercise with the hands.) An exercise mentioned by Hippocrates, which consisted of gesticulations with the hands, like our dumb-bells.

CHE'LA. (Χηλη, forceps; from χεω, to take.)

1. A forked probe, for drawing a polypus out of the

nose.

2. A fissure in the feet, or other places.
3. The claw of crabs, which lays hold like forceps.
CHELÆ CANCRORUM. See Cancer.
CHELL'DON. The bend of the arm.

CHELL CANCRORUM. See Cancer.

CHELI'DON. The bend of the arm.

CHELIDO'NIUM. (From χελιδων, the swallow. It is so named from an opinion, that it was pointed out as useful for the eyes by swallows, who are said to open the eyes of their young by it; or because it blossoms about the time when swallows appear.) Celan-

soms about the time when swallows appear.) Celandine. A genus of plants in the Linnæan system. Class, Polyandria; Order, Monogynia. There is only one species used in medicine, and that rarely.

Chelidonium Majus. Papaver corniculatum, luteum; Curcum. Tetterwort, and great celandine. The herb and root of this plant, Chelidonium—pedunculis umbellatus, of Linnæus, have a faint, unpleasant smell, and a bitter, acrid, durable taste, which is stronger in the roots than the leaves. They are aperient and diuretic, and recommended in icterus, when rient and diuretic, and recommended in icterus, when not accompanied with inflammatory symptoms. The chelidonium should be administered with caution, as it chelidoniam should be administered with caution, as it is liable to irritate the stomach and bowels. Of the dried root, from 3 ss to 3 j is a dose; of the fresh root, infused in water, or wine, the dose may be about 3 ss. The decoction of the fresh root is used in dropsy, cachexy, and cutaneous complaints. The fresh juice is used to destroy warts, and films in the eyes; but, for the latter purpose, it is diluted with milk.

CHELIDONIUM MINUS. The pill-wort. See Ranun-

CHÉLO'NE. Χελωνη. 1. The tortoise.
2. An instrument for extending a limb, and so called because, in its slow motions, it represents a tortoise.

This instrument is mentioned in Oribasius.

This instrument is mentioned in Orloadia.

Chelo'nion. (From χελωνη, the tortoise; so called from its resemblance to the shell of a tortoise.) A hump or gibbosity in the back.

CHELTENHAM. The name of a village, now be-

come a large and populous town, in Gloucestershire. It is celebrated for its purging waters, the reputation of which is daily increasing, as it possesses both a sa-

clear and colourless, but somewhat brisk; has a sa-line, bitterish, chalybeate taste. It does not keep, nor line, bitterish, chalybeate taste. It does not keep, nor bear transporting to any distance; the chalybeate part being lost by precipitation of the iron, and in the open air it even turns fætid. The salts, however, remain. Its heat, in summer, was from 50° to 55° or 59°, when the medium heat of the atmosphere was nearly 15° higher. On evaporation, it is found to contain a calcareous earth, mixed with other and a purging salt. A general survey of the component parts of this water, according to a variety of analyses, shows that it is ter, according to a variety of analyses, shows that it is decidedly saline, and contains much more salt than most mineral waters. By far the greater part of the salts are of a purgative kind, and therefore an action on the bowels is a constant effect, notwithstanding the considerable quantity of selenite and earthy carbonates, which may be supposed to have a contrary tendency. Cheltenham water is, besides, one of the strongest chalybeates we are acquainted with. The iron is suspended entirely by the carbonic acid, of which gas the water contains about an eighth of its bulk; but, from the abundance of earthy carbonates, and oxide of iron, not much of it is uncombined. It has, besides, a slight impregnation of sulphur, but so little as to be slight impregnation of sulphur, but so little as to be scarcely appreciable, except by very delicate tests. The sensible effects produced by this water, are generally, on first taking it, a degree of drowsiness, and sometimes headache, but which soon go off spontaneously, even previous to the operation on the bowels. A moderate dose acts powerfully, and speedily, as a cathartic, without occasioning griping, or leaving that faintness and languor which often follow the action of the rougher cathartics. It is principally on this acthe rougher cathartics. It is principally on this ac-count, but partly too from the salutary operation of the chalybeate, and perhaps the carbonic acid, that the Cheltenham water may be, in most cases, persevered in, for a considerable length of time, uninterruptedly, without producing any inconvenience to the body; and during its use, the appetite will be improved, the digestive organs strengthened, and the whole constitution invigorated. A dose of this water, too small to operate directly on the bowels, will generally determine pretty powerfully to the kidneys. As a purge, this water is drank from one to three pints; in general, from half a pint to a quart is sufficient. Half a pint will contain half a drachm of neutral purging salts, one-third of agrain of oxide of iron; together with an ounce in bulk of carbonic acid and half an ounce of common air, with a little sulphuretted hydrogen. Cheltenham water is used, with considerable benefit, in a number of diseases, especially of the chronic kind. in a number of diseases, especially of the chronic kind, and particularly those called bilious: hence it has been found of essential service in the cure of glandular obstructions, and especially those that affect the liver, and the other organs connected with the functions of the alimentary canal. Persons who have injured their biliary organs, by a long residence in hot climates, and who are suffering under the symptoms, either of excess of bile or deficiency of bile, and an irregularity in its secretion, receive remarkable benefit from a course of this water, judiciously exhibited. Its use may be here continued, even during a considerable degree of debility; and from the great determination to the bowels, it may be employed with advantage to check the incipient symptoms of dropsy, and general anasarca, which so often proceed from an obstruction of the liver. In scrofulous affections, the sea has the decided preference; in painful affections of the skin, called scorbutic cruptions, which make their appearance at stated intervals, producing a copious discharge of lymph, and an abundant desquamation, in common with other saline purgative springs, this is found to and the other organs connected with the functions of with other saline purgative springs, this is found to bring relief; but it requires to be persevered in for a bring relief; but it requires to be persevered in for a considerable time, keeping up a constant determination to the bowels, and making use of warm bathing. The season for drinking the Cheltenham water is during the whole of the summer months.

CHELYS. (Χελυς, a shell.) The breast is so called, as resembling, in shape and office, the shell of

some fishes.

Chely'scion. (From χελυς, the breast.) A dry, short cough, in which the muscles of the breast are very sore.

A measure mentioned by the Greek phy-CHE'MA. sicians, supposed to contain two small spoonfuls.

CHE'MIA. See Chemistry.

CHE'MICAL. Of or belonging to chemistry.

CHEMISTRY. (Xvµta, and sometimes χηµta:

Chamia, from chama, to burn, Arab. this science being the examination of all substances by fire.) Chemia;

Chimia; Chymia. The learned are not yet agreed as to the most proper definition of chemistry. Boerhaave seems to have ranked it among the arts. According to Macquer, it is a science, the object of which is to discover the nature and properties of all bodies by their analyses and combinations. Dr. Black says, it is a science which teaches, by experiments, the effects of heat and mixture on bodies; and Fourcroy defines it a science which teaches the mutual actions of all natural bodies on each other. "Chemistry," says Jacquin, "is that branch of natural philosophy which unfolds the nature of all material bodies, determines the number and properties of their component parts, the number and properties of their component parts, the number and properties of their component parts, and teaches us how those parts are united, and by what means they may be separated and recombined." Mr. Heron defines it, "That science which investigates and explains the laws of that attraction which takes place between the minute component particles of natural bodies." Dr. Ure's definition is, "the science which investigates the composition of material substances, and the permanent changes of constitution which their mutual actions produce." The objects to which the attention of chemists is directed, comprehend the whole of the substances that compose the

CHEMO'SIS. (From χαινω, to gape; because it gives the appearance of a gap, or aperture.) Inflammation of the conjunctive membrane of the eye, in which the white of the eye is distended with blood, and elevated above the margin of the transparent cor-nea. In Cullen's Nosology, it is a variety of the ophthalmia membranarum, or an inflammation of the

membranes of the eye.

Chenopodio-morus. (From chenopodium and morus, the mulberry; so called because it is a sort of chenopodium, with leaves like a mulberry.) The herb mulberry-blight. The Blitum capitatum of Lin-

CHENOPO DIUM. (From χην, a goose, and πους, a foot; so called from its supposed resemblance to a goose's foot.) The name of a genus of plants in the Linnwan system. Class, Pentandria; Order, Digynia. The herb chenopody: goose's foot.

Chenopodium Ambrosioides. The systematic name of the Mexican tea-plant. Botrys Mexicana; Botrys ambrosioides Mexicana; Chenopodium Mexicanum; Botrys Americana. Mexico tea; Spanish tea and Artemisian botrys. Chenopodium—folits lanceolatis dentatis, racemis foliatis simplicibus, of Linneus. A decoction of this plant is recommended in paralytic cases. Formerly the infusion was drank instead of Chinese tea. CHENOPODIUM AMBROSIOIDES. The systematic

CHENOPODIUM ANTHELMINTICUM. The seeds of this plant, Chenopodium—folius ovato-oblongis dentatis, racemis aphyllis, of Linnaus, though in great esteem in America, for the cure of worms, are seldom exhibited in this country. They are powdered and made into an electuary, with any proper syrup, or conserve

["The Chenopodium anthelminticum, is a native plant, found in the middle and southern states, usually known by the names of wormseed and Jerusalem oak. The name wormseed is applied in Europe to the Artemisia santonica, a very different plant. The chenopodium is accounted a good vermifuge, especially in the lumbrici of children. The expressed juice of the whole plant is sometimes given in the dose of a table-spoonful to a child two or three years old. More frequently the powdered seeds are employed, mixed with treacle or syrup. The seeds 'yield a volatile oil on distillation, which is prescribed in doses of six or eight drops, in sugar or some suitable vehicle."—Big. Mat. Med: A.] known by the names of wormseed and Jerusalem oak.

CHENOPODIUM BONUS HENRICUS. The systematic name of the English mercury. Bonus Henricus; Tota bona; Lapathum unctuosum; Chenopodium; Chenopodium—foliis triangulari-sagittatis, integerrimis, spicis compositis aphyllis azillaribus, of Linnaus. The plant to which these names are given, is a native of this country, and common in waste grounds from June to August. It differs little from spinach when cultivated the resulting the resulting the second secon cultivated; and in many places the young shoots are

eaten in spring like asparagus. The leaves are accounted emollient, and have been made an ingredient in decoctions for clysters. They are applied by the common people to fiesh wounds and sores under the notion of drawing and healing.

Chesopolicy sorreys. The systematic name of

CHENOPODIUM BOTRYS. The systematic name of the Jerusalem oak. Botrys vulgaris; Botrys; Ambrosia; Artemisia chenopodium; Atriplex odorata: Atriplex suaveolens; Chenopodium—foliis oblongis sinuatis, racemis nudis multipais, of Linnæus. This plant was formerly administered in form of decoction in some diseases of the chest; as humoral asthma, coughs, and catarrhs. It is now fallen into disuse.

Chenopodium Feridum. See Chenopodium vul-

varia.

Chenopodium vulvaria. The systematic name for the stinking orach. Atriplex fatida; Atriplex olida; Vulvaria; Garosmum: Raphex; Chenopodium fatidum; Blitum fatidum. The very fætid smell of this plant, Chenopodium—foliis integerrimis rhombeo ovatis, floribus conglomeratis axillaribus, of Linnæus, induced physicians to exhibit it in hysterical diseases. It is now superseded by more active preparations. Messrs. Chevalier and Lasseigne have detected anmonis in this plant in an uncombined state, which is Messrs. Chevatter and Lassegne have detected ammonia in this plant in an uncombined state, which is probably the vehicle of the remarkably nauseous odour which it exhales, strongly resembling that of putrid fish. When the plant is bruised with water, and the liquor expressed and afterward distilled, we procure a fluid which contains the subcarbonate of ammonia, and an oily matter, which gives the fluid a milky ap-If the expressed juice of the chenopodium be evaporated to the consistence of an extract, it is found to be alkaline; there seems to be acetic acid in it. Its basis is said to be of an albuminous nature. It it. Its basis is said to be of an albuminous nature. It is stated also to contain a small quantity of the substance which the French call osmazome, a little of an aromatic resin, and a bitter matter, soluble both in alkohol and water, as well as several saline bodies.

Che'ras. (From χεω, to pour out.) An obsolute name of struma, or scrofula.

Cherefolium. See Scandix cerefolium.

CHE'RMES. (Arabian.) A small berry, full of insects like worms: the juice of which was formerly made into a confection, called confection alkernes.

made into a confection, called confectio aikermes, which has been long disused. The worm itself was also so called.

CHERMES MINERALIS. Hydro-sulphuret of anti-

CHERNI'BIUM. Chernibion. In Hippocrates it signifies a urinal.

(From X 210 wv, the Centaur.) See CHERO'NIA.

the nape of the neck, is there crossed: it then passes under the chin, where crossing, it is carried to the top of the head, &c. until it is all taken up.

CHEYNE, George, was born in Scotland, 1670.

After graduating in medicine, he came to London, at the age of 30, and published a Theory of Fevers, and five years after a work on Fluxions, which procured his election into the Royal Society; and this was soon followed by his "Philosophical Principles of Natural Religion." Being naturally inclined to corpulency, and indulging in free living, he became, when only of a middle age, perfectly unwieldy, with other marks of a middle age, perfectly unwieldy, with other marks of an impaired constitution; against which, finding medicines of little avail, he determined to abstain from all fermented liquors, and confine himself to a milk and vegetable diet. This plan speedily relieved the most distressing symptoms, which led him after a while to resume his luxuries; but finding his complaints presently returning, he resorted again to the abstemious plan; by a steady perseverance in which he retained a tolerable share of health to the advanced age of 72. In 1722, in a treatise on the gout, &c. he first incul-In 1722, in a treatise on the gout, &c. he first inculcated this plan; and two years after greatly enlarged on the same subject, in his celebrated "Essay on Health and Long Life." His "English Malady, or Treatise on Nervous Diseases," which he regarded as especially prevalent in this country, a very popular work, published 1733, contains a candid and judicious narrative of his own case.

CHEZANAN'CE. (From χεζω, to go to stool, and αναγκη, necessity.) 1. Any thing that creates a necessity to go to stool.

essity to go to stool.

2. In P. Ægineta, it is the name of an ointment, with which the anus is to be rubbed for promoting stools

CHI'A. (From X₁₀₅, an island where they were formerly propagated.) 1. A sweet fig of the island of Cyprus, Chio, or Scio.
2. An earth from the island of Chio, formerly used

in fevers.

3. A species of turpentine. See Pistacia terebin-

CHI'ACUS. (From X105, the island of Scio.) An epithet of a collyrium, the chief ingredient of which was wine of Chios.

CHI'ADUS. In Paracelsus it signifies the same as furunculus.

Chian turpentine. See Pistacia terebinthus. Cina's surs. (From χιαζω, to form like the letter X, chi.) The name of a bandage, the shape of which is like the Greek letter X, chi.

CHIASTOLITE. The name of a mineral found in

Britany and Spain, somewhat like steatite

CHIA'STOS. The name of a crucial bandage in Oribasius; so called from its resembling the letter X,

The name of a bandage for the tempo-CHIA'STRE. ral artery. It is a double-headed roller, the middle of which is applied to the side of the head, opposite to that in which the artery is opened, and, when brought round to the part affected, it is crossed upon the com-press that is laid upon the wound, and then, the continuation is over the coronal suture, and under the chin; then crossing on the compress, the course is, as at the first, round the head, &c. till the whole roller is taken up.

CHI BOU. A spurious species of gum-elemi, spoken of by the faculty of Paris, but not known in England.
CHICHI'NA. Contracted from China China. See

CHICKEN. The young of the gallinaceous order of birds, especially of the domestic fowl. See Pha-

sianus gallus.
CHICKEN POX. See Varicella.

CHICOYNEAU, FRANCIS, was born at Montpelier CHICOYNEAU, Francis, was born at Montpelier in 1672, the second son of a professor there, who becoming blind, he was appointed to discharge his duties, after taking his degrees in medicine. Having acquitted himself very creditably, he was deputed with other physicians to Marseilles in 1720, to devise measures for arresting the progress of the plague, which in the end almost depopulated that city. The zeal which he evinced on that occasion was rewarded by a pension; and on the death of his father-in law. M. a pension; and on the death of his father in law, M.

first physician to the king; and received also other honours previously to his death in 1752. He published in 1721, in conjunction with the other physicians, an account of the plague at Marseilles, in which the opinion is advanced, that the disease was not contagious: and having received orders from the king to collect all the observations that had been made concerning that disease, he drew up an enlarged treatise with much candour, and containing a number of useful facts, which was made public in 1744.

[Chigoe, or gigger. A small insect so called in the West India islands, infesting the feet of those who go West India islands, intesting the feet of those who go barefoot, and particularly the negroes. It is a very minute insect, and, when magnified, has very much the appearance of a flea. It penetrates the skin of the feet without producing pain, and there forms its nidus. As it increases in growth in its new situation, it produces little swellings and intolerable itching. The female negroes carefully extract them with a needle. When they are not extracted, the parent deposites its When they are not extracted, the parent deposites its eggs, and as these hatch, the irritation causes increased swellings and ulceration, which sometimes cause the loss of limbs, and even death to the sufferers. Poultices of Indian meal are the only applications to heal the ulcerations and abscesses caused by the chies. A.] CHILBLAIN.

CHILBLAIN. See Pernio.
["CHILDS, TIMOTHY, M.D., was born at Deerfield,
Massachusetts, February, 1748. He was entered as a
member of Harvard College in 1764, but was under the necessity of taking a dismission at the close of his junior year, by the failure of the funds on which he had relied to carry him through the regular course of that seminary. From Cambridge he returned to Deerfield, where he studied physic and surgery with Dr. Williams; and from whence, in 1771, at the age of twenty-three, he removed to practise in Pittsfield:

An ardent and decided friend of civil liberty, he took

a deep interest in those great political questions which at that period were agitated between Great Britain and her American colonies. No young man, perhaps, was more zealously opposed to the arbitrary encroachment of the British parliament than Dr. Childs, and as a proof of the confidence reposed in him by the fathers of the town, it need only be mentioned that in 1774, when the crisis of open hostility was approaching, he was appointed chairman of a committee to draw a pe-tition to his Majesty's Justices of Common Pleas in the county of Berkshire, remonstrating against certain acts of parliament which had just been promulgated, and praying them to stay all proceedings till those unjust and oppressive acts should be repealed.

In the same year, (1774,) Dr. Childs took a commission in a company of minute-men, which, in compli-

ance with a recommendation from the convention of the New-England states, was organized in that town. When the news of the battle of Lexington in 1775 was received, he marched with his company to Boswas received, he hatched wath his company to hos-ton, where he was soon after appointed a surgeon of Colonel Patterson's regiment. From Boston he went with the army to New-York, and from thence accom-panied the expedition to Montreal. In 1777 he left the army, and resumed his practice in the town of Pittsfield, and continued in it till less than a week before his death, at the advanced age of seventy-three.

In 1792, Dr. Childs was elected a representative to the General Court, and for several years received the same pledge of public confidence. He also held a seat in the senate for a number of years, by the suffrages of the county in which he lived and died. But it was in his profession he was most highly honoured and extensively useful. He was early elected a member of the Massachusetts Medical Society, and held the office of counsellor of that society to the time of his death. In the year 1811, the University of Cambridge conferred on him the degree of Doctor of Medicine. When the district society, composed of the fellows of the state society, was established in the county in which he lived, he was appointed censor, and elected

to the office of president.

As a practitioner, Dr. Childs stood high in public es-As a practitioner, Dr. Childs stood mga in public estimation, both at home and abroad. For more than thirty years he was the only physician of note in the town; and this single fact strongly testifies to the uncommon estimation in which he was held by those who were most competent to judge of his professional

CHLORATE. A compound of chloric acid with a

salifiable basis, CHLORIC ACID. CHLORIC ACID. Acidum chloricum, "It was first eliminated from salts containing it by Gay Lussac, and described by him in his admirable memoir on iodine, published in the 91st volume of the Annales de Chimie. When a current of chlorine is passed for some time through a solution of barytic earth in warm water, a substance called hyperoxymuriate of barytes by its first discoverer, Chenevix, is formed, as well as some common muriate. The latter is separated, by boiling phosphate of silver in the compound solution. The former may then be obtained by evaporation, in fine rhomboidal prisms. Into a dilute solution of this salt Gay Lucae poured weak sulphyric acid. Though had rhombottal prishs. Into a diffuse solution of this salt, Gay Lussac poured weak sulphuric acid. Though he added only a few dreps of acid, not nearly enough to saturate the barytes, the liquid became sensibly acid; and not a bubble of oxygen escaped. By continuing to add sulphuric acid with caution, he succeeded in obtaining an acid liquid entirely free from sulphuric acid and barytes, and not precipitating nitrate of silver. It was chloric acid dissolved in water. Its cha racters are the following.

This acid has no sensible smell. Its solution in water is perfectly colourless. Its taste is very acid and it reddens litmus without destroying the colour It produces no alteration on solution of indigo in sulphuric acid. Light does not decompose it. It may be concentrated by a gentle heat, without undergoing decomposition, or without evaporating. It was kept a long time exposed to the air without sensible diminution of its quantity. When concentrated, it has something of an oily consistency. When exposed to heat, it is nearly decomposed into oxygen and shloring and it is partly decomposed into oxygen and chlorine, and partly volatilized without alteration. Muriatic acid decomposes it in the same way, at the common tem-perature. Sulphurous acid, and sulphuretted hydro-gen, have the same property; but nitric acid produces no change upon it. Combined with ammonia, it forms a fulminating salt, formerly described by M. Chenevix. It does not precipitate any metallic solution. It readily It does not precipitate any metallic solution. It readily dissolves zinc, disengaging hydrogen; but it acts slowly on mercury. It cannot be obtained in the gaseous state. It is composed of 1 volume chlorine +2.5 oxygen, or, by weight, of 100 chlorine, III.70 oxygen, if we consider the specific gravity of chlorine to be 2.4866.

To the preceding account of the properties of chloric acid, M. Vauquelin has added the following. Its taste is not only acid, but astringent, and its odour, when concentrated, is somewhat pungent. It differs from chlorine, in not precipitating gelatine. When paper stained with litmus is left for some time in con-

paper stained with litmus is left for some time in contact with it, the colour is destroyed. Mixed with muriatic acid, water is formed, and both acids are converted into chlorine. Sulphurous acid is converted into sulphuric, by taking oxygen from the chloric acid, which is consequently converted into chlorine.

Chloric acid combines with the bases, and forms the chloric acid combines with the bases, and forms the chlorates, a set of salts formerly known by the name of the hyperoxygenated muriates. They may be formed either directly by saturating the alkali or earth with the chloric acid, or by the old process of transmitting chlorine through the solutions of the bases, in Woolfe's bottles. In this case the water is decomposed to the chloric control of the chlorine. Woolfe's bottles. In this case the water is decomposed. Its oxygen unites to one portion of the chlorine, forming chloric acid, while its hydrogen unites to another portion of chlorine, forming muriatic acid; and hence, chlorates and muriates must be contemporaneously generated, and must be afterward separated by crystallization, or peculiar methods.

