to parts which appear as if they were sewed together; as the Raphe scroti, ecrebri, &c.

RAPHE CEREBRI. The longitudinal eminence of the corpus callosum of the brain is so called, because it appears somewhat like a suture.

RAPHE SCROTI. The rough eminence which divides the scrotum, as it were, in two. It proceeds from the root of the penis inferiorly towards the periusum.

RAPI'STRUM. (From rapa, the turnip; because its leaves resemble those of turnip. Originally, the wild turnip; so called from its affinity to Rapa, the

wild turnip: so called from its affinity to Rapa, the cultivated one.) 1. The name of a genus of plants.

Class, Tetradynamia; Order, Siliculosa.

2. The name of two species of Crambe, the orientalis

and hispanica.

RA'PUM. (Etymology uncertain.)

1. The turnip. See Brassica rapa.

2. The Campanula rapunculus.

RAPUNCULUS. (Diminutive of rapa, the turnip.) The trivial name of a species of Campunuta.

RAPUNCULUS CORNICULATUS. See Phyteuma orbi-

RAPUNCULUS VIRGINIANUS. The name given by Morrison to the blue cardinal flower. See Lobelia.

RA'PUS. See Brassica rapa. RASH. See Exanthema.

RASPATO'RIUM. (From rado, to scrape.) A sur-

geon's rasp.

RASPBERRY. See Rubus idaus.

RASPBERRY. See Rubus idwus.
RASU'RA. (From rado, to scrape.)
1. A rasure or scratch.
2. The raspings or shavings of any substance.
RATIFIA. A fiquor prepared by imparting to ardent spirits the flavour of various kinds of fruits.
RATTLESNAKE. See Crotalus horridus
Rattlesnaks-root. See Polygala scnega.
RAUCE'DO. (From rancus, hoarse.) Raucitas.
Hoarseness. It is always symptomatic of some other disease.

Ray of a flower. See Radius.

REAGENT. Test. A substance used in chemistry to detect the presence of other bodies. In the application of tests there are two circumstances to be attended to, viz. to avoid deceitful appearances, and to have good tests.

The principal of the content of the principal of the content of the principal of the content of the

The principal tests are the following:

1. Litmus. The purple of litmus is changed to red by every acid; so that this is the test generally made use of to detect excess of acid in any fluid. It may be used either by dipping into the water a paper stained with litmus, or by adding a drop of the tincture to the water to be examined, and comparing its hue with that of an equal quantity of the tincture in distilled water.

Litmus already reddened by an acid will have its purple restored by an alkali; and thus it may also be used as a test for alkalies, but it is much less active than

other direct alkaline tests.

2. Red cabbage has been found by Watt to furnish as delicate a test for acids as Litmus, and to be still more sensible to alkalies. The natural colour of an infusion of this plant is blue, which is changed to red by acids, and to green by alkalies in very minute quan-

3. Brazil wood. When chips of this wood are in-3. Brazil wood. When chips of this wood are infused in warm water they yield a red liquor, which readily turns blue by alkalies, either caustic or carbonated. It is also rendered blue by the carbonated earths held in solution by carbonic acid, so that it is not an unequivocal test of alkalies till the earthy carbonares have been precipitated by boiling. Acids change to yellow the natural red of Brazil wood, and restore the red when

changed by alkalies.

4. Violets. The delicate blue of the common scented violet is readily changed to green by alkalies, and this affords a delicate test for these substances. Syrup of

medicine. But a tincture of the flower will answer as well.

5. Turmeric. This is a very delicate test for alkalies, and on the whole, perhaps, is the best. The natural colour either in watery or spirituous infusion is yellow, which is changed to a brick or orange-red by alkalies, caustic or carbonated, but not by carbonated earths, on which account it is preferable to Brazil

The pure earths, such as lime and barytes, produce

the same change.

6. Rhubarb. Infusion or tincture of rhubarb undergoes a similar change with turmeric, and is equally delicate.

7. Sulphuric acid. A drop or two of concentrated sulphuric acid, added to water that contains carbonic acid, free or in combination, causes the latter to escape with a pretty brisk effervescence, whereby the presence of this gaseous acid may be detected.

8. Nitric and oxymuriatic acid. A peculiar use attends the employment of these acids in the sulphuretted waters, as the sulphuretted hydrogen is decomposed by them, its hydrogen absorbed, and the sulphur separated

in its natural form.

 Oxalic acid and oxalate of ammonia. These are the most delicate tests for time and all soluble calcareous salts. Oxalate of lime, though nearly insoluble in water, dissolves in a moderate quantity in its own or any other acid, and hence in analysis oxalate of ammonia is often preferred, as no excess of this salt can redissolve the precipitated oxalate of lime. On the other hand, the ammonia should not exceed, otherwise it might give a false indication.

10. Gallic acid and tincture of galls. These are tests of iron. Where the iron is in very minute quantities, and the water somewhat acidulous, these tests do not always produce a precipitate, but only a slight reddening, but their action is much heightened by pre-

reddening, but their action is much neightened by previously adding a few drops of any alkaline solution 11. Prussiate of potassa or lime. The presence of iron in water is equally well indicated by these prussiates, causing a blue precipitate: and if the prussiate of potassa is properly prepared, it will only be precipitated by a metallic sait, so that manganese and copper will also be detected, the former giving a white precipitate, the latter a red precipitate.

tate, the latter a red precipitate.

12. Lime-water is the common test for carbonic acid; it decomposes all the magnesian salts, and likewise the aluminous salts; it likewise produces a cloudiness with most of the sulphates, owing to the formation of sele-

13. Ammonia. This alkali when perfectly caustic serves as a distinction between the salts of lime and those of magnesia, as it precipitates the earth from the latter salts, but not from the former. There are two sources of error to be obviated, one is that of carbonic acid being present in the water, the other is the presence of aluminous salts.

14. Carbonated alkalies. These are used to precipitate all the earths; where carbonate of potassa is used, particular care should be taken of its purity, as it gene-

rally contains silex.

15. Muriated alumine. This test is proposed by Mr. Kirwan to detect carbonate of magnesia, which cannot, like carbonated lime, be separated by ebullition, but remains till the whole liquid is evaporated

16. Barytic salts. The nitrate, muriate, and acetate of barytes are all equally good tests of sulphuric

acid in any combination.

17. Salts of silver. The salts of silver are the most delicate tests of muriatic acid, in any combination, producing the precipitated luna cornea. All the salts of silver likewise give a dark-brown precipitate with the sulphuretted waters, which is as delicate a test as any that we possess.

18. Salts of lead. The nitrate and acetate of lead are the salts of this metal employed as tests. They will indicate the sulphuric, muriatic, and boracic acids,

and sulphuretted hydrogen or sulphuret of potassa.

19. Soap. A solution of soap in distilled water or in alkohol is curdled by water containing any earthy or metallic salt.

20. Tartaric acid. This acid is of use in distinguishing the salts of potassa (with which it forms a precipitate of cream of tartar), from those of soda, from which it does not precipitate. The potassa, however, violets is generally used as it is at hand, being used in | must exist in some quantity to be detected by the test

21. Nitro-muriate of platinum. This sort is still more discriminative between potassa and the other alkalies, than acid of tartar, and will produce a precipitate with a very weak solution of any salt with po-

22. Alkohol. This most useful reagent is applicable in a variety of ways in analysis. As it dissolves some substances found in fluids, and leaves others untouched, it is a means of separating them into two classes, which saves considerable trouble in the further investigation. Those salts which it does not dissolve, it precipitates from their watery solution, but more or less completely according to the salt contained, and the strength of the alkohol, and as a precipitant it also assists in many de-

REA'LGAR. Arlada; Arladar; Auripigmentum rubrum; Arsenicum rubrum factitium; Abessi. A native ore of sulphuret of arsenic.

RECEIVER. A chemical vessel adapted to the neck or beak of a retort, alembic and other distillatory vessel, to receive and contain the product of dis-

RECEPTA CULUM. (From recipio, to receive.)

1. A name given by the older anatomists to a part of the thoracic duct. See Receptaculum chyli.

2. In botany, the common basis or point of connexion of the other parts of the fructification of plants; by some called the Thalamus and the Placenta.

It is distinguished by botanists into proper and common; one flower only belongs to the former, and it is formed mostly from the apex of the peduncle or scape; as in Tulipa gesneriana, and Lilium candidum. The latter has many flowers; as in Helianthus annuus.

The proper receptacle or apex of the peduncle swells in some flowers, and becomes the fruit: thus the Fragaria vesca is not a berry, but a fleshy receptacle, with its naked seeds nestling on its surface: so, in the Ho-venia dulcis, the peduncles swell into a thick fleshy receptacle on which there are small capsules; and, in the Anacardium occidentale, the peduncle swells into a receptacle, on which the nut rests.

The varieties of the common receptacle are,

1. Planum; as in Helianthus annuus.

Convexum; as in Leontodon taraxacum.

Conicum ; as in Billis perennis.

- Punctatum ; as in Leontodon taraxacum.
- Globosum; as in Cephalanthus.
 Ovale; as in Dorstenia drakenia.
- Ocatum; as in Omphalea. Favosum, cellular on the surface, honeycomblike; as in Onopordium.
- Scrobiculatum, having round and deep holes; as in Helianthus amnuus.
- 10. Subulatum; as in Scabiosa atropurpurca. 11. Quadrangulum; as in Dorstenia houstonii, and

- 12. Turbinatum; as in Ficus carica. 13. Digitiforme; as in Arum maculatum, and Calla athiopica
- 14. Filiforme, thread-like; as in the catkins and corylus.

15. Ocelusum. The Ficus carica is a connivent fleshy receptacle enclosing the florets.

16. Nudum, without any vesture; as in Lactuca, and Leontodon taraxacum.

- Pilosum; as in Carthamus tinctorius.
 Villosum; as in Artemisia absynthium.
 Setosum; as in Echynops sphærocephalus, and Centaurea.
- 20. Paleaceum, covered with chaffy scales; as in Zeranthemum, Dipsacus, &c.

On the receptacle and seed-down are founded the most solid generic characters of syngenesious plants, admirably illustrated by the inimitable Gærtner.

The term receptacle is sometimes extended by Lin-neus to express the base of a flower, or even its internal part between the stamens and pistils, provided there be any thing remarkable in such parts, without reference to the foundation of the whole fructification. It also expresses the part to which the seeds are attached in a seed vessel, and the common stalk of a spike, or spikelet, in grasses.

RECEPTACULUM CHYLL. Receptaculum pecqueti, because Pecquet first attempted to demonstrate it; Diversorium; Sacculus chyliferus. The existence of such a receptacle in the human body is doubted. In brute animals the receptacle of the chyle is situated on and Cowper. Trachclubasitaire, of Dumas

the dorsal vertebræ where the lacteals all meet. See Absorbents.

Reciprocal affinity. See Affinity, reciprocal.
RECLINATUS. Reclining: applied to stems, leaves, &c. which are curved towards the ground; as the stem of the bramble, and leaves of the Leonurus car-

RECTIFICATION. (Rectificatio; from rectifice, to make clear.) A second distillation, in which substances are purified by their more volatile parts being raised by heat carefully managed; thus, spirit of wine, ather, &c. are rectified by their separation from the less volatile and foreign matter which altered or debased their properties.

RECTOR SPIRITUS. The aromatic part of plants.

RECTUM. (Rectum intestinum: so named from an erroneous opinion that it was straight.) Apeuthys-menos; Longanon; Longaon; Archos; Cyssaros. menos; Longanon; Longaon; Archos; Cyssaros. The last portion of the large intestines terminating in

the anus. See Intestine.

RE'CTUS. Straight. Several parts of the body, particularly muscles, are so caffed from their direction.

Parts of plants also have this term; as Caulis rectus,

the straight stem of the garden-lily, spinarecta, &c.

RECTUS ABDOMINIS. Pubio-sternal, of Dumas. A long and straight muscle situated near its fellow, at the middle and forepart of the abdomen, parallel to the linea alba, and between the aponeuroses of the other abdominal muscles. It arises sometimes by a single broad tendon from the upper and inner part of the os pubis, but more commonly by two heads, one of which is fleshy, and originates from the upper edge of the pubis, and the other tendinous, from the inside of the symphysis pubis, behind the pyramidalis muscle. From these beginnings, the muscle runs upwards the whole length of the linea alba, and becoming broader and thinner as it ascends, is inserted by a thin aponeurosis into the edge of the cartilage ensiformis, and into the cartilages of the fifth sixth and seventh ribs. the cartilages of the fifth, sixth, and seventh ribs. This aponeurosis is placed under the pectoral muscle, and soutetimes adheres to the fourth rib. The fibres of this muscle are commonly divided by three tendinous intersections, which were first noticed by Berenger, or as he is commonly called, Carpi, an Italian anatomist, who flourished in the sixteenth century. One of these intersections is usually where the muscle runs over the cartilage of the seventh rib; another is at the umbilicus; and the third is between these two. Sometimes there is one, and even two, between the umbilicus and the pubes. When one or both of these occur, however, they seldom extend more than half way across the muscle. As these intersections seldom penetrate through the whole substance of the muscle, they are all of them most apparent on its anterior surface, where they firmly adhere to the sheath; the adhesions of the rectus to the posterior layer of the internal oblique, are only by means of cellular membrane, and of a few vessels which pass from one to another.

Albinus and some others have seen this muscle extending as far as the upper part of the sternum.

The use of the rectus is to compress the forepart of

the abdomen, but more particularly the lower part; and according to the different positions of the body, it may likewise serve to bend the trunk forwards, or to raise the pelvis. Its situation between the two layers of the internal oblique, and its adhesions to this sheath, secure it in its place, and prevent it from rising into a prominent form when in action; and, lastly, its tendinous intersections enable it to contract at any of the intermediate spaces.

RECTUS ABDUCENS OCULL. See Rectus externus

RECTUS ADDUCENS OCULI. See Rectus internus

RECTUS ANTERIOR BREVIS. See Rectus capitis internus minor.

RECTUS ANTERIOR LONGUS. See Rectus capitis internus major.

RECTUS ATTOLLENS OCULL. See Rectus superior

RECTUS CAPITIS ANTICUS LONGUS. See Rectus capitis internus major.

RECTUS CAPITIS INTERNUS MAJOR. A muscle situated on the anterior part of the neck, close to the vertebra. Rectus internus major, of Albinus, Douglas,

REC REG

of the ancient anatomists, but was known to most of the ancient anatomists, but was not distinguished by any particular name until Cowper gave it the present appellation, and which has been adopted by most writers except Winslow. It is a long muscle, thicker and broader above than below, where it is thin, and terminates in a point. It arises, by distinct and flat tendons, from the anterior points of the transverse processes of the five inferior vertebrae of the neck, and ascesses of the five inferior vertebræ of the neck, and as-cending obliquely upwards is inserted into the anterior part of the cuneiform process of the occipital bone. The use of this muscle is to bend the head forwards.

RECTUS CAPITIS INTERNUS MINOR. Cowper, who was the first accurate describer of this little muscle, gave it the name of rectus internus minor, which has been adopted by Douglas and Albinus. Winslow calls it rectus anterior brevis, and Dumas petit-trachelo-basilaire. It is in part covered by the rectus major. It arises fleshy from the upper and forepart of the body of the first vertebra of the neck, near the origin of its transverse process, and, ascending obliquely inwards, is inserted near the root of the condyloid process of the occipital bone, under the last described muscle. It as-

sists in bending the head forwards.

RECTUS CAPITIS LATERALIS. Rectus lateralis Fallopii, of Douglas. Transversalis anticus primus, of Winslow. Rectus lateralis, of Cowper; and Trachelialtoido basilaire, of Dumas. This muscle seems to have been first described by Fallopius. Winslow calls it transversalis anticus primus. It is somewhat calls it transversalis anticus primus. It is somewhat larger than the rectus minor, but resembles it in shape, and is situated immediately behind the internal jugular vein, at its coming out of the cranium. It arises fleshy from the upper and forepart of the transverse process of the first vertebra of the neck, and, ascending a little obliquely upwards and outwards, is inserted into the occipital bone, opposite to the stylo-mastoid hole of the os temporis. This muscle serves to pull the head to

RECTUS CAPITIS POSTICUS MAJOR. This muscle, which is the rectus major of Douglas and Winslow, the rectus capitis posticus minor of Albinus, and the spine-azoido-occipital of Dumas, is small, short, and flat, broader above than below, and is situated, not in a straight direction, as its name would insinuate, but obliquely, between the occiput and the second vertebra of the neck, immediately under the complexus. It arises, by a short, thick tendon, from the upper and arises, by a short, thick tendon, from the upper and posterior part of the spinous process of the second vertebra of the neck; it soon becomes broader, and, ascending obliquely outwards, is inserted, by a flat tendon, into the external lateral part of the lower semicircular ridge of the os occipits. The use of this is to extend the head, and pull it backwards.

Rectus capitis posticus minor. This is the rectus minor of Douglas and Winslow, and the tuber-altoidoccipital of Dumas. It is smaller than the last-described muscle, but resembles it in shape, and is placed close by its follow, in the space between the recti majores.

by its fellow, in the space between the recti majores. It arises, by a short, thick tendon, from the upper and lateral part of a little protuberance in the middle of the back part of the first vertebra of the neck, and, becoming broader and thinner as it ascends, is inserted, by a broad, flat tendon, into the occipital bone, immediately under the insertion of the last-described muscle. The use of it is to assist the rectus major in drawing

The use of h is to the head backwards.

RECTUS CRURIS. See Rectus femoris.

RECTUS CRURIS. OCULI. See Rectus inferior

RECTUS EXTERNUS OCULI. The outer straight muscle of the eye. Abductor oculi; Iracundus; Indignabundus. It arises from the bony partition between the foramen opticum and lacerum, being the longest of the straight muscles of the eye, and is inserted into the sclerotic membrane, opposite to the outer canthus of the eye. Its use is to move the eye outwards.

RECTUS FEMORIS. A straight muscle of the thigh

RECTUS FEMORIS. A straight muscle of the thigh, situated immediately at the forepart. Rectus cive Gracil's anterior, of Winslow. Rectus cruris, of Albinus; and Rio-rotulien, of Dumas. It arises from the os ilium by two tendons. The foremost and shortest of these springs from the outer surface of the inferior and anterior spinous process of the ilium; the posterior tendon, which is thicker and longer than the other, arises from the posterior and outer part of the edge of the cotyloid cavity, and from the adjacent capsular liga-

ment. These two tendons soon unite, and form an ment. These two tendons soon unite, and form an aponeurosis, which spreads over the anterior surface of the upper part of the muscle; and through its whole length we observe a middle tendon, towards which its fleshy fibres run on each side in an oblique direction, so that it may be styled a penniform muscle. It is inserted tendinous into the upper edge and anterior surface of the patella, and from thence sends off a thin aponeurosis, which adheres to the superior and lateral part of the tibia. Its use is to extend the leg. part of the tibia. Its use is to extend the leg

RECTUS INFERIOR OCULI. The inferior of the straight muscles of the eye. Depressor oculi; Deprimens; Humilis; Amatorius. It arises within the socket, from below the optic foramen, and passes forwards to be inserted into the sclerotic membrane of the bulb on the under part. It pulls the eye downwards.

RECTUS INTERNUS FEMORIS. See Gracilis.
RECTUS INTERNUS OCULI. The internal straight muscle of the eye. Adducens oculi; Adductor oculi; Bibitorius. It arises from the inferior part of the foramen opticum, between the obliquus superior, and the rectus inferior, being, from its situation, the shortest muscle of the eye, and is inserted into the sclerotic membrane opposite to the inner angle. Its use is to turn the eye towards the nose

RECTUS LATERALIS FALLOPII. See Rectus capitis

lateralis.

RECTUS MAJOR CAPITIS. See Rectus capitis posti-

cus major.

RECTUS SUPERIOR OCULI. The uppermost straight muscle of the eye. Attollens oculi. Levator oculi. Superbus. It arises from the upper part of the foramen opticum of the sphenoid bone below the levator palpebræ superioris, and runs forward to be inserted into the superior and forepart of the sclerotic membrane by a broad and thin tendon.

RECURRENT. (Recurrens: so named from its

direction.) Reflected.

RECURRENT NERVE. Two branches of the par vagum in the cavity of the thorax are so called. The right is given off near the subclavian artery, which it surrounds, and is reflected upwards to the thyroid gland; the left a little lower, and reflected around the aorta to the œsophagus, as far as the larynx. They are both distributed to the muscles of the larynx and

RECURVUS. Recurved; reflexed; turned backward; applied to the leaves of the Erica retorta.

Red saunders. See Pterocarpus santalinus.

REDDLE. A species of other or argillaceous earth, of a dark red colour, which has been used medicinally as a tonic and antacid.

REDUCTION Registrication This word in its

REDUCTION. Revivification. This word, in its most extensive sense, is applicable to all operations by which any substance is restored to its natural state, or which is considered as such: but custom confines it to operations by which metals are restored to their metalic state, after they have been deprived of this, either by combustion, as the metallic oxides, or by the union of some heterogeneous matters which disguise them, as fulminating gold, luna cornea, cinnabar, and other compounds of the same kind. These reductions are also called revivifications.

also called revivifications.

REFLEXUS. Reflected; recurved; bent backward: applied to the leaves of plants, as the Erica retorta, and to the border of the flower-cup of the Enothera biennis, and the petals of the Pancratium zeylanicum.

REFRIGERANT. (Refrigerans; from refrigero, to cool.) Medicines which allay the heat of the body or of the blood.

REFRIGERATO'RIUM. (From refrigero, to cool.) A vessel filled with water to condense vapours, or to

make cool any substance which passes through it.

RE'GIMEN. (From rego, to govern.) A term employed in medicine to express the plan or regulation of

REGUNA. A queen. A name given by way of

excellence to some plants.

REGINA PRATI. See Spira ulmaria.

REGION. (Regio, onis. f. à rego.) A part of the body; generally applied to external parts, under which is some particular viscus, that the particular place may be known. Anatomists have divided the regions, or reveral parts of the body when entire, as follows: several parts of the body when entire, as follows:

Into caput, or head; truncus, or trunk; and extremi-tates, or extremities.

A. The head is divided into,

Facies, the face.

2. Pars capillata, the scalp.

The regions of the scalp are

a Vertex the top or crown of the head.
b. Synciput, the forepart of the scalp.
c. Occiput, the back part of the head.
d. Partes laterales, the sides.
The regions of the face are,

Frons, the forehead. b. Tempora, the temples.

c. Nasus, the nose, on which are, the radiz, or root; the dorsum or bridge; the apex, or tip; and the ala, or sides.

d. Oculus, the eye.

e. Os, the mouth, the external parts of which are, labia, the lips; anguli oris, where the lips meet; philtrum, an oblong depression in the middle of the upper

f. Mentum, the chin, the hair of which is called barba, whereas that of the upper lip is termed mistax.
g. Bucca, the cheeks.
h. Auris, the ear, on which are the auricula, helix,

- antiheliz, tragus, antitragus, concha, scapha, and lo-
- bulas.

 B. The trunk is divided into the collum, or neck; the thorax, or chest; the abdomen, or belly.

 1. Collum, the neck, which has,
 a. Pars antica, in which is the pomum adami, or

larynz.

b. Pars postica, in which is the fossa, and nucha, or nape of the neck.

Thorax, the chest, which is divided into, a. The front, on which is mamme, the breasts, and scrobiculus cordis, the pit of the stomach.

b. The back part, or dorsum.
c. The sides.

Abdomen, is divided into the forepart, which is strictly the abdomen, or belly; the hindpart, or lumbi, the loins; the lateral parts or sides.

On the abdomen, or forepart, are the following re-

The Epigastric, the sides of which are termed hypochondria

The Umbilical, the sides of which are termed the epicolic regions.

The Hypogastric, the sides of which are the ilia.

The Pubes is the region below the abdomen, covered with hair; in women, termed mons veneris: the sides are inguina, or groins.

Below the pubes are the parts of generation in men,

the scrotum and penis; in women, the labia pudendi, and the rima vulvæ. The space between the genitals and anus is called perinæum, or fork.

C. The extremities are the superior and the inferior.

The upper extremity has,

1. The shoulder or top, under which is the axilla, or

arm-pit.

2. The brachium, or arm.

3. The antibrachium, or fore-arm, in which are the bend, or flexura, and elbow.

4. The manus, or hand, which has vola, the palm; and dorsum, the back; and is divided into the carpus, or wrist, the metacarpus, and fingers.
The lower extremny embraces,

1. The femur, or thigh, the upper and outer part of which is called coxa, or the regio ischiadica.

2. The crus, or leg, in which are the genu, or knee, cavum popletis, or ham, and the sura, or calf.

3. The pes, or foot, which is divided into the tarsus, metatarsus, and toes

The upper part of the tarsus laterally has the malleolus externus and internus, or the inner and outer ankle.

RE'GIUS. (From rex, a king.) Royal: applied to a disease, and to a chemical preparation; to the former, the jaundice, because in it the colour of the skin is like

gold; and to the latter, because it dissolves gold.

REGULAR. Regularis. A term applied to diseases, which observe their usual course, in opposition to irregular, in which the course of symptoms deviate from what is usual, as regular gout, regular small-

Regular gout. See Arthritis.

RE GULUS. (Diminutive of rex, a king: so called because the alchemist expected to find gold, the king of metals, collected at the bottom of the crucible after fusion.) The name regulus was given by chemists to

metallic matters when separated from other substances by fusion. This name was introduced by alchemists, who, expecting always to find gold in the metal col-lected at the bottom of their crucibles after fusion, called this metal, thus collected, regulus, as containing gold, the king of metals. It was afterward applied to the metal extracted from the ores of the semi-metals, which formerly bore the name that is now given to the semi-metals themselves. Thus we had regulus of antimony, regulus of arsenic, and regulus of cobalt.

Regulus of antimony. See Antimony.

Regulus of arsenic. See Arsenic.

REME'DIUM. (Are, and medeer, to cure.) A re-

medy, or that which is employed with a view to prevent, palliate, or remove a disease.

REMEDIUM DIVINUM. See Imperatoria. REMEDY. See Remedium. REMINISCENCE. See Memory.

REMITTENT. (Remittens; from remitte, to assuage or lessen.) Any disorder, the symptoms of which diminish very considerably, and return again, so as not to leave the person ever free.

to leave the person ever free.

Remittent fever. See Febris intermittens.

Re'mora aratri. (From remoror, to hinder, and aratrum, a plough.) See Ononis spinosa.

Remote cause. See Exciting cause.

REN. (Ren, nis, m. Ren, απο του ρων; because through them the urine flows.) The kidney. See

Kidney.

RENAL. (Renalis; from ren, the kidney.) Appertaining to the kidney.

pertaining to the kidney.

Renal artery. See Emulgent artery.

RENAL GLAND. Glandulæ renalis. Renal capsule.

Supra-renal gland. The supra-renal glands are two hollow bodies, like glands in fabric, and placed, one on each side, upon the kidney. They are covered by a double tunic, and their cavities are filled with a liquor double tunic, and their cavities are filled with a liquor. of a brownish red colour. Their figure is triangular; and they are larger in the fætus than the kidneys; but, and they are larger in the locals than the kidneys; but, in adults, they are less than the kidneys. The right is affixed to the liver, the left to the spleen and pancreas, and both to the diaphragm and kidneys. They have arteries, veins, lymphatics, and nerves; their arteries arise from the diaphragmatic, the aorta, and the renal arteries. The vein of the right supra-renal gland empties itself into the vena cava; that of the left into the renal vein; their lymphatic vessels go directly into the thoracic duct; they have nerves common alike to these glands and the kidneys. They have no excretory duct, and their use is at present unknown. It is supposed they answer one use in the fœtus, and another in the adult, but what these uses are is uncertain. Boerhaave supposed their use to consist in their furnishing lymph to dilute the blood returned, after the secretion of the urine, in the renal vein; but this is very improbable, since the vein of the right supra-renal gland goes to the vena cava, and the blood carried back by the renal vein wants no dilution. It has also been said, that these glands not only prepare lymph, by which the blood is fitted for the nutrition of the deli-cate fœtus; but that in adults they serve to restore to the blood of the vena cava the irritable parts which it loses by the secretion of bile and urine. Some, again, have considered them as diverticula in the fortus, to divert the blood from the kidneys, and lessen the quantity of urine. The celebrated Morgagni be-lieved their office to consist in conveying something to the thoracic duct. It is singular, that in children who are born without the cerebrum, these glands are ex-

tremely small, and sometimes wanting.

Renal vein. See Emulgent vein.
Renal vessels. See Emulgent.
RENIFORMIS. Kidney-shaped. 1. In anatomy, this term is applied to any deviations of parts assuming a kidney-like form.

2. In botany, leaves, seeds, &c. are so called from their shape; it is a short, broad, roundish leaf, the base of which is hollowed out, as that of the Asarum

Beta and Phaseolus.

RENNET. Runnet. The gastric juice and contents of the stomach of calves. It is much employed in preparing cheese, and in pharmacy, for making whey. To about a pound of milk, in a silver or earthen basin, placed on hot ashes, add three or four grains of rennet, diluted with a little water; as it becomes cold, the milk curdles, and the whey, or serous

disposes the patient to sleep; takes off the gripes and tenesmus, and changes the stools to their natural colour and consistence.

QUA'TRIO. (From quatuor, four: so called because

it has four sides.) The astragalus.

Queen of the meadow. See Spiræa ulmaria

QUERCERA. See Epialus.

[QUERCITRON. See Quercus tinctoria. A.]
QUERCULA. (Quercula; diminutive of quercus,
the oak: so called because it has leaves like the oak.)
An antiquated name of the germander. See Teucrium

QUE RCUS. (From quero, to inquire; because divinations were formerly given from oaks by the Druids.)

The oak.

The name of a genus of plants in the Linnsan system. Class Monacia; Order, Polyandria.
 The pharmacopæial name of the oak. See Quer-

cus robur

QUERCUS CERRIS. The systematic name of the tree which affords the Nux galla. Galla maxima orbicu-lata. The gall-nut. By this name is usually denoted any protuberance, tubercle, or tumour, produced by the puncture of insects on plants and trees of different These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a num-ber of small cells, communicating with each other. Some of them are as hard as the wood of the tree they grow on, while others are soft and spongy; the first being termed gall-nuts, and the latter berry-galls, or

apple-galls.

The gall used in medicine is thus produced:—the cynips quercus folii, an insect of the fly-kind, deposites its eggs in the leaves and other tender parts of the tree. Around each puncture an excrescence is presently formed, within which the egg is hatched, and the worm passes through all the stages of its metamorphosis, until it becomes a perfect insect, when it eats its way out of its prison. The best oak-galls are heavy, knotted, and of a bluish colour, and are obtained from Aleppo. They are nearly entirely soluble in water, with the assistance of heat. From 500 grains of Aleppo galls, Sir Humphry Davy obtained by infusion 185 grains of solid matter, which on analysis appeared to consist of tannin 130; mucilage, and matter rendered insolubie by evaporation, 12; gallic acid, with a little extractive matter, 31; the remainder, calcareous earth and saline matter, 12. Another sort comes from the south of Europe, of a light brownish or whitish colour, smooth, round, easily broken, less compact, and of a much larger size. The two sorts differ only in size and strength, two of the blue galls being supposed equivalent in this respect to three of the others.

Oak-galls are supposed to be the strongest adstringent in the vegetable kingdom. Both water and spirit take up nearly all their virtue, though the spirituous extract is the strongest preparation. The powder is, however, the best form; and the dose is from a few grains to half a drachm.

They are not much used in medicine, though they are said to be beneficial in intermittents. Dr. Cullen has cured agues, by giving half a drachm of the powder of galls every two or three hours during the inter-mission; and by it alone, or joined with camomile flowers, has prevented the return of the paroxysms. But the Doctor states the amount of his results only to be this: that, "in many cases, the galls cured the intermittents; but that it failed also in many cases in which the Peruvian bark afterward proved successful." fomentation, made by macerating half an ounce of bruised galls in a quart of boiling water for an hour, has been found useful for the piles, the prolapsus ani, and the fluor albus, applied cold. An injection, simply ad-stringent, is made by diluting this fomentation, and used in gleets and leucorrhea. The camphorated ointment of galls has been found also serviceable in piles, after the use of leeches; and is made by incor-porating half a drachm of camphor with one ounce of hog's lard, and adding two drachms of galls in very fine powder. In fact, galls may be employed for the same purposes as oak-bark, and are used under the same forms.

QUERCUS ESCULUS. The systematic name of the Italian oak, whose acorns are, in times of scarcity, said to afford a meal of which bread is made.

QUERCUS MARINA. See Fucus vesiculosus.

QUERCUS PHELLOS. The systematic name of the willow-leaved oak, the acoms of which are much sweeter than chesnuts, and much eaten by the Indians. They afford, by expression, an oil little inferior to oil

QUERCUS ROBUR. The oak-tree. Balanos. Quercus —folis oblongis, glabris sinuatis, lobis rotundis, glandibus oblongis, of Linneus. This valuable tree is indigenous to Britain. Its adstringent effects were sufficiently known to the ancients, but it is the bark which is now directed for medicinal use by our pharmacopocias. Oak-bark manifests to the taste a strong adstringency, accompanied with a moderate bitterness. Like other adstringents, it has been recommended in agues, and for restraining hamorrhages, alvine fluxes, and other immoderate evacuations. A decoction of it has likewise been advantageously employed as a gargle, and as a fomentation or lotion in procidentia recti et uteri.

The fruit of this tree was the food of the first ages; but when corn was cultivated, acorns were neglected. They are of little use with us, except for fattening hogs and other cattle and poultry. Among the Spaniards, the acorn, or glans iberica, is said to have long remained a delicacy, and to have been served up in the form of a dessert. In dearths, acorns have been sometimes dried, ground into meal, and baked as bread. Bartholin relates that they are used in Norway for this purpose. The inhabitants of Chio held out a long siege without any other food; and in a time of scarcity in France, A. D. 1709, they recurred to this food. But they are said to be hard of digestion, and to occasion headaches, flatulency, and colics. In Smoland, how-ever, many instances occur, in which they have sup-plied a salutary and nutritious food. With this view they are previously boiled in water and separated from their husks, and then dried and ground; and the pow-der is mixed with about one-half, or one-third of corn flour. A decoction of acorns is reputed good against dysenteries and colics: and a pessary of them is said to be useful in immoderate fluxes of the menses. Some have recommended the powder of acorns in intermit tent fever; and in Brunswick, they mix it with warm ale, and administer it for producing a sweat in cases of erysipelas. Acorns roasted and bruised have restrained a violent diarrhea. For other medical uses to which they have been applied, see Murray's Appar

Medic. vol. i. page 100.

From some late reports of the Academy of Sciences, at Petersburgh, we learn that acorns are the best substitute to coffee that has been hitherto known. communicate to them the oily properties of coffee, the following process is recommended. When the acorns have been toasted brown, add fresh butter in small pieces to them, while hot in the ladle, and stir them with care, cover the ladle and shake it, that the whole may be well mixed. The acorns of the Holm oak are formed at Venice into cups about one inch and a hal, in diameter, and somewhat less in depth. They are used for dressing leather and instead of galle for this used for dressing leather, and instead of galls for dying woollen cloth black.

QUERCUS SUBER. The systematic name of the cork-Suber. The fruit of this tree is much more nutritious than our acorns, and is sweet and often eaten when roasted in some parts of Spain. The bark, called cork, when burned, is applied as an astringent application to bleeding piles, and to allay the pain usually attendant on hæmorrhoids, when mixed with an ointment. Pessaries and other chirurgical instruments are also made of this useful bark.

["QUERCUS ALBA. White oak. Most, and perhaps all the species of oak, have a high degree of astrinand the species of oak, have a high degree of astringency, depending upon tannin, which they possess in great quantities, and on account of which they are extensively used in the preparation of leather. The white oak is one of the American species, which is most esteemed for this property. The bark of the young branches is probably more astringent than that of the trunk, on account of the mass of dead cortical layers, which constitutes a part of the thickness of the latter. Oak-bark has been given in some instances. Oak-bark has been given in some instances as a substitute for cinchona, to which, however, it is greatly inferior. Its chief use is an external astringent and antiseptic. A strong decoction is employed with advantage as a gargle in cynanche, and as a lotion in gangrenous ulcers and offensive discharges of different kinds."-Big. Mat. Med. A.1

colour which is usually some shade of yellow, or brown; they are of a greater specific gravity than water; they are often odorous and sapid, easily fusi-

ble, and, on cooling, become solid.

Resin, black. See Resina nigra. Resin, elastic. See Caoutchouc. Resin-tree, elastic. See Caoutchouc.
Resin, white. See Resina alba.
Resin, yellow. See Resina flava.
RESINA. (From ρεω, to flow: because it flows spontaneously from the tree.) See Resin.

RESINA ALBA. The inspissated juice of the Pinus sylvestris, &c. is so called; and sometimes the residuum of the distillation of oil of turpentine. See Resina flava.

RESINA ELASTICA. See Caoutchouc.

RESINA FLAVA. Resina alba. Yellow resin, what remains in the still after distilling oil of turpentine, by Yellow resin, what adding water to the common turpentine. It is of very extensive use in surgery as an active detergent, and

forms the base of the unguentum resine flave.

Resina nigra. Colophonia. What remains in the retort after distilling the oil of turpentine from the common turpentine. This name is also given, in the London Pharmacopæia, to pitch.

RESINA NOVI BELGII. See Botany-bay.
RESOLUTION. (Resolutio; from resolvo, to loosen.) A termination of inflammation in which the disease disappears without any abscess, mortification, &c. being occasioned.

The term is also applied to the dispersion of swell-

ings, indurations, &c.
RESOLVENT. RESOLVENT. (Resolvens; from resolve, to loosen.) This term is applied by surgeons to such substances as discuss inflammatory and other tumours.

RESPIRATION. (Respiratio; from respiro, to take breath.) To comprehend the important function of breathing or respiration, it is not only necessary to have a knowledge of the structure of the thoracic viscera, the form of the parietes, of the chost, and to comprehend the mechanism by which the air enters and passes out of it, but also to be well acquainted with the chemical and physical properties of the air, and the circulation of the blood.

The lungs are two spongy and vascular organs of a considerable size, situated in the lateral parts of the chest. Their parenchyma is divided and subdivided into lobes and lobules, the forms and dimensions of which it is difficult to determine.

We learn, by the careful examination of a pulmo-nary lobule, that it is formed of a spongy tissue, the arcola of which are so small that a strong lens is necessary to observe them distinctly; these arcola all communicate with each other, and they are surrounded by a thin layer of cellular tissue which separates them

from the adjoining lobules.

Into each lobule enters one of the divisions of the bronchia, and one of the pulmonary artery; this last is distributed in the body of the lobule in a manner that is not well known; it seems to be transformed into nu-merous radicles of the pulmonary veins. Dr. Magen-die believes that these numerous small vessels, by which the artery terminates and the pulmonary veins begin, by crossing and joining in different manners, form the arcolæ of the tissue of the lobules. The small bronchial division that ends in the lobule, does not enter into the interior of it, but breaks off as soon

as it has arrived at the parenchyma.

This last circumstance appears remarkable: because, since the bronchia do not penetrate into the spongy tissue of the lungs, it is not probable that the surface of the cells with which the air is in contact is covered by the mucous membrane. The most minute anatomy cannot prove its existence in this place

A part of the nerve of the eighth pair, and some filaments of the sympathetic, are expended on the lungs, but it is not known how they are distributed; the surface of the organ is covered by the pleura, a serious membrane, similar to the peritonæum in its

structure and functions.

Round the bronchia, and near the place where they enter into the tissue of the lungs, a certain number of lymphatic glands exist, the colour of which is almost black, and to which the small number of lymphatic vessels which spring from the surface and from the interior of the pulmonary tissue are directed.

delicate injections some information that we ought not to neglect.

If we inject mercury, or even coloured water, into the pulmonary artery, the injected matter passes immediately into the pulmonary veins, but at the same time a part enters the bronchia, and goes out by the trachea. If the matter be injected into a pulmonary vein, it passes partly into the artery and partly into the bronchia. Lastly, if it be introduced into the trachea, it very soon penetrates into the artery, into the pulmonary veins, and even into the bronchial artery and

The lungs fill up a great part of the cavity of the chest, and enlarge and contract with it; and as they communicate with the external air by the trachea and the larynx, every time that the chest enlarges it is dis-tended by the air, which is again expelled when the chest resumes its former dimensions. We must then necessarily stop to examine this cavity.

The breast, or the thorax, is of the form of a cone, the summit of which is above, and the base below.

The apparent form and dimensions of the breast are determined by the length, disposition, and motions of the ribs upon the vertebra.

The chest is capable of being dilated vertically,

transversely, forward and backward, that is, in the direction of its principal diameters.

The principal, and almost the only, agent of the vertical dilatation, is the diaphragm, which, in contracting, tends to lose its vaulted form, and to become a plane; a motion which cannot take place without the ectoral motion of the thorax increasing, and the ab-

dominal portion diminishing.

The sides of this muscle, which are fleshy, and correspond with the lungs, descend farther than the centre, which, being aponeurotic, can make no effort by itself, and which is, besides, retained by its union with

the sternum and the pericardium.

In most cases this lowering of the diaphragm is sufficient for the dilatation of the breast; but it often happens that the sternum and the ribs, in changing the p sition between them and the vertebral column, produce

a sensible augmentation in the pectoral cavity.

In the general elevation of the thorax, its form necessarily changes, as well as the relations of the bones of which it is composed: the cartilages of the ribs seem particularly intended to assist these changes; as soon as they are ossified, and consequently lose their

elasticity, the breast becomes immoveable.

While the sternum is carried upwards, its inferior extremity is directed a little forward: it thus undergoes a slight swinging motion; the ribs become less oblique upon the vertebral column; they remove a little from each other, and their inferior edge is directed outward

by a small tension of the cartilage. All these phenomena are not very apparent except in the superior ribs.

A general enlargement of the thorax takes place by its elevation, as well from front to back, as trans-

versely, and upwards.

This enlargement is called inspiration. It presents three degrees: 1st, ordinary inspiration, which takes place by the depression of the diaphragm, and an almost insensible elevation of the thorax; 2dly, the great inspiration, in which there is an evident elevation of the thorax, and, at the same time, a depression of the diaphragm; 3dly, forced inspiration, in which the di-mensions of the thorax are augmented in every direction, as far as the physical disposition of this cavity will permit.

Expiration succeeds to the dilatation of the thorax; that is, the return of the thorax to its ordinary position

and dimensions.

The mechanism of this motion is the reverse of what we have just described. It is produced by the elasticity of the cartilages, and by the ligaments of the ribs, which have a tendency to resume their former shape, by the relaxation of the muscles that had raised the thorax, and by the contraction of a great number of muscles, so disposed that they lower and contract the chest.

The contraction of the thorax, or expiration, presents also three degrees: 1st, ordinary expiration; 2d, great expiration; 3d, forced expiration.

ack, and to which the small number of lymphatic ack, and to which the small number of lymphatic askels which spring from the surface and from the part of the pulmonary tissue are directed.

With regard to the lungs, we receive from the art of this cavity, produces the diminution of the vertical

diameter; vehement expiration is produced by the relaxation of the inspiring muscles, and a slight contraction of those of expiration, which permits the ribs to assume their ordinary relations with the vertebral column. But the contraction of the chest may go still farther. If the abdominal and other expiratory muscles contract forcibly, a greater depression of the dia-phragm takes place, the ribs descend lower, the base of the conoid shrinks, and there is, consequently, a greater diminution of the capacity of the thorax. This is called forced expiration.

We shall now consider the air as an elastic fluid, which possesses the property of exerting pressure upon the bodies it surrounds, and upon the sides of the vessels that contain it. This property supposes, in the particles of air, a continual tendency to repulse each

Another property of the air is compressibility; that is,

its volume changes with the pressure which it supports.

The air expands by heat like all other bodies; its volume augments 1-480, by an increase of one degree of Fahrenheit's thermometer.

The air has weight: this is ascertained by weighing a vessel full of air, and then weighing the same vessel after the air has been taken out by the air-pump.

The air is more or less charged with humidity Air, notwithstanding its thinness and transparency, refracts, intercepts, and reflects the light.

The air is composed of two gases that are very dif-

ferent in their properties.

1st, Oxygen: this gas is a little heavier than air, in the proportion of 11 to 10, and it combines with all the simple bodies; it is an element of water, of vegetable and animal matters, and of almost all known bodies; it is essential for combustion and respiration. 2dly, Azote: this gas is a little lighter than air; it is an element of ammonia and of animal substances; it extinguishes bodies in combustion.

It has been thus found that 100 parts in weight of air contain 21 parts of oxygen and 79 of azote. These proportions are the same in every place and at all heights, and have not sensibly changed for these fifteen years, since they were positively established by che-

Besides oxygen and azote, the air contains a variable quantity of the vapour of water, as we have already observed, and a small quantity of carbonic acid, the proportion of which has not yet been positively

The air is decomposed by almost all combustible bodies, at a temperature which is peculiar to each. In this decomposition they combine with the oxygen, and

set the azote at liberty.

Of inspiration and expiration.-If we call to mind the disposition of the pulmonary lobules, the extensi-bility of their tissue, their communication with the external air by means of the bronchia, of the trachea, and of the larynx, we will easily conceive that every time the breast dilates, the air immediately enters the pulmonary tissue, in a quantity proportionate to the degree of dilatation. When the breast contracts, a part of the air that it contains is expelled, and passes

out by the glottis.

In order to arrive at the glottis in inspiration, or to go outwards in expiration, the air sometimes traverses the nasal canal and sometimes the mouth: the position of the velum of the palate, in these two cases, de-serves to be described. When the air traverses the nasal canals and the pharynx to enter or to pass out of the larynx, the velum of the palate is vertical, and placed with its anterior surface against the posterior part of the base of the tongue, so that the mouth has no communication with the larynx. When the air travelum of the palate is horizontal, its posterior edge is embraced by the concave surface of the pharynx, and all communication is cut off between the inferior parts of the pharynx and the superior part of this canal, as well as with the nasal canals. Thence the necessity of making the sick breathe by the mouth, if it is necessary to examine the tonsils or the pharynx.

These two ways for the air to arrive at the glottis

were necessary, for they assist each other: thus when the mouth is full of food, the respiration takes place by the nose; it takes place by the mouth when the nasal canals are obstructed by mucus, by a slight swelling of the membrane, or any other cause. The

glottle opens in the instant of inspiration, and, on the contrary, it shuts in the expiration.

It appears that in a given time the number of inspirations made by one person are very different from those of another. Haller thinks there are twenty in the space of a minute. A man upon whom Menzies made experiments respired only fourteen times in a minute. Sir H. Davy informs us that he respires in the same period twenty-six or twenty-seven times, Dr. Thomson says that he respires generally nineteen times; and Dr. Magendie only respires fifteen times. Taking twenty times in a minute for the mean, this will give 28,800 in the street of the mean, this will give 28,800 in the street of the mean, this will give 28,800 in the street of the street o inspirations in twenty-four hours. But this number probably varies according to many circumstances, such as the state of sleep, motion, distention of the sto-mach by food, the capacity of the chest, moral affec-tions, &c. What quantity of air enters the chest at each inspiration? What quantity goes out at each expiration? How much generally remains?
According to Menzies, the mean quantity of air that

enters the lungs at each inspiration, is 40 cubic inches. Goodwin thinks that the quantity remaining after a complete expiration is 109 cubic inches; Menzies affirms that this quantity is greater, and that it amounts

to 179 cubic inches.

According to Davy, after a forced expiration, his lungs contained 41 cubic inches.

After a natural expiration By a forced expiration, after a forced in-

or go out at each inspiration, or expiration, 40 inches. Thus, supposing 20 inspirations in a minute, the quantity of air that would enter and pass out in this time would be 800 inches; which makes 48,000 in the hour, and in 24 hours 1,152,000 cubic inches. A great number of experiments have been made by chemists to determine if the volume of air diminishes while it remains in the lungs. In considering the latest experiments, it appears, that in most cases there is no diminution; that is, a volume of expired air is exactly the same as one of inspired air. When this diminu-tion takes place it appears to be only accidental.

By successively traversing the mouth or the nass cavities, the pharynx, the larynx, the trachia, and the bronchia, the inspired air becomes of a similar temperature with the body. It most generally becomes heated, and consequently rarified, so that the same quantity in weight of air occupies a much greater space in the lungs than it occupied before it entered them. Besides this change of volume, the inspired air is charged with the vapour that it carries away from the nucous membranes of the air-passages, and in this state always, hot and humid, it arrives in the pulmonary lobules; also this portion of air of which we treat mixes with that which the lungs contained

before.

But expiration soon succeeds to inspiration: interval, only of a few seconds, passes in general be-tween them; the air contained by the lungs, pressed by the powers of expiration, escapes by the expiratory canal in a contrary direction to that of the inspired air.

We must here remark that the portion of air expired is not exactly that which was inspired immediately before, but a portion of the mass which the lungs contained after inspiration; and if the volume of air that the lungs usually contain is compared with that which is inspired and expired at each motion of respiration, we will be inclined to believe that inspiration and expiration are intended to renew in part the considerable mass of air contained by the lungs.

This renewal will be so much more considerable as the quantity of air expired is greater, and as the fol-

lowing inspiration is more complete.

Physical and chemical changes that the air under-goes in the lungs.—The air, in its passage from the lungs has a temperature nearly the same as that of the body; there escapes with it from the breast a great quantity of vapour called pulmonary transpiration; besides, its chemical composition is different from that of the inspired air. The proportion of azote is much

air gives 0.18 or 0.19 of oxygen, and 0.3 to 0.4 of carbonic acid: generally, the quantity of carbonic acid exactly represents the quantity of oxygen which has disappeared; nevertheless, the last experiments of Gay Lussac and Davy give a small excess of acid; that is, there is a little more acid formed than the oxygen absorbed.

In order to determine the quantity of oxygen consumed by an adult in 24 hours, we have only to know the quantity of air respired in this time. According to Lavoisier, and Sir H. Davy, 32 cubic inches are con-sumed in a minute, which gives for 24 hours 46,037 cubic inches.

It is not difficult to appreciate the quantity of car-bonic acid that passes out of the lungs in the same time, since it nearly represents the volume of oxygen that disappears. Thomson values it at 40,000 cubic inches, though he says it is probably a little less; now this quantity of carbonic acid represents nearly 12 ounces avoirdupois of carbon.

Some chemists say that a small quantity of azote disappears during respiration; others think, on the contrary, that its quantity is sensibly augmented; but

there is nothing positive in this respect.

We are informed of the degree of alteration that the air undergoes in our lungs by a feeling which inclines us to renew it: though this is scarcely sensible in ordinary respiration, because we always continue it, it nevertheless becomes very painful if we do not satisfy it quickly; carried to this degree, it is accompanied with anxiety and fear, an instinctive warning of the importance of respiration. While the air contained in the lungs is thus modified

in its physical and chemical properties, the venous blood traverses the ramifications of the pulmonary artery, of which the tissue of the lobules of is partly formed: it passes into the radicles of the pulmonary veins, and very soon into these veins them-selves; but in passing from the one to the other, it changes its nature from venous to arterial blood.

Rest-harrow. See Ononis spinosa. Re'sta Bovis. The Plant named in English restharrow: so called because it hinders the plough; and

hence resta bovis. See Ononis spinosa.

RESUPINATUS. Resupinato. Reversed: applied to leaves, &c. when the upper surface is turned down-

wards; as in the leaf of the Pharus latifolius.

RESUSCITATION. (Resuscitatio; from resuscito, to rouse and awake.) Revivification. The restoring of persons, apparently dead, to life. Under this head, strictly speaking, is considered the restoring of those who faint, or have breathed noxious air; yet it is chiefly confined to the restoring of those who are apparently dead from being immersed in a fluid, or by hanging. Dr. Curry has written a very valuable treatise on this subject; from which the following account is

" From considering," he observes, "that a drowned person is surrounded by water instead of air, and that in this situation he makes strong and repeated efforts to breathe, we should expect that the water would enter and completely fill the lungs. This opinion, indeed, was once very general, and it still continues to prevail among the common people. Experience, how-ever, has shown, that unless the body lies so long in the water as to have its living principle entirely destroyed, the quantity of fluid present in the lungs is inconsiderable; and it would seem that some of this is the natural moisture of the part accumulated; for, upon drowning kittens, puppies, &c. in ink, or other coloured ti-quors, and afterward examining the lungs, it is found that very little of the coloured liquor has gained admit-tance to them. To explain the reason why the lungs of drowned animals are so free from water, it is necessary to observe, that the muscles which form the opening into the wind-pipe are exquisitely sensible, and contract violently upon the least irritation, as we frequent ly experience when any part of the food or drink happens to touch that part. In the efforts made by a drowning person, or animal, to draw in air, the water rushes into the mouth and throat, and is applied to these parts, which immediately contract in such a man-

the same, but that of oxygen and carbonic acid is quite different.

In place of 0.21 of oxygen, and a trace of carbonic acid, which the atmospheric air presents, the expired pletely fills it. On dissecting the body of a recently drowned animal, no particular fulness of the vessels within the skull, nor any disease of the brain or its membranes, are visible. The lungs are also sound, and the branches of the wind-pipe generally contain more or less of a frothy matter, consisting chiefly of air, mixed with a small quantity of colourless fluid. The right cavity of the heart, and the trunks of the large internal veins which open into it, and also the trunk and larger branches of the artery which carries the blood from this cavity through the lungs, are all distended with dark-coloured blood, approaching almost to blackness. The left cavity of the neart, on the contrary, is nearly, or entirely empty, as are likewise the large veins of the lungs which supply it with blood, and the trunk and principal branches of the great artery which conveys the blood from hence to the various parts of the body. The external blood-vessels are parts of the body. The external blood-vessels are empty; and the fleshy parts are as pale as if the animal had been bled to death. When a body has lain in the water for some time, other appearances will also be observable; such as, the skin livid, the eyes bloodshot, and the countenance bloated and swoln; but these appearances, though certainly unfavourable, do not absolutely prove that life is irrecoverably gone. is now known, that in the case of drowning, no injury is done to any of the parts essential to life; but that the right cavity of the heart, together with the veins and arteries leading to and from that cavity, are turgid with blood, while every other part is almost drained of this fluid. The practice of holding up the bodies of this fluid. drowned persons by the heels, or rolling them over a cask, is unnecessary; the lungs not being filled with any thing that can be evacuated in this way. Thereany uning that can be evacuated in this way. Therefore such a practice is highly dangerous, as the violence attending it may readily burst some of those vessels which are already overcharged with blood, and thus convert what was only suspended animation, into absolute and permanent death. The operation of inflating the lungs is a perfectly safe, and much more effectual method of removing any feetly matter than method of removing any frothy matter they may contain; and while it promotes the passage of the blood through them, also renders it capable of stimulating the left cavity of the heart, and exciting it to contraction. As soon as the body is taken out of the water, it should be stripped of any clothes it may have on, and be immediately well dried. It should then be wrapped in dry, warm blankets, or in the spare clothes taken from some of the by-standers, and be removed as quickly as possible to the nearest house that can be got convenient for the purpose. The fittest will be one that has a tolerably large apartment, in which a fire is ready or can be made. The body may be carried in men's arms, or laid upon a door; or, in case the house be at a distance from the place, if a cart can be procured, let the body be placed in it, on one side, upon some straw, with the head and upper part somewhat raised; and in this position a brisk motion will do no harm. Whatever be the mode of conveyance adopt ed, particular care should be taken that the head be through them, also renders it capable of stimulating ed, particular care should be taken that the head be neither suffered to hang backwards, nor to bend down with the chin upon the breast. When arrived at the house, lay the body on a matrass, or a double blanket, spread upon a low table, or upon a door supported by stools; the head and chest being elevated by pillows. As the air of a room is very soon rendered impure by a number of people breathing in it, for this reason, as well as to avoid the confusion and embarrassment attending a crowd, no more persons should be admitted into the apartment where the body is placed, than are necessary to assist immediately in the recovery: in general six will be found sufficient for this purpose, and these should be the most active and intelligent of the by-standers. It will be found most convenient to divide the assistants into two sets; one set being employed in restoring the heat of the body, while the other institutes an artificial breathing in the best manner they are able. Every skilful person should be pro vided with a flexible tube made of elastic gum, half a yard in length, to introduce into the wind-pipe, and also with a similar tube to which a syringe can be affixed, to be put into the œsophagus. Should these ner as to shut up the passage into the lungs. This con- not be at hand, air should be thrown into the lungs in

RES

the best manner that can be suggested at the time. Should it still be found that the air does not pass readily into the lungs, immediate recourse must be had to another and more effectual method for obtaining that object. As this method, however, requires address, and also some knowledge of the parts about the throat, we would recommend that when there is not a medical gentleman present, the mode already described, be tried repeatedly before this be attempted. As a quantity of frothy matter occupying the branches of the wind-pipe, and preventing the entrance of the air into the lungs, is generally the circumstance which renders this mode of inflation necessary, the mouth should be opened from time to time to remove this matter as it is discharged. While one set of the assistants are engaged in performing artificial respiration, the other should be employed in communicating heat to the body. The warm bath has been usually recommended for this purpose; but wrapping the body in blankets, or woolien cloths, strongly wrung out of warm water and renewing them as they grow cold, besides being a speedier and more practicable method of imparting heat, has this great advantage, that it admits of the operation of inflating the lungs being carried on without interruption. Until a sufficient quantity of warm water can be got ready, other methods of restoring warmth may be employed; such as the application of dry warm blankets round the body and limbs; bags of warm grains or sand, bladders or bottles of hot water, or hot bricks applied to the hands, feet, and under the arm-pits, the bottles and bricks being covered with flannel: or the body may be placed before the fire, or in the sunshine, if strong at the time, and be gently rubbed by the assistants with their warm hands, or with cloths heated at the fire by a warming-pan. The restoration of heat should always be gradual, and the warmth applied ought never to be greater than can be comfortably borne by the assistants. If the weather happen to be cold, and especially if the body has been exposed to it for some time, heat should be applied in a very low degree at first: and if the weather be under the freezing point, and the body, when stripped, feel cold and nearly in the same condition with one that is frozen, it will be necessary at first to rub it well with snow, or wash it with cold water; the sudden application of heat in such cases having been found very pernicious. In a short time, however, warmth must be gradually applied. To assist in rousing the activity of the vital principle, it has been customary to apply various stimulating matters to different parts of the body But as some of these applications are in themselves hurtful, and the others serviceable only according to the time and manner of their employment, it will be proper to consider them particularly. The application of all such matters in cases of apparent death, is founded upon the supposition that the skin still retains sensibi-lity enough to be affected by them. It is well known however, that even during life, the skin loses sensibi lity in proportion as it is deprived of heat, and does not recover it again until the natural degree of warmth be restored. Previous to the restoration of heat, there fore, to a drowned body, all stimulating applications are useless, and so far as they interfere with the other measures, are also prejudicial. The practice of rubbing the body with salt or spirits is now justly condemned The salt quickly frets the skin, and has, in some cases produced sores, which were very painful and difficult to heal after recovery. Spirits of all kinds evaporate fast, and thereby, instead of creating warmth, as they are expected to do, carry off a great deal of heat from the body. Spirit of hartshorn, or of sal volatile, are liable to the same objection as brandy or other distilled spirits, and are besides very distressing to the eyes of the assistants. When there is reason to think the skin has in any degree recovered its sensibility, let an assistant moisten his hand with spirit of hartshorn, or eau de luce, and ho'd it closely applied to one part : in this way evaporation is prevented, and the full stimulant effect of the application obtained. A liniment composed of equal parts of spirit of hartshorn and sallad oil, well shaken together, would appear to be sufficiently stimulating for the purpose, and as it evaporates very slowly, will admit of being rubbed on without producing cold. The places to which such remedies are usually applied, are, the wrists, ankles, temples, and the parts opposite the stomach and heart. The intestines, from their internal situation and peculiar constitution,

retain their irritability longer than the other parts of the body, and, accordingly, various means have been proposed for increasing the action of their fibres in order to restore the activity of the whole system. Tobacco-smoke, injected by way of clyster, is what has been generally employed with this view, and the fumigator, or instrument for administering it, makes a part of the apparatus which is at present distributed by the different societies established for the recovery of drowned persons. Of late, however, the use of tobacco-smoke has been objected to, and upon very strong grounds; for when we consider that the same remedy is successfully employed with the very opposite intertion, namely, that of lessening the power of contraction in the muscles, and occasioning the greatest relaxation consistent with life, it must be acknowledged to be a very doubtful, if not dangerous remedy, where the powers of life are already nearly exhausted. Instead of tobacco-smoke, then, we would recommend a clyster, consisting of a pint or more of water, moderately warmed, with the addition of one or two table-spoonfuls of spirit of hartshorn, a heaped tea-spoonful of strong mustard, or a table spoonful of essence of pep-permint; in defect of one or other of these, half a gill or more of rum, brandy, or gin may be added, or the warm water given alone. This step, however, need not be taken, until artificial respiration has been begun; for it will answer but little purpose to stimulate the heart through the medium of the intestines, unless we at the same time supply the left cavity with blood fitted to act upon it; which we cannot do without first removing the collapsed state of the lungs, and promoting the passage of the blood through them by a regular inflation. As the stomach is a highly sensible part, and intimately connected with the heart and brain, the introduction of some moderately warm and stimulating liquor into it, seems well calculated to rouse the dormant powers of life. This is very conveniently done by means of the syringe and flexible tube. The quanti-ty of fluid thrown in ought not to exceed half a pint, and may be either warm negus, or water with the addition of one or other of the stimulating matters recommended above, using, however, only half the quantities mentioned there. As soon as the pulse or beating of the heart can be felt, the inside of the nostrils may be occasionally touched with a feather dipped in spirit of hartshorn, or sharp mustard; it-being found by experience, that any irritation given to the nose, has considerable influence in exciting the action of the muscles concerned in respiration. When the natural breathing commences, the flexible tube and canula should be withdrawn, and any farther inflation that may be necessary, performed by blowing into the nostril. Letting blood has been generally thought requisite in every case of suspended animation. The practice, however, does not appear to have been founded upon any rational principle at first, and it has been continued from the force of custom, rather than from any experience of its good effects. In the case of drowned persons there is not, as in those who suffer from hanging or apoplexy, any unusual fulness of the vessels of the brain; and the quantity of blood that can be drawn from the external veins, will not sensibly diminish the accumulation of it in those near the heart. blood-letting, which always tends to lessen the action of the heart and arteries in the living body, cannot be supposed to have a directly opposite effect in cases of apparent death; on the contrary, if employed here, it will hazard the entire destruction of those feeble powers which yet remain, and to increase and support which all our endeavours should be directed. When the several measures recommended above have been steadily pursued for an hour or more, without any appearance of returning life, electricity should be tried; experience having shown it to be one of the most powerful stimuli yet known, and capable of exciting contraction in the heart and other muscles of the body, after every other stimulus had ceased to produce the least effect. Moderate shocks are found to answer best, and these should, at intervals, be passed through the chest In different directions, in order, if possible, to rouse the heart to act. Shocks may likewise be sent through the limbs, and along the spine; but we are doubtful how far it is safe or useful to pass them through the brain, as some have recommended. The body may be conveniently insulated, by placing it on a door, supported by a number of quart-bottles, whose sides are previously wiped

RET

with a towel, to remove any moisture they may have contracted. By experiments made on different animals, it is found that the blood passes through the lungs most readily when they are fully distended with air; consequently, that if the lungs of a drowned person are in-flated, and kept in the expanded state while the elec-tric shock is passed through the chest, the blood accu-mulated in the right cavity of the heart and its vessels will move forward without any resistance, should the heart be leaven to contract meet it. As seen as the heart be brought to contract upon it. As soon as the shock is given, let the lungs be emptied of the air they contain, and filled again with fresh air; then pass another shock, and repeat this until the heart is brought into action, or until it appear that all farther attempts are useless. In order more certainly to pass the shock through the heart, place the knob of one discharging rod above the collar-bone of the right side, and the knob of the other above the short ribs of the left: the position of the discharging rods, however, may be changed occasionally, so as to vary the direction of the Two thick brass wires, each about eighteen inches long, passed through two glass tubes, or wooden cases, well varnished, and having at one end a knob, and at the other a ring to fasten the brass chain to, form very convenient discharging rods; and by means of them, the shock may be administered without the risk them, the shock may be administered without the risk of its being communicated to the assistants, or carried off by the skin being wet. When the patient is so far recovered as to be able to swallow, he should be put into a warm bed, with his head and shoulders somewhat raised by means of pillows. Plenty of warm wine-whey, ale-posset, and other light and moderately nourishing drink, should now be given, and gentle sweating promoted, by wrapping the feet and legs in flannels well wrung out of hot water. If the stomach and bowels feel distended and uneasy, a clyster, consisting of a pint of warm water, with a table-spoonful of common salt, or an ounce or more of Glauher's or Epsom salt, dissolved in it, may be administered. The general practice in this case, is to give an emetic; but general practice in this case, is to give an emetic; but considering that the powers of the machine are still very weak, the agitation of vomiting is certainly hazardous. The patient should on no account be left alone, until the senses are perfectly restored, and he be able to assist himself; several persons having relapsed and been lost from want of proper attention to them, after the vital functions were, to all appearance, completely established. Either from the distention which the arteries of the lungs have suffered, or from the sudden change from great coldness to considerable warmth, it now and then happens, that the patient is attacked soon after recovery, with inflammation of some of the parts within the chest. This occurrence is pointed out by pain in the breast or side, increased on inspiration, and pain in the breast or side, increased on inspiration, and accompanied with frequent, and full or hard pulse, and sometimes with cough. Here the taking away some blood from the arm, or the application of cupping-gla-ses, leeches, or a blister, over the seat of the pain, will be very proper; but the necessity for these measures, as well as the times for putting them in practice, beautiful to the independent and discretion of a most should be left to the judgment and discretion of a medical person. Dull pain in the head, lasting sometimes for two or three days, is by no means an unfrequent complaint in those who are recovered from this and from the other states of suspended animation; and here also a moderate bleeding from the neck, either with the language or with coupling players, pay or or or the language of the coupling of the language of the coupling of the language of the coupling of the language of the with the lancet or with cupping-glasses, may prove serviceable.

In hanging, the external veins of the neck are com-pressed by the cord, and the return of the blood from the head thereby impeded, from the moment that suspension takes place; but as the heart continues to act for a few seconds after the wind-pipe is closed, the blood which is sent to the head during this interval, is necessarily accumulated there. Hence it is, that in hanged persons the face is greatly swoln, and of a dark red or purple colour: the eyes are commonly suffused with blood, enlarged, and prominent. On dissection, the blood-vessels of the brain are found considerably distended; but, in general, no further marks of disease appear within the skull. The lungs are found generally quite collapsed, and free from frothy matter. The heart, and the large blood-vessels adjoining to it exhibit the same appearances as in the bodies of drowned general. drowned persons. From the great accumulation of blood in the vessels of the head, many have been of opinion, that hanging kills chiefly by inducing apo-

plexy; but the following experiment made at Edin-burgh soveral years ago, by an eminent medical pro-fessor there, clearly proves that in hanging as well as in drowning, the exclusion of air from the lungs is the immediate cause of death. A dog was suspended by the neck with a cord, an opening having been previously made in the wind-pipe, below the place where the cord was applied so as to admit air into the lungs. In this state he was allowed to hang for three-quarters of an hour, during which time the circulation and breathing went on. He was then cut down without appearing to have suffered much from the experiment. The ing to have suffered much from the experiment. cord was now shifted below the opening into the windcord was now shifted below the opening into the wind-pipe, so as to prevent the ingress of air to the lungs; and the animal being again suspended, he was com-pletely dead in a few minutes. Upon the whole, then, it appears, that the same measures recommended for drowned persons, are also necessary here; with this addition, that opening the jugular veins, or applying cupping-glasses to the neck, will tend considerably to facilitate the restoration of life, by lessening the quantity of blood contained in the vessels of the head, and thereby taking off the pressure from the brain. Except in persons who are very full of blood, the quantity taken away need seldom exceed an ordinary tea-cupful, which will in general be sufficient to unload the vessels of the head without weakening the powers of life."

RE'TE. A net. Applied to cellular membranes; vessels, nerves, parts of plants, &c. which are formed

of meshes, like a net.

The fine net-work of the extre-RETE MALPIGHII. The fine n mities of the pulmonary arteries.

RETE MIRABILE. A network of blood-vessels in the basis of the brain of quadrupeds.

RETE MUCOSUM. Corpus reticulare; Corpus muco sum; Mucus malpigii. A mucous substance, deposited in a net-like form, between the epidermis and cutis, which covers the sensible cutaneous papillar, cutis, which covers the sensible cutaneous papilla, connects the epidermis with the cutis, and gives the colour to the body: in Europeans it is of a white colour, in Ethiopiaus black. See Skin.

RETICULAR. (Reticularis; from rete, a net.) Interwoven like a net.

RETIFORM. (Retiformis; from rete, a net, and forma, resemblance.) Net-like.

RETINA. (From rete, a net.) Amphiblestroides. The third, or innermost membrane of the eye, expanded round the choroid coat, to the ciliary ligament. It is the true organ of vision, and is formed by an ex-

panded round the choroid coat, to the chiary heament. It is the true organ of vision, and is formed by an expansion of the pulp of the optic nerve. See Vision.

RETINA'CULUM. (From retineo, to prop or restrain.) An instrument for keeping the bowels in their

RETIN-ASPHALTUM. See Retinite.
RETINITE. Retin-asphalt of Hatchet. A yellowish and reddish-brown coloured mineral, composed of

ish and reddish-brown coloured mineral, composed of resin, asphalt, and earth; found at Bovey Tracy, in Devonshire, adhering to coal.

RETORT. (Retorta; from retorqueo, to bend back again: probably so called, because its neck was curved and bent back again.) A chemical vessel employed for many distillations, and most frequently for those which require a degree of heat superior to that of boiling water. They differ in form and materials: when pierced with a They differ in form and materials: when pierced with a little hole in their roof, they are called tubulated re-torts. They are made of common glass, stone-ware, and iron.

RETRACTOR. A muscle, the office of which is to retract the part into which it is inserted.

RETRACTOR ANGULI ORIS. See Buccinator.

RETRAHENS. Drawing back.

RETRAHENS. Drawing back.

RETRAHENS AURIS. Posterior auris, of Winslow.

Retrahens auriculæ, of Albinus. Deprimens auriculæ, of Douglas. Retrahens auriculam, of Cowper; and Mastoide-conchinien, of Dumas. Two small bundles of muscular fibres which arise from the external and posterios part of the program. of muscular nores which arise from the external and posterior part of the mastoid process of the temporal bone immediately above the insertion of the sternocleido-mastoideus muscle. They are inserted into that part of the back of the ear which is opposite to that part of the back of the concharant. the septum which divides the concha and scapha. Their use is to draw the ear backwards, and stretch the concha

RETROCEDENT. Retrocedens. Retrogradus When a disease that moves about from one part to another, and is sometimes fixed, has been some time in

its more common situation, and retires from it, it is said to be retrocedent.

RETROGRADE. See Retrocedent.

Retrocedent gout. See Arthritis. RETROVERSION. Retroversio. See Uterus, re-

RETUSUS. Retuse. Applied to a leaf, which ends in a broad shallow notch, as in the Rumez diggnus.

REUSSITE. A vegetable compound saline, found

as an efflorescence on the surface, in the country round Seidlitz and Seidschutz.

REVERBERATORY. See Furnace.

REVOLUTUS. Revolute, rolled back. Applied to a leaf, the margin of which is turned or rolled back-

wards, as in Andromeda polifolia.

REVULSION. (Revulsio; from revello, to draw away.) An old term used by the humoral pathologists, signifying the drawing of humours a contrary

RHABA RBARUM. (From Rha, and barbarus, wild: so called because it was brought from the banks of the Rha, now called the Wolga, in Russia.) See Rheum.

RHABARBARUM ALBUM. See Convolvulus mechoa-

RHABARBARUM ANTIQUORUM. See Rhoum rhaponticum.

RHARLBARUM VERUM. See Rhoum.

RHACHIA'LGIA. (From $\rho \alpha \chi_{iS}$, the spine of the back, and $\alpha \lambda \gamma_{iS}$, pain.) A pain in the spine of the back.

RHA'CHIS. ($P \alpha \chi_{iS}$, the spine of the back.) 1. In anatomy, the spine.

2. In botany, the common stalk or receptacle of the florets in the spikelets of grasses, or of the spikelets themselves; as in *Lotium*, *Triticum*, *Hordeum*, &c. It also means the rib or leaf-stalk of ferns, which is

often winged or bordered.

RHACHISA'GRA. (From paxis, the spine of the back, and aypa, a prey.) A sudden pain in the spine, applied to gout fixed in the spine of the back.

RHACHITA. (From ραχις, the spine of the back.) A muscle belonging to the spine of the back.

RHACHITIS. See Rachitis.

RHACO'SIS. (From pakos, a rag.) A ragged ex-

RHA'GAS. (Rhagas, adis. f.; from payreus, to break or bruise.) Fissura. A chap or cleft. A malig-

RHAGOIDES. (From pat, a grape-stone, and ctoos, a likeness: so called from its likeness in colour to a grape-seed.) Applied to the retiform but a second colour to a

grape-seed.) Applied to the retiform tunic of the eye.
RHA'MNUS. (From ρατω, to destroy; because of its many thorns.) 1. The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Monogynia. Buckthorn.

2. The pharmacopæial name of the purging buck-

thorn. See Rhamnus catharticus.

RHAMNUS CATHARTICUS. The systematic name of the buckthorn. Spina cervina; Rhamnus solutious; Spina infectoria; Cervispina. Purging buckthorn. The fruit or berries of this shrub, Rhamnus—spinis terminalibus Moribus quadrifidis dioicis, foliis ovatis, caule erecto, of Linnæus, have been long received into the materia medica: they contain a pulpy, deep green juice, of a faint unpleasant smell, a bitterish, acrid, nauseous taste, which operates briskly by stool, producing thirst, dryness of the mouth and fauces, and severe gripings, unless some diluting liquor be drank plentifully after it: at present it is rarely prescribed except as a drastic purge. The dose is said to be about twenty of the fresh berries in substance; twice or thrice that number in decoction; a drachm or a drachm and a half of the dried berries; an ounce of the expressed juice, or half an ounce of the rob or extract, obtained by inspissating the juice.

RHAMNUS FRANGULA. The systematic name of the black alder. Frangula alnus; Alnus nigra; Rhamnus—inermis floribus monogynis hermophroditis, foliis

integerrimis, of Linnaus.

RHE

All the parts of this tree, as well as of the common aider, are astringent and bitter. The bark is most antringent; a decoction of it has cured agues, and is often used to repel inflammatory tumours of the throat, by way of gargle. The inner yellow bark of the trunk, or root, given to 3 ij, vomits, purges, and gripes; but joined with aromatics, it operates more agreeably. An infusion, or decoction in water, inspissated to an extract, acts yet more mildly than these. It is mostly tract, acts yet more mildly than these. It is mostly employed by the common people in dropsy and other disorders. The berries of alder are purgative. They are not in use under their own name, but are often substituted for buckthorn berries; to discover which, it should be observed, that the berries of the black alder have a black skin, a blue juice, and two seeds in each of them; whereas the buckthorn berries have a green juice, and commonly four seeds. The substitution of one for the other is not of material consequence, as the plants belong to the same genus, and the berries do not differ greatly.

Dr. Murray, of Gottingen, recommends, from his own experience, the leaves of alder chopped in small pieces, and heated over the fire, as the best remedy with which he is acquainted for dispersing milk in the

RHAMNUS ZIZYPHUS. The systematic name of the tree which affords the jujubs. A half-dried fruit of the plum kind, about the size and shape of an olive. Jujubes, when in perfection, have an agreeable, sweet taste, and in the southern parts of Europe, where they are common, they make an article of food in their recent state, and of medicine when half dried.

RHAPHANUS. See Raphanus.

RHAPO'NTICUM. (The Rha of Pontus, i.e. the

Rha, in Russia, a river on the banks of which it grew.) See Rheum rhaponticum.

Rhapontic rhubarb. See Rheum rhaponticum. RHAPONTICUM VULGARE OFFICINARUM. See Contaurea.

RHATA'NIA. See Krameria.
RHAZES, was born at Rhei, in the province of Khorasan, about the year 852. He is said not to have commenced the study of medicine till more than thirty years old, having previously removed to Bagdad: but by indefatigable application he obtained the highest reputation; and was selected to superintend the cele-brated hospital of that city. He has been considered as the Galen of the Arabians; and from his assiduous at-tention during the rest of a long life, to the varieties of disease, he obtained the appellation of the experienced. He travelled much in pursuit of knowledge, partien He travelled much in pursuit of knowledge, particu-larly into his native country; and was much consulted by Almanzor, the chief of that province, to whom several of his writings are dedicated, as well as by other princes. Abi Osbaia enumerated 226 treatises com-posed by Rhazes, but only a few of these are preserved through the medium of Latin translations. The ten books dedicated to Almanzor, were designed by him as a complete body of physic, and indeed may be regarded as the great magazine of all the Arabian medicine; the ninth book in particular, treating of the cure of diseases, was in such general estimation for several centuries, as to be used as a text-book by professors. However, they contain little more than the substances. However, they contain little more than the substance of the writings of the Greek physicians; though cer-tainly the small-pox, and a few other diseases, are first tainly the small-pox, and a few omer use author also distinctly described by Rhazes. He was author also the diseases of children. The use of chemical preparations in medicine appears likewise to have originated with him, or at least with some of the Arabians. He died in the year 932. Besides the ten books above mentioned, and the tract on smallpox, there are extant by him a sort of commonplace book, entitled "Continens;" and six books of Apho-risms, under the title of "De Secretis."

RHE'UM. (From Rha, a river in Russia, now called the Wolga, from the banks of which it was first brought.) 1. The name of a genus of plants in the Linnagan system. Class, Enneandria; Order, Tri-Class, Enneandria; Order, Trigynia. Rhubarb.

2. The pharmacopæial name of the officinal rhu-

barb. See Rheum palmatum.

RHEUM PALMATUM. The systematic name of the officinal rhubarb. Rhabarbarum; Rheon; Rhaum; Barbaria; Lapathum orientale; Lapathum chinense; Rhabarbarum verum; Rhabarbarum tartaricum. Rhubarbar barb. It was not until the year 1732 that naturalits

RHE RHE

edition of the Species Plantarum, under the name of Rheum rhabarbarum. This, however, was not generally received as the genuine rhubarbplant; and with a view to ascertain this matter more completely Kaw Boerbaave procured from a Tartarian rhubarb merchant the seeds of those plants whose roots he annually sold, and which were admitted at Petersburgh to be the true rhubarb. These seeds were soon propagated, and were discovered by De Gorter to produce two distinct species, viz. the Rheum rhabarbarum of Linnæus, or as it has since been called, the Rheum undulatum, and another species, a specimen of which was presented to Linnaus, who declared it to be a new one; and it was first mentioned in the second edition of the Species Plantarum, in 1762, by the name of Rheum paimatum. Previous to this time, De Gorter had repeatedly sent its seeds to Linnaus, but the young plants which they produced constantly perished; at length he obtained the fresh root, which succeeded very well at Upsal, and afterward enabled the younger Linnaus to describe this plant, ann. 1767. But two years antecedent to this, Dr. Hope's account of the Rheum palmatum, as it grew in the Botanic Garden near Edinburgh, had been read before the Royal Society at London; and of the great estimation in which this plant was held by him, we have the following proof:—"From the perfect simi-larity of this root with the best foreign rhubarb, in taste, smell, colour, and purgative qualities, we cannot doubt of our being at last possessed of the plant which produces the true rhubarb, and may reasonably entertain the agreeable expectation of its proving a very im-portant acquisition to Britain."

But from the relation we have given, it appears that both the seeds of the R. palmatum, and the R. undula-tum, were transmitted to Petersburgh, as those of the true rhubarb; we are therefore to conclude, that the former species has an equal claim to this importance with the latter; and from further inquiries made in Russia, there is the best authority for believing that the R. compactum also affords this very useful drug. The seeds of the R. palmatum were first introduced into Britain in 1762, by Dr. Hounsy (who sent them from Russia), and were supposed to be a part of that already mentioned; and since their prosperous cultivation by the late professor of botany at Edinburgh, the propagation of this plant has been gradually extended to most of our English gardens, and with a degree of success which promises, in time, to supersede the importa-tion of the foreign root. Two sorts of rhubarb roots are usually imported into this country for medical use; viz. the Chinese and the Tartary rhubarb; the first is in oblong pieces, flattish on one side, and convex on the other; compact, hard, heavy, internally of a dull-red colour, variegated with yellow and white, and when recently powdered, appears yellow, but on being kept becomes gradually redder. The second is the most valuable, and is brought to us in roundish pieces, with a large hole through the middle of each; it is more soft and friable than the former sort, and exhibits, when broken, many streaks of a bright red colour. marks of the goodness of rhubarb are, the liveliness of its colour when cut; its being firm and solid, but not flinty or hard; its being easily pulverable, and appear-ing when powdered of a fine bright yellow colour; its imparting to the spittle when chewed a deep saffron tinge, and not proving slimy or mucilaginous in the mouth; its taste is subacrid, bitterish, and somewhat styptic; the smell lightly aromatic."

The purgative qualities of rhubarb are extracted more perfectly by water than by rectified spirit: the part remaining after the action of water is almost, if not wholly, inactive; whereas after repeated digestion in spirit, it proves still very considerably purgative. The virtue of a watery infusion, on being inspissated by a gentle heat, is so much diminished, that a drachm by a gentle heat, is so much diminished, that a drachm of the extract is said to have scarcely any greater effect than a scruple of the root in substance. The spirituous tincture loses less; half a drachm of this extract proving moderately purgative. The qualities of this root, says Dr. Cullen, are that of a gentle purgative, and so gentle that it is often inconvenient on account of the bulk of the description. the dose required, which in adults, must be from 3 ss.

became acquainted with any plant which seemed to afford the rhabarbarum officinale; when some plants received from Russia by Jussieu at Paris, and Rhaud at Chelsea, were said to supply this important desideratum, and as such were adopted by Linnaeus, in his first afficient of the Species Plantague and the species of the more drastic purgatives. The purgative quality is accompanied with a bitterness, which is often useful as the species of the species o in restoring the tone of the stomach when it has been lost; and, for the most part, its bitterness makes it sit better on the stomach than many other purgatives do. Its operation joins well with neutral laxatives; and both together operate in a less dose than either of them would singly. Some degree of stypticity is always evident in this medicine; and as this quality acts when that of the purgative has ceased, so in cases of diarrhœa, when any evacuation is proper, rhubarb has been considered as the most proper remedy to be employed. It must, however, be remarked here, that, in many cases of diarrhea, no further evacuation than what is occasioned by the disease, is necessary or proper. The use of rhubarb, in substance, for keeping the belly regular, for which it is frequently employed, is by no means proper, as the astringent quality is ready to undo what the purgative has done; but it is found that the purpose mentioned may be obtained by it, if the rhubarb is chewed in the mouth, and no more is swallowed than what the saliva has dissolved. And it must be remarked, that in this way employed it is very useful to dyspeptic persons. Analogous to this, is the use of rhuharb in solution, in which it appears to me, that the astringent quality is not so largely extracted as to operate so powerfully as when the rhubarb was employed in substance.

The officinal preparations of this drug are, a watery and a vinous infusion, a simple and a compound tinc-ture. It is also an ingredient in different compositions.

RHEUM RHAPONTICUM. The systematic name of the rhapontic rhubarb. Rhaponticum; Rhabarbarum dios-coridis; Rhabarbarum antiquorum. The root of coridis; Rhabarbarum antiquorum. The root of this species appears to have been the true rhubarb of the ancients. By some it is confounded with the mo-dern rhubarb, though considerably different from that root in appearance, as well as in quality. The rha-pontic is of a dusky colour on its surface, and a loose pongy texture; is more adstringent than rhubarb, and less purgative; in this last intention, two or three

drachms are required for a dose.

RHEUM UNDULATUM. The systematic name of the Siberian rhubarb. The Rheum—folics subvillosis undulatis petiolis aqualibus, of Linnaus. It possesses similar virtues to those of the palmate species, and is in common use in Russia.

RHE UMA. (From $\rho \epsilon \omega$, to flow.) The discharge from the nostrils or lungs arising from cold; hence the following lines of the school of Salernum:

following lines of the school of Sajerham.

Si fluit ad pectus, dicatur rheuma catarrhus,

Ad fauces branchus, ad nares esto coryta!

RHEUMATISMUS. (From peppariso, to be afflicted with defluxions.) Dolores rheumatici et arthritici, of Hoffman. Myositis, of Sagar. This is a genus flicted with defluxions.) Dolores rheumatici et arthritici, of Hoffman. Myositis, of Sagar. This is a genus of disease in the Class Pyrexiæ, and Order Plegmasiæ, of Cullen; characterized by pyrexia, pains in the joints, increased by the action of the muscles belonging to the joint, and heat of the part. The blood, after venesection, exhibits an inflammatory crust. Rheumatism is distinguished into acute and chronic. The acute is preceded by shivering, heat, thirst, and frequent pulse; after which the pain commences, and scon fives on the after which the pain commences, and soon fixes on the points. The chronic rheumatism is distinguished by pain in the joints, without pyrexia, and is divided into three species; lumbago, affecting the loins; sciatica, affecting the hip; and arthrodynia, or pains in the joints. The acute rheumatism mostly terminates in one of these species.

Rheumatism may arise at all times of the year, when there are frequent vicissitudes of the weather, from heat to cold, but the spring and autumn are the seasons in which it is most prevalent; and it attacks persons of all ages; but very young people are less subject to it than adults.

Obstructed perspiration, occasioned either by wearing wet clothes, lying in damp linen, or damp rooms, or by being exposed to cool air when the body has been much heated by exercise, is the cause which usually produces rheumatism. Those who are much afflicted with this complaint, are very apt to be sensible of the approach of wet weather, by finding wandering pains about them at that period.

Acute rheumatism usually comes on with lassitude

and rigours, succeeded by heat, thirst, anxiety, restlessness, and a hard pulse; soon after which, excruciating pains are felt in different parts of the body, but more particularly in the joints of the shoulder, wrist, knees, and ankles, or perhaps in the hip; and these keep shifting from one joint to another, leaving a redness and swelling in every part they have occupied, as likewise a great tenderness to the touch. Towards evening there is assuably as ovacachation or instance. ning there is usually an exacerbation, or increase of fever; and during the night, the pains become more severe, and shift from one joint to another.

Early in the course of the disease, some degree of sweating usually occurs; but it is seldom so copious as either to remove the pains or to prove critical. beginning, the urine is without sediment; but as the disease advances in its progress, and the fever admits of considerable remissions, a lateritious sediment is deposited; but this by no means proves critical.

Chronic rheumatism is attended with pains in the head, shoulders, knees, and other large joints, which, at times, are confined to one particular part, and at others shift from one joint to another, without occasioning any fever; and in this manner the complaint continues often for a considerable time, and at length

goes off.

No danger is attendant on chronic rheumatism; but a person having been once attacked with it, is ever afterward more or less liable to returns of it; and an incurable anchylosis is sometimes formed, in consequence of very frequent relapses. Neither is the acute rheumatism frequently accompanied with much danger; but, in a few instances, the patient has been de-stroyed by general inflammation, and now and then by a metastasis to some vital part, such as the head and lungs. Acute rheumatism, although accompanied with a considerable degree of inflammation in particular parts, has seldom been known to terminate in suppuration; but a serous or gelatinous effusion takes place.

Rheumatism seldom proving fatal, very few oppor-tunities have offered for dissections of the disease. In the few which have occurred, the same appearances have been observed as in inflammatory fever, effusion within the cranium, and now and then affections of

some of the viscera.

In the acute rheumatism the general antiphlogistic plan of treatment is to be pursued, so long as the feb ile and inflammatory symptoms are severe. be sometimes proper to begin by a moderate abstraction of blood, where the patient is young and plethoric; and if the disease attacks any important part, this measure must be more actively pursued; but in general it does not appear necessary. Even the local abstraction of blood is hardly advisable, unless the affection be very much fixed to one part, and the symptoms urgent: and it may be said, that most local applications are rather likely to drive the disease from one part to another, than to afford permanent relief. After freely opening the bowels, the chief object is to en-deavour to procure a general and mild diaphoresis by antimonial and mercurial preparations, assisted by opium, or other narcotic, which may also alleviate the pain, and occasionally by the warm bath, where the skin is particularly harsh and dry. Digitalis, by moderating the circulation, will sometimes be usefully conjoined with these medicines. As the fever shates, and the strength appears impaired, tonics should be given to promote the convalescence of the patient, and obviate a relapse; and where the inflammation remains fixed in a particular joint, after the pyrexia has ceased, fomentations and other local measures, according to the state of the part, may be employed for its removal. In the arthrodynia, or chronic rheumatism, as it is commonly called, the remedies of chief efficacy are stimulant diaphoretics in moderate doses regularly persevered in, assisted by various local means of promoting the circulation through the affected part. Anodynes may be also used with advantage both internally and locally: and attention should be paid to support the strength, and correct any observable deficiency in the several functions.

RHE UME. (From ρεω, to flow.) A defluxion, a

common cold or catarrh.

RHEUMIC ACID. An acid said to be peculiar to rhubarb, but not yet sufficiently examined.

RHIBE'SIA. (From ribes, a currant.) See Ribes. RHINÆUS. (Rhinœus, sc. musculus; from prothe nose.) See Compressor naris.

RHINENCHY TES. (From ρεν, the mose, and εγχυω, to pour in.) A syringe for the nose.

RHINOPHO'NIA. (From ρεν, the nose, and φωνη,

the voice.) A nasal voice.

RHIZAGRA. (From pr\(\frac{2}{3}\), the root, and approximation, to seize.) An instrument for taking out the roots or stumps of teeth.

RHODIA. See Rhodiola.

RHODIOLA. (A diminutive of Rhodia; from podov, a rose; so called because its root smells like the damask rose) The name of a genus of plants. Class,

Diacia; Order, Octandria.

Rhodiola Rosea. The radix rhodize of some pharmacoperas is the produce of the Rhodiola rosea, of Linnaus, called rosewort. When dry, it has a very of Linnaus, Canen to Several Holes of the damask rose. In this odorous matter the medical virtue of the root resides. Poultices in which this root enters as a chief

resides. Forfittees in which this root cheers as a caller ingredient are said to aliay violent pains of the head.

RHO DIUM. (From poop, a rose; a wood which smells like roses.) 1. Rhodium, or rosewood.

2. A new metal discovered among the grains of crude plutina, by Dr. Wollaston. The mode of obtaining it in the state of a triple salt combined with muriatic acid and soda, has been given under the article Palladium.
This may be dissolved in water, and the metal precipitated from it in a black powder by zinc.
This powder, exposed to heat, continues black; but

with borax it acquires a white metallic lustre, though it remains infusible. Sulphur, or arsenic, however, renders' it fusible, and may afterward be expelled by continuing the heat. The button, however, is not Its specific gravity appears not to exmalleable.

ceed 11.

Rhodium unites easily with every metal that has been tried except mercury. With gold or silver it forms a very malleable alloy, not oxidated by a high degree of heat, but becoming incrusted with a black oxide when slowly cooled. One-sixth of it does not perceptibly alter the colour of gold, but renders it much less traitibe. Notices prints and prints are necessary to the colour of sold, but renders it much less fusible. Neither nitric nor nitro-muriatic acid acts on it in either of these alloys; but if it be fused with three parts of bismuth, lead, or copper, the alloy is entirely soluble in a mixture of nitric acid with two parts of muriatic.

The oxide was soluble in every acid Dr. Wollaston tried. The solution in muriatic acid did not crystallize by evaporation. Its residuum formed a roselize by evaporation. Its residuum formed a rose-coloured solution with alkohol. Muriate of ammonia and of soda, and nitrate of potassa, occasioned no pre-cipitate in the nurriatic solution, but formed with the oxide triple salts, which were insoluble in alkohol. Its solution in nitric acid likewise did not crystallize, but silver, copper, and other metals precipitated it.

The solution of the triple salt with muriate of soda was not precipitated by provide cachenate or backet.

was not precipitated by muriate, carbonate, or hydrosulphuret of ammonia, by carbonate or ferroprussiate potassa, or by carbonate of soda. The caustic alkalies however throw down a yellow oxide, soluble in excess of alkali; and a solution of platina occasions

in it a yellow precipitate. The title of this product to be considered as a dis-tinct metal was at first questioned; but the experi-ments of Dr. Wollaston have since been confirmed by

Descotils.

RHODODE NDRON. (From ροδον, a rose, and δενδρον, a tree: so called because its flowers resemble the rose.) 1. The name of a genus of plants in the Linnaan system. Class, Decandria; Order, Mono-

2. The pharmacopæial name of the oleander. See

Rhododendron chrysanthemum.

RHODODENDRON CHRYSANTHEMUM. The systematic name of the oleander, rosebay, or yellow rhododendron. This species of rhododendron, foliis oblongis impunctis supra scabris venosissimis, corolla rotata irregulari gemma florifera ferrugineo-tamentosa, has not yet been introduced in Britain; it is a native of Siberia, affecting mountainous situations, and flow-ering in June and July.

This plant and its medical virtues were first de-scribed in 1747, by Gmelin and Haller. Little attention, however, was paid to it, till the year 1779, when it was strongly recommended by Koelpin as an effica-cious medicine, not only in rheumatism and gout, but even in venereal cases; and it is now very generally

employed in chronic rheumatisms, in various parts of Europe. The leaves, which are the part directed for medicinal use, have a bitterish subadstringent taste. Taken in a large dose, they prove a narcotic poison; and, in moderate doses they are said to occasion heat, thirst, a degree of delirium, and a peculiar sensation

of the parts affected.

As a powerful and active medicine, this shrub, says Dr. Woodville, may probably be found an addition to the materia medica. Dr. Home, who tried it unsuc-cessfully in some cases of acute rheumatism, says, "It appears to be one of the most powerful sedatives which we have, as, in most of the trials, it made the pulse remarkably slow, and in one patient reduced it to thirty-eight beats. And in other cases, in which the rhododendron has been used at Edinburgh, it has been productive of good effects, and accordingly it is now introduced into the Edinburgh Pharmacopæia. The manner of using this plant by the Siberians, was by putting two drachms of the dried leaves in an earthen pot, with about ten ounces of boiling water, keeping it near a boiling heat for a night; and this they took in the morning, and by repeating it three or four times, generally effected a cure.

RHODO'MELL. (From ροδον, the rose, and μελι, honey.) Honey of roses.

RHŒADEÆ. (From rhæas, the red poppy.) The name of an order in Linnæus's Fragments of a Natural Method, consisting of poppy and similar plants, the calyx of which is caducous, and the fruit a capsule

RHŒ'AS. (Rhwas, ados. m.; from ρεω, to flow.) The wild poppy is sometimes so called. See Papaver

A glistening and pearly white RHCETIZITE. mineral, which is found in primitive rocks, with quartz Psitzsci, in the Tyrol.

RHOMBOIDE US. (From pop605, a geometrical

RHOMBOIDE US. (From pophos, a geometrical figure, whose sides are equal but not right-angled, and stoos, resemblance.) Rhomboideus major and minor. Rhomboides, of Douglas, Winslow, and Cowper; and Cervici dorso scapulaire, of Dumas. This muscle, which is so named from its shape, is situated immediately under the trapezius. We find it usually, though not always, divided into two portions, which Albinus describes as two distinct muscles. The uppermost of these, or rhomboideus minor, arises tendinous from the spinous processes of the three inferior vertebrae of the neck, and from the ligamentum colli; the lowermost neck, and from the ligamentum colli; the lowermost, or rhomboideus major, arises tendinous from the spinous processes of the back: the former is inserted into the basis of the scapula, opposite to its spine; the latter into all the basis of the scapula, below its spine. Its use is to draw the scapula obliquely upwards, and

Its use is to draw the scapula obliquely upwards, and directly backwards.

RHOMBSPAR. See Bitterspar.

RHOMBUS. Diamond-shaped, approaching to a square: applied to leaves, &c.; as those of the Chenopodium olidum, and to the pod of Cicer arientinum.

RHONCHUS. (Ρογκος, rhonchus, sterter.) Snoring.

RHOPALO'SIS. (From ροπαλον, a club.) A disorder in which the hair cleaves together, and hangs down in clusters resembling clubs. The plaited hair. See Plica.

RHUBARB. See Rheum. Rhubarb, monk's. See Rumex patientia.

Rhubarb, rhapontic. See Rheum rhaponticum.
RHUS. (From ρεω, to flow: so called because it stops fluxes.) The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Trigy-

nia. The sumach-tree.

RHUS BELGICA. The Dutch myrtle is sometimes so termed. See Myrica gale.

RHUS CORTARIA. Sumach. Elm leaved sumach. RHUS CORLEGA. Sumach. Elm leaved sumach. This plant, Rhus—foliis pinnatis obtusius cule serratus ovalibus subtus villosis, of Linnæus, is a small tree, a native of the south of Europe. It is singular that this native of the south of Europe. It is singular that this is the only species of the genus rhus which is perfectly innocent; the others being active poisons. Both the leaves and berries of this plant are used medicinally, as astringents and tonics; the former are the most powerful, and have been long in common use, where they may be easily obtained in various complaints indicating this class of remedies. The berries, which are red, and of a roundish compressed figure. which are red, and of a roundish compressed figure, contain a pulpy matter, in which is lodged a brown, hard, oval seed, manifesting a considerable degree of

adstringency. The pulp, even when dry, is grateful, and has been discovered to contain an essential salt, similar to that of wood-sorrel. An infusion of the dried fruit is not rendered black by a solution of iron; hence it appears to be destitute of adstringency. But its acidity is extremely grateful; therefore, like many other fruits, these berries may be advantageously taken to allay febrile heat, and to correct bilious putrescency.

(RHUS GLABRUM. The berries of this, and several other American species of sumach, have a strong, acid taste, and at times exhibit crystallized or saline particles on their surface. Dr. Harsefield supposes the acid they contain to be tartaric; but it is, not improbably, an acid sui generis. The acidulous infusion of these berries is used as a refrigerant in fevers, and a gargle in sore throats. The bark and leaves of the shrub are highly astringent, and are used in tanning leather .-

Big. Mat. Mcd. A.]
RHUS RADICANS. See Rhus vernix.
RHUS TIPHINUM. The systematic name of the Virginian sumach, the seeds of which are said to be useful

in stopping hæmorrhages.

RHUS TOXICODENDRON. Poison oak, This plant is a native of North America. Poison oak, or sumach. The stems, I'ms plant is a native of North America. The stems, if cut, exude a milky juice, which inflames the skin. The leaves, now inserted in the pharmacopæia, are inodorous, and have a mawkish, subacrid taste. Their virtues are extracted more perfectly by water than by alkohol. They prove stimulant and narcotic, when taken internally. Dr. Alderson, of Hull, found them successful in several cases of paralysis. They excite a sense of heat and pricking, and irregular twitches in a sense of heat and pricking, and irregular twitches in the affected limbs. They have been sometimes useful, also, in herpetic eruptions. The dose may be from half a grain, gradually increased, to four grains, two or three times a-day.

RHUS VERNIX. Rhus radicans. The systematic name of a poisonous plant, the efficacy of which Dr. Freshoi has endeavoured to prove, in the disease called paralysis, and herpetic affections. He, in order that others should not suffer by his experiments, began by taking an infusion of one of the three foliola of which each leaf of this plant consists; and, as this dose pro-duced no sensible effect, he increased the number to twelve. His urine and perspiration were increased in quantity, and he had some pains in his belly. He relates seven cases, in which he thinks he can remove all doubt of the efficacy of this infusion, in herpetic affections. From these, the following are selected:

"A countrywoman," says Dr. Fresnoi, "came to me in the month of July, 1780, to consult me about the herpes farinosa, with which her face had been covered for more than a year. She was ordered to take an in-

for more than a year. She was ordered to take an infusion of this plant; and, in six weeks, was entirely free from the disease." He likewise relates five cases of paralysis, which

were cured by the use of this plant.

were cured by the use of this plant.

The leaves of this plant are to be cut when in the greatest vigour, about the month of June. "Those who cut this plant," says Dr. F., "wear leathern gloves, on account of its poisonous qualities." The same gentleman observes, he saw one case in which inflammation of the eyelids was produced by the vafour from the plant. Four pounds of the leaves, being distilled with thirty-two pounds of water, give it a slight odour, although the plant is entirely free from it. Its taste is pungent, and inflames the mouth. The decertion which remains in the still is known, and is coction which remains in the still is brown, and is generally covered with a light brown pellicle. When strained and evaporated, it gives a shining black extract. The leaves inflame and swell the hands and arms of those who take them out of the still, and bring on an itching, which remains for several days. Forty-two pounds of the leaves afford twenty ounces

of extract, of a proper consistence for pills.

"A girl, in Flanders," says Dr. Fresnoi, "already subject to fits, laid down some flowers in ber bedroom. Next day she told me that she had undergone a great change: that she had had no fits, and slept much better. It occurred to me," says Dr. F. " that the flowers occasioned this change. Next day, the flowers being removed, and the window opened, the convulsions reremoved, and the window opened, the convusions reappeared; on their being again introduced, the fi s disappeared, which proved plainly it was the effect of the flowers. The success of the extract, in tussis convulsiva, exceeded my hopes; forty-two children being cured of this disorder in Valenciennes, during 247

the end of the year 1786. Four grains of extract are to be dissolved in four ounces of syrup, of which one table-spoonful, given to the child every third hour, generally abates the cough, and mostly leaves them.

RHY'AS. ('Pυας, a disease of the eye.) A decrease defect of the lachrymal caruncle. The proximate or defect of the lachrymal caruncle. cause is a native defect; or it may originate from exci-sion, erosion, or acrimony. This disorder is commonly incurable, and it induces an incurable epiphora, or a continual weeping.

(From Pupos, sordes.) Foul, sordid, RHYPIA.

ill-conditioned.

RHYTIDO'SIS. See Rutidosis.
RIB. Costa. The ribs are the long curved bones which are placed in an oblique direction at the sides of the chest. Their number is generally twelve on each side; but, in some subjects, it has been found to be thirteen, and in others, though more rarely, only ele-ven. They are distinguished into true and false ribs. The seven upper ribs, which are articulated to the sternum, are called true ribs; and the five lower ones, which are not immediately attached to that bone, are called false ribs. At the posterior extremity of each rib, we observe a small head, divided by a middle ridge into two articulating surfaces, covered with cartilage, which are received into two cavities, contiguous to each other, and formed in the upper and lower part of each dorsal vertebra, as we have observed in our description of the spine. This articulation, which is secured by a capsular ligament, is a species of ginglymus, and allows only of motion upwards and down-The head of each rib is supported by a short neck, and immediately beyond this we find a flattened tubercle, affording an oblong and slightly convex surface, which is articulated with the transverse process of the lowest of the two dorsal vertebræ, with which its head is articulated. At some little distance from this tuberosity, the rib makes a considerable curve, which is usually called its angle. From the tubercle to the angle, the ribs are of considerable thickness, and approaching to a cylindrical shape; but, from the angle to their anterior extremity, they become thinner and flatter. To this anterior extremity is fixed a long, broad, and strong cartilage, which, in each of the true ribs, reaches to the sternum, where its articulation is secured by a capsular ligament, and by other ligamen-tous fibres. The cartilages of the sixth and seventh ribs being longer than the rest, are extended upwards, in order to reach the sternum, the inferior portion of which is about on a level with the fifth rib. The cartilages of these two ribs are usually united into one, so as to leave no space between them. The false ribs are supported in a different manner; their cartilages terminate in an acute point before they reach the sternum, the eighth rib being attached by its cartilage to the lower edge of the cartilage of the seventh, or last of the true ribs; the ninth in the same manner to the eighth; and the tenth to the ninth; the cartilages of each rib being shorter than that of the rib above it. The eleventh and twelfth, which are the two lowermost ribs, are not fixed at their anterior extremities like the other ribs, but hang loose, and are supported only by their ligamentous fibres, and by muscles and other soft parts.

The external surface of each rib is somewhat convex, and its internal surface slightly concave. On the inferior and interior surface of these bones we observe a long fossa, for the lodgment of the intercostal vessels and nerves. This channel, however, does not extend through the whole length of the rib, being observable neither at the posterior extremity, where the vessels have not yet reached the bone, nor at the fore-end, where they are distributed to the parts between the ribs. We seldom see any marks of it in the short ribs, as in the first, second, eleventh, and twelfth.

Thus far we have given a description which is ap-

plicable to the ribs in general; but, as we find them differing from each other in shape, length, situation, and other respects, it will be right to speak of each rib

in particular.

The first rib, which is the shortest of any, is likewise the most curved. It is broader than the other ribs, and, instead of being placed, as they are, obliquely, and with its edges upwards and downwards, it is situated nearly in a transverse direction, one of its edges being placed inwards, or nearly so. Of these edges, the inner one is sharp, and the outer one nacia; Order, Monadelphia.

somewhat rounded. Its inner surface is smooth, and its superior surface is sometimes slightly depressed anterior y by the clavicle. The head of this rib, instead of being angular, is flattened, and slightly convex, being received into a cavity, which is formed wholly in the first vertebra, and not by two vertebra,

as in the case with the other ribs.

The second rib is longer than the first, but shorter than the ribs below it. Its angle is placed at a small distance rom its tuberosity, and its head is articulated with two vertebræ, like the other ribs. The other ten ribs, the last two only excepted, differ from the general description we have given, chiefly in the difference of their length, which goes on gradually increasing, from the first or uppermost, to the seventh or last of the true ribs, and as gradually diminishing from that to the twelfth. Their obliquity, in respect to the spine, likewise increases as they descend, as does the distance between the head and angle of each rib, from the first rib to the ninth. The two lowest ribs differ from all the rest in the following particulars:-Their heads, like that of the first rib, are rounded, and received into a cavity formed entirely in the body of one vertebra; they have no tubercle for their articulation with the transverse processes, to which they are only loosely fixed by ligaments, and, in this respect, the tenth rib is sometimes found to agree with them: they are much shorter than the rest of the false ribs, and the twelfth is still shorter than the eleventh. The length of the latter, however, is different in different subjects, and is not always found to be the same on both sides. riorly, as we have already observed, their cartilages are short and loose, not being attached to the cartilages of the other ribs; and this seems to be, because the most considerable motions of the trunk are not performed on the lumbar vertebræ alone, but likewise on the lower vertebræ of the back; so that if these two ribs had been confined anteriorly, like the rest, and likewise united to the bodies of two vertebræ, and to the transverse process, this disposition would have impeded the motion of the two last vertebræ of the back, and consequently would have affected the motion of the trunk in general.

The use of the ribs is to give form to the thorax, and to cover and defend the lungs; also to assist in breathing; for they are joined to the vertebræ by regular hinges, which allow of short motions, and to the sternum by cartilages, which yield to the motion of the

ribs, and return again when the muscles cease to act.

Ribbed-leaf. See Nervosus.

RIBES. The name of a genus of plants in the
Linnean system. Class, Pentandria; Order, Monogunia. The current-tree

gynia. The currant-tree.

RIBES NIGRUM. Black currant. This indigenous plant, Ribes-racemis pilosis, floribus oblongis, of Linnaus, affords larger berries than those of the red, which are said to be peculiarly useful in sore throats, and to possess a diuretic power in a very considerable The leaves of the black currant are extremely fragrant, and have been likewise recommended for their medicinal virtue, which Bergius states to be mundificans, pellens, diuretica. The officinal preparations of the berries are the syrupus ribis nigri, and the

succus ribis nigri inspissatus.

RIBES RUBRUM. Grossularia non spinosa. The red current. Ribes—inerme; racemis glabris pendulis, floribus planiusculis, of Linnaus. The white currant-tree is merely a variety of the red, the fruit of both is perfectly analogous; therefore, what is said of the one applies to the other. The red currant is abundantly cultivated in gardens and from its grateful acid of the one applies to the other. The reacurrant is avandantly cultivated in gardens, and, from its grateful acidity, is universally acceptable, either as nature presents it, or variously prepared by art, with the addition of sugar. Considered medicinally, it is esteemed to be moderately refrigerant, antiseptic, attenuant, and aperient. It may be used with considerable advantage to allay thirst, in most febrile complaints, to lessen an increased secretion of bile, and to correct a putrid and scorbutic state of the fluids, especially in sanguine temperaments; but, in constitutions of a contrary kind, it is apt to occasion flatulency and indigestion.

RISWORT. See Plantago lanceolata.

See Plantago lanceolata.

RICE. See Oryza.

RICINUS. (Quasi, ριν κυνος, a dog's nose: because they stick to the noses of dogs.) 1. The name of a genus of plants in the Linnæan system. Class, Mo-

2. The pharmacopoial name of the plant that affords

the seed from which the castor-oil is prepared.

RICINUS COMMUNIS. The systematic name of the castor-oil plant. Cataputia major; Kerva; Ricinus vulgaris; Palma christi Ricinus—foliis peltatis subpalmatis serratis, of Linnæus. This plant appears to be the Κικι, οr Κροτων, of Dioscorides, who observes, that the seeds are powerfully cathartic; it is also mentioned by Δείμες Paulus Fainets, and Pliny. The tioned by Actius, Paulus Ægineta, and Pliny. The ricinus was first cultivated in England, in the time of Turner, and is now annually reared in many gardens in the neighbourhood of London; and in that of Dr. Saunders, at Highbury, the plant grew to a state of great perfection. An oil extracted from the seeds of this plant, and known by the name of oleum ricini, palma christi, or castor-oil, is the drug to which the pharmacopæias refer, and which has lately come into frequent use, as a quick but gentle purgative. London College directs this oil to be expressed from the seeds in the same way as that of the oil of almonds, and without the assistance of heat, by which the oil would seem to be obtained in the purest state. However, we have some reason to believe that this method is seldom practised, and that the oil usually employed here is imported from the West Indies, where it is commonly prepared in the following manner:—"The seeds being freed from the husks, or pods, which are gathered upon their turning brown, and when beginning to burst open, are first bruised in a mortar, after-ward tied up in a linen bag, and then thrown into a large pot, with a sufficient quantity of water (about eight gallons, to one gallon of the seeds), and boiled till the oil is risen to the surface, when it is carefully skimmed off, strained, and kept for use. Thus pre-pared, the oil is entirely free from acrimony, and will stay upon the stomach when it rejects all other medi-cines." Mr. Long remarks, that the oil intended for medicinal use, is more frequently cold drawn, or ex-tracted from the bruised seeds by means of a handpress. But this is thought more acrimonious than that prepared by coction. Dr. Brown is also of this opi-nion, and prefers the oil prepared by coction to that by expression; he attributes its greater mildness to the action of the fire, observing that the expressed oil, as well as the mixed juices of the seeds, are far more ac-

tive and violent in their operation.

Dr. Culien observes, that "this oil, when the stomach can be reconciled to it, is one of the most agreeable purgatives we can employ. It has this particular advantage, that it operates sooner after its exhibition than any other purgative I know of, as it commonly operates in two or three hours. It seldom gives any griping, and its operation is generally moderate, producing one, two, or three stools only. It is particularly suited to cures of costiveness, and even to cases of

spasmodic colic.

In the West Indies, it is found to be one of the most certain remedies in the dry belly-ache, or colica picto-num. It is seldom found heating or irritating to the rectum; and, therefore, is sufficiently well suited to

hæmorrhoidal persons.

The only inconvenience attending the use of this medicine is, that as an oil it is nauseous to some persons; and that, when the dose is large, it occasions sickness at the stomach for some time after it is taken. To obviate these inconveniences, several means have been tried; and it is found that the most effectual means is the addition of a little ardent spirit. In the West Indies, they employ rum; but that I might not withdraw any part of the purgative, I employed the Tinc. sennæ comp. This, added in the proportion of one to three parts of the oil, and very intimately mixed, by being shaken together in a phial, both makes the oil less nauseous to the taste, and makes it sit more easy on the stomach. The common dose of this oil is a table spoonful, or half an ounce; but many persons require a double quantity.

RICINUS MAJOR. See Jatropha curcas. RICINUS VULGARIS. See Ricinus.

RICKETS. See Rachitis.
RICTUS. This term is applied by botanists to the grinning mouth or opening between the two lips of a ringent or personate flower.
RIGOR. A sudden coldness, attended by a shivering, more or less perfect.
RIMA. A fissure, or opening; as the rima laryngis, rima vulve.

rima vulvæ.

RIMA GLOTTIDIS. The opening of the larynz, through which the air passes in and out of the lungs. RI'MULA. (Diminutive of rima, a fissure.) A small fissure

RINÆ'US. (From piv, the nose.) See Compressor

RING-WORM. A species of herpes. See Herpes. RINGENS. Ringent: a term applied to flowers or their corolla, which are irregular and gaping, like the mouth of an animal; as those of the nettle, &c.

A ringent flower is also called a lipped or labiate by

some botanists.
Ri'sagon. See Cassumuniar.
Risigallum. The auripigmentum was so called. RISIGALLUM.
See Arsenious acid.
RI'SUS. Laughter; laughing.
RI'SUS. Laughter; laughing.
RI'SUS. Laughter; laughing.
RI'SUS. Laughter; laughing.

RIVERIUS, LAZARUS, was born at Montpeller, in 1589. Being naturally slow in his attainments, he failed in his first examinations for a degree; but this only stimulated him to redoubled exertions, so that in the following spring he accomplished his object at the age of 22. His attachment to study became then very great, and eleven years after that period he was ap-pointed to the professorship of medicine in the univerpointed to the professorant of medicine in the univer-sity; which office he filled with great honour till his death in 1655. Riverius published some valuable works, especially one, entitled "Praxis Medica;" which appeared at first in a concise form, as a sort of text-book; but finding it very favourably received by the public, he enlarged and improved it considerably: and it added greatly to his reputation, having passed

and it added greatly to his reputation, having passed through numerous editions, as well in the original, as translated into French and English.

RIVINUS, AUGUSTUS QUIRINUS, was son of a learned physician and critic, Andrew Bachmann, whose name was Latinized into Rivinus, and born at Leipsic, in 1652. He graduated at the age of 24, and fifteen years after obtained the professorships of physicalogy and botany in his native university; he was also ology and botany in his native university; he was also associated with many learned bodies; and he filled these appointments with honour to himself till his death, in 1723. Rivinus distinguished himself chiefly as a systematic botanist; but his arrangement was very defective, being founded on the number of the petals, and their being regular, or irregular. Though by no means eminent as a practical anatomist, he is said to have discovered a new salivary duct. As a medical writer, he has the merit of faithful observation and description in his treatise "De Peste Lipsiensi," published in 1680. He wrote also on dyspepsia, on intermittents, and various other subjects. His "Censura Medicamentorum officinalium," ranks very high, or account of the freedom with which he attacked oniaccount of the freedom with which he attacked opinions, however generally received, which he believed erroneous; and to the prevalence of this spirit we owe the great simplification, and other improvements, which the Materia Medica exhibits at present.

ROASTING. A chemical process, generally per-formed in crucibles, by which mineral substances are divided, some of their principles being volatilized, and others changed, so as to prepare them for other opera-

ROB.

(Rob, dense, Arabian.) An old term for an inspissated juice.
ROBORANT. (Roborans; from roboro, to strength-

That which is strengthening. See Tonic.

ROCCE LLA. See Liehen roccella. Rochelle-salt. See Soda tartarisata. ROCKAMBOLE. The Allium scorodoprasum, of The root is used for pickles and high-sea-

soned dishes ROCK-BUTTER. A greasy mineral which oozes out of rocks that contain alum, at the Hurlet alumwork, near Paisley.

Rock cork. See Asbestos.

ROCK-CRYSTAL. A white and brown-coloured crystallized silicious mineral, found of great size and beauty in some parts of Scotland, and Dauphiny affords most magnificent groupes.

Rock-oil. See Petroleum. ROCK-SALT. Of this there are two kinds, the foliated and the fibrous. The principal deposite of this salt in Great Britain is in Cheshire. In 1000 parts are contained, according to Henry, 983 of muriate of soda, 249

Rock-samphire. See Crithmum mar Rock, wood. The ligniform abestos. ROCKET. See Brassica cruca. See Crithmum maritimum.

ROCKET. See Brassica eruca.

Rocket, Roman. See Brassica eruca.

Rocket, wild. See Brassica erucastrum.

[ROMAYNE, Nicrollas, M. D. was born in the city of New-York in September, 1756, and obtained his elementary education at Hackensack in New-Jersey, under the instruction of Dr. Peter Wilson, the late professor of languages in Columbia College. About the commencement of the revolutionary war he went abroad, and completed his medical studies at Edinburgh. He also visited the continent, and spent two years in Paris. Upon his return to New York he commenced his professional career. He was advantage ously known as an able private lecturer on many branches of medical science, and it is with pleasure I bear witness to his efficient instrumentality, in the foundation of the College of Physicians and Surgeons. He was its first president, and gave instructions in that institution on Anatomy and the Institutes of Medicine. His address as president, delivered at the first opening of the college in November, 1807, is an honourable specimen of his diversified attainments and talent.

specimen of his diversified attainments and talent. He died in New-York in 1817.

"Dr. Romayne," says Dr. M'Leod, "was a man of strong mind, well cultivated and much improved by reading, by the society of learned men, and by travelling. I knew him in health and in the midst of disease; in affluence and in adversity. He had much self-command, though naturally of powerful passions, and very tender sensibilities. Bereaved of all his children in their infancy, he could not endure the recollection of their endearment. On the last evening of his life he their endearment. On the last evening of his life he gave testimony to a dear friend, of his respect for the Scriptures. He departed too suddenly for me to see him of his death bed."—Thack. Med. Biog. A.]

RORE'LLA. See Drosera rotundifolia.

ROS. Dew.

ROS CALABRINUS. The official manna is sometimes so termed.

See Drosera rotundifolia. Ros solis.

RO'SA. I. The name of a genus of plants in the Linnman system. Class, Icosandria; Order, Poly-The rose.

2. A name sometimes given to the crysipelas, be-cause it begins with a redness like that of a rose. ROSA ALBA. The white rose. The flowers of this

species possess similar but inferior virtues to those of the damask.

Rosa canina. Rosa sylvestris; Cynorrhodon; Cynosbalos. The dog rose, or wild-brier, or hip-tree. Rosa—germinibus ovatis pedunculisque glabris, caule petiolisque aculeatis, of Linnæus. The fruit of this tree, called heps, or hips, has a sourish taste, and obside a place in the Landan plantagency. tains a place in the London pharmacopæia, in the form of conserve. It is seldom employed but to give form to more active remedies, in pills, boluses, linetuses, &c.

ROSA CENTIFOLIA. The pharmacopæial and systematic name of the damask rose. Rosa damasceda; Rosa pallida. The damask rose. The pharmacopeias direct a syrup to be prepared from the petals of this rose, Rosa—germinibus oratis pedunculisque his-pidis, caule hispido aculcato petiolis inermibus, of Lin-næus; which is found to be a pleasant and useful laxa-tive for children, or to obviate costiveness in adults. Most of the roses, though much cultivated in our gardens, are far from being distinctly characterized. Those denominated varieties are extremely numerous, and often permanently uniform; and the specific differences, as hitherto pointed out, are in many respects so inadequate to the purpose of satisfactory discrimination, that it becomes a difficult matter to distinguish which are species and which are varieties only. damask rose seems to be another species widely different from the centifolia, as appears from the descrip-tion given of it by Du Roi and Miller.

The petals are directed for medical use; they are of a pale red colour, and of a very fragrant odour, which, to most people, is extremely agreeable; and therefore

61 sulphate of lime, a little muriate of lime and muriate of magnesia, and 10 parts insoluble matter. their odorous matter to watery liquors, both by infusion and distillation. Six pounds of fresh roses impregnate, by distillation, a gallon, or more, of water, strongly with their fine flavour. On distilling large quantities, there separates from the watery fluid a small portion of a fragrant butyraceous oil, which liquefies by heat, and appears yellow, but concretes in the cold into a white mass. A hundred pounds of the flowers, according to the experiments of Tachenius and Hoffman, afforded scarcely half an ounce of oil." The smell of the oil exactly resembles that of roses, and is therefore much used as a perfume. It possesses very little pun-gency, and has been highly recommended for its cordial and analeptic qualities. These flowers also contain a and analeptic qualities. These flowers also contain a bitterish substance, which is extracted by water along with the odorous principle, and remains entire in the decoction after the latter has been separated by distillation, or evaporation.

This fixed sapid matter of the petals manifests a purgative quality; and it is on this account that the flowers are received in the Materia Medica.

Rosa gallica. See Rosa centifolia.
Rosa gallica. The pharmacopoial and systematic
name of the red rose. Rosa rubra. The flowers of this species, Rosa—germinibus ovatis pedunculisque hispidis, caule petivlisque hispido aculeatis, of Linnaus, are valued for their adstringent qualities, which are most considerable before the petals expand; and therefore in this state they are chosen for medicinal use, and ordered by the pharmacoposias in different preparations, as those of a conserve, or confection, a honey, an infusion, and a syrup. The infusion of roses is a grateful cooling subadstringent, and useful in hamoptysis, and other hæmorrhagic complaints: its efficacy, however, depends chiefly on the sulphuric acid added.

ROSA PALLIDA. See Rosa centifolia.

ROSA RUBRA. See Rosa gallica.

ROSA SYLVESTRIS. See Rosa canina.

ROSA'CEUS. Rose-like. 1. Applied to corolla which spread like a rose, as those of the Dryas.

2. The term gutta rosacca is applied to little rosy-coloured spots upon the face and nose.

ROSACIC ACID. There is described from the price.

ROSACIC ACID. There is deposited from the urine of persons, labouring under gout and inflammatory fevers, a sediment of a rose colour, occasionally in red-dish crystals. This was first discovered to be a peculiar dish crystals. disherystals. This was install covered to be a peculiar acid by M. Proust, and afterward examined by M. Vauquelin. This acid is solid, of a lively cinnabar hue, without smell, with a faint taste, but reddening litmus very sensibly. On burning coal it is decomposed into a pungent vapour, which has not the odour of burning animal matter. It is very soluble in water, and it even softens in the air. It is soluble in alkohol. It forms soluble salts with potassa, soda, ammonia, ba-rytes, strontites, and lime. It gives a slight rose-coloured precipitate with acetate of lead. It also combines with lithic acid, forming so intimate a union, that the lithic acid in precipitating from urine, carries the other, though a deliquescent substance, down along with it. It is obtained pure by acting on the sediment of urine with alkohol.

ROSALIA. A name in some authors for the mea-sles, or a disease very like the measles. ROSE. See Rosa. Rose, damask. See Rosa centifolia. Rose, dog. See Rosa canina. ROSEA RADIX. See Rhodiola. Rose, red. See Rosa gallica. ROSE ROOT. See Rhodiola.

ROSE ROOT. See Rhodista.

Rose, white. See Rosa alba.

Rosebay willow herb. See Epilobium angustifolium.

ROSEMARY. See Rosmarinus.

ROSEOLA. (From rosa, a rose: so called from the colour of the rash.) A rose-coloured efforescence, variously figured, without wheals, or papulæ, and not contagious. It is mostly symptomatic, occurring in connexion with different febrile complaints, and requiring no deviation from the treatment respectively adapted to them.

Its principal varieties are comprised under the seven

following heads:

1. The Roscola astiva appears first on the face and a pale red colour, and of a very fragrant odour, which, to most people, is extremely agreeable; and therefore this and most of the other roses are much used as nosegays. We may remark, however, that in some instances, they have, under certain circumstances, produced alarming symptoms. The petals "impart irregular forms than in the measles. It is at first red, but soon assumes its deep roseate hue. The fauces are tinged with the same colour, and a slight roughness of the tonsils is felt in swallowing.

The rash continues vivid through the second day; after which it declines in brightness, slight specks only remaining of a dark bue, on the fourth day; which, with the constitutional affection, wholly disappear on

The efflorescence sometimes is partial, extending only over portions of the face, neck, and upper part of the breast and shoulders, in patches, slightly elevated, and itching considerably, but in this form the disease continues a week or longer, the rash appearing and disappearing several times; sometimes from taking warm liquors, and sometimes without any apparent cause. The retrocession is usually accompanied with disorder of the stomach, headache, and faintness; which are immediately relieved on its appearance. It commonly occurs in females of irritable constitution in summer. Light diets and acidulated drinks, with occasional lax-atives, palliate the symptoms.

2. The Roseola autumnalis occurs in children, in the

autumn, in distinct circular or oval patches, which gradually increase to the size of a shilling, and are of a dark damask rose bue. It appears chiefly on the

a dark damask rose line. It appears chieffy on the arms, sometimes desquamating, and its decline seems to be expedited by the internal use of sulphuric acid.

3. The Roscola annulata occurs on almost every part of the body, in rose-coloured rings, with central areas of the usual colour of the skin. When accompanied with fever its duration is short: at other times, without any constitutional disorder, it continues for a considerable and uncertain period. The rings are, at first, from a line to two lines in diameter, but gradually dilating leave a larger central space, sometimes of the diameter of half an inch. The efflorescence is less vivid (and in the chronic form usually fades) in the morning, but increases in the evening or night, and produces a heat and itching in the skin. When it becomes very faint in colour for several days, the stomach is disordered, and languor, giddiness, and pains of the limbs ensue, which are relieved by the use of the warm bath.

Sea-bathing and the mineral acids afford much relief

in the chronic forms of this rash.

4. Roscola infantilis is a closer rash occurring in in-4. Roscola infantitis is a closer rash occurring in in-fants during the irritation of dentition, of disordered bowels, and in fevers. It is very irregular in its ap-pearances, sometimes continuing only for a night, sometimes appearing and disappearing for several suc-cessive days with violent disorder, and sometimes arising in single patches in different parts of the body successively. It is alleviated by the remedies adapted to relieve bowel complaints, painful dentition and other febrile affections with which it is connected.

 Roscola variolosa occurs previously to the eruption both of the natural and inoculated small-pox, but seldom before the former. It appears in the inoculated disease, on the second day of the eruptive fever, which is generally the ninth or tenth after inoculation. It is first seen on the arms, breast, and face; and on the following day it extends over the trunk, and extremities.

Sometimes it is distributed in oblong irregular patches, sometimes diffused with numerous interstices, and sometimes it forms an almost continuous redness over the whole body, being in some parts slightly ele-vated. It continues about three days, on the second or last of which, the variolous pustules may be distin-guished, in the general redness, by their rounded elevation, hardness, and whiteness of their tops

6. Roscola vaccina appears generally in a congeries of dots and small patches, but sometimes diffuse like the former: takes place on the ninth or tenth day after vaccination, at the place of inoculation, and at the same time with the areola that is formed round the vesicle, from whence it spreads irregularly over the whole surface of the body.

It is usually attended with a very quick pulse, white

tongue, and great restlessness.

7. Roscola miliaris often accompanies an eruption of miliary vesicles after fever. It is sometimes connected with attacks of the gout and of the febrile rheumatism, accompanied with considerable fever, extreme languor and depression of spirits, total loss of appetite, and torpid bowels, and terminates on the seventh day by des-

ROSEWOOD. See Rhodium lignum.

ROSEWORT. See Rhodiola.
ROSIN. See Resina.
ROSMARI'NUS. (Quasi rosa, σμυρνα, because it smells like myrrh.) 1. The name of a genus of plants in the Linnaan system. Class, Diandria; Order,

2. The pharmacopæial name of the common rose-

ROSMARINUS HORTENSIS. See Rosmarinus officimalis.

ROSMARINUS OFFICINALIS. The systematic name f the common rosemary. Rosmarinus aortensis; of the common rosemary. Rosmarinus hortensis; Libanotis coronaria; Dendrolibanus; Rosmarinus, of Linnæus. The leaves and tops of this plant have a fragrant aromatic smell, and a bitterish pungent taste. Rosemary is reckoned one of the most powerful of those plants which stimulate and corroborate the nervous system; it has therefore been recommended in various affections supposed to proceed from debility, or defective excitement of the brain and nerves, as in certain headaches, deafness, giddiness, and in some hysterical and dyspeptic symptoms. The officinal pre-parations of rosemary are, an essential oil from their leaves, or from the herb in flower, a conserve of the flowers, and a spirit formerly called Hungary water,

from the flowery tops. The tops are also used in the compound spirit of Lavender, and soap liniment.

ROSMARINUS SYLVESTRIS. See Ledum palustre.

ROSTELLUM. A little beak. Applied to that part of the seed which is pointed, penetrates the earth, and becomes the root. See Corculum.

ROSTERATUS. Restrete Applied to the ped of

ROSTRATUS. Rostrate. Applied to the pod of

the Sinapis alba.

ROSTRUM. (From rodo, to gnaw; because birds use it to tear their food with.)

1. A beak.

2. The piece of flesh which hangs between the di

vision of the hare-lip is called rostrum leporinum.

Applied in botany to some elongation of a seed-vessel, originating from the permanent style; as in Geranium: though it is also used for naked seeds; as

ROTACEÆ. (From rota, a wheel.) The name of an order of plants in Linnaus's Fragments of a Natural Method, consisting of those which have one flat wheel-

shaped petal.

ROTACISMUS. The harsh or asperated vibration

of the letter r or po, which is very common in the northern parts of England.

ROTANG. See Calamus rotang.

ROTATOR. (From roto, to turn.) A muscle the office of which is to wheel about the thigh.

ROTATUS. Rotate, or wheel-like; salver-shaped.

Applied to the corolls, nectary, &c.; as the nectary of the Cyssampelos, the corolla of the Borago officinalis.

ROTULA. (Diminutive of rota, a wheel: so called from its shape.) See Patella.

ROTUNDUS. See Round.

ROTUNDUS. See Round.

ROUGE. See Carthamus tinctorius.

ROUND. Rotundus. Many parts of animals and vegetables receive this trivial name from their shape; as round ligaments, round foramen, &c.; and leaves, stems, seeds, &c. as the seed of the Pisum Brassica, &c. Round-leaved sorrel. See Rumex scutatus.

ROUND LIGAMENTS. Ligamenta rotunda. A bundle of vessels and fibres contained in a duplicature of the perilonnyum, that proceed from the sides of the

the peritonaum, that proceed from the sides of the uterus, through the abdominal rings, and disappear in the pudenda.

RUBE DO. (From ruber, red.) A diffused, but not spoited, redness in any part of the skin; such as that

spoiled, reduces an analysis which arises from blushing, RUBEFACIENT. (Rubefaciens; from rubefacie, RUBEFACIENT.) That substance which, when applied to make red.) That substance which, when applied to make red.)

RUBELUTE. Red tourmalin.
RUBE OLA. (From ruber, red; or from rubeo, to become red.) Morbili. The measles. A genus of disease in the Class Pyrexia, and Order Exanthemata, of Cullen; known by synocha, hoarseness, dry cough, sneezing, drowsiness; about the fourth day, eruption or small red points, discernible by the touch, which, after three days, ends in mealy desquamation. The blood, after venesection, exhibits an inflammatory crust. In addition to the symptoms already related, it is remarkable, that the eyes and eyelids always show the presence of this disease, being somewhat inflamed

and suffused with tears. The synocha continues during the whole progress of the disease. In systems of nosology, several varieties of measles are mentioned, but they may be all comprehended under two heads; the one attended with more or less of the symptoms of general inflammation; the other accompanied by a

putrid diathesis.

putrid diathesis.

The measles may prevail at all seasons of the year as an epidemic, but the middle of winter is the time they are usually most prevalent; and they attack persons of all ages, but children are most liable to them. They prove most unfavourable to such as are of a plethoric or scrofulous habit. Like the small-pox, they never affect persons but once in their life; their contagion appears to be of a specific nature. The eruption is usually preceded by a general uneasiness, chilliness, and shivering, pain in the head, in grown persons: and shivering, pain in the head, in grown persons but in children a heaviness and soreness in the throat sickness and vomiting, with other affections, such as happen in most fevers; but the chief characteristic symptoms are, a heaviness about the eyes, with swelling, inflammation, and a defluxion of sharp tears, and great acuteness of sensation, so that they cannot have the light characteristic symptoms. and great acuteness of sensation, so that they cannot bear the light without pain, together with a discharge of such serous humour from the nostrils, which produce sneezing. The heat and other febrile symptoms, increase very rapidly; to which succeeds a frequent and dry cough, a stuffing, great oppression, and oftentimes retching to vomit, with violent pains in the loins, and sometimes retching to vomit, with violent pains in the loins, and sometimes a looseness; at other times there is great sweating, the tongue foul and white, the thirst very great, and, in general, the fever runs much higher than in the milder sort of the regular small-pox. The eruptions appear about the fourth or fifth day, and sometimes about the end of the third. On the third or fourth day from their first appearance, the redness diminishes, the spots, or very small papula, dry up, the cuticle peels off, and is replaced by a new one. The symptoms do not go off on the eruption, as in the small-pox, except the vomiting; the cough and headache pox, except the vomiting; the cough and headache continue, with the weakness and defluxion on the eyes, and a considerable degree of fever. On the minth or eleventh day, no trace of redness is to be found, but the skin assumes its wonted appearance; yet, without there have been some considerable evacuations either by the skin, or by vomiting, the patient will bardly recover strength, but the cough will continue, the fever return with new violence, and bring on great distress and danger.

In the more alarming cases, spasms of the limbs, subsultus, tendinum, delirium, or what more frequently happens, coma, supervene. This last symptom so frequently attends the cruptive fever of measles, that by some practitioners it is regarded as one of its diagnostics.

In measles, as in other febrile diseases, the symptoms generally suffer some remission towards the morning, returning however towards the evening with

increased severity.

The measles, even when violent, are not usually attended with a putrid tendency; but it sometimes happens, that such a disposition prevails both in the course of the disease and at its termination. In such cases, petechiæ are to be observed interspersed among the cruptions, and these last become livid, or assume almost a black colour. Hæmorrhages break out from different parts of the body, the pulse becomes frequent, feeble, and perhaps irregular, universal debility ensues, and the patient is destroyed.

In those cases where there is much fever, with great

In those cases where there is much fever, with great difficulty of breathing, and other symptoms of pneu-monic inflammation, or where there is great debility, with a tendency to putrescency, there will always be considerable danger; but the consequences attendant on the measles are in general more to be dreaded than the immediate disease; for although a person may get through it, and appear for a time to be recovered, still begin a person and appear for a time to be recovered, still begin a person and appear for a time to be recovered. hectic symptoms and pulmonary consumption shall afterward arise, and destroy him, or an ophthalmia

shall ensue.

Measles, as well as small-pox, not unfrequently call into action a disposition to scrofula, where such hap-pens to exist in the habit. Another bad consequence of the measles is, that the bowels are often left by them in a very weak state; a chronic diarrhœa remaining, which has sometimes proved fatal. Dropsy has also been known as a consequence of measles.

The morbid appearances to be observed on dissec-tions of those who die of measles are pretty much confined to the lungs and intestines: the former of which always show strong marks of inflammation, and sometimes a tendency to sphacelus. Where the pa-tient dies under the cruption, the trachea and larger branches of the bronchia, as in the small-pox, are often covered with it, which may account for the increase of covered with it, which may account for the increase of

the cough after the appearance of the cruption.

In the treatment of this disorder, as it usually appears, the object is to moderate the accompanying synocha fever, and attend to the state of certain or-gans, particularly the lungs and the bowels. When there are no urgent local symptoms, it will be commonly sufficient to pursue the general antiphlogistic plan, (avoiding, however, too free or sudden exposure to cold.) keeping the bowels open, and encouraging diaphoresis by mild antimonials, &c. Sometimes, however, in plethoric habits, especially where the lungs however, in plethoric habits, especially where the lungs are weak, it will be proper to begin by a moderate abstraction of blood. Where the eruption has been imprudently checked, much distress usually follows, and it will be advisable to endeavour to bring it out again by the warm bath, with other means of increasing the action of the cutaneous vessels. Should an inflammatory determination of the lungs occur, more active executations must be practised, as evolving active evacuations must be practised, as explained under the head of *Pneumonia*. The cough may be palliated by opium, joined with expectorants, demulcents, &c.: and an occasional emetic will be proper, when there is much wheezing. Where diarrhea takes place, it is better not to attempt to suppress it at once; but if troublesome moderate it by small doese of opium. but if troublesome, moderate it by small doses of opium, assisted perhaps by astringents. At the decline of the disorder, much attention is often required to prevent phthisis pulmonalis supervening. Should the disorder ever put on a putrid character, the general plan pointed

out under Typhus must be pursued.

RUBIA. (From ruber, red: so called from its red roots.)

1. The name of a genus of plants in the Linnean system. Class, Tetrandria; Order, Monogynia.

2. The pharmacopeial name of the madder plant,

Rubia tinetorum.

RUBIA TINCTORUM. The systematic name of the madder plant. Erythrodanum; Rubia major; Radia rubra. Dyers' madder. Rubia—foliis annuis, caule aculeate, of Linnaus. The roots of this plant have a bitterish, somewhat austere taste, and a slight smell, not of the agreeable kind. It was formerly considered as a deobstruent, detergent, and diuretic, but it is now very seldom used.

RUBI GO. (Rubigo, inis. f.; à colore rubro, from its red colour.) Rust.

RUBIGO CUPRI. See Verdigris. RUBIGO FERRI. See Ferri subcarbonas.

RUBI NUS. (From ruber, red: so named from its colour.) A carbuncle. See Anthrax.
RUBINUS VERUS. See Anthrax.

RUBULI. (From rubus, a blackberry or raspberry.)
The specific name in Good's Nosology of the yaws.

RU'BUS. (From ruber, red: so called from its red fruit.) The name of a genus of plants in the Linnaan system. Class, Icosandria; Order, Polygynia.

Rubus Arcticus. The systematic name of the shrubby strawberry. Rubus—foliis alternatis, caule inermi uniflora. The berries, Bacca norlandica, are recommended by Linnaus as possessing antiseptic, refrigerant, and antiscorbuite qualities.

frigerant, and antiscorbutic qualities.

RUBUS CÆSIUS. The systematic name of the dewberry plant, the fruit of which resembles the blackberry

in appearance and qualities.

Rubus Chamamorus; Chamarubus foliis ribis cloudberry-tree. Chamamorus; Chamarubus foliis ribis Anglico; Rubus palustris humilis; Vaccinium Lancas-Anglico; Rubus palustris humilis; Vaccinium Lancas-trense; Rubus alpinus humilis Anglicus. Cloudberries and knotherries. The ripe fruit of this plant, Rubus—folius simplicibus lobatis, caule interno unifloro, of Linnæus, is prepared into a jam; and is recommended to allay thirst, &c. in fevers, phthisical diseases, hæ-moptysis, &c. As an antiscorbutic, it is said to excel the scurvy-grass and other vegetables of that tribe in common use. common use.

RUBUS FRUTICOSUS. The systematic name of the common bramble, which affords blackberries. The berries are eaten in abundance by children, and are wholesome and gently aperient. Too large quantities, wholesome and gently aperient. however, when the stomach is weak, produce vomit

RUM RUS

ing and great distention of the belly, from flatus. See | ter-dock.

Fruits, summer.

RUBUS ID MUS. The systematic name of the raspberry. Batinon; Moron. Rubus—foliis quinato-pin-natis ternatisque, caule aculeato, petiolis canaliculatis, of Linnæus. The fruit of this plant has a pleasant sweet taste, accompanied with a peculiar grateful fla-vour, on account of which it is chiefly valued. Its virtues consist in allaying heat and thirst, and promotfrom the juice is directed for officinal use.

Ruft Filula. Rufus's pills. A compound very similar to the aloctic pills with myrrh. See Pilula

ees cum myrrha. RUFUS, the Ephesian, a physician and anatomist of considerable eminence in the reign of Trajan, esteemed by Galen one of the most able of his predecessors. He traced the origin of the nerves in the brain by dissecting brutes, and considered some of them as contributing to motion, others to sensation. He even observed the capsule of the crystalline lens in the eye He considered the heart as the seat of life, and of the animal heat, and as the origin of the pulse, which he animal heat, and as the origin of the pulse, which he ascribed to the spirit of its left ventricle and of the arteries. There is a very respectable treatise by him on the Diseases of the Urinary Organs, and the Metbod of curing them. He also wrote a good work on Purgative Medicines; and a little treatise on the Names given by the Greeks to the different Parts of the Body. Galen affirms also, that Rufus was the author of an Essay on the Materia Medica, in verse; and Suidas mentions others on the Atra bilis, &c., but these are all lost.

all lost.

RUGOSUS. Rugged. A term applied to a leaf, when the veins are tighter than the surface between them, causing the latter to swell into little income them. qualities, as the various species of sage. The seeds of

the Lithospermum arvense are rugosc

RUM. A spirituous liquor, well known, the produce of the sugar-cane.

RU'MEX. (Rumez, icis. m.; a sort of pike, spear, or halberd, which the shape of the leaves in various species much resembles.) The name of a genus of plants is the Lipuor and the contraction of the contraction in the Linnean system. Class, Hexandria; Order,

In the Linnean system. Class, Hexandria; Order, Trigynia. The dock.

RUMEX ACETOSA. The systematic name of the common sorrel. Acetosa; Acetosa vulgaris; Acetosa pratensis; Acetosa arvensis. Sorrel; sour-dock. Rumex—foliis oblongis sagittatis, floribus disciis, of Linneus. The leaves of this plant are sour, but not the most which is butter. It grows in the most which is butter. the root, which is bitter. It grows in the meadows and common fields.

RUMEX ACUTUS. The systematic name of the sharppointed wild-dock. Oxylapathum; Lapathum. Rumex—floribus hermaphroditis; valvulis dentatis gramiferis, folis cordato oblongis acuminatis, of Linneus. The decoction of the root of this plant is used
in Germany to cure the itch; and it appears to have
been used in the time of Dioscorides, in the cure of
leprous and impetiginous affections, both alone and
boiled with vincent.

boiled with vinegar.

RUMEX-ALPINUS. The systematic name of the plant which affords the monk's rhubarb. See Rumex pa-

RUMEX AQUATICUS. See Rumex hydrolapathum.

["RUMEX BRITANNICA. The common American water-dock, which grows in wet, boggy soils, and upon the margin of ditches, is a moderately stimulating and astringent plant. It is esteemed by many country practitioners as a local application to indolent and the production of the state of the s try practitioners as a local application to indolent and ill-conditioned ulcers. A strong decoction of the root is usually employed as a wash in these cases. Sometimes an ointment, formed by simmering the root in hog's lard, is beneficially applied in herpes. The use of this plant, according to Colden, was learned from the Indians."—Big. Mat. Med. A.]

Rumex crisrus. The systematic name of the crispleaved dock.

leaved dock.

RUMEX HYDROLAPATHUM. The systematic name of the water-dock. Hydrolapathum; Rumex aquaticus; Herba Britannica; Lapathum aquaticum. The wa-

ter dock. Rumez-floribus hermaphroditis, valvulis integris graniferis, foliis lanceolatis, of Linnæus. The leaves of this plant manifest considerable acidity, The leaves of this plant manifest considerable acidity, and are said to possess a laxative quality. The root is strongly adstringent, and has been much employed, both externally and internally, for the cure of some diseases of the skin, as scurry, lepra, lichen, &c. The root powdered is said to be an excellent dentifrice.

["Rumex obtusifolius. This species of dock is a foreign plant, naturalized as a weed in the cultivated grounds in this country. The root is bitterish and astringent. A decoction, taken internally, is laxative. Externally it is applied for the cure of ulcers and culta-

Externally it is applied for the cure of ulcers and cuta-

Externally it is applied for the cure of ulcers and cutaneous diseases, and sometimes with very good effect. The Rumex crispus, or curled dock, another important weed, resembles this in its qualities, and, in the form of ointment or decoction, is found to cure mild cases of psora and other eruptions."—Big. Mat. Med. A.]

RUMEX PATIENTIA. The systematic name of the garden patience. Rhabarbarum monachorum; Hippolapathum; Patientia. Monk's rhubarb. The root of this plant, and that of the Rumex alpinus, according to Professor Murray, is supposed to possess the virtues of rhubarb, but in an inferior degree. It is obviously more adstringent than rhubarb, but comes very viously more adstringent than rhubarb, but comes very

far short of its purgative virtue.

RUMEX SANGUINEUS. The systematic name of the bloody dock, the root of which has an austere and adstringent taste, and is sometimes given by the vulgar in the cure of dysentery.

RUMEX SCUTATUS. The systematic name of the

Rumex scutatus. The systematic name of the French sorrel, sometimes called acctosa rotundifolia, in the shops. Acctosa romana; Acctosa rotundifolia hortensis. Roman, or garden sorrel. Rumex—foliis cordato-hastatis, ramis divergentibus, floribus hermaphroditis, of Linnæus. It is common in our gardens, and in many places is known by the culinary name of Green-sauce. Its virtues are similar to those of common sorrel. See Rumex acctosa.

RUNCINATUS. Runcinate: applied to leaves which are shaped like the tooth of a lion: that is, cut into several transverse, acute segments, pointing backwards; as in Leontodon tarazacum, called from the shape of its leaf, dens de iion, and hence Dandelion.

shape of its leaf, dens de ilon, and hence Dandelion.

Rush, sweet. See Andropogon schananthus, and

RUSSELL, ALEXANDER, was a native of Edinburgh, where he received his medical education, and afterward became physician to the English factory at Aleppo, where he resided several years. He soon obtained a proud pre-eminence above all the practitioners there, and was consulted by persons of every description. The pacha particularly distinguished him by his tion. The pacha particularly distinguished him by his friendship, and sought his advice on every act of importance. In 1755, he published his "Natural History of Aleppo," a valuable and interesting work, containing especially some important observations relative to the Plague. On his return to England four years after, he settled in London, and was elected physician to St. Thomas's hospital, which office he retained till his death in 1770. He presented several valuable communications to the Royal Society, as also to the Medical Society.

RUSSELL, PATRICK, was brother of the preceding, and his successor as physician to the English factory at Aleppo. He published a copious treatise on the Piague, having had ample opportunities of treating that disease during 1760, and the two following years. In this work he has fully discussed the important subject of Quarantine. Lazarettors, and the Police to be of Quarantine, Lazarettoes, and the Police to be adopted in times of Pestilence. He likewise gave to the public a new edition of his brother's work on a

very enlarged scale.

Russia ashes. The impure potassa, as imported from Russia.

Rust. A carbonate of iron.
RUTA. (From ρυω; to preserve, because it preserves health.) 1. The name of a genus of plants in the Linnwan system. Class, Decandria; Order, Mo-

nogynia.
2. The pharmacopæial name of the common rue.

See Ruta graveolens.

RUTA GRAVEOLENS. The systematic name of the common rue. Ruta-foliis decompositis, foribus lateratibus quadrifidis, of Linnaus. Rue has a strong ungrateful smell, and a bitter, hot, penetrating taste; the leaves are so acrid, that by much handling they have been known to irritate and inflame the skin; and the plant, in its natural or uncultivated state, is said to possess these sensible qualities still more powerfully. The imaginary quality of the rue, in resisting and expelling contagion, is now disregarded. It is doubtless a powerful stimulant, and is considered, like other medicines of the feetid kind, as possessing attenuating, deobstruent, and antispasmodic powers. In the former London Pharmacopæia it was directed in the form of an extract; and was also an ingredient in the pulvis e myrrha comp., but these are now omitted. The dose of the leaves is from fifteen grains to two scruples.

RUTA MURARIA. See Asplenium ruta muraria, RUTIDO'SIS. A corrugation and subsiding of the cornea of the eye. The species are,

1. Rutidosis, from a wound or puncture penetrating the cornea.

2. Rutidosis, from a fistula penetrating the cornea. 3. Rutidosis, from a deficiency of the aqueous hu-mour, which bappens from old age, fevers, great and continued evacuations, and in extreme dryness of the

4. Rutidosis, of dead persons, when the aqueous the Manners of the German Inhabitants of Pennsyl- humour exhales through the cornea, and no fresh hu-

mour is secreted; so that the cornea becomes obscure | really before known, which led him into several con-

and collapsed: this is a most certain sign of death.

RUTILE. An ore of titanium.

RUTULA. (From ruta, rue.) A small species of

RUYSCH, FORDERICK, was born at the Hague, in 1638. Aftergoing through the preliminary studies with great zeal, he graduated at Leyden in 1664, and then settled in his native city. In the following year he published his treatise on the lacteal and lymphatic vessels; in consequence of which he was invited to the chair of anatomy at Amsterdam. From that period his attention was chiefly devoted to anatomical researches, both human and comparative; and he con-tributed materially to the improvement of the art of in-jecting, for the purpose of demonstrating minute structure, and preserving the natural appearance of parts. His museum became ultimately the most magnificent that any private individual had ever accumulated; and being at length purchased by the czar Peter for thirty thousand florins, he immediately set about a new collection. He appears not to have paid sufficient at-tention to inform himself of the writings of others, whence he sometimes arrogated to himself what was

troversies; but his indefatigable researches in anatomy were certainly rewarded with many discoveries. In 1685, he was appointed professor of physic, and re-ceived subsequently several marks of distinction, as well in his own as from foreign countries. In 1728, he had the misfortune to break his thigh by a fall in his chamber, and the remainder of his life, for about three years, was chiefly occupied in proceeding with his new museum, in which his youngest daughter assisted him. Besides his controversial tracts, he published several other works, chiefly anatomical; "Observationum Anat. Chirurg. Centuria;" twelve essays under the title of "Thesaurus Anatomicus," at different periods, the last containing Remarks on the Anatomy of Vegetables; a "Thesaurus Animalium," with plates; three decades of "Adversaria Anat. Chirurg. Medica," &c.

RUYSCHIANA TUNICA. The internal surface of the choroid membrane of the human eye, which this celebrated anatomist imagined was a distinct lamina from

the external surface.

SABULOUS. (Sabulosis; from sabulum, finegravel) Gritty, sandy. Applied to the calcareous matter in

SABU'RRA. Dirt, sordes, filth. Foulness of the stomach, of which authors mention several kinds, as the acid, the bitter, the empyreumatic, the insipid, the

putrid.

SACCATED. (Saccatus, encysted.) Encysted or contained in a bay-like membrane, applied to tumours, &c. See Ascites saccatus.

SACCHARI ACIDUM. See Mucic acid.

SA'CCHARUM. (Σακχαρον, from sachar, Arabian.) 1. The name of a genus of plants in the Linnean system. Class, Triandria; Order, Digynia. The sugarcane.

The sugar-cane.

2. The sweet substance called sugar. See Saccharum officinale.

See Acer saccharinum. SACCHARUM ACERNUM.

SACCHARUM ALBUM. Refined sugar.

SACCHARUM ALUMINIS. Alum mixed with dragon's blood and dried.

blood and dried.

Saccharum canadense. See Acer pseudo platanus.

Saccharum canadense. Sugar-candy.

Saccharum non furificatum. Brown sugar.

Saccharum officinale. (Arundo saccharifera of Sloane. The systematic name of the cane from which sugar is obtained. Suchar; Succhar; Sutter; Zuchar; Zucaro; Zazar of the Arabiaus. Σακχαρ η σακχαρον, of the Greeks.) Sugar is prepared in the West and East Indies from the expressed juice of this plant boiled with the addition of quick-lime or common vegetable alkali. It may be extracted also from a vegetable alkali. It may be extracted also from a number of plants, as the maple, birch, wheat, corn, beet-root, skirret, parsnips, and dried grapes, &c. by digesting in alkohol. The alkohol dissolves the sugar, and leaves the extractive matter untouched, which falls to the bottom. It may be taken into the stomach falls to the bottom. It may be taken into the stomach in very large quantities, without producing any bad consequences, although proofs are not wanting of its mischievous effects, by relaxing the stomach, and thus inducing disease. It is much used in pharmacy, as it forms the basis of syrups, lozenges, and other preparations. It is very useful as a medicine, although it cannot be considered to possess much power, to favour the solution or suspension of resins, oils, &c. in water, and is given as a purgative for infants. Dr. Cullen classes it with the attenuantia, and Bergius states it to

be saponacea, edulcorans, relaxans, pectoralis, vulne-raria, antiseptica, nutriens. In catarrhal affections, both sugar and honey are frequently employed: it has also been advantageously used in calculous complaints; and from its known power in preserving animal and vegetable substances from putrefaction, it has been given with a view to its antiseptic effects. Sugar candy, by dissolving slowly in the mouth, is well suited to relieve tickling coughs and hoarseness. Sugar is every where the basis of that which is called sweetness. Its presence is previously necessary in order to the taking place of vinous fermentation. Its extraction from plants, which afford it in the greatest abundance, and its refinement for the common uses of life, in a pure state, are among the most important of the chemical manufactures.

The following is the mode of its manufacture in the The following is the mode of its manufacture in the West Indies: The plants are cultivated in rows, on fields enriched by such manures as can most easily be procured, and tilled with the plough. They are annually cut. The cuttings are carried to the mill. They are cut into short pieces, and arranged in small bundles. The mill is wrought by water, wind, or cattle. The parts which act on the canes are upright cylinders. Between these the canes are inserted, compressed till all their juice is obtained from them, and themselves. all their juice is obtained from them, and themselves, sometimes, even reduced to powder. One of these mills, of the best construction, bruises canes to such a quantity as to afford, in one day, 10,000 gallons of juice, when wrought with only ten mules. The expressed juice is received into a leaden bed. It is thence conveyed into a vessel called the receiver. The juice is found to consist of eight parts of pure water, one part of sugar, one part of oil and gummy mucilage. From the greener parts of the canes there is apt to be at times derived an acid juice, which tends to bring the whole unseasonably into a state of acid fermentation. Fragments of the ligneous part of the cane, some portions of mud or dirt which unavoidably remain on the canes, and a blackish substance called the crust, which coated the canes at the joints, are also apt to enter into conta-minating mixture with the juice. From the receiver the juice is conducted along a wooden gutter lined with lead, to the boiling-house. In the boiling-house it is received into copper pans or caldrons, which have the name of clarifiers. Of these clarifiers the number and the capacity must be in proportion to the quantity of canes, and the extent of the sugar plantation on which SAC

the receiver fills the clarifiers with fresh liquor. Lime in powder is added in order to take up the oxalic acid, and the carbonaceous matters which are mingled with the juice. The lime also in the new salts, into the composition of which it now enters, adds itself to the sugar, as a part of that which is to be obtained from the process. The lime is to be put in the proportion of somewhat less than a pint of lime to every hundred gallons of liquor. When it is in too great quantities, howmatter. Some persons employ alkaline ashes, as preferable to lime, for the purpose of extracting the extraneous matter; but it is highly probable that lime, judiciously used, might answer better than any other substance wha/soever. The liquor is now to be heated almost to eballition. The heat dissolves the mechanical union, and thus favours the chemical changes in its different parts. When the proper heat appears from a rising scum on the surface of the liquor to have been produced, the fire is then extinguished by the applica-tion of the damper. In this state of the liquor, the greater part of the impurities, being different in specific gravity from the pure saccharine solution, and being also of such a nature as to yield more readily to the chemical action of heat, are brought up to the surface in a scum. After this scum has been sufficiently formed on the cooling liquor, this liquor is carefully drawn off, either by a syphon, which raises a pure stream through the scum, or by a cock drawing the liquor at the bottom from under the scum. The scum, in either case, sinks down unbroken, as the liquor flows; and is now, by cooling, of such tenacity, as not to tend to any intermixture with the liquor. The liquor drawn, after this purification from the boiler, is received into a gutter or channel, by which it is conveyed to the grand copper, or evaporating boiler. If made from good canes, and properly clarified, it will now ap-pear almost transparent. In this copper the liquor is heated to actual ebullition. The scum raised to the surface by the boiling is skimmed off as it rises. chullition is continued till there be a considerable di-minution in the quantity of the liquor. The liquor now appears nearly of the colour of Madeira wine. It is at last transferred into a second and smaller copper. An addition of lime-water is here made, both to dilute the thickening liquor, to detach the super-abundant acid, and to favour the formation of the sugar. If the liquor be now in its proper state, the scum rises in large bubbles, with very little discoloration. The skimming and the evaporation together produce a considerable dimi-nution in the quantity of the liquor. It is then trans-ferred into another smaller boiler. In this last boiler, the evaporation is renewed, and continued till the liquor is brought to that degree of thickness at which it appears fit to be finally cooled. In the cooler, (a shallow wooden vessel of considerable length and wideness commonly of such a size as to contain a hogshead of sugar,) the sugar, as it cools, granulates, or runs into an imperfect crystallization, by which it is separated from the molasses, a mixed saccharine matter too impure to be capable even of this imperfect crystallization. determine whether the liquor be fit to be taken from the last boiler to be finally cooled, it is necessary to take out a portion from the boiler, and try separately. whether it does not separate into granulated sugar and melasses. From the cooler, the sugar is removed to the curing-house. This is a spacious, airy building. It is provided with a capacious eistern for the reception of melasses, and over the cistern is erected a frame of strong joist-work, unfilled and uncovered. Empty hogsheads open at the head, bored at the bottom with a few holes, and having a stalk of plantain leaf thrust through each of the holes, while it rises at the same time through the inside of the hogshead, are disposed upon the frames. The mass of the saccharine matter from the coolers is put into these hogsheads. The melasses drip into the cistern through the spongy plantain stalks in the holes. Within the space of three weeks the melasses are sufficiently drained off, and the sugar remains dry. By this process it is at last brought into the state of what is called muscovado or raw sugar. This is the general process in the British West Indies. In this state our West India sugar is imported into Britain. The formation of loaves of white sugar is a subsequent process. In the French West India isles it has long been customary to perform the last part of this train of processes in a manner somewhat different,

and which affords the sugar in a state of greater purity. This preparation, taking the sugar from the cooler, then puts it, not into hogsheads with holes in the bottom as above, but into conical pots, each of which has at its bottom a hole half an inch in diameter, that is, in the commencement of the process, stopped with a plug. After remaining sometime in the pot, the sugar becomes perfectly cool and fixed. The plug is then removed out of the hole; the pot is placed over a large jar, and the melasses are suffered to drip away from it. After as much of the melasses as will easily run off has been thus drained away, the surface of the sugar in the jar is covered with a stratum of fine clay, and water is poured upon the clay. The water oozing gently through the pores of the clay, pervades the whole mass of sugar redissolves the melasses, still remaining in it, with some parts of the sugar itself, and carrying these off by the holes in the bottom of the pot, renders that which resists the solution much purer than the muscovado sugar made in the English way. The sugar prepared in this manner is called clayed sugar. It is sold for a higher price in the European market than the muscovado sugar; but there is a lose of sugar in the process by claying, which deters the British planters from adopting this practice so generally as do the French.

The raw sugars are still contaminated and debased by a mixture of acid, carbonaceous matter, oil, and colouring resin. To free them from these is the basiness of the European sugar-bakers. A new solution; clarification with alkaline substances fitted to attract away the oil, acid, and other contaminating matters; slow evaporation; and a final cooling in suitable moulds, are the processes which at last produce loaves

of white sugar.

The melasses being nothing else but a very impure refuse of the sugar from which they drip, are susceptible of being employed in a new ebullition, by which a second quantity of sugar may be obtained from them The remainder of the melasses is employed to yield rum by distillation. In rum, alkohol is mixed with oil, water, oxalic acid, and a mixture of empyreumatic matter. The French prepare, from the mixture of melasses with water, a species of wine of good quality. In its preparation, the solution is brought into fermentation, then passed through strainers to purify it, then put in casks; after clearing itself in these, transferred into others, in which it is to be preserved for use. The ratio of these processes is extremely beautiful; they are all directed to purify the sugar from contaminating mixtures, and to reduce it into that state of dryness or crystallization, in which it is susceptible of being the most conveniently preserved for agreeable use. The heat in general acts both mechanically to effect a sufficient dissolution of the aggregation of the parts of the cane juice, and chemically to produce in it new combinations into which caloric must enter as an ingredient. The first gentle heat is intended chiefly to operate with the mechanical influence, raising to the surface impurities, which are more easily removed by skimming, than by any other means; a gentle, not a violent heat, is in this instance employed, because a violent heat would produce empyreumatic salts, the production of which is to be carefully avoided. A boiling heat is, in the conti-nuation of the processes, made use of, because, after the first impurities have been skimmed off, contaminating empyreumatic salts are less readily formed, because a boiling heat is necessary to effect the complete developement of the saccharine matter, and because the gradual concentration of the sugar is, by such a heat, to be best accomplished. Lime is employed, because it has a stronger affinity than sugar with all the contaminating matters, and particularly because it attracts into a neutral combination that excess of oxalic acids which is apt to exist in the saccharine solution. Skimming removes the new salts, which the most easily assume a solid form. The drippings carries away a mix-ture of water, oil, earth, and sugar, from the crystallized sugar: for, in all our crystallizations, we can never per-form the process in the great way, with such nicety as to preserve it free from an inequality of proportions that must necessarily occasion a residue. Repeated solution, clarification, evaporation, are requisite to produce pure white sugar from the brown and raw sugars; because the complete purification of this matter from acid and colouring matter, is an operation of great difficulty, and not to be finally completed without proSAC SAC

cesses which are longer than can be conveniently performed, at the first, upon the sugar plantation. From vegetables of European growth, sugar is not to be easily obtained, unless the process of germination be first produced in them; or unless they have been pene-trated by intense frost. Germination, or thorough freezing, developes sugar into all vegetables in which its principles of hydrogen and carbon, with a small proportion of oxygen, exist in any considerable plenty. It is not improbable, but that if penetration by a freezing cold could be commanded at pleasure with sufficient cheapness, it would enable us to obtain saccharine matter in a large proportion, from a variety of substances from which even generation does not yield a sufficient quantity. In the beet, and some other European vegequantity. In the beet, and some other European vegetables, sugar is naturally formed by the functions of vegetation to perfect combination. From these the sugar is obtained by rasping down the vegetable, extracting by water its saccharine juice, evaporating the water charged with the juice to the consistency of syrup, clarifying, purifying, and crystallizing it, just in the same manner as sugar from the sugar-cane. It is afforded by the maple, the birch, wheat, and Turkey corn. Margraaf obtained it from the roots of beet, red beet, skirrit, parsnips, and dried grapes.

In Canada, the inhabitants extract sugar from the maple. At the commencement of spring, they heap snow in the evening at the foot of the tree, in which they previously make apertures for the passage of the

they previously make apertures for the passage of the returning sap. Two hundred pounds of this juice afford, by evaporation, fifteen of a brownish sugar. The quantity prepared annually amounts to fifteen thousand weight.

The Indians likewise extract sugar from the pith of

the bamboo.

The beet has lately been much cultivated in Germany, for the purpose of extracting sugar from its root. For this the roots are taken up in autumn, washed clean, wiped, sliced lengthwise, strung on threads, and hung up to dry. From these the sugar is extracted by mang up to dry. From these the sugar is extracted by maceration in a small quantity of water; drawing off this upon fresh roots, and adding fresh water to the fresh roots, which is again to be employed the same way, so as to get out all their sugar, and saturate the water as much as possible with it. This water is to be strained and boiled down for the sugar.

Some merely express the juice from the fresh roots, and boil this down; others boil the roots; but the sugar extracted in either of these ways is not equal in quality

to the first.

Professor Lampadius obtained from 110 lbs. of the roots, 4 lbs. of well-grained white powder sugar; and the residuums afforded 7 pints of a spirit resembling rum. Achard says, that about a ton of roots produced him 100 lbs. of raw sugar, which gave 55 lbs. of refined

sugar, and 25 lbs. of treacle.

Sugar is very soluble in water, and is a good medium for uniting that fluid with oily matters. It is much used for domestic purposes, and appears on the whole to be a valuable and wholesome article of food, the uses of which are most probably restricted by its high

It appears that sugar has the property of rendering

some of the earths soluble in water.

The union of sugar with the alkalies has been long known; but this is rendered more strikingly evident, by carbonated potassa or soda, for instance, decomposing the solutions of lime and strontia in sugar, by

double affinity.

In making solutions of unrefined sugar for culinary purposes, a gray-coloured substance is found frequently precipitated. It is probable that this proceeds from a superabundance of lime which has been used in clarifying the juice of the sugar-cane at the plantations abroad. Sugar with this imperfection is known among the refiners of this article by the name of weak. And it is justly termed so, the precipitated matter being nothing but lime which has attracted carbonic acid from the sugar (of which there is a great probability), or from the air of the atmosphere. A bottle, in which Dr. Ure kept a solution of lime in sugar for at least four years, closely corked, was entirely incrusted with a yellowish-coloured matter, which on examination was found to be entirely carbonate of hime.

Kirchoff, an ingenious Russian chemist, accidentally discovered, that starch is convertible into sugar, by being boiled for some time with a very dilute sulphuric

Braconnot has recently extended our views concerning the artificial production of sugar and gum. Sulphuric acid (sp. gr. 1.827) mixed with well-dried elmdust, became very hot, and on being diluted with water, and neutralized with chalk, afforded a liquor which became gummy on evaporation. Shreds of linen, triturated in a glass mortar, with sulphuric acid, yield a similar gum. Nitric acid has a similar power. If the gummy matter from linen be boiled for some time with dilute sulphuric acid, we obtain a crystaltime with dilute sulphuric acid, we obtain a crystallizable sugar, and an acid, which Braconnot calls the vegeto-sulphuric acid. The conversion of wood also into sugar, will no doubt appear remarkable; and when persons not familiarized with chemical speculations are told, that a pound weight of rags can be con-verted into more than a pound weight of sugar, they

may regard the statement as a piece of pleasantry, though nothing, says Braconnot, can be more real.

Silk is also convertible into gum by sulphuric acid
Twelve grammes of glue, reduced to powder, were digested with a double weight of concentrated sulphuric acid without artificial heat. In twenty hours the light was not reach coloured than if mere water the liquid was not more coloured than if mere water had been employed. A decilitre of water was then added, and the whole was boiled for five hours, with renewal of the water, from time to time, as it wasted. It was next cliuted, saturated with chalk, filtered, and It was next chinted, saturated with chark, intered, and evaporated to a syrupy consistence, and left in repose for a month. In this period a number of granular crystals had separated, which adhered pretty strongly to the bottom of the vessel, and had a very decided saccharine taste. This sugar crystallizes much more easily than cane sugar. The crystals are gritty under the teeth, like sugarcandy; and in the form of flatthe teeth, like sugarcandy; and in the form of nat-tened prisms or tabular groupes. Its taste is nearly as saccharine as grape sugar; its solubility in water scarcely exceeds that of sugar of milk. Boiling alko-hol, even when diluted, has no action on this sugar. By distillation it yields ammonia, indicating the pre-sence of azote. This sugar combines intimately with nitric acid, without sensibly decomposing it, even with the assistance of heat, and there results a peculiar crystallized acid, to which the name nitro-saccharino has been given. Annales de Chimie, xii., or Tillock's Magazine, vols. lv. and lvi.

The varieties of sugar are; cane sug maple sugar,

liquid sugar of fruits, sugar of figs, sugar of grapes, starch sugar, the mushroom sugar of Bracon lot, man na, sugar of gelatin, sugar of honey, and sugar of

diabetes.

Sugar of grapes does not affect a peculiar form. It is deposited, from its alkoholic solution, in small grains, which have little consistence, are grouped together, which have little consistence, are grouped together, and which constitute tubercles, similar to those of cauliflowers. When put in the mouth, it produces at first a sensation of coolness, to which succeeds a saccharine taste, not very strong. Hence to sweeten to an equal degree the same quantity of water, we must employ two and a half times as ranch sugar of grapes as of that of the cane. In other respects, it possesses all the properties of cane sugar. Its extraction is very easy. The expressed juice of the grapes is composed easy. The expressed juice of the grapes is composed of water, sugar, mucilage, bitartrate of potassa, tartrate of lime, and a small quantity of other saline matters. We pour into it an excess of chalk in powder, or rather of pounded marble. There results, especially on agitation, an effervescence, due to the unsaturated tartaric acid. The liquor is then clarified with whites of eggs or blood. It is next evaluated in copper pans, till it marks a density of 1.32 at the boiling temperature. It is now allowed to cool. At the end of some days, it concretes into a crystalline mass, which, when drained, washed with a little cold water, and strongly compressed, constitutes sugar. compressed, constitutes sugar.

compressed, constitutes sugar.