The chlorate of potassa or hyperoxymuriate, has been long known, and may be procured by receiving chlorates.

tine, as it is formed, into a solution of potassa. When the solution is saturated, it may be evaporated gently, and the first crystals produced will be the salt desired, this crystallizing before the simple muriate, which is produced at the same time with it. Its crystals are in shining hexaëdral laminæ, or rhomboidal plates. It is soluble in 17 parts of cold water; and, but very sparingly, in alkohol. Its taste is cooling, and rather unpleasant. Its specific gravity is 2.0. 16 parts of water, at 60°, dissolve one of it, and 2½ of boiling water. The purest oxygen is extracted from this salt, by exposing it to a gentle red heat. One hundred grains by exposing it to a gentle red heat. One hundred grains yield about 115 cutic inches of gas. It consists of 9.5 chloric acid+6 potassa=15.5, which is the prime equivalent of the salt.

The effects of this salt on inflammable bodies are very powerful. Rub two grains into powder in a mortar, add a grain of sulphur, mix them well by gentle trituration, then collect the powder into a heap, and press upon it suddenly and forcibly with the pestle, a loud detonation will ensue. If the mixture be wrapped in strong paper, and struck with a hammer, the report will be still louder. Five grains of the salt, mixed in the same manner with two grains of charcoal, will be inflamed by strong triuvation, especially if a will be inflamed by strong trituration, especially if a grain or two of sulphur be added, but without much noise. If a little sugar be mixed with half its weight of the chlorate, and a little strong sulphuric acid poured on it, a sudden and vehement inflammation will ensue; but this experiment requires caution, as well as the following. To one grain of the powdered salt in a mortar, add half a grain of phosphorus; it will detonate, with a loud report, on the gentlest trituration. In this experiment the hand should be defended by a glove, and great care should be taken that none of the In this experiment the hand should be defended by a glove, and great care should be taken that none of the phosphorus get into the eyes. Phosphorus may be inflamed by it under water, putting into a wine-glass one part of phosphorus and two of the chlorate, nearly filling the glass with water, and then pouring in, through a glass tube reaching to the bottom, three or four parts of sulphuric acid. This experiment, too, is very hazardous to the eyes. If olive or linseed oil be taken instead of phosphorus, it may be inflamed by similar means on the surface of the water. This salt should not be kept mixed with sulphur, or perhaps any should not be kept mixed with sulphur, or perhaps any inflammable substance, as in this state it has been known to detonate spontaneously. As it is the common effect of mixtures of this salt with inflammable substances of every kind, to take fire on being projected into the stronger acids, Chenevix tried the experiment with it mixed with diamond powder in various proportions, but without success. tions, but without success.

Chlorate of soda may be prepared in the same man-ner as the preceding, by substituting soda for potassa; but it is not easy to obtain it separate, as it is nearly but it is not easy to obtain it separate, as it is nearly as soluble as the muriate of soda, requiring only 3 parts of cold water. Vauquelin formed it, by saturating chloric acid with soda; 500 parts of the dry carbonate yielding 1100 parts of crystallized chlorate. It consists of 4 soda, 9.5 acid=13.5, which is its prime equivalent. It crystallizes in square plates, produces a sensation of cold in the mouth, and a saline taste; is slightly deliquescent, and in its other properties resembles the chlorate of potassa.

Barytes appears to be the next base in order of

Barytes appears to be the next base in order of affinity for this acid. The best method of forming it is to pour hot water on a large quantity of this earth, and to pass a current of chlorine through the liquid kept warm, so that a fresh portion of barytes may be taken up as the former is saturated. This salt is soluble in about four parts of cold water, and less of warm, and crystallizes like the simple muriate. It may be obtained, however, by the agency of double affinity; for phosphate of silver boiled in the solution will decrease the simple muriate and the muriate of silver. compose the simple muriate, and the muriate of silver and phosphate of barytes being insoluble, will both fall down and leave the chlorate in solution alone. The phosphate of silver employed in this process must be perfectly pure, and not the least contaminated with

The chlorate of strontites may be obtained in the same manner. It is deliquescent, melts immediately in the mouth, and produces cold; is more soluble in alkohol than the simple muriate, and crystallizes in needles.

The chlorate of lime, obtained in a similar way, is extremely deliquescent, liquefies at a low heat, is very 214

soluble in alkohol, produces much cold in solution, and

has a sharp bitter taste.

Chlorate of ammonia is formed by double affinity, the carbonate of ammonia decomposing the earthy salts of this genus, giving up its carbonic acid to their base, and combining with their acid into chlorate of ammonia, which may be obtained by evaporation. It is very soluble both in water and alkohol, and decomposed by a moderate heat posed by a moderate heat.

The chlorate of magnesia much resembles that of

To obtain chlorate of alumina, Chenevix put some alumina, precipitated from the muriate, and well washed, but still moist, into a Woolfe's apparatus, and treated it as the other earths. The alumina shortly disappeared; and on pouring sulphuric acid into the liquor, a strong smell of chloric acid was perceivable; but on attempting to obtain the salt pure by means of phosphate of silver, the whole was decomposed, and nothing but chlorate of silver was found in the solution."

CHLORIC OXIDE. Deutoxide of chlorine. sulphuric acid is poured upon hyper-oxymuriate of potassa in a wine-glass, very little effervescence takes place, but the acid gradually acquires an orange colour, and a dense yellow vapour, of a peculiar and not disagreeable smell, floats on the surface. These phenomena led Sir H. Davy to believe, that the substance extricated from the salt is held in solution by the acid. After various unsuccessful attempts to obtain this substance in a separate state, he at last succeeded by the stance in a separate state, he at last succeeded by the following method: About 60 grains of the salt are triturated with a little sulphuric acid, just sufficient to convert them into a very solid paste. This is put into a retort, which is heated by means of hot water. The water must never be allowed to become boiling hot, for fear of explosion. The heat drives off the new gas, which may be received over mercury. This new gas has a much more intense colour than euchlorine. It does not act on mercury. Water absorbs more of it than euchlorine. Its taste is astringent. It destroys it than euchlorine. Its taste is astringent. It destroys vegetable blues without reddening them. When phos-When heat is applied, the gas exploses with more vio-lence, and producing more light than euchlorine. When thus exploded, two measures of it are converted into nearly three measures, which consist of a mixture of one measure chlorine, and two measures oxygen. Hence, it is composed of one atom chlorine and four atoms oxygen.

Deutoxide of chlorine has a peculiar aromatic odour, unmixed with any smell of chlorine. A little chlorine is always absorbed by the mercury during the explois always absorbed by the mercury during the explosion of the gas. Hence the small deficiency of the resulting measure is accounted for. At common temperatures none of the simple combustibles which Sir H. Davy tried, decomposed the gas, except phosphorus. The taste of the aqueous solution is extremely astringent and corroding, leaving for a long while a very disagreeable sensation. The action of liquid nitric acid on the chlorate of potassa affords the same gas, and a much larger quantity of this acid may be safely employed than of the sulphuric. But as the gas must be procured by solution of the salt, it is always mixed with about one-fifth of oxygen."

CHLORIDE. A compound of chlorine with different bodies.

ferent bodies.

Chloride of azot. See Nitrogen.
CHLO'RINE. (So called from χλωρος, green, because it is of a green colour.) Oxygenated muriatic acid. "The introduction of this term, marks an era acid. "The introduction of this term, marks an era in chemical science. It originated from the masterly researches of Sir H. Davy on the oxymuriatic acid gas of the French school; a substance which, after resisting the most powerful means of decomposition which his sagacity could invent, or his ingenuity apply, he declared to be, according to the true logic of chemistry, an elementary body, and not a compound of muriatic acid and oxygen, as was previously imagined, and as its name seemed to denote. He accordingly assigned to it the term chlorine, descriptive of its colour; a name now generally used. The chloridic theory of combustion, though more limited in its applications to the chemical phenomena of nature, than the antiphlogistic of Lavoisier, may justly be regarded as of equal importance to the advancement of the science itself. When we now survey the Transactions of the

Royal Society for 1808, 1809, 1810, and 1811, we fee! overwhelmed with astonishment at the unparalleled skill, labour, and sagacity, by which the great English chemist, in so short a space, prodigiously multiplied the objects and resources of the science, while he promulgated a new code of laws, flowing from views of elementary actions. elementary action, equally profound, original, and sub-lime. The importance of the revolution produced by his researches on chlorine, will justify us in presenting a detailed account of the steps by which it has been effected. How entirely the glory of this great work belongs to Sir H. Davy, notwithstanding some invidious attempts in this country to tear the well-carned laurel from his brow, and transfer it to the French chemists, we may readily judge by the following decisive facts.

The second part of the Phil. Trans. for 1809, con-

tains researches on oxymuriatic acid, its nature and combinations, by Sir H. Davy, from which the follow-

ing interesting extracts are taken.
'In the Bakerian lecture for 1808,' says he, 'I have given an account of the action of potassium upon muriatic acid gas, by which more than one third of its volume of hydrogen is produced; and I have stated, that muriatic acid can in no instance be procured from oxymuriatic acid, or from dry muriates, unless water

or its elements be present.

I 'In the second volume of the Mémoires D'Arcueil,
Gay Lussac and Thenard have detailed an extensive series of facts, upon muriatic acid, and oxymuriatic acid. Some of their experiments are similar to those I have detailed in the paper just referred to; others are peculiarly their own, and of a very curious kind; their general conclusion is, that muriatic acid gas contains about one quarter of its weight of water; and that oxymuriatic acid is not decomposable by any substances but hydrogen, or such as can form triple combinations with it.

One of the most singular facts that I have observed on this subject, and which I have before referred to, is, that charcoal, even when ignited to whiteness in oxymuriatic or muriatic acid gases, by the voltaic battery, effects no change in them, if it has been previously freed from hydrogen, by intense ignition in

'This experiment, which I have several times re-peated, led me to doubt of the existence of oxygen in that substance, which has been supposed to contain it, above all others, in a loose and active state; and to make a more rigorous investigation, than had hitherto

been attempted for its detection.'

He then proceeds to interrogate nature, with every artifice of experiment and reasoning, till he finally ex-torts a confession of the true constitution of this mysterious muriatic essence. The above paper, and his Bakerian lecture, read before the Royal Society in Nov. and Dec. 1810, and published in the first part of their Transactions for 1811, present the whole body of evidence for the undecompounded nature of oxymutations of the compounded patterns of the compounded patter riatic acid gas, thenceforward styled chlorine; and they will be studied in every enlightened age and coun-try, as a just and splendid pattern of inductive Baco-

nian logic. These views were slowly and reluctantly admitted by the chemical philosophers of Europe.

In 1812, Sir H. Davy published his Elements of Chemical Philosophy, containing a systematic account of his new doctrines concerning the combination of simple bodies. Chlorine is there placed in the same rank with oxygen, and finally removed from the class of acids. In 1813, Thenard published the first volume of his Traité de Chimie Elémentaire Théorique et Pratique. This distinguished chemist, the fellow-labourer of Gay Lussac in those able researches on the alkalies and oxymuriatic acid, which form the distinguished rivalry of the French school, to the brilliant career of Sir H. Davy, states, at p. 584, of the above volume, the composition of oxymuriatic acid as follows:

'Composition. The oxygenated muriatic gas contains the half of its volume of oxygen gas, not including that which we may suppose in muriatic acid. It thence folwhich we may suppose in muriatic acid. It thence follows, that it is formed of 1.9183 of muriatic acid, and 0.5517 of oxygen; for the specific gravity of oxygenated muriatic gas is 2.47, and that of oxygen gas 1.1034.—

'Chenevix first determined the proportion of its constituent principles. Gay Lussac and Thenard determined it more exactly, and showed that we could not decompose the oxygenated muriatic gas, but by putting

it in contact with a body capable of uniting with the two elements of this gas, or with muriatic acid. They announced at the same time that they could explain all announced at the same time that they could explain an the phenomena which it presents, by considering it as a simple or as a compound body. However, this last opinion appeared more probable to them. Davy, on the contrary, embraced the first, admitted it exclusively, and sought to fortify it by experiments which are peculiar to him.' P. 585.

In the second volume of Thenard's work, published in 1814, he explains the mutual action of chlorine and appropriate gases, solely on the oxygenous theory. 'On

ammonia gases, solely on the oxygenous theory. 'On peut démontrer par ce dernier procédé, que le gas muriatique oxigéné, doit contenir la moitié de son volume d'origéne, uni à l'acide muriatique.' P. 147. volume d'origene, uni à l'acide muriatique.' P. 147.—
In the 4th volume, which appeared in 1816, we find the following passages: 'Oxygenated muriatic gas.— Oxygenated muriatic gas, in combining with the metals, gives rise to the neutral muriates. Now, 107.6 of oxide of silver, contain 7.6 of oxygen, and absorb 26.4 of muriatic acid, to pass to the state of neutral muriate. Of consequence, 348 of this last acid supposed dry, and 100 of oxygen, form this gas. But the sp. gr. of oxygen is 1.1034, and that of oxygenated muriatic gas is 2.47; hence, this contains the half of its volume of oxygen.' P. 52.

The force of Sir H. Davy's demonstrations, pressing for six years on the public mind of the French philosophers, now begins to transpire in a note to the above

sophers, now begins to transpire in a note to the above passage. —'We reason here,' says Thenard, 'obviously passage.—'We reason here,' says Thenard, 'obviously on the hypothesis, which consists in regarding oxygenated muriatic gas as a compound body.' This pressure of public opinion becomes conspicuous at the end of the volume. Among the additions, we have the following decisive evidence of the lingering attachment to the old theory of Lavoisier and Berthollet.—'A pretty considerable number of persons who have subscribed for this work, desiring a detailed explanation of the phenomena which oxygenated muriatic gas presented. phenomena which oxygenated muriatic gas presents, on the supposition that this gas is a simple body, we are now going to explain these phenomena, on this supposition, by considering them attentively. The oxygenated muriatic gas will take the name of chlorine; its combinations with phosphorus, sulphur, azor, metals, will be called *chlorures*; the muriatic acid, which results from equal parts in volume of hydrogen and oxygenated muriatic gases, will be hydrochloric acid; the superoxygenated muriatic acid will be chlorous acid; and the hyperoxygenated muriatic, chloric acid; the first, comparable to the hydriodic acid, and the last to the iodic acid.' In fact, therefore, we evidently see, that so far from the chloridic theory originating in France, as has been more than insi-nuated, it was only the researches on iodine, so ad-mirably conducted by Gay Lussac, that, by their auximiranly conducted by Gay Eussac, that, by their auxiliary attack on the oxygen hypothesis, eventually opened the minds of its adherents to the evidence long ago advanced by Sir H. Davy. It will be peculiarly instructive, to give a general outline of that evidence, which has been mutilated in some systematic works on chemistry, or frittered away into fragments.

Sir H. Davy subjected oxymuriatic gas to the action of many simple combustibles, as well as metals, and from the compounds formed, endeavoured to eliminate oxygen, by the most energetic powers of affinity and voltaic electricity, but without success, as the following abstract will show.

If oxymuriatic acid gas be introduced into a vessel exhausted of air, containing tin, and the tin be gently heated, and the gas in sufficient quantity, the tin and the gas disappear, and a limpid fluid, precisely the same as Libavius's liquor, is formed: If this substance is a combination of muriatic acid and oxide of tin, oxide of tin ought to be separated from it by means of annonia. He admitted ammoniacal gas over mercury to a small quantity of the liquor of Libavius; it was the oxide with great heat and no gas was generated: absorbed with great heat, and no gas was generated; a solid result was obtained, which was of a dull white colour; some of it was heated, to ascertain if it contained oxide of tin; but the whole volatilized, pro-

ducing dense pungent fumes.

Another experiment of the same kind, made with great care, and in which the ammonia was used in great excess, proved that the liquor of Libavius cannot be decompounded by ammonia; but that it forms a new combination with this substance.

He made a considerable quantity of the solid com-

pound of oxymuriatic acid and phosphorus by com- in their properties and powers of combination; but bustion, and saturated it with ammonia, by heating it in a proper receiver filled with ammoniacal gas, on which it acted with great energy, producing much heat; and they formed a white opaque powder. Supposing that this substance was composed of the dry muriates and phosphates of ammonia; as muriate of imuriates and phosphates of ammonia; as muriate of ammonia is very volatile, and as ammonia is driven off from phosphoric acid by a heat below redness, he conceived that, by igniting the product obtained, he should procure phosphoric acid; he therefore introduced some of the powder into a tube of green glass, and heated it to redness, out of the contact of air, by a spirit lamp; but found, to his great surprise, that it was not at all volatile, nor decomposable at this degree of heat, and that it gave off no gaseous matter.

The circumstance, that a substance composed principally of oxymuriatic acid, and ammonia, should resist decomposition or change at so high a temperature, induced him to pay particular attention to the proper-

induced him to pay particular attention to the proper-ties of this new body.

It has been said, and taken for granted by many chemists, that when oxymuriatic acid and ammonia act upon each other, water is formed: he several times made the experiment, and was convinced that this is

He mixed together sulphurated bydrogen in a high degree of purity, and oxymuriatic acid gas, both dried, in equal volumes. In this instance the condensation was not 1-40th; sulphur, which seemed to contain a little oxymuriatic acid, was formed on the sides of the vessel; no vapour was deposited, and the residual gas contained about 19-20ths of muriatic acid gas, and the

remainder was inflammable.

When oxymuriatic acid is acted upon by nearly an equal volume of hydrogen, a combination takes place between them, and muriatic acid gas results. When muriatic acid gas is acted on by mercury, or any other metal, the oxymuriatic acid is attracted from the hydrogen by the stronger affinity of the metal, and an oxymuriate, exactly similar to that formed by combus-

tion, is produced.

The action of water upon those compounds which have been usually considered as muriates, or as dry muriates, but which are properly combinations of oxy-muriatic acid with inflammable bases, may be easily explained, according to these views of the subject. When water is added in certain quantities to Libavius's liquor, a solid crystallized mass is obtained, from which oxide of tin and muriate of ammonia can be procured by ammonia. In this case, oxygen may be conceived to be supplied to the tin, and hydrogen to the oxymuriatic acid. the oxymuriatic acid.

The compound formed by burning phosphorus in oxymuriatic acid, is in a similar relation to water. If that substance be added to it, it is resolved into two powerful acids; oxygen, it may be supposed, is furnished to the phosphorus to form phosphoric acid, hydrogen to the oxymuriatic acid to form common muri-

atic acid gas.

He caused strong explosions from an electrical jar to pass through oxymuriatic gas, by means of points of platina, for several hours in succession; but it seemed

not to undergo the slightest change.

He electrized the oxymuriates of phosphorus and sulphur for some hours, by the power of the voltaic apparatus of 1000 double plates. No gas separated, but a minute quantity of hydrogen, which he was inclined to attribute to the presence of moisture in the apparatus employed; for he once obtained hydrogen from Libavius's liquor by a similar operation. But he ascertained that this was owing to the decomposition of water adhering to the mercury: and in some late experiments made with 2000 double plates, in which the discharge was from platina wires, and in which the mercury used for confining the liquor was carefully boiled, there was no production of any permanent elastic matter. manent elastic matter.

Few substances, perhaps, have less claim to be considered as acid, than oxymuriatic acid. As yet we have no right to say that it has been decompounded; and as its tendency of combination is with pure in-flammable matters, it may possibly belong to the same

class of bodies as oxygen.

May it not in fact be a peculiar acidifying and dis-solving principle, forming compounds with combustible bodies, analogous to acids containing oxygen or oxides, 216

differing from them, in being for the most part decom-posable by water? On this idea, muriatic acid may posable by water? On this idea, muriatic acid may be considered as having hydrogen for its basis, and oxymuriatic acid for its acidifying principle; and the phosphoric sublimate as having phosphorus for its basis, and oxymuriatic acid for its acidifying matter; and Libavius's liquor, and the compounds of arsenic with oxymuriatic acid, may be regarded as analogous bodies. The combinations of oxymuriatic acid with lead, silver, mercury, potassium, and sodium, in this view, would be considered as a class of bodies related more to oxides than acids, in their powers of attraction. more to oxides than acids, in their powers of attraction.

—Bak. Lec. 1809.

On the Combinations of the Common Metals with Dzygen and Ozymuriatic Gas. Sir H. used in all cases small retorts of green glass, containing from three to six cubical inches, furnished with stop-cocks. The metallic substances were introduced, the retort exhausted and filled with the gas to be acted upon, heat was applied by means of a spirit

be acted upon, heat was applied by means of a spirit lamp, and after cooling, the results were examined, and the residual gas analyzed.

All the metals that he tried, except silver, lead, nickel, cobait, and gold, when heated, burnt in the oxymuriatic gas, and the volatile metals with flame Arsenic, antimony, tellurium, and zinc, with a white flame, mercury with a red flame. Tin became ignited to whiteness, and iron and copper to redness; tungsten and manganese to dull redness; platina was scarcely acted upon at the heat of fusion of the glass.

The product from mercury was corrosive sublimate. That from zinc was similar in colour to that from antimony, but was much less volatile.

antimony, but was much less volatile. Silver and lead produced horn-silver and horn-lead;

and bismuth, butter of bismuth.

In acting upon metallic oxides by oxymuriatic gas, he found that those of lead, silver, tin, copper, antimony, bismuth, and tellurium, were decomposed in a heat below redness, but the oxides of the volatile metals more readily than those of the fixed ones. The oxides of cobalt and nickel were scarcely acted upon at a dull red heat. The red oxide of iron was not affected at a strong red heat, while the black oxide was readily decomposed at a much lower temperature; arsenical acid underwent no change at the greatest heat that could be given it in the glass retort, while the white oxide readily decomposed. In acting upon metallic oxides by oxymuriatic gas, he oxide readily decomposed.

In cases where oxygen was given off, it was found In cases where oxygen was given off, it was found exactly the same in quantity as that which had been absorbed by the metal. Thus, two grains of red oxide of mercury absorbed 9-10ths of a cubical inch of oxymuriatic gas, and afforded 0.45 of oxygen. Two grains of dark olive oxide from calomel decomposed by potassa, absorbed about 94-100ths of oxymuriatic gas, and afforded 24-100ths of oxygen, and corrosive sub limate was produced in both cases.

In the decomposition of the white oxide of size

In the decomposition of the white oxide of zinc, oxygen was expelled exactly equal to half the volume of the oxymuriatic acid absorbed. In the case of the decomposition of the black oxide of iron, and the white oxide of arsenic, the changes that occurred were of a very beautiful kind; no oxygen was given off in either case, but butter of arsenic and arsenical acid formed in one instance, and the ferruginous sublimate and red oxide of iron in the other.

General Conclusions and Observations, illustrated

by Experiments.

Oxymuriatic gas combines with inflammable bodies, to form simple binary compounds; and in these cases, when it acts upon oxides, it either produces the expulsion of their oxygen, or causes it to enter into new combinations.

combinations.

If it be said that the oxygen arises from the decomposition of the oxymuriatic gas, and not from the oxides, it may be asked, why it is always the quantity contained in the oxide? and why in some cases, as those of the peroxides of potassium and sodium, it bears no relation to the quantity of gas?