In the south of France, where this operation was some years back carried on on the great scale, to prevent fermentation of the must, there was added to this a little sulphate of lime, or it was placed in tuns, in which sulphur matches had been previously made to burn. The oxygen of the small quantity of air left in the tuns being thus abstracted by the sulphurous acid, fermentation did not take place. By this means the must can be preserved a considerable time; whereas, in the ordinary way, it would lose its saccharine. as, in the ordinary way, it would lose its saccharine taste at the end of a few days and become vinous

SAC SAC

Must thus treated, is said to be muted. The syrup was evaporated to the density of only 1.285.—Proust. Ann. de Chimie, lvii. 131.; and the Collection of Memoirs published by Parmentier in 1813.

It is this species of sugar which is obtained from

starch and woody fibre by the action of dilute sul-

Sugar of diabetes has sometimes the sweetening force of sugar of grapes; occasionally much less.

Braconnot's mushroom sugar is much less sweet than that of the cane. It crystallizes with remarkable facility, forming long quadrilateral prisms with square bases. It yields alkohol by fermentation.

All honeys contain two species of sugar; one similar to sugar of the grape, another like the uncrystal-lizable sugar of the cane (melasses). These combined and mingled in different proportions with an odorant matter, constitute the honeys of good quality. Those of inferior quality contain, besides, a certain quantity of wax and acid: the boneys of Britanny contain even an animal secretion (convain) to which they owe their putrescent quality. A slight washing with a little alkohol separates the uncrystallizable sugar, and leaves the other, which may be purified by washing with a

very little more alkohol.

"The relation," says Dr. Prout, "which exists between urea and sugar, seems to explain in a satisfactory manner the phenomena of diabetes, which may be considered as a deprayed secretion of sugar. The weight of the atom of sugar, is just half that of the weight of the atom of urea; the absolute quantity of hydrogen in a given weight of both is equal; while the absolute quantities of carbon and oxygen in a given weight of sugar, are precisely twice those of urea."

The constituents of these two bodies and lithic acid,

are thus expressed by that ingenious philosopher;-

ELEMENTS	UREA.			SUGAR.			LITHIC ACID.		
	No.	Per. Atom.	Per Cent.	No.	Per Atom.	Per Cent.	No.	Per Atom.	Per Cent
Hydrogen Carbon . Oxygen . Azote .	2 1 1 1 1	2.5 7.5 10.0 17.5	6.66 19.99 26.66 46.66	1 1 1	1.25 7.50 10.00	6.66 39.99 53.33	1 2 1 1	1.25 15.00 10.00 17.50	2.85 34.28 22.85 40.00
	5	37.5	100.10	3	18.75	100.10	5	43.75	100.10

The above compounds appear to be formed by the union of more simple compounds; as sugar, of carbon and water; urea, of carburetted hydrogen and nitrous oxide; lithic acid, of cyanogen and water, &c.; whence it is inferred, that their artificial formation falls within the limits of chemical operations.

Saccharum officinarum. The systematic name

in some pharmacopæias of the sugar-cane. See Sac-

SACCHARUM PURIFICATUM. Double refined, or loaf-

Sugar. See Saccharum.
Saccharum saturni. See Plumbi acetas.
SACCHO-LACTIC. So called, because it is sugar prepared from milk.

Saccho-lactic acid. Acidum saccholacticum. See

SACCHOLATE. Saccholas. A salt formed by the combination of the saccholactic acid with salifiable bases, as saccholate of iron, saccholate of ammo-

SACCULUS. (Dim. of saccus, a bag.) A little

SACCULUS ADIPOSUS. The bursæ mucosæ of the joints.

SACCULUS CHYLIFERUS. See Receptaculum chyli.

SACCULUS CORDIS. The pericardium.
SACCULUS LACHRYMALIS. See Saccus lachrymalis.

SA'CCUS. A bag.

SACCUS LACHRYMALIS. The lachrymal sac is situated in the internal canthus of the eye, behind the lachrymal caruncle, in a cavity formed by the os unguis. It receives the tears from the puncta lachrymalia, and conveys them into the ductus lachrymalis.

SACER. (From sagur, secret, Heb.) Sacred. Applied to some diseases which were supposed to be immediately inflicted from heaven; as sacer morbus, the epilepsy, sacer ignis, erysipelas, &c. A bone is called the os sacrum, because it was once offered in sacrifices. Sacer also means belonging to the os

SACK. A wine used by our ancestors, which some have taken to be Rhenish, and others Canary wine. Probably it was what is called dry mountain, or some Spanish wine of that sort. Howel, in his French and Spanish wine of that sort. Howel, in his French and English Dictionary, 1650, translates sack by the words vin d'Espagne. Vin. sec.

SACLACTATE. A combination of saccholactic acid with a salifiable basis.

SACLACTIC ACID. See Mucic acid.

SACRA HERBA. Common vervain.

SACRA TINCTURA. Made of aloes, canella, alba, and mountain wine

SACRAL. Of or belonging to the sacrum; as sacraarteries, veins, nerves, &c.
SA'URO. Words compounded of this belong to the

sacrum.

SACRO-COCCYGAIUS. A muscle arising from the sacrum, and inserted into the os coccygis.

Sacro-Lumbalis. Sacro-lumbaris, of authors. Lumbo-costo trachelien of Dumas. A long muscle, thicker and broader below than above, and extending from the os sacrum to the lower part of the neck, under the serrati postici rhomboideus, trapezius, and latissimus dorsi. It arises in common with the longissimus dorsi, tendinous without, and fleshy within, from the posterior part of the os sacrum; from the posterior edge of the spine of the ilium; from all the spinous process; and from near the roots of the transverse processes of the lumbar vertebræ. At the bottom of the back it separates from the longissimus dorsi, with which it had before formed, as it were, only one mus cle, and ascending obliquely outwards, gradually di minishes in thickness, and terminates above in a very narrow point. From the place where it quits the longissimus dorsi, to that of its termination, we find it fleshy at its posterior, and tendinous at its anterior edge. This tendinous side sends off as many long and thin tendons as there are ribs. The lowermost of these tendons are broader, thicker, and shorter than those above; they are inserted into the inferior edge of each rib, where it begins to be curved forwards towards the sternum, excepting only the uppermost and last tendon, which ends in the posterior and inferior part of the transverse process of the last vertebra of the neck. From the upper part of the five, six, seven, eight, nine, ten, or eleven lower ribs, (for the number, though most commonly seven or eight, varies in different subjects,) arise as many thin bundles of fleshy fibres, which, after a very short progress, terminate in the inner side of this muscle, and have been named by Steno, musculi ad sacro lumbalem accessorii. Besides these we find the muscle sending off a fleshy slip from its upper part, which is inserted into the posterior and inferior part of the transverse processes of the five inferior vertebrae of the neck, by as many distinct tendons. This is generally described as a distinct muscle. Diemergenerally described as a distinct muscle. Diemer-broeck, and Douglas, and Albinus after him, call it cervicalis descendens. Winslow names it transver-salis collateralis colli. Morgagni considers it as an appendage to the sacro lumbalis. The uses of this muscle are to assist in erecting the trunk of the body, in turning it upon its axis or to one side, and in drawing the ribs downwards. By means of its upper slip, it serves to turn the neck obliquely backwards or to

SACRO-SCIATIC LIGAMENTS. The ligaments which | connect the ossa innominata with the os sacrum.

SA'CRUM. (So called from sacer, sacred; because it was formerly offered in sacrifices.) Os sacrum; Os basilare. The os sacrum derives its name from its Os basilare. The os sacrum derives its name from its being offered in sacrifice by the ancients, or perhaps being offered in sacrince by the ancients, or perhaps from its supporting the organs of generation, which they considered as sacred. In young subjects it is composed of five or six pieces, united by cartilage; but in more advanced age it becomes one bone, in which, however, we may still easily distinguish the marks of the former separation. Its shape has been sometimes compared to an irregular triangle; and sometimes and perhaps more properly to a pyramid. sometimes compared to an irregular triangle; and sometimes, and perhaps more properly, to a pyramid, flattened before and behind, with its basis placed towards the lumbar vertebræ, and its point terminating in the coccyx. We find it convex behind, and slightly concave before, with its inferior portion bent a little forwards. Its anterior surface is smooth, and affords four, and sometimes five transverse lines, of a colour different from the rest of the bone. These are the remains of the intermediate cartilages by which its several pieces were united in infancy. Its posterior convex surface has several prominences, the most remarkable of which are its spinous processes; these are convex surface has several prominences, the most remarkable of which are its spinous processes; these are usually three in number, and gradually become shorter, so that the third is not so long as the second, nor the second as the first. This arrangement enables us to sit with ease. Its transverse processes are formed into one oblong process, which becomes gradually smaller as it descends. At the superior part of the bone we observe two oblique processes, of a cylindrical shape, and somewhat concave, which are articulated with the last of the lumbar vertebre. At the base of each of last of the lumbar vertebræ. At the base of each of these oblique processes is a notch, which, with such another in the vertebra above it, forms a passage for the twenty-fourth spinal nerve. In viewing this bone, either before or behind, we observe four, and sometimes five holes on each side, situate at each extremity, of the transverse lines which mark the divisions of the bone. Of these holes, the anterior ones, and of these again the uppermost, are the largest, and afford a passage to the nerves. The posterior holes are smaller, covered with membranes, and destined for the same purpose as the former. Sometimes at the bottom of the bone there is only a notch, and sometimes there is a hole common to it and the os coccygis. The cavity between the body of this bone and its processes, for the lodgment of the spinal marrow, is triangular, and becomes smaller as it descends, till at length it termi-nates obliquely on each side at the lower part of the bone. Below the third division of the bone, however, the cavity is no longer completely bony, as in the rest of the spine, but is defended posteriorly only by a very strong membrane; hence a wound in this part may be attended with the most dangerous consequences. This bone is articulated above, with the last them are the spine of lumbar vertebra: laterally it is firmly united, by a broad irregular surface, to the ossa innominata, or hipbones: and below it is joined to the os coccygis. In women the os sacrum is usually shorter, broader and more curved than in men, by which means the cavity of the pelvis is more enlarged. SAFFLOWER. See Carthamus.

SAFFRON. See Crocus. Saffron, bastard. See Carthamus. Saffron, meadow. See Colchicum.

Saffron of steel. A red oxide of iron.

SAGAPE'NUM. (The name is derived from some eastern dialect.) Scrapinum. It is conjectured that this concrete gummi-resinous juice is the production of an oriental umbelliferous plant. Sagapenum is brought from Persia and Alexandria in large masses, externally yellowish, internally paler, and of a horny clearness. Its taste is hot and biting, its smell of the alliaceous and fœtid kind, and its virtues are similar to those which have been ascribed to asafortida, but weaker, and consequently it is less powerful in its effects.

SAGE. See Salvia.

Sage of Bethlehem. See Pulmonaria officinalis.

Sage of Jerusalem. See Pulmonaria officinalis.

Sage of virtue. See Salvia hortensis minor.

SAGENITE. Acicular rutile.

SAGITTAL. (Sagittalis; from sagitta, an arrow.)

Shaped like an arrow.

SAGITTAL SUTURE. Satura sagittalis, virgata, obelwa, rhabdoides. The suture which unites the two

parietal bones. It has been named sagittal, from its lying between the coronal and lambdoidal sutures, as

an arrow between the string and the bow.

SAGITTA'RIA. (So called from sagitta, an arrow, in allusion to the shape of the leaves in the original species and some others.) The name of a genus of plants in the Linnaran system. Class, Monacia; Order, Polyandria.

SAGITTARIA ALEXIPHARMICA. Malacca; Canna indica; Arundo indica. The systematic name of the plant cultivated with great care in the West Indies, for its root, which is supposed to be a remedy for the wounds of poisonous arrows. The root of this species, called radix malacea, is sometimes used medicinally.

SAGITTARIA SAGITTIFOLIA. The systematic name of the common arrow-head, the roots of which are es-

culent, but not very nutritious.

SAGITTATUS. (From sagittas, an arrow.) Arrow-shaped: applied to leaves, &c. which are triangular and hollowed out very much at the base; as the leaves of the Sagittaria sagittifolia.

SAGO. See Cycas circinalis.
SAGU. See Cycas circinalis.
SAHLITE. Malacholite. A sub-species of oblique edged augite, of a greenish colour, and found in Unst in Shetland, in Tiree, and Glentilt.

Saint Anthony's fire. See Erysipelas.
Saint Ignatius's bean. See Ignatia amara.
Saint James's wort. See Senecio jacobwa.
Saint John's wort. See Hypericum.
Saint Vitus's dance. See Chorea sancti viti.

SAL AUSINTHIL. See Potassæ subcarbonas.

SAL AUSINTHIL. See Potassæ subcarbonas.

SAL AUSINTHIL. See Oxalis acetocella.

Sal alembroth. A compound muriate of mercury

and ammonia.

SAL ALKALINUS FIXUS. See Alkali fixum.

SAL ALKALINES VOLATILIS. See Ammonia.
SAL AMMONIAC. (So called because it was found in Egypt, near the temple of Jupiter Ammon.) Murias ammoniac. A saline concrete formed by the combination of the muriatic acid with ammonia. This salt is

obtained from several sources.

1. It is found in places adjacent to volcanoes. It appears in the form of an efflorescence, or groupes of needles, separate or compacted together, generally of a yellow or red colour, and mixed with arsenic and orpiment; but no use is made of that which is procured orpiment; but no use is made of that which is procured in this way. This native sal ammoniac is distinguished by mineralogists, into, 1. Volcanic, which occurs in efforescences, imitative shapes, and crystallized in the vicinity of burning beds of coal, both in Scotland and England, at Solfaterra, Vesuvius, Ætna, &c. 2. Conchoidal, which occurs in angular pieces, it is said, along with sulphur, in beds of indurated clay, or clay-slate, in the country of Rucharia.

or clay-slate, in the country of Bucharia. 2. In Egypt it is made in great quantities from the soot of came?'s dung, which is burned at Cairo instead of wood. This soot is put into large round bottles, a foot and a half in diameter, and terminating in a neck two inches long. The bottles are filled up with this matter to within four inches of the neck. Each bottle holds about forty pounds of soot, and affords nearly six pounds of salt. The vessels are put into a furnace in the form of an oven, so that only the necks appear above. A fire of camel's dung is kindled beneath it, and continued for three days and three nights. On the second and the third days the salt is sublimated. The bottles are then broken, and the salt is taken out in cakes. These cakes, which are sent just as they have been taken out of the bottles in Egypt, are convex, and unequal on the one side; on the middle of this side they exhibit each a turbercle corresponding to the neck of the bottle in which it was prepared.

The lower side is concave, and both are sooty 3. In this country, sal ammoniac is likewise pre-pared in great quantities. The volatile alkali is ob-tained from soot, bones, and other substances known to contain it. To this the sulphuric acid is added, and the sulphate of ammonia so formed, is decomposed by muriate of soda, or common salt, through a double affinity. The liquor obtained in consequence of this decomposition contains sulphate of soda and muriate of ammonia. The first is crysatllized, and the second sublimated so as to form cakes, which are then exposed

to sale.

Aminomacal muriate has a poignant, acid, and urinous taste. Its crystals are in the form of long bexahedral pyramids; a number of them are sometimes united together in an acute angular direction, so as to exhibit the form of feathers. Rome de Lille thinks the crys tals of ammoniacal muriate to be octahedrons bundled together. This salt is sometimes, but not frequently, found in cubic crystals in the middle of the concave hollow part of the sublimated cakes. It possesses one singular physical property, a kind of ductility or elasticity, which causes it to yield under the hammer, or even the fingers, and makes it difficult to reduce to a powder. Muriate of ammonia is totally volatile, but a very strong fire is requisite to sublime it. It is liable to no alteration from air; it may be kept for a long time without suffering any change; it dissolves very readily in water. Six parts of cold water are sufficient to dissolve one of the salt. A considerable cold is produced as the solution takes place, and this cold is still keener when the salt is mixed with ice. This are tificial cold is happily applied to produce several phe-nomena, such as the congelation of water on certain occasions, the crystallization of certain salts, the fix-ation and preservation of certain liquids, naturally very subject to evaporation, &c.

SALICO RNIA. The name of a genus of plants in the Linna an system. Class, Monandria; Order, Monogynia.

SALICORNIA EUROP EA. The systematic name of the jointed glass-wort, which is gathered by the country people and sold for samphire. It forms a good pickle

with vinegar, and is little inferior to the samphire.

SALIFIABLE. Having the property of forming a salt. The alkalies, and those earths, and metallic oxides, which have the power of neutralizing acidity, entirely or in part, and producing salts, are called salifi-

able bases.

SALINE. (Salinus; from sal, salt.) Of a salt nature. The number of saline substances is very considerable; and they possess peculiar characters by which they are distinguished from other substances. These they are distinguished from other substances. characters are founded on certain properties, which, it must be confessed, are not accurately distinctive of their true nature. All such substances, however, as possess several of the four following properties, are considered several of the four following properties, are considered as saline: 1. A strong tendency to combination, or a very strong affinity of composition; 2. A greater or less degree of sapidity; 3. A greater or less degree of solubility in water; 4. Perfect incombustibility.

SALINUS. See Saline.

SALINUS. (See Valeriana celtica.

SALINUS. (See Valeriana celtica.

SALINUCA. See Valeriana celtica.

SALI'VA. (So called, a salino sapore, from its salt taste, or from oralog, spittle.) The fluid which is secreted by the salivary glands into the cavity of the mouth. The secretory organ is composed of three pair of salivary glands. 1. The parotid glands, which evacuate their saliva by means of the Stenonian duct, behind the middle dens molaris of the upper jaw. 2. The submaxillary glands, which pour out their saliva through the Warthonian ducts on each side of the fremulum of the tongue by a parrow osculum. 3 The nulum of the tongue by a narrow osculum. 3. The sublingual glands, situated between the internal surface of the maxilla and the tongue, which pour out their saliva through numerous Rivinian ducts at the

apex of the tongue. The saliva in the cavity of the mouth has mixed The saliva in the cavity of the mouth has mixed with it, I. The mucus of the mouth, which exhales from the labial and genal glands. 2. The roscid vapour, from the whole surface of the cavity of the mouth. The saliva is continually swallowed with or without masticated food, and some is also spit out. It has no colour nor smell; it is tasteless, although it contains a little salt, to which the nerves of the tongue are accustomed. tomed. Its specific gravity is somewhat greater than water. Its consistence is rather plastic and spumous, from the entangled atmospheric air. The quantity of twelve pounds is supposed to be secreted in twelve hours. During mastication and speaking, the secretion is augmented, from the mechanical pressure of the muscles upon the salivary glands. Those who are hungry secrete a great quantity, from the sight of agreeable food. It is imperfectly dissolved by water; somewhat coagulated by alkohol; and congealed with more difficulty than water. It is inspissated by a small dose, and dissolved in a large dose, of mineral acids. It is also soluble in carbonated alkali. Caustic alkali and quick-lime extract volatile alkali from saliva. It cor rodes copper and iron; and precipitates silver and lead from containing muriatic acid. It assists the spirituous fermentation of farinaceous substances; hence, barbarousnations prepare an inebriating drink from the chewed Troots of the Jatropha manihot and Piper methisticum. It possesses an antiseptic virtue, according to the experiments of the celebrated Pringle. It easily becomes putrid in warm air, and gives off volatile alkali.

Constituent Principles. Saliva appears to consist. in a healthy state of the body, of water, which constitutes at least four-fifths of its bulk, mucilage, albumen, muriate of soda, phosphate of lime, and phospha e of ammonia.

The use of the saliva is, 1. It augments the taste of the the food, by evolution of sapid matter. 2. During mas-tication it fixes with, dissolves, and resolves into its principles, the food; and changes it into a pultaceous mass, fit to be swallowed: hence it commences chy-mification. 3. It moderates thirst, by moistening the cavity of the mouth and fauces.

Of or belonging to the saliva.

SALIVAL DUCTS. The excretory ducts of the salival glands. That of the parotid gland is called the Stenonian duct; those of the submaxillary glands, the Warthonian ducts; and those of the sublingual, the Rivinian ducts.

SALIVAL GLANDS. Those glands which secrete the saliva are so termed. See Saliva.

SALIVA'NS. (From saliva, spittle.) That which

excites salivation.

SALIVA RIA. (From saliva, the spittle : so called because it excites a discharge of saliva.) See Anthomis

SALIVATIO. An increased secretion of saliva.

See Ptyalismus.

SA'LIX. (From sala, Heb.) 1. The name of a genus of plants in the Linnman system. Class, Diacia; Order, Diandria. The willow.

2. The pharmacopoial name of Saliz. See Saliz fragilis.

fragilis.

SALIX ALBA. See Salix fragilis.

SALIX CAPREA. The systematic name of a species of willow, the bark of the branches of which possess the same virtues with that of the fragilis. See Salix

fragilis.

Salix fragilis. The systematic name of the common crack willow. Salix. The bark of the branches of this species manifests a considerable degree of bitterness to the taste, and is very adstringent. It is re-commended as a good substitute for Peruvian bark, and is said to cure intermittents and other diseases requiring tonic and adstringent remedies. Not only the bark of this species of salix, but those also of several others, possess similar qualities, particularly of the Saliz alba and Saliz pentandria, both of which are recommended in the foreign pharmacopæias. But Dr. Woodville is of opinion that the bark of the Salix triandria is more effectual than that of any other of this genus; at least its sensible qualities give it a decided preference. The trials Dr. Cullen made were with the bark of the Salix pentandria, taken from its branches, the third of an inch diameter, and of four or five years' growth. Nevertheless, he adds, in intermittent fevers, Bergius always failed with this bark.

Salix pentandria. The bark of the branches of this species of willow possesses the same virtues as that of the fragilis. See Salix fragilis.

Salix virtuina. The bark of the branches of this species of this species of this seems of the salix virtuinal.

species of willow may be substituted for the fragilis.

See Salix fragilis.
SALMO. The name of a genus of fishes of the order Abdominales. The salmon.
Salmo alpinus. The red charr. This beautiful and delicate little fish, and the Palmo carpie, or gilt charr, are found in our lakes of Westmoreland, in Wales, and Scotland. They are very rich, and hard of digestion.

SALMO EPERLANUS. The smelt. A beautiful little fish, found in great abundance in the Thames and river Dee, and in the European seas, between November and

February.

Salmo fario. The common fresh-water trout, the flesh of which is very delicate and rich.

Salmo lacustris. The lake trout.

Salmo salar. The systematic name of the common salmon. This fish is considered as one of the greatest delicacies. It is rich, and of difficult digestion to weak stomachs, and with some, whose stomachs are not carticularly feeble, it uniformly disagrees. The not particularly feeble, it uniformly disagrees: The pickled, salted, and smoked, though much eaten, are

pickled, salted, and smoked, though much eaten, are only fitted for the very strong and active.

Salmo salmulus. The samlet: the least of the British species of the salmo-genus. It is found in the river Wye, and up the Severn.

Salmo thymallus. The graling salmon, which is somewhat like our trout. It inhabits the rivers of Derbyshire, and some of the north, and near Christchurch in Hampshire. It is much esteemed for the delicacy of its flesh, which is white, firm, and of a fine flavour; and is considered as in the highest season in flavour; and is considered as in the highest season in the depth of winter.

Salmo Trutta. The systematic name of the sal-

mon trout, or bill trout.

SALMON. See Salmo.

SALPINGO. (From Σαλπινέ, buczina, a trumpet.)

SALIVAL. (Salivalis; from saliva, the splttle.) | Names compounded of this word belong to the palate, and are connected with the Eustachian tube.

Salpingo-pharyngeus. This muscle is composed

of a few fibres of the palatopharyngeus, which it assists in dilating the mouth of the Eustachian tube.

Salpingo-staphilinus. See Levator palati. Salpingo-staphilinus internus. See Levator

palati.

SALSAFY. See Tragopogon pratense. SALSO'LA. (So called from its saline properties; hence the English word saltwort, most of the species affording the fossile alkali.) The name of a genus of plants in the Linnaan system Class, Pentandria; Order, Digynia.

SALSOLA KALL. Kali spinosum cochleatum; Tragus, sive Tragum Matthioli. Snail-seeded glasswort or salt-wort. The systematic name of a plant which affords the mineral alkali. See Soda.

SALSOLA SATIVA. The systematic name of a plant, which affords the mineral alkali. See Soda.

SALSOLA SODA. The systematic name of a plant which affords mineral alkali. See Soda.

which affords mineral alkali. See Soda.

SALT. This term has been usually employed to denote a compound, in definite proportions, of acid matter, with an alkali, carth, or metallic oxide. When the proportions of the constituents are so adjusted, that the resulting substance does not affect the colour of the resulting substance does not affect the colour of infusion of litmus, or red cabbage, it is then called a neutral salt. When the predominance of acid is evinced by the reddening of these infusions, the salt is said to be acidulous, and the prefix, super, or bi, is used to indicate this excess of acid. If, on the contrary, the acid matter appears to be in defect, or short of the quantity necessary for neutralizing the alkalinity of the base, the salt is then said to be with excess of base, and the prefix subject to its name. The discoveries the prefix sub is attached to its name. The discoveries of Sir H. Davy have, however, taught chemists to modify their opinions concerning saline constitution. Many bodies, such as culinary salt, and muriate of lime, to which the appellation of salt cannot be refused, have not been proved to contain either acid or alkaline matter; but must, according to the strict logic of chemistry, be regarded as compounds of chlorine with metals.

Salt, acid This is distinguished by its sour taste when diluted with water. See Acid.
Salt, alkaline. Possesses a urinous, burning, and This is distinguished by its sour taste

caustic taste, turns the syrup of violets to a green, has a strong affinity for acids, dissolves animal substances, unites readily with water, combines with oils and fat, and renders them miscible with water, dissolves sul-

phur, and is crystallizable. See Alkali.
Salt, ammoniacal, fixed. Muriate of lime.
Salt, bitter purging. Sulphate of magnesia.
Salt, cathartic. See Magnesia sulphas, and Sode

sulphas.

Salt, common. See Sode murias. Salt, divertice. Acetate of potassa.
Salt, divertice. Acetate of potassa.
Salt, Epsom. See Magnesiæ sulphas
Salt, febrifuge, of Sylvius. Muriate of potassa.
Salt, fossil. A salt found in the earth.
Salt, fusible. Phosphate of ammonia.
Salt, fusible, of urine. Triple phosphate of soda ammonia.

and ammonia.

Salt, microcosmic. Triple phosphate of soda and ammonia.

Salt, nitrous ammoniacal. Nitrate of ammonia.
Salt, neutral. Secondary salt. Under the name of neutral or secondary salts are comprehended such matters as are composed of two primitive saline substances combined together in a certain proportion. These salts are called neutral, because they do not possess the characters of primitive salts; that is to say, they are neither acid nor alkaline: such as Epsom salts, nitre, &c. But in many secondary salts the qualities of one ingredient predominate; as tartar, or supertartrate of potassa, has an excess of acid; borax, or subborate of soda, an excess of base. The former are termed acidalize the latter sub-alkalize calls.

soda, an excess of base. The form dulous, the latter sub-alkaline salts. SALT-PETRE. See Nitre. Salt of amber. Succinic acid. Salt of benzoin. Benzoic acid. Salt of coleother. Sulphate of iron.
Salt of lemons. Superoxylate of potassa.
Salt of Saturn. Acetate of lead.
Salt of Scidlitz. Sulphate of maguesia.

Superoxylate of potassa. Salt of sorrel. Salt, Rochelle. See Soda tartarizata. Salt, sea. See Soda murias. Salt of steel. See Ferri sulphas. Salt, polychrest. Sulphate of potassa. Salt, secondary. See Neutral salt. Salt, sedative. Boracic acid. Salt, spirit of. Salt of vitriol. Muriatic acid. Purified sulphate of zinc. Salt of wisdom. Sal alembroth.

Salt, primitive. Simple salt. Under this order is comprehended those salts which were formerly thought to be simple or primitive, and which are occasionally called simple salts. The accurate experiments of the moderns have proved that these are for the most part compounded; but the term is retained with greater propriety when it is observed, that these salts composed, when united, salts which are termed secondary. These salts are never met with perfectly pure in nature, but require artificial processes to render them so. This order is divided into three genera, comprehending saline terrestrial substances, alkalies, and acids.

SALTWORT. See Salsola kali. SALVATE'LLA. (From salus, health, because the opening of this vein was formerly thought to be of singular use in melancholy.) This vein runs along the little finger, unites upon the back of the hand with the cephalic of the thumb, and empties its blood into the internal and external cubical veins.

SA'LVIA. (A salvendo.) 1. The name of a genus of plants in the Linnwan system. Class, Diandria;

Order, Monogynia. Sage.

2. The pharmacopaial name of the common sage.

See Salvia officinalis.

SALVIA HORTENSIS MINOR The small sage, or sage A variety of the officinal sage, possessing similar virtues.

SALVIA OFFICINALIS. The systematic name of the garden sage. Elelisphacos. Salvia-foliis lanceolato ovatis integris crenulatis, floribus spicatis, calycibus acutis, of Linnaus. In ancient times sage was cele-brated as a remedy of great efficacy, as would appear from the following lines of the school of Salernum

" Cur moriatur homo, cui salvia crescit in horto? Contra vim mortis, non est medicamen in hortis? Salvia salvatrix, natura conciliatrix. Salvia cum ruta faciunt tibi pocula tuta."

But at present it is not considered as an article of much importance. It has a fragrant, strong smell; and a warm, bitterish, aromatic taste, like other plants containing an essential oil. It has a remarkable property in resisting the putrefaction of animal substances, and is in frequent use among the Chinese as a tonic, in the form of tea, in debility of the stomach and nervous

SALVIA SCLAREA. The systematic name of the garden clary, called horminum in the pharmacoporias. Sclarea hispanica. The leaves and seeds are recommended as corroborants and ahtispasmodics, particularly in leucorrhoas and hysterical weaknesses. They have a bitterish, warm taste, and a strong smell of the aromatic kind. The seeds are infused in white wine, and initiate muscadel.

SAMARA. (The name, according to Pliny, of the fruit of the elm.) 1. The name of a genus of plants in the Linnæan system. Class, Tetrandria; Order, Mo-

nogynia. A species of capsule of a compressed form, and dry coriaceous texture, with one or two cells, never bursting, but falling off entire, and dilated into a kind of wing at the summit or sides. In Fraxinus, it goes from the summit of the seed: in Acer and Batula, from the side: in Ulmus campestris, it goes all round. SAMBU'CUS. (From sabucca, Heb. a musical instrument formerly made of this tree.) Eider.

1. The name of a genus of plants in the Linnaran system. Class. Pentandria: Order. Triannia.

system. Class, Pentandria; Order, Trigynia.

2. The pharmacopeial name of the elder-tree.

Sambueus nigra.

Sambucus enulus. The systematic name of the dwarf-elder. Ebulus; Chamaacte; Sambucus humilis; Sambucus herbacea. Dwarf elder, or dane-wort. The root, leaves, flowers, berries, and seeds of this herbaceous plant, Sambucus—cymis trified to determine the weight of the Ingesta and Egesta, he invented an instrument for measuring the have all been administered medicinally, in moderate

doses, as resolvents and deobstruents, and, in larger doses, as hydragogues. The plant is chiefly employed by the poor of this country, among whom it is in com-mon use as a purgative, but Dr. Cullen speaks of it as a violent remedy.

SAMBUCUS NIGRA. The systematic name of the elder-tree. Sambucus vulgaris; Sambucus arborea; dete; Infelix lignum. Sambucus—cymis quinque-partitis, foliis pinnatis, caule arboreo, of Linnaus. This indigenous plant has an unpleasant narcotic smell, and some authors have reported its exhalations to be so noxious, as to render it unsafe to sleep under its shade. The parts of this tree that are proposed for medicinal use in the pharmacoperias are the inner bark, the flowers, and the berries. The first has scarcely any smell, and very little taste; on first chew-ing, it impresses a degree of sweetness, which is followed by a very slight but durable acrimony, in which its powers seem to reside. From its cathartic property it is recommended as an effectual hydragogue by Sydenham and Boerhaave: the former directs three handfuls of it to be boiled in a quart of milk and water, till only a pint remains, of which one half is to be taken night and morning, and repeated for several days; it usually operates both upwards and downwards, and upon the evacuation it produces, its utility depends. Boerhaave gave its expressed juice in doses from a drachm to half gave its expressed juice in doses from a drachin to hair an ounce. In smaller doses it is said to be a useful aperient and deobstruent in various chronic disorders. The flowers have an agreeable flavour; and infusions of them, when fresh, are gently laxative and aperient. When dry, they are said to promote chiefly the cuticu-lar excretion, and to be particularly serviceable in ery-sipelatous and cruptive disorders. Externally they are used in fomentations, &c. and in the London pharmacopeia are directed in the form of an ointment. berries in taste are somewhat sweetish, and not unpleasant; on expression they yield a fine purple juice, which proves a useful aperient and resolvent in sundry chronic diseases, gently loosening the belly, and promoting the urine and perspiration.

Samphire. Sec Crithmum maritimum.

Samphire. See Critamum martichina.
Sampsychum. (From σαω, to preserve, and ψυχη,
Sampsychum. (From σαω, to preserve, and ψυχη,
Marticken of its cordial qualities.) the mind; because of its cordial qualities.)

SANATI'VE. (From sano, to cure.) That which heals diseases

SANCTI ANTONII IGNIS. See Erysipelas. SANCTORIUS, SANCTORIUS, was born in 1561, at Capo d'Istria. He studied medicine at Padua, where he took his degree, and then settled at Venice, and practised with considerable success. At the age of fifty, however, he was appointed professor of the theory of medicine at Padua; in which office he distinguished himself for thirteen years. He was then allowed to retire on his salary, finding his health impaired by the fatigue of the visits, which he was frequently obliged to make in his professional capacity, to Venice, where he passed the remainder of his life in great reputation. On his death, in 1636, a statue of marble was raised to his memory; and an annual oration was instituted by the College of Physicians, to whom he had bequeathed an annuity, in commemoration of his benevolence. Sanctorius first called the attention of physicians to the cutaneous and pulmonary transpiration, which he proved to exceed the other excretions considerably in weight; and he maintained that this furction must have a material influence on the system, and was deserving of great consideration in the treatment of diseases. There is, no doubt, much truth, in this general observation; but in its application to practice, he appears to have gone to an extravagant length, and to have contributed much to provagant length. vagant length, and to have contributed much to pro-long the reputation of the humoral pathology. His treatise, entitled "Ars de Statica Medicina," was first published in 1614, and passed through more than twenty editions, including translations, with various commentaries: it is written in an elegant and per-spicuous Latin style. He was also author of a Method of avoiding Errors in Medicine, to which was after ward added an essay "De Inventione Remediorum;" and of Commentaries on some of the ancient chair and of Commentaries on some of the ancient physiand he was the first who attempted to determine the of a pale white colour, often with a yellowish tinge, temperature of the body by a thermometer, of which, and, being destitute of taste or odour, it is superseded temperature of the body by a thermometer, of which, indeed, he is considered as the inventor.

Sanctum semen. The worm-seed, or santo-

SA'NCTUS. Holy. A term formerly applied to diseases, herbs, &c. See Chorea, Carduus benedic-

SANDALIFORMIS. Sandal or slipper-like. Applied to the nectary of the Cypripedium calceolus

SANDARA'CHA. (From saghad narak, Arabian.)

A gummy resin.

2. A sort of arsenic.

Sandaracha arabum. Arabian sandarach. This resinous juice appears to have been the produce of a large species of juniper-tree.

Sandbath. See Bath.

SANDERS. See Pterocarpus santalinus.

SANDRACK. (An Arabian word.) See Juniperus

SANDYX. (From sani duk, red, Arabian.) Cerusse

burnt till it becomes red. SANGUIFICATION.

(Sanguificatio; from sanguis, blood, and faceo, to make.) A natural function of the body, by which the chyle is changed into blood. The uses of sanguification are the generation of blood, which serves to fill the blood-vessels, to irritate and stimulate the heart and arteries, to generate or cause heat, to secrete the humours, and to excite the vital

SANGUINALIS. (From sanguis, blood: so named from its use in stopping bleedings.) The Polygonum ariculare, or knot-grass, is sometimes so called.

SANGUINARIA. (From sanguis, blood: so named from its use in stopping bleedings.) See Polygonum

[SANGUINEOUS. Bloody. Appertaining to the blood. Applied to certain conditions of the body and diseases, and appearances of solids and fluids; as sanguineous temperament, sanguineous apoplexy.

guineous temperament, sanguineous apoplexy.

Sanguineous apoplexy. See Apoplexy.

Sanguineous apoplexy. See Apoplexy.

Sanguineous depoplexy. See Apoplexy.

Sanguineous Ever, or such a one as by its discharges is supposed to purify the blood.

SA'NGUIS, (Sanguis, guinis. m.) See Blood.

SANGUIS DRACONIS. See Calamus rotang.

SANGUIS DRACONIS. A name for the crocus.

SANGUISO'RBA. (Probably so named originally from the blood-red colour of its flowers, although the juices of this plant, being astringent, the medicinal properties it possesses of stooping hemorrhages may properties it possesses of stopping harmorrhages may be a better warrant for its name.) The name of a genus of plants in the Linnaan system. Class, *Triandria*; Order, Monogynia.

SANGUISORBA OFFICINALIS. The systematic name SANGUISORBA OFFICINALIS. The systematic name of the Italian pimpinel, which was formedy much esteemed as an astringent, but is not now in use.

SANGUISU'GA. (From sanguis, blood, and sugo, to suck.) The leech or blood-sucker. See Leech.

SANICLE. See Sanicula.

Sanicle, Yorkshire. See Pinguicula.

SANTCULA. (From sano, to heal; so called from its virtues in healing.)

1. The name of a genus of plants in the Linnman.

The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Digynia.

2. The pharmacopeial name of sanicle.

Sanicula enoracensis. See Pinguicula vulgaris.
Sanicula europea. The systematic name of the sanicle. Cucullata; Dodecatreon; Symphytum petraum; Sanicula mas; Diapensia cortusa. This herb was formerly recommended as a mild adstringent, and is supposed to have received its name from its sanative power. Its sensible qualities are a bitterish and somewhat austere taste, followed by an acrimony which chiefly affects the throat. It is only in use in the present day among the country people.

Sancula Mas. See Sanicula curopea.

Sa'NIES, Ichor. This term is sometimes applied to a thin, limpid, and greenish discharge; and at other times to a thick and bloody kind of pus.

SA'NTALUM. (From zandal, Arabian.) The name of a genus of plants in the Linnaean system.

Class, Tetrandria; Order, Monogynia. Saunders.

Santalum album. The systematic name of the yellow saunders. Santalum citrinum; Santalum pallidum. Yellow saunders. White saunders wood is

by the santalum citrinum, which is of a brownish yelby the santation citribute, which is of a brownish yellow colour, of a bitterish aromatic taste, and of a pleasant smell, approaching to that of the rose. Both kinds are brought from the East Indies in billets, consisting of large thick pieces, which, according to Rumphius, are sometimes taken from the same, and sometimes from different trees. For though the white and reallow sounders are the wood of the same species of yellow saunders are the wood of the same species of tree, yet the latter, which forms the central part of the tree, is not always to be found in sufficient quantity to repay the trouble and expense of procuring it, especially, unless the trees be old; while the white, which is the exterior part of the wood, is always more abun-

dant, and is consequently much cheaper.

Yellow saunders, distilled with water, yields a fragrant essential oil, which thickens in the cold into the consistence of a balsam, approaching in smell to ambergris, or a mixture of ambergris and roses; remaining decoction, inspissated to the consistence of an extract, is bitterish, and slightly pungent. Rectified spirit extracts, by digestion, considerably more than water; the colour of the tincture is a rich yellow. The distilled spirit is slightly impregnated with the flavour of the wood; the remaining brownish extract has a weak smell, and a moderate balsamic pungency. The wood is valued highly on account of its fragrance; hence the Chinese are said to fumigate their clothes with it, and to burn it in their temples in honour of their gods. Though still retained in the Materia Medica, it cannot be thought to possess any considerable share of medicinal paper. Heffman any considerable share of medicinal power. Hoffman considers its virtues as similar to those of ambergris; and some others have esteemed it in the character of a

corroborant and restorative. [" The sandal-wood, which is found on some of the islands of the South Sea, has been a great article of com-merce for the Chinese market. The following extract of

a letter from Coles Fanning & Co. to Dr. Mitchill gives an account of the trade and employment of this wood as

a perfume.

"In the month of August, 1806, we despatched the ship Hope, Capt. Brumley, from New-York, on a voyage to the Fejee islands, to procure a cargo of Sandal-wood, for the Canton market. The Hope having succeeded at the island of *Toconroba*, in procuring a full cargo for herself, and in part freighting an English brig that she met with at said island, arrived in No vember 1807, at Canton, where both cargoes were sold at about 25 cents per pound. While at the Fejec islands the Captain of the Hope contracted and paid in part to the chief of the island for about 270 tons more of sandal-wood, (this being about the whole quantity of good wood remaining on the islands) to be taken away in a certain time. In order therefore to seize so profitable a speculation while there were so few to participate in it, we built and sent the ship Tonquin, com-manded by E. Fanning, in May, 1807, to meet the Hope at Canton; but the Hope not having arrived in time for Capt. Fanning to fulfil our original intentions, the season was so far wasted as to compel him to load the Tonquin for New-York, and he met the Hope in the mouth of the Tigris or (Canton river). Both vessels will, therefore, return to the United States under no expectations that the trespasses of European nations would compel our government to inhibit their departure again on said voyage. Being thus situated we have taken the liberty to address you for your advice, whether, under the embargo law, or the supplements, the Executive will not have sufficient authority to permit us to proceed immediately with a ship sufficient to bring the above quantity of wood, and by that means save to ourselves and our country at least \$130,000, which will probably, if such permission is refused, fall into English hands; for you will please to observe, that there was in the first place but a small probably the weed on a contribution of the weed on the contri patch of the wood on one of the islands, that the Hope left four English vessels there, selecting from the refuse a little of very inferior quality, and in expectation too that some accident would prevent our ship from returning within the limited time, which would release the chief from his engagement, and leave him at liberty to sell the good wood purchased by Capt. Brumley to them. From the knowledge Capt. Brumley has of the chief's conduct, we rely as confidently on his keeping his engagement for the time limited as we would on the

chief of the most civilized nation. You will no doubt recollect that the Chinese have long considered sandalwood as possessing religious properties; they are ac-customed to burn it on their altars as incense; their, god Josh is supposed always out of humour, unless his nose is regaled with its delightful effluvia. We have enclosed a small piece of the wood, that you may have an opportunity of judging how far a Pagan god's taste may be deemed exquisite. The Hope is the first vessel, to the best of our knowledge, that ever proceeded from the United States on this voyage, and on her return, we presume she will pay about \$40,000 into the Treasury for duties from the proceeds of the wood, which originally cost only about nine bundred dollars." "—Mcd.

SANTALUM CITRINUM. See Santalum album. SANTALUM PALLIDUM. See Santalum album. SANTALUM RUBRUM. Red saunders. See Pterocar-

pus santalinus

SANTOLI'NA. (From santalum, saunders; because it smells like the saunders-wood.) See Artemisia SANTOLINA. santonica.

SANTOLINA CHAMÆ-CYPARISSUS. The systematic

name of the lavender cotton.

Santonicum. (From Santonio, its native place.)

See Artemisia santonica.

SAPHE'NA. (From $sa\phi\eta_{S}$, visible.) Vena saphena. The large vein of the leg, which ascends along the little toe over the external ankle, and evacuates part of the blood from the foot into the popliteal veins.

SAPIENTIE DENTES. (Sapientia, wisdom, discre-tion: so called because they appear when the person is

supposed to be at years of discretion.) See Teeth. SAPINDUS. (That is, Sape Indus, Indian soap: the rind of the fruit serving instead of soap to cleanse linen, but not without hazard of injury to the texture

of the cloth.) The name of a genus of plants. Class, Octandria; Order, Digynia. The soap-tree.

SAPINDUS SAPONARIA. The systematic name of the plant which affords soap-nuts. Saponaria nucula; Bacca bermudensis. Soap-berries. A spherical fruit, about the size of a cherry, the cortical part of which is yellow, glossy, and so transparent as to show the sphe-rical black nut which rattles within, and which includes a white kernel. The tree grows in Jamaica. It is said that the cortical part of this fruit has a bitter taste, and no smell; that it raises a soapy froth with water, and has similar effects with soap in washing; that it is a medicine of singular and specific virtue in chlorosis. They are not known in the shops of this country.

SAPO. (Sapo, nis. m.) Soap. A compound, in definite proportions, of certain principles in oils, fats, or resin, with a salifiable base. When this base is potassa or soda, the compound is used as a detergent in washing clothes. When an alkaline earth, or oxide of a common metal, as litharge, is the salifiable base, the compound is insoluble in water. The first of these combinations is scarcely applied to any use, if we except that of linseed oil with lime-water, sometimes prescribed as a liniment against burns; and the last is known only in surgery as the basis of certain plasters. Concerning the chemical constitution of soaps and saponification, no exact ideas were entertained prior to Chevreuil's researches.

Fats are compounds of a solid and a liquid substance; the former called stearine, the latter resembling vegeta-ble oil, and therefore called claine. When fat is treated with a hot ley of potassa or soda, the constituents react on one another, so as to generate the solid pearly matter margaric acid, and the fluid matter olcic acid, both of which enter into a species of saline combination with the alkali; while the third matter that is produced, the sweet principle, remains free. We must therefore regard our common soap as a mixture of an alkaline margarate and oleate, in proportions determined by the relative proportions of the two acids producible from the peculiar species of fat. It is probable, on the other hand, that the soap formed from vegetable oil is chiefly an oleate. No chemical researches have hitherto been made known, on the compounds of resin with alkalies, though these constitute the hower constitute the house constitute the with alkalies, though these constitute the brown soaps so extensively manufactured in this country. or fats do not possess in an equal degree the property of saponification. Those which saponify best, are,

1. Oil of olives, and of sweet almonds.

2. Animal oils; as bog's-lard, tallow, butter, and horse-oil.

3. Oil of colza, or rape-seed oil. 4. Oil of beech-mass and poppy-seed, when mixed with olive-oil or tallow.

The several fish-oils, mingled like the preceding.

Hempseed-oil.

Nut-oil and linseed-oil.

Palm oil.

9. Rosin.

In general, the only soaps employed in commerce, are those of olive-oil, tallow, lard, palm-oil, and rosin. A species of soap can also be formed by the union of beeswax with alkali; but this has no detergent appli cation, being used only for painting in encausto.

The specific gravity of soap is in general greater than that of water. Its taste is faintly alkaline. When sub jected to heat it speedily fuses, swells up, and is then decomposed. Exposed to the air in thin slices, it soon becomes dry; but the whole combined water does not leave it, even by careful desiccation on a sand-bath.

Soap is much more soluble in hot than in cold water. This solution is instantly disturbed by the greater num ber of acids, which seizing the alkali, either separate the fatty principles, or unite with them into an acido-soapy emulsion. The solution is likewise decomposed by almost all the earthy and metallic salts, which give birth to insoluble compounds of the olcic and margaric acids, with the salifiable bases,

Soap is soluble in alkohol, and in large quantity by the aid of heat. When boiling alkohol is saturated with soap, the liquid, on cooling, forms a consistent transparent mass of a yellow colour. When this mass is dried, it still retains its transparency, provided the soap be a compound of tallow and soda; and in this state it is sold by the perfumers in this country

Good soap possesses the property of removing from linen and cloth the greater part of fatty substances which may have been applied to them.

The medicinal soap, sapo amygdolinus, is made with oil of sweet almonds, and half its weight of caustic alkali. Common or soft soap, sapo mellis, is made of potassa and oil, or tallow. Spanish, or Castile soap, sapo durus, of oil of olives and soda, or barilla. Black soap is a composition of train oil and an alkali; and green soap of hemp, linseed, or rape oil, with an alkalf. The white Spanish soap, being made of the finer kinds of olive oil, is the best, and therefore preferred for in-ternal use. Soap was imperfectly known to the an-cients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Areteus and others inform us, that the Greeks obtained their know-ledge of its medical use from the Romans. Its virtues, according to Bergius, are detergent, resolvent, and aperient, and its use recommended in jaundice, gout, calculous complaints, and obstruction of the viscera. The efficacy of soap, in the first of these diseases, was experienced by Sylvius, and since recommended very generally by various authors who have written on this complaint; and it has also been thought of use in sup-plying the place of bile in the prime viae. The utility plying the place of bile in the prime vize. The utility of this medicine in icterical cases was inferred chiefly from its supposed power of dissolving biliary concretions; but this medicine has lost much of its reputation in jaundice, since it is now known, that gall-stones bave been found in many after death who had been daily taking soap for several months, and even years. Of its good effects in urinary calculous affections, we have the testimonies of several, especially when dis-solved in lime-water, by which its efficacy is considerably increased; for it thus becomes a powerful solvent of mucus, which an ingenious modern author supposes to be the chief agent in the formation of calculi; it is, however, only in the incipient state of the disease that however, only in the incipient state of the disease that these remedies promise effectual benefit, though they generally abate the more violent symptoms where they cannot remove the cause. With Boerhaave, soap was a general medicine; for as he attributed most complaints to viscidity of the fluids, he, and most of the Boerhaavian school, prescribed it, in conjunction with different resinous and other substances, in gout, rheumatism, and various visceral complaints. Soan is also matism, and various visceral complaints. Soap is also externally employed as a resolvent, and gives name to several officinal preparations.

["The history of personal cleanliness is very impor-tant, and has been lamentably neglected. Pliny, in his Natural History, treating of strumous swellings, makes mention, of Soap: Prodet est sapo. Galliarum hoc inventum rutilandis capillis. Fit ez sebo et cinere.

Optimus ex fagino et caprino : duobis modis, spissus | ing, was kelp or barilla ; a material possessing qualitles Optimus ex fagino et caprino: duobis modis, spissus ac liquidus: uterque apud Germanus majore in usu viris quam faminis. "Soap is good for them. This was invented in Gaul, and used for reddening the hair. It is made of fat and askes. The best is prepared from the askes of the beach-tree and the suct of the goat. There are two sorts, the thick and the liquid. Among the Germans, both kinds are more used by the men than by the women." Priscian writes of "Sapo Gallicus," or Gaulish soap; and Martial of "Spuma Batava," or Dutch lather, and "Spuma Caustica," or Caustic foam. The German soap was reckoned the best and cleanest. The Gaulish was next in quality and value. and value.

It is clear, and President Goguet is of the same opinion, (in his history of the origin of laws, &c.) that the ancient Hebrews, Greeks, and Romans knew nothing of soap. These nations used to supply the want of it by various other means. From the barbarous people of the north, the knowledge and employment of soap passed to the Romans; and from the Romans was made known to the Greeks. A very remarkable

When the Romans first became acquainted with soap, they called it "Unguentum Cineris," or *Ointment of askes*. So prevalent was the idea of its origin, that several writers have treated of it under the denomina-tion of "Cinis," or ASHES, itself. And those who con-sumed soap were in those days called "Cinerarii," or Ashes users

After a while, however, this detergent ointment was distinguished among the Romans by the word "Sapo." This term probably is of Gothic or Barbarian origin. Some of the Parthian and other nations bordering on the frontier provinces of the Roman Empire, distinguished their rulers or chiefs by the name "Sapor" or "Sapores." The good they derived from the Unguentum Cineris was so great and excellent, and it was so powerful in overcoming bodily inconveniences, and so conducive to personal comfort, that they called this preserver of private health, by a name corresponding to, and derived from the sovereigns who presided over their public safety. From Sapor, thus was derived Sapo; two terms significant of the powers which protected the political and the individual bodies of the people. The Romans adopted Sapo, and naturalized it to their language. From them the Greeks borrowed their \u03c4\u from the same source, and so have the English their

But if soap was so late an invention, and learned from the rougher nations of the north of Europe at so advanced a period of the history of their southern neighbours, how comes it to pass the Hebrews were ac-quainted with it, as we read in the English version of the Bible, translated under the auspices of king James? The term "soap" does indeed occur there in Jeremiah, chap. ii. v. 22, and in Malachi, chap. iii. v. 2. Yet there can scarcely be entertained a doubt, that the translators were mistaken. This opinion of their having misinterpreted the text is supported by the Latin vulmisinterpreted the text is supported by the Latin vulgate version, which expresses the former of these passages by the words, "herbam borith," and the latter
by "herba fullonum." What, now, is the plant Borith, and what is the Fuller's herb? Calmet, in his
Dictionary of the Bible, states, that it is the kali or saline vegetable, of whose ashes "ley and soap are made."
Gagnet thinks it was salt-wort, a plant very common Goguet thinks it was salt-wort, a plant very common in Syria, Judea, Egypt, and Arabia; which, if burned to ashes, and the ashes mingled with water, formed a strong ley fit for cleansing and whitening cloths, and

doubtless they were right.

Notwithstanding all this authority, Beza evidently missed the true meaning of the original, which he expresses in both the before-mentioned texts, by the substantive "smegma." But John Jacob Schmidt, in his stantive "smegma." But John Jacob Schmidt, in his Biblischer Medicus, mentions this cleansing article by the Hebrew name of "Bor." This substantive being derived from the root "ur" fire, plainly indicates that the purifying material in question was obtained by or through fire. Borith would thus seem to be the plant which, by the action of the fire, yielded Bor, that is, the detergent article of the washers and fullers. Or the two words might be used indifferently to signify the plant both before and after incineration. Hence the plant both before and after incineration. it may be inferred, the plant was a species of Salsola or Glass-wort, and that the saline residuum, after burn-

similar to the oriental natron or mineral alkali. The same thing has been latterly called Soda, whence comes La Soude of the French, and the Suds or Alkaline lixivium of the English."—New-York Med. Repos. A.]

Sapo terebinthine. Starkey's soap.

R. kali preparatic calidi, 3j. Olei terebinth, 3ij. The hot kali preparatum is to have the oil of turpenting gradually blended with it, in a heated mortar.

tine gradually blended with it, in a heated mortar. Indolent swellings were formerly rubbed with this ap-

plication, and perhaps some chronic affections of the joints might still be benefited by it.

SAPONA'RIA. (From sapo, soap: so called because its juice, like soap, cleans cloths.) 1. The name of a genus of plants in the Linnman system. Class,

Decandria; Order, Digynia.

2. The pharmacopæial name of the soap-wort. See

Saponaria officinalis.
Saponaria officinalis. See Sapindus saponaria.
Saponaria officinalis. The systematic name of the soap-wort, called also bruise-wort. Struthium; the soap-wort, called also bruise-wort. Struthium; Lanaria; Lychnis sylvestris; Ibizuma. The root of this plant, Saponaria—calycibus cylindricis, foliis ovato-lanceolatis, of Linnœus, is employed medicinally; it has no peculiar smell; its taste is sweetish, glutinous, and somewhat bitter. On being chewed for some time, it is said to discover a degree of acrimony, which continues to affect the mouth for a considerable time. According to Neuman, two ounces of the root yielded eleven drachms of watery extract; but Cartheuser, from a like quantity, only obtained six drachms, and twenty-four grains. This extract manifested a sweetish taste, followed by an acrid quality. The spirituous extract is less in quality, but of a more penetrating acrid taste. Decoctions of the root, on being sufficiently agitated, produces a saponaceous froth; a similar soapy quality is observable also in the extract, and still more manifestly in the leaves, insomuch that they have been used by the mendicant monks as a sub-stitute for soap in washing of their clothes; and Bergius, who made several experiments with the saponaria, declares that it had all the effects of soap itself.

From these peculiar qualities of the saponaria, there can be little doubt of its possessing a considerable share of medical efficacy, which Dr. Woodville says he could wish to find faithfully ascertained.

The diseases for which the saponaria is recommended, as syphilis, gout, rheumatism, and jaundice, are not, perhaps, the complaints in which its use is most availing; for a fancied resemblance of the roots of sa-ponaria with those of sarsaparilla, seems to have led physicians to think them similar in their effects; and hence they have both been administered with the same intentions, particularly in fixed pains, and venereal affections. Bergius says, "in arthritide, cura mercuriale, &c. nullum aptiorem potum novi." However, according to several writers, the most inveterate cases of syphilis were cured by a decoction of this plant, without the use of mercury.

Haller informs us that Boerhaave entertained a high opinion of its efficacy in jaundice and other visceral

SAPONULE. Saponulus. A combination of a vo-latile or essential oil with different bases; as saponule of ammonia, &c.
SAPOTA. (The West Indian name of several sorts

SAPOTA. (The West Indian name of several sorts of fruits of the plum kind.) See Acras sapota.

SAPPAN LIGNUM. See Hamatozylon campechianum. SAPPHIRE. Telesic of Haüy. Perfect corundum of Bournon. The oriental ruby and topaz are sapphires. Sapphire is a subspecies of rhomboidal corundum. It is one of the esteemed precious stones, a sapphire is a subspecies of rhomboidal corundum. phire of ten carats' weight being worth fifty guineas. Its colours are blue, red, and also gray, white, green, It is found in blunt-edged pieces, in and yellow. roundish pebbles, and crystallized after the diamond. It is the hardest substance in nature.

SAPPHIRINA AQUA. (So called from its sapphire or blue colour.) Aqua cupri ammoniati. Made by a solution of sal ammoniac in lime-water, standing in a

copper vessel.

Saraceus consound. See Solidago virga aurea SARATOGA. The name of a county in the State of New-York, in America, celebrated for its springs of mineral water, which are numerous throughout a cir-cuit of several miles near the centre of that county. The ground throughout this circuit is, generally speak-

ing, flat, and in two or three places is covered with ex-tensive sheets of limpid water, which are fed by streams that take their origin in the neighbouring moun-tains of granite and gueiss. The soil in which the springs rise is sandy, and rests upon a bed of compact limestone, or argillaceous slate, or gray wacke; and they are apparently more numerous where these spe-cimens of the transition and secondary formation are ascertained to meet. There is more variety in the degree of mineral impregnation at two points, about seven miles distant from each other, where accommodation has been more liberally provided for visiters, and which have taken the names of Saratoga and Ballston Spa. - The former of these seems to have been known to the Indians before the formation of European settlements, and was pointed out by them to Sir Wil-liam Johnson, in 1767. It was called in their language ham Johnson, in 1767. It was called in their language the Spring of Life, and is in temperature about 50° of Fahrenheit. Most of the American chemists have made the analysis of the Saratoga water an object of inquiry and publication, and though one or two of them differ as to the existence of some of the more trifling impregnations, they agree generally that it con-tains carbonic acid gas, muriate of soda, carbonate of soda, carbonate of lime, carbonate of iron, and carbonate of magnesia.

In two or three of the springs, there is, besides, sulphuretted hydrogen gas, and in one at least traces of silica and alumina. These incidental varieties give rise to slight differences in the medicinal effects of the springs; but, as a general-rule for guiding strangers in their selection, it may be stated, that the more abundant the muriate of soda, and carbonates of soda, lime, and magnesia, the more aperient and diuretic will be the water; while the greater the quantity of carbonic acid and of iron, in proportion to the former ingredients, the more powerful will be its tonic effects.

The great superiority of these American mineral waters over every thing of the kind to be found in Europe, consists,

lst, In their containing a greater quantity of carbo-nic acid, or fixed air, by which they are capable of re-taining in solution a much larger proportion of useful saline matter, of a particular character, than any Euro-pean mineral water.

2dly, In their possessing more efficient purgative properties than any of the springs of Europe, with the exception of Harrowgate, and perhaps Cheltenham, which are both not only destitute of the refreshing taste given by the carbonic acid, but contain (Harrowgate in particular) matters which render them to the palate in some degree offensive.

3dly, In containing such a combination of materials, in the most eligible form, as fit them to become at once a most refreshing beverage to all, and to those suffering from the diseases about to be mentioned in particular, a more perfect union of what is agreeable with that which is necessary and useful in the way of medicine, than any that has hitherto been provided, either by na-

The diseases in which the Saratoga waters have been found to be productive of the best effects, are, dyspepsia, cutaneous diseases, scrofulous affections, dyspepsia, chianeous diseases, scrolladas anectrone, dropsy, chlorosis, and other affections peculiar to the female sex, nephritic affections and gravel.

SARCITES. (From σαοξ, flesh.) See Anasarce.

SA'RCIUM. (Diminutive of σαοξ, flesh.) A carun-

cle, or small fleshy excrescence. SARCOCE'LE. (From $\sigma_{ai} \xi$, flesh, and $\kappa \eta \lambda \eta$, a tumour.) Hernia carnosa. This is a disease of the body of the testicle, and as the term implies, consists, in general, in such an alteration made in the structure of it, as produces a resemblance to a hard fleshy substance, instead of that fine, soft, vascular texture, of which it is, in a natural and healthy state, composed.

The ancient writers have made a great number of distinctions of the different kinds of this disease, according to its different appearances, and according to the mildness, or malignity of the symptoms with which it may chance to be attended. Thus, the sarcoccle, the hydro-sarcoccle, the scirrhus, the cancer, the care ad-nata ad testem, and the care adnata ad vasa, which are really little more than descriptions of different states and circumstances of the same disease, are reckoned as so many different complaints, requiring a variety of treatment, and deriving their origin from a variety of different humours.

Every species of sarcocele consists primarily in an enlargement, induration, and obstruction of the vas-cular part of the testicle; but this alteration is, in different people, attended with such a variety of circum-stances, as to produce several different appearances, and to occasion the many distinctions which have been made.

If the body of the testicle, though enlarged, and indurated to some degree, be perfectly equal in its surface, vaid of pain, has no appearance of fluid in its tunica vaginalis, and produces very little uneasiness, except what is occasioned by its mere weight, it is usually called a simple sarcocele, or an indolent scirrhus; if, at the same time that the testis is enlarged and hardencd, there be a palpable accumulation of fluid in the va-ginal coat, the disease has by many been named a hydro-sarcocele; if the lower part of the spermatic vessels, and the epididymus were enlarged, hard, and knotty, they supposed it to be a fungous, or morbid accretion, and called it the caro adnata ad vasa; if the testicle itself was unequal in its surface, but at the same time not painful, they distinguish it by the title of care adnata ad testem; if it was tolerably equal, not very painful, nor frequently so, but at the same time hard and large, they gave it the appellation of an occult benign cancer; if it was ulcerated, subject to frequent acute pain, to hamorrhage, &c. it was known by that of a malignant or confirmed cancer. ferent appearances, though distinguished by different titles, are really no more than so many stages (as it were) of the same kind of disease, and depend a great deal on several accidental circumstances, such as age, habit, manner of living, &c. It is true, that many peo-ple pass several years with this disease, under its most favourable appearances, and without encountering any of its worst; but, on the other hand, there are many, who, in a very short space of time, run through all its stages. They who are most conversant with it, know how very convertible its mildest symptoms are into its most dreadful ones, and how very short a space of time often intervenes between the one and the other.

There is hardly any disease affecting the human body, which is subject to more variety than this is, both with regard to its first manner of appearance, and the

changes which it may undergo.

Sometimes the first appearance is a mere simple enlargement and induration of the body of the testicle; void of pain, without inequality of surface, and producing no uneasiness, or inconvenience, except what is occasioned by its mere weight. And some people are so fortunate to have it remain in this state for a very considerable length of time without visible or material alteration. On the other hand, it sometimes happens that very soon after its appearance in this mild manner, it suddenly becomes unequal and knotty, and is attended with very acute pains darting up to the loins and back, but still remaining entire, that is, not bursting through the integuments. Sometimes the fury of the disease brooks no restraint, but making its way through all the membranes which envelope the testicle, it either produces a large, foul, stinking, phagedenic ulcer, with hard edges, or it thrusts forth a painful gleeting fungus, subject to frequent hæmorrhage.

Sometimes an accumulation of water is made in the tunica vaginalis, producing that mixed appearance,

called the hydro-sarcocele

Sometimes there is no fluid at all in the cavity of the funica vaginalis: but the body of the testicle itself is formed into cells, containing either a turbid kind of water, a bloody sanies, or a purolent fætid matter. Sometimes the disorder seems to be merely local, that is, confined to the testicle, not proceeding from a tainted habit, nor accompanied with diseased viscera, the patient having all the general appearances and circumstances of health, and deriving his local mischief from an external injury. At other times, a pallid, leaden countenance, indigestion, frequent nausea, colicky pains, sudden purgings, &c. sufficiently indicate a vitiated habit, and diseased viscera, which diseased viscera may also sometimes be discovered and felt.

The progress also which it makes from the testis up ward, toward the process, is very uncertain; the disease occupying the testicle only, without affecting the spermatic process, in some subjects, for a great length of time; while, in others, it totally spoils the testicle very soon, and almost as soon seizes on the spermatic

SARCOCOLLA. (From σαρξ, flesh, and κολλα, glue; because of its supposed power of gluing together wounds.) A spontaneous exudation from a tree of the fur kind, which grows in Persia, supposed to be similar to olibanum of frankincense. SARCOEPIPLOCE'LE. Enlarged testicle, with

rupture, containing omentum.

SARCOLITE. A variety of analcime.

SARCO'LOGY. (Sarcologia; from σαρξ, flesh, and λογος, a discourse.) The doctrine of the muscles and

SARCO'MA. (Sarcoma, atis. n.; from saot, flesh.)
Sarcosis; Porrus; Sarcophyia; Nævus. Å fleshy
excrescence. A genus of disease in the Class Locales,

and Order Tumores, of Cullen.

SARCO'MPHALUS. (From σαρξ, flesh, and ομφαλος, the navel.) A fleshy excrescence about the navel.

SARCOPHYIA. (From σαρξ, flesh, and φυω, to grow.)

A fleshy excrescence.

SARCOPYODES. (From $\sigma a \rho \xi$, flesh, and $\varpi v \rho \nu$, pus.) Applied to the purulent, fleshy discharge, which is thrown up in some stages of consumption.

SARCO'SIS. (From σαρξ, flesh.) 1. A fleshy tu-

mour.
2. The generation of flesh.

SARCOTICA. (From σαρξ, flesh.) Medicines which promote the generation of flesh in wounds.

SARDE. Sardoin. A variety of cornelian of a

deep blood-red colour.

SARDIASIS. (From σαρόωνιη, the sardonia, or herb, which, being eaten, causes convulsive laughter.) See

Sardonic laugh.
Sardonia, its native soil.) A

kind of smallage.
SARDONIC LAUGH. (Risus sardonicus: called from the herb sardonia, which being eaten is said to cause a deadly convulsive laughter.) A kind of convulsive laugh, or spasmodic grin. See Spasmus cynicus.

SARDONICUS RISUS. See Sardonic laugh.
SARDONYX. A variety of cornelian composed of layers of white and red.
SARMENTACEÆ. The name of a natural order of Linnæus's Fragmenta; embracing the plants with

twining or trailing stems.

SARMENTOSUS. (From sarmentum, a twig, or trailing stalk.) Trailing. Applied to a creeping stem, barren of flowers, thrown out from the root for the

purpose of increase.

SARMENTUM. (Sarmen; from sarpio, to prune, lop, or cut off.) A twig, a runner.

SARSAPARILLA. (This word is of Spanish origin, signifying a red tree.) See Smilaz sarsapa-

SARSAPARILLA GERMANICA. Sec Carex arenaria. SAR'TORIUS. (From sartor, a tailor; because tailors cross their legs with it.) Sartorius seu longissimus femoris, of Cowper; Ilio cresti tibial of Dumas. This flat and slender muscle, which is the longest of This flat and slender muscle, which is the longest of the human body, and from an inch and a half to two inches in breadth, is situated immediately under the integuments, and extends obliquely from the upper and anterior part of the thigh, to the upper, anterior, and inner part of the tibia, being enclosed by a thin membraneous sheath, which is derived from the adjacent fascia lata. It arises, by a tendon of about half an inch in breadth, from the outer surface and inferior edge of the anterior superior spinous process of the ilium, but soon becomes fleshy, and runs down a little way obliquely inwards, and then for some space upon the rectus, nearly in a straight direction, after which it passes obliquely over the vastus internus, and the lower part of the adductor longus, and then running down between the tendons of the adductor magnus, and the gracilis, is inserted, by a thin tendon, into the inner part of the tibia, near the inferior part of its tuberosity, and for the space of an inch or two below it. This tendon sends off a thin aponeurosis, which is spread over the upper and posterior part of the leg.

This muscle serves to bend the leg obliquely inwards,
or to roll the thigh outwards, and at the same time to bring one leg across the other, on which account Spigelius first gave it the name of sartorius, or the tailor's muscle

stone; or, which is most probable, from the river Sassafras, in America, on the banks of which it grows in abundance.) See Laurus sassafras.

SASSOLINE. Native boracic acid, found on the edges of hot springs near Sasso in Florence. It con-

sists of boracic acid 86, ferruginous sulphate of man-

ganese 11, and sulphate of lime 3.

SAFELLITE. The veins which accompany the brachial artery as far as the bend of the cubit, are so

SATIN SPAR. A species of fibrous limestone. SATURANTIA. Medicines which neutralize the acid

in the stomach.

SATURATION. Saturatio. A term employed in pharmacy and chemistry to express the state of a body which has a power of dissolving another, to a certain extent only, in which it has effected that degree of solution. Some substances unite in all proportions. Such, for example, are acids in general, and some other salts with water; and many of the metals with each other. But there are likewise many substances which cannot be dissolved in a fluid, at a certain temperature, in any quantity beyond a certain proportion. Thus water will dissolve only about one-third of its weight of common salt, and, if more be added, it will remain solid. A fluid, which holds in solution as much of any substance as it can dissolve, is said to be saturated with it. But saturation with one substance does not deprive the fluid of its power of acting on and dissolving some other bodies, and in many cases it increases this power. For example, water saturated with salt will dissolve sugar; and water saturated with carbonic acid will dissolve iron, though without this addition its ac-tion on this metal is scarcely perceptible.

The word saturation is likewise used in another

sense by chemists: The union of two principles produces a body, the properties of which differ from those of its component parts, but resemble those of the pre-dominating principle. When the principles are in such proportion that neither predominates, they are said to be saturated with each other; but if otherwise, the most predominant principle is said to be subsaturated or undersaturated, and the other supersaturated or over-

saturated.

SATUREI'A. (From satyri, the lustful satyrs; because it makes those who eat it luscivious. Blanch.)

1. The name of a genus of plants in the Linnaan system. Class, Didynamia; Order, Gymnospermia.

2. The pharmacopæial name of the summer savory.

2. The pharmacopeial name of the summer savory.

SATUREIA CAPITATA. The systematic name of the ciliated savory. Thymus creticus. It possesses similar virtues to our thyme, but in a stronger degree.

SATUREIA HORTENSIS. The systematic name of the summer savory. Satureia sativa; Culina sativa Plinii; Thymbra. This low shrub is cultivated in our gardens for culinary purposes. It has a warm, aromatic, penetrating taste, and smells like thyme, but milder. It is an ingredient in most of the warm stews and made dishes.

SATUREIA SATURA. See Satureia hortensis.

SATUREIA SATIVA. See Satureia hortensis.
SATU'RNUS. (From the planet or heathen god, of that flame.) The chemical name of lead.
SATYRI'ASIS. (From σατυρος, a satyr; because

they are said to be greatly addicted to venery.) Saty-riasmus; Priapismus; Salacitas; Brachuna; Aras-con. Excessive and violent desire for coition in men. A genus of disease in the Class Locales, and Order

Dysorexia, of Cullen.

SATY'RION. (From σατυρος, an animal given to venery: so called because it was supposed to excite venery if only held in the hand.) Sec Orchis mascula.

SATYRIUM. See Orchis mascula.

SATYRIUM. See Orchis mascula.

Sauce alone. See Erysimum alliaria.

SAUNDERS. See Santalum album.

Saunders, red. See Pterocarpus.

SAUR KRAUT. Cabbage preserved in brine. An article of food common in Germany, like our pickled cabbage.

SAUSSURITE. A hard mineral, placed by Jameson near Andalusite, of white and gray or green colour, found at the foot of Mount Rosa.

SAUVAGES, Francis Boissier de, was born at Alais, in Lower Languedoc, in 1706. He graduated at Montpelier when only 20, but still continued his studies, and four years after went for farther improvement to Paris. On his return to Montpelier he SA'SSAFRAS. (Quasi saxifraga; from saxum, a stone, and frango, to break; so called because a decoction of its wood was supposed good for the for ingenuity of speculation is said to have obstructed his success in practice. In 1752 he was made professor of botany, having for twelve years before officiated as demonstrator of the plants in the botanic garden. His death occurred in 1767. He was a member of several of the learned societies of Europe, and obtained the prizes given by many public bodies for the best essays on given subjects. Among his earlier publications was one, entitled "Nouvelies Classes des Maladies," the outline of the system of Nosology, which has renthe outline of the system of Nosology, which has ren-dered his name illustrious, but which did not appear in its complete form, till after an additional labour of thirty years had been bestowed upon it. This work, consisting of five octavo volumes, contains an immense body of information, indeed, almost every thing then known concerning the species of disease; but the whole is very loosely arranged. He had collected many new observations and descriptions, with a view to incorporate them in a second edition; which, however, he did not live to accomplish. These materials were used by Dr. Cramer after his death. Besides this valuable work, Sauvages was author of numerous others on different subjects relating to medicine. SAVIN. See Juniperus sabina.

Savin ointment. See Ceratum sabina.

SAVINA. See Juniperus sabina.
SAVOURY. See Satureia.
SAXI'FRAGA. (From sazum, a stone, and frango, to break: so called because it was supposed to be good against the stone in the biadder.) The name of a genus of plants in the Linnaan system. Class, Decan-

nus of plants in the Linnæan system. Class, Decandria; Order, Digynia.

Saxifraga alba. See Saxifraga granulata.

Saxifraga anglica. See Peucedanum.

Saxifraga crassifolia. The root of this species of saxifrage is extolled by professor Pallas as an antiseptic.

Saxifraga oranulata. The systematic name of the white saxifrage. Saxifraga alba. Called by Oribasius Besto. Sanicula sedum. Linnœus describes the taste of this plant to be acrid and pungent, which we have not been able to discover; neither the tubercles of the root nor the leaves manifest to the organs of taste any quality likely to be of medicinal use, and of taste any quality likely to be of medicinal use, and therefore, though this species of saxifrage has been long employed as a popular remedy in nephritic and gravelly disorders, yet we do not find either from its sensible qualities, or from any published instances of its efficacy, that it deserves a place in the Materia Medica. The superstitious doctrine of signatures suggested the superstitions doctrine of signatures. gested the use of the root, which is a good example of what Linneus has termed radix granulata. The bulbs or tubercles of such roots answer an important purpose in vegetation, by supplying the plants with nou-rishment and moisture, and thereby enabling them to resist the effects of that drought to which the dry soils

they inhabit peculiarly expose them. Saxifraga Rubra. See Spiraa filipendula. Saxifraga vulgaris. See Peucedanum silaus.

SAXIFRAGA VULGARIS. See Feuccaanum sitaus.

SAXIFRAGE. See Saxifraga.

Saxifrage, burnet. See Pimpinella saxifraga.

Saxifrage, English. See Peucedanum sitaus.

Saxifrage, meadow. See Peucedanum sitaus.

Saxifrage, white. See Saxifraga granulata.

Saxon blue. See Blue, saxon.

SCAB. A hard substance covering superficial ulcerations, and formed by a concretion of the fluid discharged from them.

charged from them.

SCABER. Rough to the touch from any little rigid inequalities: applied to several parts of plants.

SCABIES. (Scabics, et. f.; from scabo, to scratch.)

See Psora.

SCABIO'SA. (From scaber, rough: so called from its rough hairy surface.)

1. The name of a genus of plants in the Linnwan system. Class, Tetrandria;

Order, Monogynia.
2. The pharmacopoint name of the common scabi-

See Scabiosa arvensis.

SCAEIOSA ARVENSIS. The systematic name of the common field scabious. This herb, Scabiosa—corollis quadrifidis radiantibus; foliis pinnatifibis, incisis; caule hispido, of Linnæus, and its flowers are sometimes used medicinally. The whole plant possesses a bitter and subadstringent taste, and was formerly much employed in the cure of some leprous affections and diseases of the lungs.

The systematic name of the SCABIOSA SUCCISA. devil's bit scabious.

SCABRIDEÆ. (From scaber, rough.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants with rough leaves, incomplete and inelegant flowers.

SCA'LA. A ladder or staircase.

SCALA TYMPANI. The superior spiral cavity of the

cochlea.

SCALA VESTIBULI. The inferior spiral cavity of the cocblea.

SCALD. See Ambustio.

Scald head. See Tinca capitis.

SCALE. Squama. A lamina of morbid cuticle, hard, thickened, whitish, and opake, of a very small size, and irregular, often increasing into layers, denominated crusts. Both scales and crusts repeatedly fall

off, and are reproduced in a short time.

SCALE'NUS. (Scalenus, sc. Musculus; from σκα-ληνος, irregular or unequal.) A muscle about which anatomical writers have differed greatly in their de-scriptions. It is situated at the side of the neck, between the transverse processes of the cervical vertebra and the upper part of the thorax. The ancients who gave it its name from its resemblance to an irregular triangle, considered it as over the contract of the contract gave it its name from its resemblance to an irregular triangle, considered it as one muscle. Vesalius and Wipslow divide it into two, Fallopius and Cowper into three, Douglas into four, and Albinus into five portions, which they describe as distinct muscles. Without deviating in the least from anatomical accuracy, it may be considered as one muscle divided into three portions. The anterior portion arises commonly from the transverse processes of the six inferior vetebræ of the neck, by as many short tendons, and descending obliquely by as many short tendons, and descending obliquely outward, is inserted tendinous and fleshy, into the upper side of the first rib, near its cartilage. The axillary artery passes through this portion, and sometimes divides it into two stips, about an inch and a half above its insertion. The middle portion arises by distinct tendons, from the transverse processes of the four last vertebræ of the neck, and descending obliquely outwards and a little backwards, is inserted tendinous into the outer and upper part of the first rib, from its root to within the distance of an inch from its cartilage. The space between this and the anterior portion af-The space between this and the anterior portion, affords a passage to the nerves going to the upper ex-tremities. It is in part covered by the third or posterior portion, which is the thinnest and longest of the three. This arises from the transverse processes of the second, third, fourth, and fifth vertebræ of the neck, by distinct tendons, and is inserted into the upper edge of the second rib, at the distance of about an inch and a half from its articulation, by a broad flat tendon The use of the scalenus is to move the neck to one side, when it acts singly, or to bend it forwards, when both nuscles act; and when the neck is fixed, it serves to elevate the ribs, and dilate the chest.

SCALENUS PRIMUS. See Scalenus. SCALENUS SECUNDUS. See Scalenus.
SCALENUS TERTIUS. See Scalenus.
SCALPE'LLUM. A scalpel or common dissecting

SCALPRUM. A denticular raspetory, used in trepanning.

Scaly. See Squamosus. SCAMMO'NIUM. (A (A corruption of the Arabian

SCAMMO'NIUM. (A corruption of the Arabian word chamozah.) See Convolvulus scammonia. SCAMMONY. See Convolvulus scammonia. SCANDENS. Climbing, either with spiral tendrils for its support, or by adhesive fibres. Applied to stems, &c. as that of the Vitis vinifera, and Bryonia dioica. SCA'NDIX. The name of a genus of plants in the Linnean system. Class Pentandria; Order, Digynia. SCANDIX CEREFOLIUM. The systematic name of the officinal chervil. Cerefolium; Chærophyllum; Chærefolium. Chervil. This plant, Scandix—seminibus nitidis, ovato-subulatis; umbellis sessilibus laterations, of Linneus, is a salubrious culinary herb, sufficiently grateful both to the palate and stomach, slightly aromatic, gently aperient, and diuretic. Scandix odorata. The systematic name of the sweet cicely, myrrhis, which possesses virtues similar

Scandix odorata. The systematic name of the sweet cicely, myrrhis, which possesses virtues similar

to the common chervil. See Scandiz cerefolium.

SCAPHA. (A skiff, or cock-boat; from σκαπτω, to make hollow: because formerly it was made by excavating a large tree.)

1. The excavation or cavity of the auricula, or external ear, between the helix and antibelix

2. The name of a double headed roller.

SCAPHOID. See Scaphoides.
SCAPHOI'DES. (From σκαφη, a little vessel, or boat, and μόσς, resemblance.) Boat-like. See Navi-

SCAPOLITE. Pyramidal felspar. Professor Jame-

son divides this into four subspecies

I. Radiated, of a gray colour, resinous, and pearly in distinct concretions, and crystallized, found in the neighbourhood of Arendal, in Norway, associated with magnetic ironstone, and felspar.

Foliated scapolite, crystallized and of a gray, green, and black colour, found in granular granite, or whitestone, in the Saxon Erzegebirge.

3. Compact scapolite, of a red colour, found with the former species.

4. Elaplite

SCA'PULA. (From the Hebrew schipha.) Omoplata; Os homoplata; Scoptula; Epinotion. The shoulder-blade. This bone, which approaches nearly to a triangular figure, is fixed, not unlike a buckler, to the upper, posterior, and lateral part of the thorax, extending from the first to about the seventh rib. The anterior and internal surface is irregularly concave, anterior and internal surface is irregularly concave, from the impression, not of the ribs, as the generality of anatomists have supposed, but of the subscapularis muscle. Its posterior and external surface is convex and divided into two unequal fossæ by a considerable spine, which, rising small from the posterior edge of the scapula, becomes gradually higher and broader, as it represents the anterior, and superior angle of the it approaches the anterior and superior angle of the and approaches the anterior and superior angle of the bone, till at length it terminates in a broad and flat process, at the top of the shoulder, called the processus acromion. On the anterior edge of this processus acromion, we observe an oblong, concave, articulating surface covered with cartilage, for the articulation of the scapula with the clavicle. At its lower part, the acromion is hollowed, to allow a passage to the supra and infra spirati muscles. The ridge of the spine afand infra spinati muscles. The ridge of the spine af-fords two rough, flat surfaces, for the insertion of the trapezius and deltoid muscles. Of the two fossæ into which the external surface of the bone is divided by the spine, the superior one, which is the smallest, serves to lodge the supra spinatus muscle; and the inferior fossa, which is much larger than the other, gives origin to the infra spinatus. The triangular shape of the scapula leads us to consider its angles and its sides. The upper posterior angle is neither so thick, nor has so rough a surface, as the inferior one; but the most remarkable of the three angles of this bone is the anterior one, which is of great thickness, and formed into a glenoid cavity of an oval shape, the greatest diameter of which is from below upwards. cavity, in the recent subject, is furnished with cartilage, and receives the head of the os humeri. The cartila-ginous crust, which surrounds its brims, makes it appear deeper in the fresh subject than in the skeleton.