If there existed any acid matter in oxymuriatic gas, combined with oxygen, it ought to be exhibited in the fluid compound of one proportion of phosphorus, and two of oxymuriatic gas; for this, on such an assumption, should consist of muriatic acid (on the old hypothesis, free from water) and phosphorous acid; but this substance has no effect on litmus paper, and does not act under common circumstances, on fixed alkaline

bases, such as dry lime or magnesia. Oxymuriatic | gas, like oxygen, must be combined in large quantity with peculiar inflammable matter, to form acid matter. In its union with hydrogen, it instantly reddens the driest litmus paper, though a gaseous body. Contrary to acids, it expels oxygen from protoxides, and com-bines with peroxides.

When potassium is burnt in oxymuriatic gas, a dry compound is obtained. If potassium combined with oxygen is employed, the whole of the oxygen is expelled, and the same compound formed. It is contrary to sound logic to say, that this exact quantity of oxygen is given off from a body not known to be compound, when we are certain of its existence in another; and

all the cases are parallel.

Scheele explained the bleaching powers of the oxy-muriatic gas, by supposing that it destroyed colours by combining with phlogistan. Berthollet considered it as acting by supplying oxygen. He made an experi-ment, which seems to prove that the pure gas is in-capable of altering vegetable colours, and that its operation in bleaching depends entirely upon its property of

decomposing water, and liberating its oxygen.

He filled a glass globe, containing dry powdered muriate of lime, with oxymuriatic gas. He introduced some dry paper tinged with litmus that had been just heated, into another globe containing dry muriate of lime: after some time this globe was exhausted, and then connected with the globe containing the oxymuriatic gas, and by an appropriate set of stop-cocks, the paper was exposed to the action of the gas. No change of colour took place, and after two days there was scarcely a perceptible alteration.

Some similar paper dried, introduced into gas that had not been exposed to muriate of lime, was instantly

rendered white.

It is generally stated in chemical books, that oxymuriatic gas is capable of being condensed and crystal-lized at a low temperature. He found by several experiments that this is not the case. The solution of oxymuriatic gas in water freezes more readily than pure water, but the pure gas dried by muriate of lime undergoes no change whatever, at a temperature of 40 below 0° of Fahrenheit. The mistake seems to have arisen from the exposure of the gas to cold in bottles containing moisture.

He attempted to decompose boracic and phosphoric acids by oxymuriatic gas, but without success; from which it seems probable, that the attractions of boracium and phosphorus for oxygen are stronger than for oxymuriatic gas. And from the experiments already detailed, iron and arsenic are analogous in this re-

spect, and probably some other metals.

Potassium, sodium, calcium, strontium, barium, zinc, mercury, tin, lead, and probably silver, antimony, and gold, seem to have a stronger attraction for oxy-

muriatic gas than for oxygen.

*To call a body which is not known to contain oxygen, and which cannot contain muriatic-acid, oxymuriatic acid, is contrary to the principles of that nomen-clature in which it is adopted; and an alteration of it seems necessary to assist the progress of discussion, and to diffuse just ideas on the subject. If the great discoverer of this substance had signified it by any simple name, it would have been proper to have recurred to it; but dephlogisticated marine acid is a term which can hardly be adopted in the present advanced era of

After consulting some of the most eminent chemical philosophers in this country, it has been judged most proper to suggest a name founded upon one of its obvious and characteristic properties-its colour, and to

call it chlorine or chloric gas.

'Should it hereafter be discovered to be compound,

and even to contain oxygen, this name can imply no error, and cannot necessarily require a change.

'Most of the salts which have been called muriates, are not known to contain any muriatic acid, or any oxygen. Thus Libavius's liquor, though converted into a muriate by water, contains only tin and oxymutatic account here silver seems in the contains only the salt of heins. riatic gas, and horn-silver seems incapable of being converted into a true muriate. —Bak. Lec. 1811.

We shall now exhibit a summary view of the preparation and properties of chlorine.

Mix in a mortar 3 parts of common salt and 1 of black oxide of manganese. Introduce them into a glass retort, and add 2 parts of sulphuric acid. Gas will

issue, which must be collected in the water-pneumatic trough. A gentle heat will favour its extrication. In practice, the above pasty-consistenced mixture is apt to boil over into the neck. A mixture of liquid muriatic acid and manganese is therefore more convenient for the production of chlorine. A very slight heat is adequate to its expulsion from the retort. Instead of manganese, red oxide of mercury, or puce-coloured oxide of lead, may be employed.

This gas, as we have already remarked, is of a issue, which must be collected in the water-pneumatic

This gas, as we have already remarked, is of a greenish yellow-colour, easily recognised by daylight, but scarcely distinguishable by that of candles. Its odour and taste are disagreeable, strong, and so characteristic, that it is impossible to mistake it for any other gas. When we breather it even much diluted other gas. When we breathe it, even much diluted with air, it occasions a sense of strangulation, constriction of the thorax, and a copious discharge from the nostrils. If respired in larger quantity, its excites violent coughing, with spitting of blood, and would speedily destroy the individual, amid violent distress. Its specific gravity is 2.4733. This is better inferred from the specific gravities of hydrogen and muriatic acid gases, than from the direct weight of chlorine, from the impossibility of confining it over mercury. On volume of hydrogen, added to one of chlorine, form two of the ccid gas. Hence, if from twice the specific gravity of muriatic gas=2.5427, we subtract that of hydrogen=0.0694, the difference 2.4733 is the sp. gr. of chlorine. 100 cubic inches at mean pressure

and temperature weigh 75½ grains. See Gas.

In its perfectly dry state, it has no effect on dry vegetable colours. With the aid of a little moisture, it bleaches them into a yellowish-white. Scheele first remarked this bleaching property; Berthollet applied it to the art of bleaching in France; and from him Mr. Watt introduced its use into Great Britain.

If a lighted wax taper be immersed rapidly into this gas, it consumes very fast, with a dull reddish flame, and much smoke. The taper will not burn at the surface of the gas. Hence, if slowly introduced, it is apt to be extinguished. The alkaline metals, as well as copper, tin, arsenic, zinc, antimony, in fine laminæ or filings, spontaneously burn in chlorine. Metallic chlorides result. Phosphorus also takes fire at ordinary temperatures, and is converted into a chloride. Sulphur may be melted in the gas without taking fire, It forms a liquid chloride, of a reddish colour. When dry, it is not altered by any change of temperature. Enclosed in a phial with a little moisture, it concretes into crystalline needles, at 40° Fahr.

According to Thenard, water condenses, at the temperature of 68° F. and at 29.92 barom. 11-2 times its

volume of chlorine, and forms aqueous chlorine, for-merly called liquid oxymuriatic acid. This combina-tion is best made in the second bottle of a Woolfe's apparatus, the first being charged with a little water, to intercept the muriatic acid gas, while the third bottle may contain potassa-water or milk of lime, to condense the superfluous gas. Thenard says, that a kilogramme of salt is sufficient for saturating from 10 to 12 litres of water. These measures correspond to 2 1-3 lbs. avoirdupois, and to from 21 to 25 pints English. There is an insemious apparatus for making 2 1-3 lbs. avoirdupois, and to from 21 to 25 pints English. There is an ingenious apparatus for making aqueous chlorine, described in Berthollet's Elements of Dying, vol. i.; which, however, the happy substitution of slacked lime for water, by Mr. Charles Tennant, of Glasgow, has superseded, for the purposes of manufacture. It congeals by cold at 40° Fahr. and affords crystallized plates, of a deep yellow, containing a less proportion of water than the liquid combination. Hence when chlorine is passed into water at temperatures under 40°, the liquid finally becomes a concrete mass, which at a gentle heat liquefies with temperatures under 40°, the liquid finally becomes a concrete mass, which at a gentle heat liquefies with effervescence, from the escape of the excess of chlorine. When steam and chlorine are passed together through a red-hot porcelain tube, they are converted into muriatic acid and oxygen. A like result is obtained by exposing aqueous chlorine to the solar rays; with this difference, that a little chloric acid is formed. Hence aqueous chlorine should be kept in a dark place, aqueous chlorine attacks almost all the metals at an ordinary temperature, forming muriates or chlorides, and heat is evolved. It has the smell, taste, and colour of chlorine; and acts, like it, on vegetable and animal colours. Its taste is somewhat astringent, but not in the least degree acidulous.

When we put in a perfectly dark place, at the ordi-

When we put in a perfectly dark place, at the ordi-

nary temperature, a mixture of chlorine and hydrogen, nary temperature, a mixture of chlorine and hydrogen, it experiences no kind of alteration, even in the space of a great many days. But if, at the same low temperature, we expose the mixture to the diffuse light of day, by degrees the two gases enter into chemical combination, and form muriatic acid gas. There is no change in the volume of the mixture, but the change of its nature may be proved, by its rapid absorbability by water, its not exploding by the lighted taper, and the disappearance of the chlorine hue. To produce the complete discoloration, we must expose the mixture finally for a few minutes to the sunbeam. If exture finally for a few minutes to the sunbeam. posed at first to this intensity of light, it explodes with posed at first to this intensity of light, it explodes with great violence, and instantly forms muriatic acid gas. The same explosive combination is produced by the electric spark and the lighted taper. Thenard says, a heat of 392° is sufficient to cause the explosion. The proper proportion is an equal volume of each gas. Chlorine and nitrogen combine into a remarkable detonating compound, by exposing the former gas to a solution of an ammoniacal salt. Chlorine is the most powerful agent for destroying contagious miasmata. The disinfecting phials of Morveau evolve this gas."

— Ure.

CHLORITE. A mineral usually friable or very easy to pulverize, composed of a multitude of little spangles, or shining small grains, falling to powder under the pressure of the fingers. There are four sub-

1. Chlorite earth. In green, glimmering, and somewhat pearly scales, with a shining green streak.

2. Common chlorite. A massive mineral of a black-ish-green colour, a shining lustre, and a foliated fracture passing into earthy.

3. Chlorite slate. A massive, blackish-green mineral, with a resinous lustre, and curve slaty or scaly-foliated fracture.

4. Foliated chlorite. Colour between mountain and

blackish-green.
CHLORIODATE. A compound of the chloriodic acid with a salifiable basis.
CHLORIODE ACID. Acidum chloriodicum. See

Chloriodic acid.

CHLORIODIC ACID. Acidum chloriodicum. Chlorinde acid. Sir H. Davy formed it, by admitting chlorine in excess to known quantities of iodine, in vessels exhausted of air, and repeatedly heating the sublimate. Operating in this way, he found that iodine absorbs less than one-third of its weight of chlorine.

absorbs less than one-third of its weight of chlorine.

Chloriodic acid is a very volatile substance, formed by the sublimation of iodine in a great excess of chlorine, is of a bright yellow colour; when fused it becomes of a deep orange, and when rendered elastic, it forms a deep orange-coloured gas. It is capable of combining with much iodine when they are heated together; its colour becomes, in consequence, deeper, and the chloriodic acid and the iodine rise together in the elastic state. The solution of the chloriodic acid in water, likewise dissolves large quantities of iodine, so that it is possible to obtain a fluid containing very different proportions of iodine and chlorine.

When two bodies so similar in their characters, and in the compounds they form, as iodine and chlorine, act

in the compounds they form, as iodine and chlorine, act upon substances at the same time, it is difficult, Sir H. observes, to form a judgment of the different parts that they play in the new chemical arrangement produced. It appears most probable, that the acid property of the chloriodic compound depends upon the combination of the two bodies: and its action upon solutions of the alkalies and the earths may be easily explained, when it is considered that chlorine has a greater tendency than iodine to form double compounds with the metals, and that iodine has a greater tendency than chlorine to form triple compounds with oxygen and

A triple compound of this kind with sodium may exist in sea water, and would be separated with the first crystals that are formed by its evaporation. Hence, it may exist in common salt. Sir H. Davy ascertained, by feeding birds with bread soaked with water, holding some of it in solution, that it is not poisonous like iodine itself.—Ure's Ch. Dict.

CHLORO-CARBONOUS ACID. "The term chloro-carbonic which has been given to this compound is incorrect, leading to the belief of its being a compound of chlorine and acidified charcoal, instead of being a compound of chlorine and the protoxide of 218

charcoal. Chlorine has no immediate action on carcharcoal. Calorine has no immediate action on carbonic oxide, when they are exposed to each other in common daylight over mercury: not even when the electric spark is passed through them. Experiments made by Dr. John Davy, in the presence of his brother Sir H. Davy, prove that they combine rapidly when exposed to the direct solar beams, and one volume of each is condensed into one volume of the compound. The resulting gas possesses very curious properties, approaching to those of an acid. From the peculiar potency of the sunbeam in effecting this combination, Dr. Davy called it phosgene gas. The constituent gases, dried over muriate of lime, ought to be introduced from separate reservoirs into an exhausted globe, perfectly dry, and exposed for fifteen minutes to bright sunshine, or for twelve hours to daylight. The colour of the chloring disappears, and on opening the colour of the chlorine disappears, and on opening the stop-cock belonging to the slobe under mercury recently boiled, an absorption of one-half the gaseous volume is indicated. The resulting gas possesses properties perfectly distinct from those belonging to either

carbonic oxide or chlorine.

It does not fume in the atmosphere. Its odour is different from that of chlorine, something like that which might be imagined to result from the smell of chlorine combined with that of ammonia. It is in fact more intolerable and suffocating than chlorine itself, and affects the eyes in a peculiar manner, producing a rapid flow of tears, and occasioning painful

It reddens dry litmus paper; and condenses four volumes of ammonia into a white salt, while heat is evolved. This ammoniacal compound is neutral, has no odour, but a pungent saline taste; is deliquescent, decomposable by the liquid mineral acids, dissolves without effervescing in vinegar, and sublimes unaltered in muriatic, carbonic, and sulphurous acid gases. Sulphuric acid resolves itself into carbonic and muriatic acids, in the proportion of two in volume of the latter, and one of the former. Tin, zinc, anti mony, and arsenic, heated in chloro-carbonous acid, abstract the chlorine, and leave the carbonic oxide expanded to its original volume. There is neither ignition nor explosion takes place, though the action of the metals is rapid. Potassium acting on the compound gas produces a solid chloride and charcoal. White oxide of zinc, with chloro-carbonous acid, gives a metallic chloride, and carbonic acid. Neither sulphur, phosphorus, oxygen, nor hydrogen, though aided by heat, produce any change on the acid gas. But oxygen and hydrogen together, in due proportions, explode in it; or mere exposure to water converts it into muriatic and carbonic acid gases.

From its completely neutralizing ammonia, which carbonic acid does not; from its separating carbonic acid from the subcarbonate of this alkali, while itself is not separable by the acid gases or acetic acid, and its reddening vegetable blues, there can be no hesitation in pronouncing the chloro-carbonous compound to be an acid. Its saturating powers indeed surpass every other substance. None condenses so large a

proportion of ammonia.

One measure of alkohol condenses twelve of chlorocarbonous gas without decomposing it; and acquires the peculiar odour and power of affecting the eyes.

the peculiar odour and power of affecting the eyes.

To prepare the gas in a pure state, a good air-pump is required, perfectly tight stop-cocks, dry gases, and dry vessels. Its specific gravity may be inferred from the specific gravities of its constituents, of which it is the sum. Hence 2.4733 + 0.9722 = 3.4455, is the specific gravity of chloro-carbonous gas; and 100 cubic inches weigh 105.15 grains. It appears that when hydrogen, carbonic oxide, and chlorine, mixed in equal volumes, are exposed to light, muriatic and chloro-carbonous acids are formed, in equal proportions, indicating an equality of affinity.

The paper in the Phil. Trans. for 1812, from which the preceding facts are taken, does honour to the school of Sir H. Davy. Gay Lussac and Thenard, as well as Dr. Murray, made controversial investigations on the subject at the same time, but without success. Thenard has, however, recognised its distinct existence

subject at the same time, but without success. The-nard has, however, recognised its distinct existence and properties, by the name of carbo-muriatic acid, in the 2d volume of his System, published in 1814, where he considers it as a compound of muriatic and carbonic acids, resulting from the mutual actions of the ozygenated muriatic acid and carbonic oxide."- Ure.

CHLOROCYANIC ACID. Acidum ckloro-cyani-cum. Chloroprussic acid. "When hydrocyanic acid is mixed with chlorine, it acquires new properties. Its odour is much increased. It no longer forms prussian blue with solutions of iron, but a green precipitate, which becomes blue by the addition of sulphurous acid. Hydrocyanic acid, thus altered, had acquired the name of oxyprussic, because it was supposed to have acquired oxygen. Gay Lussac subjected it to a minute examination, and found that it was a compound of equal volumes of chlorine and cyanogen, whence he proposed to distinguish it by the name of chlorocyanic acid. To prepare this compound, he passed a current of chlorine into solution of hydrocyanic acid. nic acid, till it destroyed the colour of sulphate of in-digo; and by agitating the liquid with mercury, he deprived it of the excess of chlorine. By distillation, afterward, in a moderate heat, an elastic fluid is disengaged, which possesses the properties formerly assigned to oxyprussic acid. This, however, is not pure chlorocyanic acid, but a mixture of it with carbonic acid, in proportions which vary so much as to make it difficult to determine them.

When hydrocyanic acid is supersaturated with chlorine, and the excess of this last is removed by mercury, the liquid contains chlorocyanic and muriatic acids. the liquid contains chlorocyanic and muriatic acids. Having put mercury into a glass jar until it was 3-4ths full, he filled it completely with that acid liquid, and inverted the jar in a vessel of mercury. On exhausting the receiver of an air-pump, containing this vessel, the mercury sunk in the jar, in consequence of the elastic fluid disengaged. By degrees, the liquid itself was entirely expelled, and swam on the mercury on the outside. On admitting the air, the liquid could not enter the tube, but only the mercury, and the whole elastic fluid condensed, except a small bubble. Hence it was concluded, that chlorocyanic acid was not a permanent gas, and that, in order to remain not a permanent gas, and that, in order to remain gaseous under the pressure of the air, it must be mix-

ed with another gaseous substance.

The mixture of chlorocyanic and carbonic acids has the following properties. It is colourless. Its smell is very strong. A very small quantity of it irritates the pituitory membrane, and occasions tears. dens litmus, is not inflammable, and does not detonate when mixed with twice its bulk of oxygen or hydrogen. Its density, determined by calculation, is 2.111. Its aqueous solution does not precipitate nitrate of silver nor barytes water. The alkalies absorb it rapidly, but an excess of them is necessary to destroy its odour. If we then add an acid, a strong efferyescence. odour. If we then add an acid, a strong effervescence of carbonic acid is produced, and the odour of chloroof carbonic acid is produced, and the odour of chlorocyanic acid is no longer perceived. If we add an excess of lime to the acid solution, ammonia is disengaged in abundance. To obtain the green precipitate from solution of iron, we must begin by mixing chlorocyanic acid with that solution. We then add a little potassa, and at last a little acid. If we add the alkali before the iron, we obtain no green precipitate. Chlorocyanic acid exhibits with potassium almost the same phenomena as cyanogen. The inflammation is equally slow, and the gas diminishes as much in volume."—Ure.

CHLOROPHANE.

CHLOROPHANE. A violet fluor spar, found in

CHLOROPHILE. The name lately given by Pelletter and Caventou to the green matter of the leaves of plants. They obtain it by pressing, and then wash-ing in water, the substance of many leaves, and aftering in water, the substance of many leaves, and afterward treating it with alkohol. A matter was dissolved, which, when separated by evaporation, and purified by washing in hot water, appeared as a deepgreen resinous substance. It dissolves entirely in alkohol, wither, oils, or alkalies; it is not altered by exposure to air; it is softened by heat, but does not melt; it burns with flame, and leaves a bulky coal. Hot water slightly dissolves it. Acetic acid is the only acid that dissolves it in great quantity. If an earthy or metallic salt be mixed with the alkoholic solution, and then alkali or alkaline subcarbonate be added, the then alkali or alkaline subcarbonate be added, the oxide or earth is thrown down in combination with much of the green substance, forming a lake. These lakes appear moderately permanent when exposed to the air. It is supposed to be a peculiar proximate

CHLOROPRUSSIC ACID. See Chlorocyanic acid-

χλοα, or χλοη, herba virens · and hence χλωρασμα and χλωριασις, viror, pallor; so called from the yellow-greenish look those have who are affected with it.) Febris alba; Febris amatoria; Icterus albus; Chlorasma. The green-sickness. A genus of disease in the class Cachexia, and order Impetigines of Cullen. It is a disease which affects young females who labour under a retention or suppression of the meness. Hea-It is a disease which affects young females who labour under a retention or suppression of the menses. Heaviness, listlessness to motion, fatigue on the least exercise, palpitations of the heart, pains in the back, loins, and hips, flatulency, and acidities in the stomach and howels, a preternatural appetite for chalk, lime, and various other absorbents, together with many dyspeptic symptoms, usually attend on this disease. As it advances in its progress, the face becomes pale, or assumes a yellowish hue; the whole body is flaccid, and likewise pale; the feet are affected with ædematous swellings; the breathing is much hurried by any considerable exertion of the body; the pulse is quick, but small; and the person is apt to be affected with many of the symptoms of hysteria. To procure a flow of the menses, proves in some cases a very difficult matter; and where the disease has been of long standing, various morbid affections of the viscera are often brought on, which at length prove fatal. Dissections of those who have died of chlorosis, have usually shown the ovaria to be in a scirrhous, or dropsical state. In some cases, the liver, spleen, and mesenteric glands, have likewise been found in a diseased state. The cure is to be attempted by increasing the tone of the system, and eveiting the action of the province.

The cure is to be attempted by increasing the tone The cure is to be attempted by increasing the lone of the system, and exciting the action of the uterine vessels. The first may be effected by a generous nutritive diet, with the moderate use of wine; by gentle and daily exercise, particularly on horseback; by agreeable company, to amuse and quiet the mind; and by tonic medicines, especially the preparations of iron, joined with myrrh, &c. Bathing will likewise help much to strengthen them, if the temperature of the bath be made gradually lower, as the patient bears it; and sometimes drinking the mineral chalybeate waters may assist. The bowels must be kept regular, and ters may assist. The bowels must be kept regular, and occasionally a gentle emetic will prepare for the tonic plan. The other object of stimulating the uterine ves-sels may be attained by the exercises of walking and dancing; by frequent friction of the lower extremities; by the pediluvium, hip-bath, &c.; by electric shocks, passed through the region of the uterus; by active purgatives, especially those formula containing aloes, which acts particularly on the rectum. These means may be resorted to with more probability of success, when these appear efforts of the system to produce the when there appear efforts of the system to produce the discharge, the general health having been previously improved. Various remedies have been dignified with the title of emmenagogues, though mostly little to be depended on, as madder, &c. In obstinate cases, the tinctura lyttæ, or savine, may be tried, but with proper caution, as the most likely to avail.

CHLOROUS ACID. Acidum chlorosum. See

Chlorous oxide.
Chlorous oxide.
CHLOROUS OXIDE. Euchorine. Protoxide of chlorine. "To prepare it, put chlorate of potassa into a small retort, and pour in twice as much muriatic acid as will cover it, diluted with an equal volume of water. By the application of a gentle heat, the gas is evolved. It must be collected over mercury.

Its tint is much more lively, and more yellow than chlorine, and hence its discoverer named it euchlorine. chlorine, and hence its discoverer named it euchlorine. Its smell is peculiar, and approaches to that of burnt sugar. It is not respirable. It is soluble in water, to which it gives a lemon colour. Water absorbs 8 or 10 times its volume of this gas. Its specific gravity is to that of common air nearly as 2.40 to 1; for 100 cubic inches weigh, according to Sir H. Davy, between 74 and 75 grains. If the compound gas result from 4 volumes of chlorine + 2 of oxygen, weighing 12.1154, which undergo a condensation of one-sixth, then the specific gravity comes out 2.423, in accordance with Sir H. Davy's experiments. He found that 50 measures detonated in a glass tube over pure mercury, lost their brilliant colour, and became 60 measures, of their brilliant colour, and became 60 measures, of which 40 were chlorine and 20 oxygen.

which do were chrome and 20 oxygen.

This gas must be collected and examined with much prudence, and in very small quantities. A gentle heat, the air. It is supposed to be a peculiar proximate finciple.

CHLOROPRUSSIC ACID. See Chlorocyanic acid.

CHLORO'SIS. (From χλωρος, green, pale; from the chrome and 20 oxygen.

This gas must be collected and examined with much prudence, and in very small quantities. A gentle heat, even that of the hand, will cause its explosion, with such force as to burst thin glass. From this facility of decomposition, it is not easy to ascertain the action of combustible bodies upon it. None of the metals that

CHO CHO

burn in chlorine act upon this gas at common temperatures; but when the oxygen is separated, they then inflame in the clorine. This may be readily exhibited, by first introducing into the protoxide a little Dutch foil, which will not be even tarnished; but on applying a heated glass tube to the gas in the neck of the bottle, decomposition instantly takes place, and the foil burns with brilliancy. When already in chemical union, therefore, chlorine has a stronger attraction for oxygen than for metals; but when insulated, its affinity for the latter is predominant. Protoxide of chlorine has no action on mercury, but chlorine is rapidly condensed by this metal into calomel. Thus, the two gases may be completely separated. When phosphorus is introduced into the protoxide, it instantly burns, as it would do in a mixture of two volumes of burn in chlorine act upon this gas at common temperburns, as it would do in a mixture of two volumes of chlorine and one of oxygen; and a chloride and acid of phosphorus result. Lighted taper and burning sulphur likewise instantly decompose it. When the protoxide, freed from water, is made to act on dry vegetable colours, it gradually destroys them, but first cives to the blues a tire of red, from which from its getable colours, it gradually destroys them, but hist gives to the blues a tint of red; from which, from its absorbability by water, and the strongly acrid taste of the solution approaching to sour, it may be considered as approximating to an acid in its nature."—Ure.

Chlorure of iodine. The chloriodic acid.

CHNUS. (From χνανω, to grind; or rasp.) 1. Chaff;

2. Fine wool, or lint, which is, as it were, rasped from lint.

(Xoava, a funnel; from χεω, to pour Cho'ana. (Χοανα, a funnel; from χεω, to out.)
1. A funnel.
2. The infundibulum of the kidney and brain.

Cho'ANUS. A furnace made like a funnel, for melt-

ing metals. CHO'COLATE. CHO'COLATE. (Dr. Alston says this word is compounded of two Indian words, choco, sound, and atte, water; because of the noise made in its preparation.) An article of diet prepared from the cacao-nut; highly nourishing, particularly when boiled with milk and eggs. It is frequently recommended as a restoration. tive in cases of emaciation and consumption. See Theobroma cacao.

Chocolate tree. See Theobroma caeao. Chœ'nicis. (From χοινικις, the nave of a wheel.) The trepan; so called by Galen and P. Ægineta.

CHE'RADES. (From Xotpos, a swine.) The same as scrofula.

as scrofula.

Cherapole'thron. (From χοιρος, a swine, and ολιθρος, destruction; so named from its being dangerous if eaten by hogs.) Hogbane. A name in Aētius for the Xanthium, or louse-bur.

CHOI'RAS. (From χοιρος, a swine; so called because hogs are diseased with it.) See Scrofula.

Choke damp. The name given by miners to a noxious air, which is now known to be carbonic acid gras, found in mines, wells, and mineral springs. See Carbonic acid.

bonic acid.

CHO'LADES. (From χολη, the bile.) So the smaller intestines are called, because they contain bile. CHOLÆUS. (Χολαιος, bilious.) Biliary. CHOLA'GO. See Cholas.

CHOLAGO'GA. (From χολη, bile, and αγω, to evacuate.) Cholegon. By cholagogues, the ancients meant only such purging medicines as expelled the internal faces, which resembled the cystic bile in their release and other properties. internal faces, which resembled the cystic bile in their yellow colour, and other properties.

Cho'Las. (From χολη, the bile.) Cholago. All the cavity of the right hypochondrium, and part of the neighbourhood, is so called because it contains the liver which is the strainer of the gall.

CHO'LE. Χολη. The bile.

CHOLE DOCHUS. (From χολη, bile, and ἐεχομαι, to receive; receiving or retaining the gall.) The receptacle of bile.

CHOLEDOCHUS DECENS.

CHOLEDOCHUS DUCTUS. Ductus communis chole-dochus. The common biliary duct, which conveys both cystic and hepatic bile into the intestinum duodenum.

CHOLE'GON. See Cholagoga.

CHOLERA. (Celsus derives it from χολη, and ἡτω, literally a flow of bile, and Trailian, from χολας, and ἡτω, intestinal flux.) Diarrhæa cholerica; Felliflua passio. A genus of disease arranged by Cullen in the class Neuroses, and order Spasmi. It is a purging and vomiting of bile, with anxiety, painful gripings, spasms of the abdominal muscles, and those of the spasms of the abdominal muscles, and those of the

calves of the legs. There are two species of this genus:—1. Cholcra spontanca, which happens, in hot seasons, without any manifest cause. 2. Cholcra seasons, without any manifest cause. 2. Cholera accidentalis, which occurs after the use of food that digests slowly, and irritates. In warm climates it is met with at all seasons of the year, and its occurrence is very frequent; but in England, and other cold climates, it is apt to be most prevalent in the middle of summer, particularly in the month of August; and the violence of the disease has usually been observed to be greater in proportion to the intenseness of the heat. It usually comes on with soreness, pain, distension, and flatulency in the stomach and intestines, succeeded quickly by a severe and frequent vomiting, and purging of bilious matter, heat, thirst, a hurried respiration, and frequent but weak and fluttering pulse. When the disease is not violent, these symp-When the disease is not violent, these symppulse. When the disease is not violent, these symptoms, after continuing for a day or two, cease gradually, leaving the patient in a debilitated and exhausted state; but where the disease proceeds with much violence, there arises great depression of strength, with cold clammy sweats, considerable anxiety, a hurried and short respiration, and hiccups, with a sinking, and in the process of the makes which quickly terminate. and irregularity of the pulse, which quickly terminate in death; an event that not unfrequently happens

in death; an event that not unitequency happens within the space of twenty-four hours.

The appearances generally observed on dissection are, a quantity of bilious matter in the prime viæ; the ducts of the liver relaxed and distended; and several of the viscera have been found displaced, probably by the violent vomiting. In the early period of the disease, when the strength is not much exhausted, the object is to lessen the irritation, and facilitate the disobject is to lessen the irritation, and facilitate the dis-charge of the bile, by tepid demulcent liquids, fre-quently exhibited. It will likewise be useful to procure quently exhibited. It will likewise be useful to procure a determination to the surface by fomentations to the abdomen, the pediluvium, or even the warm bath. But where the symptoms are urgent, and the patient appears rapidly sinking from the continued vomiting, violent pain, &c. it is necessary to give opium freely, but in a small bulk; from one to three grains, or even more, in a table spoonful of linseed infusion, or with an effervescing saline draught; which must be repeated at short intervals, every hour perhaps, till relief be obtained. Sometimes, where the stomach could not be got to retain the opium, it has answered in the form of clyster; or a liniment containing it may be rubbed into the abdomen; or a blister, applied over the stomach, may lessen the irritability of that organ. Afterward the bile may be allowed to evacuate itself downwards; or mild aperients, or clysters, given, if necessary, to promote its discharge. When the urgent symptoms are relieved, the strength must be restored by gentle tonics, as the aromatic bitters, calumba, and the like with a light purificus distributions. the like, with a light nutritious diet: strong toast and water is the best drink, or a little burnt brandy may be added if there is much langour. Exposure to cold must be carefully avoided, particularly keeping the abdomen and the feet warm; and great attention is necessary to regulate the bowels, and procure a regular discharge of bile, lest a relapse should happen. It will also be proper to examine the state of the abdomen, whether pressure give pain at any part, because inflammation in the primæ viæ is very liable to supervene, often in an insidious manner; should that be the case, leeches, blistering the part, and other suitable means, must be promptly resorted to.

CHOLE RICA. (From χολερα, the cholera.) Medicines which relieve the cholera.

CHOLESTERIC ACID. "When the fat matter of the human biliary calculi is treated with nitric acid, which Ghevreuil proposed to call cholesterine, there is formed a peculiar acid, which is called the cholesteric. To obtain it, the cholesterine is heated with its weight of concentrated nitric acid, by which it is speedily attacked and dissolved. There is discongreted water is the best drink, or a little burnt brandy may be

To obtain it, the cholesterine is neated with its weight of concentrated nitric acid, by which it is speedily attacked and dissolved. There is disengaged, at the same time, much oxide of azot; and the liquor, on cooling, and especially on the addition of water, lets fall a yellow matter, which is the cholesteric acid impure, or impregnated with nitric acid. It may be purified by repeated washings in boiling water. However, after having washed it, it is better to effect its fusion in the midst of hot water; to add to it a small quantity of midst of hot water; to add to it a small quantity of carbonate of lead; to let the whole boil for some hours, decanting and renewing the water from time to time; then to put the remaining dried mass in contact with alkohol, and to evaporate the alkoholic solution. The

residuum now obtained is the purest possible choleste-

This acid has an orange-yellow colour when it is in mass; but it appears in white needles, when dissolved in alkohol, and left to spontaneous evaporation. Its taste is very feeble, and slightly styptic; its taste resembles that of butter; and its specific gravity is intermediate between that of alkohol and water. It fuses mediate between that of alkohol and water. It uses at 58° C. and is not decomposed till the temperature be raised much above that of boiling water. It then affords oil, water, carbonic acid, and carburetted hydrogen, but no trace of ammonia. It is very soluble in alkohol, sulphuric and acetic æther, in the volatile oils of lavender, rosemary, turpentine, bergamot, &c. It is, on the other hand, insoluble in the fixed oils of olives, sweet almonds, and castor oil. It is equally so in the recentable acids, and almost entirely insoluble in water. vegetable acids, and almost entirely insoluble in water, which takes up merely enough to make it redden litmus. Both in the cold, and with heat, nitric acid dissolves without altering it. Concentrated sulphuric acid acting on it for a considerable time, only carbonizes it.

It appears that the cholesteric acid is capable of uniting with the greater part of the salifiable bases. All the resulting saits are coloured, some yellow, others orange, and others red. The cholesterates of potassa, orange, and others red. The cholesterates of potassa, soda, ammonia, and probably of morphia, are very soluble and deliquescent; almost all the others are insoluble, or nearly so. There is none of them which cannot be decomposed by all the mineral acids, except the carbonic, and by the greater part of the vegetable acids; so that on pouring one of these acids into a solution of the cholesterate, the cholesteric acid is instantly separated in flocks. The soluble cholesterates form precipitates in all the metallic solutions, whose form precipitates in all the metallic solutions, whose base has the property of forming an insoluble or slightly soluble salt with cholesteric acid.

Pelletier and Caventou found the cholesterate of barytes to consist of 100 of acid, and 56.259 base; whence the prime equivalent of the former appears to be about 17.35. Yet they observed, on the other hand, that on treating the cholesterate of lead with sulphuric acid, they obtained as much sulphate of lead as of cholesterate. From this experiment, the equivalent of the dry acid would seem to be 5; hence we may ima-gine, that when the cholesteric acid unites to the oxide of lead, and in general to all the oxides which have a slight affinity for oxygen, there takes place something

similar to what happens in the reaction of oxide of lead and oxalic acid."—Journ. de Phar. iii. 292.

CHOLESTERINE. The name given by Chevreuil to the pearly substance of human biliary calculi. It consists of 72 carbon, 6.66 oxygen, and 21.33 hydrogen, by Bearly 2019. by Berard.

by Berard.

CHOLICE'LE. (From $\chi o \lambda \eta$, bile, and $\chi \eta \lambda \eta$, a tumour.) A swelling formed by the bile accumulated in the gall-bladder.

CHOLOLITHUS. (From $\chi o \lambda \eta$, bile, and $\lambda \iota \theta o s$, a stone, gall-stone.) A name of a genus of disease in the Class, Caliaca; Order, Splanchnica, of Good's Nosology, characterized by pain about the region of the liver, catenating with pain at the pit of the stomach; the pulse unchanged; sickness; dyspepsy; inactivity; bilious concretion in the gall bladder, or bile ducts. It has two species, Chololithus quiescens, the quiescent has two species, Chololithus quiescens, the quiescent gall-stone, and C. means, the passing of gall-stones. CHOLOLITHICUS. Of or belonging to gall-stone.

Cholo'MA. (From χωλος, lame, or maimed.) A halting, or lameness in the leg.

2. Galen says that, in Hippocrates, it signifies any distortion of a limb.

CHONDRO. Some muscles have this word forming a part of their name, because they are connected with

a particular cartilage. CHONDROGLO'SSUS. (From χονδρον, a cartilage, and γλωσση, the tongue.) A muscle so named from its insertion, which is in the basis or cartilaginous part of

the tongue. See Hyoglossus.
CHONDRO LOGY. (Chondrologia; from χονόρος, a cartilage, and λογος, a discourse.) A discourse on cartilages

CHONDRO PHARYNG EUS. (From χονδρος, a cartilage, and φαρνγξ, the upper part of the fauces.) A muscle so named because it rises in the cartilaginous part of the tongue, and is inserted in the pharynx.

CHONDROS. Χονδρος. 1. A cartilage.

2. A food of the ancients, the same as alica.

3. Any grumous concretion.

CHONDROSYNDE'SMUS. (From χονδρος, a cartilage, and συνδεω, to tie together.) A cartilaginous ligament.

CHO'NDRUS. A cartilage.

Cho'ne. $X\omega\nu\eta$. The infundibulum. Cho'ra. $X\omega\nu\eta$. The infundibulum. Galen, in his book De Usu Partium, expresses by it particularly the cavities of the eyes; but, in others of his writings, he intimates by it any void space. CHO'RDA. (From

CHO'RDA. (From χορόη, which properly signifies an intestine, or gut, of which a chord may be made.)

 A cord, or assemblage of fibres. 2. A tendon.

3. A painful tension of the penis in the venereal disease.

Sometimes the intestines are called chordes.

CHORDA MAGNA. A name of the tendo Achillis.
CHORDA TYMPANI. A branch of the seventh pair of nerves. The portio dura of the seventh pair of nerves, having entered the tympanum, sends a small branch to the stapes, and another more considerable one, which runs across the tympanum from behind forwards, passes between the long leg of the incus and the handle of the malleus, then goes out at the same place where the tendon of the anterior muscle of the malleus enters. It is called chorda tympani, because it crosses the tympanum as a cord crosses the bottom of a drum. Dr. Monro thinks, that the chorda tympani is formed by the second branch of the fifth pair, as well as by the portio dura of the seventh.

CHORDA TENDINEA. The tendinous and cord-like

substances which connect the carnew columna of the ventricles of the heart to the auricular valves.

CHORDA WILLISII. The small fibres which cross the sinuses of the dura mater. They are so termed, because Willis first described them.

cause Willis first described them.

Chorda Psus. (From χορδη, a cord, and απ7ω, to knit.) A sort of painful colic, where the intestines appear to be twisted into knots.

CHORDEE'. (Chorde. French.) A spasmodic contraction of the penis, that sometimes attends gonorrhæa, and is often followed by a hæmorrhæge.

CHOREA. (Χορτα; from χορος, a chorus, which of old accompanied dancing. It is called St. Vitus's dance, because some devotees of St. Vitus exercised themselves so long in dancing, that their intellects were disordered, and could only be restored by dancing again at the anniversary of St. Vitus') Chorea Sancti Viti. Synclonus chorea of Good. St. Vitus's dance. Convulsive motions of the limbs, as if the person were dancing. It is a genus of disease, arranged by Cullen in the class Neuroses; and order Spasmi. These conin the class Neuroses; and order Spasmi. These convulsive motions, most generally, are confined to one side, and affect principally the arm and leg. When any motion is attempted to be made, various fibres of other muscles act which ought not; and thus a contrary effect is produced from what the patient intended. It is chiefly incident to young persons of both sexes, and makes its attack between the age of ten and fifteen, occurring but seldom after that of puberty.

By some practitioners it has been considered rather

as a paralytic affection than as a convulsive disorder, and has been thought to arise from a relaxation of the muscles, which, being unable to perform their func-tions in moving the limbs, shake them irregularly by jerks. Chorea Sancti Viti is occasioned by various irritations, as teething, worms, offensive smells, poi-sons, &c. It arises likewise in consequence of violent affections of the mind, as horror, fear, and anger. In many cases it is produced by general weakness; and, in a few, it takes place from sympathy, at seeing the disease in others.

disease in others.

The fits are sometimes preceded by a coldness of the feet and limbs, or a kind of tingling sensation, that ascends like cold air up the spine, and there is a flatulent pain in the left hypochondrium, with obstinate costiveness. At other times, the accession begins with yawning, stretching, anxiety about the heart, palpitations, nausea, difficulty of swallowing, noise in the ears, giddiness, and pains in the head and teeth; and then come on the convulsive motions.

These discover themselves at first by a kind of lame-

These discover themselves at first by a kind of lameness, or instability of one of the legs, which the person draws after him in an odd and ridiculous manner; nor can he hold the arm of the same side still for a mo-ment: for if he lays it on his breast, or any other part of his body, it is forced quickly from thence by an in-

CHR CHR

voluntary motion. If he is desirous of drinking, he uses many singular gesticulations before he can carry the cup to his head, and it is forced in various directions, till at length he gets it to his mouth; when he pours the liquor down his throat in great haste, as if he meant to afford amusement to the by-standers. Sometimes various attempts at running and leaping take place; and at others, the head and trunk of the body are affected with convulsive motions. In many instances, the mind is affected with some degree of fatuity, and often shows the same causeless emotions (such as weeping and laughing) which occur in hyste-(such as weeping and laughing) which occur in hysteria. When this disease arises in children, it usually ceases about the age of puberty; and in adults, is often carried off by a change from the former mode of living. Unless it passes into some other disease, such as epilesse, it is hardly attended with danger.

carried off by a change from the former mode of living. Unless it passes into some other disease, such as epilepsy, it is hardly attended with danger.

The leading indications in the treatment of this complaint are, 1. To obviate the several exciting causes; 2. To correct any faulty state of the constitution, which may appear to give a predisposition; 3. To use those means which experience has shown best calculated to allay irregular muscular action. Among the sources of irritation, the most common is the state of the bowels; and the steady, but moderate, use of active cathartics has often a great effect upon the disease, improving the appetite and strength at the same time. Senna, scammony, jalap, &c. may be exhibited according to circumstances, often in conjunction with calomel, particularly where the liver is torpid. The general debility usually attending indicates the employment of tonics, as the cinchona, chalybeates, or sulphate of zinc, which is particularly useful; and with these, cold bathing, not too long continued, may be advantageously conjoined; also requiring the patient to use muscular exertion, as much as they can readily, will assist materially in the cure. Sometimes in violent cases, and in irritable constitutions, the occasional exhibition of opium, or other sedative, may be required, taking care, however, that the bowels are not confined thereby. Occasionally too, where the above means are not successful, the more powerful antispasmodics may be tried, as æther, camphor, musk, &c. Electricity also has been by some recommended. CHO'RION. (From χωρεω, to escape; because it Electricity also has been by some recommended.

CHO'RION. (From χωρεω, to escape; because it always escapes from the uterus with the fœtus.) Shaggy chorion. The external membrane of the fœtus

CHO ROID. (Choroidea; from χοριον, the chorion, and ειέος, resemblance.) Resembling the chorion, a

membrane of the fætal ovum.

CHOROID MEMBRANE. Membrana choroides. second tunic of the eye, lying immediately under the sclerotica, to which it is connected by vessels. The true knowledge of this membrane is necessary to a perfect idea of the iris and uvea. The tunica choroidea commences at the optic nerve, and passes for-wards, with the sclerotic coat, to the beginning of the cornea transparens, where it adheres very firmly to the sclerotic membrane, by means of a cellular mem-brane, in the form of a white fringe, called the *ciliary circle*. It then recedes from the sclerotica and cornea circle. It then recedes from the sclerotica and cornea and ciliary circle, directly downwards and inwards, forming a round disk, which is variously coloured; hence, blue, black eyes, &c. This coloured portion, reflected inwards, is termed the iris, and its posterior surface is termed uvea. The choroid membrane is highly vascular, and its external vessels are disposed like stars, and termed vasa vortices. The internal surface of this membrane is covered with a black pigment, called the pigment of the choroid membrane.

Chapter Plexus. Plexus choroideus. A plexus

CHOROID PLEXUS. Plexus choroideus. A plexus of blood-vessels, situated in the lateral ventricles of the

brain.

Choroid tunic. See Choroid membrane. CHRI'SIS. (From χοιω, to anoint.) An inunction,

or anointing of any part. Christmas rose. See Helleborus niger.

Christmas rose. See Helleborus niger.
Chris'Tum. (From χοιω, to anoint.) An unguent,
or ointment of any kind.
CHRO'MAS. A chromate, or salt, formed by the

union of chromic acid with salifiable bases; as chromate of lead, &c.