A little beyond this glenoid cavity, the bone becomes narrower, so as to give the appearance of a neck: and above this rises a considerable process, which, from being thick at its origin, becomes thinner, and, in some degree, flattened at its extremity. This process projects considerably, and is curved downwards. From its supposed resemblance to a beak of a bird, it is called the *coracoid* process. From the whole external side of this process, a strong and broad ligament is stretched to the processus acromion, becoming narrower as it approaches the latter process, so as to be of a some-what triangular shape. This ligament, and the two processes with which it is connected, are evidently intended for the protection of the joint, and to prevent a luxation of the os humeri upwards. Of the three sides of the scapula, the posterior one, which is the longest, is called the basis. This side is turned towards the vertebræ. Its other two sides are called costæ. The superior costa, which is the upper and shortest side, is likewise thinner than the other two, having a sharp edge. It is nearly horizontal, and parallel with the second rib; and is interrupted near the basis of the coracoid process, by a semicircular niche, which is closed by a ligament that extends from one end of it to the other, and affords a passage to vessels and nerves. Besides this passage, there are other niches in the scapula for the transmission of vessels; viz. one be-tween the coracoid process and the head of the bone, and another between its neck and the processus acro-mion. The third side of the scapula, or the inferior

extends obliquely from the neck of the bone to its inferior angle, reaching from about the third to the eighth rib. The scapula has but very little cellular substance, and is of unequal thickness, being very thin at its middle part, where it is covered by a great number of muscles, and having its neck, the acromion, and extend the strength. In the and coracoid process, of considerable strength. In the foctus, the basis and the neck of the scapula, together with its glenoid cavity, acromion, coracoid process, and the ridge of the spine, are so many epiphyses with respect to the rest of the bone, to which they are not completely united till a considerable time after birth. The scapula is articulated to the clavicle and os humeri, to which last it serves as a fulcrum; and, by altering its position, it affords a greater scope to the bones of the arm in their different motions. It likewise affords attachment to a great number of muscles, and

posteriorly serves as a defence to the thorax.

SCAPULAR. (Scapularis; from scapula, the shoulder bone.) Belonging to the scapula; as the scapulary arteries and veins, which are branches of the subclavian and axillary.

SCAPULARIA. (From scapula, the shoulderbone.) A scapulary. A bandage for the shoulderblade.

SCAPUS. (Scapus, i. m.; from gkanta, to lean or rest upon: because it rests as it were on the root or base.) A stalk which springs from the root, and bears the flowers and fruit, but not the leaves. The prim rose and cowslip are good examples of it.

The following are the principal varieties:

 Teres; as in Plantago major.
 Angulosus; as in Plantago lanceolata.
 Ventricosus, hollow at the bottom; as in Allium cepa.

Flexuosus; as in Orchis flexuosa.
 Anceps; as Alium angulosum.

6. Filiformis; as Bellis bellidoides.
7. Triquetrus; as Allium triquetrum.
8. Spiralis; as Anthericum spirale, and that wonderful plant, Valisueria spiralis.

Pentagonus; as Ophris paludosa.
 Articulatus; as Statice echioides.
 Erectus; in Tulipa gesneriana.

12. elscendens; in Silymbrium vimineum.
13. Declinatus; as Astragalus incanus.
14. Decumbens; as Potentilla sabacaulis.
15. Dichotomus; as Statice tartarica.
16. Nudus; as Convallaria majalis.

17. Foliosus; as Ophris insectifera.

Bracteatus, and most of the Orchides.
 Imbricatus; as Tussilago farfara.
 Setaceus; as Schænus bulbosus.

21. Vaginatus; as Arethusa bulbosa. When several species of the same plant have a sca pus, and it is wanting in one of the same species, it is

pus, and it as wanting in one of the same species, it is termed exseapus; as in Astragalus exscapus.

SCARBOROUGH. I. The name of a town in Yorkshire, noted for its ferruginous spring. There are two species of chalybeate water found in this spot, and they differ considerably in their composition, though they rise nearly contiguous to each other. The one is a species as heartest chalybeate similar to the Tuna simple carbonated chalybeate, similar to the Tun-bridge water; the other, which is better known and more frequented, and more particularly distinguished as Scarborough water, has, in conjunction with the iron, a considerable admixture of a purging salt, which adds much to its value. The diseases in which it is ordered are similar to those in which Cheltenham water is prescribed, only it is necessary to increase the purgative effect of this water by adding similar salts. It is, therefore, chiefly as an alterative that this water can be employed in its natural state.

Scarborough has an advantage belonging to its situation which Cheltenham does not possess, that of af-fording an opportunity for sea-bathing, the use of which will, in many cases, much assist in the plan of cure for many of the disorders for which the mineral

water is resorted to.

2. The name of a physician. Sir Charles, born about the year 1616. Intending to follow the medical profession, he went to study at Cambridge, and applied himself particularly to the mathematics, in which he made great proficiency. During the civil wars he was obliged to remove to Oxford, where he entered under the celebrated Harvey, then warden of Merton College, who, being employed in writing his treatise " De 1

Generatione Animalium," gladly accepted the assistance of Mr. Scarborough. Upon taking the degree of doctor of medicine, he settled in the metropolis, where he practised with great reputation. He became a fellow of the college of physicians, in which he was much respected for his talents; and being appointed to intro-duce the Marquis of Dorchester, who was admitted into that body in 1658, he made an elegant Latin speech on that occasion. In the mean time he began to deliver anatomical lectures at Surgeons' Hall, which were highly approved, and continued for sixteen or seventeen In 1669 the order of knighthood was conferred upon him by Charles II., who also appointed him his upon him by Charles II., who also appointed him his chief physician; and he enjoyed the same office under the two succeeding monarchs. He was likewise made physician to the Tower of London, which appointment he retained till his death about the year 1702. The works left by him were chiefly mathematical. SCARF-SKIN. See Caticle and Skin. SCARIFICATION. (Scarificatio; from scarifico, to scarify.) A superficial incision made with a lancet, or a chirurgical instrument called a scarificator, for the purpose of taking away blood, or letting out fluids. &c.

taking away blood, or letting out fluids, &c.

SCARIFICATOR. An instrument used by surgeons and cuppers to evacuate blood. It is made in form of a box, in which are fitted, ten, twelve, or more

form of a box, in which are fitted, ten, twelve, or more lancets, all perfectly in the same plane; which being, as it were, cocked, by means of a spring are all discharged at the same time, by pulling a kind of trigger, and driven equally within the skin.

SCARIOLA See Lactuca scariola.

SCARIOLA GALLORUM. See Lactuca scariola.

SCARLATINA. (From scarlatto, the Italian for a deep red.) The scarlet fever. A genus of disease in the Class Pyrexia, and Order Exanthemata, of Cullen; characterized by contagious synocha; the fourth day the face swells; a scarlet eruption appears on the skin in patches; which, after three or four days, on the skin in patches; which, after three or four days, ends in the desquamation of the cuticle, and is often succeeded by anasarca. It has two species:

1. Scarlatina simplex, the mild.

2. Scarlatina cynanchica, or anginosa, with ulcerated

sore throat.

Dr. Willan has added to these a third, called malig na, agreeing with the cynanche maligna, of Cullen.

Some have asserted that scarlatina never attacks the same person a second time; more extensive observation has confuted this opinion. It seizes persons of all ages, but children and young persons are most subject to it, and it appears at all seasons of the year; but it is more frequently met with towards the end of autumn, or beginning of winter, than at any other periods, at which time it very often becomes a prevalent epidemic. It is, beyond all doubt, a very contagious dis-

The one to which it bears the greatest resemblance is the measles; but from this it is readily to be distinguished by the absence of the cough, watery eye, running at the nose and sneezing, which are the predominant symptoms in the early stage of the measles, but which do not usually attend on the scarlatina, or at

least in any high degree.

It begins, like other fevers, with languor, lassitude, confusion of ideas, chills, and shiverings, alternated by fits of heat. The thirst is considerable, the skin dry, and the patient is often incommoded with anxiety, nausea, and vomiting. About the third day, the scar-let efflorescence appears on the skin, which seldom pro-duces, however, any remission of the fever. On the departure of the efflorescence, which usually continues out only for three or four days, a gentle sweat comes on, the fever subsides, the cuticle or scarf-skin then falls off in small scales, and the patient gradually regains his former strength and health.

On the disappearance of the efflorescence in scarlatina, it is, however, no uncommon occurrence for an anasarcous swelling to affect the whole body, but this

is usually of a very short continuance.

Scarlatina anginosa, in several instances, approaches very near to the malignant form. The patient is seized not only with a coldness and shivering, but likewise with great languor, debility, and sickness, succeeded by heat, nausea, vomiting of bilious matter, soreness of the threat inflammation and algorithm in the language. of the throat, inflammation, and ulceration in the tonsils, &c., a frequent and laborious breathing, and a quick and small depressed pulse. When the efflorescence appears, which is usually on the third day, it antiphlogistic regimen. But where the throat is af-

brings no relief; on the contrary, the symptoms are much aggravated, and fresh ones arise.

In the progress of the disease, one universal redness

unattended, however, by any pustular eruption, pervades the face, body, and limbs, which parts appear somewhat swollen. The eyes and nostrils partake likewise more or less of the redness, and, in proportion as the former have an inflamed appearance, so does the

tendency to delirium prevail.

On the first attack, the fauces are often much inflamed; but this is usually soon succeeded by grayish sloughs, which give the parts a speckled appearance, and render the breath more or less fætid. The patient is often cut off in a few days; and even if he recovers, it will be by slow degrees; dropsical swellings, or tumours of the parotid, and other glands, slowly sup-purating, being very apt to follow. In the malignant form of the disease the symptoms at first are pretty much the same; but some of the following peculiarities are afterward observable. The pulse is small, indistinct, and irregular; the tongue, teeth, and lips, covered with a brown or black incrustation; a dull redness of the eyes, with a dark-red flushing of the cheeks, deafness, delirium, or coma; the breath is extremely fætid; the respiration rattling and laborious, partly from viscid phlegm clogging the fauces; the deglutition is constricted and painful; and there is a fulness and livid colour of the neck, with retraction of the head. Ulcerations are observed on the tonsils and adjoining parts, covered with dark sloughs, and sur-rounded by a livid base; and the tongue is often so ten-der as to be excoriated by the slightest touch. An acrid discharge flows from the nostrils, causing soreness, or chaps, nay, even blisters, about the nose and lips; the fluid discharged being at first thin, but afterward thick and yellowish. The rash is usually faint, except in a few irregular patches; and it presently changes to a dark, or livid red colour: it appears late, is very uncer-tain in its duration, and often intermixed with petechiæ; it sometimes disappears suddenly a few hours after it is formed, and comes out again at the expira-tion of two or three days. In an advanced stage of the disease, where petechiæ, and other symptoms characteristic of putrescency, are present, hæmorrhages frequently break forth from the nose, mouth, and other

When scarlatina is to terminate in health, the fiery redness abates gradually, and is succeeded by a brown colour, the skin becomes rough, and peels off in small scales, the tumefaction subsides, and health is gradually restored. On the contrary, when it is to terminate fatally, the febrile symptoms run very high from the first of its attack, the skin is intensely hot and dry, the pulse is very frequent but small, great thirst pre vails, the breath is very fætid, the efflorescence makes its appearance on the second day, or sooner, and about the third or fourth is probably interspersed with large livid spots; and a high degree of delirium ensuing, or hæmorrhages breaking out, the patient is cut off about the sixth or eighth day. In some cases a severe purging arises, which never fails to prove fatat. Some, again, In some cases a severe purging where the symptoms do not run so high, instead of re covering, as is usual, about the time the skin begins to regain its natural colour, become dropsical, fall, into a kind of lingering way, and are carried off in the course

of a few weeks.

Scarlatina, in its inflammatory form, is not usually attended with danger, although a considerable degree of delirium sometimes prevails for a day or two; but when it partakes much of the malignant character, or degenerates into typhus putrida, which it is apt to do, it often proves fatal. On dissection of those who die of this disease, the fauces are inflamed, suppurated, and gangrenous; and the trachea and larynx are like wise in a state of inflammation, and lined with a viscid feetid matter. In many instances the inflammatory affection extends to the lungs themselves. swellings of the lymphatic glands about the neck, occasioned by an absorption of the acrid matter poured out in the fauces, are now and then to be found. same morbid appearances which are to be met with in putrid fever, present themselves in other parts of the

The plan to be pursued will differ according to the

fected, and the fever runs higher, more active means become necessary, varying according to the type of this, whether synochal, or typhoid. In general, we may begin by exhibiting a nauscating emetic, which, besides its effect on the fever, may be useful in check-ing inflammation in the throat; and occasionally the repetition, of such a remedy after a time, may answer a good purpose; but commonly it will be better to follow up the first by some cathartic remedy of sufficient ac-tivity. Then, so long as the strength will allow, we may endeavour to moderate the fever by mercurial and antimonial preparations, or other medicines promoting the several secretions, by steadily pursuing the anti-phlogistic regimen, and occasionally applying cold water to the skin, when this is very hot and dry. Sometimes severe inflammation in the throat at an early period may render it advisable to apply a few leeches externally, or blisters behind the ears; and gar-gles of nitrate of potassa, the mineral acids, &c. should be used from time to time. But where the disorder exhibits the typhoid character, with ulcers in the throat, tending perhaps to gangrene, it is necessary to support the system by a nutritious diet, with a moderate quantity of wine, and tonic or stimulant medicines, as the ciuchona, calumba, ammonia, capsicum, &c.; the acids will also be very proper from their antiseptic, as well as tonic power; and stimulant antiseptic gargles should be frequently employed, as the mineral acids sufficiently diluted, with the addition of tructure of myrrh, or these mixed with the decoction of bark, &c. sides the general measures, thus varied according to the character of the disease, particular alarming symp-toms may require to be palliated; as vomiting by the effervescing draught, and occasionally a blister to the stomach, if there be tenderness on pressure; diarrhea by small doses of opium, &c. The management of these, however, as well as of the dropsical swellings, and other sequels of the disease, will be understood from what is said under those heads respectively.

SCARLATINA ANGINOSA. See Scarlatina. SCARLATINA CYNANCHICA. See Scarlatina.

SCARLATINA SIMPLEX. See Scarlatina.
Scarlet fever. See Scarlatina.
Scelotyrrbe. (From σκιλος, the leg, and τυρόη, riot, intemperance.) A debility of the legs from scurvy,

riot, intemperance.) A debility of the legs from scurvy, or an intemperate way of life.

Schaultein. See Tabular spar.

Schaum earth. See Aphrite.

SCHERO MA. A dryness of the eye from the want of the lachrymal fluid. The effects of this lachrymal fluid being deficient are, the eyes become dry, and in their motions produce a sensation as though sand, or some gritty substances, were between the eye and the greeklet, the vision is observed the eye for the greeklet. eyelid; the vision is obscured, the globe of the eye appears foulish and dull, which is a bad omen in acute diseases. The species are,

1. Scheroma febrite, or a dryness of the eyes, which is observed in fevers complicated with a phlogistic den-

sity of the humours.

2. Scheroma exhaustorum, which happens after great evacuations, and in persons dying.

3. Scheroma inflammatorum, which is a symptom of the ophthalmia sicca.

4. Scheroma itinerantium, or the dryness of the eyes, which happens in sandy places, to travellers, as in hot Syria, or from dry winds, which dry up the humidity necessary for the motion of the eyes.

SCHIDACE DON. (From σχεδαξ, a splinter.) A longitudinal fracture of the bone.

SCHILLER SPAR. This mineral contains two

See Bronzite.

2. The common Schiller spar, which is of an olive green colour, and occurs imbedded in serpentine in Shetland, Cornwall, &c.
Schinelæum. (From σχινος, mastich, and ελαιον,

Oil of mastich.

SCHNEIDER, CORRAD VICTOR, was born at Bitter-feld, in Misnia. He filled the offices of professor of anatomy, botany, and medicine, at Wittemberg, with great reputation: and was father of the faculty when he died in 1680. He wrote many treatises; those on anatomical subjects relating chiefly to the bones of the cranium, and to the pituitary membrane of the nostrils, to which his name is still attached. He refuted an ancient error, that the mucus in catarrh distilled through the cribriform bone from the brain, showing that it was peated at more distant intervals, or by the joining of an

secreted by the pituitary membrane. In other respects, his writings, except in anatomy, are diffuse and ob-scure, and full of ancient hypothetical doctrines.

Schneider's membrane. So called from its dis-overer. See Membrana Schneideriana. SCHCENA'NTHUS. (From σχοινος, a rush, and

Scholna NTHUS. (From σχοινος, a rush, and arθος, a flower.) See Andropogon schanunthus. Scholnacurus. (From σχοινος, a rush, λαγως, a hare, and ουρα, a tail: so called from its resemblance to a hare's-tail.) Hare's-tail. The Trifolium ar-

SCHORL. A sub-species of rhomboidal tourmaline, of a velvet black colour, found imbedded in granite, SCHORL. gneiss, &c. in Scotland and Cornwall.

Schorl, blue. A variety of Hauyne. Schorl, red and titanic. Rutile.

SCHORLITE. Schorlous topaz. Pycnite of Werner. This mineral is of a straw-yellow colour, and becomes electric by heating. It is found at Altenberg in Saxony, in a rock of quartz and mica in porphyry. SCIATIC. (Sciaticus; from ischiaticus.) Belong-

ing to the ischium.

SCIATIC ARTERY Arteria sciatica. Ischiatic re-

tery. A branch of the internal iliac.

SCIATIO NERVE. Nervus sciaticus. Ischiatic nerve. A branch of a nerve of the lower extremity, formed by the union of the lumbar and sacral nerves. It is divided near the poplical cavity into the tibial and peroneal, which are distributed to the leg and foot.

Sciatic Notch. Ischiatic notch. See Innomina-

SCIATIC VEIN. Vena sciatica. The vein which accompanies the sciatic artery in the thigh.

SCIATICA. A rheumatic affection of the hip-

joint.

nt.
Sciatica cresses. See Lepidium iberis.
SCILLA. (From σκιλλω, to dry: so called from SCILLA. (From σκιλλω). 1. The name of a Class Here. SCI'LLA. (From σκιλλω, to dr its property of drying up humours.) geous of plants in the Linnaan system. Class, Hez-andria; Order Monogynia.

2. The pharmacopoial name of the medicinal squill

See Scilla maritima.

SCILLA HISPANICA. The Spanish squill.
SCILLA MARITICA. The systematic name of the SCILLA MARITICA. The systematic name of the officinal squill. Ornithogalum maritimum; Squilla. Scilla—nudiflora, bracteis refractis, of Linnaus. A native of Spain, Sicily, and Syria, growing on the seacoast. The red-rooted variety has been supposed to be more efficacious than the white, and is, therefore, still preferred for medicinal use. The root of the squill, which appears to have been known as a medicine in the early ages of Greece, and has so well maintained its character ever since, as to be deservedly in great estimation, and of very frequent use at this time, seems to manifest a poisonous quality to several animais. In proof of this, we have the testimonies of Hillefield, Bergius, Vogel, and others. Its acrimony is so great, that even if much handled, it exulcerates the skin, and if given in large doses, and frequently repeated, it not only excites nausea, tormina, and violent vomiting, but it has been known to produce strangury, bloody urine, hypercatharsis, cardialgia, hæmorrhoids, convulsions, with fatal inflammation, and gangrene of the volsions, with fatal inhammation, and gangrene of the stomach and bowels. But as many of the active articles of the Materia Medica, by injudicious administration, become equally deleterious, these effects of the scilla do not derogate from its medicinal virtues; on the contrary, we feel ourselves fully warranted, says Dr. Woodville, in representing this drug, under proper management, and in certain cases and constitutions, to be a medicine of great practical utility and real importance in the cure of many obstinate diseases. effects, as stated by Bergius, are incidens, diuretica, emetica, subpurgans, hydragoga, expectorans, emme-nagoga. In dropsical cases it has long been esteemed the most certain and effectual diuretic with which we are acquainted; and in asthmatic affections, or dysp-nce, occasioned by the lodgement of tenacious phlegm, it has been the expectorant usually employed. squill, especially in large doses, is apt to stimulate the stomach, and to prove emetic; and it sometimes acts on the intestines, and becomes purgative; but when these operations take place, the medicine is prevented from reaching the blood vessels and kidneys, and the patient is deprived of its diuretic effects, which are to be obtained by giving the squill in smaller doses, re-

oplate to this medicine, which was found by Dr. Cullen to answer the same purpose. The Doctor further observes, that from a continued repetition of the squill, the dose may be gradually increased, and the interval of its exhibitions shortened; and when in this way the dose becomes to be tolerably large, the opiate may be most conveniently employed to direct the operation of the squill more certainly in the kidneys. "In cases of dropsy, that is, when there is an effusion of water into the cavities, and therefore less water goes to the kidneys, we are of opinion that neutral salt, accompany ing the squill, may be of use in determining this fluid more certainly to the kidneys; and whenever it can be perceived that it takes this course, we are persuaded that it will be always useful, and generally safe, during the exhibition of the squills, to increase the usual quantity of drink."

The diuretic effects of squills have been supposed to be promoted by the addition of some mercurial; and the less purgative preparations of mercury, in the opi-nion of Dr. Cullen, are best adapted to this purpose; he therefore recommends a solution of corrosive sublimate, as being more proper than any other, because most diuretic. Where the prime viae abound with mucous matter, and the lungs are oppressed with viscid phlegm, this medicine is likewise in general estima-

As an expectorant, the squill may be supposed not only to attenuate the mucus in the follicles, but also to excite a more copious secretion of it from the lungs, and thereby lessen the congestion, upon which the difficulty of respiration very generally depends. There-fore in all pulmonic affections, excepting only those of actual or violent inflammation, ulcer, and spasm, the squill has been experienced to be a useful medicine. The officinal preparations of squills are, a conserve, dried squills, a syrup, and vinegar, an oxymel, and Practitioners have not, however, confined themselves to these. When this root was intended as a diuretic, it has most commonly been used in powder, as being, in this state, less disposed to nauseate the stomach; and to the powder it has been the practice to add neutral salts, as nitre, or crystals of tartar, espe-cially if the patient complained of much thirst; others recommend calomel; and with a view to render the squills less offensive to the stomach, it has been usual to conjoin an aromatic. The dose of dried squills is from one to four or six grains once a day, or half this quantity twice a day; afterward to be regulated ac-cording to its effects. The dose of the other preparations of this drug, when fresh, should be five times this weight; for this root loses in the process of drying four-fifths of its original weight, and this loss is merely a watery exhalation.

SCILLITES. (From σκιλλα, the squill.) A wine

impregnated with squills.

SCILLITIN. A white transparent, acrid substance, extracted by Vosel from squills.

SCINCUS. (From sheque, Hebrew.) The skink. This amphibious animal is of the lizard kind, and caught about the Nile, and thence brought dried into this country, remarkably smooth and glossy, as if varnished. The flesh of the animal, particularly of the belly, has been said to be diuretic, alexipharmic, aphrodisiac, and useful in leprous disorders.
SCIRRHO'MA. (From σκιρροω, to harden.) See

SCI'RRHUS. (From σκιρροω, to harden.) Scirrhoma; Scirrhosis. A genus of disease in the Class Locales, and Order Tumores, of Cullen; known by a hard tumour of a glandular part, indolent, and not readily suppurating. The following observations of Pearson are deserving of attention. A scirrhus, he says, is usually defined to be a hard, and almost insensible tumour, commonly situated in a glandular part, and accompanied with little or no discoloration of the surface of the skin. This description agrees with the true or exquisite scirrhus; but when it has proceeded from the indolent to the malignant state, the tumour is then unequal in its figure, it becomes painful, the skin acquires a purple or livid hue, and the cutaneous veins are often varicose. Let us now examine whether this enumeration of symptoms be sufficiently accurate for practical purposes.

It is probable, that any gland in the living body may be the seat of a cancerous disease, but it appears more frequently as an idiopathic affection in those glands

that form the several secretions than in the absorbent glands; and of the secreting organs, those which sepa-rate fluids that are to be employed in the animal economy, suffer much oftener than the glands which secrete the excrementitious parts of the blood. Insecrete the excrementinous parts of the secrete deed, it may be doubted whether an absorbent gland deed, it may be doubted whether an absorbent gland be ever the primary seat of a true scirrhus. Daily experience evinces, that these glands may suffer contamination from their connexion with a cancerous part; but under such circumstances, this morbid altera-tion being the effect of a disease in that neighbouring part, it ought to be regarded as a secondary or conse quent affection. I never yet met with an unequivocal proof of a primary scirrbus in an absorbent gland; and if a larger experience shall confirm this observation, and establish it as a general rule, it will afford material assistance in forming the diagnosis of this disease. The general term scirrhus hath been applied, with too little discrimination, to indurated tumours of lymphatic glands. When these appendages of the absorbent sys-tem enlarge in the carly part of life, the disease is com-monly treated as strumous; but as a similar alteration of these parts may, and often does, occur at a more advanced period, there ought to be some very good reasons for ascribing malignity to one rather than the other. In old people the tumour is indeed often larger, more indurated, and less tractable than in children, but when the alteration originated in the lymphytic glands, it will very rarely be found to possess any thing cancerous in its nature.

If every other morbid alteration in a part were at tended with pain and softness, then induration and defective sensibility might point out the presence of a scirrhus. But this is so far from being the case, that even encysted tumours, at their commencement, frequently excite the sensation of impenetrable hardness.

All glands are contained in capsule, not very elas-tic, so that almost every species of chronic enlarge-ment of these bodies must be hard; hence this induration is rather owing to the structure of the part, than to the peculiar nature of the disease; and as glands in their healthy state are endowed with much sensibility every disease that gradually produces induration, will rather diminish than increase their perceptive powers. Induration and insensibility may, therefore, prove that the affected part does not labour under an acute disease; but these symptoms alone can yield no certain information concerning the true nature of the morbid alteration. Those indolent affections of the glands that so frequently appear after the meridian of life, commonly manifest a hardness and want of sensation, not inferior to that which accompanies a true scirrhus; and yet these tumours will often admit of a cure by the same mode of treatment which we find to be succes ful in scrofula; and when they prove unconquerable by the powers of medicine, we generally see them con-tinue stationary and innocent to the latest period of life. Writers have indeed said much about certain tumours changing their nature, and assuming a new character; but I strongly suspect that the doctrine of the mutation of diseases into each other, stands upon a very uncertain foundation. Improper treatment may, without doubt, exasperate diseases, and render a complaint, which appeared to be mild and tractable, dangerous, or destructive; but to aggravate the symptoms, and to change the form of the disease, are things that ought not to be confounded. I do not affirm, that a breast which has been the seat of a mammary abscess, or a gland that has been affected with scrofula, may not become cancerous: for they might have suffered from this disease had no previous complaint existed; but these morbid alterations generate no greater tendency to cancer than if the parts had always retained their natural condition. There is no necessary connexion between the cancer and any other disease, nor has it been proved that one is convertible into the

Chirurgical writers have generally enumerated tumour as an essential symptom of the scirrhus; and it is very true, that this disease is often accompanied with an increase of bulk in the part affected. From long and careful observation, I am however induced to think, that an addition to the quantity of matter is rather an accidental than a necessary consequence of the presence of this affection.

When the breast is the seat of a scirrhus, the altered part is hard, perhaps unequal in its figure, and definite;

hut these symptoms are not always connected with an actual lacrease in the dimensions of the breast. On the contrary, the true scirrhus is frequently accompanied with a contraction and diminution of bulk, a retraction of the nipple, and a puckered state of the

The irritation produced by an indurated substance lying in the breast, will very often cause a determina-tion of blood to that organ, and a consequent enlargement of it; but I consider this as an inflammatory state of the surrounding parts, excited by the scirrhus, acting as a remote cause, and by no means essential to the original complaint. From the evident utility of topical blood-letting under these circumstances, a notion has prevailed that the scirrhus is an inflammatory disease; but the strongly-marked dissimilarity of a phlegmon but the strongly-marked dissimilarity of a phlegmon and an exquisite scirrhus, in their appearances, pro-gress, and mode of termination, obliges me to dissent from that opinion. That one portion of the breast may be in a scirrhous state, while the other parts are in a state of inflammation, is agreeable to reason and ex-perience; but that an inflammation, which is an acute disease, and a scirrhus, whose essential characters are almost directly the reverse of inflammation, shall be coexistent in the same part, is not a very intelligible coexistent in the same part, is not a very intelligible proposition. Tumour and inflammation are commonly

met with on a variety of other occasions, and in this particular instance they may be the effects of the disease, but are not essentially connected with its presence.

An incipient scirrhus is seldom accompanied with a discoloration of the skin; and a dusky redness, purple, or even livid appearance of the surface, is commonly seen when there is a malignant scirrhus. The presence or absence of solour can be wreage at the best sence or absence of colour can, however, at the best, afford us but a very precarious criterion of the true asture of the complaint. When the disease is clearly known, an altered state of the skin may assist us in judging of the progress it has made; but as the skin may suffer similar variations in a number of very disease.

may suffer similar variations in a number of very dis-similar diseases, it would be improper to found an opi-nion upon so delusive a phenomenon. SCITAMINEÆ. (From scitamentum, a dainty.) The name of an order of plants in Linnaus's Frag-ments of a Natural Method, consisting of those which have an herbaceous stalk, broad leaves, and the ger-men obtusely angled under an irregular corolla; as

amomum, canna, musa, &c.

SCLA'REA. (From ακληρος, hard; because its stalks are hard and dry, Blanch.) See Salvia sclarea.

SCLAREA HISPANICA. See Salvia sclarea.

SCLERI'ASIS. (From ακληροω, to barden.) Scleroma; Sclerosis. A hard tumour or induration; a

SCLEROPHTHA'LMIA. (From σκληρος, hard, and οφθαλμος, the eye.) A protrusion of the eyeball. An inflammation of the eye, attended with hardness of the parts.

Scienosarcoma. (From σκληρος, and σαρκωμα, a fleshy tumour.) A hard fleshy excrescence on the

SCLERO'TIC. (Scleroticus; from σκλησοω, to harden.) The name of one of the coats of the eye. See Sclerotic acid.

Scientic coat. Tunica sclerotica; Membrana sclerotica; Scientis. The outermost coat of the eye, of a white colour, dense, and tenacious. Its anterior part, which is transparent, is termed the cornea trans-It is into this coat of the eye that the muscles of the bulb are inserted.

SCLEROTIS. See Sclerotic coat.

Schopetraria aqua. (From schopetum, a gum: so called from its supposed virtues in healing gun-shot wounds.) Arquebusade. It is made of sage, mugwort, and mint, distilled in wine.

SCLOPETOPLA'GA. (From sclopetum, a gun, and plaga, a wound.) A gun-shot wound. SCOLI'ASIS. (From σκολιοω, to twist.) A dis-

SCOLOPE NDRIA. See Asplenium ceterach.
SCOLOPE NDRIUM. (From σκολοπενόρα, the earwig: so called because its leaves resemble the earwig.) See Asplenium ceterach.

Scotopomach καιυμ. (From σκολωπαξ, the woodcock, and μαχαιρα, a knife: so called because it is bent a little at the end like a woodcock's bill.) An incision-

SCO'LYMUS. (From exolog, a thorn: so named from its prickly leaves.) See Cinara scolymus.

SCOMBER. The name of a genus of fishes, of the

order Thoracici.

Scomber scomber. The systematic name of the common mackarel, a beautiful fish, of easy digestion, which frequents our shore in vast shoals, between the months of April and July.

Scomber thynnus. The systematic name of the tunny-fish, which frequents the shore of the Mediterranean, and, though a coarse fish, was much esteemed by the Greeks and Permanean and still considered a de-

by the Greeks and Romans, and is still considered a delicacy by some.

Scopa Regia. See Ruscus aculcatus. Scorbu'tia. (From scorbutus, the scurvy.) Me-

dicines for the scurvy.

SCORBU'TUS. (From schorboct, Germ.) Gingi-SCORBUTUS. (From schorboct, Germ.) Gingibrachium, when the gums and arms, and gingipedium, when the gums and legs, are affected by it. The scurvy. A genus of disease in the Class Cacheria, and Order Impetigines, of Cullen; characterized by extreme debility; complexion pale and bloated; spongy gums; livid spots on the skin; breath offensive; cedematous swellings in the legs; hæmorrhages; foul ulcers; fottid urine; and extremely offensive stools. The scurvy is a disease of a putrid nature, much more prevalent in cold climates than in warm ones, and which chiefly affects sailors, and such as are shut up in besieged places, owing, as is supposed, to their being deprived affects sailors, and such as are shut up in besieged places, owing, as is supposed, to their being deprived of fresh provisions, and a due quantity of acescent food, assisted by the prevalence of cold and moisture, and by such other causes as depress the nervous energy, as indolence, confinement, want of exercise, neglect of cleanliness, much labour and fatigue, sadness, despondency, &c. These several debilitating causes, with the concurrence of a diet consisting principally of saited or putrescent food, will be sure to procipally of salted or putrescent food, will be sure to pro-duce this disease. It seems, however, to depend more on a defect of nourishment, than on a vitiated state; and the reason that salted provisions are so productive and the reason that sated provisions are so productive of the scurvy, is, most probably, because they are drained of their nutritious juices, which are extracted and run off in brine. As the disease is apt to become pretty general among the crew of a ship when it has once made its appearance, it has been supposed by many to be of a contagious name; but the conjecture seems by no means well founded. seems by no means well founded.

A preternatural saline state of the blood has been assigned as its proximate cause. It has been con-tended, by some physicians, that the primary morbid affection in this disease is a debilitated state of the solids, arising principally from the want of aliment. solids, arising principally from the want of aliment. The scurvy comes on gradually, with heaviness, weariness, and unwillingness to move about, together with dejection of spirits, considerable loss of strength, and debility. As it advances in its progress, the countenance becomes sallow and bloated, respiration is hurried on the least motion, the teeth become loose, the gums are spongy, the breath is very offensive, livid spots appear on different parts of the body, old wounds which have been long healed up break out afresh, severe wandering pains are felt, particularly by night, the which have been long heared up break out arresh, severe wandering pains are felt, particularly by night, the skin is dry, the urine small in quantity, turning blue vegetable infusions of a green colour; and the pulse is small, frequent, and, towards the last, intermitting; but the intellects are, for the most part, clear, and distinct. By an aggravation of the symptoms, the disease, in its last stage, exhibits a most wretched appearance. The points become swelled and stiff the tendons of the The joints become swelled and stiff, the tendons of the legs are rigid and contracted, general emaciation en-sues, hæmorrhages break forth from different parts, fætid evacuations are discharged by stool, and a diar-rhæa or dysentery arises, which soon terminates the

tragic scene.

Scurvy, as usually met with on shore, or where the person has not been exposed to the influence of the reperson has not been exposed to the influence of the remote causes before enumerated, is unattended by any violent symptoms, as slight blotches, with scaly eruptions on different parts of the body, and a sponginess of the gums, are the chief ones to be observed.

In forming our judgment as to the event of the discase, we are to be directed by the violence of the symptoms, by the situation of the patient with respect to

toms, by the situation of the patient with respect to a vegetable diet, or other proper substitutes, by his for-mer state of health and by his constitution, not having been impaired by previous diseases.

Dissections of scurvy have always discovered the

blood to be in a very dissolved state. The thorax | usually contains more or less of a watery fluid, which, in many cases, possesses so high a degree of acrimony, as to excoriate the hands by coming in contact with it the cavity of the abdomen contains the same kind of fluid; the lungs are black and putrid; and the heart itself has been found in a similar state, with its cavity filled with a corrupted fluid. In many instances, the epiphyses have been found divided from the bones, the cartilages separated from the ribs, and several of the bones themselves dissolved by caries. The brain sel-

dom shows any disease.

In the cure, as well as the prevention of scurvy, much more is to be done by regimen, than by medicines, ob-viating as far as possible the several remote causes of the disease, but particularly providing the patient with a more wholesome diet, and a large proportion of fresh vegetables; and it has been found that those articles vegetables; and it has been found that those articles are especially useful, which contain a native acid, as oranges, lemons, &c. Where these cannot be procured, various substitutes have been proposed, of which the best appear to be the inspissated juices of the same fruits, or the crystallized citric acid. Vinegar, sour crout, and farinaceous substances made to undergo the acctous fermentation, have likewise been used with much advantage: also brisk fermenting liquors, as spruce beer, cider, and the like Formerly many plants of the Class Tetradynamia, as mustard, horse-raddish, &c. likewise garlic, and others of a stimulant quality, promoting the secretions, were much relied upon, and, no doubt, proved useful to a certain extent. The spongy doubt, proved useful to a certain extent. The spongy state of the gums may be remedied by washing the mouth with some of the mineral acids sufficiently di-luted, or perhaps mixed with decoction of cinchona. The stiffness of the limbs by fomentations, cataplasms, and friction; and sometimes in hot climates, the earth-hath has afforded speedy relief to this symptom. SCO RDIUM. (From σκοροδον, garlic: so called because it smells like garlic.) See Teucrium scor-

SCO'RIÆ. (Scoria; from σκω, excrement.) Dross.

The refuse or useless parts of any substance.

Scoroporrasum. (From σκορούον, garlie, and πρασον, the leek.) The wild garlie, or leek shalot.

SCO'RODUM. (Απο του σκωρ οξειν, from its filthy smell.) Garlic.

Scorplaca. (From σκορπιος, a scorpion.) Medicines against the bite of serpents.

SCORPIOI DES. (From σκορπιος, a scorpion, and dos, a likeness; so called because its leaves resemble the tail of a scorpion.) Scorpiurus. The Myosurus scorpioides. SCORPIU'RUS. See Seerpioides.

SCORZA. A variety of epidote.
SCORZONE' RA. (From escorza, a serpent,
Spanish: so called because it is said to be effectual against the bite of all venomous animals.) 1. The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Polygamia aqualis.

2. The pharmacopæial name of the viper grass. See

Scorzonera humilis.

SCORZONERA HISPANICA. The systematic name of the esculent vipers' grass. Serpentaria hispanica. The root of this plant is mostly sold for that of the

Scorzonera humilis. The systematic name of the officinal vipers' grass. Escorzonera; Viperaria; Serpentaria hispanica. Goats' grass; Vipers' grass. The roots of this plant, Scorzonera—caule subnudo, unifloro; foliis lato-lanceolatis, nervosis, planis, of Linnæus, have been sometimes employed medicinally as alexipharmics, and in hypochondriacal disorders and obstructions of the viscera. The Scorzonera hispanica mostly supplies the shops, whose root is esculent, oleranger of the second of the story.

obstructions of the viscera. The Scorzonera hispanica mostly supplies the shops, whose root is esculent, oleraceous, and against diseases inefficacious.

SCOTODINE. See Scotodinus.

SCOTODINUS. (From σκοτος, darkness, and δινος, a giddiness.) Scotodinia; Scotodinos; Scotoma; Scotodine; Scotomia. Giddiness, with impaired sight. SCOTOMA. (From σκοτος, darkness.) Blindness.

SCRIBONIUS, LARGUS, a Roman physician in the reign of Claudius, who wrote a treatise, "De Compositione Medicamentorum." Many of these formulæ are perfectly trifling and superstitions; and the whole work displays a great attachment to empiricism. The " De Compostyle is also very deficient in elegance for the time in

which he lived, whence he appears to have been a per-

which he lived, whence he appears to have been a person of inferior education.

SCROBICULATUS. (Scrobiculus, a ditch, or furrow.) Hollowed; having a deep, round foramina: applied to the receptacle of the Helianthus annuus.

SCROBICULUS CO'RDIS. (Diminutive of scrobs, a ditch.) The pit of the stomach.

SCROFULA. (From scrofa, a swine; because this animal is said to be much subject to a similar disorder.)

Scrombula: Struma: Corras: Chronas: Ecruelles: Fr.

anima is said to Scrophula; Struma; Coiras; Chræas; Ecruelles; Fr. Scrofula. The king's evil. A genus of disease in the Scrofula. Scrofula. The king's evil. Agenus of disease in the Class Cachexia, and Order Impetigines, of Cullen. He distinguishes four species. 1. Scrofula vulgaris, when it is without other disorders external and permanent. 2. Scrofula mesenterica, when internal, with loss of appetite, pale countenance, swelling of the belly, and an unusual factor of the excrements. 3. Scrofula fugax. This is of the most simple kind; it is seated only about the neck, and for the most part is caused only about the neck, and for the most part is caused by absorption from sores on the head. 4. Scrofula americana, when it is joined with the yaws. Scrofula consists in hard indolent tumours of the conglobate glands in various parts of the body; but particularly in the neck; behind the ears, and under the chin, which, after a time, suppurate and degenerate into ulcers, from which, instead of pus, a white curdled matter, somewhat resembling the coagulum of milk is discharged.

The first appearance of the disease is most usually.

The first appearance of the disease is most usually between the third and seventh year of the child's age; but it may arise at any period between this and the age of puberty; after which it seldom makes its first attack. It most commonly affects children of a lax habit, with smooth, fine skins, fair hair, and rosy cheeks. It likewise is apt to attack such children as cheeks. It likewise is apt to attack such condren as show a disposition to rachitis, marked by a protuberant forehead, enlarged joints, and a tumid abdomen. Like this disease, it seems to be peculiar to cold and variable climates, being rarely met with in warm ones. Scrofula is by no means a contagious disease, but, beyond all doubt, is of an hereditary nature, and is often entailed by passets on their children. There are, indeed, some by parents on their children. There are, indeed, some practitioners who wholly deny that this, or any other disease, can be acquired by an hereditary right; but that a peculiar temperament of body, or predisposition in the constitution of some diseases, may extend from in the constitution of some diseases, may extend from both father and mother to their offspring, is, observes Dr. Thomas, very clearly proved. For example, we very frequently meet with gout in young persons of both sexes, who could never have brought it on by intemperance, sensuality, or improper diet, but must have acquired the predisposition to it in this way.

Where there is any predisposition in the constitution to scrofula, and the person happens to contract a venereal taint, this frequently excites into action the causes of the former; as a venereal bube not unfre-

causes of the former; as a venereal bubo not unfre-quently becomes scrofulous, as soon as the virus is destroyed by mercury. The late Dr. Cullen supposed scrofula to depend upon a peculiar constitution of the lymphatic system. The attacks of the disease seem much affected or influenced by the periods of the sca-sons. They begin usually some time in the winter and spring, and often disappear, or are greatly amended in summer and autumn. The first appearance of the dis-order is commonly in that of small oval, or spherical order is commonly in that of small-oval, or spherical tumours under the skin, unattended by any pain or discoloration. These appear, in general, upon the sides of the neck, below the ear, or under the chin; but, in some cases, the joints of the clows or ankles, or those of the fingers and toos, are the parts first affected. In these instances, we do not, however, find small moveable swellings; but, on the contrary, a tumour almost uniformly surrounding the joint, and tumour almost uniformly surrounding the joint, and interrupting its motion.

After some length of time the tumours become larger and more fixed, the skin which covers them acquires a purple or livid colour, and, being much inflamed. they at last suppurate, and break into little holes, from which, at first, a matter somewhat puriform oozes out; but this changes by degrees into a kind of viscid serous discharge, much intermixed with small pieces of a white

substance, resembling the curd of milk

The tumours subside gradually, while the ulcers at the same time open more, and spread unequally in various directions. After a time some of the ulcers heal; but other tumours quickly form in different parts of the body, and proceed on, in the same slow manner as the former ones, to suppuration. In this manner the disease goes on for some years, and appearing at last to have exhausted itself, all the ulcers heal up, without being succeeded by any fresh swellings; but leaving behind them an ugly puckering of the skin, and a scar of considerable extent. This is the most mild form under which scrofula ever appears. In more virulent cases, the eyes are particularly the seat of the disease, and are affected with ophthalmia, giving rise to ulcerations in the tarsi, and inflammation of the tunica adnata, terminating not unfrequently in an opacity of the transparent cornea.

In similar cases, the joints become affected, they swell and are incommoded by excruciating deep-seated pain, which is much increased upon the slightest motion. The swelling and pain continue to increase, the muscles of the limb become at length much wasted. Matter is soon afterward formed, and this is dis-charged at small openings made by the bursting of the skin. Being, however, of a peculiar acrimonious nature, it crodes the ligaments and cartilages, and pro-duces a caries of the neighbouring bones. By an absorption of the matter into the system, hectic fever at last arises, and, in the end, often proves fatal.

When scrofula is confined to the external surface, it is by no means attended with danger, although on leaving one part, it is apt to be renewed in others; but when the ulcers are imbued with a sharp acrimony, spread, erode, and become deep, without showing any disposition to heal; when deep-seated collections of matter form among the small bones of the hands and feet, or in the joints, or tubercles in the lungs, with hectic fever, arise, the consequences will be fatal.

On opening the bodies of persons who have died of

this disease, many of the viscera are usually found in a diseased state, but more particularly the glands of the mesentery, which are not only much tumified, but often ulcerated. The lungs are frequently discovered besetwith a number of tubercles or cysts, which contain matter of various kinds. Scrofulous glands, on being examined by dissection, feel somewhat softer to the touch than in their natural state and when laid ones. touch than in their natural state, and when laid open, they are usually found to contain a soft curdy matter, mixed with pus. The treatment consists chiefly in the use of those means, which are calculated to improve the general health; a nutritious diet, easy of digestion, a pure dry air, gentle exercise, friction, cold bathing, especially in the sea, and strengthening medicines, as the preparations of iron, myrrh, &c.; but, particu-larly the Peruvian bark, with soda. Various mineral waters, and other remedies which moderately pronote the secretions, appear also to have been often useful. In irritable states of the system, hemlock has been employed with much advantage. Mercury is generally injurious to scrofulous persons, when carried so far as to affect the mouth; yet they have sometimes improved under the use of the milder preparations of that metal, determined principally towards the skin. Moderate antimonials also, decoctions of sarsaparilla, mezereon, guaiacum, &c., burnt sponge, muriate of lime, and other such remedies, have been serviceable in many cases, perhaps chiefly in the same way. The application to scrofulous tumours and ulcers must vary according to the state of the parts, whether indolent or irritable: where the tumours show no disposition to enlarge, or become inflamed, it is, perhaps, best to interfere little with them; but their inflammation must be checked by leeches, &c., and when ulcers exist, stimulant lotions or dressings must be used to give them a disposition to heal; but if they are in an irrita-bie state, a cataplasm, made, perhaps, with hemlock, or other narcotic.

SCROPHULA. See Scrofula.

SCROPHULA'RIA. (From serofula, the king's evil; so called from the unequal tubercles upon its

evil: so called from the unequal tubercles upon its roots, like scrofulous tumours.) The name of a genus of plants in the Linnæan system. Class, Didynamia; Order, Angiospermia. The fig-wort.

Scrophularia Aquatica. Betonica aquatica. Greater water fig-wort. Water-betony. The leaves of this plant, Scrophularia—foliis cordatis obtusis, petiolatis, decurrentibus; caule membranis angulato; racemis terminalibus, of Linnæus, are celebrated as correctors of the ill-flavour of senna. They were, also, formerly in high estimation against piles, tumours of a scrofulous nature, inflammatious. &c. lous nature, inflammations, &c.

SCROPHULARIA MINOR. The pile wort is sometimes so called. See Ranunculas ficaria.

SCROPHULARIA RODOSA. The systematic name of the fig-wort. Scrophularia vulgaris; Millemorbia; Scrophularia. Common fig-wort or kernel-wort. The root and leaves of this plant, Scrophularia-foliis cor-datis, trinervatis; caule obtusangulo, of Linnæus, have been celebrated both as an internal and external remedy against inflammations, the piles, scrofulous remedy against inflammations, the piles, scrounds tumours and old ulcers; but they are now only used in this country by the country people.

SCROTHULARIA VULGARIS, See Scrophularia nodosa.

SCROTAL. Belonging to the scrotum.

SCROTAL HERNIA. Scrotoccle. A protrusion of any part of an abdominal viscus or viscera into the scrotum.

SCROTIFORMIS. Bag-like: applied to the nectary

of the genus Satyrium.

SCROTOCE'LE. (From scrotum, and κηλη, a tumour.) A rupture or hernia in the scrotum.

SCROTUM. (Quasi scrotum, a skin or hide.)

Bursa testium; Oscheus; Oscheon; Orchea, of Galen
The common integuments which cover the testicles.

SCRU'PULUS. (Dim. of scrupus, a small stone.)

A scruple or weight of 20 grains.

SCULTETUS, John, was born at Ulm, in 1595, and, after the requisite studies, graduated at Padua. He then practised with considerable reputation in his then practised with considerable reputation in his native city, as well in surgery as in physic, and he appears to have been very bold in his operations. He was carried off by an apoplectic stroke, in 1645. His principal work is entitled, "Armamentarium Chirurgicum," with plates of the instruments; which was published after his death, and has passed through many editions, and been translated into most European languages.

SCURF. Furfura. Small exfoliations of the cuti-cle, which take place after some eruptions on the skin, a new cuticle being formed underneath during

skin, a new the exfoliation. the exfoliation. See Scorbutus. Scurvy-grass. See Cochlearia officinalis.
Scurvy-grass, lemon. See Cochlearia officinalis.
Scurvy-grass, Scotch. See Convolvulus soldanella.
SCUTIFORM. (Scutiformis; from oxuros, a shield, and woos, resemblance.) Shield-like. See Thyroid

SCUTIFORM CARTILAGE. See Thyroid cartilage. SCUTELLA. A little dish or cup. Applied to the round, flat, or shallow fruit, of the calyculate alga,

seen in Lichen stellaris.

SCUTELLA'RIA. (From scutella, a small dish or saucer, apparently in allusion to the little concave ap-

saucer, apparently in allusion to the little concave appendage which crowns the calyx. Some have thought it to be more directly derived from scutellum, a little shield, to which they have compared the shield.) The name of a genus of plants in the Linnman system. Class, Didynamia; Order, Gymnospermia.

Scutellaria galericulata. The systematic name of the skull-cap. Tertianaria. The Scutellaria, foliis cordato lanccolatis, crenatis; floribus axillaribus, of Linnmus, which is common in the hedges and ditches of this country. It has a bitter taste and a garlic smell, and is said to be serviceable against that species of ague which attacks the patient every other day.

ague which attacks the patient every other day. SCY BALUM. Σκρθαλα Dry hard excrement, SCY BALUM. Σκυθαλα rounded like nuts or marbles.

SCYTHICUS. (From Scythia, its native soil.) An epithet of the liquorice root, or any thing brought from Scythia.

Mare. The air of the sea, the motion of the vessels, the exhalation from the tar as well as the water of the ocean, and its contents all come under the

attention of the physician.

1. Sea-air is prescribed in a variety of complaints, being considered as more medicinal and salubrious than that on land, though not known to possess in its com-position a greater quantity of oxygen. This is a most powerful and valuable remedy. It is resorted to with the happiest success against most cases of debility, and

the happiest success against most cases of debility, and particularly against scrofulous diseases affecting the external parts of the body. See Bath, cold.

2. Sea-sickness. A nausea or tendency to vomit, which varies, in respect of duration, in different persons upon their first going to sea. With some it continues only for a day or two; while with others it remains throughout the voyage. The diseases in which sea sickness is principally recommended are asthmatically recommended as the recommended are asthmatically recommended as the recommended are recommended as the rec sea sickness is principally recommended are asthma

and consumption.

3. Sea-water. This is arranged among the simple saline waters. Its chemical analysis gives a proportion of one of saline contents to about twenty-three and one-fourth of water; but on our shores it is not greater than one of salt to about thirty of water. Seawater on the British coast may therefore be calculated to contain in the wine pint of muriated soda 186.5 grains, of muriated magnesia fifty-one, of selenite six grains; total 243 one-half grains; or half an ounce and three and one-half grains of saline contents. The dis-orders for which the internal use of sea-water has been and may be resorted to, are in general the same for which all the simple saline waters may be used. The peculiar power of sea-water and sea-salt as a discutient, employed either internally or externally in scrofulous habits, is well known, and is attended with considerable advantage when judiciously applied.

Sca-holly. See Eryngium. Sca-moss. See Fucus helminthocorton.

Sca-noise. See Fucus helminthocorton.
Sca-oak. See Fucus vesiculosus.
Sca-onion. See Scilla.
SEA-SALT. Muriate of Soda. See Soda murias.
SEA-WAX. Maltha. A white, solid, tallowylooking fusible substance, soluble in alkohol, found on

the Baikal lake, in Siberia.

Sealed earths. See Sigillata terra.

SEARCHING. The operation of introducing a metallic instrument through the urethra into the bladder for the purpose of ascertaining whether the patient lass the steps of rest.

has the stone of not.

SEBACEOUS. (Schaceus; from sehum, suet.) A term applied to glands, which secrete a suetty hu-

SEBACIC ACID. Subject to a considerable heat, 7 or 8 pounds of hog's lard, in a stoneware retort capa-ble of holding double the quantity, and connect its beak by an adopter with a cooled receiver. The con-densible products are chiefly fat, altered by the fire, mixed with a little acetic and sebacic acids. Treat this product with boiling water several times, agitating the liquor, allowing it to cool, and decanting each time. Pour at last into the watery liquid, solution of acetate of lead in excess. A white flocculent precipitate of sebate of lead will instantly fall, which must be tate of sebate of lead will instantly fall, which must be collected on a filter, washed, and dried. Put the sebate of lead into a phial, and pour upon it its own weight of sulphuric acid, diluted with five or six times its weight of water. Expose this phial to a heat of about 2120. The sulphuric acid combines with the oxide of lead, and sets the sebacic acid at liberty. Filter the whole while hot. As the liquid cools, the sebacic acid crystallizes, which must be washed to free it completely from the adhering sulphuric acid. Let it be then dried at a gentle heat.

The sebacic acid is inodorous: its taste is slight, but

The sebacic acid is inodorous; its taste is slight, but It perceptibly reddens litmus paper; its specific gravity is above that of water, and its crystals are small white is above that of water, and is crystals are small white needles of little coherence. Exposed to heat, it melts like fat, is decomposed, and partially evaporated. The air has no effect upon it. It is much more soluble in hot than in cold water; hence boiling water saturated with it, assumes a nearly solid consistence on cooling. Alkohol dissolves it abundantly at the ordinary tempe-

With the alkalies it forms soluble neutral salts; but if we pour into their concentrated solutions, sulphuric, nitric, or muriatic acids, the sebacic is immediately de-

nitric, or muriatic acids, the sebacic is immediately deposited in large quantity. It affords precipitates with the acetates and nitrates of lead, mercury, and silver. Such is the account given by Thenard of this acid, in the third volume of his Traité de Chimic, published in 1815. Berzelius, in 1806, published an elaborate dissertation, to prove that Thenard's new sebacic acid was only the benzoic contaminated by the fat, from which however it may be freed, and brought to the state of common benzoic acid. Thenard takes no notice of Berzelius whatever, but concludes his account by stating that it has been known only for twelve or thirteen years, and that it must not be confounded thirteen years, and that it must not be confounded with the acid formerly called sebacic, which possesses a strong disgusting odour, and was merely acetic or muriatic acid; or fat which had been changed in some way or other according to the process used in the pre-

SEBATE. (Sebas; from sebum, suet.) The name mary. 276

in the neutral compound of the acid of fat, with a sali-

SEBESTEN. (An Egyptian word.) See Cordia myza.
SECA'LE. (Secale, t. neut. A name in Pliny,
which some etymologists, among whom is De Theis, dewhich some etymologists, among whom is De I neis, derive from the Ceitic segal. This, says he, comes from sega, a sickle in the same language, and thence segas, the Latin appellation of all grain that is cut with a similar instrument. Those who have looked no farther for an etymology than the Latin seco, to cut or mow, have come to the same conclusion.) 1. The name of a genus of plants in the Linnæan system. Class, Triendria: Order, Digwnia. Rye. andria; Order, Digynia. Rye.
2. The common name of the seed of the Secale ce-

reale, of Linnaus.

The systematic name of the Secale cereale. The systematic name of the rye-plant. Rye-corn is principally used as an article of diet, and in the northern countries of Europe is employed for affording an ardent spirit. Rye-bread is common among the northern parts of Europe; it is less nourishing than wheat, but a sufficiently nutritive and wholesome grain. It is more than any other grain strongly disposed to accescency; hence it is liable to ferment in the stomach, and to produce purging, which

ment in the stomach, and to produce purging, which people on the first using it commonly experience.

Secale cornutum. Secale corniculatum; Clavius secalinus. Mutterkom kornzapfeu, of the Germans. Ergot; Seigle ergote of the French. A black, curved, morbid excrescence, like the spur of a fowl, which is found in the spike of the Secale coreale of Linnaus, escentially in hot climates, when a great heat suddenly succeeds to much moisture. The seed, which has this diseased growth, gives off, when powdered, an odour which excites sneezing, and tifilates the nose, like to-bacco. It has a mealy, and then a rancid, nauseous, and biting taste, which remains a long time, and causes the mouth and fauces to become dry; which sensation is not removed by watery fluids, but is soon. sensation is not removed by watery fluids, but is soon relieved by milk. The cause of this excrescential disease in rye appears to be an insect which penetrates the grain, feeds on its amylaceous part, and leaves its poison in the parenchyma; hence it is full of small foramina or perforations made by the insect

The secale cornutum has a singular effect on the animal economy. The meal or flour sprinkled on a wound coagulates the blood, excites a heat and then a numbness in the part, and soon after in the extremities. Bread which contains some of it, does not ferment well, nor bake well, and is glutinous and nauseous. well, nor bake well, and is glutinous and nauscous. The bread when eaten produces intoxication, lassitude, a sense of something creeping on the skin, weakness of the joints, with convulsive movements occurring periodically. This state is what is called raphanio, and convulsiones cerealia. Of those so affected, some can only breathe in an upright posture, some become maniacal, others epileptic, or tabid, and some have a thirst not to be quenched; and livid eruptions and cutaneous ulcers are not uncommon. The disease continues from ten days to two or three months and longer. Those who have formication, pain, and numbness of the extremities in the commencement, generally lose the feeling in these parts, and the skin, from the fingers to the fore-arm, or from the toes to the middle of the tibia, becomes dry, hard, and black, as if covered with soot. This species of mortification is called Necrosis cerealis.

As a medicine, the secale cornutum is given internally to excite the action of the uterus in an atonic state of that organ, producing amenorrhoa, &c. and during parturition. Given in the dose of ten grains, it soon produces a desire to make water, and the labour pains quickly follow; but it is a dangerous medicine, the

effect not being controllable.

The antidote to the ill effects produced in the mouth and fauces by eating bread which has this poison, is Against the convulsions, vomits, saline purgatives, clysters, submuriate of mercury as a purgative, are first to be given, and after the prime vize have been duly cleaned, stimulants of camphire, ammonia, and ather with opium. To the necrosis, rectified oil of turpentine is very beneficial in stopping its progress, and then warm stimulating fomentations and poultices.

[See pulvis parturiens. A.]
SECONDARY. This term denotes something that acts as second or in subordination to another. Thus, in diseases, we have secondary symptoms. See Pri-

Secondary fever. That febrile affection which arises after a crisis, or the discharge of some morbid matter, as after the declension of the small-pox or the

SECRETION. Secretio. "The generic name of secretion is given to a function, by which a part of the blood escapes from the organs of circulation, and diffuses itself without or within; either preserving its chemical properties, or dispersing after its elements have undergone another order of combinations.

The secretions are generally divided into three sorts; the exhalations, the follicular secretions, and the

glandular secretions.

Exhalations.—The exhalations take place as well within the body as at the skin, or in the mucous membranes; thence their divisions into external and in-

Internal exhalations .- Wherever large or small surfaces are in contact, an exhalation takes place; wherever fluids are accumulated in a cavity without any apparent opening, they are deposited there by exhalations: the phenomenon of exhalation is also manifested in almost every part of the animal economy. It exists in the serous, the synovial, the mucous mem-branes; in the cellular tissue, the interior of vessels, the adipose cells, the interior of the eye, of the ear, the parenchyma of many of the organs, such as the thymus, thyroid glands, the capsulæ suprarenales, &c. &c. by exhalation that the watery humour, the vitreous humour, the liquid of the labyrinth, are formed and renewed. The fluids exhaled in these different parts have not all been analyzed; among those that have been, several approach more or less to the elements of the blood, and particularly to the serum; such are the fluids of the serous membranes of the cellular tissue, of the chambers of the eye; others differ more from it,

as the synovia, the fat, &c.

Serous exhalation.—All the viscera of the head, of the chest, and the abdomen, are covered with a scrous membrane, which also lines the sides of these cavities, so that the viscera are not in contact with the sides, or so that the viscera are not in contact with the sides, or with the adjoining viscera, except by the intermediation of the same membrane; and as its surface is very smooth, the viscera can easily change their relation with each other, and with the sides. The principal circumstance which keeps up the polish of their surface is the exhalation of which they are the seat; a very thin fluid constantly passes out of every point of the membrane, and mixing with that of the adjoining parts, forms with it a humid layer that favours the frictions of the organs.

It appears that this facility of sliding upon each

It appears that this facility of sliding upon each of appears that this facility of shaing upon each for as soon as they are deprived of it by any malady of the serous membrane, their functions are disordered, and they sometimes cease entirely.

In the state of health, the fluid secreted by the serous membranes appears to be the serum of the blood, a

certain quantity of albumen excepted.

Serous exhalation of the cellular tissue. -- This tissue, which is called cellular, is generally distributed through animal bodies; it is useful at once to separate through animal bodies; it is useful at once to separate and unite the different organs, and the parts of the organs. The tissue is every where formed of a great number of small thin plates, which, crossing in a thousand different ways, form a sort of felt. The size and arrangement of the plates vary according to the different parts of the body. In one place they are larger, thicker, and constitute large cells; in another, they are very narrow and thin, and form extremely small cells; in some points the tissue is capable of extension; in others, it is little susceptible of it, and presents a considerable resistance. But whatever is the disposition of the cellular tissue, its plates, by their two surfaces, exhale a fluid which has the greatest analogy with that of the serous membranes, and which appears to have the same uses; these are to render the frictions of the plates easy upon each other, and therefore to favour the reciprocal motions of the organs, and even the relative changes of the different parts of

which they are composed.

Fatty exhalation.—Independently of the serosity, a fluid is found in many parts of the cellular tissue of a very different nature, which is the fat.

Under the relation of the presence of the fat, the cellular tissue may be divided into three sorts; that which contains it always, that which contains it some-

times, and that which never contains it. The orbit, the sole of the foot, the pulp of the fingers, that of the toes, always present fat; the subcutaneous cellular tissue, and that which covers the heart, veins, &c. present it often; lastly, that of the scrotum, of the eyelids, of the interior of the skull, never contain it.

The fat is contained in distinct cells that never communicate with the adjoining ones. It has been supposed, from this circumstance, that the tissue that contains, and that forms the fat, was not the same as that by which the serosity is formed; but as these fatty cells have never been shown, except when full of fat, this anatomical distinction seems doubtful. The size, the form, the disposition of these cells, are not less variable than the quantity of fat which they contain. In some individuals scarcely a few ounces exist, while in others there are several hundred pounds.

According to the last researches, the human fat is composed of two parts, the one fluid, the other con-crete, which are themselves compounded, but in dif-

ferent proportions, of two new proximate principles.

Synovial exhalations.—Round the moveable articu lations a thin membrane is found, which has much analogy with the serous membranes; but which, how-ever, differs from them by having small reddish prolongations that contain numerous blood-vessels. These are called synovial fringes; they are very visible in the great articulations of the limbs.

Internal exhalation of the eye.—The different ha-mours of the eye are also formed by exhalation; they are each of them separately enveloped in a membrane that appears intended for exhalation and absorption.

The humours of the eye are, the aqueous humour, the formation of which is at present attributed to th: ciliary processes; the vitreous humour, secreted by the hyaloid; the crystalline, the black matter of the choroid; and that of the posterior surface of the iris. Bloody exhalations.—In all the exhalations of which

we have spoken, it is only a part of the principle of the blood that passes out of the vessels; the blood itself appears to spread in several of the organs, and fill in them the sort of cellular tissue which forms their parenchyma; such are the cavernous bodies of the penis and of the clitoris, the urethra and the glans, penis and of the citoris, the urethra and the glans, the spicen, the mamilla, &c. The anatomical examination of these different issues seems to show that they are habitually filled with venous blood, the quantity of which is variable according to different circumstances, particularly according to the state of action or inaction of the organs.

Many other interior exhalations exist also, among those of the cavities of the internal ear, of the paren chyma, of the thymus, of the thyroid gland; that of the cavity of the capsulæ suprarenales, &c.: but the fluids formed in these different parts are scarcely un derstood: they have never been analyzed, and their

uses are unknown.

External exhalations.—These are composed en-tirely of the exhalations of the mucous membranes, and of that of the skin, or cutaneous transpiration.

Exhalation of the mucous membranes.—There are two mucous membranes; the one covers the surface of the eye, the lachrymal ducts, the nasal cavities, the sinuses, the middle ear, the mouth, all the intestinal canal, the excretory canals which terminate in it;

lastly, the larynx, the trachea, and the bronchia.

The other mucous membrane covers the organs of

generation and of the urinary apparatus.

Cutaneous transpiration.—A transparent liquid, of an odour more or less strong, salt, acid, usually passes through the innumerable openings of the epidermis See Perspiration. This liquid is generally evapo-rated as soon as it is in contact with the air, and at other times it flows upon the surface of the skin. In the first case it is imperceptible, and bears the name of insensible transpiration; in the second it is called

Follicular secretions .- The follicles are small hollow organs lodged in the skin or mucous membranes, and which on that account are divided into mucous and

The follicles are, besides, divided into simple and compound. The simple mucous follicles are seen upon nearly the whole extent of the mucous membranes, where they are more or less abundant; however, there are points of considerable extent of these membranes where they are not seen.

SEC SEC

The bodies that bear the name of fungous papille of the tongue the amygdale, the glands of the cardia, the prostate, &c. are considered by anatomists as collections of simple follicles. Perhaps this opinion is

The fluid that they secrete is little known; it appears analogous to the mucous, and to have the same uses. In almost all the points of the skin, little openings exist, which are the orifices of small hollow organs, with membraness sales generally filled with an almost all the points of the skin, little openings exist, when he are the orifices of small hollow organs, with membraness sales generally filled with an almost a little or the skin and the sales are the same transfer of the skin and the sales are the same transfer of the skin and the sales are the same transfer or the same uses. with membranous sides, generally filled with an al-buminous and fatty matter, the consistence, the colour, the odour, and even the savour of which are variable, according to the different parts of the body, and which is continually spread upon the surface of the skin.

These small organs are called the follicles of the

skin; one of them at least exists at the base of each hair, and generally the hairs traverse the cavity of a follicle in their direction outwards.

The follicles form that mucous and fatty matter which is seen upon the skin of the cranium, and on that of the pavillion of the ear; the follicles also secrete the ceramen in the auditory canal; that whitish matter, of considerable consistence, that is pressed out of the skin of the face, in the form of small worms, is also contained in follicles; it is the same matter which, by its surface being in contact with the air, becomes black, and produces the numerous spots that are seen upon some persons' faces, particularly on the sides of the nose and checks.

The follicles also appear to secrete that odorous, The follicles form that mucous and fatty matter

The follicles also appear to secrete that odorous, whitish matter, which is always renewed at the external surface of the genital parts.

By spreading on the surface of the epidermis, of the heir of the head of the skin for the matter of the hair of the head, of the skin, &c., the matter of the follicles supports the suppleness and elasticity of those parts, renders their surface smooth and polished, favours their frictions upon one another. On account of its unctuous nature, it renders them less penetrable by

humidity, &c.

Glandular Secretions.—The name of gland is given to a secreting organ which sheds the fluid that it forms upon the surface of a mucous membrane, or of the

skin, by one or more excretory glands.

The number of glands is considerable, the action of each bears the name of glandular secretion. There are six secretions of this sort, that of the tears, of the saliva, of the bile, of the pancreatic fluid, of the urine, of the semen, and lastly, that of the milk. We may add the action of the mucous glands, and of the glands of Cowper.

Secretion of Tears.—The gland that forms the tears is very small; it is situated in the orbit of the eye, above and a little outward; it is composed of small grains, united by cellular tissues; its excretory canals, small and numerous, open behind the external angle of the upper eyelid: it receives a small artery, a branch of the ophthalmic, and a nerve, a division of the fifth

In a state of health, the tears are in small quantity In a state of health, the tears are in small quantity; the liquid that forms them is limpid, without odour, of a salt savour. Fourcroy and Vauquelin, who analyzed it, found it composed of much water, of some centesimals of mucus, muriate and phosphate of soda, and a little pure soda and lime. What are called tears, are not however, the fluid secreted entirely by the are not, however, the fluid secreted entirely by the lachrymal gland; it is a mixture of this fluid with the matter secreted by the conjunctiva, and probably with that of the glands of Meibomius.

The tears form a layer before the conjunctiva of the eye, and defend it from the contact of air; they facili-tate the frictions of the eyelids upon the eye, favour the expulsion of foreign bodies, and prevent the action the expulsion of foreign bodies, and prevent the action of irritating bodies upon the conjunctiva; in this case the quantity rapidly augments. They are also a means of expressing the passions: the tears flow from vexation, pain, joy, and pleasure. The nervous system has therefore a particular influence upon their secretion. This influence probably takes place by means of the nerve that the fifth pair of cerebral nerves sends to the lack reveal sland. to the lachrymal gland.

Secretion of the Saliva.—The salivary glands are, 1st, the two parotids, situated before the ear and behind the neck, and the branch of the jaw; 2d, the submaxillaries, situated below and on the front of the body of this bone; 3d, lastly, the sublinguals, placed immediately below the tongue. The parotids and the submaillaraies have only one excretory canal; the sublinguals.

guals have several. All these glands are formed by the union of the granulations of different forms and dimensions; they receive a considerable quantity of arteries relatively to their mass. Several nerves are distributed to them, which proceed from the brain or the spinal marrow

The saliva which these glands secrete flows con-The saliva which these glands secrete lows com-stantly into the mouth, and occupies the lower part of it; it is at first placed between the anterior and lateral part of the tongue and the jaw; and when the space is filled, it passes into the space between the lower lip, the check, and the external side of the jaw. Being thus deposited in the mouth, it mixes with the fluids se-

creted by the membranes and the mucous follicles.

Secretion of the Pancreatic Juice.—The pancreas is situated transversely in the abdomen, behind the stomach. It has an excretory canal, which opens into the duodenum, beside that of the liver. The granulous structure of this gland has made it be considered a salivary gland; but it is different from them by the smallness of the arteries that it receives, and by not appearing to receive any cerebral nerve.

It is impossible to explain the use of the pancreatic

Secretion of the Bile.—The liver is the largest of all the glands; it is also distinguished by the singular circumstance among the secretory organs, that it is constantly traversed by a great quantity of venous blood, besides the arterial blood, which it receives as well as every other part. every other part. Its parenchyma does not resemble, in any respect, that of the other glands, and the fluid formed by it is not less different from that of the other glandular fluids.

The excretory canal of the liver goes to the duodenum; before entering it, it communicates with a small membranous bag, called vesicula fellis, and on this account, that it is almost always filled with bile.

Few fluids are so compound, and so different from the blood, as the bile.

the blood, as the bile. Its colour is greenish, its taste very bitter; it is viscous, thready, sometimes limpid, and sometimes muddy. It contains water, albumen, a matter called resinous by some chemists, a yellow comatter called resinous by some chemists, a yellow co-louring principle, soda, and some salts, viz muriate, phosphate, and sulphate of soda, phosphate of lime and oxide of iron. These properties belong to the bile contained in the gall bladder. That which goes out directly from the liver, called hepafic bile, has never been analyzed; it appears to be of a less deep colour, less viscous, and less bitter than the cystic bile. The formation of the bile appears constant.

The liver receiving venous blood at the same time by the even porta, and arterial blood by the hepatic artery, physiologists have been very eager to know which of the two it is that forms the bile. Several have said that the blood of the vena porta, having more carbon and hydrogen than that of the hepatic artery, is more proper for furnishing the elements of the bile. Bichat has successfully contested this opinion; he has shown, that the quantity of arterial blood which arrives at the liver is more in relation with the quantity of bile formed that that of the venous blood; that the volume of the hepatic canal is not in proportion with the volume of the hepatic canal is not in proportion with the vena porta; that the fat, a fluid much hydrogenated, is secreted by the arterial blood, &c. He might have added, that there is nothing to prove that the blood of the vena porta has more analogy with the bile than the arterial blood. We shall take no part in this discussion; both opinions are equally destitute of proof. Besides, nothing recels the idea that both sorts of blood serve in thing repels the idea, that both sorts of blood serve in the secretion. This seems even to be indicated by anatomy; for injections show that all the vessels of the liver, arterial, venous, lymphatic, and excretory, com-municate with each other.

The bile contributes very usefully in digestion, but the manner is unknown. In our present ignorance relative to the causes of diseases, we attribute noxious properties to the bile, which it is probably far from possessing.

Secretion of the Urine.-This secretion is different in several respects from the preceding. The liquid which results from it is much more abundant than that of any other gland; in place of serving in any internal uses, it is expelled; its retention would be attended by the most dangerous consequences. We are advertised of the necessity of its expulsion by a particular feeling, which, like the instinctive phenomena of this sort, becomes very painful if not quickly attended to.

In explaining the glandular secretions, physiologists have given full scope to their imagination. The glands have been successively considered as sieves, filters, as a focus of fermentation. Bordeu, and, more recently, Bichat, have attributed a peculiar motion and sensibility to their particles, by which they choose, in the blood which traverses them, the particles that are fit to blood which traverses them, the particles that are it to enter into the fluids that they secrete. Atmospheres and compartments have been allotted to them; they have been supposed susceptible of erection, of sleep, &c. Notwithstanding the efforts of many learned men, the truth is, that what passes in a gland when it acts, is entirely unknown. Chemical phenomena necessarily take place.

cessarily take place.

Several secreted fluids are acid, while the blood is alkaline. The most of them contain proximate principles which do not exist in the blood, and which are formed in the glands, but the particular mode of these

combinations is unknown.

We must not, however, confound among these sup-positions upon the action of the glands, an ingenious conjecture of Dr. Wollaston. This learned man supposes that very weak electricity may have a marked influence upon the secretions. He rests his opinion upon a curious experiment, of which we will here give an account.

Dr. Wollaston took a glass tube, two inches long, and three quarters of an inch diameter: he closed one of its extremities with a bit of bladder. He poured a little water into the tube, with 1-240 parts of its weight of muriate of soda. He wet the bladder on the outside, and placed it on a piece of silver. He then bent a zinc wire, so that one of its ends touched the silver, and the other entered the tube the length of an inch. In the same instant the external face of the bladder gave indications of the presence of pure soda; so that, under the influence of this very weak electricity, there was a decomposition of muriate of soda, and a passage of the soda, separated from the acid, through the bladder. Dr. Wollaston thinks it is not impossible that something analogous may happen in the secretions; but, before admitting this idea, many other proofs are necessary.

Several organs, such as the thyroid and thymus bo-dies, the spleen, the supra-renal capsules, have been called glands by many anatomists. Professor Chaussier has substituted for this denomination that of the glandiform ganglions. The use of these parts is en-tirely unknown. As they are generally more nume-rous in the fœtus, they are supposed to have important functions, but there exists no proof of it. Works of physiology contain a great many hypotheses intended to explain their functions."—Magendie's Physiology.

Sectio franconia. See Lithotomy.

SECUNDINES. The after-birth, and membranes

which are expanded from its edge, and which form a complete involucrum of the fœtus and its waters, go

under the term of secundines. See Placenta.

SECUNDUM ARTEM. According to art. A term frequently used in prescription, and denoted by the letters S. A., which are usually affixed, when the making up of the recipe in perfection requires some uncommon

SECUNDUS. Applied by hotanists to leaves and parts of the fructification which are unilateral, all leaning towards one side; as the leaves and flowers of

the Convallaria majalis.

SECURIDACA. (From securis, an axe: so called because its leaves resemble a small axe.) See Hyoscy-

SEDATIVE. (Selativus; from sedo, to ease or ssuage.) Sedantia. Medicines which have the power assuage.) Sedantia. Medicines which have the power of diminishing the animal energy, without destroying life. They are divided into sedativa soporifica, as opinm, papaver, hyoscyamus; and sedativa refrigerantia, as neutral salts, acids, &c.

Sedative salt. See Boracic acid.

The bones on which we sit.

SEDENTARIA OSSA. The bones on which we sit. The os coccygis and ischia.

SEDGE. See Iris pseudacorus. SEDIMENT. The heavy parts of liquids which fall to the bottom.

Sediment, lateritious. See Lateritious sediment.

SEDLITZ. Scydschutz. The name of a village of Bohemia, in the circle of Saartz, where Hoffman discovered a simple mineral water, Aqua Sedlitziana.

From chemical analysis it appears, that it is strongly impregnated with sulphate of magnesia or Epsom salt, and it is to this, along with, probably, the small quantity of muriate of magnesia, that it owes its bitter and saline taste, and its purgative properties. The diseases in which this water is recommended are, crudities of the stomach, hypochondriasis, amenorrhea, and the anomalous complaints succeeding the cessation of the catamenia, ædematous tumours of the legs in literary men, hæmorrhoidal affections, and scorbutic erup-

SE'DUM. (From sedo, to assuage: so called because it allays inflammation.) The name of a genus of plants in the Linnwan system. Class, Decandria; Order, Pentagynia.

SEDUM ACRE. Illecebra; Vermicularis; Piper mu-rale; Sedum minus. Wall-pepper; Stone-crop. The plant thus called is, in its recent state, extremely acrid, like the hydropiper; hence, if taken in large doses, it acts powerfully on the prime viæ, proving both emetic and cathartic; applied to the skin as a cataplasm, it frequently produces vesications and erosions. Boerhaave therefore imagines, that its internal employment must be unsafe; but experience has discovered, that a decoction of this plant is not only safe, but of great effi-cacy in scorbutic complaints. For which purpose, a handful of the herb is directed, by Below, to be boiled in eight pints of beer, till they are reduced to four, of which three or four ounces are to be taken every, or every other morning. Milk has been found to an this purpose better than beer. Not only ulcers simply scorbutic, but those of a scrofulous or even cancerous tendency, have been cured by the use of this plant; of which Marquet relates several instances. He likewise found it useful as an external application in destroying fungous flesh, and in promoting a discharge in gan-grenes and carbuncles. Another effect for which this plant is estcemed, is that of stepping intermittent fevers.

SEDUM LUTEUM MURALE. Navel-wort. SEDUM MAJUS. See Sempervivum tectorum. SEDUM MINUS. See Sedum acre.

SEDUM TELEPHIUM. The systematic name of the orpine. Faba crassa; Telephium; Fabaria crassula; Anacampseros. The plant which bears these names in various pharmacopæias, is the Sedum-foliis planiusculis serratis, corymbo folioso, caule erecto, of Lin næus. It was formerly ranked as an antiphlogistic, but

næus: It was formerly ranked as an antiphlogistic, but now forgotten.

Seed vessel. See Pericarpium.

SEEING. See Vision.

SEIGNETTE'S SALT. A neutral salt: first prepared and made known by Peter Seignette, who lived at Rochelle, in France, towards the end of the seventeenth See Soda tartarizata.

SELENITES. (From σεληνη, the moon.) 1. Sparry

gypsum, a sulphate of lime.

2. A white stone having a figure on it resembling a moon.

SELENIUM. (From σεληνη, the moon: so called from its usefulness in lunacy.) 1. A kind of peony.

2. A new elementary body extracted by Berzelius

from the pyrites of Fahlun, which, from its chemical

properties, he places between sulphur and tellurium, though it has more properties in common with the former, than with the latter substance.

SELF-HEAL. See Prunella.

SELINE. (From σιληνη, the moon; because they are opake, and look like little moons.) A disease of the nails, in which white spots are occasionally seen in their substance. their substance.

SELINIC ACID. Acidum selinicum. If selinium be heated to dryness it forms with nitric acid, a volatile and crystallizable compound, called selinic acid, which unites to some of the metallic oxides producing

salts, called seleniates.

SELI'NUM. (The ancient generic name of Theophrastus and Dioscorides, whose Σελιον is said to be
derived from παρα το εν ελει φυεσθαι, on account of its
growing in mud; whence Homer's ελεοθρεπ ζον σελινον.
De Theis says, that selinum is derived from σεληνη,
the moon, because of the shape of its growing seeds; and that it is the foundation of many other compound names of umbelliferous plants among the Greeks, as ορισσελινον, πετροσελινον, &c.) The name of a genus of plants. Class, Pentandria; Order, Digynia.

SELLA. (Sella, quasi sedda; from sedeo, to sit.)

A saddle. Se'lla TURCICA. A saddle.

SE'LLA TURCICA. (So called from its supposed resemblance to a Turkish saddle.) Ephippium. A cavity in the sphenoid bone, containing the pituitary gland, surrounded by the four clinoid processes.

SELTZER. The name of a place in Germany, Neider Seltzer, about ten miles from Frankfort on the Mayne, where a soling mineral major rivers which is

Mayne, where a saline mineral water rises, which is slightly alkaline, highly acidulated with carbonic acid, containing more of this volatile principle than is sufficient to saturate the alkali, and the earths which it holds in solution. It is particularly serviceable in relieving some of the symptoms that indicate a morbid affection of the lungs; in slow hectic fever, exanthematous eruptions of the skin, foulness of the stomach, billious romiting, acidity, and hearthway spreamedic matous eruptions of the skin, foulness of the stomach, bilious vomiting, acidity, and heartburn, spasmodic pains in any part of the alimentary canal, and bloody or highly offeasive stools. On account of its property in relieving spasmodic pains, and from its rapid determination to the kidneys, and perhaps its alkaline contents, it has been sometimes employed with great advantage in diseases of the urinary organs, especially those that are attended with the formation of calculus. A large proportion of the Selver, water, either genuine or artiproportion of the Seltzer water, either genuine or arti-ficial, that is consumed in this country, is for the relief of these disorders. Even in gonorrhœa, either simple or venereal, Hoffmann asserts, that advantage is to be derived from this medicine. The usual dose is from half a pint to a pint. SEMECA'RPUS.

SEMECA'RPUS. (From σημειω, to mark, and καρπος, a fruit: a name evidently derived from the use
that is made of its nut in the East Indies to mark table
linen and articles of apparel.) The name of a genus
of plants, Class Pentandria; Order, Trigynia.

SEMECARPUS ANACARDIUM. The marking nut-tree.
The systematic name, according to some, of the tree
which is supposed to afford the Malacca bean. See

Avicenna tomentosa.

SEMEIO'SIS. (From σημειοω, to notify.) See Se-

SE'MEN. (Semen, inis. n.; sero, to sow.) A. The seed or prolific liquor of animals secreted in the testicles, and carried through the epididymis and vas deferens into the vesiculæ seminales, to be emitted sub coitu into the female vagina, and there, by its aura, to penetrate and impregnate the ovulum in the ovarium.

In castrated animals, and in eunuchs, the vesiculæ seminales are small, and contracted; and a little lym-phatic liquor, but no semen, is found in them. The semen is detained for some time in the vesiculæ seminales, and rendered thicker from the continual absorp-tion of its very thin part, by the oscula of the lym-phatic vessels. In lascivious men, the semen is sometimes, though rarely, propelled by nocturnal pollution from the vesiculæ seminales, through the ejaculatory ducts (which arise from the vesiculæ seminales, per-forate the urethra transversely, and open themselves forate the urethra transversely, and open themselves by narrow and very nervous mouths at the sides of the caput gallinaginis), into the urethra, and from it to some distance. But in chaste men, the greatest part is again gradually absorbed from the vesiculæ seminales through the lymphatic vessels, and conciliates strength to the body. The smell of semen is specific, heavy, affecting the nostrils, yet not disagreeable. The same odour is observed in the roots of the orchis, the iuli of chesnuts, and the antheræ of many plants. The smell odour is observed in the roots of the orchis, the full of chesnuts, and the antheræ of many plants. The smell of the semen of quadrupeds, when at heat, is so penetrating, as to render their flesh fortid and useless, unless castrated. Thus the flesh of the stag, tempore coitus, is unfit to eat. The taste of semen is fatuous, and somewhat acrid. In the testes, its consistence is thin and diluted; but in the vesiculæ seminales, viscid, desse and rather pellucid; and by venery and debility dense, and rather pellucid; and by venery and debility

it is rendered thinner.

Specific gravity. The greatest part of the semen sinks to the bottom in water, yet some part swims on its surface, which it covers like very fine threads mutually connected together in the form of a cobweb.

Colour. In the testicles it is somewhat yellow, and in the vesiculæ seminales it acquires a deeper hue. That emitted by pollution or coition, becomes white from its mixture with the whitish liquor of the prostate gland during its passage through the urethra. In those people who labour under jaundice, and from the abuse of saffron, the semen has been seen yellow, and, in an atrabilary young man black.