["Chromate of iron, is found in large quantities, at the bare hills, near Baltimore, (Maryland.) massive and granular, in veins and masses disseminated through a sementine rock. serpentine rock. Perhaps in no part of the world has

voluntary motion. If he is desirous of drinking, he iso much been discovered at one place, it furnishes the means of preparing the beautiful paint called the chromic yellow, with which carriages and furniture are now painted in the United States. Chromate of iron, now painted in the United States. Chromate of Iron, in octaedral crystals, very small and magnetic, is found at the same place, and has nowhere else been discovered, as far as we can learn from the writings of mineralogists. The crystals are found in the ravines, and on the sand of the rivulets of the barehills, mixed with granular chromate of iron. The hills, mixed with granular chromate of iron. The green oxide of chrome is also found there, colouring the tale, as well as the ruby or violet coloured ore."—

Bruce's Min. Jour. A.]
Curomati's Mus. (From χρωμαζίζω, to colour.)
The morbid discoloration of any of the secretions, as

of the urine, or blood. CHRO'MIC ACID. CHRO'MIC ACID. Acidum chromicum. "This acid was extracted from the red lead ore of Siberia, by treating this ore with carbonate of potassa, and separating the alkali by means of a more powerful acid. In this state it is a red or orange-coloured powacid. In this state it is a red or orange-coloured pow-der, of a peculiar rough metallic taste, which is more sensible in it than in any other metallic acid. If this-powder be exposed to the action of light and heat, it loses its acidity, and is converted into green oxide of chrome, giving out pure oxygen gas. The chromic acid is the first that has been found to deoxygenate itself easily by the action of heat, and afford oxygen rose by this simple operation. It appears that executgas by this simple operation. It appears that several of its properties are owing to the weak adhesion of a part at least of its oxygen. The green oxide of chrome part at least of its oxygen. The green oxide of chrome cannot be brought back to the state of an acid, unless its oxygen be restored by treating it with some other

The chromic acid is soluble in water, and crystallizes, by cooling and evaporation, in longish prisms of a ruby red. Its taste is acrid and styptic. Its specific gravity is not exactly known; but it always exceeds that of water. It powerfully reddens the tincture of tornsole. Its action on combustible substances is little known.

If it be strongly heated with charcoal, it grows black, and passes to the metallic state without melting

and passes to the metallic state without melting
Of the acids, the action of the muriatic on it is themost remarkable. If this be distilled with the chromic
acid, by a gentle heat, it is readily converted into chlorine. It likewise imparts to it by mixture the property
of dissolving gold; in which the chromic resembles
the nitric acid. This is owing to the weak adhesion
of its oxygen, and it is the only one of the metallicacids that possesses this property.

The extraction of chromic acid from the French ore,
is performed by igniting it with its own weight of nitre.

is performed by igniting it with its own weight of nitre in a crucible. The residue is lixiviated with water, which being then filtered, contains the chromate of potassa. On pouring into this a little nitric acid and potassa. On pouring into this a little little acid and muriate of barytes, an instantaneous precipitate of the chromate of barytes takes place. After having procured a certain quantity of this salt, it must be put in its moist state into a capsule, and dissolved in the smallest possible quantity of weak nitric acid. The barytes is to be then precipitated by very dilute sulphuric acid, taking care not to add an excess of it. When the liquid is found by trial to contain neither sulphuric acid nor barytes, it must be filtered. It was a sulphuric acid nor barytes, it must be filtered. sulphuric acid nor barytes, it must be filtered. It now consists of water, with nitric and chromic acids. The whole is to be evaporated to dryness, conducting the heat at the end so as not to endanger the decomposition of the chromic acid, which will remain in the capsule under the form of a reddish matter. It must be kept in a glass phial well corked.

Chromic acid, heated with a powerful acid, becomes

combinations of the chromic acid with barytes, and oxide of lead, its prime equivalent seems to be 6.5; consisting of 3.5 chromium, and 3.0 oxygen.

It readily unites with alkalies, and is the only acid that has the property of colouring its salts, whence the name of chromic has been given it. If two parts of the red lead ore of Siberia in fine powder be boiled with one of an alkali saturated with carbonic acid, in forty parts of water, a carbonate of lead will be precipitated, and the chromate remain dissolved. The solutions are of a lemon colour, and afford crystale solutions are of a lemon colour, and afford crystals

of a somewhat deeper hue. Those of chromate of ammonia are in yellow laminæ, having the metallic

The chromate of barytes is very little soluble, and that of lime still less. They are both of a pale yellow, and when heated give out oxygen gas, as do the

alkaline chromates.

If the chromic acid be mixed with filings of tin and the muriatic acid, it becomes at first yellowish-brown, and afterward assumes a bluish-green colour, which preserves the same shade after desiccation. preserves the same shade after desiccation. Æther alone gives it the same dark colour. With a solution of nitrate of mercury, it gives a precipitate of a dark cinnabar colour. With a solution of nitrate of silver, it gives a precipitate, which, the moment it is formed, appears of a beautiful carmine colour, but becomes purple by exposure to the light. This combination, exposed to the heat of the blow-pipe, melts before the charcoal is inflamed and assumes a blackbefore the charcoal is inflamed, and assumes a black-ish and metallic appearance. If it be then pulver-ized, the powder is still purple; but after the blue flame of the lamp is brought into contact with this powder, it assumes a green colour, and the silver appears in globules disseminated through its sub-

With nitrate of copper it gives a chesnut-red precipitate. With the solution of sulphate of zinc, muriate of bismuth, muriate of antimony, nitrate of nickel, at of plating it produces yellowish precipiand muriate of platina, it produces yellowish precipi-tates, when the solutions do not contain an excess of acid. With muriate of gold it produces a greenish

precipitate.

When melted with borax, or class, or acid of phosphorus, it communicates to it a beautiful emeraldgreen colour.

If paper be impregnated with it, and exposed to the sun a few days, it acquires a green colour, which remains permanent in the dark.

A slip of iron, or tin, put into its solution, imparts to it the same colour.

The aqueous solution of tannin produces a floccu-

The aqueous solution of tannin produces a flocculent precipitate of a brown fawn colour.

Sulphuric acid, when cold, produces no effect on it; but when warm it makes it assume a bluish-green colour."—Ure's Dict.

CHROMIUM. (Chromium, ii. n.; from χρωμα, colour: because it is remarkable for giving colour to its combinations.) The pame of a metal which may be extracted either from the pative chromate of lead or extracted either from the native chromate of lead or of iron. The latter being cheapest and most abun-

dant, is usually employed.

The brown chromate of iron is not acted upon by nitric acid, hut most readily by nitrate of potassa, with the aid of a red heat. A chromate of potassa, soluble in water, is thus formed. The iron oxide thrown out of combination may be removed from the residual part of the ore by a short digestion in dilute muriatic acid. A second fusion with 4 of nitre, will give rise to a new portion of chromate of potassa. Having decomposed the whole of the ore, we saturate the alkaline excess with nitric acid, evaporate and crystallize. The pure crystals, dissolved in water, are to be added to a solution of neutral nitrate of mercury; whence, by complex affinity, red chromate of mercury precipitates. Moderate ignition expels the mercury from the chromate, and the remaining chromic acid may be reduced to the metallic state, by being exposed in contact of the charcoal from sugar, to a violent heat.

Chromium thus procured, is a porous mass of ag-glutinated grains. It is very brittle, and of a grayish-white, intermediate between tin and steel. It is somewinte, intermediate netween tin and steel. It is sometimes obtained in needleform crystals, which cross each other in all directions. Its sp. gravity is 5.9. It is susceptible of a feeble magnetism. It resists all the acids except nitromuriatic, which, at a boiling heat, oxidizes it and forms a muriate. Thenard describes only one oxide of chromium; but there are probably two, besides the acid already described.

1. The protoxide is green, infusible, indecomposable by heat, reducible by voltaic electricity, and not acted on by oxygen or air. When heated to dull redness with the half of its weight of potassium or sodium, it forms a brown matter, which, cooled and exposed to the air, burns with flame, and is transformed into chromate of potassa or soda, of a canary-yellow colour. It is this oxide which is obtained by calcining

the chromate of mercury in a small earthen retort for about of an hour. The beak of the retort is to be surrounded with a tube of wet linen, and plunged into water, to facilitate the condensation of the merinto water, to facilitate the condensation of the mer-cury. The oxide, newly precipitated from acids, has a dark-green colour, and is easily redissolved; but exposure to a dull-red heat ignites it, and renders it denser, insoluble, and of a light-green colour. This change arises solely from the closer aggregation of the particles, for the weight is not altered. 2. The deutoxide is procured by exposing the pro-tonitrate to heat, till the fumes of nitrous gas cease to issue. A brilliant brown powder, insoluble in

to issue. A brilliant brown powder, insoluble in acids, and scarčely soluble in alkalies, remains. Muriatic acid digested on it exhales chlorine, showing the increased proportion of oxygen in this oxide.

3. The tritoxide has been already described among

the increased proportion of oxygen in this oxide.

3. The tritoxide has been already described among the acids. It may be directly procured by adding nitrate of lead to the above nitrochromate of potassa, and digesting the beautiful orange precipitate of chromate of lead with moderately strong muriatic acid, till its power of action be exhausted. The fluid produced is to be passed through a filter, and a little oxide of silver very gradually added, till the whole solution becomes of a deep red tint. This liquor, by slow evaporation, deposites small ruby-red crystals, which are the hydrated chromic acid. The prime equivalent of chromic acid deduced from the chromates of barytes and lead by Berzelius, is 6.544, if we suppose them to be neutral salts. According to this chemist, the acid contains double the oxygen that the green oxide does. But if those chromates be regarded as subsalts, then the acid prime would be 13.088, consisting of 6 oxygen = 7.088 metal; while the protoxide would consist of 3 oxyxen + 7.088 metal; while the protoxide would consist of 3 oxyxen + 7.088 metal; and the deutoxide of an intermediate proportion.

CHRO'NIC. (Chromicus; from χρονος, time.) A term applied to diseases which are of long continuance, and mostly without fever. It is used in opposition to the term acute. See Acute.

CHRU'PSIA. (From χροα, colour, and οψις, sight.) Visus coloratus. A disease of the eyes, in which the person perceives objects of a different colour from their natural one.

CHRYSA'NTHEMUM. (From χρονος, gold, and

natural one.

CHRYSA'NTHEMUM. (From χουσος, gold, and ανθεμον, a flower.) 1. The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Polygamia. Sun-flower, or marigold.

2. Many herbs are so called, the flowers of which are

of a bright yellow colour.

Chrysanthemum leucanthemum. The systematic name of the great ox-eye daisy. Maudlin-wort. Bellis-major; Buphthalmum majus; Leucanthemum vulgare; Bellidioides; Consolida media; Oculus bovis. The Chrysanthemum;—foliis amplexicaulibus, oblongis, supernè serratis, infernè dentatis, of Linnæus. The flowers and herb were formerly esteemed in asthmatic, and phthisical diseases, but have now deserved by follow into disease. deservedly fallen into disuse.

CHRY'SE. (From xovoos, gold.) The name of a

yellow plaster.

CHYSELE CTRUM. (From χρυσος, gold, and ηλεκ γρου, amber.) Amber of a golden yellow colour.

CHRYSI'PPEA. (From Chrysippus, its discoverer.)

An herb enumerated by Pliny.

Chrysi'tis. (From χουσος, gold.) 1. Litharge. 2. The yellow foam of lead.

3. The herb yarrow, from the golden colour of its

CHRYSOBA'LANUS. (From χρυσος, gold, and βαλανος, a nut; so named because of its colour, which, before it is dried, is yellow.) The nutmeg. CHRYSOBERYL. Cymophane of Haüy. A mineral of an asparagus green colour and vitreous lustre, found in the Brazil, and Ceylon.

[CHRYSOBERYL is found in the United States, and is sometimes employed in jewelry. In the township of sometimes employed in jewelry. In the township of Haddam, on the Connecticut river, and in the State of Connecticut, it occurs in granite in six-sided prisms and six-sided tables; its colour varies from greenish yellow to yellowish green. A.]

CHRYSOCO'LLA. (From χουσος, gold, and κολλη, cement.) Gold solder; Borax.

CHYSO'COMA. (From χουσος, gold, and κολη, thir; so called from its golden, hair-like appearance.) The herb milfoil, or yarrow. See Achillea millefolium.

223

CHRYSOGO'NIA. (From χουσος, gold, and γινομαι, to become.) A tincture of gold.

CHRYSOLA'CHANON. (From χουσος, gold, and λα-χανον, a pot-herb; so named from its having a yellow leaf.) The herb orach; a species of atriplex.

CHRYSOLITE. Peridot of Haüy. Topaz of the ancients, while our topaz is their chrysolite. The hard-

ancients, while our topas is then carysome. The natesest of all gems of a pistachio-green colour. It comes from Egypt and Bohemia.

CHRYSOSPLE NIUM. (From χρυσος, gold, and ασπλενιον, spleenwort.) The name of a genus of

CHRYSOSPLE NIUM. (From χρυσος, gold, and ασπλεινίον, spleenwort.) The name of a genus of plants in the Linnæan system. Class, Decandria; Order, Digynia. Golden saxifrage.

CHRYSOPRASE. A variety of calcedony.

CHRYSULCUS. (From χρυσος, gold, and ελκω, to take away.) The aqua regia which has the property of dissolving gold.

[CHURCH, Dr. Benjamin, was graduated at Howard College in 1754. He established himself as a physician in the town of Boston, where he rose to very considerable eminence in his profession. As a skilful considerable eminence in his profession. As a skilful and dexterous operator in surgery, he was inferior to no one of his contemporaries in New-England; and as a physician, he was in a career of distinguished re-putation. He possessed a brilliant genius, a lively poetic fancy, and was an excellent writer. For several years preceding the American revolution, he was a conspicuous character, and had great influence among the leading whigs and patriots of the day. When the war commenced in 1775, his character was so high that he was appointed physician-general to the army.

But while he was performing the duties assigned him,

circumstances occurred which led to a suspicion that he held a treacherous correspondence with the enemy. Certain letters in cipher were intercepted, which he had written to a relation in Boston. He was immehad written to a relation in Boston. diately arrested, imprisoned, and tried before a military tribunal appointed to investigate his conduct, and was pronounced guilty of a criminal correspondence with the enemy. It appears that the only evidence by which he was convicted, rested on an intercepted letter directed to a friend in Boston. This letter was written in cipher, and when it was deciphered and examined, its contents seemed in a considerable degree to justify the plea which he had made, that it was designed as an innocent stratagem to deceive and draw from the enemy some information for the benefit of the public. Dr. C. was, at the same time, a member of the House of Representatives, from which he would have been expelled had he not resigned his seat. He was, however, arraigned before the House, subjected to a rigid examination, and his letter was read by him-self by paragraphs, and commented upon, and explain-ed. His defence before the House may be considered as a specimen of brilliant talents and great ingenuity. "Confirmed," said he, in assured innocence, "I stand prepared for your keenest searchings. The warmest bosom here does not flame with a brighter zeal for the bosom here does not hame with a brighter zeal for the security, happiness, and liberties of America, than mine." So high was party zeal, and such the jealousy and prejudice of the day, that a torrent of indignation was ever at hand to sweep from the land every guilty or suspected character. In the instance of Dr. C., there were not a few among the most respectable and intelligent of the community, who expressed strong doubts of a criminal design in his conduct. It was, however, his hard fate to pine in prison until the following year, when he obtained permission to depart for the West Indies. The vessel in which he sailed was supposed to have foundered at sea, as no tidings respecting her

were ever obtained. A.]
CHUSITE. A yellowish-green translucent mineral,
found by Saussure in the cavities of porphyries, in the environs of Limbourg.

CHYAZIC ACID. See Prussic acid.

CHYLA'RIA. (From χυλος, chyle.) A discharge of a whitish mucous urine, of the colour and consistence of chyl

CHYLE. Chylus. The milk-like liquor observed some hours after eating, in the lacteal vessels of the mesentery, and in the thoracic duct. It is separated by digestion from the chyme, and is that fluid substance from which the blood is formed. See Digestion.

"The chyle may be studied under two different forms."

forms:

1st, When it is mixed with chyme in the small intestine.

2d, Under the liquid form, circulating in the chyliferous vessels, and the thoracic duct.

No person having particularly engaged in the examination of the chyle during its stay in the small intestine, our knowledge on this point is little. The liquid chyle contained in the chyliferous vessels has been examined with great care.

In order to procure it, the best manner consists in giving food to an animal, and, when the digestion is supposed to be in full activity, to strangle it, or to cut the spinal marrow behind the occipital bone. The whole length of the breast is cut open; the hand is thrust in so as to pass a ligature which embraces the aorta, the œsophagus, and the thoracic duct, the near-est to the neck possible; the ribs of the left side are then twisted or broken, and the thoracic duct is seen, closely adhering to the œsophagus. The upper part is detached, and carefully wiped, to absorb the blood; it is cut, and the chyle flows into the vessel intended to

The ancients were acquainted with the existence of the chyle, but their ideas of it were very inexact; it was observed anew at the beginning of the seventeenth century; and being, in certain conditions, of an opaque white, it was compared to milk: the vessels that contain it were even named lacteal vessels, a very

improper expression, since there is very little other similarity between chyle and milk except the colour. It is only in modern times, and by the labours of Dupuytren, Vauquelin, Emmert, and Marcet, that positive notions concerning the chyle have been acquired.

We shall give the observations of these learned

men, with the addition of our own.

If the animal from which the chyle is extracted has eaten animal or vegetable substances of a fatty nature, the liquid drawn from the thoracic duct is of a milky white, a little heavier than distilled water, of a strong spermatic odour, of a salt taste, slightly adhering to the tongue, and sensibly alkaline.

Chyle, very soon after it has passed out of the vessel that earliered it has passed out of the vessel that earliered it has passed out of the vessel.

that contained it, becomes firm, and almost solid: after some time, it separates into three parts; the one solid that remains at the bottom, another liquid at the top, and a third that forms a very thin layer at the surface of the liquids. The chyle, at the same time, assumes a vivid rose colour.

When the chyle proceeds from food that contains no fat substance, it presents the same sort of properties, but instead of being opaque white, it is opaline, and almost transparent; the layer which forms at the top is less marked than in the former sort of chyle. Chyle never takes the hue of the colouring sub-

stances mixed in the food, as many authors have pre-

Animals that were made to eat indigo, saffron, and madder, furnished a chyle, the colour of which had no relation to that of the substances.

Of the three substances into which the chyle separates when abandoned to itself, that of the surface, of

an opaque white colour, is a fatty body; the solid part is formed of fibrin and a little colouring matter; the liquid is like the serum of the blood.

The proportion of these three parts is variable according to the nature of the food. There are species of chyle, such as that the sugar, which contain very little fibrin; others, such as that of flesh, contain more. The same thing happens with the fat matter, which is very abundant when the food contains grease or oil, while there is scarcely any seen when the food is nearly deprived of fatty bodies.

The absorption of the chyle has been attributed to the capillarity of the lactcal radicles, to the com-pression of the chyle by the sides of the small intespression of the chyle by the sides of the small intes-tine, &c. Latterly, it has been pretended that it takes place by virtue of the proper sensibility of the absorb-ing mouths, and of the insensible organic contractility that they are supposed to possess. It first enters the threads of the lacteal vessels, it then traverses the me-senteric glands, it arrives at the thoracic duct, and at last enters the subclavian vein.

The causes that determine its motion are the contractility proper to the chyliferous vessels, the unknown cause of its absorption, the pressure of the abdominal muscles, particularly in the motions of respiration, and, perhaps, the pulsation of the arteries of the abdomen.

If we wish to have a correct idea of the velocity with which the chyle flows into the thoracic duct, we must open this canal in a living animal, at the place where it opens into the subclavian vein. We find that where it opens into the subclavian vein. We find that this rapidity is not very great, and that it increases every time that the animal compresses the viscera of the abdomen, by the abdominal muscles; a similar effect is produced by compressing the belly with the hand.

However, the rapidity of the circulation of the chyle appears to me to be in proportion to the quantity formed in the small intestine; this last is in proportion to the quantity of the chyme: so that if the food is in great abundance, and of easy digestion, the chyle will flow quickly; if, on the contrary, the food is in small quantity, or, which is the same thing, if it is of difficult direction as less chyle will be formed so its procult digestion, as less chyle will be formed, so its pro-

gress will be more slow.

It would be difficult to appreciate the quantity of chyle that would be formed during a given digestion, though it ought to be considerable. In a dog of ordinary size, that had eaten animal food at discretion, an incision into the thoracic duct of the neck (the dog being alive) gave about half an ounce of liquid in five fninutes, and the running was not suspended during the whole continuance of the formation of the chyle,

that is, during several hours.

It is not known whether there is any variation in the rapidity of the motion of the chyle during the same digestion; but, supposing it uniform, there would enter six ounces of chyle per hour into the venous system. We may presume that the proportion of chyle is more considerable in man, whose chyliferous organs are more voluminous, and in whom the digestion is, in general, more rapid than in the dog."—Magendie's Physics.

The chyle is mixed with the albuminous and gelatinous lymph in the thoracic duct, which receives

them from the lymphatics.

The uses of the chyle are, 1. To supply the matter from which the blood and other fluids of our body are prepared; from which fluids the solid parts are formprepared; from which fluids the solid parts are formed. 2. By its acescent nature, it somewhat restrains the putrescent tendency of the blood: hence the dreadful putridity of the humours from starving; and thus milk is an excellent remedy against scurvy. 3. By its very copious aqueous latex, it prevents the thickening of the fluids, and thus renders them fit for the various secretions. 4. The chyle secreted in the breasts of puerperal women, under the name of milk, forms the most excellent nutriment of all aliments for new-born infants.

CHYLIFICA'TION. (Chylificatio; from chylus, and fio, to become.) Chylificatio. The process carried on in the small intestines, and principally in the duodenum, by which the chyle is separated from the

CHYLI'SMA. (From xulos, juice.) An expressed

CHYLOPOIE TIC. (Chylopoieticus; from xulos, nyle, and worth, to make.) Chylopoietic. Any thing chyle, and worre, to make.) Chylopoietic. Any thing connected with the formation of chyle; thus chylopoi-

etic viscera, chylopoietic vessels, &c.

CHYLO'SIS. (From χυλος, juice.) Chylification, or the changing the food into chyle.

CHYLOSTA'GMA. (From χυλος, juice, and ςαζω, to distil.) The distillation or expression of any juice, or

The Chinese hold it in great estimation as a stomachic, infused in wine

Chy'sis. (From χυω, to pour out.) Fusion, or the reduction of solid bodies into fluid by heat.

Chy'tlon. (From χυω, to pour out.) An anointing with oil and water. Fusion, or the

CIBA'LIS. (From cibus, food.) Of or belonging to food.

CIBALIS FISTULA. An obsolete term for the œso-

CIBA'TIO. (From cibus, food.) The taking of food.

CI'BUR. An obsolete term for sulphur.
CICATRISANT. (Cicatrisans; from cicatrico, to
skin over.) Such applications as dispose wounds and
ulcers to dry up and heal, and to be covered with a

skin.

CICA'TRIX. (From cicatrico, to heal up or skin over.) A seam or scar upon the skin, after the healing of a sore or ulcer.

Cicety, sweet. See Scandix odorata.

CI'CER. (A plant so called. The Cicerones had their name from this pulse, as the Pisones had from the pisum or pea, and the Lentuli from the lens or lentil.) 1. The name of a genus of plants in the Linmean system. Class, Diadelphia; Order, Decandria. The vetch. The vetch.

2. The pharmacopoial name of the common cich

or ciches.

CICER ARIETINUM. The systematic name of the eicer plant. Erebinthus; Cicer-folius serratis, of Linnæus. The seeds have been employed medicinally, Linneus. The seeds have been employed medicinally, but are now fallen into disuse. In some places they are toasted, and used as coffee; and in others, ground into a flour for bread. The colour of the arillus of the seed is sometimes white, red, or black; hence the distinction into cicer album, rubrum, and nigrum.

CI CERA. (From cicer, the vetch.) A small pill of

the size of a vetch.

the size of a vetch.

CICERA TARTARI. Small pills composed of turpentine and cream of tartar, of the size of a vetch.

CICHO'RIUM. (Originally, according to Pliny, an Egyptian name, and adopted by the Greeks. It is written sometimes Κιχορειον: whence Horace has cichoreæ, levesque malvæ: sometimes Κιχοριον οτ Κιχωριον. It is supposed by some to have this name, παρα το δια των χωριων κιειν, from its creeping through the fields. Others derive it from κιχεω, invenio; on account of its being so readily found, or so common.) Succory. 1. The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Polygamia æqualis. mia equalis.

2. The pharmacopæial name of the wild cichory.

See Cichorium intybus.
Cichorium intybus.
The systematic name of the endive. Endivia; Endiva; Cichorium;—floribus solitariis, pendunculatis, foliis integris; crenatis, of Linnæus, is an extremely wholesome salad, possessing bitter and anodyne qualities

Cichorium intybus. The systematic name of the wild succory. Cichorium; Oichoreum; Cichorium sylvestre vel efficinarum, Cichorium;—floribus geminis, sessilibus; foliis runcinatis, of Linnæus. It belongs to the same family with the garden endive, and by some botanists has been supposed to be the same plant in its uncultivated state; but the endive commonly used as salad is an annual or at most a bien-Chylosta'gma. (From χυλος, juice, and gaζω, to distil.) The distillation or expression of any juice, or humid part from the rest.

Chylostagma distillation of Venice treacle and mithridate.

Chylostagma distillation of Venice treacle and mithridate.

Chylos. (Χυλος, succus, from χυω, juice.) See Chyle.

Chylms. (Chymus; from χυωος, which signifies humour or juice.) The ingested mass of food that passes from the stomach into the duodenum, and from which the chyle is prepared in the small intestines by the admixture of the bile, &c. See Digestion

CHYMIA TER. A chemical physician.

CHYMIA TRIA. (From χυμα, chemistry, and taoμαι, to heal.) The art of curing diseases by the application of chemistry to the uses of medicine.

CHYNER RADIX. A cylindrical root, of the thickness of a goose-quill, brought from China. It has a bitterish taste, and imparts a yellow tinge to the saliva.

Possible botchlists has been supposed to be the same plant in its uncultivated state; but the endive commonly used as salad is an annual, or at most a biennial plant, and its parent is now known to be the cichorium endivia. Wild succory of cichory, abounds with a milky juice, of a penetrating bitterish taste, and on or ermarkable smell, or particular flavour: the roots are more bitter than the leaves or stalks, and these much more so than the flowers. By culture in gardens, and by blanching, it loses its bitterness, and may be caten early in the spring in salads. The roots, if gathered before the stem shoots up, are also catable, and when dried may be made into bread. The roots and leaves of this plant are stated by Lewis to be very useful aperients, acting mildly and without irritation, tending rather to abate than to increase heat, and which may therefore be given with safety in hectic and influence of the saliva.

Possible botchlist, and it is an annual, or at most a biennial plant, and its parent is now known to be the cichorium end of the like kind, in whey, and rendered purgative by a suitable addition of polychrest salt, was found a useful remedy in cases of biliary calculi, and promises advantage in many complaints requiring what have been termed attenuants and resolvents. The virtues of succory, like those of dandelion, reside in its milky juice; and we are warranted, says Dr. Woodville, in asserting, that the expressed juice of both these plants, taken in large doses frequently repeated, has been asserting, that the expressed pince of both these plants, taken in large doses frequently repeated, has been found an efficacious remedy in phthisis pulmonalis, as well as the various other affections above mentioned. The milky juice may be extracted by boiling in water, or by pressure. The wild and the garden sorts are used indifferently. If the root is cut into small pieces, dried, and roasted, it resembles coffee, and is sometimes a good substitute for it.

dried, and roasted, it resembles coffee, and is sometimes a good substitute for it.

CI'CHORY. See Cichorium intybus.

Cichory, wild. See Cichorium intybus.

Cichory, wild. See Cichorium intybus.

Cichory taile. See Cichorium intybus.

By some thought to be anodyne, lithontriptic, though probably neither. Not used in the present day.

Cichory taile. See Cichorium taile. Anoil, obtained by boiling the bruised seeds of the Jatropha curcas of Linneus. It is somewhat similar in its pro-

cureas of Linnwus. It is somewhat similar in its properties to castor oil.

A name for the white beet.

CICLA. A name for the winte beet.

CICU'TA. (Quasi cacuta, blind; because it destroys the sight of those who use it. Cicuta signifies also the internode, or space between two joints of a reed; or the hollow stem of any plant which the shepherds used for making their rural pipes. Est mikidisparibus septem conjuncta cicutis fistula. Virgil.) Hemlock. 1. The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Diamaia. CICUTA.

Linnwan system. Class, Pentandria; Order, Digynia.

2. The name, in most pharmacopæias, of the common hemlock. See Conium.

CICUTA AQUATICA. See Cicuta virosa.

CICUTA VIROSA. The systematic name of the Cicuta aquatica; Cicutaria virosa; Sium majus alterum angustifolium; Sium crucæ folio; long-leaved water hemlock and cow-bane. This plant, Cicuta—umbellis oppositifoliis; petiolis marginatis obtusis, of Linnæus, is seldom employed medicinally in the present day. It is an active poison, and often eaten by mistake for the wild smallage, the Apium graveoleus, of Linnæus; when it produces tremors, vertigo, a violent-burning at the stomach, epilepsy, convulsions, spasms of the jaw, a flowing of blood from the ears, tumefaction of the abdomen, and death.

CICUTA'RIA. (From cicuta, hemlock.) Bastard hemlock. See Charophyllum sylvestre.

hemlock. See Charophyllum sylvestre.
Cicutaria aquatica. See Phellandrium aqua-

CICUTARIA VIROSA. See Cicuta virosa.
CIDO'NIUM. See Pyrus cydonia.
CILIA: (The plural of cilium.) A species of pubescence of plants which consists of hairs on the margin of a leaf or petal, giving it a fringed appearance.
CILIAR. (Ciliaris; from cilium, the cyclid.) Belonging to the cyclid.
CILIAR LAGAMENT. Ligamentus ciliare. The cir.

CILIAR LIGAMENT. Ligamentum ciliare. The circular portion that divides the chroid membrane from the iris, and which adheres to the sclerotic membrane. It appears like a white circular ring. See Choroid

Membrane.

CILIARE LIGAMENTUM. See Choroid membrane.

CILIARIS MUSCULUS. That part of the musculus orbicularis palpebrarum which lies nearest the cilia, considered by Riolan as a distinct muscle.

CILIATUS. Bordered, fringed: applied to leaves, corolla, petals, &c.: hence folium ciliatum, anthodium ciliatum, and petala ciliata. See Leaf, Corolla, Anthodium, Petalum.

CILIUM. (From cilleo, to move about.) The eyelid or eyelesh. See also Cilia.

CILIARY INOCESSES. The white folds at the margin of the uvea in the eye, covered with a black mat-

CIMICIFUGA. Black snake root. This is the root. Actae racemosa of Wildenow, an American plant. According to the late Dr. Barton, a decoction of it forms a useful astringent gargle in sore throats, and also cures psora. We are told that the Indians made

According to the late Dr. Barton, a decoction of it forms a useful astringent gargle in sore throats, and also cures psora. We are tool that the Indians made great use of it in rheumatism; also as an agent ad partum accelerandum. Dr. Tully acquaints me, that he has found it diaphoretic, diurene, and moderately tonic, forming a useful auxiliary in the treatment of acute and chronic rheumatism, and of dropsy; likewise operating very beneficially in hysteria. It is usually given in the form of decoction—Big. Mat. Med. A.]

CIMOLIA ALBA. (From Kμωλος, Cimolus, an island in the Cretan sea, where it is procured.) See Cimolite.

CIMOLITE. Cimolian carth. The Cimalia of Pliny. An earth of a grayish white colour, which consists of silex, alumina, oxide of iron, and water.

CI'NA CINA. See Cinchona.

CI'NARA. (From kuves, to move; quasi movet ad venerum vel urinam.) Artichoke. 1. The name of a genus of plants in the Linnacan system. Class, Syngenesia; Order, Polygamia aqualis.

2. The pharmacopæial name for the common artichoke. See Cinara scolymus.

CINARA scolymus. The systematic name of the artichoke, called in the pharmacopæias Alcocalum; Agriocinara; Articocalus; Artischocas lævis; Costus nigra; Carduus sativus non spinosus; Cinara hortensis; Scolymus sativus; Carduus domesticus capite majore; Carduus altilis. The Cinara—foliis subspinosis pinnatis indivisique, calycinis squamis ovatis, of Linnæus. A native of the southern parts of Europe, but cultivated here for culinary purposes. The leaves are bitter, and afford, by expression, a considerable quantity of juice, which, when strained, and mixed with an equal quantity of white wine, has been given successfully in dropsies, in the dose of 3 or 4 table-sponfuls night and morning, but it is very uncertain in the operation.

CINCHO'NA. (Geoffroy states that the use of this bark was first learned from the following circumstance:—Some cinchona trees being thrown by the winds into a root of water by there till the varter.

bark was first learned from the following circumstance:-Some cinchona trees being thrown by the winds into a pool of water, lay there till the water became so bitter, that every body refused to drink it. However, one of the neighbouring inhabitants being seized with a violent paroxysm of fever, and finding scized with a violent paroxysm of lever, and finding no other water to quench his thirst, was forced to drink of this, by which he was perfectly cured. He afterward related the circumstance to others, and pre vailed upon some of his friends, who were ill of fevers, to make use of the same remedy, with whom it proved equally successful. The use of this excellent remedy, however, was very little known till about the year 1638, when a signal cure having been performed by it. however, was very little known till about the year 1638, when a signal cure having been performed by it on the Spanish viceroy's lady, the Countess del Cinchon, at Lima, it came into general use, and hence it was distinguished by the appellation of cortex cinchonæ, and pulvis comitissæ, or the Countess's powder. On the recovery of the Countess, she distributed a large quantity of the bark to the Jesuits, in whose hands it acquired still greater reputation, and by them it was first introduced into Europe, and thence called contex first introduced into Europe, and thence called cortex, or pulvis jesuticus, pulvis patrum; and also Cardinai del Lugo's powder, because that charitable prelate bought a large quantity of it at great expense for the use of the religious poor at Rome.) 1. The name of a genus of plants in the Linnæan system. Class, Pen tandria; Order, Monogynia. Cinchona, or Peruvian bark-tree.

CILIARY PROCESSES. The white folds at the margin of the uvea in the eye, covered with a black matter, which proceed from the uvea to the crystalline lens, upon which they lie.

CILLO. (From cilium, the eyelid.) One who is affected with a spasm or trembling of the eyelids.

CILLO SIS. (From cilium, the eyelid.) A spasnedic trembling of the eyelids.

CILLOSIS. (From cilium, the eyelid.) A spasnedic trembling of the eyelids.

Circeter shaped. See Leaf.

CIMEX. (From supar, to inhabit; so called bebark-tree.

2. The pharmacopæial name of several kinds of barks; called also Cortex. Cortex china; China; Chinchina; Kina kina, Kinkina; Quina quina, Quinquina; the trees affording which, grow wild in the hilly parts of Peru; the bark is stripped from the branches, trunk, and root, and dried. Three kinds of it are now

the Cinchona afficinalis, of Linnaus; the Cinchona macrocarpa, of Wildenow. Heart-leaved cinchona. macrocarpa, of Wildenow. Heart-leaved cinchona. The bark of this tree is called yellow bark, because it approaches more to that colour than either of the others does. It is in flat pieces, not convoluted like the pale, nor dark-coloured like the red; externally smooth, internally of a light cinnamon colour, friable and fibrous, has no peculiar odour different from the others, but a taste incomparably more bitter, with some degree of astringency

2. Cortex cinchona lancifolia.—This species is obtained from the Cinchona lancifolia of Zea. Lance-leaved cinchona. This is the quilled bark, which comes in small quilled twigs, breaking close and smooth, friable between the teeth, covered with a smooth of the property rough coat of a brownish colour, internally smooth, and of a light brown; its taste is bitter, and slightly astringent; flavour slightly aromatic, with some degree

of mustiness.

3. Cortez cinchonæ oblongifolia.—This kind is pro-cured from Cinchona oblongifolia of Zea. Oblong-leaved cinchona. This is the red bark; it is in large thick pieces, externally covered with a brown rugged coat, internally more smooth and compact, but fibrous, of a dark red colour; taste and smell similar to that of the cinchonæ lancifoliæ cortex, but the taste rather

From the general analysis of bark, it appears to consist, besides the woody matter which composes the greater part of it, of gum, resin, gallic acid, of very small portions of tannin and essential oil, and of several salts having principally lime for their basis. Seguin also supposed the existence of gelatin in it, but without sufficient proof. Cold water infused on pale bark for some hours, acquires a bitter taste, with some share of its odour; when assisted by a moderate heat, the water takes up more of the active matter; by decoction, a fluid, deep coloured, of a bitter styntic taste. coction, a fluid, deep coloured, of a bitter styptic taste, is obtained, which, when cold, deposites a precipitate of resinous matter and gallic acid. By long decoction, the virtues of the bark are nearly destroyed, owing to the oxygenation of its active matter. Magnesia entire to dissolve a larger portion of the principles water to dissolve a larger portion of the principles. the oxygenation of its active matter. Magnesia enables water to dissolve a larger portion of the principles of bark, as does lime, though in an inferior degree. Alkohol is the most powerful solvent of its active matter. Brandy and other spirits and wines, afford also strong solutions, in proportion to the quantity of alkohol they contain. A saturated solution of ammonia is also a powerful solvent; vinegar is less so even than water. By distillation, water is slightly impregnated with the flavour of bark; it is doubtful whether any essential oil can be obtained.

The action of menstrua on the red bark is nearly the same, the solutions only being considerably stronger, or containing a larger quantity of resinous matter, and of the astringent principle.

The analysis of the yellow bark shows that its active principles are more concentrated than in either of the others, affording to water, alkohol, &c. tinctures, much stronger both in bitterness and astringency, especially in the former principle.

Vauquelin made infusious of all the varieties of cinchona he could procure, using the same quantities of the barks and water and leaving the provides infusions of the barks and water and leaving the provides infusions

chona he could procure, using the same quantities of the barks and water, and leaving the powders infused for the same time. He observed, 1. That certain infor the same time. He observed, 1. That certain infusions were precipitated abundantly by infusion of
galls, by solution of glue and tartar emetic. 2. That
some were precipitated by glue, but not by the two
other reagents; and, 3. That others were, on the contrary, by nutgalls, and tartar emetic, without being affected by glue. 4. And that there were some which
yielded no precipitate by nutgalls, tannin, or emetic
tartar. The cinchonas that furnished the first infusion
were of excellent quality: those that afforded the were of excellent quality; those that afforded the fourth were not febrifuge; while those that gave the second and third were febrifuge, but in a smaller degree than the first. Besides mucilage, kinate of lime, and woody fibre, he obtained in his analyses a resinous woody fibre, he obtained in his analyses a resinous substance, which appears not to be identic in all the species of bark. It is very bitter, very soluble in alkohol, in acids, and alkalies; scarcely soluble in cold water, but more soluble in hot. It is this body which gives to infusions of cinchona the property of yielding precipitates by emetic tartar, galls, gelatin; and in it the febrifuge virtue seems to reside. It is this substance in part which falls down on cooling decoctions of cinchona, and from concentrated infusions. A table

P 2

employed, occasionally, and in small doses of two or three drachms, as a stomachic. The extract is a preparation of considérable power, when properly prepared, and is adapted to those cases where the remedy requires to be continued for some time. It is then given in the form of pill, in doses of from five to fifteen grains.

Bark is likewise sometimes given in the form of enema; one scruple of the extract, or two drachms of the powder, being diffused in four ounces of starch

of precipitations by glue, tannin, and tartar emetic, from infusions of different barks, has been given by

Pelletier and Caventou analyzed the Cinchona condaminea, gray bark, and found it composed of, 1. cinchonina, united to kinic acid; 2. green fatty matter; 3. red colouring matter, slightly soluble; 4. tannin; 5. yellow colouring matter; 6. kinite of lime; 7. gum;

5. yellow colouring matter; 6. kinite of lime; 7. gum; 8. starch; 9. lignine.

The red bark has been considered as superior to the pale, the yellow is represented, apparently with justice, as being more active than either of the others.

The effects of Peruvian bark are those of a powerful and permanent tonic, so slow in its operation, that its stimulating property is scarcely perceptible by any alteration in the state of the pulse, or of the temperature of the body. In a large dose, it occasions nausea and headache; in some habits it operates as a laxative. and headache; in some habits it operates as a laxative: in others it occasions costiveness. It is one of those medicines, the efficacy of which, in removing disease, is much greater than could be expected, a priori, from

its effects on the system in a healthy state.

Intermittent fever is the disease, for the cure of which bark was introduced into practice, and there is still no remedy which equals it in power. The disputes respecting the mode of administering it are now settled. It is given as early as possible, after clearing the stomach and bowels, in the dose of from one scruble to a drachm every second or third hear during the ple to a drachm every second or third hour, during the interval of the paroxysm; and it may even be given during the hot fit, but it is then more apt to excite

nausea.

In remittent fever it is given with equal freedom, even though the remission of the fever may be ob-

In some forms of continued fever which are connected with debility, as in typhus, cynanche maligna, confluent small-pox, &c. it is regarded as one of the most valuable remedies. It may be prejudicial, however, in those diseases where the brain or its membranes are inflamed, or where there is much irritation, marked by subsultus tendinum, and convulsive motions of the extremities; and in pure typhus it appears to be less useful in the beginning of the disease than in

Even in fevers of an opposite type, where there are marks of inflammatory action, particularly in acute rheumatism, bark has been found useful after bloodletting. In crysipelas, in grangrene, in extensive suppuration, and venereal ulceration, the freeuse of bark is of the greatest advantage.

puration, and venereal ulceration, the freeuse of bark is of the greatest advantage.

In the various forms of passive hemorrhagy, in many other diseases of chronic debility, dyspepsia, hypochondriasis, paralysis, rickets, scrofula, dropsy, and in a variety of spasmodic affections, epilepsy, chorea, and hysteria, it is administered as a powerful and permanent tonic, either alone, or combined with other remedies suited to the particular case.

The officinal preparations of bark are an infusion, decoction, an extract, a resinous extract, a simple tincture, an ammoniated and a compound tincture. The usual dose is half a drachm of the powder. The only

usual dose is half a drachm of the powder. The only inconvenience of a larger dose is its sitting uneasy on the stomach. It may therefore, if necessary, be fre-quently repeated, and in urgent cases may be taken to the extent of an ounce, or even two ounces, in twenty-

The powder is more effectual than any of the preparations; it is given in wine, in any spirituous liquor; or, if it excite nausea, combined with an aromatic. The cold infusion is the least powerful, but most grateful; the decoction contains much more of the active matter of the bark, and is the preparation generally used when the powder is rejected; its dose is from two to four ounces. The spirituous tincture, though containing still more of the bark, cannot be extensively used on account of the menstruum, but is principally employed, occasionally, and in small doses of two or

mucilage. The decoction is also sometimes applied as a fomentation to ulcers.

CINCHONA CARIDEA. The systematic name of the Caribean bark-tree. It grows in Jamaica, where it is called the sea-side beech. According to Dr. Wright, the bark of this tree is not less efficacious than that of the cinchona of Peru, for which it will prove a useful substitute; but by the experiments of Dr. Skeete, it appears to have less astringent power.

CINCHONA SANCTA FE'. Several species of cinchona have been lately discovered at Sancta Fé, yielding barks both of the pale and red kind; and which, from their sensible qualities, are likely upon trial to become canally useful with these produced in the kingdom of equally useful with those produced in the kingdom of

CINCHONIA. See Cinchonina.
CINCHONINA. Cinchonia; Quinia; Quinia.
Cinchonine or Quinine is the salifiable base, or vegetable alkali, discovered in the Cinchona condaminea, by Pelletier and Caventou. The person, however, who first recognised its existence, though he did not ascertain its alkaline nature, or study its combinations with neide was Gornia of Lishon.

with acids, was Gornis of Lisbon.

The following process for extracting cinchonina is that of Henry, the younger, which the above chemists approve. A kilogramme of bark reduced into a fine powder, is to be acted on twice with heat, by a diluted with the solid consisting of 50 or 60 gramme of the solid consisting of 50 or 60 gramme. sulphuric acid, consisting of 50 or 60 grammes, diluted with 8 kilogrammes of water for each time. The filtered decoctions are very bitter, have a reddish colour, which assumes on cooling a yellowish tint. To discolour (blanch) these liquors, and saturate the acid, either pulverized quicklime or magnesia may be employed. The liquors, entirely deprived of colour, are to be passed through a cloth, and the precipinate which to be passed through a cloth, and the precipitate which forms is to be washed with a small quantity of water, to separate the excess of lime (if this earth has been used). The deposite on the cloth, well drained and almost completely deprived of moisture for twelve hours, after having been put three successive times to digest in alkohol of 36° (0.837), will furnish, by distilling of the liquid alkohol, a brown viscid matter, becoming brittle on cooling. It is to be acted on with water sharpened with sulphuric acid, and the refrigerated liquor will afford about thirty grammes of white crystals, entirely soluble in alkohol, scarcely soluble in cold water, but more in boiling water, particularly if this be slightly acidulated. They consist of pure sulphate of cinchonina. They ought to be brilliant, crystallized in parallelopipeds, very hard, and of a glassy-white. It should burn without leaving any residuum. Other processes have been given, of which a full account will be found in the 12th volume of the Journal of Science, p. 325. From a solution of the a full account will be found in the 12th volume of the Journal of Science, p. 325. From a solution of the above salt, the cinchonina may be easily obtained by the addition of any alkali. The cinchonina falls down, and may be afterward dissolved in alkohol, and crystallized by evaporation. Its form is a rhomboidal prism, of 1080 and 720, terminated by a bevelment. It has but little taste, requiring 7000 parts of water for its solution; but when dissolved in alkohol, or an acid, it has the bitter taste of bark. When heated it does not fuse before decomposition. It consists of oxygen,

mucilage. The decoction is also sometimes applied hydrogen, and carbon, the latter being predominant as a fomentation to ulcers.

It dissolves in only very small quantities in the oils, and in sulphuric ether.

Robiquet gives as the composition of a subsulphate of cinchonina of the first crystallization,

Sulphuric acid Cinchonina 79.0 The alkaline base found in yellow barks is called Quining. It is extracted in exactly the same way. Red bark contains a mixture of these two alkalies. The febrifuge virtue of the sulphates is considered to be very great. Cinci'nnus.

The hair on the temples. CINCLE'SIS. (From κιγκλιζω, to move.) Cin-ismus. An involuntary nicritation or winking clismus.

CINERA'RIUM (From cinis, ashes.) The ash-

CINERA'RIUM (From cines, ashes.) The ashhole of a chemical instrument.