Quality. Semen, exposed to the atmospheric air, loses its pellucidity, and becomes thick, but after a few hours it is again rendered more fluid and pellucid than it was immediately after its emission. This phenomenon cannot arise from water or oxygen attracted from the air. At length it deposites phosphate of lime, and forms a cornectic structure. forms a corneous crust.

Experiments with semen prove, that it turns the syrup of violets green, and dissolves earthy, neutral, and metallic salts. Fresh semen is insoluble in water, until it has undergone the above changes in atmospheric air. It is dissolved by alkaline salts. By wthereal oil it is dried into a pellucid pellicle, like the cortex of the brain. It is dissolved by all acids, except the oxymuriatic, by which it is coagulated in the form of white flakes. It is also acted upon by alkaline of wine.

It is also acted upon by alkohol of wine.

it possesses the wonderful and stupendous power of impregnating the ovulum in the female ovarium. The impregnating the ovulum in the female ovarium. The odorous principle, or aura spermatica only, appears to penetrate through the cavity of the uterus and Fallopian tubes to the female ovarium, and there to impregnate the albuminous latex of the mature ovulum by its vital power. The other principles of the semen appear to be only a vehicle of the seminal aura. 2. In chaste men, the semen returning through the lymphatic vessels into the mass of the blood, gives strength to the body and mind; hence the bull is so fierce and brave, the castrated ox so gentle and weak; hence every animal languishes post coitum; and hence tabes dersalis from onanism. 3. It is by the stimulus of the semen absorbed, at the age of puberty, into the mass of the humours, that the beard and hair of the pubes, but in animals, the horns, are produced; and the weep-

but in animals, the horns, are produced; and the weeping voice of the boy changed into that of a man.

B. The seed of plants or nucleus formed in the germen of a plant, for the purpose of propagating its species, the sole "end and aim" of all the organs of fructification. tification. Every other part is in some manner subservient to the forming, perfecting, or dispersing of these.

A seed consists of several parts, some of which are

more essential than others, viz.

The hilum, or scar.
 The funiculus umbilicalis, or filament, by which the immature seed is connected to the receptacle.

3. The testa, or tunica seminis.
4. The seed lobes, or cotyledons. These parts are beautifully seen by macerating the seeds of a kidney or other bean, or gourd, in water.

The less essential parts are,
1. The arillus.
4. The copsula.
2. The pappus.
5. The ala.

The arillus.
The pappus.
The cauda.

From the difference in the form, surface, situation, and number, rise the following distinctions of seeds.

Semina arillata; as in Jasminum. Paposa; as in Leontodon tarazacum. Caudata; as in Clematis vitalba.

Calyculata, covered with a bony calyx; as in Coiz

lachryma.
5. Alata; as in Bignonia.
6. Hamosa, furnished with one or three hooks; as in Daucus muricatus.

in Daucus muricalus.
7. Lanata, covered with wool; as in Bombax, Gossipium, and Anemone hortensis.
8. Rotuda; as in Pisum, and Brassica.
9. Rotunda-compressa; as Ervum lens.
10. Oblonga; as in Boerhavia diffusa.
11. Conica; as in Bellium.
12. Ovata; as in Quercus robur.
13. Triquetra; as in Rheum, and Rumex.
14. Lanceolata; as in Fraxinus.
15. Acuminata; as Cucumis sativus.
16. Reniformia; as in Phaseolus.

17. Aculeata; as Ranunculus arvensis.

18. Cochleata; as in Salsola.

19. Cymbiformia; as in Calendula officinalis.

20. Linearia; as in Crucianella.
21. Aristata; as in Holcus saccharatus.
22. Echinata; as in Verbena lopulacea.
23. Hispida; as Daucus carota.
24. Hirsuta; as in Scandiz trichosperma.

24. Hirsuta; as in Scandiz trichosperma.
25. Muricata; as Ranunculus parviflorus.
26. Glabra; as in Galium montanum.
27. Rugosa; as in Lithospermum arvense.
28. Callosa; as in Citrus medica.
29. Lapidea; as in Charophyllum aureum.
30. Colorata; as in Charophyllum aureum.

31. Striata; as in Conium maculatum. 32. Sulcata; as in Scandiz odorata. 33. Transversim sulcatu; as Picris.

Nuda; as in the Gymnospermial plants.
 Tecta; as in Angiospermial plants.
 Nidulantia, adhering to the external surface; as

30. National and an anisation of the external surface; as in Fragaria vesca.
37. Pendula, suspended by a filament external to the seed vessel; as in Magnolia grandiflora.
38. Pauca, when few in number.
39. Plurima, many; as in Papaver.
The parts of a seed when germinating are,

1. Cotyledones. 2. Corculum.

The variety of forms of seeds are not without their uses, and the various modes by which seeds are dispersed, cannot fail to strike an observing mind with admiration. "Who has not listened," says Sir James admiration. "Who has not listened," says Sir James Smith, "in a calm and sunny day, to the crackling of furze bushes, caused by the explosion of their little clastic pods; nor watched the down of innumerable seeds floating on the summer breeze, till they are overtaken by a shower, which, moistening their wings, stops their further flight, and at the same time accomplishes its final purpose, by immediately promoting the germination of each seed in the moist earth? How little are children aware, as they blow away the seeds of dandelion, or stick burs, in sport, on each other's clothes, that they are fulfilling one of the greatest ends of nature. Sometimes the calyx, beset with hooks, of nature. Sometimes the calyx, beset with hooks, forms the bur; sometimes hooks encompass the fruit itself. Pulpy fruits serve quadrupeds and birds as food, while their seeds, often small, hard, and indigestible, pass uninjured by them through the intestines, and are deposited far from their original place of growth, in a condition peculiarly fit for vegetation. Even such seeds as are themselves eaten, like the various sorts of nuts, are hoarded up in the cracked ground, and occa-sionally forgotten, or the earth swells and encloses them. The ocean itself serves to waft the larger kinds of seeds from their native soil to far distant

SEMEN ADJOWAEN. A seed imported from the East, of a pleasant smell, a grateful aromatic taste, somewhat like savory. It possesses exciting, stimulating, and carminative virtues, and is given in the East in nervous weakness, dyspepsia, flatulency, and heartburn.

SEMEN AGAVE. An East Indian seed, exhibited

there in atonic gout.

Semen contral. See Artemisia santonica.

Semen sanctum. See Artemisia santonica.

SEMI. (From ημισυ, half.) Semi, in composition, universally signifies half; as semicupium, a half-bath, or bath up to the navel; semilunaris, in the shape of a

SEMICIRCULAR. Semicircularis. Of the shape

of half a circle.

SEMICIRCULAR CANALS. These canals are three in number, and take their name from their figure. They belong to the organ of hearing, and are situated in the petrous portion of the temporal bone, and open into the vestibulum.

SEMICU'PIUM. A half-bath, or such as receives

only the hips, or extremities. SEMICYLINDRACEUS. Semicylindrical; flat on one side, round on the other, as the leaves of the Conchium gibbosum.

SEMI INTEROSSEUS INDICIS. See Abductor indicis

SEMILUNAR. Semilunaris. Half-moon shaped. SEMILUNAR VALVES. The three valves at the beginning of the pulmonary artery and aorta are so termed, from their half-moon shape.

SEMI-MEMBRANO'SUS. Ischio-popliti-femoral, of Dumas. This muscle arises from the outer surface of the tuberosity of the ischium, by a broad flat ten-don which is three inches in length. From this tendon it has gotten the name of semi-membranosus. It then begins to grow fleshy, and runs at first under the long head of the biceps, and afterward between that mus-cle and the semi-tendinosus. At the lower part of the thigh it becomes narrower again, and terminates in a short tendon, which is inserted chiefly into the upper and back part of the head of the tibia, but some of its fibres are spread over the posterior surface of the capsular ligament of the knee. Between this cupsular ligament and the tendon of the muscle, we find a small bursa mucosa. The tendons of this and the last-described muscle form the inner ham-string. This muscle bends the leg, and seems likewise to prevent the capsular ligament from being pinched.

SEMI-NERVOSUS. See Semitendinosus.
SEMINIS CAUDA. See Canda seminis.
SEMINIS EJACULATOR. Bee Accelerator uring.

Semiopal. See Opal.

SEMI-ORBICULARIS ORIS. See Orbicularis oris. SEMIO'TICE. (From onuctor, a sign.) Cemeiosis. That part of pathology which treats on the signs of

SEMI-SPINALIS COLDI. Semi-spinalis sive trans-verso-spinalis colli, of Winslow; Spinalis cervicis, of Albinus; Spinalis colli, of Douglas; Transversalis colli, of Cowper; and Transverso-spinal, of Dumas. A muscle situated on the posterior part of the neck, which turns the neck obliquely backwards, and a little to one side. It arises from the transverse processes of the uppermost six vertebre of the back by as many distinct tendous ascending obliquely under the comdistinct tendons, ascending obliquely under the com-plexus, and is inserted into the spinous processes of all the vertebræ of the neck, except the first and last. Semi-spinalis dorsi, of Winslow. Semi-spinal transverso-spinalis dorsi, of Winslow. Semi-spina

tus, of Cowper; and Transcerso-spinal, of Dumas. A muscle situated on the back, which extends the spine obliquely backwards. It arises from the transverse processes of the seventh, eighth, ninth, and tenth vertebræ of the back, by as many distinct tendons, which soon grow fleshy, and then become tendi-nous again, and are inserted into the spinous pro-cesses of all the vertebræ of the back above the eighth, and into the lowermost of the neck, by as many ten-

SEMI-SPINALIS EXTERNUS. See Semi-spinalis dorsi.

SEMI-SPINALUS EXTERNUS. See Semi-spinalis dorsi.
SEMI-SPINATUS. See Semi-spinalis dorsi.
SEMI-TENDINOSUS. This muscle, which is the seminervosus, of Douglas and Winslow; and Ischio-cretitibial, of Dumas, is situated obliquely along the back
part of the thigh. It arises tendinous and fleshy from
the inferior, posterior, and outer part of the tuberosity
of the ischium, in common with the long head of the
biceps cruris, to the posterior edge of which it continues to adhere, by a great number of oblique fibres, for
the space of two or three inches. Towards the lower
part of the os femoris, it terminates in a round tenpart of the os femoris, it terminates in a round tendon, which passes behind the inner condyle of the thigh bone, and, becoming flat, is inserted into the upper and inner part of the ridge of the tibia, a little below its tuberosity. This tendon sends off an aponeurosis, which helps to form the tendinous fascia that covers the muscles of the leg. This muscle assists in bending the leg, and at the same time draws it a little inwards.

SEMPERVIRENS. Evergreen. Applied to leaves which are permanent through one, two, or more winters, so that the branches are never stripped; as the

ivy, fir, laurel, bay, &c. SEMPERVI'VUM. SEMPERVI'VUM. (From semper, always, and vivo, to live: so called because it is always green.)

1. The name of a genus of plants in the Linnaran system. Class, Dodecandria; Order, Polygynia.

2. The pharmacopæial name of some plants.

SEMPERVIVUM ACRE. The stone-crop is occasionally so termed.

so termed. See Cedum acre. Sempervivum Tectorum.

SEMPERVIVUM TECTORUM. The systematic name of the houseleek. Cedum majus; Æonion; Aizoum; Aizoon; Barba jovis. Houseleek, or sengreen. The leaves of this plant have no remarkable smell, but discover to the taste a mild subacid austerity; they are frequently applied by the vulgar to bruises and old SENAC, John, was born in Gascony, about the close of the seventeenth century. He is stated to have received the degree of doctor at Rheims, and that of bachelor of physic at Paris. He was a man of profound erudition, united with great modesty; and by his industry acquired much experience. His merits procured him the favour of Louis XV. who appointed him his consulting, and afterward his chief physician, which office he retained till his death in 1770, which office he retained till his death in 1770. He was also a member of the Royal Academy of Sciences at Paris, and of the Royal Society of Nancy. He left some works, which will probably maintain a lasting reputation, particularly his treatise on the Structure, Function, and Diseases of the Heart. An edition of Heister's Anatomy, with some interesting Observations, was published by him when young. A paper on Drowning, in the Memoirs of the Academy of Sciences, refuting certain erroneous onintons respecting Sciences, refuting certain erroneous opinions respecting the Cause of Death, and the Treatmen founded upon them, is also due to him; as well as some other minor publications.

SENE CIO. (Senecio; from senesco, to grow old: so called because it has a grayish down upon it, like

the beard of old men.)

1. The name of a genus of plants in the Linnman stem. Class, Syngenesia; Order, Polygamia susystem. perflua.
2. The pharmacopæial name also of the groundsel.

See Senecio vulgaris.

Senecio Jacobea. The systematic name of the Jacobea, of old writers. St. James's wort. Ragwort. The leaves of this common plant have a roughish, bitter, sub-acrid taste, extremely nauseous. A decoc-tion is said to have been of infinite service in the cure of epidemic camp dysentery. A poultice made of the fresh leaves is said to have a surprising effect in removing pains of the joints, and to remove the sciatica, or hip gont, in two or three applications when ever so violent. The root is of an adstringent nature. A de-coction of it was formerly good for wounds and

SENECIO MADRASPATANUS. See Senecio pseudo-

Senecio pseudo-china. China supposita; Senecio madraspatanus. Bastard China. It grows in Malabar. The root greatly resembles the China root in appearance and qualities.

Senecto vulgaris. Erigerum; Scnecio; Erigeron. Groundsel. This very common plant is frequently applied bruised to inflammations and ulcers, as refrigerant and antiscorbutic.

Senecta and antiscoroutic.

Senecta anguium. The cast skin of a serpent; its decoction is said to cure deafness.

SENECTUS. See Age.

[Seneca oil. See Genessee oil.]

SE'NEGA. (So called because the Seneca or Sene-

SE'NEGA. (So called because the Seneca or Senegaw Indians use it against the bite of the rattlesnake.)
See Polygala senega.
Senegal gum. See Mimosa senegal.
Senegaw milkwort. See Polygala senega.
SE'NEKA. See Senega.
SENGREEN. See Sempervivum tectorum.
SE'NNA. (From senna, an Arabian, word, signifying acute: so called from its sharp-pointed leaves.) See Cassia senna.

SENNA ALEXANDRINA. See Cassia senna.
SENNA ITALICA. Pee Cassia senna
SENNA PAUPERUM. Bastard senna, or milk-vetch.
SENNA SCORPIUM. The scorpion senna.

SENNE EXTRACTUM. Extract of senna. SENNERTUS, Daniel, was born at Breslaw in 1572. He was sent to Wittemberg at the age of twenty-one, and exhibited such marks of talent, that every opportunity was afforded him of visiting the other ce lebrated universities of Germany. On his return in 1601, he received the degree of doctor, and the next year was appointed to a professorship of medicine. He distinguished himself greatly by his eloquence and sound knowledge, and his publications concurred in raising his fame, insomuch that he was consulted by patients from all parts of the world; towards whom he evinced great disinterestedness. The plague prevailed seven times at Wittemberg, while he was professor there, yet he never quitted his post, nor declined his services, even to the poorest sick: however, he was at last a victim to that disease in 1637. Sennertus was a voluminous writer, and has been represented by

some as a mere compiler; but his works are valuable, as containing a full and clear epitome of ancient learning; and besides, display much judgment, and freedom, in criticising their doctrines, which indeed involved him in many controversies. He first introduced the study of chemistry at Wittemberg; and in his writings he maintained the propriety of admitting chemical as well as Galenical theories and remedies into medicine. medicine.

SENSATION. Sensatio. Sensation, or feeling, is the consciousness of a change taking place in any part, from the contact of a foreign body with the extremities of our nerves. The seat of sensation is in the pulp

of the nerves.

The impression produced on any organ by the action of an external body constitutes sensation. This sensation, transmitted by nerves to the brain, is perceived, that is, felt by the organ; the sensation then becomes perception; and this first modification implies, as must be evident, the existence of a central organ, to which impressions produced on the senses are conveyed. The cerebral fibres are acted on with greater or less force by the sensations propagated by all the senses influ-enced at the same time; and we could only acquire confused notions of all bodies that produce them, if one particular and stronger perception did not oblite-rate the others, and fix our attention. In this collective state of the mind on the same subject, the brain is weakly affected, by several sensations which leave no trace behind. It is on this principle that, having read a book with great attention, we forget the different sensations produced by the paper and character.

When a sensation is of short duration, the knowledge we have of it is so weak, that soon afterward there does not remain any knowledge of having experienced it. In proportion as a sensation, or an idea, which is only a sensation transformed or perceived by the cerebral organ, has produced in the fibres of this organ a stronger or weaker impression, the remembrance of it becomes more or less lively and permanent. Thus we have a reminiscence of it, that is, call to mind that we have already been affected in the same manner; a memory, or the act of recalling the object of the sensa-

when the brain is easily excitable, and, at the same time, accurately preserves impressions received, it possesses the power of representing to itself ideas with all their connexions, and all the accessory circumstances by which they are accompanied, of reproducing them in a certain degree and of received. them in a certain degree, and of recalling an entire object, while the memory only gives us an idea of its qualities. This creative faculty is called imagination. When two ideas are brought together, compared, and their analogy considered, we are said to form a judgment; several judgments connected together constitute reasoning. Besides the sensations that are carried from the organs of sense to the brain, there are others, internal, that seem to be transmitted to it by a kind of sympathetic reaction. It is well known what uneasiness the affection of certain organs conveys to the mind, how much an habitual obstruction of the liver is connected with a certain order of ideas; these internal sensations are the origin of our moral faculties, in the same manner as impressions that are conveyed by the organs of sense are the source of intellectual faculties. We are not on that account to place the seat of the passions of the mind in the viscera; it is only necessary to remember that the appetites, whence arise the passions, reside in their respective organs, and are a phenomenon purely physical, while passion consists, at the same time, in the intellectual exertion. Thus an accumulation of semen in the cavities that are employed as a reservoir for it, excites the appetite for venery, very distinct from the passion of love, although it may be frequently the determinate cause of it.

The senses may be enumerated under the following heads, viz. the sense of vision, hearing, smelling, tasting, touching.

SENSIBILITY. Sensibilitas. That action of the brain by which we receive impressions, either from

within, or from without.

"What is said of sensation generally, is applicable to sensibility; for this reason, we only mention here that this faculty exerts itself in two ways very different. In the first, the phenomena happens, unknown to us; in the second, we are aware of it, we perceive the sensation. It is not enough that a body may act

apon one of our senses, that a nerve transmits to the | a string; so called from the seven strings upon its leaf.) brain the impression which is produced-it is not enough that this organ receive the impression: in order that there may be really a sensation, the brain must perceive the impression received. An impression thus perceived is called, in *Idcology*, a Perception, or an Idea.

These two modes of sensibility may be easily verified upon ourselves. For example, it is easy to see that a number of bodies have a continual action upon our senses without our being aware of it: this depends in a great measure upon habit.

a great measure upon nabit.

Sensibility is infinitely variable: in certain persons it is very obtuse; in others it is very elevated: generally a good organization keeps between the extremes. Sensibility is vivid in infancy and youth; it continues in a degree something less marked until past the age of manhood; in old age it suffers an evident dimination, and ware old presented to the certain persons. nution; and very old persons appear quite insensible

nution; and very old persons appear quite insensible to all the ordinary causes of sensations."

All parts possessed of a power of producing a change, so as to excite a sensation, are called sensible; those which are not possessed of this property, insensible. To the insensible parts by nature belong all our fluids, the blood, bile, saliva, &c. and many of the solids, the hair, epidermis, nails, &c.; but the sensible parts are the skin, eyes, tongue, ear, nose, muscles, stomach, intestines, &c.

SENSO'RIUM. 'The organ of any of the senses. See Cerebrum.

SENSORIUM COMMUNE. See Cerebrum.
SENSUS. (Sensus, 4s. m.; & sentiendo.) The senses are distinguished into external and internal. The external senses are seeing, hearing, tasting, smelling, and feeling. The internal, imagination, memory, internal external external

The external senses are seeing, hearing, tasting, smelling, and feeling. The internal, imagination, memory, judgment, attention, and the passions.

SENTICOSÆ. (From sentis, a brier.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as resemble the bramble, rose, &c.

SENTIENT. This term is applied to those parts which are more susceptible of feeling than others, as the sentient extremities of the nerves, &c.

SENTIS CANINUS. (Sentis, a thorn; from its being prickly like a thorn.) See Rosa canina.

SEPARATO'RIUM. (From separo, to separate.) An instrument for separating the pericanium from the skull, and a chemical vessel for separating essential parts of liquids.

SE'PIA. The name of a genus of fish, of the Class,

parts of liquids.

SEPIA. The name of a genus of fish, of the Class, Vernes; Order, Molusca. The cuttle-fish.

SEPIA OFFICINALIS. Sepium; Pracipitans magnum. The cuttle-fish. The systematic name of the fish, the shell of which is a phosphate of lime, and is often mixed into tooth-powders.

SEPIR Os. See Sepia officinalis.

SEPIARIÆ. (From sepes, a hedge.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of woody plants, which form a hedge-like appearance; the flowers are mostly a thy-

hedge-like appearance; the howers are mostly a my mus or panicle.

SEPIUM. See Sepia officinalis.

SEPTARIA. Ludi helmontii. Spheroidal concretions that vary from a few inches to a foot in diameter. When broken in a longitudinal direction, the interior of the mass is observed intersected by a number of fissures, sometimes empty, sometimes filled with calcareous spar. The body of the concretion is ferruginous marle. From these septaria is manufactured that excellent material for building under water, called Parke's cament, or Roman cement. cement, or Roman cement.

cement, or Roman cement.

Septenary years. Climacteric years. A period, or succession of years in human life, at which, important constitutional changes are supposed to take place; and the end of this period is therefore judged critical. This period is fixed at every seventh year. The grand climacteric is fixed at 63, and, passing that time, age, it is considered, may be protracted to 90. So general is this belief, that the passing of 60 generally gives much anxiety to most people.

SEPTFOIL. See Tormentilla.

SEPTIC. (Septicus; from σηπω, to putrefy.) Relating to putrefaction.

SEPTIFO'LIA. (From septem, seven, and folium, a leaf: so named from the number of its leaves.) Coralwort, or septfoil toothwort.

SEPTINE'RVIA. (From septem, seven, and norvus,

A species of plantain.
SE'TUM. A partition.
SEPTUM CEREBELLI. A process of the dura mater, dividing the cerebellum perpendicularly into two prin cipal parts.

SEPTUM CEREBRI. The falciform process of the dura mater is sometimes so called. See Falciform process.

SEPTUM CORDIS. (Septum; from sepio, to separate.)

The partition between the two ventricles of the heart.

SEPTUM LUCIDUM. Septum pellucidum. The thin and tender portion of the brain, dividing the lateral ventricles from each other.

SEPTUM NARIUM. Interseptum. The partition between the nostrils.

SEPTUM PALATI. The partition of the palate. SEPTUM PELLUCIDUM. See Septum lucidum. SEPTUM THORACIS. See Mediastinum.

SERTUM TRANSVERSUM. See Diaphragm.
SERAPIAS. (From Serapis, a lascivious idol: so called because it was thought to promote venery; or from the testiculated shape of its roots.) The name of a genus of plants in the Linnæan system. Class, Gynandria; Order, Diandria.

SERAPINUM. The gum-resin sagapenum is sometimes so called. See Sagapenum.

SERAPION, of Alexandria, lived about 280 years before Christ, and is affirmed by Celsus to have been the founder of the empiric sect of physicians; though others have attributed the origin of this sect to Philinus.

SERAPION, John, an Arabian physician who lived between the time of Mesue and Rhazes, towards the between the time of Mesue and Rhazes, towards the middle of the ninth century, and is supposed to have been the first writer on physic in the Arabic language. Haly Abbas describes his writings as containing only the cure of diseases, without any precepts concerning the preservation of health, or relating to surgery: and they are frequently quoted by Rhazes. He often transcribes the remarks of Alexander Trallian, with whom the other Arabians appear to be little acquainted. Some confusion appears to exist respecting another Serapion, who is supposed to have lived 180 years later, and to have been the author of a work on the Materia Medica, entitled "De Medicamentistam simplicibus, quam compositis;" in which authors are quoted, much posterior to Rhazes, Avenzoar for instance, so that it posterior to Rhazes, Avenzoar for instance, so that it must have been written towards the latter part of the must have believenth century.

SERICUM. Silk. A species of hairy pubescence of plants, which consists of a white shining silkiness: hence the leaves of the Potentilla anserina, Alche-

nence the leaves of the Potentilla anserina, Alchemilla alpina, &c. are called Folia sericea.

SERI PHIUM. (Seems to have been applied to this genus on account of the analogy in its habit and foliage with the Artemisia pontica of Pliny, called by the Greeks Σερεφιον. The origin of this name may be traced to Seriphion, or, as it is now called, Serpho, an island in the Ægean sea, the soil of which is of so dry and sterile a nature, as only to abound in plants of this rough kind.) The name of a genus of plants. Class Sungenesia: Order, Polygamia segregata.) Flixweed Syngenesia; Order, Polygamia segregata.) Flix-weed. SERIS. Seorg. Endive. SERMOUNTAIN. See Laserpitium siler. SEROUS. (Serosus; from serum.) Relating to

Serous apoplexy. See Apoplexia.

SERPENTA'RIA. (Serpentaria, e. f.: so called from the resemblance of the roots of the plant which first bore this name to the tail of the rattle-snake.) See Aristolochia serpentaria.

SERPENTARIA GALLORUM. See Arum dracunculus. SERPENTARIA HISPANICA. The viper's grass. See Scorzonera hispanica.

SERPENTARIA VIRGINIANA. See Aristolochia ser-

SERPENTINE. A hard mineral, of which there are two kinds, the common and precious. The com mon is of a green colour, and is found in various mountains in Scotland and Ireland. Of the precious, there are two species; the splintery, found in Corsica, and is cut into snuff boxes; and the concholdal, which is of a leck green colour.

SERPENTUM LIGNUM. See Ophioxylum scrpenti-

SERPI'GO. (From serpo, to creep; because it

ereeps on the surface of the skin by degrees.) A ring-worm, or tetter. See Herpes.

SERPY'LLUM. (From ερπω, to creep, or à ser-pendo, by reason of its creeping nature.) See Thymus serpyllum.

SERPYLLUM CITRATUM. See Thymus serpyllum.

SERPYLLUM VULGARE MINUS. See Thymus ser-

pyllum

SERRATA. (From serra, a saw: so called from

its serrated leaves.) See Serratula.

SERRA'TULA. (From serra, a saw: so called from its serrated leaves.) The name of a genus of plants in the Linnaan system. Class, Syngenesia; Order, Polygamia equalis.

Serratula amara. The systematic name of a species of saw-wort, which is said to cure agues.

Serratula arvensis. The common creeping way-

thistle. Carduns arvensis; Carduns hamorrhoidalis; Circium arvense. This plant was formerly used in an application to resolve scirrhous tumours, and is now considered useful against piles.

SERRA'TUS. (From serra, a saw.) Serrated; a botanical term applied to leaves when the teeth are sharp, and resemble those of a saw, pointing towards the extremity of the leaf, as in Urtica; and the petals of the Dianthus arboreus, and Cystus polyfolius.

Some leaves are called duplicato-serrate; these are doubly serrate, having a series of smaller serratures in-

doubly serrate, having a series of smaller serratures intermixed with the larger; as in Campanula trachelium. Serratus anticus. See Pectoralis minor.

Serratus magnus. (So called from its saw-like appearance.) Serratus major anticus, of Douglas and Cowper. Serratus major, of Winslow; and Costo basi-scapulaire, of Dumas. This muscle is so named by Albinus. Douglas calls it Serratus major anticus, but improperly, as it is seated at the side, and not at the anterior part of the thorax. It is a broad fleshy muscle, of a very irregular shape, and is in part covered by the subscapularis, pectoralis, and latissimus dorsi. It arises, by fleshy digitations, from the eight superior ribs, and is inserted fleshy into the whole basis of the scapula internally, between the insertion of the rhomscapula internally, between the insertion of the rhom-boides, and the origin of the sub-scapularis, being fold-ed, as it were, about the two angles of the scapula. This muscie may easily be divided into two and even three portions. The latter division has been adopted by Winslow. The first of these portions is the think This muscie may easily be divided into two and even three portions. The latter division has been adopted by Winslow. The first of these portions is the thick and short part of the muscle that arises from the first and second ribs, and is inserted into the upper angle of the scapula, its fibres ascending obliquely backwards. The second portion arises from the second rib, behind the origin of the first portion, and likewise from the third and fourth ribs; this portion is thin and short, and its fibres run nearly in a horizontal direction, to be inserted into the basis of the scapula. The third, and most considerable portion, is that which arises from the fifth, sixth, seventh, and eighth ribs, and is inserted into the lower angle of the scapula. The serratus magnus serves to move the scapula forwards, and it is chiefly by the contraction of this muscle that the shoulchiefly by the contraction of this muscle that the shoulder is supported, when loaded with any heavy weight. The ancients, and even many of the moderns, particularly Douglas and Cowper, supposed its chief use to be to dilate the thorax, by elevating the ribs; but it can only do this when the scapula is forcibly raised.

Serratus major anticus. See Serratus magnus.

Serratus minor anticus. See Pectoralis minor.

SERRATUS POSTICUS INPERIOR. Dorso-lumbo-costal, of Dumas. This is a thin muscle of considerable breadth, situated at the bottom of the back, under the middle part of the latissimus dorsi. It arises by a broad thin tendon, in common with that of the lastmentioned muscle from the spinous processes of the two, and sometimes of the three inferior dorsal vertebræ, and from three, and sometimes four of those of the lumbar vertebræ. It then becomes ficshy, and, ascending a little obliquely outwards and forwards, divides into three, and sometimes four fleshy slips, which are inserted into the lower edges of the three or four infe-rior ribs, at a little distance from their cartilages. Its use seems to be to pull the ribs downwards, backwards, and outwards.

SERRATUS SUPERIOR POSTICUS. Cervici-dorso-cos tal, of Dumas. This is a small, flat, and thin muscle, Cervici-dorso-cos situated at the upper part of the back, immediately under the rhomboideus. It arises, by a broad thin tendon, from the lower part of the ligamentum colli,

creeps on the surface of the skin by degrees.) A ring- from the spinous process of the last vertebræ of the neck, and the two or three uppermost of the back, and is inserted into the second, third, fourth, and sometimes fifth ribs, by as many distinct slips. Its use is to expand the thorax, by pulling the ribs upwards and outwards.

SERRULATUS. Minutely serrate: applied to such saw-like edged leaves which have their teeth very fine;

as in Polygonum amphibium.

SERTCLA CAMPANA. See Trifolium melilotus.
SERUM. (From serus, late; because it is the remainder of the milk, after its better parts have been taken from it.)

1. Whey.
2. The yellow and somewhat greenish fluid, which eparates from the blood when cold and at rest. See

Alum whey. SERUM ALUMINOSUM.

SERUM LACTIS. Whey. SERVETUS, MICHAEL, was born at Villanueva, in Arragon, in 1509. He first studied the law at Tou-louse; but his attention was drawn to theology by the discussions of the reformers; and as he was disposed to carry his dissent from the church of Rome even to a to carry his dissent from the church of Rome even to a greater length, he judged it prudent to retire into Switzerland, where he published his opinions concerning the Trinity. He afterward went to study physic at Paris, where he took his degree, and then gave mathematical lectures, while he followed the profession of a physician: but having quarrelled with the faculty, and his "Apology" being suppressed by the parliament, he removed to Charlieu, and soon after to Vienna, at the invitation of the archbishop. Here he published a more full account of his religious opinions under a feigned name; but Calvin, the reformer, in whom he had confided, betrayed him to the magistrates, so that had confided, betrayed him to the magistrates, so that he was thrown into prison, from which, however, he escaped. But as he was passing through Geneva, Calvin, whose treachery he did not suspect, procured his arrest, and a charge of blasphemy and heresy to be brought against him; of which, being found guilty, he was cruelly burnt alive in 1553. Servetus is numbered among those anatomists who made the nearest approach to the doctrine of the circulation of the blood : in the work already mentioned, which led to his death, the passage of the blood through the lungs is clearly stated. He was a man of great learning and unfeigned piety, and generally admired for his worth and talents, and the discoveries which he made in medicine, as well as other branches of knowledge.

Service-tree. See Sorbus aucuparia. SESAMOID. (Os sesamoideum; fr SESAMOID. (Os sesamoideum; from σησαμη, an Indian grain, and ειδος, likeness.) This term is applied to the little bones, which, from their supposed general resemblance to the seeds of the sesamum, are called Ossa sesamoidea. They are found at the articulation of the great toes, and sometimes at the joints of the thumbs; now and then we meet with them upon the condyles of the os femoris, at the lower extremity of the fibula, under the os cuboides of the tarsus, &c. They do not exist in the fœtus; but as we advance in life, begin first to appear in a cartilaginous state, and, at length, in adult subjects, are completely ossified. Age and hard labour seem to add to the number and size of these bones, and being most commonly found wherever the tendons and ligaments are most exposed to pressure from the action of the muscles, they are now generally considered by anatomists as the ossified parts of tendons and ligaments. These bones are usually smooth and flat on the side of the bone on which they are placed: their upper surface is convex, and, in general, adheres to the tendon that covers it, and of which it may, in some measure, be considered as a part. though their formation seems to be owing to accidental circumstances; yet, as the two at the first joint of the great toe are much larger than the rest, and are seldom wanting in an adult, it would seem as if these bones were of some utility; perhaps by removing the tendons farther from the centre of motion, and thus increasing the power of the muscles. The ossa sesamoidea of the great toe and thumb seem likewise to be of the property of the great toe and thumb seem likewise to be of the property of the great toe and thumb seem likewise to be of the property of the great toe. of use, by forming a groove for lodging the flexor ten-

dons secure from compression.

Sesamoidal bones. See Sesamoid.

SE'SAMUM. (An Egyptian word.) 1. The name of a genus of plants in the Linnman

2. The pharmacopæial name of the oriental sesa-

mum. See Sesamum orientale.

SESAMUM ORIENTALE. Sesamum. this plant are in much esteem in South Carolina, where they are called oily grain; they are made into soups and puddings, after the manner of rice. Toasted over the fire, they are mixed with other ingredients, and stewed into a delicious food. The fresh seed affords a considerable quantity of a warm pungent oil, otherwise not unpalatable. In a year or two the pungency leaves it when the oil is used for salad, &c. The seeds of the Sesamum indicum are used in the same manner. The leaves are also used medicinally in some countries, being of a mucilaginous quality. [See Benne seed and enne oil. A.] SE SELI. (Παρα τα σαωσαι ελλον; because it is

salutary for young fawns.)

1. The name of a genus of plants. Class, Pentan-

dria; Order, Digynia.
2. An old name of the hart-wort. See Laserpitium

siler.

Servi creticum. There is great confusion among the species of the seseii. The plant which bears this epithet in the pharmacopoias is the Tordylium officinale, of Linneus. The seeds are said to be diuretic.

Seseli massiliense. See Seseli tortuosum.
Seseli tortuosum. The systematic name of the hart-wort of Marseilles. Seseli masiliense. The seeds of this plant are directed for medicinal use, and have a warm biting taste, and a greater degree of pungency

than those of the Laserpitium.

SESQUI. This word, joined with any number, weight, measure, &c. signifies one integer and a half; as sesqui granum, a grain and a half.

SESSILIS. (Sessilis, that sitteth, as it were.) Sessile. This term is applied to many parts of plants, as flowers, leaves, and parts of the fructification, and implies that they are without footstalk, flowerstalk, or novers, leaves, and parts of the fructineation, and implies that they are without footstalk, flowerstalk, or what often supports them: hence, flores sessilis, as in Centaurea calciptrapa; folia sessilia, as in Pinguicula vulgaris; stigma sessile, Tulipa gesneriana, &c.

SETA. (Seta, x. f.; from xarra, a bristle.) A. The fruitstalk of mosses, which is either solitary, aggregate, terminal axillary or lateral

terminal, axillary, or lateral.

B. A bristle, as applied in botanical language to a hollow, rigid, sharp-pointed pubescence, which either wounds the finger when it is pressed upon it, or gives a very harsh scabrous, or prickly character to the surface of the stem, or of the leaves when the finger is rubbed over them.

Bristles are often arranged into aculei in elementary works, but they have more affinity to hairs. They are simple and compound.

Setæ simplices are of two kinds, awl-shaped and

spindle-shaped.

a. The subulate is the most common of the simple from the base to the apex, which is rigid and very sharp. These bristles, when they all incline in the same direction, produce the scabrous character of some leaves, as in symphitum orientale. A variety of the awi-shaped bristle, found on the stem and branches of the sensitive plant, is barbed on its sides; and another variety, as exemplified on the leaves of the Borago officinalis, is seated on a vesicular tubercle containing a fluid, which is ejected through the bristle when it is compressed so as to wound the finger and when it is compressed, so as to wound the finger, and which being left in the wound excites inflammation in the part. But the sting of the nettle is the best example of this form of bristle.

b. The fusiform is, as its name implies, thickest in the centre, and accumulated at each end. It lies parallel to the surface of the leaf, to which it is affixed by a very small footstalk, is hollow, and contains a coloured liquid, which apparently enters it through the footstalk. This form of bristle is peculiar to the genus

Malphigia.

Setæ compositæ. These are almost always solid.
 The term comprehends two species of bristles, furcatæ

and fasciculate.

The forked are, in some instances, merely rigid hair-like bodies terminating in two or three diverging points, as in *Thrincia hispida*: but in other instances, as the stems and leaves of the hop plant, the stalk of the bristle, which is supported on a firm cellular tubercle, is very short, and its forking extremities resemble two

flattish, awl-shaped bristles, pointing in opposite directions.

The fasciculated consist of a number of simple, straight bristles, diverging from a papillary knob; as in

Cactus flagilliformis.

There is still another species of pubescence which cannot properly be arranged with the pilus or seta: it is found on a species of house-leek, extending like a very fine thread, stretching from the tip of one leaf to that of another, and resembling so exactly a spider's web, that the plant has been named Arachnoideum .-Thompson.

Bristles are also distinguished into erect, as in Leontodon hirtum; hamose, as in the pericarp of 'Arcti-cum lappa; stellate and plumpse. The t ties of plants have received other denominations.

Striga, that variety of the subulate which is seen in Borago officinalis.

2. Hamus, that which is hooked at its extremity; as in Galium aperine, Caucalis daucoides, &c.

3. Glochis when several sharp tooth-like processes are turned back from the apex of the bristle.

5. Arista, a long bristle proceeding from the husk of grasses; as in Hordeum vulgare.

SETACEUM. (From seta, a bristle; because horse-

hairs were first used to keep open the wound.) A se-

Bristly. Applied to the petals of SETACEUS.

Trapæolum majus.
SETIFORMIS. Setiform: bristly. Applied to the

nectary, as that of the Periplea graca.

SETON. Setaceum. An artificial ulcer made under the skin by means of an instrument called the seton needle, which carries with it a portion of thread or silk, that is moved backwards or forwards, and thus keeps up a constant irritation.

SETOSUS. Setose: bristly; applied to the recepta-cle of the Echynops sphærocephalus, and of Centaurea. SETTERWORT. See Helleborous fatidus. SEVERINUS, MARCUS AURELIUS, was born in Calabria, in 1580. He graduated at Naples, where he became one of the most celebrated professors in anatomy and surgery. He was, however, somewhat harsh in his practice; and in his work, "De Efficaci Medi-cina," condemned his contemporaries for neglecting the use of the cautery, and of the knife, as practised by the ancients. He died in 1656. Many publications were written by him, evincing much boldness and originality of thought, but too great attachment to paradox. His treatise on abscesses, in eight books, passed through many editions. He paid considerable attention to comparative anatomy, on which subject some of his works are composed.

of his works are composed.

Dispensatory; and gave to the world some other minor Lectures," which was deemed a scientific work, and translated into French. He also edited the Edinburgh two volumes, 1726, containing a brief Description of Diseases, and their Treatment. He then published an a Inquiry into the Virtues of the Scarborough Spa Waters," and about the same time his "Obenical Lectures," which was deemed a scientific work and Sharp-pointed dock. See Rumer acutus.

SHAW, Perren, a physician of considerable reputation in the early part of the last century. His tirst
publication was entitled "New Practice of Physic," in three parts of pure potassa in a silver crucible, dissolve the fused compound in water, add to the solution a quantity of acid, equivalent to saturate the alkali, and evaporate to dryness, we shall obtain a fine gritty powder, which being well washed with hot water, and ignited, will leave pure silica. By passing the vapour of potassium over silica in an ignited tube, Sir H. Davy obtained a dark-coloured powder, which apparently contained silicon, or silicium, the basis of the earth. Like boron and carbon, it is capable of sustaining a high temperature without suffering any change.

SILICON. The base of silica.

SILICULA. A pouch, or pod, that is scarcely longer than it is broad. It is,

1. Orbiculate, in Thlaspi arvense.

2. Cordate, in Isatis armena.

3. Obcordate, in Thlaspi bursæ partoris, alpestre, three parts of pure potassa in a silver crucible, dissolve

Obcordate, in Thiaspi bursæ partoris, alpestre,

and Myagrum perfoliatum.
4. Lanceolate, in Lepedium alpinum, and Isatis tinctoria.

5. Angulate, in Myagrum agyptiacum.
6. Emarginate, in Alyssum, and Cochlearia.
7. Drupaceous, if the membrane is double, soft externally, and hard within; as in Erucago and

Bunias.

SILIGO. Σιλιγνις. Fine wheat or rye.

SI'LIQUA. (From sile, a nose turned up, a hooked nose.) A long, dry, membranaceous pericarpium, or seed-vessel, of two valves, separated by a linear receptacle, along the edges of each of which, the seeds are arranged alternately. The dissepiment is a partition dividing a sitiqua and silicula into two loculaments, or cells. Botanists distinguish,

1. The round pod in Fumaria lutea, and Cheiranthy, tricus pidatus.

thus tricus pidatus.

2 The compressed, with level valves, in Cheiranthus

3. The four-edged, in Erysimum; Cheiranthus erysimoides, and Brassica orientalis.
4. Articulate, in Raphanus raphanistrum.
5. The tortulose, which has elevated nodes here and there, in Raphanus sativus.

6. Rostrate, having the partition very prominent at

6. Rostrate, having the partition very prominent at the apex; as in Sinapis alba.

Siliqua dulcis. See Ceratonia siliqua.

Siliqua hirsuta. See Dolichos pruriens.

Siliqua strum. (From siliqua, a pod: named from its pods.) Judas-tree. The Capsicum, or Guinea-pepper, was so termed by Pliny. See Capsicum.

Siliquo'SE. (From siliqua, a pod.) Cruciformis. The name of an order of plants in Linnaus's Fragments of a Natural Method, consisting of such as have a siliqua or silicula, the flower tetradynamous and cruciate. and cruciate.

Soliquosa indica. An American plant; its juice

is alexipharmic.

SILK-WORM. See Bombyz.

Silk-worm, acid of. See Bombic acid.

SILPHIUM. (Zalaph, Arabian.) Asafætida, or the plant which affords it.

SILVER. Argentum. This metal is found both native and mineralized, and combined with lead, copper, mercury, cobalt, sulphur, areenic, &c. The principal ores of this metal are the following: Native silver; antimoniated silver; sulphuret of silver; sulphuretted oxide of silver and antimony; muriate of silver; native oxide of silver, &c. It is found in different parts of the earth. The mines of the Erzgebürge or the metalliferous rocks of Mexico and Potosi, Bohemia, Norway, Transylvania, &c. are the richest.

barge or the metalliferous rocks of Mexico and Potosi, Bohemia, Norway, Transylvania, &c. are the richest. Mative silver possesses all the properties of this metal, and it appears in series of octahedra inserted in one another; in small capillary flexible threads intwined together; in plates; or in masses. The colour of native silver is white, often tarnished. Silver alloyed with gold forms the auriferous native silver ore. The colour of this ore is a yellowish white. It has much metallic lustre. The autimoniated silver ore belongs to this class. Silver, combined with sulphur, forms the sulphuretted oxide of silver, or vitreous silver ore. This ore occurs in masses, sometimes in threads, and sometimes crystallized in cubes or regular cetahedra. Its colour is dark bluish gray, inclined to black. Its fracture is uneven, and its lustre metallic. black. Its fracture is uneven, and its lustre metallic. It is softenough to be cut with a knife. It is sometimes found alloyed with antimony (gray silver ore). Silver united with muriatic acid forms the corneous silver ore

(muriate of silver), which appears under different colours and shapes. Silver united to oxygen constitutes the caliform silver ore, of which there are several varieties. The colour of these ores is a lead gray, or grayish black. They occur massive, disseminated, and crystallized.

crystallized.

Germany, and other countries of Europe, but more especially Peru and Mexico in South America, contain the principal silver mines. There are, however, silver mines in Ireland, Norway, France, and many other

mines in Ireland, Norway, France, and many other parts in the world.

Method of obtaining silver.—Different methods are employed in different countries to extract silver from its ores. In Mexico, Peru, &c. the mineral is pounded, roasted, washed, and then triturated with mercury in vessels filled with water. A mill is employed to keep the whole in agitation. The silver combines by that means with the mercury. The alloy thus obtained is afterward washed, to separate any foreign matters from it, and then strained and pressed through leather. This being done, heat is applied to drive off the mercury from the silver, which is then melted and cast into bars or logots.

In order to extract silver from sulphuretted or vitreous silver ore, the mineral is roasted, and then melted
with lead and borax, or some other flux to assist the
fusion. By the first operation the sulphur is volatilized,
and by the second the silver is obtained, though for
the most part alloyed with other metals, from which
it is converted by expellation, or fusion with lead or it is separated by cupellation, or fusion with lead or

bismuth.
"Silver is the whitest of all metals, considerably harder than gold, very ductile and malleable, but less malleable than gold; for the continuity of its parts begins to break when it is hammered out into leaves of about the hundred and sixty thousandth of an inch thick, which is more than one-third thicker than gold leaf; in this state it does not transmit the light. Its specific gravity is from 10.4 to 10.5. It ignites before melting, and requires a strong hear to fuse it. heat of common furnaces is insufficient to oxidize it; but the heat of the most powerful burning lenses vitrifies a portion of it, and causes it to emit fumes; which when received on a plate of gold, are found to be silver in the metallic state. It has likewise been partly oxidized by twenty successive exposures to the heat of the porcelain furnace at Sevres. By passing a strong electric shock through a silver wire, it may be converted into a black oxide; and by a powerful galvanic battery, silver leaf may be made to burn with a beautiful green light. Lavoisier oxidized it by the blow-pipe and oxygen gas; and a fine silver wire burns in the kindled united stream of oxygen and burns in the kindled united stream of oxygen and hydrogen gases. The air alters it very little, though it is disposed to obtain a thin purple or black coating from the sulphureous vapours which are emitted from animal substances, drains, or, putrifying matters. This coating, after a long series of years, has been ob-served to scale off from images of silver exposed in churches; and was found, on examination, to consist of silver united with sulphur.

There seems to be only one oxide of silver, which is formed either by intense ignition in an open vessel, when an olive-coloured glass is obtained; or by adding a solution of caustic barytes to one of the nitrate of a solution of causic paryies to one of the hitrate of silver, and heating the precipitate to dull redness. Sir H. Davy found that 100 of silver combined with 7.3 of oxygen in the above oxide; and if we suppose it to consist of a prime equivalent of each constituent, we shall have 13.7 for the prime of silver. Silver leaf burned with a voltaic battery, affords the same olive-coloured oxide.

Silver combines with chlorine, when the metal is heated in contact with the gas. This chloride is, however, usually prepared by adding muriatic acid or a muriate, to nitrate of silver. It has been long known by the name of luna-cornea, or horn silver, because though a white powder, as it falls down from the nitrate solution, it fuses at a moderate heat, and forms of 13.875 silver + 4.5 chlorine.

The sulphuret of silver is a brittle substance, of a

black colour and metallic lustre. It is formed by heating to redness thin plates of silver stratified with sulphur. It consists of 13.875 silver + 2 sulphur.

Silver is soluble in the sulphuric acid when concentrated and boiling, and the metal in a state of division.

made use of be pure; if it contain copper, the solu-tion remains greenish; and if the acid contain either sulphuric or muriatic acid, these combine with a por-tion of the silver, and form scarcely soluble compounds, which fall to the bottom. If the silver contain gold, this metal separates in blackish-coloured flocks.

The nitric acid dissolves more than half its weight of silver; and the solution is very caustic, that is to say, it destroys and corrodes animal substances very

powerfully.

The solution of silver, when fully saturated, deposites thin crystals as it cools, and also by evaporation. These are called lunar nitre, or nitrate of silver. A gentle heat is sufficient to fuse them, and drive off their water of crystallization. In this situation the nitrate, or rather subnitrate, for the heat drives off part of the acid, is of a black colour, may be cast into small sticks in a mould, and then forms the lapis infernalis, or lunar caustic used in surgery. A stronger heat decom-poses nitrate of silver, the acid flying off, and the silver remaining pure. It is obvious that, for the purpose of forming the lunar caustic, it is not necessary to suffer the salt to crystallize, but that it may be made by evaporating the solution of silver at once to dryness; and as soon as the salt is fused, and ceases to boil, it may be poured out. The nitric acid driven off from nitrate of silver is decomposed, the products being oxygen and nitrogen.

The sulphate of silver, which is formed by pouring sulphuric acid into the nitric solution of silver, is sparingly soluble in water; and on this account forms crystals, which are so small, that they compose a white powder. The muriatic acid precipitates from nitric acid the saline compound called Inna-cornea, or hornsilver; which has been so distinguished, because, when melted and cooled, it forms a semitransparent and partiy flexible mass, resembling horn. It is supposed that a preparation of this kind has given rise to the accounts of malleable glass. This effect takes place with aqua regia, which acts strongly on silver, but precipitates it in the form of muriate, as fast as it is

dissolved.

If any salt with base of alkali, containing the muriatic acid, be added to the nitric solution of silver, the same effect takes place by double affinity; the alkaline base uniting with the nitric acid, and the silver falling down

in combination with the muriatic acid.

Sulphur combines very easily with silver, if thin plates imbedded in it, be exposed to a heat sufficient to melt the sulphur. The sulphuret is of a deep violet colour, approaching to black, with a degree of metallic lustre, opake, brittle, and soft. It is more fusible than silver, and this in proportion to the quantity of sulphur combined with it. A strong heat expels part of the sulphur.

Sulphuretted hydrogen soon tarnishes the surface of polished silver, and forms on it a thin layer of sul-

The alkaline sulphurets combine with it by heat, and form a compound, soluble in water. Acids precipitate sulphuret of silver from this solution.

Phosphorus left in a nitric solution of silver, becomes covered with the metal in a dendritic form. By boil-ing this becomes first white, then a light black mass, and is ultimately converted into a light brown phosphuret. The best method of forming a phosphuret of silver is Pelletier's, which consists in mixing phos-phoric acid and charcoal with the metal, and exposing the mixture to heat.

Most metallic substances precipitate silver in the

metallic state from its solution.

Silver unites with gold by fusion, and forms a pale alloy, as has been already mentioned in treating of that metal. With platina it forms a hard mixture, rather yellower than silver itself, and of difficult fusion.

Silver very readily combines with mercury. A very sensible degree of heat is produced, when silver leaf and mercury are kneaded together in the palm of the hand. With lead it forms a soft mass, less sonorous than pure silver. With copper it becomes harder and more sonorous, at the same time that it remains sufficiently ductile: this mixture is used in the British

The muriatic acid does not act upon it, but the nitric acid, if somewhat diluted, dissolves it with great rapidity, and with a plentiful disengagement of nitrous gas; which, during its extrication, gives a blue or green colour to the acid, and entirely disappears if the silver made use of he pure; if it contain corporative with the same metal, has been said to be brittle, how-made use of he pure; if it contain corporative with the same metal, has been said to be brittle, how-made use of he pure; if it contain corporation, though there is probably as with the same metal, has been said to be brittle, how-ever small the proportion; though there is probably as little foundation for the assertion in the one case as in the other. With bismuth, arsenic, zinc, and antimony, it forms brittle compounds. It does not unite with nickel. The compound of silver and tungsten, in the proportion of two of the former to one of the latter, was extended under the hammer during a few strokes; but afterward split in pieces.

The uses of silver are well known: it is chiefly applied to the forming of various utensils for domestic use, and as the medium of exchange in money. Its disposition to assume a black colour by tarnishing, and its softness, appear to be the chief objection to its use in the construction of graduated instruments for astronomical and other purposes, in which a good white metal would be a desirable acquisition. The nitrate of silver, besides its great use as a caustic, has been

employed as a medicine."

SILVER-WEED. See Potentilla anserina.

SIMAROU'BA. (A patronymic name of America.)

See Quassia simarouba.

Si'MIR LAYIS. See Bezoar simios. Simple affinity. See Affinity simple. Simple attraction. See Affinity simple.

Simple leaf. See Leaf.

Simple substance. See Element.

S'IMPLEX. Simple: applied very generally in every department of nature to designate that which is not compound.

SIMPLEX OCULUS. A bandage for the eye.
SINAPE. See Sinapis.
SINAPELÆ'UM. (From σιναπ, mustard, and

SINAPELÆUM. (From σιναπι, mustard, and thatov, oil.) Oil of mustard.

SINAPI. See Sinapis.

SINAPIS. (Οτι σιντι τους ωπας, because it hurts the eyes.) 1. The name of a genus of plants in the Linnwan system. Class, Tetradynamia; Order, Siliquosa. Mustard.

2. The pharmacopæial name of the black mustard.

See Sinapis nigra.

Sinapis alba. The systematic name of the white mustard plant, which is directed for medicinal use in the

mustard plant, which is directed for medicinal use in the Edinburgh pharmacopæia. It is somewhat less pungent than the black species. See Sinapis nigra.

SINAPIS NIGRA. The systematic name of the common black mustard. Napus; Eruca; Sinapi; Sinapi; Sinapi. Common black mustard. Sinapis—siliquis glabris racemo appressis, of Linnæus. The seeds of this species of mustard, which are directed by the London College, and those of the Sinapis alba, which are preferred by that of Edinburgh, manifest no remarkable difference to the taste, nor in their effects, and, therefore, answer equally well for medicinal and culitherefore, answer equally well for medicinal and culinary purposes. They have an acrid purgent taste, and, when bruised, this purgency shows its volatility by powerfully affecting the organs of smell. Mustard is considered as capable of promoting appetite, assisting digestion, attenuating viscid juices, and, by stimulating the fibres, it proves a general remedy in paralytic affections. Joined to its stimulant qualities, it frequently, if taken in considerable quantity, opens the body, and increases the urinary discharge, and hence it has been found useful in dropsical complaints. Externally, flower of mustard is frequently used mixed with vinegar, as a stimulant or sinapism.

SINAPI'SMUS. Sinapismum; Cataplasma sina-pios. A sinapism or mustard poultice. A term given to a mixture of mustard and vinegar in form of poultice, generally applied to the calves of the legs, or soles of the feet, as a stimulant, and employed in low states of feet, as a simulation, and employed in low states of fevers and other diseases, and intended to supercede the use of a blister. See Cataplasma sinapis.

SINA PIUM. (From σιναπι, mustard.) An in-

fusion or decoction of mustard-seed.

SINCIPUT. The forepart of the head. See Caput. SINE PARI. Several muscles, veins, arteries, &c. are so called which are without a fellow. See

Single elective attraction. See Affinity simple.
SINGU'LTUS. Lygmos. The hiccough. A convulsive motion of the diaphragm and parts adjacent.
SINUATUS. Sinuated: applied to leaves which

are cut into rounded or wide openings; as in Statice

1. A cavity or depression.

2. In surgery it means a long, narrow, hollow track, leading from some abscess, diseased bone, &c.

3. The veins of the dura mater are termed sinuses. They are several in number, the principal of which are, 1. The longitudinal sinus, which rises anteriorly from the crista galli, ascends and passes between the two lamins of the falciform process to where this process ends. It then opens into, 2. Two lateral sinuses, distinguished into right and left, which lie in the cricial spine of the os occipitis: 3. The inferior longitudinal dinal, which is a small sinus situated at the acute inferior margin of the falx.

SINUS COX E. The acetabulum.

SINUS GENÆ PITUITARIUS. See Antrum of High-

Si'philis. See Syphilis.

SiPHO'NIA. (From σιφων, a pipe; alluding to the uses made of the exudation of the tree, called Indian rubber.) The name of a genus of plants in the Linnaran system. Class, Monacia; Order, Monadelphia.

Siphonia elastica. The systematic name of the elastic resin-tree. See Caontehoue.

SIRI'ASIS. (From σιρος, a cavity.) An inflammation of the brain peculiar to children, and attended with a hollowness of the eyes and depression of the footanella.

fontanella.

Sirium Myrtifolium. The systematic name of the tree which is supposed by some to afford the yellow saunders. See Santalum album.

Si'SARUM. (Sisa, Hebrew.) Siser or skirret. See

Sium sisarum.

SI'SER. Sec Sium sisarum. SI'SON. (Σισων. A name adopted by Dioscorides.) The name of a genus of plants. Class, Pentandria,

Order, Monogynia.

Swox AMMI. The systematic name of the plant Sison ammi. The systematic name of the plant which affords the ammi verum of the shops. The seeds of this plant, Sison—folias tripinnatis, radicalibus linearibus. caulinis setaceis stipularibus longio-ribus, of Linnæus, have a grateful smell, somewhat like that of origanum, and were formerly administered as a carminative.

SISY MBRIUM. (From σισυδος, fringe; so named from its fringed roots.) The name of a genus of plants in the Linnwan system. Class, Tetradynamia; Order,

Siliquosa.

Siliquosa.

Sisymbrium nasturtium. The systematic name of the water-cress. Nasturtium aquaticum; Laverodoratum; Cratena sium; Gressi; Cardamines. Water-cress. This indigenous plant, Sisymbrium—siliquis declinatis, foliis pinnatis, foliolis subcordatis, of Linnæus, grows plentifully in brooks and stagnant waters. The leaves have a moderately pungent taste, emit a quick penetrating smell, like that of mustardseed, but much weaker. Water-cresses obtain a place in the Materia Medica, for their antiscorbutic qualities, which have been long very generally acknowledged by physicians. The most pleasant way of administering them is in form of a salad.

Sisymbrium sorhia. The systematic name of the

SISYMBRIUM SOPHIA. The systematic name of the herb sophia. Sophia chirurgorum. This plant is now almost banished from practice. It was formerly in high estimation in the cure of wounds. It has been given internally in hysterical affections and uterine hæmor-rhages, and the seeds are said to be efficacious in de-

stroying intestinal worms.

SITIOLOGY. (Sitiologia: from oi7os, aliment, and λογος, a discourse or treatise.) A doctrine or treatise on aliment.

SI'UM. (From σειω, to move; from its agitation in water. 1. The name of a genus of plants in the Linnean system. Class, Pentandria; Order, Digynia.

2. The pharmacopæial name of the creeping water-

parsaip.

SIUM AROMATICUM. The amomum is sometimes so called.

SIUM NINEI. The systematic name of the plant, the root of which is called radiz ninsi; Ninzin: Nindsin.

This root was long supposed to be the same as ginseng It now appears, however, to be the produce of this plant. It possesses similar, though weaker properties, than

SIUM NODIFLORUM. The systematic name of the creeping water-parsnip. This plant was admitted into the London pharmacopæia in the character of an antiscorbutic. It is not nauseous, and children take it rea-

dily if mixed with milk.

SIUM SISARUM. The siser or skirret. The root of this plant is eatable, but now out of use, though culti-vated in the days of Gerarde and Parkinson. Its flavour is said to be aromatic, with a sweetness not acceptable to every palate, and of a flatulent and indigestible

SKELETON. (Sceletus, from σκελλω, to dry.) Sceleton. When the bones of the body are preserved SKELETON. in their natural situation, and deprived of the fiesh, the

assemblage is called a skeleton. See Bone.

SKELETON, ARTIFICIAL. The assemblage of all the bones of the animal, when hung in their respective situations by means of wire. See Bone.

SKELETON, NATURAL. A skeleton is so termed in opposition to an artificial one, when the bones are retained in their proper places by means of their natural ligaments. ligaments.

SKIN. Acouts. Pellis; Cutis. The skin, though apparently a simple membrane, is in reality laminated, consisting of several subdivisions; the outermost lamina is termed with us scarf skin, or cuticle; the second has no English name, is known only to anatomists, and is called rete mucosum. After these two are removed, we come to, as is commonly thought, the surface of the skin

When a blister has been applied to the skin of a negro, if it has not been very stimulating, in twelve hours after a thin transparent grayish membrane is raised, under which we find a fluid. This membrane is the cuticle or scarf skin. When this, with the fluid, is removed, the surface under them appears black; but if the blister had been very stimulating, another mem-brane, in which this black colour resides, would also have been raised with the cuticle. This is the rete mucosum, which is itself double, consisting of another gray transparent membrane, and of a black web, very much resembling the nigrum pigmentum of the eye. When this membrane is removed, the surface of the true skin (as has hitherto been believed) comes in view, and is white, like that of a European. The rete mugro; white, brown, or yellowish, in the European. The reason why this membrane is black in the Negro, is, perhaps, that his body may be better able to defend itself against the sun's rays, and that the heat may be pre-vented from penetrating. The intention of a similar membrane behind the retina in the eye, appears to be not only that of absorbing the superfluous rays of light, but, like the amalgam behind the looking-glass, it may enable the retina to reflect the rays, in order to perfect vision. It is not very improbable that some such purpose, as enabling the cuticle to reflect the sun's rays in those warm climates, where the inhabitants originally go naked, may be the intention of nature, in giving them the black membrane. Perhaps, too, the circumstance of the countenance becoming brown, when exposed to the sun's rays in summer, in our own climate, may be a process of nature to defend herself against the access of external heat into the body.

Both cuticle and rete mucosum send innumerable processes into the pores of the true skin. The process of the rete mucosum is always within that of the cuticle, and in contact with the sides of the pore, as formed by the true skin. These processes are remarkable in the cuticle and rete mucosum of the elephant, some of them are almost an inch long; the cuticle, or rete mucosum, or a membrane very similar, having the same proper ties with these, appears to be also continued into the inside of the mouth, over the tongue, internal surface of the lungs, esophagus, stomach, and intestinal tube. In most of the last-named parts, the cuticle, however, forms sheaths for villi, and not processes which line pores. On viewing the surface of the skin, even with the naked eye, we find it porous; more so in some places than in others; and the pores are also larger in some parts than others. Some of these pores are ducts of sebaceous glands, and others serve not only to transmit hairs, but, it is supposed, the greatest part of the per

SLE SLE

spirable matter itself. Absorption on the skin also, in all probability, begins on the sides of these pores. They are particularly remarkable about the mouth, nose, palms of the hands, soles of the feet, external ear, scalp, mons veneris, and around the nipple in women.

The skin itself was given to man not only for feeling in a general sense, but for perspiration, absorption, and particularly for touch, in which he excels all other animals, and which resides principally in the fires of the

mals, and which resides principally in the tips of the fingers. He was intended for examining, reasoning, forming a judgment, and acting accordingly; he was fitted by this sense to examine accurately the properties of surrounding bodies, not capable of being examined by his other senses. This, among other reasons, was one why he was made erect, that the point of his fingers should not be made callous, or less sensible, by walking on them.

When carefully dissected off and separated from all adventitious matter in a middle-sized man, the skin weighs about four pounds and a half.

The skin of human bodies is always of a white colour, in the dead body, let the colour of the rete mucosum be what it may; it is extremely full of pores, and extremely vascular; a child in full vigour comes into the world from this circumstance, scarlet; it is endowed with intense sensibility. Almost all the pain, in the different operations of surgery, is past when we have divided the skin. Some parts of the skin have more feeling than others; the lips, for example, as Haller says, "ad basia destinata." The glans clitaridis, and the glans penis, with a similar intention; there, though the nerves are not so large as in some other parts, they are longer, more numerous, and endowed with more are longer, more numerous, and endowed with more exquisite feeling; but where the common offices of life merely are intended, the marks of superior feeling or touch, in the skin, are the projections, above the com-mon surface, of those packets of arteries, veins, and absorbents, called *villi*. The nerves are there not only also longer, but larger, as in the points of the fingers and

We are not certain that the skin is muscular, but it has properties very like those of muscle; it contracts, relaxes, and even vibrates in some places, on certain occasions. It is extremely distensible; the skin of the perinaum has stretched in labour from a quarter of an inch to six inches. It is also extremely elastic, and instantly after labour has returned again to the original quarter of an inch; it is thickest on those parts intended by nature to bear weight or pressure; of course it is thickest on the back, on the soles of the feet, and palms of the hands. It is thinner on the forepart of the body, on the insides of the arms and legs, and where its surfaces touch opposite surfaces. It is extremely thin on the lips, and allows the colour of the blood to shine through it. It is also extremely thin on the glans penis in men, glans clitoridis in women, and on the inside of the labia pudendi. Skin dried and dressed is extremely strong and durable, and therefore complexed to tremely strong and durable, and therefore employed in making harness for horses, clothing for men, and a variety of other purposes

Skin, scarf. See Cuticle, and Skin. SKINK. See Scincus. SKORODITE. An arsenate of iron, without cop-

SKORODITE. An arsenate of fron, without copper, of a green colour, found in quartz and hornstone in primitive rocks in Saxony.

SKULL. Cranium. The skull, or that bony box which contains the brain. It forms the forehead, and every part of the head, except the face. It consists of eight bones, namely, one os frontis, one os occipitis, one os sphenoides, one os ethmoideum, two ossa temporation and two ossa parietalia. lia, and two ossa parietalia.
[Skunk cabbage. See Dracontium. A.]

Slaters. See Oniscus asellus. SLEEP. Somnus. That state of the body in which the internal and external senses and voluntary motions are not exercised. The end and design of sleep is both to renew, during the silence and darkness of the night, the vital energy which has been exhausted through the

day, and to assist nutrition.
"When the time of being awake has continued for "When the time of being awake has continued for sixteen or eighteen hours, we have a general feeling of fatigue and weakness; our motions become more difficult, our senses lose their activity, the mind becomes confused, receives sensations indistinctly, and governs muscular contraction with difficulty. We recognise, by these signs, the necessity of sleep; we choose such a position as can be preserved with little effort; we

spirable matter itself. Absorption on the skin also, in | seek obscurity and silence, and sink into the arms of oblivion.

The man who slumbers loses successively the use of his senses. The sight first ceases to act by the closing of the eyelids, the smell becomes dormant only after the taste, the hearing after the smell, and the touch after the hearing: the muscles of the limbs, being relaxed, cease to act before those that support the relaxed, cease to act before those that support the head, and these before those of the spine. In proportion as these phenomena proceed, the respiration becomes slower and more deep; the circulation diminishes; the blood proceeds in greater quantity to the head; animal heat sinks; the different secretions become less abundant. Man, although plunged in this sopor, has not, however, lost the feeling of his existence; he is conscious of most of the changes that happen in him, and which are not without their charms; ideas, more or less incoherent, succeed each other in his mind. more or less incoherent, succeed each other in his mind; he ceases, finally, to be sensible of existence: he is

During sleep, the circulation and respiration are retarded, as well as the different secretions, and, in conse-

quence, digestion becomes less rapid.

I know not on what foundation the most part of authors say that absorption alone acquires more energy. Since the nutritive functions continue in sleep, it is evident that the brain has ceased to act, only with regard to muscular contraction, and as an organ of intelligence; and that it continues to influence the muscles of respiration, the heart, the arteries, the secretions, and nu-

Sleep is profound when strong excitants are necessary to arrest it; it is light when it ceases easily.

Sleep, such as it has been described, is perfect, that is, it results from the suspension of the action of the relative organs of life, and from the diminution of the action of the nutritive functions; but it is not extraoraction of the nutritive functions; but it is not extraordinary for some of the relative organs of life to preserve their activity during sleep, as it happens when one sleeps standing; it is also frequent for one or more of the senses to remain awake, and transmit the impressions which it perceives to the brain; it is still more common for the brain to take cognizance of different internal sensations that are developed devices the properties of the sensations. that are developed during sleep, as wants, desires, pain, &c. The understanding itself may be in exercise in man during sleep, either in an irregular and incoherent manner, as in most dreams, or in a consequent and regular manner, as it happens in some persons happily organized.

The turn which the ideas assume during sleep, or the nature of dreams, depends much on the state of the organs. If the stomach is overcharged with indigested food, the respiration difficult on account of position, or food, the respiration difficult on account of position, or other causes, dreams are painful, fatiguing; if hunger is felt, the person dreams of eating agreeable food; if it is the venereal appetite, the dreams are erotic, &c. The character of dreams is no less influenced by habitual occupations of the mind; the ambitious dream of success or disappointment, the poet makes verses, the lover sees his mistress, &c. It is because the judgment is sometimes correctly exercised in dreams, with regard to future events, that in times of ignorance the gift of divination was attributed to them. gift of divination was attributed to them.

Nothing is more curious in the study of sleep than

the history of sleep-walkers.

Those individuals being first profoundly asleep, rise all at once, dress themselves, see, hear, speak, employ their hands with ease, perform certain exercises, write, compose, then go to bed, and preserve, when they awake, no recollection of what happened to them. What difference is there, then, between a sleep-walker of this kind, and a man awake? A very evident difference,-the one is conscious of his existence, and the

Many hypotheses have been offered on the proximate cause of sleep, as the depression of the laminæ of the cerebrum, the afflux of blood to the brain, &c. Sleep, which is the immediate effect of the laws of organization, cannot depend on any physical cause of this kind. Its regular return is one of the circumstances

SME SME

plied sensations, prolong it, as well as habits of idle-ness, the immoderate use of wine, and of too strong Infancy and youth, whose life of relation is wery active, have need of longer repose. Riper age, more frugal of time, and tortured with cares, devotes to it but a small portion. Very old people present two opposite modifications; either they are almost always slumbering, or their sleep is very light; but the reason of this latter is not to be found in the foresight they have of their supressibility and have of their approaching end.

By uninterrupted peaceable sleep, restrained within By uninterrupted peaceable steep, restrained within proper limits, the powers are restored, and the organs recover the facility of action; but if sleep is troubled by disagreeable dreams, and painful impressions, or even prolonged beyond measure, very far from repairing, it exhausts the strength, fatigues the organs, and sometimes becomes the occasion of serious diseases, as idiotism and madness."

SMELLIE, WILLIAM, was born in Scotland, where he practised midwifery for nineteen years, and then settled in London. He attained considerable reputation as a lecturer, which he appears to have merited by his assiduity and talents. He introduced many improvements in the instruments employed in that branch of the profession, and established some useful rules for their application. He was the first writer rules for their application. He was the first writer who, by accurately determining the shape and size of the pelvis, and of the head of the fœtus, and considering its true position in utero, clearly pointed out the whole progress of paturition: and his opinions were subsequently confirmed, especially by his pupil, the celebrated Dr. W. Hunter. He abolished many superstitious notions, and erroneous customs, that prevailed in the management of parturient women, and of the children; and had the satisfaction of seeing most of these improvements adopted, as well in this as in other countries of Europe. In 1752, he published the substance of his lectures in an octavo volume; to which he added, two years after, a second volume of cases; he added, two years after, a second volume of cases; and a third appeared about five years after his death, in 1768. In 1754, he also published a set of anatomi-cal plates, of a large folio size, to elucidate his doctrines

SMELL. "There escapes from almost every body in nature certain particles of an extreme tenuity, which are carried by the air often to a great distance. These particles constitute odours. There is one sense destined to perceive and appreciate them. Thus an important relation between animals and bodies is esta-

blished.

All bodies of which the atoms are fixed are called inodorous.

The difference of bodies is very great relative to the manner in which odours are developed. Some permit them to escape only when they are heated; others only when rubbed. Some again produce very weak odours, while others produce only those which are highly pow-Such is the extreme tenuity of odoriferous particles, that a body may produce them for a very long time without losing weight in any sensible degree. Every odoriferous hody has an odour peculiar to

As these bodies are very numerous, there have been attempts made to class them, which have nevertheless

all failed.

Odours can be distinguished only into weak and rong, agreeable and disagreeable. We can recognise strong, agreeable and disagreeable. We can recognise odours which are musky, aromatic, feetid, rancid, spermatic, pungent, muriatic, &c. Some are fugitive, others tenacious. In most cases an odour cannot be distinguished but by comparing it with some known body. There have been attributed to odours properties which are nourishing, medical, and even venomous; but in the cases which have given rise to these opinions, might not the influence of odours have been confounded with the effects of absorption? A man who pounds jalap for some time will be purged in the same manner as if he had actually swallowed part of it. This ought not to be attributed to the effects of odours, but rather to

the particles which, being spread around, float in the air, and are introduced either with the saliva or with the breath. We ought to attribute to the same cause the drunkenness of persons who are exposed for some time to the vapours of spirituous liquors. The air is the only vehicle of odours; it transports them to a distance; they are also produced, however, in vacue, and there are bodies which project odoriferous parti-cles with a certain force. This matter has not yet been carefully studied; it is not known if, in the pro-pagation of odours, there be any thing analogous to the divergence, the convergence, to the reflection, or the refraction of the rays of light. Odours mix or combine with many liquids, as well as solids. This is the means employed to fix or preserve them. Liquids, gases, vapours, as well as many solid bodies reduced to powder, possess the property of acting on the organs of smell.

Apparatus for smelling.—The olfactory apparatus ought to be represented as a sort of sieve, placed in the passage of the air, as it is introduced into the chest,

and intended to stop every foreign body that may be mixed with the air, particularly the odours.

This apparatus is extremely simple; it differs essentially from that of the sight and the hearing; since it tially from that of the sight and the hearing; since it presents no part anterior to the nerve, destined for the physical modification of the external impulse, the nerve is to a certain degree exposed. The apparatus is composed of the pituitary membrane, which covers the nasal cavities, of the membrane which covers the sinuses, and of the olfactory nerve.

The pituitary membrane the whole extent of the postrils increases the thickness of the sneary bones.

the nostrils, increases the thickness of the spongy bones very much, is continued beyond their edges and their extremities, so that the air cannot traverse the nostrils but in a long narrow direction. This membrane is thick, and adheres strongly to the bones and cartilages that it covers. Its surface presents an infinity of small projections, which have been considered by some as

projections, which have been considered by some as nervous papilla, by others as mucous follicles, but which, according to all appearance, are vascular.

These small projections give to the membrane an appearance of velvet. The pituitary is agreeable and soft to the touch, and it receives a great number of vessels and nerves. The passages through which the air proceeds to arrive at the fauces deserve attention.

These are three in number. They are distinguished in anatomy by the names of inferior, middle, and superior meatus. The inferior is the broadest and the longest, the least oblique and least crooked; the middle one is the narrowest, almost as long, but of greater extent from top to bottom. The superior is much shorter, more oblique, and narrower. It is necessary to add to these the interval, which is very narrow, and which separates the partition of the external side of the nostrils in its whole extent. These canals are so narrow, that the least swelling of the pituitary renders the passage of the air in the nostrils difficult, and sometimes impossible.

sage of the air in the nostris difficult, and sometimes impossible.

The two superior meatus communicate with certain cavities, of dimensions more or less considerable, which are hollowed out of the bones of the head, and are called sinuses. These sinuses are the mazillary, the palatine, the sphenoidal, the frontal; and those which are hollowed out of the ethmoid bone, better known by the name of ethmoidal cells.

The sinuses communicate only with the two superiors.

The sinuses communicate only with the two supe-

rior meatus.

The frontal, the maxillary sinus, the anterior cells of the ethmoid bone, open into the middle meatus; the of the ethmoid bone, open into the middle meatus; the sphenoidal, the palatine sinus, the posterior cells of the ethmoid, open into the superior meatus. The sinuses are covered by other soft membranes, very little adherent to the sides, and which appear to be of the mucous kind. It secretes more or less abundantly a matter called nasal mucus, which is continually spread over the pituitary, and seems very useful in smelling. A more considerable extent of the sinus appears to coincide with a greater perfection of the smell. This is at least one of the most positive results of comparative physiology.

The olfactory nerve springs, by three distinct roots, from the posterior, inferior, and internal parts of the anterior lobe of the brain. Prismatic at first, it proceeds towards the perforated plate of the ethmoid bone. It swells all at once, and then divides itself into a great number of small threads, which spread them-

SMI SME

It is important to remark, that the filaments of the ol-factory nerves have never been traced upon the infe-rior spongy bones, upon the internal surface of the middle measure, nor in any of the sinuses. The pituitary membrane receives not only the nerves of the first pair, but also a great number of threads, which spring from the internal aspect of the spheno-palatine gan-glion. These threads are distributed in the meatus, and in the inferior part of the membrane. It covers also, for a considerable length, the ethmoidal thread of the nasal nerve, and receives from it a considerable number of filaments. The membrane which covers the sinus receives also a number of nervous ramifi-

The nasal fossa communicate outwardly by means of the nostrils, the form and size of which are very variable. The nostrils are covered with hair on the inside, and are capable of being increased in size by muscular action. The nasal fossæ open into the pha-

rynx by the posterior nostrils.

Mechanism of Smelling.—Smell is exerted essentially at the moment when the air traverses the nasal fossæ in proceeding towards the lungs. We very rarely perceive any odour when the air proceeds from the lungs; it happens sometimes, however, particularly in

organic diseases of the lungs.

The mechanism of smell is extremely simple. It is only necessary that the odoriferous particles should be stopped upon the pituitary membrane, particularly in the places where it receives the threads of the olfac-

tory nerves.

As it is exactly in the superior part of the nasal fossæ, where the extremes are so narrow, that they are covered with mucus, it is also natural that the parti-

cles should stop there.

We may conceive the utility of mucus. Its physical properties are such that it appears to have a much greater affinity with the odoriferous particles than with air; it is also extremely important to the olfactory sense, that the nasal mucus should always preserve the same physical properties. Whenever they are changed, as it is observed in different degrees of coryza, the smell is either not exerted at all, or in a very imperfect

After what has been said of the distribution of the olfactory nerves, it is evident that the odours that reach the upper part of the nasal cavities will be perceived with greater facility and acuteness: for this reason, when we wish to feel more acutely, and with greater exactness, the odour of any body, we modify the air in such a manner that it may be directed towards this point. For the same reason, those who take spuff on point. For the same reason, those who take snuff endeavour also to make it reach the upper part of the nasal fosse. The internal face of the ossa spongiosa appears well disposed to stop the odours at the instant the air passes. And, as there is an extreme sensibility in this point, we are inclined to believe that here the smell is exerted, though the filaments of the first pair

have not been traced so far.

Physiologists have not yet determined the use of the external nose in smelling; it appears intended to direct the air charged with odours towards the superior part

of the nasal cavities.

Those persons who have their noses deformed, par-ticularly if broken; those who have small nostrils, di-rected forward, have in general almost no smell. The loss of the nose, either by sickness or accident, causes almost entirely the loss of smell. Such people recover the benefit of this sense by the use of an artificial

The only use of the sinuses which is generally admitted, is that of furnishing the greater part of the nasal mucus. The other uses which are attributed to them are, to serve as a depot to the air charged with odoriferous particles, to augment the extent of the surface which is sensible to odours, and to receive a portion of the air that we inspire for the purpose of putting the power of smell in action, &c. These are far from

Vapours and gases appear to act in the same manner upon the pituitary membrane as odours. The mechanism of it ought, however, to be a little different. Bodies reduced to a coarse powder have a very strong action on this membrane; even their first contact is painful; but habit changes the pain into pleasure, as is most ample experience, and whoever shall be so un

selves upon the pituitary membrane, principally on the superior part of it.

seen in the case of taking snuff. In medicine, this propurpose of exciting a sharp instantaneous pain.

In the history of smell, the use of those hairs with

which the nostrils and the nasal fossæ are provided, must not be forgotten. Perhaps they are intended to prevent the entrance of foreign bodies along with the air into the nasal fossæ. In this case, they would bear a strong analogy to the eyelashes, and the hairs with

which the ear is provided.

It is generally agreed that the olfactory nerve is especially employed in transmitting to the brain the impressions produced by odoriferous bodies; but there is nothing to prove that the other nerves, which are placed upon the pituitary, as well as those near it, may not concur in the same function."—Magendie's Phy-

siology.

SMELT. See Salmo eperlanus.
SMI'LAX. (From σμιλενω, to cut: so called from the roughness of its leaves and stalk.) The name of a genus of plants in the Linnæan system. Class, Diæcia;

Order, Octandria. Rough bind-weed.

SMILAX CHINA. The systematic name of the China root tree. China; China orientalis; Sankira; Guaquara; Smilax aspera Chinensis. China root. It was formerly in esteem, as sarsaparilla now is, in the cure

of the venereal disease, and cutaneous disorders.

Smilax, Chinese. See Smilax china.

Smilax sarsaparilla. The systematic name of the plant which affords the sarsaparilla. Sarsaparilla; Smilax aspera Peruviana; Sarsa; Carivillandi; Iva pecanga; Macapatli; Zarza; Zarzaparilla; Salsa-parilla; Zarcaparilla. The root of this plant, Smilax -caule aculeato angulato, foliis inermibus ovatis re-tuso mucronatis trinerviis, of Linnaus, has a farinaceous, somewhat bitter taste, and no smell. About two centuries ago it was introduced into Spain, as an undoubted specific in syphilitic disorders; but owing to difference of climate, or other causes, it has not answered the character which it had acquired in the Spanish West Indies. It is now considered as capable of improving the general habit of body, after it has been

reduced by the continued use of mercury.

To refute the opinion that sarsaparilla possesses antisyphilitic virtues, Mr. Pearson, of the Lock Hospital, divides the subject into two distinct questions. 1. Is urvides the subject into two distinct questions. 1. Is the sarsaparilla root, when given alone, to be safely relied on in the treatment of lues venerea? The late Mr. Bloomfield, his predecessor, and during some years his colleague at the Lock Hospital, has given a very decided answer to this question: "I solemnly declare," says he, "I never saw a single instance in my life where it cured that disorder without the assistance of mercury, either at the same time with it or miner. mercury, either at the same time with it, or when it had been previously taken before the decoction was directed." Pearson's experience, during many years, co-incides entirely with the observations of Bloomfield. He has employed the sarsaparilla, in powder and in decoctions, in an almost infinite variety of cases, and feels himself fully authorized to assert, that this plant has not the power of curing any one form of the lues venerea. The sarsaparilla, indeed, like the guaiacum, is capable of alleviating symptoms derived from the venereal virus; and it sometimes manifests the power of suspending, for a time, the destructive ravages of that contagion; but where the poison has not been pre-viously subdued by mercury, the symptoms will quick-ly return; and, in addition to them, we often see the most indubitable proofs that the disease is making an actual progress, during the regular administration of

the vegetable remedy.

2. When the sarsaparilla root is given in conjunction with mercury, does it render the mercurial course more certain and efficacious? In replying to this query, it is necessary to observe that the phrase, "to increase the efficacy of mercury," may imply, that a smaller quantity of this mineral antidote will confer security on an infected person, when sarsaparilla is added to it; or it may mean, that mercury would be sometimes unequal to the cure, without the aid of sarsaparilla. If a equal to the cure, without the and of sarsaparina. If a decoction of this root did indeed possess so admirable a quality, that the quantity of mercury, necessary to effect a cure, might be safely reduced, whenever it was given during a mercurial course, it would form a most valuable addition to our Materia Medica. This opi-

disappointed.

If the sarsaparilla root be a genuine antidote against the syphilitic virus, it ought to cure the disease administered alone; but, if no direct proof can be adduced of its being equal to this, any arguments founded on histories where mercury has been previously given, or where both the medicines were administered at the

or where both the medicines were administered at the same time, must be ambiguous and undecisive. It appears probable, that Sir William Fordyce, and some other persons, entertained a notion, that there were certain venereal symptoms which commonly resisted the potency of mercury, and that the sarsapa-rilla was an appropriate remedy in these cases. This opinion, it is presumed, is not correct, for it militates against all Mr. P. has ever observed of the progress and treatment of lues venerea. Indeed, those patients who have lately used a full course of mercury, often complain of nocturnal pains in their limbs; they are sometimes afflicted with painful enlargements of the elbow and knee-joints; or they have membranous nodes, cutaneous exulcerations, and certain other symptoms, resembling those which are the offspring of the venereal virus.