1. The uvula was formerly so named from its pyra-

midal shape.

2. An enlargement of the uvula.

Cio'Nis. (From kiw, the uvula.) An enlargement and painful swelling of the uvula.

CIPOLIN. A marble from Rome and Autun.

CIRCÆ'A. (From Circe, the enchantress: so named from the opinion that it was used by Circe in her enchanted preparations.) I. The name of a genus of plants in the Linnaan system. Class, Diandria;

of plants in the Linnaan system. Class, Diandria; Order, Monogynia. Enchanter's nightshade.

2. The name in some pharmacopeias for the Circaa httetiana, which is now fallen wholly into disuse.

CIRCOCE'LE. (Κιρσοκηλη; from κιρσος, varix, or a dilatation of a vein, and κηλη, a tumour.) Varicocele. A morbid or varicose distention and enlargement of the spermatic veins; it is frequently mistaken for a descent of a small portion of omentum. The uneasiness which it occasions is a kind of pain in the back, generally relieved by suspension of the scrotum: back, generally relieved by suspension of the scrotum; and whether considered on account of the pain, or on account of the wasting of the testicle, which now and then follows, it may truly be called a disease. It has been resembled to a collection of earth-worms. It is most frequently confined to that part of the spermatic process, which is below the opening in the abdominal tendon; and the vessels generally become rather larger as they approach the testes. There is abdominal tendon; and the vessels generally become rather larger as they approach the testes. There is one sure method of distinguishing between a circocele and omental hernia; place the patient in a horizontal posture, and empty the swelling by pressure upon the scrotum; then put the fingers firmly upon the upper part of the abdominal ring, and desire the patient to rise; if it is a hernia, the tumour cannot reappear, as long as the pressure is continued at the ring; but if a circocele, the swelling returns with increased size, on account of the return of blood into the abdomen being prevented by the pressure.

Circos. (From \$5005, a circle.) A ring. It is sometimes used for the sphincter muscle which is round like a ring.

round like a ring.

CIRCULA'TION. (Circulatio; from circulo, to compass about.) Circulatio sanguinis. Circulation of the blood. A vital action performed by the heart in the following manner: the blood is returned by the dethe following manner: the blood is returned by the de-scending and ascending vense cave into the right auri-cle of the heart, which, when distended, contracts, and sends its blood into the right ventricle; from the right ventricle it is propelled through the pulmonary artery ventricle it is propelled through the pulmonary artery to circulate through, and undergo a change in the lungs, being prevented from returning into the right auricle by the closing of the valves, which are situated there for that purpose. Having undergone this change in the lungs, it is brought to the left auricle of the heart by the four pulmonary veins, and from thence it is evacuated into the left ventricle. The left ventricle, when distended, contracts, and throws the blood through the aorta to every part of the body, to be returned by the veins into the two venæ cavæ. It is prevented from passing back from the left ventricle juto turned by the veins into the two venæ cavæ. It is prevented from passing back from the left ventricle into the auricle by a valvular apparatus; and the pulmonary artery and aorta at their origin are also furnished with similar organs, to prevent its returning into the ventricles. This is a brief outline of the circulation, the particulars of which we shall now describe. "The best informed physiologists avow that the circulation of the venous blood is still very little understood. We shall describe here only its most apparent phenomena, leaving the most delicate questions until we treat of the relation of the flowing of the blood in the veins, with that in the arteries. We will then speak of the cause that determines the entrance of

speak of the cause that determines the entrance of

blood into the venous radicles

To have a general, but just idea of the course of the blood in the veins, we must consider that the sum of the small veins forms a cavity much larger than that of the larger but less numerous veins, into which they pass; that these bear the same relation to the tranks in which they terminate: consequently, the blood which flows in the veins from branches towards the trunks, passes always from a larger to a smaller cavity; now, the following principle of hydro-dynamics may here be perfectly applied:

When a liquid flows in a tube which it fills completely, the quantity of this liquid which traverses the different sections of the tube in a given time ought to be every where the same: consequently, when the tube increases, the velocity diminishes; when the tube diminishes, the velocity increases in rapidity.

Experience confirms this principle, and its just application to the current of venous blood. If a very small vein is cut, the blood flows from it very slowly; it flows quicker from a larger vein, and it flows with considerable rapidity from an open venous trunk.

Generally there are several veins to transport the blood that has traversed an organ towards the larger trunks. On account of their anastomoses, the compressure or ligature of one or several of these veins does not prevent-or diminish the quantity of blood that returns to the heart; it merely acquires a greater rapi-

does not prevent or diminish the quantity of blood that returns to the heart; it merely acquires a greater rapidity in the veins which remain free.

This happens when a ligature is placed on the arm for the purpose of bleeding. In the ordinary state, the blood, which is carried to the fore-arm and the hand, returns to the heart by four deep veins, and at least as many superficial ones; but as soon as the ligature is tightened, the blood passes no longer by the subcutaneous veins, and it traverses with difficulty those which are deeper seated. If one of the veins is then opened at the bend of the arm, it passes out in form of a continued jet, which continues as long as the ligature retinued jet, which continues as long as the ligature remains firm, and stops as soon as it is removed.

Except in particular cases, the veins are not much distended by the blood; however, those in which it moves with the greatest rapidity are much more so: the small veins are scarcely distended at all. For a reason very easy to be understood, all the circum-stances that accelerate the rapidity of the blood in a vein, produce also an augmentation in the distention

of the vessel.

The introduction of blood into the veins taking place in a continued manner, every cause which arrests its course produces distention of the vein, and

arrests its course produces distention of the vein, and the stagnation of a greater or less quantity of blood in its cavity, below the obstacle.

The sides of the veins seem to have but a small influence upon the motion of the blood; they easily give way when the quantity augments, and return to their usual form when it diminishes; but their contraction is limited; it is not sufficiently strong to expel the blood completely from the vein, and therefore those of dead bodies always contain some

of dead bodies always contain some.

A great number of veins, such as those of the bones, of the sinuses of the dura mater, of the testicles, of the liver, &c., the sides of which adhere to an inflexible canal, can have evidently no influence upon the mo-tion of the blood that flows in their cavity. However, it is to the elasticity of the sides of the

veins, and not to a contraction similar to that of the muscles that we must attribute the faculty which they possess of diminishing the size when the column of blood diminishes: this diminution is also much more marked in those that have the thickest sides, such as

the superficial veins.

If the veins have themselves very little influence upon the motion of the blood, many other necessary causes exert a very evident effect. Every continued or alternate pressure upon a vein, when strong enough or alternate pressure upon a vein, when strong enough to flatten it, may prevent the passage of the blood; if it is not so strong, it will oppose the dilatation of the vein by the blood, and consequently favour its motion. The constant pressure which the skin of the members exert upon the veins that are below it, renders the flow of the blood more easy and rapid in these vessels. We cannot doubt this, for all the circumstances that diminish the contractility of the tissue of the skin, are sooner or later followed by a considerable dilatation of the veins, and in certain cases by varix; we know also that mechanical compression, exerted by a proper bandage, reduces the veins again to their ordinary dimensions, and also regulates the motion of the blood mensions, and also regulates the motion of the blood

mensions, and also regulates the motion of within them.

In the abdomen, the veins are subject to the alternate pressure of the diaphragm, and of the abdominal muscles, and this cause is equally favourable to the flow of the venous blood in this part.

The veins of the brain support also a considerable pressure, which must produce the same result.

Whenever the blood runs in the direction of its weight it flows with greater facility; the contrary takes

We must not neglect to notice the relations of these accessory causes with the disposition of the veins. Where they are very marked, the veins present no valves, and their sides are very thin, as is seen in the abdomen, the chest, the cavity of the skull, &c.; where these have less influence, the veins present valves, and have thicker sides; lastly, where they are very weak, as in the subcutaneous veins, the valves are numerous, and the sides have a considerable thickare numerous, and the sides have a considerable thick-

We must take care, however, not to confound among

the circumstances favourable to the motion of the blood in the veins, causes which act in another manner.

For example, it is generally known that the contraction of the muscles of the fore-arm and the hand during bleeding, accelerate the motion of the blood which passes through the opening of the vein; phy-siologists say that the contraction of the muscles compresses the deep veins, and expels the blood from them, which then passes into the superficial veins. Were it thus, the acceleration would be only instantaneous, or at least of short duration, while it generally con-tinues as long as the contraction. We shall see, farther on, how this phenomenon ought to be explained.

When the feet are plunged some time in hot water, the subcutaneous veins swell, which is generally attri-buted to the rarefaction of the blood; though the true cause is the augmentation of the quantity of blood in the feet, but particularly at the skin, an augmentation which ought naturally to accelerate the motion of the blood in the veins, since they are in a given time tra-versed by a greater quantity of blood.

After what has preceded, we can easily suppose that the venous blood must be frequently stopped or hindered in its course, either by the veins suffering too strong a pressure in the different positions of the body, or by other bodies pressing upon it, &c.: hence the necessity of the numerous anastomoses that exist not only in the small veins, but among the large, and even among the largest trunks. By these frequent communications, one or several of the veins being compressed in such a way, that they cannot permit the passage of the blood, this fluid turns and arrives at the heart by other di-rections:—one of the uses of the azygos vein appears to be to establish an easy communication between the superior and inferior vena cava." Its principal utility, however, seems to consist in its being the common termination of most of the intercostal veins.

There is no obscurity in the action of the valves of the veins; they are real valves, which prevent the re-turn of the blood towards the venous radicles, and which do this so much better in proportion as they are

large, that is to say, more suitably disposed to stop entirely the cavity of the vein.

The friction of the blood against the sides of the veins; its adhesion to these same sides, and the want of fluidity, must modify the motion of the blood in the veins, and tend to retard it; but in the present state of physiology and hydrodynamics, it is impossible to assign the precise effect of each of these particular. sign the precise effect of each of these particular

We ought to perceive, by what has been said upon the motion of the venous blood, that it must undergo great modifications, according to an infinity of circum-

At any rate, the venous blood of every part of the body arrives at the right auricle of the heart by the trunks that we have already named; viz. two very large, the venæ cavæ, and one very small, the coro-

The blood probably flows in each of these veins with different rapidity: what is certain, is, that the three columns of liquid make an effort to pass into the auricle, and that the effort must be considerable. If it is contracted, this effort has no effect: but, as soon as is contracted, this enor has a country, fills it completely, and even distends the sides a little; it would immediately enter the ventricle, if it did not contract itself at this instant. The blood then confines itself to filling up exactly the cavity of the aircle; but this very soon contracts, compresses the blood, which escapes into the place where there is least compression. Now it has only two issues: 1st, by the vena cava; 2dly, by the opening which conducts into the ventricle. The columns of blood which are coming to the auricle pre-

place when it flows against the direction of its | sent a certain resistance to its passage into the cave or coronary veins. On the contrary, it finds every facility to enter the ventricle, since the latter dilates itself with force, tends to produce a vacuum, and consequently draws on the blood instead of repulsing it.

However, all the blood that passes out of the auricle does not enter the ventricle; it has been long observed that, at each contraction of the auricle, a certain quantity of blood flows back into the superior and inferior venæ cavæ; the undulation produced by this cause is superiors felt as for as the external like. cause is sometimes felt as far as the external iliac veins, and into the jugulars; it has a sensible influence,

as we will see, upon the flowing of the blood in several organs, and particularly in the brain.

The quantity of blood which flows back in this manner, varies according to the facility with which this liquid enters the ventricle. If at the instant of its dilatation, the ventricle still contains much blood, which has not passed into the pulmonary artery, it can

only receive a small quantity of that of the auricle, and then the reflux will be of greater extent.

This happens when the flowing of the blood in the pulmonary artery is retarded, either by obstacles in the lungs, or by the want of sufficient force in the ventricle. This reflux, of which we speak, is the cause of the beating which is seen in the veins of certain sick persons, and which bears the name of venous pulse. Nothing similar can take place in the coronary vein, for its opening is furnished with a valve, which shuts on the instant of the contraction of the au-

The instant in which the auricle ceases to contract, the ventricle enters into contraction, the blood it contains is strongly pressed, and tends to escape in every direction: it would return so much more easily into the auricle, that, as we have already frequently said, it dilates just at this instant; but the tricuspid valve which shuts the auriculo-ventricular opening prevents this reflux. Being raised by the liquid introduced below it, and which tends to pass into the auricle, it gives way until it has become perpendicular to the axis of way until it has become perpendicular to the axis of the ventricle; its three divisions then shut almost completely the opening, and as the tendons of the columna carnes do not permit them to go farther, the valve resists the effort of the blood, and thus prevents it from passing into the auricle.

It is not the same with the blood, which, during the dilatation of the ventricle, corresponded to the auricular surface of the valve; it is evident that in the mo-tion of the ventricle it is carried forward into the auricle, where it mixes with that which comes from the

venæ cavæ and coronary veins

Not being able to overcome the resistance of the tricuspid valve, the blood of the ventricle has no other issue than the pulmonary artery, into which it enters by raising the three sigmoid valves that supported the column of blood contained in the artery during the dilatation of the ventricle.

Suppose the artery full of blood, and left to itself, the liquid will be pressed in the whole extent of the vessel, by the sides which tend to contract upon the cavity; the blood, being thus pressed, will endeavour to escape in every direction; now it has only two ways to pass, by the cardiac orifice, and by the numerous small vessels that terminate the artery in the tissue of the lungs.

The orifice of the pulmonary artery in the heart heing very large, the blood would easily pass into the ventricle, if there were not a particular apparatus at this orifice, intended to prevent this; the three sigmoid valves. Being pressed against the sides of the artery, at the instant that the ventricle sends a wave of blood that way, these folds become perpendicular to its axis; as soon as the blood tends to flow back into the ventricle, they place themselves so as to shut up the cavity of this vessel completely.

On account of the bag-like form of the sigmoid valves, they are swelled by the blood that enters into their cavity, and their margin tends to assume a circular figure. Now, three circular portions, placed upon each other, necessarily leave a space between them.

When the valves, therefore, of the pulmonary artery are lowered by the blood, there ought to remain an opening by which this liquid may flow back into the ventricle.

If each valve were alone, it would undoubtedly take a semicircular form; but there are three of thems

being pressed by the blood, they lie all close together: | the lungs, the quickness of the blood necessarily diand, as they cannot extend as far as their fibres permit them, they press upon each other, on account of the small space in which they are contained, and which does not permit their extending themselves. The valves then assume the figure of three triangles, whose summit is in the centre of the artery, and the sides are in juxta position, so as completely to intercept the ca-vity of the artery. Perhaps the knots, or buttons, which are upon the summit of some of the triangles, are intended to shut more perfectly the centre of the

Finding no passage into the ventricle, the blood will pass into the radicles of the pulmonary veins, with which the small arteries that terminate the pulmonary artery form a continuation, and this passage will continue as long as the sides of the artery press the contained blood with sufficient force; and, except in the trunk and the principal branches, this effect continues until the whole of the blood is expelled.

We might suppose the smallness of the vessels that

We might suppose the smallness of the vessels that terminate the pulmonary artery an obstacle to the flowing of the blood: that might be, if they were not numerous, or if the capacity of the whole were less, or even equal to that of the trunk; but as they are innumerable, and their capacity is much greater than that of the trunk, there is no difficulty in the motion. It is true that the distention or subsidence of the lungs renders this passage more or less easy.

In order that this flowing may take place with facility, the force of contraction of the different divisions

lity, the force of contraction of the different divisions of the artery ought to be every where in relation to their size; if, on the contrary, that of the small were greater than that of the large, as soon as the first had expelled the blood by which they were filled, they would not be sufficiently distended by the blood coming from the second, and the flowing of the blood would be retarded: now, what takes place is quite the contrary of this supposition. If the pulmonary artery of a living animal were tied immediately above the beart almost all the blood contained in the artery at heart, almost all the blood contained in the artery at the instant of the ligature, would pass quickly into the pulmonary veins, and arrive at the heart.

This is what happens when the blood contained in

the pulmonary artery is exposed to the single action of this vessel; but in the common state, at each contraction of the right ventricle, a certain quantity of blood is thrown with force into the artery; the valves are immediately raised; the artery, and almost all its divisions, are so much more distended, in proportion as the heart is more forcibly contracted, and as the quantity of blood injected into the artery is greater. The ventricle dilates immediately after its contraction, and at this instant the sides of the artery contract also the sigmoid valves descend and shut the pulmonary artery, until they are raised by a new contraction of

Such is the second cause of the motion of the blood in the artery that goes towards the lungs: we see it is intermittent; let us endeavour to appreciate its effects for which purpose, let us consider the most apparent phenomena of the flow of the blood in the pulmonary

It has been just observed, that in the instant the ventricle injects the blood into the artery, the trunk, and all the divisions of a certain size, undergo an evident dilatation. This phenomenon is called the pulsa-tion of the artery. The pulsation is very sensible near the heart; it becomes feeble in proportion to its dis-tance from it; when the artery, by being divided, has become very small, it ceases.

Another phenomenon, which is only the consequence of the preceding, is observed when the artery

it be near the heart, and in a place where the beating is sensible, the blood spouts out by jerks; if the opening be made far from the heart, and in a small

minishes

With regard to the pulsation of the artery, and the jet of blood that escapes from it when it is open, we see plainly that these two effects depend on the contraction of the right ventricle, and the introduction of a certain quantity of blood into the artery, which takes place by this means while flowing through the small vessels that terminate the artery, and that give commencement to the relevant to ment to the pulmonary veins; the venous blood changes its nature by the effect of the contact of the air; it acquires the qualities of arterial blood; it is this change in the properties of the blood which essentially constitutes respiration.

At the instant in which the venous blood traverses the small vessels of the pulmonary lobules, it assumes a scarlet colour; its odour becomes stronger, and its taste more distinct, its temperature rises about a degree; a part of its serum disappears in the form of va-pour in the tissue of the lobules, and mixes with the air. Its tendency to coagulate augments considerably, air. Its tendency to coagulate augments considerably, which is expressed by saying that its plasticity becomes stronger, its specific gravity diminishes, as well as its capacity for caloric. The venous blood, having acquired these characters, now becomes arterial blood, and enters the radicles of the pulmonary veins, which have their origin, like the veins properly so called, in the tissue of the lungs; that is, they form at first an infinite number of radicles, which appear to be the continuation of the pulmonary artery. These radicles unite to form thicker roots, which become still thicker. Lastly, they all terminate in four vessels, which over Lastly, they all terminate in four vessels, which open, after a short passage, into the left auricle. The pulmonary veins are different from the other veins, in their not anastomosing after they have acquired a certain thickness; a similar disposition has been seen in the divisions of the artery which is distributed to the lungs.

The pulmonary veins have no valves, and their structure is similar to that of the other veins; their middle membrane is, however, a little thicker, and it appears to possess more elasticity. The blood passes into the radicles of the pulmonary veins, and very soon reaches the trunk of these veins: in this passage it presents a gradually accelerated motion, in proportion as it passes from the small veins into the larger: finally, it does not at all flow by jerks, and it appears nearly equally rapid in the four pulmonary veins. From the pulmonary veins the left auricle receives

the blood.

The mechanism by which the blood traverses the left auricle and ventricle is the same as that by which the venous blood traverses the right cavities.

When the left auricle dilates, the blood of the four pulmonary veins enters and fills it; when it contracts, part of the blood passes into the ventricle, and part flows back into the pulmonary veins; when the ventricle dilates it receives the blood which comes from tricle dilates, it receives the blood which comes from the auricle, and a small quantity of that of the aorta; when it contracts, the mitral valve is raised, it shuts the auriculo-ventricular opening, and the blood, not being able to return into the auricle, it enters into the aorta by raising the three sigmoid valves, which were shut during the dilatation of the ventricle.

It is necessary to remark, however, that the fleshy columns having no existence in the auricle, their influence cannot exist as in the right, and the arterial ven-tricle being much thicker than the venous, it com-presses the blood with a much greater force than the right, which was indispensable on account of the dis-

tance to which it has to send this liquid.

Course of the blood in the aorta, and its divisions .-Notwithstanding the differences which exist between this and the pulmonary artery, the phenomena of the motion of the blood are nearly the same in both; thus a ligature being applied upon this vessel, near the heart, in a living animal, it contracts in its whole length, and, except a small quantity that remains in the

the opening be made far from the heart, and in a small division, the jet is continued and uniform; lastly, if one of the very small vessels that terminate the artery be opened, the blood flows, but without forming any jet: it flows uniformly in a sheet.

We see at first, in these phenomena, a new application of the principle of hydro-dynamics, as already mentioned, with regard to the influence of the size of the tube upon the liquid that flows in it: the greater the tube upon the liquid that flows in it: the greater the tube is, the rapidity is the less. This capacity of the vessel increasing according as it advances towards

blood; make a small opening in the sides of this portion of the artery, you will immediately see almost the whole of the blood pass out, and it will even spout to a certain distance. Then measure the breadth with the compasses, and there will be no doubt of the artery being much contracted, if the rapid expulsion of the blood has not already convinced you. This experi-ment also proves that the force with which the artery contracts is sufficient to expel the blood that it con-

Passage of the blood of the arteries into the veins.—
When, in the dead body, an injection is thrown into an artery, it immediately returns by the corresponding vein: the same thing takes place, and with still more facility, if the injection is thrown into the artery of a living animal. In cold-blooded animals, the blood can be seen, by the aid of a microscope, passing from the arteries into the veins. The communication between these vessels is then direct, and very easy; it is natural to suppose that the heart, after having forced the blood to suppose that the heart, after having forced the blood to the last arterial twigs, continues to make it move into the venous radicles, and even into the veins. Harvey, and a great number of celebrated anatomists, thought so. Lately, Bichat has been strongly against this doctrine: he has limited the influence of the blood; this doctrine: he has limited the influence of the blood; he pretends that it ceases entirely in the place where the arterial is changed into venous blood, that is, in the numerous small vessels that terminate the arteries and commence the veins. In this place, according to him, the action of the small vessels alone is the cause of the motion of the blood.

Remarks on the Movements of the Heart.—A. The right auricle and ventricle, and the left auricle and ventricle, the action of which we have studied separately, in reality form only one organ, which is the heart.

The auricles contract and dilate together; the same thing takes place with the ventricles, whose movements are simultaneous.

When the contraction of the heart is spoken of, that of the ventricle is understood. Their contraction is called systole, their dilatation diastole.

B. Every time that the ventricles contract, the whole of the heart is rapidly carried forward, and the point of this organ strikes the left lateral side of the chest, opposite the internal of the sixth and seventh

The number of the pulsations of the heart is considerable; it is generally greater in proportion as the person is younger.

At birth it is from 130 to 140 in a minute.

At one year..... 120 to 130. At two years.... 100 to 110. At three years... 90 to 100. At seven years... 85 to 90. At fourteen years 80 to 85. At adult age. . . . 75 to 80. At first old age. . . . 65 to 75. At confirmed old age 60 to 65.

But these numbers vary according to an infinity of circumstances, sex, temperament, individual disposi-

The affections of the mind have a great influence upon the rapidity of the contractions of the heart; every one knows that even a slight emotion immediately modifies the contractions, and generally accelerates them. In this respect great changes take place also by diseases.