It may and does often happen, that appearances like these are mistaken for a true venereal affection, and, in consequence of this error, mercury is administered, which never fails to exasperate the disease. Now, if a strong decoction of sarsaparilla root be given to per-sons under these circumstances, it will seldom fail of producing the most beneficial effects; hence it has been contended, that symptoms derived from the contagion of lucs venerea, which could not be cured by mercury, of lues venerea, which could not be cured by mercury, have finally yielded to this vegetable remedy. It must be acknowledged, that representations of this kind have a specious and imposing air; nevertheless, Mr. Pearson endeavours to prove, that they are neither exact nor conclusive. If any of the above-named symptoms should appear near the conclusion of a course of mercury, when that medicine was operating power-fully on the whole system, it would be a strange and inexplicable thing if they could possibly be derived im-mediately from the uncontrolled agency of the venereal virus.

This would imply something like a palpable contra-diction that the antidote should be operating with sufficient efficacy to cure the venereal symptoms, for which it was directed, while, at the same time the venereal virus was proceeding to contaminate new parts, and to

One source, and a very common one, to which some of the mistakes committed upon this subject may be traced, is a persuasion that every morbid alteration which arises in an infected person is actually tainted with the venereal virus, and ought to be ascribed to it as its true cause.

Every experienced surgeon must, however, be aware, that very little of truth and reality exists in a representation of this kind. The contagious matter, and the mineral specific may jointly produce, in certain habits of body, a new series of symptoms, which, strictly speaking, are not venereal, which cannot be cured by mercury, and which are sometimes more to be dreaded than the simple and natural effects of the venereal virus.

Some of the most formidable of these appearances may be sometimes removed by sarsaparilla, the venereal virus still remaining in the system; and, when the force of that poison has been completely subdued by mercury, the same vegetable is also capable of freeing the patient from what may be called the sequelæ of a mercurial course.

The root of the sarsaparilla is sometimes employed in rheumatic affections, scrofula, and cutaneous com-plaints, where an acrimony of the fluids prevails.

["SMITH, ELHIUH, M. D. Dr. Smith was one of the first projectors of the New-York Medical Reposi-tory, uniting with Drs. Mitchill and Miller in establishing one of the first Medical and Scientific Journals in this country. He, however, survived but a short time after its commencing, having died of the Yellow-Fever in New-York, in 1798. Dr. E. H. Smith was born in Litchfield, in Connecticut, in 1771, and died in the 27th year of his age.

"In announcing the death of Dr. Smith, the surviving editors of the Medical Repository thus speak:

As a Physician his loss is irreparable. He had explored

wary as to act upon such a presumption, will be sure to at his early age an extent of Medical learning, for which find his own and his patient's expectations egregiously the longest lives are seldom found sufficient. The the longest lives are seldom found sufficient. The love of science, and the impulse of philanthropy, directed his whole professional career, and left little room for the calculations of emolument. He had formed vast designs of medical improvement, which embraced the whole family of mankind; was animated by the soul of benevolence, and aspired after every object of a liberal and a dignified ambition. He was ripe for the highest honours of his profession; his merits were every day becoming more conspicuous, and nothing but his premature fate deprived him of that extraordinary de-

premature fate deprived film of that extraordinary degree of public confidence which awaited a longer continuance of his life."—N. Y. Med. Repos. A.]

SMY'RNION HORTENSE. See Imperatoria ostruthium.

SMY'RNIUM. (So called from σμυρνα, myrrh, the smell of the seed resembling that of myrrh very much.) The name of a genus of plants. Class, Pentandria; Order, Digynia.

SMYRNIUM OLUSATRUM. The systematic name of the plant called Alexanders. Hipposclinum; Smyr-nium; Macerona; Macedonisium; Herba alexan-drina; Grielum; Agrioselinum. Common Alexan-ders. This plant was formerly cultivated in our gardens, for culinary use, but is now superseded by scelery.
The seeds are bitter and aromatic, and the roots are more powerfully bitter. They stand recommended as resolvents, diuretics, and emmenagogues, though seldom

used in medical prescriptions. SMYRNIUM ROTUNDIFOLIUM. The blanched leaves of this species are said to be more agreeable than those of the olusatrum.

See Alor.

SO'DA. (An Arabian word.) universally given by chemists and physicians to the mineral alkali.

It is obtained from several sources, but principally from plants growing on the sea coast. It occurs in the mineral kingdom, united with sulphuric, muriatic, and boracic acids; it is also found in large quantities in Egypt, combined with carbonic acid. It appears to be deposited in large impure masses, under the surface of deposited in large impure masses, under the surface of the earth, in various countries, from which it is extracted by running waters. Thus it is found, after the spontaneous evaporation of the water, mixed with sand in the bottom of lakes in Hungary; in the neighbourhood of Bilin in Bohemia; and in Switzerland. It occurs also in China, and near Tripoli; in Syria, Egypt, Persia, and India. It frequently oozes out of walls and crystallizes on their surface. Like potassa, it is procured by lixiviation from the ashes of burnt plants, but only from those which grow upon the sea-shores. The only from those which grow upon the sea-shores. The variety of plants employed for this purpose is very considerable. In Spain, soda is procured from different species of the Salsola and Salicornia, and the Batis maritima. The Zostera maritima is burnt in some places on the borders of the Baltic. In this country

carbonate of soda.

"To procure pure soda, we must boil a solution of the pure carbonate with half its weight of quicklime, and after subsidence decant the clear ley, and evapo-rate in a clean iron or silver vessel, till the liquid flows quietly like oil. It must then be poured out on a po-lished iron plate. It concretes into a hard white cake, which is to be immediately broken in pieces, and put up, while still hot, in a phial, which must be well corked. If the carbonate of soda be somewhat impure, then, after the action of lime, and subsequent concentration of the ley, alkohol must be digested on it, which will dissolve only the caustic pure soda, and leave the heterogeneous salts. By distilling of the alkohol in a silver alembic, the alkali may then be obtained pure.

This white solid substance is, however, not absolute soda, but a hydrate, consisting of about 100 soda + 28 water; or of nearly 77 + 23, in 100. If a piece of this soda be exposed to the air, it softens and becomes pasty; but it never deliquesces into an oily looking liquid, as potassa does. The soda in fact soon becomes drier, because by absorption of carbonic acid from the air it passes into an efflorescent carbonate. Soda the air it passes into an efflorescent carbonate. Soda is distinguishable from potassa by sulphuric acid, which forms a very soluble salt with the former, and a sparingly soluble one with the latter; by muriate of

platina and tartaric acid, which occasions precipitates with potassa salts, but not with those of soda.

The basis of soda is a peculiar metal, called sodium, discovered by Sir H. Davy in 1807, a few days after he discovered potassium. It may be procured in exactly the same manner as potassium, by electrical or chemical decomposition of the pure hydrate. A rather higher degree of heat, and greater voltaic power, are required to decompose soda than potassa. Sodium resembles potassium in many of its characters. It is as white as silver, possesses great lustre, and is a good conductor of electricity. It enters into fusion at about 280° Fahr., and rises in vapour at a strong red heat. Its sp. gr. is, according to Gay Lussac and Thenard, 0.972, at the temperature of 59° Fahr. In the cold, it exercises scarcely any action on dry air, or oxygen. But when heated strongly in oxygen or chlorine, it burns with great brilliancy. When thrown upon water, it effervesces violently, but does not inflame, swims on the surface, gradually diminishes with great agitation, and renders the water a solution of soda. It acts upon most substances in a manner similar to potassium, but with less energy. It tarnishes in the air, but more slowly; and, like potassium, it is best preserved under

Sodium forms two distinct combinations with oxygen; one is pure soda, whose hydrate is above described; the other is the orange oxide of sodium, ob-served, like the preceding oxide, first by Sir H. Davy in 1807, but of which the true nature was pointed out, in 1810, by Gay Lussac and Thenard.

Pure soda may be formed by burning sodium in a quantity of air, containing no more oxygen than is sufficient for its conversion into this alkali; i. e. the metal must be in excess: a strong degree of heat must

be employed.

Pure soda is of a gray colour, it is a non-conductor of electricity, of a vitreous fracture, and requires a strong red heat for its fusion. When a little water is added to it, there is a violent action between the two bodies; the soda becomes white, crystalline in its appearance, and much more fusible and volatile. It is then the substance commonly called pure or caustic soda; but properly styled the hydrate.

The other oxide or peroxide of sodium may be formed by burning sodium in oxygen, in excess. It is of a deep orange colour, very fusible, and a non-conductor of electricity. When acted on by water, it gives off oxygen, and the water becomes a solution of soda. It deflagrates when strongly heated with combustible

The proportions of oxygen in soda, and in the orange peroxide of sodium, are easily learned by the action of sodium on water and on oxygen. If a given weight of

we burn the various species of fuci; and in France they burn the Chenopodium maritimum. See Soda impura.

The alkali thus procured is more or less pure, according to the nature of the particular plant from which it is obtained. The greatest part, however, is a subcarbonate of soda. oxygen in great excess, from the quantity of oxygen ab sorbed the composition of the peroxide may be learned. From Sir H. Davy's experiments, compared with those of Gay Lussac and Thenard, it appears that the prime equivalent of sodium is 3.0, and that of dry soda, or protoxide of sodium, 4.0; while the orange oxide or deutoxide is 5.0. The numbers given by Thenard are, for the first, 100 metal + 33.995 oxygen; and for the second, 100 metal + 67.990 oxygen.

Another oxide is described containing less oxygen than soda; it is therefore a sub-oxide. When sodium

is kept for some time in a small quantity of moist air, or when sodium in excess is heated with hydrate of soda, a dark grayish substance is formed, more inflammable than sodium, and which affords hydrogen by its

action upon water

Only one combination of sodium and chlorine is known. This is the important substance, common salt. It may be formed directly by combustion, or by decomposing any compound of chlorine by sodium. Sodium has a much stronger attraction for chlorine than for oxygen: and soda, or its hydrate, is decomposed by chlorine, oxygen being expelled from the first, and oxygen and water from the second.

Potassium has a stronger attraction for chlorine than sodium has; and one mode of procuring sodium easily, is by heating together to redness common salt and po-tassium. The chloride of sodium, improperly called the muriate, consists of 4.5 chlorine + 3.0 sodium. There is no known action between sodium and hydro-

gen or azote.

Sodium combines readily with sulphur and with Sodium combines readily with sulphur and with phosphorus, presenting similar phenomena to those presented by potassium. The sulphurets and phosphurets of sodium agree in their general properties with those of potassium, except that they are rather less inflammable. They form, by burning, acidulous compounds of sulphuric and phosphoric acid and soda. Potassium and sodium combine with great facility, and form peculiar compounds, which differ in their properties, according to the proportions of the constituents. By a small quantity of sodium, potassium is rendered fluid at common temperatures, and its sport

rendered fluid at common temperatures, and its sp. gr. is considerably diminished. Eight parts of potassium, and one of sodium, form a compound that swims in naphtha, and that is fluid at the common temperature of the air. Three parts of sodium, and one of potassium, make a compound fluid at common temperatures. A little potassium destroys the ductility of so-dium, and renders it very brittle and soft. Since the prime of potassium is to that of sodium as 5 to 3, it will require the former quantity of potassium to eliminate the latter quantity of sodium from the chloride. The attractions of potassium, for all substances that have been examined, are stronger than those of so-

Soda is the basis of common salt, of plate and crown-glass, and of all hard soaps.

The compounds of soda used in medicine are the

following:

6. Sodæ murias. 1. Sodæ acetas. 2. -- boras. - phosphas 3. - carbonas. sulphas. 4. — subcarbonas. 9. — - tartras. ---ex- 10. Soda tartarizata. siccata. 11. Sapo durus.

Soda Acktata. A neutral salt formed of a combination of acetic acid with the mineral alkali. Its virtues are similar to those of the acetate of potassa.

Soda Boraxata. See Borax.
Soda, carbonate of. See Sodæ carbonas.
Soda Hispanica. See Soda impura.
Soda Hispanica Furificata. See Sodæ subcar-

Soda impura. Impure soda. Soda; Barilla; Ba-riglia; Barillor; Anatron; Natron; Anaton; Ni-trum antiquorum; Aphronitrum; Baurach; Sal alkalinus fixus fossilus; Carbonas sodæ impurus; Sub-carbonas sodæ impura. Soda. Barilla is the term given, in commerce, to the impure mineral alkali, or imperfect carbonate of soda, imported from Spain and

the Levant. It is made by burning to ashes different plants that grow on the sea-shore, chiefly of the genus black. The soda which is mixed with small stones, Salsola. Many have referred it to the Salsola kali, of Linnæus; but various other plants, on being burned, are found to afford this alkali, and some in a greater

proportion than this: these are,

The Salsola sativa, of Linnxus. Salsola sonda, of Lotling. Kali hispanicum supinum annuum sedi-foliis brevibus. Kali d'alicante. This grows abun-dantly on that part of the Spanish coast which is washed by the Mediterranean sea. This plant is de-servedly first enumerated by Professor Murray, as it supplies all the best soda consumed in Europe, by us is called Spanish or Alicant soda, and by the Spanish merchants Barilla de Alicante.

 Salsola soda, of Linnzus. Kali majus cochleato semine; Le Salicor. This species, which grows on the French Mediterranean coast, is much used in Languedoc for the preparation of this salt, which is usually

exported to Sicily and Italy.

3. Salsola tragus, of Linnæus, affords an ordinary kind of soda, with which the French frequently mix that made in Lauguedoc. This adulteration is also practised by the Sicilians, who distinguish the plant by the term salvaggia.

4. Salicornia herbacea, of Linnæus, is common in salt marshes, and on the sea-shore all over Europe. Linnæus prefers the soda obtained from this plant to that of all the others; but though the quantity of all the others. kali which it yields is very considerable, it is mixed

with much common salt.

5. Salicornia arabica, of Linnæus, and also the Mesembryanthemum nodiflorum, and Plantago squarrosa. All these, according to Alpinus, afford this alkali. has also been procured from several of the fuci, esp cially F. vesicolosus, and distinguished here by the name kelp. Various other marine plants might also be noticed as yielding an impure soda by combustion; but the principal are confined to the genus salsola, and that of salicornia. The salsola kali, on the authority of Rawolf, is the species from which the salt is usually obtained in eastern countries; which is brought to us in hard porous masses, of a speckled brown colour. Kelp, a still more impure alkali, made in this country by burning various sea-weeds, is sometimes called British The marine plants, collected for the purpose of procuring barilla in this country, are the Salsola kali, Salicornia europa, Zostera maritima, Triglochen ma-ritimum, Chenopodium maritimum, Atriplez portula-coides et littoralis, Plantago maritima, Tamariz gal-lica, Eryngium maritimum, Sedum telephium, Dipsacus fullonum, &c. &c.

It is to be regretted, that the different kinds of soda which are brought to European markets have not been sufficiently analyzed to enable us to ascertain with tolerable certainty the respective value of each; and, in deed, while the practice of adulterating this salt continues, any attempts of this kind are likely to prove fruitless. The best information on this subject is to be had from Jessica, Mascorelle, Cadet, Bolate, and Sestini. In those places where the preparation of soda forms a considerable branch of commerce, as on the coast of the Mediterranean, seeds of the salsola are regularly sown in a proper situation near the sea, which usually shoot above ground in the course of a fortnight. About the time the seeds become ripe, the plants are pulled up by the roots, and exposed in a suitable place to dry, where their seeds are collected; this being done, the plants are tied up in bundles, and burned in an oven constructed for the purpose, where the ashes are then, while hot, continually stirred with long poles. The saline matter, on becoming cold, forms a hard solid mass, which is broken in pieces of a convenient

size for exportation.

According to chemical analysis, the impure sodas of commerce generally contain a portion of vegetable alkali, and neutral salts, as muriate of soda and sulphate of potassa, and not unfrequently some portion of iron is contained in the mass; they are, therefore, to be considered as more or less a compound, and their goodness to be estimated accordingly. The Spanish soda, of the best sort, is in dark-coloured masses, of a bluish tinge, very ponderous, sonorous, dry to the touch, and externally abounding with small cavities, without any offensive smell, and very salt to the taste; if long ex-posed to the air, it undergoes a degree of spontaneous calcination. The best French soda is also dry, sonoblack. The soda which is mixed with small stones, which gives out a fætid smell on solution, and is white, soft, and deliquescent, is of the worst kind. Soda muriata. See Soda murias.

Soda MURIATICA. See Soda murias.

Soda Muriatica. See Sous marias. Soda Phosphorata. Phosphorated sods. Alkali Soda Phosphorata. Of Bergman. This preparaminerale phosphoratum, of Bergman. tion is a compound of phosphoric acid and soda. cathartic in the dose of half an ounce to an ounce; dissolved in gruel it is not unpleasant, and it is said to be useful in scrofula, bronchocele, rachitis, and gout, in small doses.

Soda, subcarbonate of. See Sodæ subcarbonas. Soda, subcarbonate of, dried. See Sodæ subcarbonas exsiccata.

Soda, sulphate of. See Sodæ sulphas.

Soda tartarizata. Tartarized soda, formerly known by the names of sal rupellensis, sal polychrestum Seignetti, and lately by that of natron tartarizatum. Take of subcarbonate of soda twenty ounces; supertartrate of potassa, powdered, two pounds; ing water ten pints. Dissolve the subcarbonate of soda in the water, and add gradually the supertartrate of potassa; filter the solution through paper, and evaporate it until a pellicle forms upon the surface; then set it by that crystals may form. Having poured away the water, dry these crystals upon bibulous paper. This salt consists of tartaric acid, soda, and potassa, the soda only combining with the superabundant acid of the super salt; it is therefore a triple salt, and it has been judged by the London College more convenient to express this difference by the adjective tartarizata, than to introduce the three words necessary to its descrip-tion. It possesses mildly cathartic, diuretic, and deob struent virtues, and is administered in doses from one drachm to an ounce, as a cathartic, and in the dose of twenty to thirty grains in abdominal physconia, and torpidity of the kidneys.

Soda tartarized. See Soda tartarizata. Sodæ boras. See Boraz.

Sobe carbonas. Carbonate of soda. Take of subcarbonate of soda, a pound; subcarbonate of ammonia, three ounces; distilled water, a pint. Having previously dissolved the soda in water, add the ammonia, then by means of a sand bath apply a heat of 180° for three hours, or until the ammonia be driven off. Lastly, set the solution by to crystallize. The remaining solution may be evaporated and set by in the same manner, that crystals may again form. This salt, which is called also agrated soda, and natron, bears to the subcarbonate of soda the same relation that the carbonate of potassa does to its subcarbonate. It is prepared in the same way, possesses the same compara-tive advantages, and contains, in like manner, double the quantity of carbonic acid.

Sod & MURIAS. Muriate of soda. Alkali minerals

salinum; Sal communis; Sal culinaris; Sal fontium; Sal gemmæ; Sal marinus; Natron muriatum; Soda muriata. Common culinary salt. This salt is more abundant in nature than any other. It is found in proabundant in nature than any other. It is found in pro-digious masses in the internal part of the earth, in Calabria, in Hungary, in Muscovy, and more especially Weilicska, in Poland, near Mount Capax, where the mines are very large, and afford immense quantities of salt. It is also obtained by several artificial means from sea-water. It possesses antiseptic, diuretic, and resolvent qualities, and is frequently employed in form of clyster, fomentation, lotion, pediluvium, and bath, in obstipation, against worms, gangrene, scrofulous tumours, herpetic eruptions, arthritis, &c.

Sod & Subboras. See Borax.

SODÆ SUBCARBONAS. Subcarbonate of soda, for-Sobe subcarbonas. Subcarbonate of soda, formerly called natron praparatum and sal sodæ. Take of impure soda, powdered, a pound; boiling distilled water, half a gallon. Boil the soda in the water for half an hour, and strain the solution; let the solution evaporate to two pints, and be set by, that crystals may form. Throw away the remaining solution. The pure crystals, thus formed of Alicant barilla, are colourless, transparent, lamellated, of a rhomboidal figure; and one hundred parts are found to contain twenty of alkali, sixteen of aerial acid, and sixty-four of water; but upon keeping the crystals for a length of time, if the air be not excluded, the water evaporates, and they assume the form of a white powder. According to Islin, one ounce of water, at the tempe-

antacid; and joined with bark and aromatics, it is highly praised by some in the cure of scrofula. It is likewise a powerful solvent of mucus, a deobstruent and diuretic; and has been thought an antidote against oxide of arsenic and corrosive sublimate. The other diseases in which it is administered are those arising from an abundance of mucus in the primæ viæ; calculous complaints, gout, some affections of the skin, rickets, tinea capitis, crusta lactea, and worms. Externally it is recommended by some in the form of lotion, to be applied to scrofulous ulcers.

SODÆ SUBCARBONAS EXSICCATA. Dried subcarbonate of soda. Take of subcarbonate of soda, a pound. Apply a boiling heat to the soda in a clean iron vessel, until it becomes perfectly dry, and constantly stir it with an iron rod. Lastly, reduce it into powder. Its virtues are similar to those of the subcarbonate.

SODE SULPHAS. Sulphate of soda, commonly known by the name of natron vitriolatum, and formerly sal catharticus glauberi. Take of the salt which remains after the distillation of muriatic acid, two pounds. Boiling water, two pints and a half. Dissolve the salt in the water, then add gradually as much subcarbonate of soda as may be required to saturate the acid; boil the solution away until a pellicle forms upon the surface, and, after having strained it, set it by, that crystals may form. Having poured away the water, dry these crystals upon bibulous paper. It possesses cathar-tic and diuretic qualities, and is in high esteem as a mild cathartic. It is found in the mineral kingdom formed by nature, but that which is used medicinally is prepared by art. The dose is from one drachm to one ounce.

SODALITE. A green-coloured mineral discovered in a bed of mica slate in West Greenland.

SODIUM. See Soda.

SOL. The sun. Gold was so called by the older

SOLA'MEN. (From solor, to comfort.) Anise-seed is named solamen intestinorum, from the comfort it affords in disorders of the intestines.

SOLANO IDES. (From solanum, night-shade, and

atos, likeness.) Bastard night-shade.
SOLA'NUM. (From solor, to comfort, because it gives ease by its stupifying qualities.) 1. The name of a genus of plants in the Linnæan system. Class,

Pentandria: Order, Monogynia.

2. The pharmacopeial name of the solanum nigrum.
Solanum pulcamara. The systematic name of the bitter-sweet. Dulcamara; Solanum scandens; Glycypicros, sive amaradulcis; Solanum lignosum. Στρυχνος of Theophrastus. Woody night-shade. Solanum—caule inermi frutescente flexuosa; folius superiorische des superiorische state of Linguist. rioribus hastatis; racemis cymosis, of Linnæus. The roots and stalks of this night-shade, upon being chewed, first cause a sensation of bitterness, which is soon fol-lowed by a considerable degree of sweetness; and hence the plant obtained the name of bitter-sweet. The berries have not yet been applied to medical use; they seem to act powerfully upon the prime viæ, exciting violent vomiting and purging. Thirty of them were given to a dog, which soon became mad, and died in the space of three hours; and, upon opening his sto-mach, the berries were discovered to have undergone no change by the powers of digestion; there can, there-fore, be little doubt of the deleterious effects of these berries; and, as they are very common in the hedges, and may be easily mistaken, by children, for red currants, which they somewhat resemble, this circumstance is the more worthy of notice. The stipites, or younger branches, are directed for use in the Pharm., and they may be employed either fresh or dried, making a proportionate allowance in the dose of the latter for some diminution of its powers by drying. In autumn, when the leaves are fallen, the sensible qualities of the plant are said to be the strongest; and, on this account, it should be gathered in autumn rather than spring. Dulcamara does not manifest those strong narcotic qualities which are common to many of the night-shades; it is, however, very generally admitted to be a medicine of considerable efficacy. Murray says it promotes all the secretions; Haller observes, that it partakes of the milder powers of the night shade joined to a resolvent | membranes, muscles, nerves, and vessels.

rature 62° of Fahr. dissolves five drachms and fifteen grains of the crystals. This salt consists of soda imperfectly saturated with carbonic acid, and is therefore called soda subcarbonas. It is given in doses of from ten grains to half a drachm as an attenuant and saponaceous quality; and the opinion of Bergus seems to coincide with that of Murray:—"Virtus: pellens urinam, sudorum, menses, lochia, sputa; mundificans." The diseases in which we find it recommended by different authors, are extremely various; but Bergus and iniped with hark and are consistent of the consists of soda imperfectly saturated with that of Murray:—"Virtus: pellens urinam, sudorum, menses, lochia, sputa; mundificans." The diseases in which we find it recommended by different authors, are extremely various; but Bergus gius confines its use to rheumatisms, retentio mensium, et lochiorum. Dulcamara appears, also, by the experiments of Razoux and others, to have been used with advantage in some obstinate cutaneous affections. Dr. Cullen says, "We have employed only the stipites, or slender twigs of this shrub; but, as we have collected them, they come out very unequal, some parcels of them being very mild and inert, and others of them considerably acrid. In the latter state, we have employed a decoction of them in the cure of rheumatism, sometimes with advantage, but at other times without any effect. Though the dulcamara is here inserted in the catalogue of diuretics, it has never appeared to us as powerful in this way; for, in all the trials made here, it has hardly ever been observed to be in any measure diuretic." This plant is generally given in decoction, or infusion, and, to prevent its exciting nausea, it is ordered to be diluted with milk, and to begin with small doses, as large doses have been found to produce very dangerous symptoms. Razoux directs the following: B. Stipitum dulcam. rec. drac. ss in aque font unc. 16 coquater ad unc. 8. This was taken in the dose of three or four drachms, diluted with an equal quantity of milk, every four hours. Linnaus directs two drachms, or half an ounce of the dried stipites, to be injused half an hour in boiling water, and then to be boiled ten minutes; and of this decoction he gives two teacups full morning and evening. For the formula of a decoction of this plant, according to the London Pharm. See Decoctum dulcamara.

SOLANUM FORTIDUM. The thorn-apple plant. See Datura stramonium.

SOLANUM LETHALE. See Atropa belladonna.

SOLANUM LIGHOSUM. See Solanum dulcamara.
SOLANUM LYCOPERSICUM. The love-apple plant.
The fruit of this, called Tomata and love-apple, is so much esteemed by the Portuguese and the Spaniards, that it is an ingredient in almost all their soups and sauces, and is by them considered as cooling and nu-

Solanum melongena. The systematic name of the mad-apple plant. Its oblong egg-shaped fruit is often boiled in their native places, in soups and sauces, the same as the love-apple; is accounted very nutritive, and is much sought after by the votaries of Venus.

SOLANUM NIGRUM. The systematic name of the garden night-shade, which is highly deleterious.

SOLANUM SANCTUM. The systematic name of the Palestine night-shade. The fruit of which is globular,

and in Egypt much eaton by the inhabitants.

Solanum Tuberosum. Batatas; Solanum escu-lentum; Kippa; Kelengu; Popas Americanus; Pappus Americanus; Convolvulus Indicus. The potato plant, a native of Peru, first brought into Europe by Sir Francis Drake, 1486, and planted in London. See

SOLANUM VESICARIUM. The winter-cherry plant is so called by Caspar Bauhin. See Physalis alkekengi.
SOLDANELLA. (A solidando; from its uses in healing fresh wounds.) The sea convolvulus. See Convolvulus soldanella.

SO'LEN. Σωλην. A tube or channel. A cradle

for a broken limb.

SOLENA'RIUM. (Diminutive of σωλην, a tube.) A catheter. SO'LEUS.

(From solea, a sole: from its shape being like the sole-fish.) See Gastrocnemius internus. SOLIDA'GO. (From solido, to make firm: so called from its uses in consolidating wounds.) The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia superflua. The herb

Solidago virgaurea. The systematic name of the golden rod. Virga aurea; Herba dorea; Conyza coma aurea; Symphytum; Petræum; Elichrysum; Conso-lida saracenica and aurea. Golden rod. The leaves and flowers of this plant are recommended as aperients and corroborants in urinary obstructions, ulcerations of the kidneys and bladder, and it is said by some to be particularly useful in stopping internal hæmorrhages.

In anatomy, are the bones, ligaments; SOLIDS.

SOLITARIUS. Solitary. Applied to worms in the body, and to leaves, stems, footstalk, &c. when either

single on a plant, or only one in the same place.
SO'LIUM. (From solus, alone: so called because it

infests the body singly.) The tape-worm. See Tænia.

Solomon's seal. See Convallaria polygonatum.

SOLSE'QUIUM. (From sol, the sun, and sequor, to follow: so called because it turns its flowers toward the sun.) Marigold or turnsole. See Heliotropium.

SOLVENT. See Menstruum.

SOLVENT. See Menstruum.

SOLUTION. Solutio. An intimate commixture of solid bodies with fluids, into one seemingly homogeneous liquor. The dissolving fluid is called a menneous Induor. The dissolving fluid is called a menstruum or solvent.

SOLUTI'VA. (From solvo, to loosen.) Laxative
medicines, gentle purgatives.

SOMMITE. See Nepheline.

SOMNAMBULISM. See Oncirodynia.

SOMNI'FEROUS. (Somniferus; from somnus,
sleep, and fero, to bring.) Having the power of inducing
sleep.

Sleep. [Somnium. This is a term introduced by Dr. Mitchill, to designate the state between sleeping and waking, in which persons perform acts of which they are unconscious. It includes all those states of the system in which persons walk, talk, sing, dream, &c. during which they are neither perfectly asleep nor awake. This state of Somnium may be divided into Symptomatic, and Idiopathic. Symptomatic, and Idiopathic,

I. Symptomatic Somnium.

1. Somnium, from indigestion (a dyspepsia), when from too much food, or too feeble a condition of the stomach, there is a fermentation with acidity, eructations, and pain or uneasiness, followed by troublesome

Somnium from the nightmare (ab incubo), sup-osed to arise from some impediment to the free circulation of the blood through the heart and lungs; always unpleasant and sometimes frightful. The memory here is active, but the will is suspended, and the efforts to exert it fails. Persons are supposed to have died in

3. Somnium from effusions of water in the chest (ab hydrothorace), believed to proceed from anxiety about the vital parts, caused by lymph in the pericardium or thorax. Terrifying dreams rousing the patient suddenly are the common consequences of this disorder. This and the preceding are the Oneirodynia of Nosologists.

4. Somnium from a feverish state of the body (a febre), caused by an undue and irregular excitement of the brain. This is known by the name of high deliri-

um, or sometimes furor.

5. Somnium from debility (cum debilitate), where there is not excitement enough to embody ideas in steady trains. Memory and imagination act in a con-

fused and irregular manner. Low delirium.

6. Somnium from fainting (cum asphyxia), where, though there is an exhaustion of vital power, and the individual appears to be dead, there is life enough in the body to prevent putrefaction. The animal functions do not seem to be so much depressed as the vital; for, on recovery, the individual relates what he witnessed during the trance in which he lay, while in the very lowest ebb of life:
7. Somnium from fresh and vivid occurrences (a re-

Somnium from fresh and vivid occurrences (a recentibus), as when dreams can be traced to some conversation or occurrence of the day, or to some actual

condition of the body. Common dreaming.

8. Somnium from old and forgotten occurrences (ab obsoletis), when long-lost images are renewed to the memory, and dead friends are brought before us.

9. Somnium from an overloaded brain (a plethora), with symptoms bordering on epilepsy, apoplexy, and

catalepsy. Sometimes called typhomania.

10. Somnium of a prospective character (a prophetia), when the dreamer is engaged in seeing funeral protessions, and foretelling events by a sort of second sight, as it is called. This disease is symptomatic of a pecullar state of body, running in families like gout, consumption and insanity.

11. Somnium, from vivid impressions on the internal organ of sight (a visione), where visual images are so strong, that the dreamers are called Seers, because they see so much, and their sights are termed Visions,

inasmuch as the eyes are so peculiarly concerned.

12. Somnium from the conditions of other corporeal volumitu). causing dreams.

13. Somnium (a respiratione) from inhaling nitrous oxide gas, depriving the person of consciousness and will, and inspiring delightful sensations.

14. Somnium (a toxico) from doses of opium, hyoncyamus datura, and other narcotic plants, taken into the stomach, disturbing the will and exciting strange

15. Somnium from drunkenness (ab ebrietate), caused by drinking spirituous liquors, overcoming consciousness and spontaneity.

 II. Idiophathic Somnium.
 Somnium, from abstraction, where the internal senses are so engaged that there is no knowledge, or an imperfect one, of the passing events, constituting what is termed Reverie; where fanciful trains of the thought are indulged at considerable length.

2. Somnium, with partial or universal lunacy (cum insanitate), vitiating the mind with some fundamental error on a particular subject, or disturbing and con-founding all the operations of the animal mind. This

characterizes some forms of madness and melancholy.

3. Somnium, with talking (cum sermone), where the ideas of the mind are uttered in audible words, as in a wakeful state : called frequently, Somniloquism, or

4. Somnium, with walking (cum ambulatione), where the person rises from hed, walks about, frequently goes abroad, without the smallest recollection that any volition had been exerted on the occasion: the whole affair is forgotten, and not a trace left in the memory: this is called somnambulism.

Somnium, with invention (cum inventione), as when unbidden ideas rise in the mind in a methodical series, and form a poetical sonnet, different from any-thing known before, and unattainable by the waking powers. These are sometimes reduced to writing at the time and found afterward, though the act of committing them to paper is generally forgotten. On other occasions the memory preserves the particulars of such dreams.

 Somnium, (cum hallucinatione) with mistaken impressions of sight, and sometimes of hearing, so strong as to enforce a conviction of their reality. Many visions, conversations, and mistaken representations gain currency in this way. The patients being unwittingly deceived themselves, propagate with an honest zeal their delusions, and labour to gain the assent of their friends and acquaintances.

7. Somnium, with singing (cum musica), wherein the person, though unable to raise a note when awake, becomes capable in the somnial condition of uttering

sounds in most melodious accents.

 Somnium, with ability to pray and preach (cum re-ligione), or to address the Supreme Being and human auditors in an instructive and eloquent manner, without any recollection of having been so employed, and with utter incompetency to perform such exercises of devotion and instruction when awake.

See these states of Somnium, illustrated by cases, published in New-York, in 1815, under the title of "Devotional Somnium," &c. containing the account of Rachel Baker, &c. Notes from Dr. M.'s lectures on Mat. Med. A.]

SONCHI'TES. (From σογχος, the sow-thistle: so named from its resemblance to the sonchus.) The

herb hawkweed.

SO'NCHUS. (Παρα το σωον, χεειν; from its whole-some juice.) The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Polyga-mia æqualis. The sow-thistle.

Sonchus oleraceus. The systematic name of the ow-thistle. Most of the species of sonchus abound sow-thistle. with a milky juice, which is very bitter, and said to possess diuretic virtues. This is sometimes employed with that intention. Boiled it may be eaten as a sub stitute for cabbage.

SOOT. See Fuligo.

SO PHIA. (From σοφος, wise: so named from its great virtues in stopping fluxes.) Flix-weed or fluxweed. See Sisymbrium.

SOPHISTICATION. A term employed in pharmacy, to signify the counterfeiting or adulterating any medicine. This practice unhappily obtains with most dealers in drugs, &c.; and the cheat is carried on so artificially by many as to prevent a discovery even by persons of the most discerning faculties.

SPA SOR

SOPHO'RA. (A name of most whimsteal origin. Sophera is, according to Prosper Alpinus, the Egyptian denomination of a species of cassia, the Cassia sophera of Linnaus, nearly related to this genus. Linngus, spelling it sophora, calls it a genus sophorum, or of wise men; as teaching that separate stamens, in the papilionaceous family, if ever the limits of that family can be determined, afford so decisive a mark of discrimination, as almost to exclude the plants furnished with such, from the same natural class, or order, with those the filaments of which are combined.) The name of a genus of plants. Class, Decandria; Order, Monogynia.

SOPHORA REPTAPHYLLA. The systematic name of the shrub, the root and seeds of which are sometimes called anticholerica; they are both intensely bitter, and said to be useful in cholera, colic, and dysury.

SOPHRONISTE RES. (From σωφρονίζω, to become wise: so called because they do not appear till

after puberty.) The last of the grinding-teeth.
SOPIE'NTIA. (From sopio, to make sleep.) Me-

SOPIE NTIA. (From sopio, to make sieep.) Medicines which procure sleep.

SOPOR. Profound sleep.

SOPORIFEROUS. (Soporiferus; from sopor, sleep, and fero, to hear.) A term given to whatever induces sleep. See Anodyne.

So'ra. (Arabian.) The nettle-rash.

Sorbastre'lla. (From sorbeo, to suck up; because it stres hemorrhages.) The herb burnet. See

Pimpinella saxifraga.

SORBATE. A compound of sorbic or malic acid, with the salifiable basis.

SORBIC ACID. (Acidum sorbicum; from sorbus, the mountain ash, from the berries of which it is obtained.) "The acid of apples called malic, may be obtained most conveniently and in greatest purity from the berries of the mountain ash, called sorbus, or pyrus ancuparia, and hence the present name, sorbic acid. This was supposed to be a new and peculiar acid by Donovan and Vauquelin, who wrote good dissertations upon it. But it now appears that the sorbic and

pure malic acids are identical.

Bruise the ripe berries in a mortar, and then squeeze them in a linen bag. They yield nearly half their weight of juice, of the specific gravity of 1.077. This viscid juice, by remaining for about a fortnight in a warm temperature, experiences the vinous fermentation, and would yield a portion of alkohol. By this change, it has become bright, clear, and passes easily through the filter, while the sorbic act itself is not altered. Mix the clear juice with filtered solution of acetate of lead. Separate the precipitate on a filter, and wash it with cold water. A large quantity of boiling water is then to be poured upon the filter, and allowed to drain into glass jars. At the end of some hours, the solution de-posites crystals of great lustre and beauty. Wash these with cold water, dissolve them in boiling water, filter, and crystallize. Collect the new crystals, and boil them for half an hour in 2.3 times their weight of sulphuric acid, specific gravity 1.090, supplying water as fast as it evaporates, and stirring the mixture diligently with a glass rod. The clear liquor is to be decanted into a tall narrow glass jar, and while still hot, a stream of sulphuretted hydrogen is to be passed through it. When the lead has been all thrown down in a sulphuret, the liquor is to be filtered, and then boiled in an open vessel to dissipate the adhering sulphuretted hydrogen. It is now a solution of sorbic acid.

When it is evaporated to the consistence of a syrup, it forms manimelated masses of a crystalline structure. It still contains a considerable quantity of water, and deliquesces when exposed to the air. Its solution is transparent, colourless, void of smell, but powerfully acid to the taste. Lime and barytes waters are not precipitated by solution of the sorbic acid, although the sorbate of lime is nearly insoluble. One of the most characteristic properties of this acid, is the precipitate which it gives with the acetate of lead, which is at first white and flocculent, but afterward assumes a bril liant crystalline appearance. With potassa, soda, and ammonia, it forms crystallizable salts containing an excess of acid."

SO'RBUS. (From sorbes, to suck up; because its fruit stops fluxes.) The name of a genus of plants in the Linnman system. Class, Icosandria; Order, Tri-Gynia. The service-tree.

SORBUS AUGUPARIA. The wild service-tree. The

SO'RDES. When the matter discharged from ul-cers is rather viscid, glutinous, of a brownish-red colour, somewhat resembling the grounds of coffee, or grumous blood mixed with water, it is thus named. Sardes, Saines, and Ichor, are all of them much more feetid than purulent matter, and none of them are altogether free from acrimony; but that which is generally termed Ichor, is by much the most acrid of them, being freequently so sharp and corrosive as to destroy large. frequently so sharp and corrosive as to destroy large quantities of the neighbouring parts.

Sore, bay. A disease which Dr. Mosely considers as

a true cancer, commencing with an ulcer. It is ende-

mic at the Bay of Honduras.

SORE-THROAT. See Cynanche. SORREL. See Rumex acctosa.

Sorrel, French. See Rumez scutatus.
Sorrel, round-leaved. See Rumez scutatus.
Sorrel, wood. See Oxalis acetosella.
SOUND. 1. An instrument which surgeons introduce through the urethra into the bladder, to discover whether there is a stone in this viscus or not.

2. See Hearing. SOUR DOCK. See Rumex acetosa.

SOUTHERNWOOD. See Artemisia abrotanum. SOW-BREAD. See Cyclamen.

SPA. A town in France, in the department of the Ourte, famous for its mineral water, which appears to be a very strongly acidulous chalybeate, containing more iron and carbonic acid than any other mineral spring. What applies to the use of chalybeates will apply to this water.

SPADIX. An elongated receptacle or flower-bearing column, which emerges, mostly, from a spathe or sheath, as it does in Arum maculatum, Calla athiopica, and palustris; but the Acorus calamus has a spadix with-

out any sheath.

The inflorescence of palms, and some other plants, is a branched spadix; as the Chamarops humilis, Mu-

Spain, pellitory of. See Anthemis pyrethrum. Spanish fly. See Cantharis.

Spanish liquorice. See Glycyrrhiza.

Spar, fluor. See Fluor.
Spar, ponderous. See Heavy-spar, and Barytes.
Spar, tabular. See Tabular spar.
SPARGANO'SIS. (From σπαργαω, to swell.) Λ milk abscess.

Sparry anhydrite. A sulphate of lime. See Anhy-

SPARRY IRON. A carbonate of iron, of a pale yellowish gray colour, found in limestone in Eng-land, Scotland, and Ireland, and in large quantities in

SPARSUS. Dispersed, irregularly scattered. Frequently used in medicine, anatomy, and botany, to

eruptions, glands, leaves, flower-stalks.

SPA'RTIUM. (Σπαρδιον of Dioscorides: so called from $\sigma\pi\alpha\rho\gamma\eta$, a rope; because of the use of the long, slender, tough branches, or bark, in making cordage.) The name of a genus of plants in the Linnman system.

The name of a genus of plants in the Linna an system. Class, Diadelphia; Order, Decandria.

Spartium scoparium. The systematic name of the common broom. Genista. The tops and leaves of this indigenous plant, Spartium—foliis ternatis solitariisque, ramis incrmibus angulatis, of Linnaus, are the parts that are employed medicinally; they have a bitter-taste, and are recommended for their purgative and diuretic qualities, in hydropic cases.

SPASMI. Spasmodic diseases. The third order of the Class Neuroses, of Cullen; characterized by a morbid contraction or motion of muscular fibres.

morbid contraction or motion of muscular fibres.

SPASMODIC. Spasmodicus. Belonging to a spasm,

or convulsion.

Spasmodic colic. See Colica. SPASMOLOGY. (Spasmologia; from σπασμος, a spasm, and λογος, a discourse.) A treatise on convul-

SPASMUS. (Spasmus; from σπαω, to draw.) A cramp, spasm, or convulsion. An involuntary contraction of the muscular fibres, or that state of the con-SPASMUS. traction of muscles which is not spontaneously dis-posed to alternate with relaxation, is properly termed spasm. When the contractions alternate with relaxation, and are frequently and preternaturally repeated,

they are called convulsions. Spasms are distinguished by authors into clonic and tonic spasms. In *clonic* spasms, which are the true convulsions, the contractions and relaxations are alternate, as in epilepsy; but in tonic spasms the member remains rigid, as in locked jaw. See Convulsion, Tonic spasm, and Te-

SPASMUS CYNICUS. Sardonic laugh. affection of the muscles of the face and lips on both sides, which involuntarily forces the muscles of those parts into a species of grinning distortion. If one side parts into a species of griming distortion. It one side only be affected, the disorder is nominated tortura oris. When the masseter, buccinator, temporal, nasal, and labial muscles, are involuntarily excited to action, or contorted by contraction or relaxation, they form a species of malignant sneer. It sometimes arises from eating hemlock, or other acrid poisons, or succeeds to

eating nembors, or other active posses, or lade.) A bota-an apoplectic stroke. SPATHA. (From $\sigma\pi\alpha\theta\eta$, a slice, or ladle.) A bota-nical term. A sheath, or covering of an immature flower which bursts longitudinally, and is more or less remote from the flower. From the number of mem-branes, which are called valves, and of the flowers,

and their duration, it is named,

1. Spatha univalvis, having only one membranous leaf; as in Arum maculatum, and Crocus sativus.

2. Bivalvis, in Stratiates alioides.

Dimidiata, or lacera, there being only one valve, and that covering the flower only partially; as in Ixia uniflora, and africana.

4. Vaga, the common sheath enclosing several partial ones; as in Iris germanica, and helonica.
5. Uniflora, containing only one flower; as the Narcissus poeticus, Pseudo-narcissus, and Amaryllis formosissima.

6. Biflora, with two; as in Alpina racemosa, and

Moraa vegeta.

7. Multiflora; as in Allium, Narcissus jonquilla, and Pancreatium carabeum.

8. Spatha persistens, remaining with the fruit; as in Heliconia bibai.

9. Marcescens, withering before or soon after the flowering; as in Allia and Leucojum vernum.

SPATHOME'LE. (From σπαθη, a sword, and μηλη, a probe.) An edged probe.

SPATULA. (Diminutive of spatha, a broad instrument.) An instrument for spreading salve. Also a name of the herb spurgewort, from its broad leaves. SPATULATUS. Spatulate: applied to leaves, &c.

of a roundish figure, tapering into an oblong base; as

SPEARMINT. See Mentha viridis.

Spearwort, water. See Ranunculus flammula. SPECIFIC. Specificus. A remedy that has an infallible efficacy in the cure of disorders. The existence of such remedies is doubted.

Specific gravity. See Gravity, specific.

SPECILLUM. (From specio, to examine.)

SPE'CULUM. (From specio, to view.) An instru-ment for opening or obtaining a view of parts within each other; as Speculum oculi, Speculum oris, Speculum ani, &c.

Speculum ani. An instrument for distending the anus, while an operation is performed upon the parts

An instrument to assist in SPECULUM MATRICIS. any manual operation belonging to the womb.

SPECULUM OCULL An instrument used by oculists to keep the eyelids open and the eye fixed.

SPECULUM ORIS. An instrument to force open the

Speculum veneris. See Achillea millefolium.

SPECULUM VENERIS. See Acause management SPEECH. See Voice.

SPEEDWELL. See Veronica.

Specdwell, female. See Antirrhinum elatine. Specdwell, mountain. See Veronica.

SPERMA-CETI. (From σπερμα, seed, and cete, or cetus, the whale.) See Physeter macrocephalus.

SPERMA'TIC. (Spermaticus; from σπερμα, seed.)

Relanging to the testicle and ovary; as the sperma-Belonging to the testicle and ovary; as the sperma-tic artery, chord, and veins.

SPERMATOCE'LE. (From σπερμα, seed, and λη, a tomour.) Epididymis distensa. A swelling κηλη, a tumour.) Epididymis distense. A swelling of the testicle or epididymis from an accumulation of semen. It is known by a swelling of those organs, SPERMATOPOE'TICA. (From σπιρμα, and ποιεφ, to make.) Medicines which increase the generation of

SPERMORRHŒ'A. (From σπτρμα, semen, and οεω, fluo.) The name of a genus of diseases in Good's Nosology. Class, Genetica; Order, Cenotica. Semi nal flux. It has two species, viz. Spermorrhæa ento SPERMORRHŒ'A. nica, and atonica

SPHACELI'SMUS. (From σφακελίζω, to gan-

grene.) 1. A gangrene. 2. A phrenitis. SPHA CELUS. (Fr

SPHA'CELUS. (From σφακω, to destroy.) A mortification of any part. See Gangrene.

SPHÆ'NOIDES. See Sphenoides.

SPHÆRI'TIS. (From σφαιρα, a globe: so called from its round head.) Sphærocephalia elatior. Sphærocephalus. The globe-thistle.

SPHÆROCE'PHALUS. See Sphæritis.

SPHÆROCE'PHALUS. See Sphæritis.

SPHÆRO'MA. (From σφαιρα, a globe.) A fleshy,

globular protuberance.

SPHÆRULITE. A brown and gray-coloured mineral, found in imbedded roundish balls and grains, in pearlstone and pitchstone porphyries, near Schem-

SPHE'NO. Names compounded of this word belong to the sphenoid bone.

SPHENO-MAXILLARIS. An artery, and a fissure of the orbit of the eye, is so called.

SPHENO-SALPINGO-STAPHYLINUS. See Circumfexus. SPHENO-STAPHYLINUS. See Levator palati.

SPHENOIDAL. Sphenoidalis. Belonging to the

sphenoid bone.

sphenoid bone.

Sphenoidal sutures. Sutura sphenoidalis. The sphenoidal and ethmoidal sutures are those which surround the many irregular processes of these two bones, and join them to each other and to the rest.

SPHENOIDES OS. (From σφην, a wedge, and ειδος, a likeness; because it is fixed in the cranium like a wedge.) Os cunciforme; Os multiforme; Os azygos; Papillare os; Basilare os; Os polymorphos. Pterygoid bone. The os sphenoides, or cunciforme, as it is called from its wedge-like situation amidst the other bones of the head, is of a more irregular figure than any other bone. It has been compared to a bat than any other bone. It has been compared to a bat with its wings extended. This resemblance is but faint, but it would be difficult perhaps to find any thing

it resembles more. We distinguish, in this bone, its body or middle part, and its wings or sides, which are much more extensive

than its body.

Each of its wings or lateral processes is divided into two parts. Of these, the uppermost and most consi derable portion, helping to form the deepest part of the temporal fossa on each side, is called the temporal process. The other portion makes a part of the orbit, and is therefore named the orbitar process. The tack part of each wing, from its running out sharp to meet the os petrosum, has been called the spinous process; and the two processes, which stand out almost perpendicular to the basis of the skull, have been named pterygoid or aliform processes, though they may be said rather to resemble the legs than the wings of the bat. Each of these processes has two plates and a middle fossa facing backwards; of these plates, the external one is the broadest, and the internal one the longest. The lower end of the internal plate forms a kind of hook, over which passes the round tendon of the musculus circumflexus palati. Besides these, we observe a sharp middle ridge, which stands out from the mid-dle of the bone. The forepart of it, where it joins the nasal lamella of the ethmoidal bone, is thin and straight; the lower part of it is thicker, and is received into the vomer.

The cavities, observable on the external surface of the bone, are where it helps to form the temporal,

nasal, and orbitar fossæ

It has likewise two fossæ in its pterygold processes. Behind the edge, which separates these two fossæ, we observe a small groove, made by a branch of the superior maxillary nerve, in its passage to the temporal muscle. Besides these, it has other depressions, which serve chiefly for the origin of the muscles.

Its foramina are four on each side. The three first serve for the passage of the optic, superior maxillary, and inferior maxillary nerves; the fourth transmits the largest artery of the dura mater. On each side we observe a considerable fissure, which, from its situation, may be called the superior orbitar fissure. Through it pass the third and fourth pair of nerves, a branch of the fifth, and likewise the sixth pair. Lastly, at the basis of each pterygoid process, we observe a foramen which is named pterygoidean, and sometimes Vidian, from Vidius, who first described it. Through it passes a branch of the external carotid, to

be distributed to the nose.

The os sphenoides, on its internal surface, affords three fossæ. Two of these are considerable ones; they are formed by the lateral processes, and make part of the lesser fossæ of the basis of the skull. third, which is smaller, is on the top of the body of the bone, and is called sella turcica, from its resem-blance to a Turkish saddle. In this the pituitary gland is placed. At each of its four angles is a process.

They are called the *clinoid* processes, and are distinguished by their situation into anterior and posterior processes. The two latter are frequently united into one.

Within the substance of the os sphenoides, immediately under the sella turcica, we find two cavities, separated by a thin bony lamella. These are the sphenoidal sinuses. They are lined with the pituitary membrane, and, like the frontal sinuses, separate a mucus which passes into the nostrils. In some subjects, there is only one cavity; in others, though more rarely we find three.

rarely, we find three.

In infants, the os sphenoides is composed of three pieces, one of which forms the body of the bone and its pterygoid processes, and the other two its lateral processes. The clinoid processes may even then be perceived in a cartilaginous state, though some writers have asserted the contrary; but we observe no appearance of any sinus.

This bone is connected with all the bones of the cranium, and likewise with the ossa maxillaria, ossa malarum, ossa palati, and vomer. Its uses may be

collected from the description we have given of it. SPHI'NCTER. (From $\sigma\phi\iota\gamma\gamma\omega$, to shut up.) The name of several muscles, the office of which is to shut

or close the aperture around which they are placed.

SPHINCTER ANI. Sphincter externus, of Albinus and Douglas. Sphincter cutancus, of Winslow; and coccigio-cutane-sphincter, of Dumas. A single muscle of the anus, which shuts the passage through the anus into the rectum, and pulls down the bulb of the urethra, by which it assists in ejecting the urine and semen. It arises from the skin and fat that surrounds the verge of the anus on both sides, nearly as far as the the verge of the anus on both sides, nearly as far as the tuberosity of the ischium; the fibres are gradually collected into an oval form, and surround the extremity of the rectum. It is inserted by a narrow point into the perineum, acceleratores urinæ, and transversi perinei; and behind into the extremity of the os coccygis, by an acute termination.

SPHINCTER ANI CUTANEUS. See Sphincter ani.
SPHINCTER ANI EXTERNUS. See Sphincter ani.
SPHINCTER ANI INTERNUS. Albinus and Douglas

call the circular fibres of the muscular coat of the rectum, which surround its extremity, by this name.

SPHINCTER CUTANEUS. See Sphincter ani. SPHINCTER EXTERNUS. See Sphincter ani. SPHINCTER GULE. The muscle which contracts the top of the throat.

SPHINCTER LABIORUM. See Orbicularis oris. SPHINCTER ORIS. See Orbicularis oris.

SPHINCTER VAGINE. Constrictor cunni, of Albinus. Second muscle of the clitoris, of Douglas; and anulo-syndesmo-clitoridien, of Dumas. This muscle arises from the sphincter ani and from the posterior side of the vagina, near the perineum; from thence it runs up the side of the vagina near its external orifice, opposite to the nymphæ, covers the corpus cavernosum, and is inserted into the crus and body, or union of the crura elitoridis. Its use is to contract the mouth of the vagina.

Sphingo'nta. (From σφιγ/ω, to bind.) Astringent

medicines

SPHONDY'LIUM. (From σπονόνλος, vertebra; named from the shape of its root, or probably because it was used against the bite of a serpent, called σπονόν-Acc.) This is supposed to be the branckursine. See

SPHRAGIDE. A species of Lemnian earth.
SPHRONGIDIUM. See Columnula.
SPICA. A spike. I. A species of inflorescence,
consisting of one common stalk bearing numerous flowers, all ranged along it without any, or having very

small partial stalks, as the flower-stalk of the greater plantain. From its figure, the situation of the flowers, and its vesture, it is called,

and its vesture, it is called,

1. Cylindrica; as in Plantago media, and albicans.

2. Ovata, in Sanguisorba officinalis.

3. Articulata, with joints; as in Salicornea herbacca, and Polygonum articulatum.

4. Conjugata, two spikes going from the summit of the peduncle; as in Heliotropium europaum and paraideems. viflorum.

5. Ramosa, divided into branches; as in Chenopo-

dium bonus henricus, and Osmunda. 6. Imbricata; as in Salvia hispanica.

Secunda, the flowers leaning all to one side; as in Anchusa officinalis.

8. Interrupta, in separate groupes; as in Betonica

officinalis, and Gomphrena interrupta.

9. Disticka, two series of spikes; as in Gladiolus alopecuroides.

10. Terminalis; as in Lavendula.

Azillares; as in Justitia spinosa.
 Foliosa, leaflets between the flowers; as in Agri-

monia cupatoria. 13. Comosa, having a leafy bundle at the apex; as in

Lavendula stachas, and Bromelia ananas.
14. Ciliata, hairs between the flowers; as in Nardus oiliaris.

II. An ear of corn.

III. A bandage resembling an ear of corn.

SPICA BREVIS. The Alopecuris pratensis.
SPICA CELTICA. See Valeriana celtica.
SPICA FÆMINA. Common lavender.
SPICA INDICA. See Nardus indica.

SPICA INGUINALIS. A bandage for ruptures in the groin.

SPICA INGUINALIS DUPLEX. Double bandage for ruptures.

SPICA MAS. Broad-leaved 'avender.

SPICA NARDI. See Nardus indica.
SPICA SIMPLEX. A common roller or bandage.
SPICULA. A spikelet. A term applied exclusively to grasses that have many florets on one calyx, such florets ranged on a little stalk, constituting the spikelet, which is therefore a part of the flower itself, and not of the efflorescence; as in Briza minor, and Poa aquatica. Locusta means the same as spicula.

SPIGE LIA. (So called by Linnaus in commemoration of an old botanist, Adrian Spigelius, who wrote Isagoge in rem herbariam, in 1606.) 1. The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Monogynia.

2. The name in some pharmacopæias for the Spigelia marilandica.

SPIGELIA ANTHELMIA. The systematic name of the

Spigelia anthelmia. The systematic name of the spigelia of some pharmacopæias. It is directed as an anthelmintic; its virtues are very similar to those of the Indian pink. See Spigeliamarilandica.

Spigelia Lonicera. See Spigelia marilandica.

Spigelia Marilandica. Spigelia lonicera. Perennial worm-grass, or Indian pink. Spigelia—caule tetragono, foliis omnibus, oppositis, of Linnæus. The whole of this plant, but most commonly the root, is employed as an anthelmintic by the Indians, and inhabit ants of America. Dr. Hope has written in favour of this plant, in continued and remitting low worm fevers. this plant, in continued and remitting low worm fevers. Besides its property of destroying the worms in the primæ viæ, it acts as a purgative.

Spigelion lobe. See Liver.

SPIGELIUS, ADRIAN, was born at Brussels, in 1578. He studied at Louvain, and afterward at Padua, where he took his degree. He became thoroughly skilled in every branch of his profession, particularly in anatomy and surgery; and after travelling some time to the different schools in Germany, he settled in Moravia, where he was soon appointed physician to the States of the Province. In 1616 he was invited to occupy the principal professorship in anatomy and surgery at Padua, where he acquitted himself with so much success, that he was created a knight of St. Mark, and presented with a collar of gold. He died in His writings evince him to have possessed very extensive medical knowledge. The first, which he published, contains some interesting information concerning the virtues of plants, respecting which he appears to have learned much from the Italian peasantry He wrote also concerning some diseases and other matters. But the most valuable of his works are those

death, by his son-in-law, Crema.

SPIGNEL. See JEthusa meum.

SPIKELET. See Spicula.

SPIKENARD. See Nardus indica.

SPILA'NTHUS. (From σπιλος, a spot, and ανθος, a flower; because of its dotted or speckled flowers.)

The name of a genus of plants. Class, Syngenesia; Order, Polygamia agualis.

Order, Polygamia aqualis.

SPILANTHUS ACMELLA. Achmella. Achamella. The systematic name of the balm-leaved spilanthus, which ossesses a glutinous bitter taste, and a fragrant smell. The herb and seed are said to be diuretic and emmenagogue, and useful in dropsies, jaundice, fluor albus, and calculous complaints, given in infusion.

SPI'NA. (Quasi spiculina, diminutive of spica.)

A thorn.

A. The back-bone: so called from the thorn-like arocesses of the vertebræ. See Vertebræ, and Spine.

B. The shin-bone.

C. A thorn of a plant. A prickly armature of plants, sot easily removed by the finger, and proceeding from the woody part of the plant. It is either,

1. Culine; as in Prunus spinosa.

2. Terminal, at the end of a branch; as in Rhamnus

- catharticus.
- Foliar, on the surface of the leaf; as in Carduus
- 4. Marginal, on the margin of the leaf; as in Ilex aquifolium.

5. Axillary, going from the axilla of the leaf; as in Gleditschia triacanthos.

- Calycine, on the calyx; as in Carduus marianus.
 Pericarpial, on the pod; as in Datura stramonium.
 Stipular, on the stipule; as in Mimosa nilotica,
- and horrida.
 - 9. Straight; as in Mimosa nigra.
 10. Recurve; as in Costus nobilis.
 11. Decussate; as in Genista lucitanica.
 12. Setaceous; as in Cactus opuntia.
 13. Subulate; as in Cactus tuna.
- 14. Inerm, covered with soft and not prickly spines, also called muricate; as in Convolvulus muricatus, and Mimosa muricata.

Simple, when not divided; as Genista anglica.
 Germinal; as in Limonia trifoliata.

Ternate; as in Zanthium spinosum.
 Ramose; as in Gleditschia horrida.

SPINA ACIDA. See Berberis.
SPINA ACUTA. The hawthorn.
SPINA EGYPTIACA. The Egyptian thorn or sloe-tree. See Acacia vera.

SPINA ALBA. The white-thorn tree.

SPINA ALBA. The white-thorn tree.

SPINA ARABICA. The chardon, or Arabian thistle.

SPINA BIFIDA. Hydrops medullæ spinalis; Hydrocele spinalis; Hydrorachytis spinosa. A tumour upon the spine of new-born children, immediately about the lower vertebræ of the loins, and upper parts of the sacrum; at first, it is of a dark blue colour; but in proportion as it increases in size, approaches nearer and nearer to the colour of the skin, becoming perfectly diaphynous.

From the surface of this tumour a pellucid watery fluid sometimes exudes, and this circumstance has been noticed by different authors. It is always attended with a weakness, or more properly speaking, a paralysis of the lower extremities. The opening of it rashly has proved quickly fatal to the child. Tulpius, therefore, strongly dissuades us from attempting this operation. Acrel mentions a case where a nurse rashly opened a tumour, which, as he described it, was a blood bag on the back of the child at the time of its birth, in bigness equal to a hen's egg, in two hours after which, the child died. From the dissection it ap-peared, that the bladder lay in the middle of the os sacrum, and consisted of a coat, and some strong mem-brane, which proceeded from a long fissure of the bones. The extremity of the spinal marrow lay bare, and the spinal duct, in the os sacrum, was uncommonand the spinal duct, in the os sacrum, was uncommonly wide, and distended by the pressure of the waters. Upon tracing it to the head, the brain was found nearly in its natural state, but the ventricles contained so much water, that the infundibulum was quite distended with it, and the passage between the third and fourth ventricle was greatly enlarged.

He likewise takes notice of another case, where a child lived show right was playing under this common that the same player in the common tracks and the same player in the same

child lived about eight years labouring under this com-

composed on anatomical subjects, published after his | plaint, during which time it seemed to enjoy tolerable death, by his son-in-law, Crema. Nothing seemed amiss in him, but such a degree of debility as rendered him incapable to stand on his legs.

The tumour, as in the former case, was in the middle of the os sacrum, of the bigness of a man's fist, with little discolouring; and upon pressing it became less. When opened it was found full of water, and the coats were the same as in the former, but the separation of the bones was very considerable. The spinal marrow, under the tumour, was as small as a packthread, and rigid; but there were no morbid appearances in the brain.

SPINA BURGHI MONSPELIENSIS. Evergreen privet. SPINA CERVINA. (So called from its thorns resembling those of the stag.) See Rhamnus catharticus.

SPINA HIRCI. The goat's-thorn of France, yielding gum-tragacanth.

SPINA INFECTORIA. See Rhamnus catharticus.
SPINA PURGATRIX. The purging thorn.

SPINA SOLSTITIALIS. Barnaby's thistle. The calcitrapa officinalis.

Barnaby's thistle.

STINA VENTOSA. (The term of spina seems to have been applied by the Arabians to this disorder, because it occasions a prickling in the flesh like the puncture of thorns; and the epithet ventosa is added, because, upon touching the tumour, it seems to be filled with wind, though this is not the cause of the distention.) Spina ventositas; Teredo; Fungus articuli; Arthrocace: sideratio ossis; Cancer ossis; Gangrana ossis, and some French authors term it exostosis. When children are the subjects of this disease, Severinus calls it. Padarthrocaca. A tumour arising from rinus calls it Padarthrocace. A tumour arising from an internal caries of a bone. It most frequently occurs in the carpus and tarsus, and is known by a continual pain in the bone, and a red swelling of the skin, which has a spongy feel.

SPINA'CHA. See Spinacia.
SPINA'CHA. (From Ismania, Spain, whence it originally came; or from its spinous seed.) The name of a genus of plants. Class, Diacia; Order, Pentandria. Spinage

Spinacia Oleracea. The systematic name of the Spinacha. Spinach. Spinage. This plant is sometimes directed for medicinal purposes in the cure of phthisical complaints; made into a poultice, by boiling the leaves and adding some oil, it forms an excellent emollient. As an article of food it may be considered as similar to cabbage and other oleraceous plants. See

Brassica capitata.

Sping crates. The spine of the back.

Sping ventositas. A caries, or decay of a bone. Spina ventosa.

SPINAL. Spinalis. Belonging to the spine of the back.

Spinal-marrow. See Medulla spinalis.
SPINA'LIS. See Spinal.
SPINALIS CERVICIS. This muscle, which is situated close to the vertebræ at the posterior part of the neck and upper part of the back, arises, by distinct tendons, from the transverse processes of the five or six uppermost vertebræ of the back, and ascending obliquely under the complexus, is inserted, by small tendons, into the spinous processes of the sixth, fifth, fourth, third, and second vertebræ of the neck. Its use is to extend the neck obliquely backwards.

Spinalis colli. See Semi-spinalis colli.
Spinalis dorsi. Transversalis dorsi, of Winslow; and inter-épineux, of Durbas. This is the name given by Albinus to a tendinous and fleshy mass, which is situated along the spinous processes of the back and the inner side of the longissimus dorsi.

It arises tendinous and fleshy from the spinous processes of the uppermost vertebræ of the loins, and the lowermost ones of the back, and is inserted into the spinous processes of the nine uppermost vertebræ of the

Its use is to extend the vertebræ, and to assist in raising the spine.

SPINALES LUMBORUM. Muscles of the loins.
SPINE. (Spina; from spina, thorn: so called from the spine-like processes of the vertebræ.) 1. Spina dorsi; Columna spinalis; Columna vertebralis. A bony column or pillar extending in the posterior part of the trunk from the great occipital foramen to the sacrony. crum. It is composed of twenty-four bones called vertebræ. See Vertebræ.

301

2. An armature of plants. See Spina. SPINEL. A sub-species of octohedral corundum, of a red colour, and equal value with a diamond. It tomes from Pegu and Ceylon.

SPINELLANE. A plumb, blue-coloured crystallized mineral, found on the shores of the lake of Laach.

SPINESCENS. Spinescent. Becoming thorny, ap-

plied to the leaf-stalk, when it hardens into a thorn, and the leaf falls, as is the case in Rhamnus cathartius, and Robinia spinosa, and to the stipulæ of the Ro-

binia pseudacacia, which also become thorns.

Spinosa. See Spina bifidi.

Spino'sum syriacum. The Syrian broom.

SPINTHERE. A greenish gray-coloured mineral, believed to be a variety of prismatic titanium ore.

SPIN BY A (From Spinosa) illustration and from Spinosa and from Spinosa and from Spinosa and from Spinosa and Spinosa a

SPIRÆ'A. (From Spira, a pillar: so named from s spiral stalk.) Meadow-sweet. The name of a its spiral stalk.) genus of plants in the Linnaean system. Class, Icosandria; Order, Pentagynia.

Spir & Africana. African meadow-sweet.

SPIREA FILIPENDULA. The systematic name of the officinal dropwort. Filipendula; Saxifraga rubra. Dropwort. The root of this plant, Spirea—foliis pennatis, foliolis uniformibus serratis; caule herbaceo; floribus corymbosis, of Linnœus, possesses adstringent, and, it is said, lithontriptic virtues. It is seldom used in the practice of the present den

and, it is said, lithontriptic virtues. It is seidom used in the practice of the present day.

Spir. Ea Ulmaria. The systematic name of the meadow-sweet. Ulmaria; Regina prati; Barba capra. Meadow-sweet. Queen of the meadows. This is a beautiful and fragrant plant. The leaves are recommended as mild adstringents. The flowers have a strong smell, resembling that of May; they are supposed to possess antispasmodic and diaphoretic virtues, and as they are very rarely used in medicine, Linnaus. and as they are very rarely used in medicine, Linnæus suspects that the neglect of them has arisen from the plant being supposed to be possessed of some noxious qualities, which it seemed to betray by its being left untouched by cattle. It may be observed, however, that the cattle also refuse the Angelica and other herbs, whose innocence is apparent from daily experience.

Whose innocence is apparent from daily experience. [SPIREA TRIFOLIATA. See Gillenia. A.]
SPIRITUS. (Spiritus, us. m.; spirit.) This name was formerly given to all volatile substances collected by distillation. Three principal kinds were distinguished: inflammable or ardent spirits, acid spirits, and alkaline spirits. The word spirit is now almost exclusively confined to alkohol.

SPIRITUS ATTURNIS NUTRICL. Spiritus atheria ni

SPIRITUS ATHERIS NITRICI. Spiritus etheris ni-trosi: Spiritus nitri dulcis. Take of rectified spirits, two pints; nitric acid, by weight, three ounces; add the acid gradually to the spirit, and mix them, taking care that the heat do not exceed 120°; then with a gentle heat distil twenty-four fluid ounces. A febrifuge, diaphoretic, and diuretic compound mostly administered in asthenia, nervous affections, dysuria, and calculous complaints.

Spiritus atheris aromaticus. Take of cinnamon-bark, bruised, three drachms; cardamom seeds powdered, a drachm and a half; long pepper powdered, ginger-root sliced, each a drachm; spirit of sulphuric ather, a pint; macerate for fourteen days, in a closed glass vessel, and strain. An excellent stimution lating and stomachic compound, which is administered in debility of the stomach and nervous affections.

SPIRITUS ÆTHERIS SULPHURICI. Spiritus vitrioli dulcis; Spiritus ætheris vitriolici. Take of sulphuric ather, half a pint; rectified spirit, a pint: mix them. A diaphoretic, antispasmodic, and tonic preparation, mostly exhibited in nervous debility and weakness of

the primæ viæ.

STRITUS ETHERIS SULPHURICI COMPOSITUS. Take of spirit c sulphuric æther a pint; ætherial oil, two fluid drachms; mix them. A stimulating anodyne, supposed to be similar to the celebrated liquor mineralis anodynus, of Hoffman. It is exhibited in fevers, nervous affections, hysteria, &c.; and in most cases of fever where medicines are rejected by the stomach, this is of infinite service. this is of infinite service.

SPIRITUS AMMONIE. Spirit of ammonia. Formerly called Spiritus salis ammoniaci dulcis; Spiritus salis ammoniaci. Take of proof spirit, three pints; muriate of ammonia, four ounces; subcarbonate of potassa, six ounces; mix them, and, with a gentle fire, let a pint and a half be distilled into a cooled receiver. A stimu-lating antispasmodic, occasionally exhibited in cases of asphyxia, asthenia, and in nervous diseases, but mostly

used as an external stimulant against rheumatism, sprains, and bruises.

SPIRITUS AMMONIX AROMATICUS. Aromatic spirit of ammonia. Formerly known by the name of Spiritus ammonia compositus: Spiritus volatilis aromaticus: Spiritus salis volatilis oleosus. Take of cinnamonbark bruised, cloves bruised, each two drachms; lemonpeel, four ounces; subcarbonate of potassa, half a pound; muriate of ammonia, five ounces; rectified spirit, four pints; water, a gallon; mix and distil six A stimulating antispasmodic and sudorific in pints. very general use, to smell at in faintings and lowness of spirits. It is exhibited internally in nervous affections, hysteria, and weakness of the stomach. The dose is from half a drachm to a drachm.

SPIRITUS AMMONIA PETIDUS. Fætid spirit of am-Take of spirit of ammonia, two pints; asafætida, two ounces. Macerate for twelve hours, then by a gentle fire distil a pint and a half into a cooled receiver. stimulating antispasmodic, often exhibited to children against convulsions, and to gouty and asthmatic persons. The dose is from half to a whole fluid drachm.

SPIRITUS AMMONIÆ SUCCINATUS. Succinated spirit of ammonia. Formerly known by the names of Eau de luce; Spiritus salis ammoniaci succinatus; Liquor cornu cervi succinatus. Take of mastich, three drachms; rectified spirit, nine fluid drachms; oil of lavender, fourteen minims; oil of amber, four minims, solution of ammonia, ten fluid ounces. Macerate the mastich in the spirit that it may dissolve, and pour off the clear tincture; to this add the remaining articles, and shake them together. This preparation is much esteemed as a stimulant and nervine medicine, and is employed internally and externally against spasms, hysteria, syncope, vertigo, and the stings of insects. The dose is from ten minims to half a fluid drachm.

Spiritus anisi. Spirit of aniseed. Formerly called Spiritus anisi compositus; Aqua seminum anisi composita. Take of aniseed, bruised, half a pound; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for twenty-four hours, and distil a gallon by a gentle fire. A stimulating carminative and stomachic calculated to relieve flatulency, borborygmus, colic, and spasmodic affections of the bowels. The dose is

from half to a whole fluid drachm.

Spiritus armoraciæ compositus. Compound spirit of horse-radish, formerly called Spiritus raphani compositus: Aqua raphani compositus. Take of horsecompositus; Aqua raphani composita. Take of horse-radish root, fresh and sliced, dried orange-peel, of each a pound; nutmegs, bruised, half an ounce; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for twenty-four hours, and distil a gallon by a gentle fire. A very warm stimulating compound, given in gouty, rheumatic, and spasmodic affections of the stomach, and in scorbutic disorders. The dose is from half a fluid drachm to half a fluid ounce.

SPIRITUS CAMPRORE. Spirit of camphor. For-merly known by the names of Spiritus camphoratus; Spiritus vinosus camphoratus; Spiritus vini camphoratus. Take of camphor, four ounces; rectified spirit, two pints. Mix, that the camphor may be dissolved. A stimulating medicine, used as an external application against chilblains, rheumatism, palsy, numbness, and

gangrene.

Spiritus carui. Spirit of caraway. Formerly called Aqua seminum carui. Take of caraway seed, bruised, a pound and a half; proof spirit a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil a gallon by a gentle fire. The dose is from a fluid drachm to half a fluid ounce.

SPIRITUS CINNAMONI. Spirit of cinnamon. For merly called Aqua cinnamoni spirituosa; Aqua cinnamomi fortis. Take of cinnamon-bark, bruised, a pound; proof spirit a gallon; water sufficient to prevent empyreama. Macerate for 24 hours, and distil a gallon by a gentle fire. Spirit of cinnamon is mostly used in conjunction with other carminatives to give a pleasant flavour; it may be exhibited alone as a cert pleasant flavour; it may be exhibited alone as a car-minative and stimulant. The dose is from a fluid drachm to half a fluid ounce.

SPIRITUS CORNU CERVI. See Ammonia subcar-

Spiritus juniperi compositus. Compound spirit of juniper. Formerly called Aqua juniperi composita. Take of juniper-berries, bruised, a pound carawayseeds, bruised, fonnel-seeds, bruised, of each an ounce

and a half; proof spirits, a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil

a gallon by a gentle fire.

SPIRITUS LAVENDULE. Spirit of lavender. Formerly called Spiritus lavendulæ simplex. Take of fresh lavender flowers, two pounds; rectified spirit, a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil a gallon by a gentle fire. Though mostly used as a perfume, this spirit may be given internally as a stimulating nervine and antispasmodic. The dose is from a fluid drachm to half a fluid modic. The dose is from a fluid drachm to half a fluid ounce.

SPIRITUS LAVENDULÆ COMPOSITUS. Compound spirit of lavender. Formerly called Spiritus lavendulæ compositus matthiæ. Take of spirit of lavender, three pints; spirit of rosemary, a pint; cinnamon-bark, bruised, nutmegs, bruised, of each half an ounce; red saunders wood, sliced, an ounce. Macerate for fourteen days, and strain. An elegant and useful antispasmodic and stimulant in very general use against nervous diseases, lowness of spirits, and weakness of the stomach, taken on a lump of sugar. stomach, taken on a lump of sugar.

Spiritus Lumbricorum. The spirit obtained by

the distillation of the earth-worm is similar to harts-

horn.

Spiritus Menthæ Piperitæ. Spirit of peppermint. Formerly called Spiritus menthæ piperitidis; Aqua menthæ piperitidis spirituosa. Take of peppermint, dried, a pound and a half; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil a gallon by a gentle fire. This pos-sesses all the properties of the peppermint, with the stimulating virtues of the spirit. The dose from one fluid drachm to a fluid onnce.

SPIRITUS MENTHÆ VIRIDIS. Spirit of spearmint. Formerly called Spiritus menthæ sativæ; Aqua menthæ vulgaris spirituosa. Take of spearmint, dried, a pound and a half; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil a gallon. This is most commonly added to and distil a gallon. This is most commonly added to carminative or antispasmodic draughts, and seldom exhibited alone. The dose from one fluid drachm to

a fluid ounce.

SPIRITUS MILLEPEDARUM. A volatile virtues of which are similar to hartshorn. A volatile alkali, the

SPIRITUS MINDERERI. See Ammonia acetatis liquor. Spiritus myristica. Spirit of nutmeg. Formerly alled Aqua nucis moschata. Take of nutmegs, called Aqua nucis moschate. Take of nutmegs, bruised, two ounces; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for twenty-four hours, and distil a gallon by a gentle fire. A stimulating and agreeable spirit possessing the virtues of the nutmeg. The dose from one fluid drachm to a fluid ounce.

SPIRITUS NITRI DULCIS. See Spiritus otheris ni-

SPIRITUS SITRI DUPLEX. The nitrous acid. See

Acidum nitrosum, and Nitric acid.

SPIRITUS NITRI FUMANS. See Acidum nitrosum, and Nitris acid.

SPIRITUS NITRI GLAUBERI. See Acidum nitrosum,

and Vitric acid.

SPIRITUS NITRI SIMPLEX. The dilute nitrous acid. See Acidum nitricum dilutum.

SPIRITUS NITRI VULGARIS. This is now called aci-

dum nitricum dilutum.

dum nitricum dilutum.

STRITUS PIMENTÆ. Spirit of pimento. Formerly called Spiritus pimento. Take allspice, bruised, two ounces; proof spirit, a gallon; water sufficient to prevent emplyreuma. Macetate for 24 hours, and distil a gallon by a gentle fire. A stimulating aromatic tincture mostly employed with adstringent and carminative medicines. The dose is from half a fluid drachm to half a fluid ounce. half a fluid ounce.

half a fluid ounce.

SPIRITUS PULEGII. Spirit of pennyroyal. Formerly called Aqua pulegii spirituosa. Take of pennyroyal, dried, a pound and a half; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil a gallon by a gentle fire. This is in very general use as an emmenagogue among the lower orders. It possesses nervine and carminative return. The dose is from half a fluid deacher to half. The dose is from half a fluid drachm to half a fluid ounce.

SPIRITUS RECTOR. Boerhaave and other chemists give this name to a very attenuated principle, in which the smell of odorant bodies peculiarly reside. It is now called aroma.

Spiritus Rosmarini. Spirit of rosemary. Take of rosemary tops, fresh, two pounds; proof spirit, a gallon; water sufficient to prevent empyreuma. Macerate for 24 hours, and distil a gallon by a gentle fire A very fragrant spirit, mostly employed for external purposes in conjunction with other resolvents.

SPIRITUS SALIS AMMONIACI AQUOSUS. See Ammo-

niæ subcarbonas.

SPIRITUS SALIS AMMONIACI DULCIS. See Spiritus

SPIRITUS SALIS AMMONIACI SIMPLEX. See Ammoniæ subcarbonas.

SPIRITUS SALIS GLAUBERI. See Muriatic acid.
SPIRITUS SALIS MARINI. See Muriatic acid.

SPIRITUS VINI RECTIFICATUS. See Alkohol. Rec-tified spiritof wine is in general use to dissolve resinous and other medicines. It is seldom exhibited internally, though it exists in the diluted state in all vinous and

spirituous liquors.

Spiritus vini tenuior. STRITUS VINI TENUIOR. Proof spirit, which is about half the strength of rectified, is much employed for preparing tinctures of resinous juices, barks,

roots, &c.

SPIRITUS VITRIOLI DULCIS. See Spiritus etheris sulphurici.

SPIRITUS VOLATILIS PETIDUS. See Spiritus am-

monie fatidus.

SPISSAME'NTUM. (From spisso, to thicken.)
A substance put into oils and ointments to make them

Spitting of blood. See Hamatemesis and Hamoptysis

SPLANCHNIC. (Splanchnicus; from σπλαγχνον,

an entrail.) Belonging to the viscera.

SPLANCHNIC NERVE. The great intercostal nerve.

SPLANCHNIC NERVE. The great intercostal nerve. See Intercostal nerve.
SPLA'NCHNICA. (From σπλαγχνον, an intestine.)
Remedies for diseased bowels.
SPLANCHNOLOGY. (Splanchnologia; from σπλαγχνον, an entrail, and λογος, a discourse.) The doctrine of the viscera.
SPLEEN. Σπλην. Lien. The spleen or milt is a spongy viscus of a livid colour, and so variable in form, situation, and magnitude, that it is hard to determine situation, and magnitude, that it is hard to determine either. Nevertheless, in a healthy man it is always placed on the left side, in the left hypochondrium, be-tween the eleventh and twelfth false ribs. Its circumference is oblong and round, resembling an oval figure. It is larger, to speak generally, when the stomach is

empty, and smaller when it is compressed, or evacuated by a full stomach.

It should particularly be remembered of this viscus, that it is convex towards the ribs, and concave inter-nally: also, that it has an excavation, into which ves-

sels are inserted.

It is connected with the following parts: 1. With the stomach by a ligament and short vessels. 2. With the omentum, and the left kidney. 3. With the diaphragm, by a portion of the peritonæum. 4. With the beginning of the pancreas, by vessels. 5. With a colon, by a ligament.

In man the spleen is covered with one simple, firm membrane, arising from the peritonaum, which adheres to the spleen, very firmly, by the intervention of

cellular structure.

The vessels of the spleen are, the splenic artery coming from the codiac artery, which, considering the size of the spleen, is much larger than is requisite for the mere nutrition of it. This goes by serpentine movements, out of its course, over the pancreas, and behind the standard of the horizon given of beauties to the the stomach, and after having given off branches to the adjacent parts, it is inserted into the concave surface of the spleen. It is afterward divided into smaller the spleen. It is afterward divided into smaller branches, which are again divided into other yet smaller, delivering their blood immediately to the veins, but emitting it nowhere else. The veins, at length, come together into one, called the splenic vein, and having received the larger coronary vein of the sto-mach, besides others, it constitutes the left principal

branch of the vena portæ.

The nerves of the spleen are small; they surround the arteries with their branches; they come from a particular plexus, which is formed of the posterior branches of the eighth pair, and the great intercostal nerve.

Lymphatic vessels are almost only seen creeping

along the surface of the human spleen. 303 The use of the spleen has not hitherto been determined; yet if the situation and fabric be regarded, one would imagine its use to consist chiefly in affording some assistance to the stomach during the progress of

SPLEEN-WORT. See Asplenium ceterach, and

SPLEEN-WORT. See Asplenium ceterach, and Asplenium trichomanes.

SPLENA'LGIA. (From σπλην, the spleen, and αλγος, pain.) A pain in the spleen or its region.

SPLENETIC. (Spleneticus; from σπλην, the spleen.) Belonging to the spleen.

SPLENITIS. (From σπλην, the spleen.) Inflammation of the spleen. A genus of disease in the Class Pyrexiæ, and Order Phlegmasiæ, of Cullen; characterized by pyrexia, tension, heat, tumour, and pain in the left hypochondrium, increased by pressure. This disease, according to Juncker, comes on with a redisease, according to Juncker, comes on with a re-markable shivering, succeeded by a most intense heat, and very great thirst; a pain and tumour are perceived in the left hypochondrium, and the paroxysms for the most part assume a quartan form; when the patients expose themselves for a little to the free air, their extremities immediately grow very cold. If a hæmorrhagy happen, the blood flows out of the left nostril. The other symptoms are the same with those of the hepa-titis. Like the liver, the spleen is also subject to a chronic inflammation, which often happens after agues, and is called the ague cake, though that name is also frequently given to a scirrhous tumour of the liver suc-ceeding intermittents. The causes of this disease are in general the same with those of other inflammatory disorders; but those which determine the inflammation to that particular part more than another, are very much unknown. It attacks persons of a very plethoric and sanguine habit of body rather than others.

During the acute stage of splenitis, we must follow

the antiphlogistic plan, by general and topical bleedings, by purging frequently, and by the application of blisters near the part affected. If it should terminate in suppuration, we must endeavour to discharge the pus externally, by fomentations or poultices. When the organ is in an enlarged scirrhous state, mercury may be successful in preventing its farther progress, or even producing a diminution of the part: but proper cau-tion is required in the use of it, lest the remedy do

more harm than the disease.

Sple'Nium. (From οπλην, the spleen: so called from its efficacy in disorders of the spleen.) 1. Spleen-

2. A compressed shape like the spleen.

SPLE'NIUS. (From σπλην, the spleen: so named from its resemblance in shape to the spleen, or, according to some, it derives its name from splenium, a ferula, or splint, which surgeons apply to the sides of a fractured bone.) Splenius capitus, and splenius colli, of Albinus; and cervico-dorsi-mastoidien et dorso-trache-lien, of Dumas. The splenius is a flat, broad, and oblong muscle, in part covered by the upper part of the trapezius, and obliquely situated between the back of the ear, and the lower and posterior part of the neck.

It arises tendinous from the four or five superior spinous processes of the dorsal vertebræ; tendinous and fleshy from the last of the neck, and tendinous from the ligamentum colli, or rather the tendons of the two splenii unite here inseparably; but about the second or third vertebræ of the neck they recede from each other, so that part of the complexus may be

It is inserted, by two distinct tendons, into the transverse processes of the two first vertebrae of the neck, sending off some few fibres to the complexus and levator scapulæ; tendinous and fleshy into the upper and posterior part of the mastoid process, and into a ridge on the occipital bone, where it joins with the root of

that process

This muscle may easily be separated into two parts. Eustachius and Fallopius were aware of this; Winslow has distinguished them into the superior and inferior portions; and Albinus has described them as two distinct muscles, calling that part which is inserted into the mastoid process and os occipitis, splenius capitis, and that which is inserted into the vertebræ of the neck, splenius colli. We have here followed Douglas, and the generality of writers, in describing these two portions as one muscle, especially as they are intimately united near their origin. united near their origin.

When this muscle acts singly, it draws the head and

upper vertebræ of the neck obliquely backwards; when both act, they pull the head directly backwards.

SPLENIUS CAPITIS. See Splenius.
SPLENIUS COLLI. See Splenius.
SPLENOCE'LE. (From σπλην, the spleen, and κηλη,

a tumour.) A hernia of the spleen.

SPLINT. A long piece of wood, tin, or strong
pasteboard employed for preventing the ends of broken bones from moving, so as to interrupt the process by which fractures unite.

SPO DIUM. Σωσδιον. The spodium of Diosco-rides and of Galen are now not known in the shops, It is said to have been produced by burning cadmia alone in the furnace; for having thrown it in small pieces into the fire, near the nozzle of the bellows, they blow the most fine and subtle parts against the roof of the furnace: and what was reflected from thence was called spodium. It differed from the pompholyx in not being so pure, and in being more heavy. Pliny distinguishes several kinds of it, as that of copper, silver, gold, and lead.

SPODIUM ARABUM. Burnt ivory, or ivory black.

See Abaisir.

SPODUMENE. Prismatic triphane spar of Mohs. A mineral of a greenish white colour, first found in the island of Uton, in Sudermannland, and lately in the vicinity of Dublin. It contains the new alkali called lethia.

SPONDY'LIUM. (From σπονδυλος, a vertebra: so named from the shape of its root, or probably because it was used against the bite of a serpent called onov-

δυλις.) See Heracleum spondylium. SPO'NDYLUS. Σπονόυλος. Some have thought fit to call the spine or backbone thus, from the shape and fitness of the vertebræ, to move every way upon

one another.

SPONGE. See Spongia.
SPONGE-TENT. See Spongia præparata.
SPO'NGIA. Σπογγος; Σπογγια. Sponge.
Spongia officinalis. See

SPONGIA OFFICINALIS. The systematic name of the spongia officinalis. The systematic name of the sponge. A sea-production: the habitations of insects. A soft, light, very porous and compressible substance, readily imbibling water, and distending thereby. It is found adhering to rocks, particularly in the Mediterra nean sea, about the islands of the Archipelago. It was formerly supposed to be a vegetable production, but is now classed among the zoophytes; and analyzed, it vields the same principles with animal substances. yields the same principles with animal substances in general. Burnt sponge is said to cure effectually the bronchocele, and to be of infinite utility in scrofulous complaints. Sponge tents are employed by surgeons to dilate fistulous ulcers, &c.

SPONGIA PREPARATA. Prepared sponge. Sponge tent. This is formed by dipping pieces of sponge in hot melted emplastrum ceræ compositum, and pressing them between two iron plates. As soon as cold, the substance thus formed may be cut into pieces of any shape. It was formerly used for dilating small openings, for which it was well adapted, as when the wax melted, the elasticity of the sponge made it expand and distend the opening, in which it had been put. Sir Ashley Cooper informs us that the best modern sur-

geons seldom employ it.

SPONGIAUSTA. Burnt sponge. Cut the sponge into pieces, and beat it, that any extraneous matters may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it to a very fine powder. This preparation is exhibited with bark in the cure of scrotulous complaints, and forms the basis of a lozenge, which has been known to cure the bronchocele in many instances. The dose is from a scruple to a december of the control of the co

scruple to a drachm.

Sponglosa ossa. Ossa turbinata inferiora; Ossa nucoluta. These bones are situated in the under part of the side of the nose; they are of a triangular form and spongy appearance, resembling the os spongiosum and spongy appearance, resembling the os sponglosum superius; externally they are convex; internally they are concave; the convexity is placed towards the septum nasi, and the concavity outwards. The under edge of each bone is placed horizontally near the outer part of the nose, and ending in a sharp point behind. At the upper part of the bone are two processes, the anterior of which ascends and forms part of the lachry-

The ossa spongiosa afford a large surface for extend-ing the organ of smell by allowing the membrane of the nose to be expanded, on which the olfactory nerves are dispersed.

In the fœtus, these bones are almost complete.

Spongio'sum os. I. The ethinoid bone.

2. See Spongiosa ossa.

SPONGIO SUS. Spongy.

SPONGOI DES. (Σωργοιιδης; from σωργος, a sponge, and αδος, forma, shape: so called because it is hollow and porous, like a sponge or sieve.) See Eth-

SPORADIC. (Sparadieus; from σπειρω, to sow.) An epithet for such infections and other diseases as seize a few persons at any time or season.

Spotted lung-wort. See Pulmonaria.
SPRAIN. See Subluxatio.
SPRAT. The Clupea sprattus, of Linnæus. A small herring-like fish which comes to us between November and Marc's, and are eaten fried and pickled.
They are strong and hard of digestion.
SPRONGIDIUM. See Columnula.

SPRUCE. 1. A particular species of fir. See Pinus

2. A fermented liquor called spruce heer prepared from the spruce fir. From the quantity of carbonic acid it contains, it is found a useful antiscorbutic.

Spurge flaz. See Daphne gnidium.

Spurge laurel. See Daphne laureola.

Spurge olive. See Daphne mezereum.

[Spurge, large flowering. See Euphorbia corollata.

Spurred rye. See Pulvis parturiens: A.]

SPUTA'MEN. See Sputum.

SPUTUM. (From spuo, to spit.) Sputamen. Saliva. Any kind of expectoration.

SQUAMA'RIA. (From squama, a scale: so called from its scaly roots.) The great tooth-wort, or Plum-2. A fermented liquor called spruce beer prepared

from its scaly roots.) The great tooth-wort, or Plum-

SQUAMATUS. Scaly: applied to the nectary of the Ranunculus genus, &c. See Nectarium. SQUAMOSE. (Squamosus; from squama, a scale, because the bones be over each other like scales.)

SQUAMOSE SUTURE. The suture which unites the squamose portion of the temporal bone with the parictal.

SQUAMOSUS. Squamose. Scaled: applied to roots which are covered with fleshy scales; as in La-Scaled: applied to

thraa squamaria. SQUARROSUS. (From squarra; rough.) Squarrose. Rough, scabby, scaly. Applied to plants, &c.;

ns.Juneus squarrosus.
SQUILL. See Scilla.
Squi'lla. See Scilla.
Squi'lla. See Scilla.
Squi'lla. See Scilla.
Squi'lla. Vinegar of. See Acetum scilla.
Squina nthus. (From squinanthia, the quinsy: so named from its uses in the quinsy.) See Andropogon schananthus

STA'CHYS. (Σταχυς, a spike: so named from its spicated stalk and seed.) 1. The name of a genus of plants in the Linnwan system. Class, Didynamia; Order, Gymnospermia.

2. Some species of wild sage, and hoarhound, nettle,

&c. were formerly so called.

STACHYS FORTDA. Yellow archangel. Hedge-net-ile, or Ballote nigra.
STACHYS PALUSTRIS. Clown's woundwort or all-

STA'CTE. ($\Sigma \tau a \kappa \tau \eta$ from $\varsigma a_s^2 \omega$, to distil.) This term signifies that kind of myrrh which distils or falls in drops from the trees. It is also used by some writers for a more liquid kind of amber than what is commonly met with in the shops; whence in Scribonius Largus, Paulus Ægineta, and some others, we meet with a collyrium, and several other forms, wherein this was the Stattica.

STA'CTICON. Instillation: also an eye-water. STA'GMA. (From 50%, to distil.) 1. Any distilled

diquor.
2. The vitriolic acid.

the connexion of this bone is to the os maxillare, os palati, and os unguis, by a distinct suture in the young subject; but in the adult, by a concretion of substance. appointed to a medical professorship, at the solicitation of Hoffman: and he became the leader of a sect of physicians, in opposition to the mechanical theorists, in which he was followed by many eminent persons, as well in Germany as in other countries, notwithstanding the very fanciful nature of the hypothesis, on which his system was founded. It had been always observed, that there is a certain power in the animal body served, that there is a certain power in the animal body of resisting injuries, and correcting some of its disorders; and Van Helmont had ascribed some degree of intelligence to this power: but it was reserved for Stahl to refer it entirely to the rational soul, which, he affirmed, not only originally formed the body, but is the sole cause of all its motions, in the constant excitement of which life consists. Whence diseases were generally regarded as salutary efforts of the presiding soul to avert the destruction of the body. This siding soul, to avert the destruction of the body. This hypothesis, besides its visionary character, was justly deprecated, as leading to an inert practice, and the ne-glect of the collateral branches of medical science, even of anatomical researches, which Stahl maintained, had little or no reference to the art of heating. And in fact both he and his followers, trusting principally to the operations of nature, zealously opposed the use of some of the most efficacious remedies, as opium, cinchona, and mercury; and were extremely reserved in the employment of bleeding, vomiting, &c., although their system led them to refer most diseases to plethora. This hypothesis was maintained by Stahl with much This hypothesis was maintained by Stahl with much ingenuity in several publications, particularly in his "Theoria Medica vera," printed in 1708. The merits of Stahl, as a chemical philosopher, are of a much higher character; and the school, which he founded in this science, has only been superseded of late by farther discoveries. He was the inventor of the celebrated theory of phlogiston, which appeared to account brated theory of phlogiston, which appeared to account for the phenomenon of combustion, and was received every where with high applause. His chief chemical work was entitled "Fundamenta Chemiæ dogmaticæ et Experimentalis," first printed in 1729; but this had been preceded more than thirty years, by others, in which his doctrino was fully displayed. Stahl was elected a member of the Academy Natura Curiosorum; and he was called, in 1716, to visit the king of Prussia at Berlin, whither he went also on several subsequent occasions, and on one of these he was attacked sequent occasions, and on one of these he was attacked with a disease, which proved fatal, in the 74th year of

STALACTITES. The calcareous substances found suspended from vaults, being formed by the oozing of water charged with calcareous particles gradually eva-

porating, and leaving these particles behind.

STALAGMI'TIS. (From γαλαγμος, a dropping or distillation, because the gum which it yields escapes in that manner.) The name of a genus of plants. Class, Polygamia; Order, Monæcia.

STALAGMITIS CAMPOGIOTIES. This is now ascertained to be the tree which affords gamboge. This days from its supercoord virtues is also called gums and

drug, from its supposed virtues, is also called gummi ad podagram; gummi gutta; and, by corruption, gotta; gutta gamba; gamen; germandra; catagemu; gamboidea, &c.; and, from its gold colour, chrysopus; and, from its pargative quality, succus laxativus; succus Indicus purgans; and scammonium orientale. Gamboge is a concrete vegetable juice, which was supposed to be the produce of two trees both called by the Indicas to be the produce of two trees, both called by the Indians, to be the produce of two trees, both called by the Indians, Caracapulli, and by Linnarus, Gambogia gutta; but Kænig ascertained its true source. It is partly of a gummy, and partly of a resinous nature. It is brought to us chiefly from Gambaja, in the East Indies, either in form of orbicular masses, or of cylindrical rolls of various sizes; and is of a dense, compact, and firm texture and of a beautiful yellow colour. In medicine it is chiefly used as a drastic purge; it operates a controlle both unwards and downwards. Some cine it is chiefly used as a drastic purge; it operates powerfully both upwards and downwards. Some condemn it as acting with too great violence, while others are of a contrary opinion. The dose is from two to four grains, as a cathartic; from four to eight grains it proves emetic and purgative. The roughness of its operation is said to be diminished, by giving it in a liquid form sufficiently diluted. Rubbed with almonds from its want of taste, it is a good laxative for children. STAHL, GRORGE ERNEST, was born at Anspach, I from its want of taste, it is a good laxative for children.

It has been given in dropsy, with cream of tartar, to correct its operation. It has also been recommended by some, to the extent of fifteen grains, joined with an equal quantity of vegetable alkali, to destroy the tape-This dose is ordered in the morning, and if the worm is not expelled in two or three hours, it is repeated even to the third time, with safety and efficacy. It is asserted, that it has been given to this extent even in delicate habits. This is said to be the remedy al-luded to by Dr. Van Swieten, which was employed by Dr. Herenchwand, and with him proved so successful in the removal of the tænia lata. It is an ingredient, and probably the active one, in most of the nostrums

for expelling tæniæ.

Dr. Cullen says, that, on account of the quick passage of gamboge through the intestines, he was induced to give it in small, and frequently repeated doses, as three or four grains, rubbed with a little sugar, every three hours; and thus found it operate without griping or sickness, and, in three or four exhibitions, evacuate

a great quantity of water, both by stool and urine. STALA'GMUS. (From 5αλαξω, to distil.) Distil-

lation.

(From 5ελλω, to contract.) Healing STA LTICA.

applications

STAMEN. The male genital organ of plants, found generally within the corolla, near the pistil. Stamens were formerly called chives. They are various in number in different flowers, from one to some hundreds. This organ is essential to a plant, no one having yet been discovered, after the most careful research, that is destitute of it, either in the same flower with the pistils, or a separate one of the same species.

A stamen consists of three parts.

1. The filamentum, or filament, the part which sup-

ports the anther.

2. The anthera, placed on the filament, and the most essential part of all.

3. The pollen, or powder adhering to the anther.

STANNI PULVIS. Tin finely divided is exhibited internally as a vermifuge. It acts mechanically, and the

ternally as a vermitinge. It acts mechanically, and the fine filings are more effectual than the powder.

STANNIC ACID. A name which has been given to the peroxide of tin, because it is soluble in alkalies.

STA'NNUM. See Tin.

STAPE'DIUS. (Stapedius, sc. musculus; from stapes, one of the bones of the ear.) Musculus stapes, of Courses, and accounted stapeslies. of Dumas. of Cowper; and pyramdal-stapedien, of Dumas. A muscle of the internal ear, which draws the stapes obliquely upwards towards the cavern, by which the posterior part of its base is moved inwards, and the anterior part outwards.

STA PES. (In quo pes stat, a stirrup.) A bone of the internal ear, so called from its resemblance to a

STAPHILI'NUS. See Azygos uvula.
STAPHILINUS EXTERNUS. See Circumflexus.
STA'PHIS. Σταφις, is strictly a grape, or a bunch

of grapes; whence, from their likeness thereunto, it is applied to many other things, especially the glands of

the body, whether natural or diseased.

STAPHISA'GRIA. Σταφις αγοια, wild vine; from the resemblance of its leaves to those of the vine.) Sec Delphinium.

STAPHYLE. (Σταφυλη. A grape or raisin: so called from its resemblance.) The uvula.

STAPHYLI'NUS. (Staphylinus; from ζαφυλη, the uvula.) See Azygos uvula.

STAPHYLINUS EXTERNUS. See Circumflexus. STAPHYLINUS GRECORUM. Staphylinus sylvestris.

The wild carrot

STAPHYLO'MA. (From 5αφυλη, a grape: so named from its being thought to resemble a grape.) Staphylosis. A disease of the eyeball in which the cornea loses its natural transparency, rises above the level of the eye, and successively even projects beyond the eyelids, in the form of an elongated, whitish, or pearl-coloured tumour, which is sometimes smooth, sometimes uneven, and is attended with a total loss of sight. The proximate cause is an effusion of thick numour between the lamellæ of the cornea, so that the internal and external superfices of the cornea, very much protuberates. The remote causes are, an habitual ophthalmia, great contusion, and frequently a deposition of the variolous humour in the small-pox. The species are:

1st. Staphyloma totale, which occupies the whole transparent cornea; this is the most frequent species. The symptoms are, the opaque cornea protuberates, and if in the form of a cone, increasing in magnitude it pushes out and inverts the lower eyelid; and sometimes the morbid cornea is so elongated, as to lie on the cheek, causing friction and excoriation. The bulb of the eye being exposed to the air, sordes generate, the inferior palpebra is irritated by the cilia, and very painful red and small papilie are observable.

2d. Staphyloma racemosum, is a staphyloma formed by carnous tubercles, about the size of a small pin's

3d. Staphyloma partiale, which occupies some part of the cornea: it exhibits an opaque tumour prominent from the cornea, similar to a small bluish grape.

4th. Staphyloma scleroticæ is a bluish tumour attached to some part of the sclerotica, but arises from the tunica albuginea.

5th. Staphyloma pellucidum, in which the cornea is not thickened or incrassated, but very much extended and pellucid.

6th. Staphyloma complicatum, which is complicated with an ulcer, ectropium, caruncles, or any other disorder of the eye.

7th. Staphyloma iridis. For this species, see Ptosis

iridis.

Star thistle. See Carlina acaulis.

STARCH. Amylum. A white, insipid, combustible substance, insoluble in cold water, but forming a jelly with boiling water. It exists chiefly in the white and brittle parts of vegetables, particularly in tuberose roots, and the seeds of the gramineous plants. It may be extracted by pounding these parts, and agitating them in cold water; when the parenchyma, or fibrous parts, will first subside; and these being removed, a fine, white powder, diffused through the water, will gradually subside, which is the starch. Or the pounded or grated substance, as the roots of arum, potatoes, acorns, or horse-chesnuts, for instance, may be put into a hair-sieve, and the starch washed through with cold water, leaving the grosser matters behind. Farinaceous seeds may be ground and treated in a similar manner. Oily seeds require to have the oil expressed from them before the farina is extracted.

Starch is one of the constituent parts in all mealy farinaceous seeds, fruits, roots, and other parts of plants. Our common starch is made from wheat. It is not necessary that the grain be first bruised in mills. The entire corn, well cleansed, is soaked in cold water until the husks separate; and the grains, having become quite soft, give out, by pressure, a milky fluid. The grains are then taken out of the water by means of a sieve, put into a coarse linen sack, and transferred into the treading-tub; where they are trodden, after cold water has been poured upon them.

By this operation the starchy part is washed out, and, mingling with the water, makes it milky. The water is now drawn off, running through a sieve into the settling-tub. Fresh water is again effused upon the grains, and the same operation is continued till the water in the treading-tub is no longer rendered milky. The starch here precipitates by repose from the water that held it suspended; during which, especially in a warm season, the mucilaginous saccharine matter of the flour, that was dissolved by the water, goes into the acetous fermentation. From this cause the starch grows still purer and whiter. The water is next let off from the starch, which is several times more washed with clear fresh water; the remaining part of which is suffered to drip through linen cloths, supported by hurdles, upon which the wet starch is placed. When the starch has fully subsided, it is wrapped in, wrung between these cloths, or pressed, to extort still, more of the remaining liquid.

It is afterward cut into pieces, which are laid in airy places, on slightly burnt bricks, to be completely dried, partly by the free currency of air, and partly bricks imbibing their moisture. Lastly, the outer crust is scraped off, and they are broken into smaller

If starch be subjected to distillation, it gives out water impregnated with empyreumatic acetous acid, a little red or brown oil, a great deal of carbonic acid, and carburetted hydrogen gas. Its coal is bulky, easily burned, and leaves a very small quantity of potassa and phosphate of lime If when diffused in water it be exposed to a heat of 60° F., or upward, it will fer-ment, and turn sour; but much more so if it be not freed from the gluten, extract, and colouring matter. Thus, in starch-making, the farina ferments and becomes sour, but the starch that does not undergo fermentation is rendered the more pure by this process. Some water, already soured, is mixed with the flour and water, which regulates the fermentation, and pre-vents the mixture from becoming putrid; and in this state it is left about ten days in summer, and fifteen in winter, before the scum is removed, and the water poured off. The starch is then washed out from the bran, and dried, first in the open air, and finally in an

With boiling water, starch forms a nearly transparent mucilage, emitting a peculiar smell, neither disagreeable nor very powerful. This mucilage may be dried, and will then be semitransparent, and much resembling gum, all the products of which it affords. When dissolved, it is much more easily digested and nutritious than before it has undergone this operation.

Both acids and alkalies, combined with water, dissolve it. It separates the oxides of several metals from their solutions, and takes oxygen from many of them. It is found naturally combined with all the immediate principles of vegetables, and may easily be united with

most of them by art.
When starch is triturated with iodine, it forms combinations of various colours. When the proportion of iodine is small, these compounds are violet; when

somewhat greater, blue; and, when still greater, black.
We can always obtain the finest blue colour, by
treating starch with an excess of iodine, dissolving the
compound in liquid potassa, and precipitating by a
vegetable acid. The colour is manifested even at the instant of pouring water of iodine into a liquid which contains starch diffused through it. Hence iodine becomes an excellent test for detecting starch; and starch for detecting iodine. Besides these combinations, it appears that there is another of a white colour, in which the iodine exists in very small quantity. All of them possess peculiar properties.

Starch is not affected in the cold, by water, alkohol, or ether. But it dissolves readily, when triturated with potassa water.

Starch is convertible into sugar by dilute sulphuric Starch is convertible into sugar by dilute sulphuric acid. To produce this change we must take 2000 parts of starch, diffuse them in 8000 parts of water, containing 40 parts of strong oil of vitriol; and boil the mixture for 36 hours in a basin of silver or lead, taking care to stir the materials with a wooden rod, during the first hour of ebullition. At the end of this time, the mass having become liquid, does not require to be stirred, except at intervals. In proportion as the water evaporates, it ought to be replaced. When the liquid has been sufficiently boiled, we must add to it chalk and animal charcoal, then clarify with white of chalk and animal charcoal, then clarify with white of egg, filter the mixture through a flock of wool, and then concentrate the liquid till it has acquired a syrupy consistence. After this, the basin must be removed from the fire, in order that, by cooling, the greater part of the sulphate of lime may fall down. The pure syrup is now to be decanted off, and evaporated to the proper dryness. The greater the quantity of acid em-ployed, the less ebullition is required to convert the

starch into the saccharine matter.

The discovery of the preceding process is due to Kirchoff, of St. Petersburgh.

The presence of sulphuric acid is not indispensable for obtaining sugar from starch. It may also be obromanding sight from starch. It may also be ob-mined by leaving the starch to itself, either with or without contact of air, or by mixing it with dried gluten. At the same time, indeed, several other pro-ducts are formed. M. Theod. de Saussure's interest-ing observations on this subject are published in the Annales de Chemie et de Physique, xi. 379. The starch, brought to the state of a pulpy mass, must be left to spontaneous decomposition. The products are, lst, a sugar, like the sugar of grapes; 2d, Gum, like that from roasted starch; 3d, Amidine, a body whose properties are intermediate between those of starch and gum: and 4th, an insoluble substance, like ligneous matter. In these experiments, the mass on which he operated was made by pouring 12 parts of boiling water on 1 of starch. When it was fermented by dried gluten, he obtained-

Lignin with charcoal A trace	0.3
Undecomposed starch 4.0	3.8

Potato starch differs perceptibly from that of wheat; it is more friable; is composed of ovoid grains, about

twice the size of the other.

As starch forms the greatest part of flour, it cannot be doubted but that it is the principal alimentary substance contained in our bread. In a medical point of view, it is to be considered as a demulcent; and, accordingly, it forms the principal ingredient of an officinal lozenge in catarrhs, and a mucilage prepared from it often produces excellent effects, both taken by the mouth and in the form of clyster, in dysenteries and diarrhea, from irritation of the intestines. Milk and starch, with the addition of suct finely shred, and incorporated by boiling, was the soup employed by Sir John Pringle, in dysenteries, where the mucous membrane of the intestines had been abraded. Externally,

surgeons apply it as an absorbent in erysipelas.

STA'TICE. (From 5αrιζω, to stop: so named from its supposed property of restraining hæmorrhages.)

The name of a genus of plants in the Linnæan system. Glass, Pentandria; Order, Pentagynia. The

herb sea-thrift.

STATICE LIMONIUM. The systematic name of the sea-thrift. Sea-lavender, or rod behen. Bohen ru-brum; Limonium: Limonium majus; Behen. The roots possess astringent and strengthening qualities,

but not in a very remarkable degree.

STATIONA'RIA FEBRIS. A stationary fever. So Sydenham called those fevers which happen when there are certain general constitutions of the years, which owe their origin neither to heat, cold, dryness, nor moisture; but rather depend on a certain secret and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with such kinds of effluvia as subject the body to particular distempers, so long as that kind of constitution prevails, which, after a certain course of years, declines and gives way to another.

STAUROLITE. Grenatite, or prismatic garnet. STAUROTIDE. Grenatite. Prismatic garnet. crystallized, dark, reddish-brown garnet, found in Scotland, and Ireland.

STAVESACRE. See Delphinium staphisagris.

STEARINE. See Fat.

A subspecies of rhom

A subspecies of rhomboidal mica

STEATOCE'LE. (From ςταρ, suet, and κηλη, a tumour.) A collection of a suety substance in the scrotum

STEATOMA. (From grap, suet.) An encysted tumour, the contents of which are of a suety con-

STEEL. Chalybs. The best, hardest, finest, and closest grained iron, combined with carbon by a parti-

Cular process.

STEINHEILITE. The blue quartz of Finland.
STELOCHITES. See Osteocolla.

STELOCHITES. See Osteocolla.

STE'LLA. (From τελλω, to arise.) A star. A bandage with many crossings, like a star.

STELLA'RIA. (From stella, a star: so named from the star-like appearance of its flowers.) The name of a genus of plants. Class, Decandria; Order, Trigynia. Stitchwort.

STELLATUS. (From stella, a star.) Stellate. Starlike. Applied to the nectary of the Stapelia, &c.

STELLATE. The name of an order of plants in Linguis's Fragments of a Natural Method, consisting

Linnæus's Fragments of a Natural Method, consisting of such as have stellate leaves, and quadrified corolla mostly tetrandrous; as Galium, Asperula, Rubea tinc

STE'MA. (From 57144, to stand.) The penis.
Stemless milkvetch. See Astrgalus excapus.
STENO, Nicholas, was born at Copenhagen, in STE'MA.

Having studied with great diligence, under the celebrated Bartholin, he passed several years in visiting the best schools in different parts of Europe. His re putation was then increased, so that about the age of 29 he was appointed Physician to Ferdinand II. Grand Duke of Tuscany, with a liberal salary. He was 307

afterward honoured with the esteem of Cosmo III. who | selected him as preceptor to his son. He had been led, by the eloquence of Bossuet, to change from the Protestant to the Roman Catholic persuasion; which proved an obstacle to his accepting the invitation of Prederick III. Frederick III. to return to Copenhagen; but the succeeding King of Denmark, not imposing any religious restraint, he was induced about the year 1672 to go to his native city, where he was appointed professor of anatomy. But finding his situation less agreeable than he had expected, he resumed the education of the young prince at Florence. Some time after this he embraced the ecclesiastical profession, was speedily appointed a bishop, and then vicar apostolical to all the states of the north, in which capacity he became a zealous preacher in various parts of Germany, and died in the course of his labours in 1686. The works extant by him relate principally to medical subjects. He was a diligent cultivator of anatomy, and made some discoveries relative to the minute structure of the eye, and other parts; which are detailed in papers communicated to the academy of Copenhagen, and in some small works published by himself.

STENOTHORA CES. (From 5τρος, narrow, and θωραξ, the chest.) Those who have narrow chests are so called. STERILITY. Sterilitas. Barrenness. In women this sometimes happens from a miscarriage, or violent labour, injuring some of the genital parts; but one of the most frequent causes is the suppression of the menstrual flux. There are other causes, however, arising from various diseases incident to those parts; by which the uterus may be unfit to receive or retain the male seed;—from the tube Fallopiane being too short, or having lost their erective power; in either of which debility and relaxation; or a local debility of the genital system; by which means the parts having lost their tone, or contractile power, the semen is thrown off immediately post coitum;—from imperforation of the vagina, of the uterus, or tubæ, or from diseased

STERNO. Names compounded of this word belong to muscles which are attached to the sternum; as, STERNO-CLEIDO-HYOTDEUS. See Sterno-hyoideus.

STERNO-CLEIDO MASTOIDEUS. Sterno-mastoideus, and cleido-mastoideus, of Albinus. Mastoideus, of Douglas and Cowpu; and sterno-clavio-mastoidien, of Dumas. A muscle, on the anterior and lateral part of the neck, which turns the head to one side, and hends it forward. It arises by two distinct origins; the anterior tendinous and fleshy, from the top of the ster-num near its junction with the clavicle; the posterior fleshy, from the upper and anterior part of the clavicle. Both unite a little above the anterior articulation of the clavicie, to form one muscle, which runs obliquely up-wards and outwards to be inserted, by a thick strong tendon, into the mastoid process of the temporal bone, which it surrounds; and gradually becoming thinner, is inserted as far back as the lambdoidal suture.

STERNO-COSTALES. Vesalius considered these as forming a single muscle on each side of a triangular shape; hence we find the name of triangular adopted by Douglas and Albhus; but Verheyen, who first taught that they ought to be described as four or five distinct muscles, gave them the name of sterna costales; and in this he is very properly followed by

Winslow, Haller, and Lieutaud.

These muscles are situated at each side of the under surface of the sternum, upon the cartilages of the third, fourth, fifth, and sixth ribs. Their number varies in different subjects; very often there are only three, sometimes five, and even six, but most usually we find

The lowermost of the sterno-costales, or what would be called the inferior portion of the triangularis, arises tendinous and fleshy from the edge and inner surface of the lower part of the cartilago ensiformis, where its fibres intermix with those of the diaphragm and transversalis abdominis. Its fibres run nearly in a transverse direction, and are inserted, by a broad thin ten-don, into the inner surface of the cartilage of the sixth rib, and lower edge of that of the fifth.

The second and largest of the sterno-costales, arises tendinous from the cartilago ensiformis and lower part of the stern up, laterally, and, running a little obliquely outwards, is inserted into the lower edge of the cartilage of the fifth, and sometimes of the fourth rib.

The third arises tendinous from the sides of the middle part of the sternum, near the cartilages of the fourth and fifth ribs, and ascending obliquely outwards, is inserted into the cartilage of the third rib.

The fourth and uppermost, which is the most frequently wanting, arises tendinous from the beginning of the cartilage of the third rib and the adjacent part of the sternum, and running almost perpendicularly upwards, is inserted by a thin tendon (which covers a part of the second internal intercostal,) into the cartilage and beginning of the bony part of the second

All these muscles are more or less intermixed with one another at their origin, and this probably oceasioned them to be considered as one muscle. Fallo-pius informs us, that the plate Vesalius has given of them was taken from a dog, in which animal they are much larger than in man. Douglas has endeavoured to account for this difference, but his explanation is far

from being satisfactory.

from being satisfactory.

As this muscle arises from the Winslow calls it clavicle, as well as from the sternum, Winslow calls it sterno-cleido-hyoideus. It is a long, flat, and thin muscle, situated obliquely between the sternum and os hyoides, behind the lower part of the mastoideus, and covering the sterno-thyroideus and the kyo-thyroideus. It arises, by very short tendinous fibres, from the carpart of the sternum, from the capsular ligament that connects that bone with the clavicle, and commonly from a small part of the clavicle itself; from thence, ascending along the anterior and lateral part of the neck, we see it united to its fellow, opposite to the inferior part of the laryox, by means of a thin mem-brane, which forms a kind of linea alba. After this the two muscles separate again, and each possing over the side of the thyroid cartilage, is inserted into the basis of the os hyoides, immediately behind the insertion of the last described muscle.

Its use is to draw the os hyoides downwards.

STERNO-MASTOIDEUS. See Sterno-cloido-mastoideus. STERNO-THYROTORUS. Sterno-thyroidien, of Dumas. This is flat and thin, like the sterno-hyoideus, but longer and broader. It is situated at the forepart of the neck, between the sternum and thyroid cartilage, and behind the sterno-hyoideus. It arises broad and fleshy from the upper and inner part of the ster-num, between the carriages of the first and second ribs, from each of which it receives some few fibres, as well as from the clavicie, where it joins with the sternum. From thence, growing somewhat narrower, it ascends, and, passing over the thyroid gland and the cricoid cartilage, is inserted tendinous into the lower and posterior edge of the rough line of the thyroid cartilage, immediately under the insertion of the sterno-

hyoideus. Now and then a few of its fibres pass on to the os hyoides. Its use is to draw the thyroid cartilage, and consequently the larynx, downwards.

STERNUM. Pectoris os. The breast-bone. The sternum, os pectoris, or breast-bone, is the oblong, flat bone, placed at the forepart of the thorax. The ossification of this bone in the fortus begins from many ossification of this bone in the foctus begins from many different points at the same time, we find it, in young subjects, composed of several bones united by cartilages; but as we advance in life, most of these cartilages ossify, and the sternum, in the adult state, is found to consist of three, and scenetimes only of two pieces, the two lower portions being united into one; and very often, in old subjects, the whole is formed into one bone. But, even in the latter case, we may still observe the marks of its former divisions; so that, in describing the hone, we may very properly divide it into its upper, middle, and inferior portions.

The upper portion forms an irregular square, which,

without much reason, has, by many writers, been compared to the figure of a heart as it is painted on cards. It is of considerable thickness, especially at its upper part. Its anterior surface is irregular, and slightly convex; posteriorly, it is somewhat concave. Its upper middle part is hollowed, to make way for the trachea. On each side, superiorly, we observe an oblong articulating surface, covered with cartilage in the recent subject, for receiving the ends of the clavicies. Immediately below this, on each side, the bone becomes thinner, and we observe a rough surface for receiving the cartilage of the first rib, and, almost close to the inferior edge of this, we find the balf of such another

surface, which, combined with a similar surface in the | apart from each other. They sometimes assume a livid middle portion of the sternum, serves for the articula-tion of the carniage of the second rib.

The middle portion is much longer, narrower, and thinner than the former; but is somewhat broader and thinner below than above, where it is connected with the upper portion. The whole of its anterior surface is slightly convex, and within it is slightly concave. Its edge, on each side, affords four articulating surfaces, for the third, fourth, fifth, and sixth ribs; and parts of articulating surfaces at its upper and lower parts, for the second and seventh ribs. About the middle of this portion of the sternum we sometimes find a considerable hole, large enough in some subjects to admit the end of the little finger. Sylvius seems to have been the first who described it. Riolanus and some others after him have, without reason, supposed it to be more frequent in women than in men. In the recent subject it is closed by a cartilaginous substance; and, as it does not seem destined for the transmission of vessels, as some writers have asserted, we may, perhaps very properly, with Hunauld, consider it as an accidental circumstance, occasioned by an interruption of the ossification, before the whole of this part of the bone is completely ossified.

The third and inferior portion of the sternum is separated from the former by a line, which is seldom alto-gether obliterated, even in the oldest subjects. It is smaller than the other parts of the bone, and descends between the ribs, so as to have been considered as an appendix to the rest of the sternum. From its shape, and its being constantly in a state of cartilage in young subjects, it has been commonly named cartilage xi-phoides, ensiformis, or sword-like cartilage; though many of the ancients gave the name of xiphoides to the whole sternum; comparing the first two bones to the handle, and this appendix to the blade of the sword. The shape of this appendix varies in different subjects; in some it is longer and more pointed, in others shorter and more obtuse. Veslingins has seen it reaching as low as the navel, and incommoding the motion of the trunk forwards. In general it terminates obtusely, or in a single point; sometimes, however, it is bifurcated, and Eustachius and Haller have seen it trifid. Very often we find it perforated, for the transmission of branches of the mammary artery. In the adult it is usually ossified and tipped with cartilage, but it very often continues cartilaginous through life, and Haller once found it in this state in a woman who died in her hundredth year.

The substance of the sternum, internally, is of a light, spongy texture, covered externally with a thin bony plate; hence it happens that this bone is easily fractured. From the description we have given of it, its uses may be easily understood. We have seen it serving for the articulation of seven true ribs on each side, and hence we shall find it of considerable use in respiration. We likewise observed, that it is articurespiration. We likewise observed, that it is articulated with each of the clavicles. It serves for the origin and insertion of several muscles; it supports the mediatinum; and lastly, defends the heart and lungs; and it is observable, that we find a similar bone in almost all animals that have lungs, and even in such as have no ribs, of which latter we have an instance in the

STERNUTAMENTO RIA. So called because the powdered flowers and roots have the property of exciting

sneezing. See Achillea ptarmica.

STERTOR. A noisy kind of respiration, as is observed in apoplexy. A snoring or snorting.

STHENIA. A term employed by the followers of Dr. Brown, to denote that state of the body which dis-poses to inflammatory diseases, in opposition to those of debility, which arise from asthenia.

STIBIA'LIS. (From stibium, antimony.) An anti-

monial or medicine, the chief ingredient of which is

STIBIC ACID. Berzelius's name of the yellow oxide of antimony.

STIBIOUS ACID. So Berzelius calls the white

oxide of antimony.

STIBIUM. (Στιβιον: from σιλδω, to shine.) An ancient name of antimony. See Antimony.

STIGMA. (Στιγμα: from σιζω, to inflict blows.)

I. A small red speck in the skin, occasioning no elevation of the cuticle. Stigmata are generally distinct, or

colour, and are then termed petechia.

II. A natural mark or spot on the skin. See Navus

III. That part of the female organ of a plant which is placed at the summit of the style. It is an indispen-sable part of the fructification, and consists of a vast number of absorbing papillæ, rarely observable by the naked eye, but best seen in the Mirabilis jalapa. Botanists distinguish the following differences in the form of stigmas:

 Globose; as in Trachelium.
 Capitale, round, but flat below; as in Sorbus and Vinca.

3. Acute, ending in a point; as in Piscidia.

Obtuse; as in Nigrina. Clubbed; as in Genipi.

Emarginate, cut; as in Dentaria.

7. Peltate; as in Garcinia.
8. Uncinate, acute and reflected; as in Lantana.
9. Triangular; as in Lilium candidum.
10. Trilobed; as in Tulipa gesneriana.

Petaliform; as in Iris germanica.
 Convolute; as in Crocus.

Revolute; as in Leontodon.
 Pennicilliform, resembling a pencil-brush; as in

Milium pespalium.

15. Perforatum; as in Sloanea
16. Concave; as in Viola.
17. Bifid; as in Menyanthes.
18. Trifid; as in Amaryllis.
19. Multifid; as in Castus.
20. Strate; as in Papaver.
21. Plumose, on each side, like

21. Plumose, on each side, like a hairy pen; as in grasses

22. Four-sided; as in Amyris.

23. Pubescent, covered with hair; as in Vicia. 24. Simple, not differing from the stile at its summit;

as in Galanthus and Hippuris.

25. Sessile, on the germen; there being no stile.

The stigma is always more or less moist with a peculiar viscid fluid, which in some plants is so conspicuous as to form a large drop, though never big enough to fall to the ground. This moisture is designed for the reception of the pollen, which explodes on neeting with it; and hence the seeds are rendered capable of ripening, which, though in many plants fully formed, they would not otherwise be.

STILBITE. See Zeolite.

STILBO'MA. (From 5ιλδω, to polish.) A cosmetic STILLICI DIUM. (From stille, to drop, and cade, to fall.) A strangury, or discharge of the urine drop by dear.

to fall.) A strangury, or discharge of the urine drop by drop. Also the pumping upon a part.

STILPNOSIDERITE. A brownish black-coloured mineral, said to contain phosphoric acid. It occurs along with brown iron in Saxony and Bavaria.

STIMML Στιμμι. Antimony.

STIMULANT. (Stimulans; from stimulo, to stir up.) That which possesses a power of exciting the animal energy. Stimulants are divided into,

1. Stimulantia tonica; as sinapi, cantharides, hydrarayri praparationes.

drargyri praparationes.
2. Stimulantia diffusibilia; as alkali volatile, elec

tricity, heat, &c. 3. Stimulantia cardiaca; as cinnamomum, nux mos-

chata, wine, &c.
STIMULUS. (Stimulus, i. m.; from 5τιγμος, stigmulus, per sync. stimulus, a sting or spur.) That which rouses the action or energy of a part.

Stinking lettuce. See Lactuca virosa. STINKSTONE. Swinestone. A variety of compact luculitie, a subspecies of limestone.

STIPES. (Stypes, itis. m.; from the Greek, ςυπος.)

A stipe, or stem of a fungus, fern, or palm.

A stipe, or stem of a tangus, tern, or pain.

STIPULA. A leafy appendage to the proper leaves, or to their footstalks. In some instances they are so like unto leaves, that they are believed to be so, and can only be distinguished from leaves by their situation on the footstalk. Stipulæ are,

1. Solitary; as in Astragalus onebryckis.

2. In pairs; as in Lathyrus annuu

3. Lateral, on the side of the footstalk; as in Lotus tetraphyllus.

4. Oppositifoliar, in the side of the opposite leaves; as in Trifolium pratense.
5. Extrafoliaceous, external with respect to the leaf or footstalk; as in Astragalus onobrichis.

alba.
7. Caducous, falling off before the leaves are expanded; as in Prunus avium

Persistent, remaining after the fall of the leaf; as in Trifolium pratense.

9. Deciduous, falling with the leaves; as in many stipulated plants.

10. Spinescent, becomes thorns; as in Robinia pseudacacia.

11. Sessile; as in Pisum sativum.

12. Adnate; as in Rosa canina.
13. Decurrent; as in Crotullaria sagittalis.
14. Sheathed; as in Hedysum vaginale.
15. Lanceolate; as in Cistus helianthemum.

Subulate; as in Cassia glandulosa. Sagittate; as in Pisum maritimum. Lunate; as in Lathyrus tingitanus. Ovate; in Ononis repens. 19.

Cordate; in Ocymum sanctum. 21. Filiform; in Ononis mauritanica.

21. Filiform; in Ononis mauritanica.
22. Foliaceous; in Sambucus ebulus.
23. Entire; in Vicia cracca.
24. Serrate; in Pisum sativum.
25. Ciliate; in Passiflora fatida.
26. Toothed; in Orobus lathyroides.
27. Pinnatifid; in Viola tricolor.
STIPULARIS. Stipular: belonging to the stipula

of plants; as the spina stipularis of the Mimosa nilotica

STIZOLO BIUM. The cowage. See Dolichos. STOE CHAS. (From σοιχαδες, the islands on which

it grew.) See Lavendula stachas.
STOECHAS ARABICA See Lavendula stachas.
STOECHAS CITRINA See Gnaphalium stachas.
STOLO, (Stolo, onis. m.; a shoot, branch, or twig.)
A sucker or seyon. A runner which proceeds from the roots of some plants, and takes root in the earth. It is distinguished into a supraterraneous, which runs on the markets shows around as in Fragaria wesses, and the surface above ground; as in Fagaria vesca, and Potentilla reptans; and subterraneous, which runs under the surface, as in Triticum repens, the stolos of which are erroneously taken for the roots.

STOMACA'CE. (Stomacace, es. f.; from ςομα, the mouth, and κακος, evil.) Canker. A fetor in the mouth, with a bloody discharge from the gums. It is generally a symptom of the scurvy. It is also a name for the scurvy.

STOMACH. (Stomachus, chi. m.; from 50μα, the mouth, and χεω, to pour.) Vontriculus; called also Anocalia; Gaster; Nedys. A membraneous receptacle, situated in the epigastric region, which receives the food from the æsophagus; its figure is somewhat oblong and round: it is largest on the left side, and gradually diminishes towards its lower orifice, where it is the least. Its superior orifice, where the asophagus terminates, is called the cardia: the inferior orifice, where the intestine begins, the pylorus. The anterior surface is turned towards the abdominal muscles, and the posterior opposite the lumbar vertebre. It has two curvatures: the first is called the great curvature of the stomach, and extends downwards from one orifice to the other, having the omentum adhering to it; the second is the small curvature, which is also between both orifices, but superiorly and posteriorly. The stoboth orifices, but superiorly and posteriorly. The sto-mach, like the intestinal canal, is composed of three coats, or membranes: 1. The outermost, which is very firm, and from the peritonaum. 2. The muscular, which is very thick, and composed of various muscular fibres; and, 3. The innermost, or villeus coat, which is covered with exhaling and inhaling vessels, and mu-cus. These coa's are connected together by cellular membrane. The glands of the stomach which sepa-rate the mucus are situated between the villous and muscular coat, in the cellular structure. The arteries of the stomach come chiefly from the celiac artery, and are distinguished into the coronary, gastro-epiploic, both orifices, but superiorly and posteriorly. and are distinguished into the coronary, gastro-epiploic, and short arteries; they are accompanied by veins which have similar names, and which terminate in the vena portæ. The nerves of the stomach are very numerous, and come from the eighth pair and intercostal nerves. The lymphatic vessels are distributed throughout the whole substance, and proceed immediately to the thoracic duct. The use of the stomach is to excite hunger and partly thirst, to receive the food from the esophagus, and to retain it, till, by the motion of the stomach, the admixture of various fluids, and many

6. Intrafoliaceous, internal; as in Morus nigra and other changes, it is rendered fit to pass the right orifice lba.
7. Caducous, falling off before the leaves are exampled; as in Prunus avium.
8. Persistent remaining after the California of the Stomach, inflammation of See Gastritis.
[Stomach Pump. This is an instrument introduced] of late for the purpose of emptying the stomach of its of late for the purpose of emptying the stomach of its contents, when poison has been swallowed. It is a long catheter made of gum elastic, which being introduced into the mouth, is passed into the œsophagus and pressed forwards, until the point reaches the stomach A syringe adapted to the upper end is then applied, and the stomach is emptied of its fluid contents. If poison be swallowed in a liquid state, it may thus be most effectually removed, and rendered harmless. A.]

STOMACHIC. (Stomachicus; from ςομαχος, the stomach.) That which excites and strengthens the action of the stomach.

action of the stomach.

STOMA'CHICA PASSIO. A disorder in which there is an aversion to food; even the thought of it begets a nausea, anxiety, cardialgia, and effusion of saliva, and often a vomiting. Fasting is more tolerable than eat-ing; if obliged to eat, a pain follows that is worse than hunger itself.
STO'MACHUS. See Stomach.

STONE. See Calculus.
STONE. CROP. See Sedum acre.
STO'RAX. Tropal. See Styrax.
Storax, liquid. See Liquidambra.
STORAX LIQUIDA. See Liquidambra.

STORAX RUBRA OFFICINALIS. Cascarilla bark was so called.

Storax, white. See Myroxylon peruferum.
STORCK, Anthony, a medical professor of considerable note at Vienna, who succeeded the celebrated Van Swieten as president and director of the faculty of medicine in that university, and was also a with the appointment of principal consulting honoured with the appointment of principal consulting physician to the Empress Maria Theresa. He distinguished himself chiefly by a long and assiduous course of experiments, with various narcotic vegetables, as hemlock, henbane, stramonium, aconite, colchicum, &c.; of which, though he appears to have overrated the efficacy, yet certainly he had the merit of calling the attention of practitioners to a class of active remedies, which may often be highly useful under prudent management. His various tracts on these subjects were printed between 1760 and 1771, and they have since passed through several editions and translations. He was also author of a collection of cases, which oc-curred under his observation in the hospital at Vienna; and this work was afterward continued by his successor, Dr. Collin.

STRABALI'SMUS. See Straismus.

STRABI'SMUS. (From ςραβιζω, to squint.) Strabalismus: Strabositas. Squinting. An affection of the eye by which a person sees objects in an oblique manner, from the axis of vision being distorted. Cullen arranges this disease in the Class Locales, and Order Dyscinesiæ. He distinguishes three species:—
1. Strabismus habitualis, when from a custom of

using only one eye.

2. Strabismus commodis, when one eye in comparison with the other, from greater weakness, or mobility, cannot accommodate itself to the other.

3. Strabismus necessarius, when some change takes place in the situation or figure of the eye, or a part

STRABO'SITAS. See Strabismus. STRAHLSTEIN. See Actinolite.

STRA'MEN CAMELORUM. Camel's hay. See Andro-

pogon schænanthus.

STRAMMO'NIUM. See Stramonium.

STRAMO'NIUM. (From stramen, straw: so called from its fibrous roots.) See Datura stramonium.

from its fibrous roots.) See Datura stramonium.

STRAMONIUM OFFICINALE. See Datura stramonium.

STRAMONIUM SPINOSUM. See Datura stramonium.

STRA'NGALIS. (From γραγγενω, to torment.) A
hard, painful tumour in the breast, from milk.

STRANGURIA. See Strangury.

STRA'NGURY. (Stranguria, æ. f.; from γραγξ, a drop, and ουρου, urine.) A difficulty in making water, attended with pain and dripping. See Ischuria.

STRATIO'TES. (From γραγος, an army: so named from its virtues in healing fresh wounds, and its usefulness to soldiers.) See Achillea mille folium.

Fulness to soldiers.) See Achillea millefolium.

STRATIO TICUM. See Achillea millefolium.

STRAWBERRY. See Fragaria.

STREATHAM. A village in Surrey, where is a

weak purging water, drunk to the amount of one, two,

or more pints in a morning.

STRE MMA. (Στρεμμα: from ςρεφω, to turn.) A strain or sprain of the parts about a joint.

STRIATUS. Striate. Applied to stems, seeds, &c.;

as the stem of the Œnanthe fistula, and seeds of the

STRICTURE. Strictura. A diminution, or con-tracted state of some tube, or duct, of the body, as the cesophagus, intestines, urethra, vagina, &c. They are either organic or spasmodic. STRICTUS. In botanical language it means straight,

as Caulis strictus.

STRI'DOR. A noise of crashing

STRIDGR DENTIUM. Grinding of the teeth.
STRIGA. A species of pubescence of plants, white,
bristle-like, with broad bases mostly decumbent; as in
Borago officinalis.

STRYGIL. Strigilis. An instrument to scrape off the sweat during the gymnastic exercises of the ancients, and in their baths: strigils were made of metal, horn, or ivory, and were curved. Some were made of linen.

STRIGME'NTUM. The strigment, filth, or sordes, scraped from the skin, in baths and places of exercises. STROBILUS. A cone. A species of pericarpium, or seed-vessel. A catkin hardened and enlarged into a seed-vessel; an example of which is in the pinus, or fir. It is either conic, cylindric, ovate, globose, squamase, or spurious, consisting of membraucous and not
woody scales; as in Origanum marjorana.

STRONTIA. (So called because it was first found
in a lead mine at Strontian, in Scotland.) A grayish

white-coloured earth, found in combination with carbonic acid in the mineral called Strontianite.

Pure strontia is of a grayish-white colour; a pungent, acrid taste; and when powdered in a mortar, the dust that rises irritates the lungs and mostrils. Its specific that rises irritates the lungs and nostrils. Its specific gravity approaches that of barytes. It requires rather more than 160 parts of water at 60° to dissolve it; but of boiling water much less. On cooling, it crystallizes in thin, transparent, quadrangular plates, generally parallelograms, seldom exceeding a quarter of an inch in length, and frequently adhering together. The edges are most frequently bevelled from each side. Sometimes they assume a cubic form. These crystals contain about .68 of water; are soluble in 51.4 times their weight of water at 60°, and in little more than twice their weight of boiling water. They give a blood-red colour to the flame of burning alkohol. The solution of strontia changes vegetable blues to a green. Strontia combines with sulphur either in the wet or dry way, tia combines with sulphur either in the wet or dry way, and its sulphuret is soluble in water.

In its properties, strontia has a considerable affinity to barytes. It differs from it chiefly in being infusible, much less soluble, of a different form, weaker in its affinities, and not poisonous. Its saline compounds afford differences more marked.

The basis of strontia is strontium, a metal first procured by Sir H. Davy, in 1808, precisely in the same manner as barium, to which it is very analogous, but has less lustre. It appeared fixed, difficultly fusible, and not volatile. It became converted into strontia by exposure to air, and when thrown into water, decomposed in the strong of the s posed it with great violence, producing hydrogen gas, and making the water a solution of strontia. By igniting the mineral strontianite intensely with charcoal powder, strontia is cheaply procured.

Strontianite. See Heavy spar. STRONTIUM. The metallic base of strotnia. See

STROPHIOLUM. A little curved gland-like part near the scar or base of some seeds; as that of Asarum, but especially in several papilionaceous genera, as Ulez, Spartium, &c. Stro Phos. (From 5ρεφω, to turn.) A twisting of

STRO'PHULUS. A papulous eruption peculiar to infants, and exhibiting a variety of forms, which are described by Dr. Willan, under the titles of intertinc-

tus, albidus, confertus, volaticus, and candidus.

1. Strophulus intertinctus, usually called the red gum, and, by the French, Efforesce ce benigne. The papulæ characterizing this affection, rise sensibly above the level of the cuticle, are of a vivid red colour, and commonly distinct from each other. Their number and extent vary much in different cases. They ap-

pear most constantly on the cheeks, forearm, and back of the hand, but are sometimes diffused over the whole body. The papulæ are, in many places, intermixed with stigmata, and often with red patches of a larger size, which do not, however, occasion any elevation of the cuticle. A child's skin thus variegated, somewhat resembles a piece of red printed linen; and hence this eruption was formerly called the red gown, a term which is still retained in several counties of England, and may be found in old dictionaries. Medical writers have changed the original word for one of a similar sound, but not more significant. The strophulus intertinctus has not, in general, any tendency to become pustular; a few small pustules, containing a straw-coloured watery fluid, occasionally appear on the back of the hand, but scarcely merit attention, as the fluid is al-ways reabsorbed in a short time, without breaking the cuticle. The eruption usually terminates in scurf, or exfoliation of the cuticle; its duration, however, is very uncertain; the papulæ and spots sometimes remain for a length of time without an obvious alteration; sometimes disappear and come out again daily; but, for the most part, one eruption of them succeeds another, at longer intervals, and with more regularity. This comlonger intervals, and with more regularity. This com-plaint occurs chiefly within the first two months of lactation. It is not always accompanied with, or pre-ceded by any disorders of the constitution, but appears occasionally in the strongest and most healthy children. Some authors connect it with aphthous ulcerations common in children, supposing the latter to be a part of the same disease diffused along the internal surfaces of the mouth and intestines. The fact, however, seems to be, that the two affections alternate with each other: for those infants who have the papulous eraption on the skin are less liable to appthbe; and when the aphtha take place to a considerable degree, the skin is generally pale and free from eruption. The skin is generally pale and free from eruption. The strophulus intertinctus is, by most writers, said to originate from an acidity, or acrimonious quality of the milk taken into a child's stomach, communicated afterward to the blood, and stimulating the cutaneous excretories. This opinion might, without difficulty, be proved to have little foundation. The predisposition to the complaint may be deduced from the delicate and tender state of the skin, and from the strong determination of blood to the surface, which evidently takes place in infants. The papulous eruption is, in many cases, connected with a weak, irritable state of the alimentary canal, and consequent indigestion. For if it be by any means suddenly repelled from the surface, diarrhea, vomiting, spasmodic affections of the bowels, and often general disturbance of the constitution succeed; but as soon as it reappears, those internal com-plaints are wholly suspended. Dr. Armstrong and others have particularly noted this reciprocation, which makes the red gum, at times, a disease of some import-ance, though in its usual form it is not thought to be in any respect dangerous. On their remarks a necessary caution is founded, not to expose infants to a stream of very cold air, nor to plunge them unseasonably in a cold bath. The most violent, and even fatal symptoms, have often been the consequence of such imprudent conduct.

2. The Strophulus albidus, by some termed the white gum, is merely a variety of strophulus intertinctus, but deserves some notice on account of the different appearance of its papulæ. In place of those de-scribed as characterizing the red gum, there is a number of minute whitish specks, a little elevated, and sometimes, though not constantly, surrounded by a slight redness. These papulæ, when their tops are removed, do not discharge any fluid; it is, however, probable, that they are originally formed by the deposition of a fluid, which afterward concretes under the cuticle. They appear chiefly on the face, neck, and breast, and are more permanent than the papulæ of the red gum. In other respects, they have the same nature and tendency, and require a similar plan of treatment. Although a distinctive name has been applied to this eruption, when occurring alone, yet it is proper to ob-serve, that, in a great number of cases, there are red papulæ and spots intermixed with it, which prove its connexion with the strophulus intertinctus.

 The Strophulus confertus. An eruption of numerous papulæ, varying in their size, appears on different parts of the body in Infants, during dentition, and has thence been denominated the tooth-rash. It

STR STR

is sometimes also termed the rank red gum. About the fourth or fifth month after birth, an eruption of this kind usually takes place on the cheeks and sides of the nose, extending sometimes to the forehead and arms, but rarely to the trunk or body. The papular on the face are smaller, and set more closely together than in the red gum; their colour is not so vivid, but they are generally more permanent. They terminate at length with slight exfoliations of the cuticle, and often appear again in the same places, a short time afterward. The papulæ which, in this complaint, occasionally appear on the back or loins, are much larger, and somewhat more distant from each other, than those on the face. They are often surrounded by an extensive circle of inflammation, and a few of them contain a semi-pellucid watery fluid, which is reabsorbed when the inflammation subsides. In the seventh or eighth month, the strophulus confertus assumes a somewhat different form; one or two large irregular patches appear on the arms, shoulder, or neck; in which the papulæ are hard, of a considerable size, and set so close together, that the whole surface is of a high red colour. Most commonly the forearm is the seat of this eruption, the papulæ rising first on the back of the hand, and gradually extending upwards along the arm. Sometimes, however, the eruption commences at the clbow, and proceeds a little upwards and downwards on the outside of the arm. It arrives at its height in about a fortnight; the papule then begin to fade, and become flat at the top; afterward the cuticle exfo-liates from the part affected, which remains discoloured, rough, and irregular, for a week or two longer.

An obstinate and very painful modification of this disease takes place, though not often, on the lower extremities. The papulæ spread from the calves of the legs to the thighs, nates, loins, and round the body, as high as the navel: being very numerous and close together, they produce a continuous redness over all these parts.

these parts.

The cuticle, presently, however, shrivelled, cracks in various places, and finally separates from the skin in large pieces. During this process a new cutiele is formed, notwithstanding which the complaint recurs in a short time, and goes through the same course as before. In this manner successive eruptions take place, during the course of three or four months, and perhaps do not cease till the child is one year old, or somewhat Children necessarily suffer great uneasiness from the heat and irritation occasioned by so extensive an eruption, yet while they are affected with it, they often remain free from any internal or febrile com-This appearance should be distinguished from the intertrigo of infants, which exhibits a uniform, red, smooth, shining surface, without papulæ; and which affects only the lower part of the nates and inwhich anects only the lower part of the hates and inside of the thighs, being produced by the stimulus of the urine, &c. with which the child's clothes are almost constantly wetted. The strophulus confertus, where the child is otherwise healthy, is generally ascribed to a state of indigestion, or some feverish complaint of the mother or nurse. Dr. Willan, however, asserts, that he has more frequently seen the eruption when no such cause was evident. It may, with more probability, be considered as one of the numerous symptoms of irritation, arising from the inflamed and painful state of the gums in dentition; since it always occurs during that process, and disappears soon after the first teeth have cut the gums.

4. The Strophulus volaticus is characterized by an appearance of small circular patches, or clusters of papulæ, arising successively on different parts of the body. The number of papulæ in each cluster is from six to twelve. Both the papulæ and their interstices are of a high red colour. These patches continue red, with a little heat, or itching, for about four days, when they turn brown, and begin to exfoliate. As one patch declines another appears at a small distance from it. declines, another appears at a small distance from it: and in this manner the complaint often spreads graand in this manner the complaint often spreads gradually over the face, body, and limbs, not terminating in less than three or four weeks. During that time the child has sometimes a quick pulse, a white tongue, and seems uneasy and fretful. In many cases, however, the cruption takes place without any symptoms of internal disorder. The above complaint has been by some writers denominated ignis volaticus infantum; under this title Astruc and Lowry have described one of the forces of gratia lactes in which a successive of the forms of crusta lactea, in which a successive | that liquid, without losing its bitter taste.

eruption of pustules takes place on the same spet generally about the mouth or eyes, in children of different ages, and sometimes in adults. The macula velatica infantum mentioned by Wittichius, Sennertus, and S. bizeus, agree in some respects with the strophulus volaticus; but they are described by other German authors as a species of erysipelas, or as irregular efflores-cences affecting the genitals of infants, and often proving fatal. The strophulus volaticus is a complaint by no means frequent. In most cases which have come under Dr. Willan's observation, it appeared between the third and sixth month; in one instance, however, it occurred about ten days after birth, and continued three weeks, being gradually diffused from the checke and forehead to the scalp, afterward to the trunk of the body and to the extremities; when the patches exfoli-ated, a red surface was left, with a slight border of detached cuticle.

Strophulus candidus. In this form of strophulus, the papulæ are larger than in any of the foregoing spe-They have no inflammation round their base; their surface is very smooth and shining, whence they appear to be of a lighter colour than the adjoining cuticle. They are diffused, at a considerable distance from each other, over the loins, shoulders, and upper part of the arms; in any other situation they are seldom found.

This eruption affects infants about a year old, and most commonly succeeds some of the acute diseases to which they are liable. Dr. Willan has observed it on their recovery from a catarrhal fever, and after in-flammation of the bowels, or lungs. The papulæ continue hard and elevated for about a week, then gradually subside and disappear.

STRU'MA. (Struma, a. f.; from strue, to heap up, or a struendo, because they grow insensibly.) This term is generally applied to scrofula, and by some to bronchocele, or an induration of the thyroid gland.

STRU'MEN. (From struma, a scrofulous tumour.) An herb so called from its uses in healing strumous tumours.

STRUMOUS, (Strumosus; from struma, a wen or scrofula) Of the nature of scrofula.

STRUMUS. An obsolete name of the berry bearing chickweed, which was supposed to be efficacious in

the cure of scrofula. See Cucubalas bacciferus.

STRUTHIUM. (From 500θ05, a sparrow: so named from the resemblance of its flowers to an unfledged sparrow.) The master-wort. See Imperatoria ostruthium.

STRYCHNIA. Strychnine. An alkaline substance obtained from the bean of the strychnos ignatia by the following process: The bean was rasped down as small as possible. It was then exposed to the action of nitric ather in a Fapin's digester. The residue, thus deprived of a quantity of fatty matter, was digested in alkohol as long as that reagent was capable of dissolving any thing. The alkoholic solutions were evaporated to dryness, and the residue redissolved in water. Caustic potassa being dropped into the solution, a white crystalline precipitate fell, which was strychnia. It was purified by washing it in cold water, dissolving it in alkohol, and crystallizing it. Strychnia was obtained likewise from the bean of the strychnos ignatia, by boiling the infusion of the bean with mag nesia, in the same manner as Robiquet had obtained morphia from the infusion of opium.

The properties of strychnia, when in a state of pu

rity, are as follows:

It is crystallized in very small four-sided prisms, terminated by four-sided low pyramids. It has a white colour; its taste is intolerably bitter, leaving a metal-lic impression in the mouth. It is destitute of smell. It is not altered by exposure to the air. It is neither fusible nor volatile, except at temperatures at which it undergoes decomposition. It is charred at the temperature at which oil enters into ebullition (about 580°). When strongly heated, it swells up, blackens, gives out empyreumatic oil, a little water, and acetic acid; car-bonic acid and carburetted hydrogen gases are disengaged, and a bulky charcoal remains behind. When heated with peroxide of copper, it gives out only carbonic acid gas and water. It is very little soluble in cold water, 100,000 parts of that liquor dissolving only 15 parts of strychnia; but it dissolves in 2,500 times its weight of boiling water. A cold solution of strychnis in water may be diluted with 100 times its volume of

312

acts with prodigious energy. A locked jaw is induced in a very short time, and the animal is speedily destroyed. Half a grain of strychnia blown into the throat of a rabbit proved fatal in five minutes, and brought on locked jaw in two minutes.

Sulphate of strychnia is a salt which crystallizes in transparent cubes, soluble in less than ten times its

weight of cold water. Its taste is intensely bitter, and the strychnia is precipitated from it by all the soluble salifiable bases. It is not altered by exposure to the air.

Muriate of strychnia grystallizes in very small needles, which are grouped together, and before the microscope exhibit the form of quadrangular prisms. When exposed to the air it becomes opaque. It is more soluble in water than the sulphate, has a similar taste, and acts with the same violence upon the animal economy as all the other salts of strychnia.

Phosphate of strychnia crystallizes in four-sided isms. It can only be obtained neutral by double deprisms.

composition.

Nitrate of strychnia can be obtained only by dissolving strychnia in nitric acid, diluted with a great deal of water. The saturated solution, when cautiously evaporated, yields crystals of neutral nitrate in pearly needles. This salt is much more soluble in hot than in cold water. Its taste is exceedingly bitter, and it acts with more violence upon the animal economy than pure strychnia. It seems capable of uniting with an excess of acid. When heated, it becomes yellow, and undergoes decomposition. It is slightly soluble in alko-

hol, but is insoluble in ather.

When concentrated nitric acid is poured upon strychnia, it immediately strikes an amaranthine colour, followed by a shade similar to that of blood. To this colour succeeds a tint of yellow, which passes afterward into green. By this action the strychnia seems to be altered in its properties, and to be converted into a substance still capable of uniting with

Carbonate of strychnia is obtained in the form of white flocks, little soluble in water, but soluble in carbonic acid.

Acetic, oxalic, and tartaric acids form with strychnia neutral salts, which are very soluble in water, and more or less capable of crystallizing. They crystal-lize best when they contain an excess of acid. The neutral acetate is very soluble, and crystallizes with

Hydrocyanic acid dissolves strychnia, and forms

with it a crystallizable salt.

Strychnia combines neither with sulphur nor carbon. When boiled with iodine, a solution takes place, and iodate and hydriodate of strychnia are formed. Chlorine acts upon it precisely in the same way.

Strychnia, when dissolved in alkohol, has the property of precipitating the greater number of metallic oxides from their acid solutions. It is precipitated by the alkalies and alkaline earths; but the effect of the

from στρωννυμι, to overthrow, and applied most probably from the overpowering narcotic quality of the panely from the everyowering narcolic quanty of the plant to which it was assigned, $\sigma r \rho \nu \chi \nu \sigma_0$ of the Greeks being a kind of nightshade. Linneus adopted this name for the present genus, on account of the analogy of its narcotic properties with the plant of the ancients. Some derive it from $\varsigma \rho \nu \chi \omega_0$, to torment: from its properties of producing insanity.) The name of a genus of plants in the Linneus parton. of plants in the Linnman system. Class, Pentandria; Order, Monogynia.

STRYCHNOS NUX VOMICA. The systematic name of the tree, the seed of which is called the poison-nut. Nux vomica; Nux metelle. The nux vomica, lignum rolubrinum, and faba sancti Ignatii, have been long known in the Materia Medica as narcotic poisons, brought from the East Indies, while the vegetables which produced them were unknown, or at least not

botanically ascertained.

When strychnia is introduced into the stomach, it of Caniram cucurbitifera malabariensis, of Plukenet,

now called Strychnos nux vomica.

To this genus also, but upon evidence less conclusive, he likewise justly referred the colubrinum. But the fahi sancti Ignatii he merely conjectured might belong to this family, as appears by the query, An Strychni species? Which subsequent discoveries have enabled us to decide in the negative; for in the Supp. Plant. it constitutes the new genus Ignatia, which Lourelro has lately confirmed, changing the specific name amara to that of pailippinica. The strychnos and ignatia are, however, nearly allied, and both rank under the Order Solanaceæ.

Dr. Woodville has inquired thus far into the botanical origin of these productions, from finding that, by medical writers, they are generally treated of under the same head, and in a very confused and indiscrimi-nate manner. The seed of the fruit, or berry of this tree, Strychnos nux vomica, is the officinal nux vomica: it is flat, round, about an inch broad, and near a quarter of an inch thick, with a prominence in the middle on both sides, of a gray colour, covered with a kind of woolly matter; and internally hard and tough To the taste it is extremely bitter, but has no remarkable smell. It consists chiefly of a gummy matter, which is moderately bitter; the resinous part is very inconsiderable in quantity, but intensely bitter; hence rectified spirit has been considered as its best menstruum.

Nux vomica is reckoned among the most powerful poisons of the narcotic kind, especially to brute animals; nor are instances wanting of its deleterious effects upon the human species—It proves fatal to dogs in a very short time, as appears by various authorities. Hillefield and others found that it also poisoned hares, foxes, wolves, cats, rabbits, and even some birds, as crows and ducks; and Loureiro relates, that a horse died in four hours after taking a drachm of the seed in a half-roasted state.

The effects of this baneful drug upon different animals, and even upon those of the same species, appear to be rather uncertain, and not always in proportion to the quantity of the poison given. With some animals it produces its effects almost instantaneously; with others, not till after several hours, when laborious respiration, followed by torpor, tremblings, coma, and convulsions, usually precede the fatal spasms, or tetanus, with which this drug commonly extinguishes life.

From four cases related of its mortal effects upon human subjects, we find the symptoms corresponded nearly with those which we have here mentioned of brutes; and these, as well as the dissections of dogs killed by this poison, not showing any injury done to the stomach or intestines, prove that the nux vomica acts immediately upon the nervous system, and destroys life by the virulence of its narcotic influence.

The quantity of the seed necessary to produce this effect upon a strong dog, as appears by experiments, need not to be more than a scruple; a rabbit was killed by five, and a cat by four, grains; and of the four persons to whom we have alluded, and who unfortunately perished by this deleterious drug, one was a girl ten years of age, to whom fifteen grains were exhibited at twice for the cure of an ague. Loss, however, tells us, that he took one or two grains of it in substance, without discovering any bad effect; and that a friend of his swallowed a whole seed without

In Britain, where physicians seem to observe the rule Saltem non nocere, more strictly than in many other countries, the nux vomica has been rarely, if ever, employed as a medicine. On the Continent, however, and especially in Germany, they have cer-tainly been guided more by the axiom, "What is incapable of doing much harm, is equally unable to do much good." The truth of this remark was very fully exemplified by the practice of Baron Störck, and is farther illustrated by the medicinal character given of nux vomica, which, from the time of Gesner till that of a modern date, has been recommended by a succession of authors as an antidote to the plague, as a febrifuge, as a vermifuge, and as a remedy in mania, hypochondriasis, hysteria, rheumatism, gout, and canine madness. In Sweden, it has of late years been suc-By the judicious discrimination of Linnaus, the nux vomica was found to be the fruit of the tree described and figured in the Hortus malabaricus, under the name flux for twelve hours, which afterward returned 313

A woman who took a scruple of this drug night and morning, two successive days, is said to have seized with convulsions and vertigo, notwithstanding which the dysenteric symptoms returned, and the disorder was cured by other medicines; but a pain in the stomach, the effect of the nux vomica, continued

afterward for a long time.

Bergius, therefore, thinks it should only be adminis-tered in the character of a tonic and anodyne, in small doses (from five to ten grains), and not till after proper laxatives have been employed. Loureiro recommends it as a valuable internal medicine in fluor albus; for which purpose he roasts it till it becomes perfectly black and friable, which renders its medicinal use safe, without impairing its efficacy. It is said to have been used successfully in the cure of agues, and has also been reckoned a specific in pyrosis, or water-brash.

STRYCHNOS VOLUBILIS. The systematic name of

bean. See Ignatia amara.

STUPEFACIENT. (Stupefaciens; from stupefacio, to stupify.) Of a stupifying quality.

STUPHA. (From ςυφω, to bind.) Stupa; Stuppa.

A stupe, or fomentation. STU POR. (From Stupeo, to be senseless.) Insensibility.

STUPPA. See Stupha.
STYE. See Hordeolum.
STY GIA. (From Styx, a name given by the poets to one of the rivers in hell.) A water made from sublimate, and directed in old dispensatories, was so called from a supposition of its poisonous qualities. A name

of the Aqua regia also, from its corrosive qualities. STYLIFORM. (Styliformis; from stylus, a bodkin, and forma, a likeness.) Shaped like a bodkin, or

style.

STYLISCUS. (From 50205, a bodkin.) A tent made

in the form of a bodkin.

STYLO. Names compounded of this word belong to muscles which are attached to the styloid process of the temporal bone; as,

STYLO-CERATO-HYOIDEUS. Sec Stylo-hyoideus.

STYLO-CHONDRO-HYOIDEUS. See Stylo-hyoideus.
STYLO-GLOSSUS. Stylo-glosse, of Dumas. A muscle situated between the lower jaw and os hyoides laterally, which draws the tongue aside and backwards. It arises tendinous and fleshy from the styloid process, and from the ligament which connects that process to the angle of the lower jaw, and is inserted into the root of the tongue, runs along its rides, and is

insensibly lost near its tip.

STYLO-HYODEUS. Stylo-hyoidien, of Dumas. A muscle situated between the lower jaw, and os hyoides laterally, which pulls the os hyoides to one side and a little upwards. It is a small, thin, fleshy muscle, situated between the styloid process and os hyoides, under the posterior belly and middle tendon of the digastricus, near the upper edge of that muscle. It arises by a long thin tendon, from the basis and posterior edge of the styloid process, and, descending in an oblique directhe styloid process, and, descending in an conque direc-tion, is inserted into the lateral and anterior part of the os hyoides, near its horn. The fleshy belly of this muscle is usually perforated on one or both sides, for the passage of the middle tendon of the digastricus. Sometimes, though not always, we find another smaller muscle placed before the stylo-hyoideus, which, from its having nearly the same origin and insertion, and the same use is called stylo-hyoideus-alter. It seems the same use, is called stylo-hyoideus-alter. It seems to have been first known to Eustachius: so that Doug-It seems las was not aware of this circumstance when he placed it among the muscles discovered by himself. It arises from the apex of the styloid process, and sometimes by a broad and thin aponeurosis, from the inner and posterior part of the angle of the lower jaw, and is inserted into the appendix, or little horn, of the os hyoides.

The use of these muscles is to pull the os hyoides. The use of these muscles is to pull the os hyoides to one side, and a little upwards.

STYLO-HYOIDEUS-ALTER. See Stylo-hyoideus.

STYLO-MASTOID FORAMEN. Foramen stylo-mastoideum. A hole between the styloid and mastoid process of the temporal bone, through which the portio dura of the auditory nerve passes to the temples.

STYLO-PHARYNGEUS. Stylo-thyro-pharyngien, of Dumas. A muscle situated between the lower jaw and os hyoides laterally, which dilates and traises the pharents.

os hyoides laterally, which dilates and raises the pha-rynx and thyroid cartilage upwards. It arises fleshy from the root of the styloid process, and is inserted into | ambra.

the side of the pharynx and back part of the thyroid

cartilage.
STYLUS. The style of a flower is the column which proceeds from the germen, and bears the stigma It is,

1. Filiform, in Jasminum, and Zea mays.

2. Linear, in Orobus.
3. Subulate, thicker below than towards apex; asin Geranium.

4. Clavate, thicker at its summit than towards ite base; as in Leucojum vernum.
5. Triangular, in Pisum.

6. Bifid, in Polygonum persicaria. Trifid, in Bryonia and Momordica.

8. Dichotomous, divided into two, which again bifurcate; as in Cordia.

Long, much more so than the stamina; as in Campanula and Dianthus.

Campanula and Dinathus.

10. Persistent, not going off after the fecundation of the germen; as Synapis.

STYMATO SIS. (From ςνω, to have a priapism.) A violent erection of the penis, with a bloody discharge. STYPTE RIA. (From ςνψω, to bind: so called from its astringent properties.) Alum.

STYPTIC. (Stypticus; from ςνψω, to adstringe.) A term given to those substances which posses the power of stopping harmographyses such as turnenting. power of stopping hamorrhages such as turpentine, aluni, &c.

STYRACI'FLUA. (From styrax, storax, and fluo, to

STYRACI FLOX. (From styrax, storax, and fluo, to flow.) See Liquidambra.

STYRAX. (Styrax, acis. m. and f.; from swax, a reed in which it was used to be preserved.) 1. The name of a genus of plants in the Linnean system. Class, Decandria; Order, Monogynia.
2. The pharmacopoial name of the Styraz ca-

lamita.

STYRAX ALBA. See Myroxylon peruiferum.
STYRAX BENZOIN. The systematic name of the tree which affords the gum benzoin. Benzoe; Benjoinum; Assa dulcis; Assa odorata; Liquor cyreniacus; Balzoinum; Benzoin; Benjui; Benjuin. Gum-benjamin. This substance is classed, by modern chemists, among the balsams. There are two kinds of benzoin; benzoe amygdaloides, which is formed of white tears, tesembling almonds, united together by a brown matresembling almonds, united together by a brown matter; and common benzoin, which is brown and without tears. The tree which affords this balsam, formerly called Laurus benzoin; Benzoifera; Arbor benici, is the Styrax-foliis oblong is acummatis, subtus tomen-tosis, racemis compositis longitudine foliorum, of Dryander, from which it is obtained by incisions. The benzoin of the shops is usually in very large brittle masses. When chewed it imparts very little taste, except that it impresses on the palate a slight sweetness; its smell, especially when rubbed or heated, is extremely fragrant and agreeable. Gum-benjamin was trenely fragrant and agreeane. Gum-benjamin was analyzed by Brande. The products obtained by distillation were, from 100 grains, benzoic acid, 9 grains; acidulated water, 5.5; butyraceous and empyreumatic oil, 60; brittle coal, 22; and a mixture of carburetted hydrogen and carbonic acid gas, computed at 3.5. On treating the empyreumatic oil with water, however, 5 grains more of acid were extracted, making 14 in the

From 1500 grains of benzoin, Bucholz obtained J250 of resin; 187 benzoic acid; 25 of a substance similar to balsam of Peru; 8 of an asomatic substance soluble in water and alkohol; and 30 of woody fibres and impurities.

Æther, sulphuric and acetic acids, dissolve benzoin; so do solutions of potassa and soda. Nitric acid acts violently on it, and a portion of artificial tannin is formed. Ammonia dissolves it sparingly. It has rarely been used medicinally in a simple state, but its preparations are much esteemed against inveterate preparations are much esteemen against inveterate coughs and phthisical complaints, unattended with much fever; it has also been used as a cosmetic, and in the way of fumigation, for the resolution of indolent tumours. The acid of benzoin is employed in the tinctura camphora composita, and a tincture is directed to be made of the balsam.

STYRAX CALAMITA. Storax in the cane, because it was formerly brought to us in reeds, or canes. See Styrax officinalis.

STYRAX COLATA. Strained storax.

STYRAX LIQUIDA. Liquid storax. See Liquid

Styrax officinalis. The systematic name of the tree which affords the solid storax. Officinal storax. weight of nitric acid, of the specific gravity of 1.26, in a tubulated retort, and distil the mixture with a gen-Styrax-foliis ovatis, subtus villosis, racemis simpli-cibus folio brevioribus, of Linnaus. There are two kinds of storax to be found in the shops; the one is usually in irregular compact masses, free from impurities, of a reddish-brown appearance, and interspersed with whitish tears, somewhat like gum ammoniac, or benzoin; it is extremely fragrant, and upon the appli-cation of heat readily melts. This has been called storax in lump, red storax, and, when in separate tears, storax in tears. The other kind, which is called the common storax, is in large masses, very light, and bears no external resemblance whatever to the former storax, as it seems almost wholly composed of dirty saw-dust, caked together by resinous matter. Storax was formerly used in catarrhal complaints, coughs, asthmas, obstructions, &c. In the present practice it is almost totally disregarded, notwithstanding it is an efficacious remedy in nervous diseases.

STYRAX RUBRA. Red storax, or storax in the tear.

SUB. 1. In anatomy, it is applied to parts which lie under the other word or name, which sub precedes; as subscapularis, under the scapula, &c.

2. In pathology, it is used to express an imperfect disease or a feeble state of a disease, as subjuvation.

disease, or a feeble state of a disease; as subluxation,

subacute, &c.
3. In botany, when shape, or any other character, cannot be precisely defined, sub is prefixed to the term

used; as subrotundus, roundish; subsessiles, not quite destitute of a footstalk, &c.
4. In chemistry, this term is applied, when a salinable base is predominant in a compound, there being a deficiency of the acid; as subcarbonate of potassa,

SUBACE TAS CUPRI. See Verdigris.

SUBACETATE. Subacetas. An imperfect acetate.

Subacetate of copper. See Verdigris.
Subala'ris vena. The vein of the axilla or

Subcarbo'nas potassæ. See Potassæ subcarbonas.

SUBCARBONAS FERRI. See Ferri subcarbonas. SUBCARBONAS PLUMBI. See Plumbi subcarbonas. SUBCARBONATE. Subcarbonas. An imperfect

SUBCARTILAGI'NOUS. (Subcartilaginosus; from sub, under, and cartilage, a cartilage.) Of a structure approaching to that of cartilage.

SUBCLAVIAN. (Subclaviculus; from sub, beneath, and clavicula, the clavicle.) That which is, or

passes, under the clavicle.

SUBCLAVIAN ARTERY. The right subclavian arises from the arteria innominata, and proceeds under the clavicle to the axilla. The left subclavian arises from the arch of the aorta, and ascends under the left clavicle to the axilla. The subclavians in their course give off the internal mammary, the cervical, the vertebral, and the superior intercostal arteries.

Subclavian vein. This receives the blood from the

veins of the arm, and runs into the vena cava superior.
SUBCLA'VIUS. (From sub, under, and clavicula,
the channel bone: as being situated under the clavicle,
or channel bone.) Subclavianus. Costo-claviculaire, of Dumas. A muscle, situated on the anterior part of the thorax, which pulls the clavicle downwards and forwards. It arises tendinous from the cartilage that joins the first rib to the sternum, is inserted after becoming fleshy into the inferior part of the clavicle, which it occupies from within half an inch of the sternum as far outwards as to its connexion, by a ligament,

with the coracoid process of the scapula.

SUBCRURÆ'US. A name of two little muscular slips sometimes found under the cruræus; they are inserted into the capsular ligament which they pull up.

SUBCUTANEOUS. (Subcutaneus; from sub, under, and cutts, the skin.) Under the skin; a name given to some nerves, vessels, glands, &c. which are very superficial.

SUBCUTANEOUS GLANDS. Glandula subcutanea. These are sebaceous glands lying under the skin, which

they perforate by their excretory ducts.

SUBCUTA'NEUS. See Platysma myoides.

SUBER. Cork. See Quercus suber.

SUBCUTA NEUS. See Platysma myotaes.

SUBER. Cork. See Quercus suber.