D. Many researches have been made to determine with what force the ventricles contract. In order to appreciate that of the left ventricle, an experiment has been made, which consists in crossing the legs, and placing upon one knee the ham of the other leg, with a weight of 55 pounds appended to the extremity of the foot. This considerable weight, though placed at the extremity of such a long lever, is raised at each contraction of the ventricle, on account of the tendency to straighten the accidental curvature of the popliteal artery, when the legs are crossed in this

This experiment shows that the force of contraction of the heart is very great; but it cannot give the exact value of it. Mechanical physiologists have made great efforts to express it in numbers. Borelli compares the force which keeps up the circulation to that which would be necessary to raise 180,000 pounds; Hales believes it to be 51 pounds 5 ounces; and Keil reduces

bably varies according to numerous causes, such as age, the volume of the organ, the size of the individual, the particular disposition, the quantity of blood, the state of the nervous system, the action of

the organs, the state of health or of sickness, &c.
All that has been said of the force of the heart relates only to its contraction, its dilatation having been considered as a passive state, a sort of repose of the fibres; however, when the ventricles dilate, it is with a very great force, for example, capable of raising a weight of twenty pounds, as may be observed in animals recently dead. When the heart of a living animal is taken hold of by the hand, however small it may be, it is impossible by any effort to prevent the dilatation of the ventricles. The dilatation of the heart, then, cannot be considered as a state of inaction or repose.

E. The heart moves from the first days of existence

E. The heart moves from the first days of existence of the embryo to the instant of death by decrepitude. Why does it move? This question has been asked by ancient and modern philosophers and physiologists. The wherefore of phenomena is not easy to be given in physiology; almost always what is taken for such is only in other terms the expression of the phenomena; but it is remarkable how easily we deceive ourselves in this respect; one of the we deceive ourselves in this respect; one of the strongest proofs of it is afforded by the different explanations of the motion of the heart.

The ancients said that there was a pulsific virtue in

the heart, a concentrated fire, that gave motion to this organ. Descartes imagined that an explosion as sudden as that of gunpowder took place in the heart. The motion of the heart was afterward attributed to the animal spirits, to the nervous fluid, to the soul, to the process of the nervous system, to the archea: Haller considers it as an effect of irritability. Lately, Legallois has endeavoured to prove, by experiments, that the principle or cause of the motion of the heart has its seat in the spinal marrow.

Remarks upon the circular Motion of the Blood, or the Circulation.-We now know all the links of the circular chain that the sanguiferous system represents; we know how the blood is carried from the lungs toward all the other parts of the body, and how it returns from these parts to the heart. Let us examine these phenomena in a general manner, in order to show the most important.

A. The quantity of blood contained in the system is very considerable. It has been estimated by several authors at from 24 to 30 pounds. This value cannot be at all exact, for the quantity of blood varies according to numerous causes.

The relation of the mass of the arterial with that of the venous blood, is somewhat better known. This last, contained in vessels larger than that of the arteries, is necessarily in greater quantity, though we cannot say exactly how much greater its mass is than that of the arterial blood.

B. The circulatory path of the blood being continuous, and the capacity of the canal variable, the rapidity of this fluid must be variable also; for the same quantity must pass through all the points in a given time: observation confirms this. The rapidity is great in the trunk, and the principal divisions of the pulmonary artery and aorta: it diminishes much in the secondary divisions; it diminishes still more at the instant of the passage from the arteries into the veins; it continues passage from the arteries into the veins; it continues to augment in proportion as the blood passes from the roots of the veins into larger roots, and lastly into the large veins; but the rapidity is never so great in the venæ cavæ as in the aorta. In the trunks and the principal arterial divisions, the course of the blood is not only continued under the influence of the contraction of the arteries, but, besides, it flows in jerks by the effect of the contraction of the ventricles. This

by the effect of the contraction of the ventricles. This jerking manifests itself in the arteries by a simple dilatation in those that are straight, and by a dilatation and tendency to straighten in those which are flexuous.

The pulse is formed by the first of these phenomena, to which the second is sometimes joined. It is not easy to study, in man or in the animals, except where the arteries are laid close upon a bone, because they do not then retire from under the finger when it is placed upon them, as harmony to straight in red parteries. placed upon them, as happens to arteries in soft parts.

In general, the pulse makes known the principal modification of the contraction of the left ventricle, its modification of the contraction of the left ventricle, its quickness, its intensity, its weakness, its regularity, its irregularity. The quantity of the blood is also known by the pulse. If it is great, the artery is round, thick, and resisting. If the blood is in small quantity, the artery is small and easily flattened. Certain dispositions in the arteries have an influence also upon the pulse, and may render it different in the principal

C. The beating of the arteries is necessarily felt in the organs which are next them, and so much more in proportion as the arteries are more voluminous, and as the organs give way with less facility. The jerk which they undergo is generally considered as favour-The jerk able to their action, though no positive proof of it

exists

In this respect none of the organs ought to be more affected than the brain. The four cerebral arteries unite in circles at the base of the skull, and raise the brain at each contraction of the ventricle, as it is easy to be convinced of by laying bare the brain of an animal, or by observing this organ in wounds of the head. Probably, the numerous angular bendings of the internal carotid arteries, and of the vertebrals before their entrance into the skull, are useful for moderating this shaking; these bendings must also neces-sarily retard the course of the blood in these vessels.

When the arteries penetrate in a voluminous state into the parenchyma of the organs, as the liver, the kidneys, &c., the organ must also receive a jerk at each contraction of the heart. The organs into which the vessels enter, after being divided and subdivided,

can suffer nothing similar.

D. From the lungs to the left auricle the blood is of the same nature; however, it sometimes happens that it is not the same in the four pulmonary veins. For instance, if the lungs are so changed that the air can-not penetrate into the lobules, the blood which tra-verses them will not be changed from venous to arterial blood; it will arrive at the heart without having undergone this change; but in its passage through the left cavities it will be intimately mixed with that of the lungs opposite. The blood is necessarily homogeneous from the left ventricle to the last divisions of the aorta; but, being arrived at these small divisions, its elements separate; at least there exists a great num-ber of parts, such as the serous membranes, the cellu-lar tissue, the tendons, the aponeuroses, the fibrous membranes, &c., into which the red part of the blood is never seen to penetrate, and the capillaries of which contain only serum.

This separation of the elements of the blood takes place only in a state of health; when the parts that I have mentioned become diseased, it often happens that their small vessels contain blood, possessed of all

its characteristic properties.

There have been endeavours to explain this particular analysis of the blood by the small vessels. Boerhaave, who admitted several sorts of globules of different sizes in the blood, said, that globules of a certain largeness could only pass into vessels of an appropriate size: we have seen that globules, such as they were admitted by Boerhaave, do not exist.

Bichat believed that there exist in the small vessels a particular sensibility, by which they admitted

sels a particular sensibility, by which they admitted only the part of the blood suitable to them. We have already frequently contested ideas of this kind; neither can they be admitted here; for the most irritating liquids, introduced into the arteries, pass immediately into the veins, without any opposition to their passage

by the capillaries.

E. The elements of the blood separate in traversing the small vessels; sometimes the serum escapes, and spreads upon the surface of the membrane: sometimes spreads upon the surface of the membrane: sometimes the fatty matter is deposited in cells; here the mucus, there the fibrine; elsewhere are the foreign substances, which were accidentally mixed with the arterial blood. In losing these different elements, the blood assumes the qualities of venous blood. At the same time that the arterial blood supplies these losses, the small veins absorb the substances with which they are in contact. In the intestinal canal, for example, they absorb the drinks; on the other hand, the lymphatic trunks pour the lymph and the chyle into the venous system; it is certain, then, that the venous blood cannot be home which were accidentally mixed with the arterial blood. In losing these different elements, the blood assumes the qualities of venous blood. At the same time that the arterial blood supplies these losses, the small veins absorb the substances with which they are in contact. In the intestinal canal, for example, they absorb the drinks; on the other hand, the lymphatic trunks pour the lymph and the chyle into the venous system; it is certain, then, that the venous blood cannot be homogeneous, and that its composition must be variable in

the different veins; but, having reached the heart, by the motions of the right aurick; and ventricle, and the disposition of the fleshy columns, the elements all mix

disposition of the fleshy columns, the elements all mix together, and when they are completely mixed, they pass into the pulmonary artery.

F. A general law of the economy is, that no organ continues to act without receiving arterial blood; from this results, that all the other functions are dependent on the circulation; but the circulation, in its turn, cannot continue without the respiration by which the arterial blood is formed, and without the which the arterial blood is formed, and without the which the arterial blood is formed, and without the action of the nervous system, which has a great influence upon the rapidity of the flowing of the blood, and upon its distribution in the organs. Indeed, under the action of the nervous system, the motions of the heart, and consequently the general quickness of the course of the blood, are quicknesd or retarded. Thus, when the organs act voluntarily or involuntarily, we learn from observation, that they receive a greater quantity of blood without the motion of the general circulation being accelerated on that account; and if their action predominates, the arteries which are directed there, increase considerably. If, on the contrary, the action diminishes, or ceases entirely, the arteries become smaller, and permit only a small quantity to reach the organ. These phenomena are manifest in the muscles: the circulation becomes more rapid in them when they contract; if they are often contracted, the volume of their arteries increases; if they are para-lyzed, the arteries become very small, and the pulse is scarcely felt.

The circulation, then, may be influenced by the nervous system in three ways: 1st, By modifying the motions of the heart; 2dly, By modifying the capillaries of the organs, so as to accelerate the flowing of the blood in them; 3dly, By producing the same effects in the lungs, that is, by rendering the course of the blood more or less easy through this organ.

The acceleration of the motions of the heart becomes sensible to us by the magner in which the point

comes sensible to us by the manner in which the point of the organ strikes the walls of the chest. The difficulty of the capillary circulation is discovered by a feeling of numbness and a particular prickling; and when the pulmonary circulation is difficult, we are informed of it by an oppression or sense of suffocation, more or less strong.

Probably the distribution of the filaments of the great sympathetic on the sides of the arteries, has some important use; but this use is entirely unknown; we have received no light on the point by any experiment."—Magendie's Elements of Physiology.

CIRCULA'TOR. (From circulo, to compass about.)

A wandering practiser in medicine. A quack; a

mountebank.

CIRCULATO'RIUM. (From circulo, to move round.) chemical digesting vessel in which the fluid performs a circulatory motion.

CI'RCULUS. (Dim. of circus, a circle.) 1. A cir-

cle or ring.

2. Any part of the body which is round or annular, as circulus oculi.

3. A round chemical instrument sometimes called 3. A round chemical mass. abbreviatorium by the old chemists.

The artery which

runs round the iris and forms a circle, is so termed.

CIRCULUS QUADRUPLEX. A bandage

CIRCUMCAULA'LIS. A name of the adnata of the

CIRCUMCI'SION. (Circumcisio, from circumcido, to cut about.) The cutting off the prepuce from the glans penis; an ancient custom, still practised among the Jews, and rendered necessary by the heat of the climate in which it was first practised, to prevent collections and a vitiated state of the sebaceous secretion from the odoriferous glands of the part.

CIRCUMFLE'XUS. (Circumflexus, sc. musculus.) A muscle of the palate. Tensor palati of Innes. Circumflexus palati mollis of Albinus. Spheno-salpingo-staphilinus, seu staphilinus externus of Winslow. CIRCUMCI'SION. (Circumcisio, from circumcido,

internal plate of the pterygoid process by a round ten-don, which soon spreads into a broad membrane. It don, which soon spreads into a broad membrane. It is inserted into the velum pendulum palati, and the semilunar edge of the os palati, and extends as far as the suture which joins the two bones. Generally some of its posterior fibres join with the constrictor pharyngis superior, and palato-pharyngasus. Its use is to stretch the velum, to draw it downwards, and to the side towards the hook. It hath little effect upon the tube, being chiefly connected to its osseous part. CIRCUMGYRA'TIO. (From circumgyra, to turn round). Circumgyration, or the turning a limb round

round.) Circumgyration, or the turning a limb round

in its socket.

CIRCUMLI'TIO. (From circumlino, to anoint all over.) A medicine used as a general unction or lini-

ment to the part.

CIRCUMOSSA'LIS. (From circum, about, and os, a bone.) Surrounding a bone as the periosteum does; or surrounded by a bone.

CIRCUMSCISUS. Circumcised. Applied to a membranous capsule, separating into two parts by a membraneous capsule, separating into two parts by a complete circular fissure.

Cl'RCUS. (Kipkos; from carka, a Chaldean word, to surround.) 1. A circle or ring.

2. A circular bandage.

CIRNE'SIS. (From κ.ρναω, to mix.) A union of

separate things.

CIRRUS. (From scras, a horn, because it has the appearance of a horn) Cirrhus. A clasper or tendral. One of the fulcra or props of plants. A long, cylindrical, sleender, spiral body, issuing from various parts of plants.

cylindrical, stender, spinal parts of plants.

From their origin, Ciri are distinguished into,

1. Foliar, when they are a continuation of the midrib of a simple leaf; as in Fumaria claviculata, Mimosa scandens, and Gleriosa superba.

2. Petiolar, when terminating the common petiole

1. This is of a compound leaf; as in Pisum sativum. This is sometimes distinguished by the number of leaflets which grow under it: sence cirri diphylli, tetraphylli, and polyphylli.

3. Peduncular, when they proceed from the pedun-

cle; as in Vitis vinifera.

4. Azillary, which arise from the stem or branches in the axilla of the leaves; as in Passiflora incarnata.

5. Subaxillary, when they originate below the leaf.

6. Lateral, when at the side of it; as in Bryonia.

From the division of its apex, a Cirrus is,

1. Simple, consisting of one undivided piece; as in Momordica balsamizea, Passiflora quadrangularis, and Bryonia dioica. 2. Compound, consisting of a stalk variously branched or divided.

3. Bifid, when it has two divisions; as in Vitis vinifera, Lathyrus patastris, Ervum tetraspermum, &c. 4. Trifid, when there are three; as in Bignonia unguis, and Lathyrus hirsutus.

5. Multifid, or branched, when the divisions are

more numerous; as in Lathyrus latifolius, and Cobea

From its convolution into,

1. Convolute, when all the gyrations are regular in

the same direction; as in Hedera quinquefolia.

2. Revolute, winding itself irregularly, sometimes on one side, sometimes on the other; as in Passiflora in-

CIRROSUS. Having a cirrus or tendril. Applied to a leaf tipped with a tendril; as in Gloriosa and

Hagellaria, two Indian plants.

C'essum arvense. (From κιρσος, a vein, or swelling of a vein, which this herb was supposed to heal.)

The common way thistle, or Serratula arvensis of Linnæus.

CIRSOL'LE. See Circocele.
CIRSOL'DES. (From κιρσος, a varix, and ειδος, likeness.) Resembling a varix: an epithet applied by Rufus Ephesius to the upper part of the brain.
CIRSOS. (Κιρσος; from κιρσοω, to dilate.) A preternatural distention of any part of a vein. See

Ci'ssa. (From RIGGA, a gluttonous bird.) A de-praved appetite, proceeding from previous gluttony

CISSA'MPELOS. (From εισσος, ivy, and αμπελος, the vine.) The name of a genus of plants in the Linnæan system. Class, Diæcia; Order, Monadelphia. The wild vine with leaves like ivy.

CISSAMPELOS PAREIRA. The systematic name of CISSAMPELOS PAREIRA. The systematic name of the Pareira brava; Parcyra; Ambutua; Butua; Overo butua. The root of this plant, Cissampelos—foliis peltatis cordatis emarginatis, of Linnœus; a native of South America and the West Indies, has no remarkable smell, but to the taste it manifests a notable sweetness of the fiquorice kind, together with a considerable bitterness, and a slight roughness covered by the sweet matter. The facts adduced on the utility of the radix pareira brava in nephritic and calculous complaints, are principally by foreigners, and no remarkable instances of its efficacy are recorded by English practitioners. lish practitioners.

lish practitioners.

Cissa'rus. See Cistus Creticus.

Cissa'rus. (From κισσος, ivy.) The name of a plaster mentioned by Ægineta.

CISTA. (From κειμαι, to lie.) A cyst.

CISTE'RNA. (From cista, a cyst.) The fourth ventricle of the brain is so called from its cavity; also the lacteal vessels in the breasts of women.

Ci'sthorus. See Cistus Creticus.

CISTIC. See Cystic.
CISTIC See Cystic.
CISTIC OXIDE. See Calculus.
CISTUS: (Kto7oz, the derivation of which is uncertain; perhaps from kis, Heb.) The name of a genus of plants in the Linnæan system. Class, Polyandria; Order, Monogynia. The Cistus.
CISTUS CRETICUS. The systematic name of the plant from which the ladanum of the shops is obtained.

plant from which the ladanum of the shops is obtained, called also Cistus ladanifera, Cistorus; Cissarus; Dorycinium. Cistus—arborescens extipulatus, foliis spatulata-ovatis petiolatis enerviis scabris calycinis lanceolatis, of Linnaus. The resinous juice called ladanum expude upon the leave of this plant in Comladanum exudes upon the leaves of this plant in Can-dia, where the inhabitants collect it by lightly rubbing the leaves with leather, and afterward scraping it off, and forming it into irregular masses for exportation. Three sorts of ladanum have been described by authors, but only two are to be met with in the shops. The best, which is very rare, is in dark-coloured masses, of the consistence of a soft plaster, and growing still softer on being handled; the other is in long rolls, coiled up, much harder than the preceding, and not so dark. The first has commonly a small, and the last a large admixture of fine sand, without which they cannot be collected pure, independently of designed abuses: the dust blown on the plant by winds, from the loose sands among which it grows, being retained by the tenacious juice. The soft kind has an agreeable smell, and a lightly pungent bitterish taste: the hard is much weaker. Ladanum was formerly much employed internally as a pectoral and adstringent in catarrhal affections, dysenteries, and several other diseases; at present, however, it is wholly confined to external use, and is an ingredient in the stomachic plaster, emplastrum ladani. the leaves with leather, and afterward scraping it off, trum ladani.

CISTUS HUMILIS. A name most probably of the

Lichen caninus of Linnwus.

Lichen caninus of Linnæus.

CISTUS LADANIFERA. See Cistus creticus
CISTUS LEDON. See Ledum palustre.
CITE'SIUS (CITOIS), FRANCIS, of Poitiers, in
France, who, after graduating at Montpelier in 1596,
and practising a few years in his native city, went to
Paris, and acquired great celebrity, being made physician to Cardinal Richelieu. He published a treatise
on the Colica Pictonum, which was much esteemed,
noticing its termination in paralysis of the extremities.
He also gave an account of a girl who had fasted for
three years; in which case he appears to have been
imposed upon. In another publication he advocates
repeated bleeding, as well as purging, in small-pox,
and other fevers of an inflammatory type. He died in
1652, at the advanced age of 80.

1652, at the advanced age of 80.

Ct'Tharus. (From κιθαρα, a harp.) The breast is sometimes so named from its shape.

CITRA'GO. (From citrus, a citron; so called from its citron-like smell.) Citraria. Baum. See Me-

lissa.

CITRAS. (Citras, atis. fcm.: from citrus, the lemon.) A citrate. A salt formed by the union of the citric acid, or acid of lemons, with the salifiable bases; as citrate of ammonia, citrate of potassa.

CITRATE. See Citras.

CITRELM. See Citrus medica.

CITREUM. (From citrus.) The citron-tree. See Citrus medica.

CITRIC ACID. Acidum citricum. "The juice of

lemons, or limes, has all the characters of an acid of considerable strength; but on account of the mucilaginous matter with which it is mixed, it is very soon altered by spontaneous decomposition. Various methods have been contrived to prevent this effect from taking place, in order that this wholesome and agreeable acid might be preserved for use in long voyages, or other domestic occasions. The juice may be kept in bottles under a thin stratum of oil, which indeed prevents, or greatly retards, its total decomposition; though the original fresh taste soon gives place to one which is much less grateful. In the East Indies it is evaporated to the consistence of a thick exdies it is evaporated to the consistence of a thick extract. If this operation be carefully performed by a very gentle heat, it is found to be very effectual. When the juice is thus heated, the mucitage thickens, and separates in the form of flocks, part of which subside, and part rise to the surface: these must be taken out. The vapours which arise are not acid. If the evaporation he not control to the surface in the limit of the surface in ration be not carried so far as to deprive the liquid of its fluidity, it may be long preserved in well closed bottles; in which, after some weeks standing, a farther portion of mucilage is separated, without any perceptible change in the acid.

ceptible change in the acid.

Of all the methods of preserving lemon-juice, that of concentrating it by frost appears to be the best, though in the warmer climates it cannot conveniently be practised. Lemon-juice, exposed to the air in a temperature between 50° and 60°, deposites in a few hours a white semi-transparent mucilaginous matter, which leaves the fluid, after decantation and filtration, much less alterable than before. This mucilage is not of a gummy nature, but resembles the gluten of wheat in its properties: it is not soluble in water when dried. in its properties: it is not soluble in water when dried. More mucilage is separated from lemon-juice by standing in closed vessels. If this depurated lemon-juice be exposed to a degree of cold of about seven or eight degrees below the freezing point, the aqueous part will freeze, and the ice may be taken away as it forms; and if the process be continued until the ice begins to exhibit signs of acidity, the remaining acid will be found to be reduced to about one eighth of its original quantity, at the same time that its acidity will be eight times as intense, as is proved by its requiring eight times the quantity of alkali to saturate an equal portion of it. This concentrated acid may be kept for use, or, if preferred, it may be made into a dry lemonade, by adding six times its weight of fine loaf sugar

The above processes may be used when the acid of lemons is wanted for domestic purposes, because they leave it in possession of the oils, or other principles, on which its flavour peculiarly depends; but in chemical researches, where the acid itself is required to be had in the utmost purity, a more elaborate process must be used. Boiling lemon-juice is to be saturated with powdered chalk, the weight of which is to be with powdered chalk, the weight of which is to be noted, and the powder must be stirred up from the bottom, or the vessel shaken from time to time. The neutral saline compound is scarcely more soluble in water than selenite; it therefore falls to the bottom, while the mucilage remains suspended in the watery fluid, which must be decanted off; the remaining precipitate must then be washed with warm water until it comes off clear. To the powder thus edulcorated, a quantity of sulphuric acid, equal the chalk in weight, and diluted with ten parts of water, must be added. and diluted with ten parts of water, must be added, and the mixture boiled a few minutes. The sulphuric and the mixture boiled a few minutes. The sulphuric acid combines with the earth, and forms sulphate of lime, which remains behind when the cold liquor is filtered, while the disengaged acid of lemons remains dissolved in the fluid. This last must be evaporated to the consistence of a thin syrup, which yields the pure citric acid in little needle-like crystals. It is necessary that the sulphuric acid should be rather in excess, because the presence of a small quantity of lime will prevent the crystallization. This excess is allowed for above. ed for above.

Its taste is extremely sharp, so as to appear caustic. It is among the vegetable acids the one which most powerfully resists decomposition by fire.

In a dry and warm air it seems to effloresce; but it absorbs moisture when the air is damp, and at length