SUBERIC ACID. Acidum subericum. This acid
was obtained by Brugnatelli from cork, and afterward
more fully examined by Bouillon la Grange. To pro
and mergo, to sink.) Drowning. A variety of the

the heat as long as any red fumes arise. As the distil-lation advances, a yellow matter, like wax, appears on the surface of the liquid in the retort. While its con-tents continue hot, pour them into a glass vessel, placed on a sand heat, and keep them continually stirring with a glass rod; by which means the liquid will gradually grow thicker. As soon as white penetrating vapours appear, let it be removed from the sand heat, and kept stirring till cold. Thus an orange-coloured mass will be obtained, of the consistence of honey, of a strong sharp smell while hot, and a peculiar aromatic smell when cold. On this, pour twice its weight of boiling water, apply heat till it liquefies, and filter. As the filtered liquor cools, it deposites a powdery sediment, and acquires a thin pellicle. Separate the sediment by filtration, and evaporate the fluid nearly to dryness. The mass thus obtained is the suberic acid, which may be purified by saturating with an alkali, and precipitating by an acid, or by boiling it with charcoal

Chevreuil obtained the suberic acid by mere digestion of the nitric acid on the grated cork, without distillation, and purified it by washing with cold water. 12 parts of cork may be made to yield one of acid. When pure, it is white and pulverulent, having a feeble taste, and little action on litmus. It is soluble in 80 parts of water at 55½° F. and in 38 parts at 140°. It is much more soluble in alkohol, from which water throws down a portion of the suberic acid. It occasions a white precipitate when poured into acetate of lead, nitrates of lead, mercury, and silver, muriate of tin, and proof lead, mercury, and silver, muriate of tin, and pro-tosulphate of iron. It affords no precipitate with solu-tions of copper or zinc. The subcrates of potassa, soda, and ammonia are very soluble. The two latter may be readily crystallized. Those of barytes, lime, magnesia, and alumina, are of sparing solubility. Sublimane'stun. (From sublime, to lift up.) The

pendulous substance which floats in the middle of the

urine,
SUBLIMATE. See Hydrargyri oxymurias.
Sublimate, corrosive. See Hydrargyri oxymurias.
SUBLIMATION. (Sublimatio; from sublimo, to raise or sublime.) A process by which volatile substances are raised by heat, and again condensed in a solid form. This chemical process differs from evaporation only in being confined to solid substances. It is usually performed either for the purpose of purifying certain substances, and disengaging them from extranceous matters: or else to reduce into yapour, and comneous matters; or else to reduce into vapour, and com bine, under that form, principles which would have united with greater difficulty if they had not been

As all fluids are volatile by heat, and consequently capable of being separated, in most cases, from fixed matters, so various solid bodies are subjected to a similar treatment. Fluids are said to distil, and solids to sublime, though sometimes both are obtained in one and the same operation. If the subliming matter concretes into a solid, hard mass, it is commonly called a sublimate; if into a powdery form, flowers.

The principal subjects of this operation are, volatile

alkaline salts; neutral salts, composed of volatile alkali and acids, as sal ammoniac; the salt of amber, and flowers of benzoin, mercurial preparations, and sulphur. Bodies of themselves not volatile are frequently made to sublime by the mixture of volatile ones; thus iron is carried over by sal ammoniac in the preparation

of the flores martiales, or ferrum ammoniatum.

The fumes of solid bodies in close vessels rise but a little way, and adhere to that part of the vessel where

SUBLI'MIS. See Flexor brevis digitorum pedis, and Flexor sublimis perforatus.

SUBLINGUAL. (Sublingualis; from sub, under,

and lingua, the tongue.) A name given to parts immediately under the tongue.

SUBLINGUAL GLANDS. Glandulæ sublinguales, vel Bortholiniana, vel Riviniana. The glands which are situated under the tougue, and secrete saliva. Their excretory ducts are called Rivinian from their dis-

apoplexia suffocata. Sauvages terms it asphyxia im-

mersorum.
SUBMERSUS. Plunged under water: applied to leaves which are naturally under water, while others of the plants are above; as in Ranunculus aquatilis.

SUBMU'RIAS HYDRARGYRI. Sec Hydrargyri sub-

SUBMURIATE. Submurias. An imperfect mu-SUBORBITA'RIUS. The suborbitary nerve; a branch

of the fifth pair.

Subphosphuretted hydrogen. See Phosphorus.
SUBROTUNDUS. Roundish: applied to several
parts of plants. The leaf of the Pyrola is subrotund.
SUBSALT. A salt having an excess of base beyond what is requisite for saturating the acid, as supersalt is one with an excess of the acid. The sulphate of potassa is the neutral compound of sulphuric acid and potassa; subsulphate of potassa, a compound of the same ingredients, in which there is an excess of pase; supersulphate of potassa, a compound of the same acid and the same base, in which there is an excess of

SUBSCAPULA'RIS. (From sub, under, and scapula, the shoulder-blade.) Sous-scapulo-trockinien, of Dumas. Infra-scapularis. The name of this muscle sufficiently indicates its situation. It is composed of many fasciculi of tendinous and fleshy fibres, the marks of which we see imprinted on the under surface These fasciculi, which arise from all of the scapula. the basins of that bone internally, and likewise from its superior, as well as from one-half of its inferior costa, unite to form a considerable flat tendon which adheres to the capsular ligament, and is inserted into the upper part of the less tuberosity at the head of the os humeri.

The principal use of this muscle is to roll the arm inwards. It likewise serves to bring it close to the ribs; and, from its adhesion to the capsular ligament,

it prevents that membrane from being pinched. SUBSU'LTUS. (From subsulto, to leap.) Sub-sultus tendinum. Weak convulsive motions or twitchings of the tendons, mostly of the hands, generally observed in the extreme stages of putrid fever.

SUBU'BERES. (From sub, under, and ubera, the breasts.) This term hath been used by some writers for those infants who yet suck, in distinction from those who are weaned, and then are called exuberes.

SUBULATUS. Subulate. Awl shaped: applied in botany to leaves, receptacles, &c. which are tapering from a thick base to a point like an awl; as the leaf of the Salsola kali, and receptacle of the Scabiosa atropurparea.

SUCCEDA'NEUM. A medicine substituted for another.

SUCCENTURIA'TI MUSCULI. The pyramidal muscles of the belly.

SUCCENTURIATI RENES. Two glands lying above the kidneys.

Su'cci scorbutici. The juice of English scurvy-

SUCCINATE. Succinas. A salt formed by the combination of the acid of smiler, or succinic acid, with a salifiable base, succinate of potassa, succinate of copper, &c.

SUCCINIC. (Succinicus; from Succinum, amber.)

Of or belonging to amber.

SUCCINIC ACID. Acidum succinicum. Sal succini. It has long been known that amber, when exposed to distillation, affords a crystallized substance, which subtimes into the upper part of the vessel. Before its na-ture was understood it was called salt of amber; but it is now known to be a peculiar acid, as Boyle first discovered. The crystals are at first contaminated with a little oil, which gives them a brownish colour; but they may be purified by solution and crystalliza-tion, repeated as often as necessary, when they will become transparent and shining. Pott recommends to put on the filter, through which the solution is passed, a little cotton previously wetted with oil of amber. Their figure is that of a triangular prism. Their taste Their taste is acid, and they redden the blue colour of litmus, but not that of violets. They are soluble in less than two parts of boiling alkohol, in two parts of boiling water, and in twenty-five of cold water.

Planche, of Paris, observes, that a considerable quantity might be collected in making amber varnish, as it sublimes while the amber is melting for this pur-

pose, and is wasted.

Several processes have been proposed for purifying this acid: that of Richter appears to be the best. The acid being dissolved in hot water, and filtered, is to be saturated with potassa or soda, and boiled with char-coal, which absorbs the oily matter. The solution being filtered, nitrate of lead is added; whence results an insoluble succinate of lead, from which, by digestion in the equivalent quantity of sulphuric acid, pure succinic acid is separated. Nitrate or muriate of ba-rytes will show whether any sulphuric acid remains mixed with the succinic solution; and if so, it may be withdrawn by digesting the liquid with a little more succinate of lead. Pure succinic acid may be obtained by evaporation, in white transparent prismatic crys-Their taste is somewhat sharp, and they redden powerfully tincture of turnsole. Heat melts, and par-tially decomposes succinic acid. Air has no effect upon it. It is soluble in both water and alkohol, and much more so when they are heated.

SU'CCINUM. (Succinum, i. n.; from succus, joice: because it was thought to exude from a tree.)

See Amber.

Ambergris is so called by SUCCINUM CINEREUM.

some authors. See Ambergris.
Succisum griseum. Ambergris is sometimes so

called. See Ambergris.

SUCCINUM OLEUM. See Oleum succini.

SUCCINUM PREPARATUM. Prepared amber. See

SUCCI'SA. "(From succido, to cut: so named from

its being indented, and, as it were, cut in pieces.) Applied to a species of the genus Scabiosa.

SUCCORY. See Cichorium. Su'ccubus. See Incubus.

SUCCULENS. See Incubus.
SUCCULENS. Succulent, juicy, rich. Applied to

fruits, pods, soils, &c.
SUCCULENTÆ. The name of an order of Lin
næus's Fragments of a Natural Method, containing those which have fleshy and succulent leaves; a Csactus, Sedum, Sempervivum, &c. SUCCULENTUS. Juicy: full of juice. Applied

to pods, leaves, &c. SU CCUS. Juice.

SUCCUS COCHLEARIX COMPOSITUS. A WARM aperient and diuretic, mostly exhibited in the cure of diseases of the skin, arising from scurvy.

Succus Gyreniacus. Juice of laserwort. Succus Gastricus. See Gastric juice. Succus heliotroph. See Croton tinctorium

Succus indicus purgans. Gamboge.

Succus Liquoritie. See Glycyrrhiza glabra. SUDA'MINA. (Sudamen, ints. n.; from sudor, sweat.) Hidroa. Boa. Vesicles resembling millet-seeds, in form and magnitude, which appear suddenly, without fever, especially in the summer-time, after much labour and sweating.

SUDATIO. (From sudor, sweat.) A sweating.

See Ephidrosis.
SUDATO'RIUM. (From sudo, to sweat.) A stew or sweating-house.

SUDOR. Sweat or perspiration.
SUDOR ANGLICUS. Hydronosus; Gargeatio. The sweating sickness of England; and endemic fever.
Dr. Cullen thinks it a species of typhus. This disor der is thus named from its first appearing in this island, and acquires the title of sudor, from the national island, and acquires the title of sudor, from the patient suddenly breaking out into a profuse sweat, which forms the great character of the disease.

SUDORI'FIC. (Sudorificus; from sudor, sweat,

(Sudorificus: from sudor, sweat, and facio, to make.) A synonyme of diaphoretic. See

SUFFIME'NTUM. (From suffimen, a perfume)

A perfume. SUFFITUS.

SUFFITUS. A perfume. SUFFOCA'TIO. Suffication. SUFFOCATIO STRIDULA. The croup.

Suffractions Plants. Under shrubby plants Such ligneous or somewhat woody vegetables that are of a nature, in some degree, between that of the shrubby, and the herbaceous; as thyme, sage, hys-

SUFFUMIGATION. SUFFUMIGATION. (Suffumigatio; from sub, under, and fumigo, to smoke.) The burning odoroum

substances to remove an evil smell, or destroy mi-

SUFFUSIO. (From suffundo, to pour down: so called because the ancients supposed the opacity proceeded from something running under the crystalline humour.)

 A cataract.
 An extravasation of some humour, as the blood: thus we say, a suffusion of blood in the eye, when it is what is vulgarly called bloodshot.

SUFFUSIO AURIGINOSA. A jaundice. SUGAR. See Saccharum.

SUGAR. See Saccharum.
SUGAR. See Saccharum.
Sugar of lead. See Plumbi acetas.
Sugar of milk. A substance produced from whey, which, if not sour, contains a saline substance, to which this name has been given.
SUGILLATION. (Sugillatio; from sugillo, to stain.) A bruise. A spot or mark made by a leech or

SULCATUS. Furrowed: applied to stems, leaves, seeds, &c. of plants; as the seeds of the Scandiz odo-

rata, and australis.
SU'LCUS. A groove or furrow; generally applied

to the bones

SU LPHAS. (Sulphas, atis. m.; from sulphur, brimstone.) A sulphate or sait formed by the union of the sulphuric acid with a salifiable base.

SULPHAS ALUMINOSUS. Alum. Sec Alumen. SULPHAS AMMONIA. Alkali volatile vitriolatum, of Bergman. Sal ammoniacum secretum, of Glauber. Vitriolum ammoniacale. This salt has been found native in the neighbourhood of some volcanoes. It is esteemed diuretic and deobstruent, and exhibited in the same diseases as the muriate of ammonia.

SULPHAS CUPRI. See Cupri sulphas. SULPHAS FERRI. See Ferri sulphus.

SULPHAS HYDRARGYRI. See Hydrargyrus vitrio-

Sulphas magnesiæ. See Magnesiæ sulphas. Sulphas potassæ. See Potassæ sulphas. Sulphas quininæ. See Cinchonina.

SULPHAS SODE. See Sode sulphas.
SULPHAS ZINCI. See Zinci sulphas.
SULPHATE. See Sulphas.
SULPHITE. Sulphis. A salt formed by the combination of a definite quantity of the sulphurous acid with a salifiable base; as sulphite of potassa, ammo-

SULPHOVINIC ACID. Sulphovinous acid. The name given by Vogel to an acid, or a class of acids, which may be obtained by digesting alkohol and sul-pluric acid together by heat. It seems probable that this acid is merely the hyposulphuric, combined with a peculiar oily matter.—Ure's Chem. Dict. SU'LPHUR. (Sulphur, uris. n.; from sal or sul,

SU'LPHUR. (Sulphur, uris. n.; from sal or sul, and \(\pi \) p, fire: so named from its great combustibility. \(Abric; Alcubrith; Anpater; Appebrioc; Aquala; \(Appila : Chibur; Chybur; Cibur. Sulphur, which is also known by the name of brimstone, is the only simple combustible substance which nature offers pure and in abundance. It was the first known of all. It is found in the earth, and exists externally in depositions, in sublimed incrustations, and on the surface of certain waters, principally near burning volcances. certain waters, principally near burning volcanoes It is found combined with many metals. It exists in vegetable substances, and has lately been discovered in the albumen of eggs

Sulphur, in the mineral kingdom, is either in a loose powder, or compact; and then either detached or in veins. It is found in the greatest plenty in the neighbourhood of voicanoes, or pseudo-voicanoes, whether modern or extinct, as at Solfatara, &c. and is deposited as a crust on stones contiguous to them, either crystallized or amorphous. It is frequently met with in mineral waters and in cayeens adjacent to veins. in mineral waters, and in caverns adjacent to volcanoes; sometimes also in coal-mines. It is found in combination with most of the metals. When united to iron, it forms the mineral called martial pyrites, or iron pyrites. All the ores known by the name of pyrites, of which there are a vast variety, are combi-nations of sulphur with different metals; and hence the names of copper, tin, arsenical, &c. pyrites. It exists likewise in combination with alumine and lime; it then constitutes different kinds of schistus, or alum

Method of obtaining Sulphur.—A prodigious quantity of sulphur is obtained from Solfatara, in Italy.

This volcanic country every where exhibits marks of the agency of subterraneous fires; almost all the ground is bare and white; and is every where sensibly warmer than the atmosphere, in the greatest heat of summer; so that the feet of persons walking there are burnt through their shoes. It is impossible not to observe the sulphur, for a sulphurous vapour which rises through different apertures is every where perceptible, and gives reason to believe that there is a subterraneous fire underneath, from which that vapour pro-

From pyrites, sulphur is extracted in the large way

by the following process:

Pyrites is broken into small pieces, and put into large earthen tubes, which are exposed to the heat of a fur-nace. A square vessel of cast iron, containing water, is connected as a receiver with the tube in the furnace. The action of the fire proceeds, and the sulphur, being thus melted, is gradually accumulated on the water in the receiver. It is then removed from this receiver, and melted in large iron ladies; in consequence of which, the earthy parts with which it was contaminated are made to subside to the bottom of the ladle, leaving the purified sulphur above. It is then again melted, and suffered to cool gradually, in order to free it from the rest of the impurities. It is then tolerably pure, and constitutes the sulphur we meet with, in large masses or lumps, in the market. large masses or lumps, in the market.

In order to form it into rolls, it is again melted, and poured into cylindrical wooden moulds; in these it takes the form in which we usually see it in com-merce, as roll sulphur.

Flowers of sulphur, as they are called, are formed by subliming purified sulphur with a gentle heat, in close rooms, where the sublimed sulphur is collected though the article met with in general, under that

name, is nothing but sulphur finely powdered.

Method of purifying sulphur.—Take one part of flowers of sulphur, boil it in twenty parts of distilled water, in a glass vessel, for about a quarter of an hour; let the sulphur subside, decant the water, and then wash the sulphur repeatedly in distilled water. Having done this, pour over it three parts of pure nitro-muriatic acid, diluted with one part of distilled water, boil it again in a glass vessel for about a quarter of an hour, decant the acid, and wash the sulphur ter of an hour, decaul the acid, and wash the sulphur in distilled water till the fluid passes tasteless, or till it does not change the blue colour of tincture of cabbage or litmus. The sulphur, thus carefully treated, is pure sulphur, fit for philosophical experiments.

Physical properties.—" Sulphur is a combustible, dry, and exceedingly brittle body, of a pale lemon-yellow colour. Its specific gravity is 1.990. It is destinated advantage of the part of the properties of the property of the part of the

tute of odour, except when rubbed or heated. It is of a peculiar faint taste. It frequently crystallizes in ena peculiar faint taste. It frequently crystallizes in en-tire or truncated octahedra, or in needles. If a piece of sulphur, of a considerable size, be very gently heated, as, for example, by holding it in the hand and squeezing it firmly, it breaks to pieces with a crackling noise. It is a non-conductor of electricity, and hence it becomes electric by friction. When heated, it first softens before it melts, and its fusion commences at \$180 Fabre it is example of subliming at a lower tem-218° Fahr.; it is capable of subliming at a lower temperature; and takes fire at 500°. In the beginning of fusion it is very fluid, but by continuing the heat it grows tough, and its colour changes to a reddish-brown. If, in this condition, it be poured into water, it remains as soft as wax, and yields to any impression. In time, however, it hardens again, and recovers its former consistence.

When a roll of sulphur is suddenly seized in a warm hand, it crackles, and sometimes fails in pieces. This is owing to the unequal action of heat on a body which conducts that power slowly, and which has little cohesion. If a mass of sulphur be melted in a crucible, and after the surface begins to concrete, if the liquid matter below be allowed to run out, fine acicular crys-

tals of sulphur will be obtained.

Sulphur is insoluble in water; but in small quantity in alkohol and other, and more largely in oil.

Sulphur combines with oxygen in four definite proportions, constituting an interesting series of acids. See Sulphuric acid.

Sulphur combines readily with chlorine. This com-pound was first made by Dr. Thomson, who passed chlorine gas through flowers of sulphur. It may be made more expeditiously by heating sulphur in a

SUL SUL

retert containing chlorine. The sulphur and chlorine unite, and form a fluid substance, which is volatile below 2000 F., and distils into the cold part of the retort. This substance, seen by reflected light, appears of a red colour, but is yellowish-green when seen by transmitted light. It smokes when exposed to air, and has an odour somewhat resembling that of resemble that of resembling t an odour somewhat resembling that of seaweed, but much stronger; it affects the eyes like the smoke of peat. Its taste is acid, hot, and bitter. Its sp. gr

It does not redden perfectly dry paper tinged with litmus; when it is agitated in contact with water, the water becomes cloudy from the appearance of sulphur, and strongly acid, and it is found to contain oil of

Iodide of sulphur is easily formed by mixing the two ingredients in a glass tube, and exposing them to such a heat as melts the sulphur. It is grayish-black, and has a radiated structure like that of sulphuret of anti-When distilled with water, iodine is disenmony.

Sulphur and hydrogen combine. Their union may be effected, by causing sulphur to sublime in dry hydro-There is no change of volume; but only a part of the hydrogen can be united with the sul-

phur in this mode of operating.

The usual way of preparing sulphuretted hydrogen is to pour a dilute sulphuric or muriatic acid on the black sulphuret of iron or antimony in a retort. For accurate experiments it should be collected over mercury. It takes fire when a lighted taper is brought in contact with it, and burns with a pale blue flame, de-positing sulphur. Its smell is extremely fætid, resemvegetable blues. It is absorbable by water, which takes up more than an equal volume of the gas. Its sp. gr., according to Gay Lussac and Thenard, is to that of air as 1,1912 to 1.0.

Of all the gases, sulphuretted hydrogen is perhaps the most deleterious to animal life. A greenfinch, plunged into air, which contains only 1-1500th of its volume, pe-

into air, which contains only 1-1500th of its volume, perishes instantly. A dog of middle size is destroyed in air that contains 1-800th; and a horse would fall a victim to an atmosphere containing 1-250th.

Dr. Chaussier proves, that to kill an animal, it is sufficient to make the sulphuretted hydrogen gas act on the surface of its body, when it is absorbed by the inhalants. He took a bladder having a stop-cock at one end, and at the other an opening, into which he introduced the body of a rabbit, leaving its head outside, and securing the bladder air-tight round the neck by adhermatical contains the bladder air-tight round the neck by adhermatical contains the bladder air-tight round the neck by adhermatical contains the bladder air-tight round the neck by adhermatical contains the bladder air-tight round the neck by adhermatical contains the bladder air-tight round the neck by adhermatical contains the supplier to the supplie securing the bladder air-tight round the neck by adhesive plaster. He then sucked the air out of the bladder, and replaced it by sulphuretted hydrogen gas. young animal in these circumstances usually perishes in 15 or 20 minutes. Old rabbits resist the poison much

When potassium or sodium is heated, merely to fusion, in contact with sulphuretted hydrogen, it becomes luminous, and burns with extrication of hydrogen, while a metallic sulphuret remains, combined with sulphuretted hydrogen, or a sulphuretted hydrosul-

Sulphuretted hydrogen combines with an equal volume of ammonia; and unites to alkalies and oxides, so that it has all the characters of an acid. These com-

pounds are called hydrosulphurets.

All the hydrosulphurets, soluble in water, have an acrid and bitter taste, and, when in the liquid state, the odour of rotten eggs. All those which are insoluble are, on the contrary, insipid, and without smell. There are only two coloured hydrosulphurets, that of iron, which is black, and of antimony, which is chestnutbrown.

All the hydrosulphurets are decomposed by the action of fire. That of magnesia is transformed into sulphuretted hydrogen and oxide of magnesium; those of potassa and soda, into sulphuretted hydrogen, hydrogen, and sulphuretted alkalies; those of manganese, zinc, iron, tin, and antimony, into water and metallic

When we put in contact with the air, at the ordinary temperature, an aqueous solution of a hydrosulphuret,

hydrosulphurets, and disengage sulphuretted hydrogen with a lively effervescence, without any deposition of sulphur, unless the acid be in excess, and be capable, like the nitric and nitrous acid, of yielding a portion of its oxygen to the hydrogen of the sulphuretted hy-

The hydrosulphurets of potassa, soda, ammonia, lime, and magnesia, are prepared directly, by transmitting an excess of sulphuretted hydrogen gas through

these bases, dissolved or diffused in water.

The composition of the hydrosulphurets is such, that the hydrogen of the sulphuretted hydrogen is to the oxygen of the oxide in the same ratio as in water. Hence, when we calcine the hydrosulphurets of iron, tin, &c. we convert them into water and sulphurers.

tin, &c. we convert them into water and surphurets. Hydrosulphuret of potassa crystallizes in four-sided prisms, terminated by four-sided pyramids. Its taste is acrid and bitter. Exposed to the air, it attracts humidity, absorbs oxygen, passes to the state of a sulphuretted hydrosulphuret, and finally to that of a hydrosulphite. It is extremely soluble in water. Its solution in this limit describes a presentials refrigeration. in this liquid occasions a perceptible refrigeration. Subjected to heat, it evolves much sulphuretted hydrogen, and the hydrosulphuret passes to the state of a subhydrosulphuret.

Hydrosulphuret of soda crystallizes with more diffi-

Hydrosulphuret of ammonia is obtained by the direct union of the two gaseous constituents in a glass balloon, at a low temperature. As soon as the gases mingle, transparent white or yellowish crystals are formed. When a mere solution of this hydrosulphuret is wished for medicine or analysis, we pass a current of sulphuretted hydrogen through aqueous ammonia till saturation.

The pure hydrosulphuret is white, transparent, and crystallized in needles or fine plates. It is very volatile. Hence, at ordinary temperatures, it gradually sublimes into the upper part of the phials in which we preserve it. We may also by the same means separate it from the yellow sulphuretted hydrosulphuret, with which it is occasionally mixed. When exposed to the air, it absorbs oxygen, passes to the state of a sulphuretted hydrosulphuret, and becomes yellow. When it retted hydrosulphuret, and becomes yellow. When it contains an excess of ammonia, it dissolves speedily in water, with the production of a very considerable cold.

Sub-hydrosulphuret of barytes is prepared by dissolving, in five or six parts of boiling water, the sulphuret of the earth obtained by igniting the sulphate with charcoal. The solution being filtered while bot, will deposite, on cooling, a multitude of crystals, which must be drained, and speedily dried by pressure between the folds of blotting paper. It crystallizes in white scaly plates. It is much more soluble in hot than in cold water. Its solution is colourless, and capable of absorbing, at the ordinary temperature, a very large quantity of sulphuretted hydrogen.

Sub-hydrosulphurct of strontites crystallizes in the same manner as the preceding. The crystals obtained in the same way must be dissolved in water; and the solution being exposed to a stream of sulphuretted bydrogen, and then concentrated by evaporation in a re-tort, will afford, on cooling, crystals of pure sub-hydro-

sulphuret.

Hydrosulphurets of lime and magnesia have been stained only in aqueous solutions. The metallic hyobtained only in aqueous solutions. drosulphurets of any practical importance are treated

of under their respective metals.

When we expose sulphur to the action of a solution of a hydrosulphuret, saturated with sulphuretted hydrogen, as much more sulphuretted hydrogen is evolved as the temperature is more elevated. But when the solu-tion of hydrosulphuret, instead of being saturated, has a sufficient excess of alkali, it evolves no perceptible quantity of sulphuretted hydrogen, even at a boiling heat; although it dissolves as much sulphur as in its state of saturation. It hence follows, 1st, That sulphuretted hydrogen, sulphur, and the alkalies, have the property of forming very variable triple combinations; 2d, That all these combinations contain less sulphuretthere results, in the space of some days, 1st, water, and a sulphuretted hydrosulphuret, which is yellow and soluble; 2d, water, and a colourless hydrosulphite, which, if its base be potassa, soda, or ammonia, remains in solution in the water; but which falls down 318

hydrosulphurets; but the name of hydrogenated sulphurets is more particularly given to those combinations which are saturated with sulphur at a high temperature, because, by treating them with acids, we precipitate a peculiar compound of sulphur and hydrogen, of

which we shall now treat.

This compound of hydrogen and sulphur, the proportions of the elements of which have not yet been accurately ascertained, is also called hydruret of sulphur. It is formed by putting flowers of sulphur in contact with nascent sulphuretted hydrogen. With this view, we take an aqueous solution of the hydrogenated sulphuret of potassa, and pour it gradually into liquid muriatic acid, which seizes the potassa, and forms a soluble salt, while the sulphur and sulphuretted hydro-gen unite, fall down together, collecting by degrees at the bottom of the vessel, as a dense oil does in water. To preserve this hydruret of sulphur, we must fill with it a phial having a ground stopper, cork it, and keep it inverted in a cool place. We may consider this sub-stance either as a combination of sulphur and hydro-gen, or of sulphur and sulphuretted bydrogen. gen, or of sulphur and sulphuretted hydrogen; but its properties, and the mode of obtaining it, render the lat-ter the more probable opinion. The proportion of the constituents is not known.

The most interesting of the hydrogenated sulphurets, is that of ammonia. It was discovered by the Hon. Robert Boyle, and called his fuming liquor. To pre-Robert Boyle, and called his furning inquot. To pre-pare it, we take one part of muriate of ammonia and of pulverized quicklime, and half a part of flowers of sulphur. After mixing them intimately, we introduce the mixture into an earthen or glass retort, taking care that none of it remains in the neck. A dry cooled receiver is connected to the retort by means of a long adopter-tube. The heat must be urged slowly almost to redness. A yellowish liquor condenses in the receiver, which is to be put into a phial with its own weight of flowers of sulphur, and agitated with it seven or eight minutes. The greater part of the sulphur is dissolved, the colour of the mixture deepens remarkably, and becomes thick, constituting the hydrogenated

sulphuret.

The distilled liquor diffuses, for a long time, dense vapour in a jar full of oxygen or common air, but scarcely any in azote or hydrogen; and the dryness or humidity of the gases makes no difference in the effects. It is probably owing to the oxygen converting the liquor into a hydrogenated sulphuret, or perhaps to the state of sulphite, that the vapours appear.

Hydrogenated sulphurets are frequently called by

droguretted sulphurets.

Sulphur combines with carbon, forming an interesting compound, to which the name of sulphuret of carbon is sometimes given."

Sulphur has been long an esteemed article of the Materia Medica; it stimulates the system, loosens the belly, and promotes the insensible perspiration. It pervades the whole habit, and manifestly transpires through the pores of the skin, as appears from the sulphurous smell of persons who have taken it, and from silver being stained in their pockets of a blackish colour. In the stomach it is probably combined with hydrogen. It is a celebrated remedy against cutaneous diseases, particularly psora, both given internally and applied externally. It has likewise been recommended in rheumatic pains, flying gout, rickets, atrophy, coughs, asthmas, and other disorders of the breast and lungs, and particularly catarrhs of the chronic kind, also in solica pictonum, worm cases, and to lessen, salivation.

In bæmorrhoidal affections it is almost specific; but in most of these cases it is advantageously combined with some cooling purgative, especially supertartrate

of potassa.

The preparations of sulphur directed to be used by the London and Edinburgh Colleges, are the Sulphur lotum, Sulphur præcipitatum, and Sulphur sublimatum.

Sulphur antimonil Pracipitatum, and Sulphur summatum.

Sulphur antimonil Pracipitatum. Sulphur auratum antimonii. This preparation of antimony appears to have rendered that called kermes mineral unnecessary. It is a yellow hydrosulphuret of antimony, and therefore called hydro-sulphuretum stibii luteum. As an alterative and sudorific it is in high estimation, and given in diseases of the skin and glands; and joined with calonel, it is one of the most powerful and remetation. ful and penetrating alteratives we are in possesaion of.

SULPHUR AURATUM ANTIMONII. See Sulphur anti monii pracipitatum.

SULPHUR LOTUM. Washed sulphur; Flores sulphuris loti. Take of sublimed sulphur, a pound Pour on boiling water so that the acid, if there be any, may be entirely washed away; then dry it. The dose is from half a drachm to two drachms.

SULPHUR PRECIPITATUM. Lac sulphuris. Take of sublimed sulphur, a pound; fresh lime, two pounds; water, four gallons: boil the sulphur and lime together in the water, then strain the solution through paper, and drop in it as much muriatic acid as may be necessary to precipitate the sulphur; lastly, wash this by repeated effusions of water until it is tasteless. This preparation is mostly preferred to the flowers of sul-phur, in consequence of its being freed from its im-purities. The dose is from half a drachm to three drachms.

sulphur.

Sulphuretum stibii nativum. Sulphuretum stibii nigrum; Antimonium crudum. Native sulphuret of antimony. It is from this ore that all our preparations of antimony are made. See Antimony.

Sulphuric. Sulphuricus. Belonging to sulphur. Sulphuric acid. "When sulphuricum. Oil of vitriol. Vitriolic acid. "When sulphur is heated to 180° or 190° in an open vessel, it melts, and soon afterward emits a bluish flame, visible in the dark, but which, in open daylight, has the appearance of a white fume. This flame has a suffocating smell, and has so little heat that it will not set fire to flax, or even gunpowder, so that in this way the sulphur may be engunpowder, so that in this way the sulphur may be engunpowder, so that in this way the sulphur may be en-tirely consumed out of it. If the heat be still augmented the sulphur boils, and suddenly bursts into a much more luminous flame, the same suffocating vapour still continuing to be emitted.

The suffocating vapour of sulphur is imbibed by water, with which it forms the fluid formerly called volatile vitriolic, now sulphurous acid. If this fluid be exposed for a time to the air, it loses the sulphurous smell it had at first, and the acid becomes more fixed. It is then the fluid which was formerly called the spirit of vitriol. Much of the water may be driven off by heat, and the dense acid which remains is the sulphuric heat, and the dense acid which remains is the support acid commonly called oil of vitriol; a name which was probably given to it from the little noise it makes when poured out, and the unctuous feel it has when rubbed between the fingers, produced by its corroding 319

SUL SUL

compound.

The stone or mineral called martial pyrites, which consists for the most part of sulphur and iron, is found to be converted into the salt vulgarly called green vitriol, but more properly sulphate of iron, by exposure to air and moisture. In this natural process the pyrites breaks and fails in pieces; and if the change takes place rapidly, a considerable increase of temperature follows, which is sometimes sufficient to set the mass By conducting this operation in an accurate way, it is found that oxygen is absorbed. The sulphate is obtained by solution in water and subsequent evaporation; by which the crystals of the salt are separated from the earthy impurities, which were not

suspended in the water.

The sulphuric acid was formerly obtained in this country by distillation from sulphate of iron, as it still is in many parts abroad: the common green vitriol is made use of for this purpose, as it is to be met with at a low price, and the acid is most easily to be extracted from it. With respect to the operation itself, the fol-lowing particulars should be attended to: First, the vitriol must be calcined in an iron or earthen vessel, till it appears of a yellowish-red colour; by this opera-tion it will lose half its weight. This is done in order to deprive it of the greater part of the water which it has attracted into its crystals during the crystallization, and which would otherwise, in the ensuing distilliza-tion, greatly weaken the acid. As soon as the calcina-tion is finished, the vitriol is to be put immediately, while it is warm, into a coated earthen retort, which is to be filled two-thirds with it, so that the ingredients may have sufficient room upon being distended by the heat, and thus the bursting of the retort be prevented. It will be most advisable to have the retort immediately enclosed in brick-work in a reverberatory furnace, and to stop up the neck of it till the distillation begins, in order to prevent the materials from attracting fresh humidity from the air. At the beginning of the distil-lation the retort must be opened, and a moderate fire is to be applied to it, in order to expel from the vitriol ail that part of the phlegm which does not taste strongly of the acid, and which may be received in an open vessel placed under the retort. But as soon as there appear any acid drops, a receiver is to be added, into which has been previously poured a quantity of the acidulous fluid which has come over, in the proportion of half a pound of it to twelve pounds of the calcined vitriol; when the receiver is to be secured with a proper luting. The fire is now to be raised by little and intle to the most intense degree of heat, and the re-ceiver carefully covered with wet cloths, and, in winter time, with snow or ice, as the acid rises in the form of a thick white vapour, which towards the end of the operation becomes hot, and heats the re-ceiver to a great degree. The fire must be continued at this high ritch for several days till no vapour issues. at this high pitch for several days, till no vapour issues from the retort, nor any drops are seen trickling down its sides. In the case of a great quantity of vitriol being distilled, Bernhardt has observed it to continue emitting vapours in this manner for the space of ten days. When the vessels are quite cold, the receiver must be opened carefully, so that none of the luting may fail into it; after which the fluid contained in it is to be poured in a bottle, and the air carefully excluded. The fluid that is thus obtained is the German sulphuric acid, of which Berahardt got sixty-four pounds from six hundredweight of vitriol; and, on the other hand, when no water had been previously poured into the receiver, fifty-two pounds only of a dry concrete acid. This acid was formerly called glacial oil of vitriol, and its consistence is owing to a mixture of sulphurous acid, which occasions it to become solid at a moderate temperature.

It has been lately stated by Vogel, that when this fuming acid is put into a glass retort, and distilled by a moderate heat into a receiver cooled with ice, the fuming portion comes over first, and may be obtained in a solid state by stopping the distillation in time. This has been supposed to constitute absolute sulphuric acid, or acid entirely void of water. It is in silky fila-ments, tough, difficult to cut, and somewhat like ashestos. Exposed to the air, it fumes strongly, and gradually evaporates. It does not act on the skin so rapidly as concentrated oil of vitriol. Up to 66° it continues solid, but at temperatures above this it becomes a

and destroying the skin, with which it forms a soapy I colourless vapour, which whitens on contact with air. colourless vapour, which whitens on contact with dir. Dropped into water in small quantities, it excites a hissing noise, as if it were red-hot iron; in larger quantities it produces a species of explosion. It is said to be convertible into ordinary sulphuric acid, by the addition of a fifth of water. It dissolves sulphur, and assumes a blue, green, or brown colour, according to the proportion of sulphur dissolved. The specific gravity of the black furning sulphuric acid, prepared in large quantities from conperas, at Nordhausen, is in large quantities from copperas, at Nordhausen, is Its constitution is not well ascertained.

The sulphuric acid made in Great Britain is produced by the combustion of sulphur. There are three conditions requisite in this operation. Oxygen must be present to maintain the combustion; the vessel must be so close as to prevent the escape of the volatile mat-ter which rises, and water must be present to imbibe it. For these purposes, a mixture of eight parts of sulphur with one of circuit in the control of the con with one of nitre is placed in a proper vessel enclosed within a chamber of considerable size, lined on all sides with lead, and covered at bottom with a shallow stratum of water. The mixture being set on fire, will burn for a considerable time by virtue of the supply of oxygen which nitre gives out when heated, and the water imbibing the sulphurous vapours, becomes gradually more and more acid after repeated combustions, and the acid is afterward concentrated by distillation.

Such was the account usually given of this opera-tion, till Clement and Desormes showed, in a very interesting memoir, its total inadequacy to account for the result. 100 parts of nitre, judiciously managed, will produce, with the requisite quantity of sulphur, 2000 parts of concentrated sulphuric acid. Now these contain 1200 parts of ox; gen, while the hundred parts of nitre contain only 39g of oxygen; being not 1-30th part of what is afterward found in the resulting sulphuric acid. But after the combustion of the sulphur, the nitre is converted into sulphate and bisulphate of potassa, which mingled residuary salts contain nearly as much oxygen as the nitre originally did. Hence the origin of the 1200 parts of the oxygen in the sulphuric acid is still to be sought for. The following ingenious theory was first given by Clement and Desormes. The burning sulphur or sulphurous acid, taking from the price as earlier of its oxygen forms sulphurous the nitre a portion of its oxygen, forms sulphuric acid, which unites with the potassa, and displaces a little nitrous and nitric acids in vapour. These vapours little nitrous and nitric acids in vapour. These vapours are decomposed by the sulphurous acid, into nitrous gas, or deutoxide of azote. This gas, naturally little denser than air, and now expanded by the heat, suddenly rises to the roof of the chamber; and might be expected to escape at the aperture there, which ma-nufacturers were always obliged to leave open, otherwise they found the acidification would not proceed. But the instant that nitrous gas comes in contact with atmospherical oxygen, nitrous acid vapour is formed, which being a very heavy aëriform body, immediately precipitates on the sulphurous flame, and converts it into sulphuric acid; while itself resuming the state of nitrous gas, reascends for a new charge of oxygen, again to redescend, and transfer it to the flaming sulphur. Thus we see, that a small volume of nitrous vapour, by its alternate metamorphoses into the states of oxide and acid, and its consequent interchanges, may be capable of acidifying a great quantity of sulphur.

This beautiful theory received a modification from Sir II. Davy. He found that nitrous gas had no action on sulphurous gas, to convert it into sulphuric acid, unless water be present. With a small proportion of water, four volumes of sulphurous acid gas, and three of nitrous gas, are condensed into crystalline solid, which is instantly decomposed by abundance of water; oil of vitriol is formed, and nitrous gas given off, which with contact of air becomes nitrous acid gas, as above described. The process continues, according to the same principle of combination and decomposition, till the water at the bottom of the chamber is become strongly acid. It is first concentrated in large leaden pans, and afterward in glass retorts heated in a sand-Platinum alembics, placed within pots of castiron of a corresponding shape and capacity, have been lately substituted in many manufactories for glass, and have been found to save fuel, and quicken the process of concentration.

The proper mode of burning the sulphur with the nitre, so as to produce the greatest quantity of oil

of vitriol, is a problem, concerning which chemists hold a variety of opinions. Thenard describes the following as the best. Near one of the sides of the leaden chamber, about a foot above its bottom, an iron plate, furnished with an upright border, is placed horizontally over a furnace, whose chimney passes across, under the bottom of the chamber, without having any connexion with it. On this plate, which is enclosed in a little chamber, the mixture of sulphur and nitre is laid. The whole being shut up, and the bottom of the large chamber covered with water, a gentle fire is kindled in the furnace. The sulphur soon takes fire, and gives birth to the products described. When the combustion is finished, which is seen through a little pane adapted to the trap-door of the chamber, this is pane adapted to the trap-door of the chamber, this is opened, the sulphate of potassa is withdrawn, and is replaced by a mixture of sulphur and nitre. The air replaced by a mixture or support and mixture in the great chamber is meanwhile renewed by opening in the great chamber is meanwhile renewed by opening in the opposite side. Then, its lateral door, and a valve in its opposite side. Then, after closing these openings, the furnace is lighted anew. Successive mixtures are thus burned till the acid acquires a specific gravity of about 1.330, taking care never to put at once on the plate more sulphur than the air of the chamber can acidify. The acid is

then withdrawn by stop-cocks, and concentrated.

The following details are extracted from a paper on sulphuric acid, which Dr. Ure published in the fourth volume of the Journal of Science and the Arts.

"The best commercial sulphuric acid that I have been able to meet with," says he, "contains from one-half to three quarters of a part in the hundred, of solid saline matter, foreign to its nature. These fractional parts consist of sulphate of potassa and lead, in the proportion of four of the former to one of the latter. It is, I believe, difficult to manufacture it directly, by the usual methods, of a purer quality. The ordinary acid sold in the shops contains often three or four per cent. of saline matter. Even more is occasionally introduced, by the employment of nitre, to remove the brown conby the employment of nitre, to remove the brown co-lour given to the acid by carbonaceous matter. The amount of these adulterations, whether accidental or fraudulent, may be readily determined by evaporating, in a small capsule of porcelain, or rather platinum, a definite weight of the acid. The platinum cup placed on the red cinders of a common fire, will give an exact result in five minutes. If more than five grains of matter remain from five hundred of acid, we may

pronounce it sophisticated.

Distillation is the mode by which pure oil of vitriol is obtained. This process is described in chemical treatises as both difficult and hazardous; but since adopting the following plan, I have found it perfectly safe and convenient. I take a plain glass retort, capable of holding from two to four quarts of water, and put into it about a pint-measure of the sulphuric acid, (and a few fragments of glass,) connecting the retort with a large globular receiver, by means of a glass tube four feet long, and from one to two inches in diameter. The tube fits very loosely at both ends. The retort is placed over a charcoal fire, and the flame is made to play gently on its bottom. When the acid begins to boil smartly, sudden explosions of dense vapour rush forth from time to time, which would infallibly break small vessels. Here, however, these expansions are safely permitted, by the large capacity of the retort and receiver, as well as by the easy communication with the air at both ends of the adopter tube. Should the retort, indeed, be exposed to a great intensity of flame, the vapour will no doubt be generated with incoercible rapidity, and break the apparatus. But this accident can proceed only from gross imprudence. It resembles in suddenness, the explosion of gunpowder, and illustrates admirably Dr. Black's observation, that, but for the great latent heat of steam, (and a few fragments of glass,) connecting the retort gunpowder, and illustrates admirably Dr. Black's ob-servation, that, but for the great latent heat of steam, a mass of water, powerfully heated, would explode on reaching the boiling temperature. I have ascertained, that the specific caloric of the vapour of sulphuric acid is very small, and hence the danger to which rash operators may be exposed during its distillation. Hence, also, it is unnecessary to surround the receiver with cold water, as when alkohol and most other liquids are distilled. Indeed, the application of cold to the bottom of the receiver generally causes it, in the present operation, to crack. By the above method, I have made the concentrated oil of vitriol flow over in a continuous siender stream, without the globe becoming sensibly hot

I have frequently boiled the distilled acid till only one-half remain in the retort; yet at the temperature of 60° Fahrenheit, I have never found the specific gravity of acid so concentrated, to exceed 1.8455. It is, I believe, more exactly 1.8452. The number 1.850, which it has been the fashion to assign for the density of pure oil of vitriol, is undoubtedly very erroneous, and ought to be corrected. Genuine commercial acid should never surpass 1.6485; when it is denser we may infer sophistication, or negligence, in the manufac-

The sulphuric acid strongly attracts water, which it takes from the atmosphere very rapidly, and in larger quantities, if suffered to remain in an open vessel, imbibing one-third of its weight in twenty-four hours, and more than six times its weight in a twelvemonth. If four parts by weight be mixed with one of water at 50°, they produce an instantaneous heat of 300° F.; and four parts raise one of ice to 212°: on the contrary, four parts of ice, mixed with one of acid, sink the thermometer to 4 below 0. When pure it is colourless, and emits no fumes. It requires a great degree of cod to freeze it; and if diluted with half a part or more of water, unless the dilution be carried very far, it becomes more and more difficult to congeal; yet at the specific gravity of 1.78, or a few hundredths above or below this, it may be frozen by surrounding it with melting snow. Its congelation forms regular prismatic crystals with six sides. Its boiling point, according to Bergman, is 540°; according to Dalton,

Pure sulphuric acid is without smell and colour, and of an oily consistence. Its action on litmus is so strong, that a single drop of acid will give to an immense quantity of water the power of reddening. It is a most violent caustic; and has sometimes been administered with the most criminal purposes. The person who unfortunately swallows it, speedily dies in dreadful agonies and convulsions. Chalk, or common carbonate of magnesia, is the best antidote for this, as well as for the strong uitric and muriatic acids. When transmitted through an ignited porcelain tube

of one fifth of an inch diameter, it is resolved into two parts of sulphurous acid gas, and one of oxygen gas, with water. Voltaic electricity causes an evolution of sulphur at the negative pole; while a sulphate of the metallic wire is formed at the positive. Sulphuric acid has no action on oxygen gas or air. It merely abstracts their agueous vapour.

their aqueous vapour.

If the oxygenized muriatic acid of Thenard be put If the oxygenized marriate acts of Thenard be partial in contact with the sulphate of silver, there is immediately formed insoluble chloride of silver, and oxygenized sulphuric acid. To obtain sulphuric acid in the highest degree of oxygenation, it is merely necessary to pour barytes water into the above oxygenized acid, so as to precipitate only a part of it, leaving the rest in union with the whole of the oxygen. Oxygenized sulphuric acid partially reduces the oxide of

silver, occasioning a strong effervescence.

All the simple combustibles decompose sulphuric acid, with the assistance of heat. About 400° Fahr. sulphur converts sulphuric into sulphurous acid. Several metals at an elevated temperature decompose this acid, with evolutions of sulphuric acid gas, oxi-

this acid, with evolutions of sulphuric acid gas, exidizement of the metal, and combination of the exide with the undecomposed portion of the acid.

The sulphuric acid is of very extensive use in the art of chemistry, as well as in metallurgy, bleaching, and some of the processes for dying; in medicine, it is given as a tonic and stimulant, and is sometimes used

externally as a caustic.

The combinations of this acid with the various bases are called sulphates, and most of them have long been known by various names. With barytes it is found native and nearly pure in various forms, in coarse powder, rounded masses, stalactites, and regular crystallizations, which are in some lamellar, in others

needly, in others prismatic or pyramidal.

This salt, if at all deleterious, is less so than the carbonate of barytes, and is more economical for preparing the muriate for medicinal purposes. It requires 43,000

parts of water to dissolve it at 60°.

Sulphate of strontian has a considerable resemblance to that of barytes in its properties. It is found native in considerable quantities at Aust Passage and other places in the neighbourhood of Bristol. It requires 3840 parts of boiling water to dissolve it. Its composition is 5 acid + 6.5 base.

The sulphate of potassa, vitriolated kali, formerly vitriolated tartar, sal de duobus, and arcanum duplica-tum, crystallizes in hexahedrai prisms, terminated by hexagonal pyramids, but susceptible of variations. nexagonal pyramids, but susceptible of variations. Its crystallization by quick cooling is confused. Its taste is bitter, acrid, and a little saline. It is soluble in 5 parts of boiling water, and 16 parts at 60°. In the fire it decrepitates, and is fusible by a strong heat. It is decomposable by charcoal at a high temperature. It may be prepared by direct mixture of its component parts; but the usual and cheapest mode is to neutralize the acidulous sulphate left after distilling nitric acid, the sal enixen of the old chemists, by the addition of carsal enizen of the old chemists, by the addition of car-bonate of potassa. The sal polychrest of old dispen-satories, made by deflagrating sulphur and nitre in a crucible, was a compound of the sulphate and sulphite of potassa. The acidulous sulphate is sometimes employed as a flux, and likewise in the manufacture of alum. In medicine, the neutral salt is sometimes used as a deobstruent, and in large doses as a mild cathartic dissolved in a considerable portion of water, and taken daily in such quantity as to be gently aperient, it has been found serviceable in cutaneous affections, and is sold in London for this purpose as a nostrum; and cer-tainly it deserves to be distinguished from the generality of quack medicines, very few indeed of which can be taken without imminent hazard.

It consists of 5 acid + 6 base; but there is a com-bound of the same constituents, in the proportion of

10 acid + 6 potassa, called the bisulphate

The sulphate of soda is the vitriolated natron of the college, the well known Glauber's salt, or sal mirabile. It is commonly prepared from the residuum left after distilling muriatic acid, the superfluous acid of which may be saturated by the addition of soda, or precipitated by lime; and is likewise obtained in the manufacture of th facture of the muriate of ammonia. Scherer mentions another mode by Funcke, which is, making 8 parts of calcined sulphate of lime, 5 of clay, and 5 of common salt, into a paste with water; burning this in a kiln; and then powdering, lixiviating, and crystallizing. It exists in large quantities under the surface of the earth in some countries, as Persla, Bohemia, and Switzerland; is found mixed with other substances in mineral springs and sea-water; and sometimes effloresces on walls. Sulphate of soda is bitter and saline to the taste. It is soluble in 2.85 parts of cold water, and 0.8 at a boil-ing heat. It crystallizes in hexagonal prisms bevelled at the extremities, sometimes grooved longitudinally, and of very large size, when the quantity is great. These effloresce completely into a white powder if exposed to a dry air, or even if kept wrapped up in a paper in a dry place, yet they retain sufficient water of crystallization to undergo the aqueous fusion on exposure to heat, but by urging the fire, melt. Barytes and strontian take its acid from it entirely, and potassa partially; the nitric and muriatic acids, though they have a weaker affinity for its base, combine with a part of it when digested on it. Heated with charcoal, its acid is decomposed. As a purgative, its use is very general; and it has been employed to furnish soda. Pajot des Charmes has made some experiments on it in fabricating glass; with made some experiments on it in fabricating glass; with sand alone it would not succeed, but equal parts of carbonate of lime, sand, and dried sulphate of soda, produced a clear, solid, pale yellow glass.

It is composed of 5 acid + 4 base + 11.25 water in

crystals; when dry, the former two primes are its con-

stituents.

Sulphate of soda and sulphate of ammonia form to-

Sulphate of soda and sulphate of ammonia form together a triple salt.

Sulphate of lime, selenite, gypsum, plaster of Paris, or sometimes alabaster, forms extensive strata in various mountains. The specular gypsum, or glacies Mariæ, is a species of this salt, and affirmed by some French travellers to be employed in Russia, where it abounds, as a substitute for glass in windows. Its specific gravity is from 1.872 to 2.311. It requires 500 parts of cold water, and 450 of hot, to dissolve it. When calcined, it decrepitates, becomes very friable and white, calcined, it decrepitates, becomes very friable and white, and heats a little with water, with which it forms a solid mass. In this process it loses its water of crystallization. In this state it is found native in Tyrol, dral or hexahedral prisms, and is called anhydrous sulphate of lime. Both the natural and artificial anhydrous sulphate consists of 56.3 lime, and 43.6 acid, ac
322

sulphate of magnesia, and 32 sulphate of ammonia.

Sulphate of glucina crystallizes with difficulty, its solution readily acquiring and containing a syrupy consistence; its taste is sweet, and slightly astringent; it crystallized in rectangular parallelopipeds, or octahe

cording to Chenevix. The calcined sulphate is much employed for making casts of anatomical or orna-mental figures as one of the bases of stucco; as a fine cement for making close and strong joints between stone, and joining rims or tops of metal to glass; for making moulds for the Staffordshire potteries; for comices, mouldings, and other ornaments in building. For these purposes, and for being wrought into columns, chimney-pieces, and various ornaments, about eight hundred tons are raised annually in Derbyshire, where it is called alabaster. In America, it is laid on grass land as a manure.

[Sulphate of lime, gypsum, or plaster of Paris, is extensively and beneficially employed in some parts of the United States as a manure. It is reduced to a fine powder, and applied by the spoonful to a hill of Indian corn (maize), or it is thinly scattered over grass land, and it has a most powerful and fertilizing effect. The gypsum of Nova Scotia afforded the principal supply for this and other purposes some time since, but the states of New-York and Pennsylvania now furnish large quantities, and of an excellent quality, from their own quarries. Gypsum, as a manure, will not answer on the sea-coast, or within the influence of a saline own quarries. Gypsum, as a manure, will not answer on the sea-coast, or within the influence of a saline atmosphere. It begins to produce fertilizing effects about 40 or 50 miles from the sea-shore. A.)

Ordinary crystallized gypsum consists of 5 sulphuric acid + 3.5 lime + 2.25 water; the anhydrous variety wants of course the last ingredient.

wants of course the last ingredient.

Sulphate of magnesia, the vitriolated magnesia of the late, and sal catharticus amarus of former London Pharmacopeias, is commonly known by the name of Epsom salt, as it was furnished in considerable quantity by the mineral water at that place, mixed however with a considerable portion of sulphate of soda. It is afforded, however, in greater abundance and more pure from the bittern left after the extraction of salt from sea-water. It has likewise been found efflorescing on brick walls, both old and recently erected, and in small quantity in the ashes of coals. The capillary salt of Idria, found in silvery crystals mixed with the aluminous schist in the mines of that place, and hitherto considered as a feathery alum, has been ascer-tained by Klaproth to consist of sulphate of magnesia, mixed with a small portion of sulphate of iron. When pure, it crystallizes in small quadrangular prisms, terminated by quadrangular pyramids or dihedral summits. Its taste is cool and bitter. It is very soluble, requiring only an equal weight of cold water, and three-fourths its weight of hot. It effloresces in the air, though but showly. If it attract moisture it contains muriate of magnesia or of time. Exposed to heat it dissolves in its over nesia, or of lime. Exposed to heat it dissolves in its own water of crystallization, and dries, but is not decom-posed nor fused, but with extreme difficulty. It consists, according to Bergman, of 33 acid, 19 magnesia, 48 water. A very pure sulphate is said to be prepared in the neighbourhood of Genoa, by roasting a pyrites found there; exposing it to the air in a covered place for six months; watering it occasionally, and then lixiviating.

Sulphate of magnesia is one of our most valuable purgatives; for which purpose only it is used, and for furnishing the carbonate of magnesia.

It is composed of 5 acid + 2.5 magnesia + 7.875

water, in the state of crystals.

Sulphate of ammonia crystallizes in slender, flat-tened, hexabedral prisms, terminated by hexagonal pyramids; it attracts a little moisture from very damp air, particularly if the acid be in excess; it dissolves in air, particularly if the acid be in excess; it dissolves in two parts of cold and one of boiling water. It is not used, though Glauber, who called it his secret ammoniacal salt, vaunted its excellence in assaying.

It consists of 5 acid + 2.125 ammonia + 1.125 water in its most desiccated state; and in its crystalline state of 5 acid + 2.125 ammonia + 3.375 water.

If sulphate of ammonia and sulphate of magnesia has added together in solution, there exembine in the combine in the c

be added together in solution, they combine into a triple salt of an octahedral figure, but varying much; less soluble than either of its component parts; unalterable in the air; undergoing on the fire the watery fusion; after which it is decomposed, part of the ammonia flying off, and the remainder subliming with an excess of acid. It contains, according to Fourcroy, 68 sulphate of magnesia, and 32 sulphate of ammonia.

is not alterable in the air; a strong heat expels its acid, [and leaves the earth pure; heated with charcoal, it forms a sulphuret; infusion of galls forms a yellowish-white precipitate with its solution.

Yttria is readily dissolved by sulphurle acid; and as the solution goes on, the sulphate crystallizes in small brilliant grains, which have a sweetish taste, but less so than sulphate of glucina, and are of a light amethyst-red colour. They require 30 parts of cold water to dissolve them, and to give up their acid when exposed to a high temperature. They are decomposed by oxalic acid, prussiate of potassa, infusion of galls, and phosphate of soda.

Sulphate of alumina in its pure state is but recently known, and it was first attentively examined by Vau-It may be made by dissolving pure alumina in pure sulphuric acid, heating them for some time, evaporating the solution to dryness, drying the residuum with a pretty strong heat, redissolving it, and crystal-lizing. Its crystals are soft, foliaceous, shining, and pearly; but these are not easily obtained without cautious evaporation and refrigeration. They have an astringent taste; are little alterable in the air; are pretty soluble, particularly in hot water; give out their acid on exposure to a high temperature: are decomposable by combustible substances, though not readily; and do not form a pyrophorus like alum.

If the evaporation and desiccation directed above be omitted, the alumina will remain supersaturated with acid, as may be known by its taste, and by its reddening vegetable blue. This is still more difficult to crystallize than the neutral salt, and frequently thickens

into a gelatinous mass.

A compound of acidulous sulphate of alumina, with potassa or ammonia, has long been known by the name

Sulphate of zircon may be prepared by adding sulphuric acid to the earth recently precipitated, and not yet dry. It is sometimes in small needles, but commonly pulverulent; very friable; insipid; insoluble in water, unless it contain some acid; and easily decomposed by heat."—Ure's Chem. Dict.

Sulphuric acid is a powerful antiseptic and tonic: it is given, properly diluted, in the dose of from one to three drops with cinchona and other medicines in the cure of fevers and debilities, and it is often applied ex-ternally, when very much diluted, against psora and some chronic affections of the skin.

SULPHURIS FLORES. See Sulphur sublimatum. SULPHUROPRUSSIC ACID. The sulphuretted

chyazic acid of Porrett.

Dissolve in water one part of sulphuret of potassa, and boil it for a considerable time with three or four parts of powdered Prussian blue added at intervals. Sulphuret of iron is formed, and a colourless liquid containing the new acid combined with potassa, mixed with hyposulphate and sulphate of potassa. Render this liquid sensibly sour, by the addition of sulphuric acid. Continue the boiling for a little, and when it cools, add a little peroxide of manganese in fine powder, which will give the liquor a fine crimson colour. To the filtered liquid add a solution containing persulphate of copper, and protosulphate of iron, in the proportion of two of the former salt to three of the latter, until the crimson colour, diagnosars. Sulphuroproposition of the crimson colour disappears. Sulphuroprussiate of copper falls. Boil this with a solution of potassa, which will separate the copper. Distil the liquid mixed with sulphuric acid in a glass retort, and the peculiar acid will come over. By saturation with carbonate of barytes, and then throwing down this by the equivalent quantity of sulphuric acid, the sulphuroprussic acid is obtained pure.

It is a transparent and colourless liquid, possessing a

strong colour, somewhat resembling acetic acid. Its specific gravity is only 1.022. It dissolves a little sulphur at a boiling heat. It then blackens nitrate of silver; but the pure acid throws down the silver white. By repeated distillations sulphur is separated and the

acid is decomposed.
SULPHUROUS ACID. "Sulphur burned at a low temperature absorbs less oxygen than it does when ex-posed to greater heat, and is consequently acidified in a slighter degree, so as to form sulphurous acid. This in the ordinary state of the atmosphere is a gas; but on reducing its temperature very low by artificial cold, and exposing it to strong compression, it becomes a liquid. To obtain it in the liquid state, however, for E e e 2

practical purposes, it is received into water, by which it is absorbed

As the acid obtained by burning sulphur in this way is commonly mixed with more or less sulphuric acid, when sulphurous acid is wanted it is commonly made by abstracting part of the oxygen from sulphuric acid by means of some combustible substance. Mercury or tin is usually preferred. For the purposes of manu-factures, however, chopped straw or saw-dust may be employed. If one part of mercury and two of concentrated sulphuric acid be put into a glass retort with a long neck, and heat applied till an effervescence is produced, the sulphurous acid will arise in the form of gas, and may be collected over quicksilver, or received into water, which, at the temperature of 61°, will absorb thirty-three times its bulk, or nearly an eleventh of its weight.
Water thus saturated is intensely acid to the taste,

and has the smell of sulphur burning slowly. stroys most vegetable colours, but the blues are reddened by it previous to their being discharged. A pleasing instance of its effect on colours may be exhibited by holding a red rose over the blue flame of a common match, by which the colour will be discharged wherever the sulphurous acid comes into contact with it, so as to render it beautifully variegated, or entirely white. If it be then dipped into water, the redness after a time

will be restored.

Sulphurous acid is used in bleaching, particularly for lks. It likewise discharges vegetable stains, and iron-

moulds from linen.

In combination with the salifiable bases, it forms sulphites which differ from the sulphates in their properties. The alkaline sulphites are more soluble than the sulphates, the earthy less. They are converted perties. The alkaline sulphites are more soluble than the sulphates, the earthy less. They are converted into sulphates by an addition of oxygen, which they acquire even by exposure to the air."

Sultan flower. The Centaurea moschata, of Linnæus. SUMACH. (Sumak; from samak, to be red; so called from its red berry.) See Rhus coriaria.

Sumach, elm-leaved. See Rhus coriaria.

Su'men. (Arabian.) The lower or fat part of the belly.

SUN-DEW. See Drosera rotundifolia.

SUPER. 1. This term is applied, in chemistry and pharmacy, to several saline substances, in which there is an excess of one of its constituents beyond what is necessary to form the ordinary compound; as supersulphate of potassa, supercarbonate of soda, &c.

2. In anatomy, it regards situation; as superscapula-

ris, supergenualis.

3. In physiology, it means an additional; as superfætation.

4. In medicine, it means excess; as superpurgation. SUPERACE'TAS PLUMBI. See Plumbi acetas.

SUPERARCE'NIAS POTASSÆ. Superarseniate of potassa. A compound of potassa with excess of arsenic acid. It was called Macquer's Arsenical Salt, from its discoverer; and has been sometimes given in medi cine, possessing similar properties to those of the white

oxide of arsenic. SUPE'RBUS.

SUPERBUS. See Rectus superior oculi. SUPERCI'LIUM. See Eyebrow. SUPERCILIUM VENERIS. The milfoil. See Achillea

SUPERFŒTATION. (Superfatatio; from super, above or upon, and fatus, a fetus.) The impregna-

tion of a woman already pregnant.

SUPERGEMINA'LIS. (From super, above, and gemini, the testicles.) The epididymis, or body above the tes-

SUPERGENUA'LIS. (From super, above, and genu, the knee.) The patella, or knee-pan.
SUPERIMPREGNA'TIO. (Superimpregna tio; from super, above, and impregnatio, a conception.) Superfectation.
SUPE'RIOR. Some muscles were so named from

their relative situation.

their relative situation.

SUPERIOR AURIS. See Attollens aurem.

SUPERLI'GULA. (From super, above, and ligula, a little tongue, the glottis.) The epiglottis.

SUPERPURGA'TIO. (From super, beyond, and purgo, to purge.) An excessive evacuation by stool.

SUPERSALT, See Subsalt.

SUPERSCAPULA'RIS. (From super, upon, and scapula, the shoulder-blade.) A muscle seated upon the scapula.

398

SUPERUS. Above: applied to the perianthium of flowers when placed above the germen; as in roses, and the genus Pyrus.

SUPINATION. (Supinatio; from supinus, placed upward.) The act of turning the palm of the hand upwards, by rotating the radius upon the ulna.

SUPINATOR. (From supinus, upwards.) A name given to those muscles which turning the hand upwards.

SUPINATOR BREVIS. See Supinator radii brevis. Supinator Longus. See Supinator radii longus. Supinator Radii Brevis. A supinator muscle of the hand, situated on the forearm. Supinator brevis, sive minor, of Winslow; and epicondylo-radial, of Dumas. This small muscle, which is tendinous externally, is situated at the upper part of the forearm under the supinator longus, the extensor carpi radialis brevis, the extensor carpi ulnaris, the extensor digitorum communis, and the extensor minimi digiti.

It arises tendinous from the lower and anterior part of the outer condyle of the os humeri, and tendinous and fleshy from the outer edge and posterior surface of the ulna, adhering firmly to the ligament that joins the radius to that bone. From these origins its fibres the radius to that bone. From these origins its fibres descend forwards and inwards, and are inserted into the upper, inner, and anterior part of the radius around the cartilaginous surface, upon which slides the ten-don of the biceps, and likewise into a ridge that runs downwards and outwards below this surface. It assists in the supination of the hand by rolling the radius

SUPINATOR RADII LONGUS. Supinator longus, of Albinus. Supinator longus sive major, of Winslow; and humerosus radial, of Dumas. A long flat muscle, covered by a very thin tendinous fascia, and situated immediately under the integuments along the outer immediately under the integuments along the outer convex surface of the radius. It arises, by very short tendinous fibres, from the anterior surface and outer ridge of the os humeri, about two or three inches above its external condyle, between the brachialis internus and the triceps brachii; and likewise from the anterior surface of the external intermuscular membrane, or ligament, as it is called. About the middle of the radius, its fleshy fibres terminate in a flat tendon, which is inserted into the inner side of the inferior extrewhich is inserted into the inner side of the inferior extre-

This muscle not only assists in rolling the radius outwards, and turning the palm of the hand upwards, on which account Riolanus first gave it the name of supinator, but it likewise assists in pronation, and in bending the forearm.

SUPPOSITO'RIUM. (From sub, under, and pono, to put.) A suppository, i. e. a substance to put into the rectum, there to remain and dissolve gradually.

Suppressed menses. See Amenorrhaa.
SUPPURATION. (Suppuratio; from suppuro, to suppurate.) That morbid action by which pus is deposited in inflammatory tumours. See Pus.
SUPRA. Above. This word before any other name, implies its situation being above it; as supra spinatus, above the spine of the scapula, &c.
Supra-costalas. A portion of the intercostal

SUPRA-COSTALES. A portion of the intercostal muscles. See Intercostal muscles.
SUPRA-DECOMPOSITUS. See Decompositus.
SUPRA-SPINA'TUS. Supra-spinatus seu super-scapularis, of Cowper; and sous-spino-scapulo-trochiterien, of Dumas. A muscle of the arm first so named by Riolanus, from its situation. It is of considerable thickness, wider behind than before, and fills the whole of the cavity or fossa that is above the spine of the scapula. It arises fleshy from the whole of the base of the scapula that is above its spine, and likewise from the spine itself, and from the superior costa. Op-posite to the basis of the coracoid process, it is found beginning to degenerate into a tendon, which is at first covered by fleshy fibres, and then passing under the acromion, adheres to the capsular ligament of the os acromion, adheres to the capsular ligament of the os humeri, and is inserted into the upper part of the large tuberosity at the head of the os humeri. This muscle is covered by a thin fascia, which adheres to the upper edge and superior part of the basis, as well as to the upper edge of the spine of the scapula. The principal use of the supra spinatus seems to be to assist in raising the arm upwards; at the same time, by drawing the capsular ligament upwards, it prevents it from being pinched between the head of the os humeri and that of the scapula. It may likewise serve to move the scapula upon the humerus. SURA. (An Arabian word.) 1. The calf of the leg-2. The fibula. SURCULUS. A term applied by botanists to the

2. The fibula.

SURCULUS. A term applied by botanists to the stem of mosses, or that part which bears the leaves. It is simple, in Polytricum; branched, in Minium androgynum; with branches turned downward, in Sphagnum palustre; decumbent, creeping, or creet.

SURPITAS. Deafness. See Paracusis.

SURFEIT. The consequence of excess in eating or dipking or of semething proveholesome or impresser.

or drinking, or of something unwholesome or improper in the food. It consists in a heavy load or oppression of the stomach, with nausea, sickness, impeded perspiration, and at times eruptions on the skin.

SURGERY. Chirurgia. A branch of the healing art, having for its object the cure of external diseases.

SURTURBRAND. Fibrous brown coal, or bituminous wood, is so called in Iceland, where it occurs in

great quantities.

SUS. The name of a genus of animals. Class, Mammalia; Order, Bellux. The hog. The flesh called pork is considered a great delicacy, especially the young and well fed, and is much used in most countries. Salted, it affords a harder food, still very nutritious to hard-working people, whose digestion is great.

SUS SCROPA. The systematic name of the hog, the fat of which is called lard.

Suspended animation. See Resuscitation.

SUSPENSO'RIUM. (From suspendee, to hang.)

A suspensory; a bag, or bandage, to suspend any part.

SUSPENSORIUM REPATIS. The broad ligament of the

Suspensorius testis. The cremaster muscle of

SUSU'RRUS. (From susurro, to murmur.)

imaginary sound in the ear.

SUTURE. (Sutura; from suo, to join together.)

1. In surgery, this term signifies the uniting the lips of a wound by sewing. Clavata commissura. A number of different kinds of sutures have been recommended by writers on surgers. ber of different kinds of sutures have been recom-mended by writers on surgery, but all of them are now reduced to two; namely, the twisted, and the inter-rupted, called also the knotted suture. The twisted suture is made in the following manner: having brought the divided parts nearly into contact, a pin is to be introduced from the outside inwards, and carried out through the opposite side to the same distance from the edge that it entered at on the former side; a firm wax ligature is then to be passed around it, making the figure of 8, by which the wounded parts are drawn gently into contact. The number of pins is to be determined by the extent of the wound; half an inch, or at most three quarters, is the proper distance between two pins. The interrupted suture is practised where a number of stitches is required, and the interruption is the only distance between the stitches

2. In anatomy, the word suture is applied to the union of bones by means of dentiform margins, as in the bones of the cranium. See Temporal, sphenoidal, zygomatic, transverse, coronal, lambdoidal, and sagittal

3. In botany, it is applied to that part of a capsule, which is a kind of furrow on the external surface in which the valves are united. See Capsula.

SWALLOW-WORT. See Asclepias vincetoxicum. SWAMMERDAM, John, was born at Amsterdam, in 1637, and displayed an early predilection for natural history, particularly entomology. At Leyden, where he studied physic, he was distinguished by his skill and assiduity in anatomical experiments and the art of making preparations; and on taking his degree there, in 1667, he published a thesis on Respiration. At this time he began to practise his invention of injecting the vessels with ceraceous matter, from which anatomy vessels with ceraceous matter, from which anatomy has derived very important advantages. In the dissection of insects, he was singularly dexterous by the aid of instruments of his own invention. The Grand Duke of Tuscany invited him about this period to Florence on very liberal terms, but he declined the offer from aversion to a court-life, and to any religious restraints. In 1669 he published in his native language "A General History of Insects," afterward reprinted and translated into French and Latin, the latter with splendid figures. In 1672 another work appeared, entitled "Miraculum Natura," detailing the structure of the uterus; of which there were many subsequent editions. By intense application he became hypochonhas derived very important advantages. In the dissec-

driacal and infatuated mysticism, so as to abandon all his scientific pursuits; and his constitution was worn out by his mortifications, so that he died in 1680. Several of his papers, which came long after into the hands of Boerhaave, were published under the title of Biblia Nature;" in which the history of bees is particularly esteemed.

SWIETEN, GERARD VAN, was born at Leyden, in 1700. Prom the loss of both his parents, his early education is said to have been somewhat neglected; but being sent at sixteen to the university of Louvain, be soon distinguished himself by his superior attainments. He then returned to his native place, and became a favourite pupil of the illustrions Boerhaave; and after studying seven years, took the degree of doctor in 1725; and so much had he profited by the instruction of that great master, as well as by his own unwearied researches, that he was immediately appointed to a medical professorship, which he occupied for many pedical professorship, which he occupied for many years with great reputation. At length, however, his success excited envy, and there being a law, which prohibited those not professing the religion of the State from holding any public appointment, Van Swieten, being a Roman Catholic, was obliged to resign his chair. He devoted the leisure thus acquired to the composition of his excellent Commentaries on the Aphorisms of Roerhaave, and while separated in this Aphorisms of Boerhaave: and while engaged in this work, he was invited by the Empress Maria Theresa work, he was invited by the Empress Maria Theresa to settle at Vienna, which he accepted in the year 1745, after stipulating, that he should be allowed to follow his usual mode of life, which was not well adapted for a court. The intellectual and moral endowments of this physician qualified him in every respect for conducting the medical school at Vienna; and that science in Germany was ultimately essentially benefitted by his exertions. He executed, during eight years, the office of professor with singular zeal; and having obtained the full confidence of his royal mishaving obtained the full confidence of his royal mis-tress, he was enabled to reform many abuses, and pro-cure great advantages for the study of medicine in that city. His extensive erudition gained him the farther honour of being intrusted with the interests of learn-ing in general in the Austrian dominions; he was ap-pointed Imperial Librarian, President of the Censorship of Books, &c.; and also created a Baron of the Empire. He was likewise voluntarily enrolled in the list of almost all the distinguished literary societies of Europe. The inflexibility of his character led him to maintain a long opposition to small-pox inoculation. He died in 1772, and a statue was erected to his memory by the Empress at Vienna. His commentaries will always maintain their reputation, from the immense number of facts, well selected and well arranged, and the judicious summary of ancient and modern medical knowledge which they contain. He also published another useful work on the Diseases which pre-

vail in Armies.

SWIETE'NIA. (Named after Van Swieten.) The name of a genus of plants. Class, Decandria; Order,

SWIETENIA MAHAGONI. The systematic name of the mahogany-tree. The bark of the wood of this tree is of a red colour internally; has an astringent bitter taste; and yields its active matter to water. It has been prepared as a substitute for Peruvian bark, and has been used as such with advantage. Dose, half a

SWINE-POX. See Varicella.

SWINESTONE. A variety of compact lucullite, a subspecies of limestone.

SWINGING. See Eora.
Sword-shaped. See Lanccolatus.
SYCO'MA. (From συκη, a fig.) Sycosis. A wart or excrescence resembling a fig on the eyelid, about the

anus, or any other part.

SYDENHAM, Thomas, was born at Winford-Eagle, in Dorsetshire, about the year 1624. He was entered at Oxford; but during the civil war, when that city was occupied by the royal party, he retired to

London. On this occasion, the illness of his brotoer brought him acquainted with Dr. Coxe, an eminent physician, who, finding Sydenham undecided as to the choice of his profession, persuaded him to study medi-cine on his return to Oxford. Accordingly, in 1648, he took the degree of bachelor of physic, and about the same period obtained a fellowship; then pursuing his studies a few years longer, he procured a doctor's degree from Cambridge, and settled as a physician in Westminster. The extensive practice which he is said to have enjoyed from 1660 to 1670, must be chiefly ascribed to the superior success of the means employed by him, which, being so different from those previously in use, became more readily a matter of notoriety; for, after the Restoration, his connexions could have contributed little to his advancement. He appears to have paid little attention to the prevailing medical doctrines, being early persuaded that the only mode of acquiring a correct knowledge of his art was to observe diligently the progress of diseases, whence the natural indications of cure might be derived; in which opinion he had the sanction of the celebrated Mr. Locke. It was to febrile diseases that he first applied this inductive method, and it cost him several years of anxious attention to satisfy himself as to the proper mode of treating them: the result of which he published in 1666, under the title of "Methodus curandi Febres," and again, nine years after, with additional remarks, suggested by subsequent experience. His writings are not altogether free from hypothesis; but he seems to have been little influenced by these in his practice; and by closely observing the operations of nature, and the effects of remedies, he was enabled to introduce very essential improvements. In small-pox especially, by checking the eruptive fever by means of cool air, and other antiphlogistic means, he ascertained that the eruption and consequent danger were greatly diminished; which plan applies likewise to other eruptive and febrile diseases, as has been since determined by general experience. His sagacity was also manifested in the correct histories which he has left of some diseases, as particularly small-pox, measles, gout, and hysteria. He was likewise very attentive to the varieties occurring, especially in febrile disorders at different seasons, or in different years; and was led to suppose these connected with a particular constitution of the air. He had been subject, for above thirty years, to gout, and stone in the kidney, which impaired his constitution, and at last terminated his life in 1689. After his death, a manual of practice, composed for his son, was published under the title of "Processus Integri in Morbis fere omnibus curandis." Sydenham ever maintained the character of a green sydenham ever maintained the character of a generous and public-spirited man; he conducted himself without that arrogance which too often accompanies original talent; and he has been universally acknowledged the first physician of his age. The numerous editions of his works, both singly and The numerous editions of his works, both singly and collectively, in almost every country of Europe, the deference paid to his authority, and the commendations bestowed upon him by almost all practical writers since, amply prove the solidity of his title to the high reputation attached to his name. The college of physicians, though he was only late in life admitted a licentiate, have subsequently placed his bust in their hall, near that of Harvay. hall, near that of Harvey

hall, near that of Harvey.

Sy'lphium. Assafætida is so termed by some writers. See Ferula assafætida.

SYLVANITE. Native tellurium.

Sylvius, digestive salt of. The muriate of potassa.

SY'LVIUS, Francis de le Boe, was born at Hanau, in 1614. He took his degree at Basle, and then visited, for improvement, some of the chief universities in France and Germany. He settled first at his native place, but removed to Amsterdam, where he enjoyed a high reputation for several years, till he was native place, but removed to Amsterdam, where he enjoyed a high reputation for several years, till he was called to Leyden, in 1658, to assume the office of first professor of medicine. He soon drew together, by his genius and eloquence, a numerous audience from all parts of Europe. He was one of the earliest advocates for Harvey's doctrine of the circulation of the blood, and chiefly effected its reception into that school. But, on the other hand, he materially retarded the progress. on the other hand, he materially retarded the progress of medicine by a fanciful hypothesis, which attracted much notice, referring all diseases to chemical changes, producing an excess of acid, or of alkali. His works were chiefly controversial tracts, in which he defended his peculiar notions. He died in 1672.

SYM SYM

Sylvius James by Bois, was born at Amiens, in like manner, suffer from their association or con1478. Having chosen the profession of physic, he studied diligently the writings of the ancients, especially Hippocrates and Galen, and was no less assiduous in the pursuit of other branches of medicine, by the increased inflammatory action of the uterus. particularly anatomy, pharmacy, and botany. Before taking a degree, he undertook a private course of lectures at Paris, in which he so distinguished himself, that in two years he collected a crowd of pupils from various parts of Europe; but the jealousy of the Parisian physicians obliged him to go to Montpelier, in 1520, for the purpose of graduation. His extreme parsimony, however, would not permit the necessary expenses; and he was at last successful in compromising simony, however, would not permit the necessary expenses; and he was at last successful in compromising his differences with the Parisian faculty. He subsequently continued his lectures with very great success; and in 1550 he was appointed professor of medicine at the royal college; but his death occurred five years afterward. His works were popular during the reign of the old school, but are now obsolete. As an anatomist he merits great praise, having made various discounted to the control of the old school, but are now obsolete. mist, he merits great praise, having made various dis-coveries, notwithstanding the few opportunities he had of human dissection. He wrote with great violence against Vesalius, his pupil, because he had presumed

to correct Galen.

SYMBLE PHARUM. (From συν, with, and βλεφαρον, the eyelid.) A concretion of the eyelid to the
globe of the eye. This chiefly happens in the supeglobe of the eye. This chiefly happens in the seperior, but very rarely in the inferior palpebra. The causes of this concretion are a bad conformation of the parts, or from ulcers of the cornea, the membrana conjunctiva, or internal superficies of the palpebra, or imprudent scarifications, or burns, especially if the eye remains long closed. There are two species, the partial, or total; in the former, the adhesion is partial, in the latter, the membrana conjunctiva and cornea are concreted to the eyelid together.

concreted to the eyelid together.

Sy'mbole. (From συμβαλλω, to knit together.) It is said either of the fitness of parts with one another, or of the consent between them by the intermediation of nerves, and the like.

(From συμβυλον, a sign, and The doctrine of the signs and SYMBOLO'GIA. λογος, a discourse.)

symptoms of disease.

SYMMETRY. The exact and beautiful proportion

of parts to one another.

SYMPATHETIC. Sympatheticus.

Relating to sympathy.

1. Relating to sympathy.
2. See Intercostal nerve.
Sympathetic nerve. See Intercostal nerve.
SYMPATHY. (Sympathia; from συμπασχω, to suffer together, to sympathize.) All the body is sympathetically connected together, and dependent, the one part upon the rest, constituting a general sympathy. But sometimes we find particular parts more intimately dependent upon each other than upon the rest of the body, constituting a particular sympathy. Action cannot be greatly increased in any one organ, without being diminished in some other; but certain parts are ing diminished in some other; but certain parts are more apt to be affected by the derangement of particular organs than others; and it was the observance of this fact which gave foundation to the old and well known doctrine of sympathy, which was said to proceed "tum ob communionem et similitudinem generis, tum ob viciniam." It may be thought that this posi-tion of action being diminished in one organ, by its increase, either in the rest or in some other part, is contradicted by the existence of general diseases or contradicted by the existence of general diseases or actions affecting the whole system. But in them we find, in the first place, that there is always some part more affected than the rest. This local affection is sometimes the first symptom, and affects the constitution in a secondary way, either by the irritation which it produces, or by an extension of the specific action. At other times the local affection is coeval with the general disease, and is called sympathetic. It is obgeneral disease, and is called sympathetic. It is observed, in the second place, that as there is some part which is always more affected than the rest, so also is there some organ which has its action, in consequence of this, diminished lower than that of the rest of the system, and most commonly lower than its natural standard. From the extended as a standard of the rest of the system, and most commonly lower than its natural standard. From the extensive sympathy of the sto-mach with almost every part of the body, we find that this most frequently suffers, and has its action dimi-nished in every disease, whether general or local, pro-vided that the diseased action arises to any consider-able degree. There are also other over any which me able degree. There are also other organs which may,

instance, we see, in the general disease called here-ral fever, that the action of the breasts is diminished by the increased inflammatory action of the aterus.

In consequence of this balance of action, or general connexion of the system, a sudden pain, consequent to violent action of any particular part, will so weaken the rest as to produce fainting, and occasionally death. But this dependence appears more evidently in what may be called the smaller systems of the body, or those parts which seem to be more intimately connected with each other than they are with the general system. Of this kind is the connexion of the breasts with the utethis kind is the connexion of the breasts with the uterus of the female; of the urethra with the testicles of the male; of the stomach with the liver; and of the intestines with the stomach, and of this again with the brain; of the one extremity of the bone with the other; and of the body of the muscle with its insertion; of the skin with the parts below it.

These smaller systems, or circles, shall be treated regularly; but first it may be proper to observe, that these are not only intimately connected with themselves, but also with the general system, a universal

sympathy being thus established.

That there is a very intimate connexion between the breasts and uterus has been long known; but it has not been very satisfactorily explained. Fallopius, and all the other authors, declare plainly that the sympathy is produced by an anastomosis of vessels; Bartholin adding that the child being born, the blood no longer goes to the uterus, but is directed to the breasts and changed into milk. But none of all those who talk of this derivation assign any reasonable cause which many this derivation, assign any reasonable cause which may produce it.

In pregnancy, and at the menstrual periods, the uterus is active; but, when the child is delivered, the action of the uterus subsides, while the breasts in their turn become active, and secrete milk.

If, at this time, we should again produce action in the uterus, we diminish that of the breasts, and destroy the secretion of milk, as is well illustrated by the case of inflammation of the uterus, which is incident to lying-in women. When the uterus, at the cessation of the menses, ceases to be active, or to secrete, we often find that the breasts have an action excited in them, becoming slowly inflamed, and assuming a cancerous disposition. The uterus and breasts seem to be a set of glands balancing each other in the system, one only being naturally active, or secreting properly, at a time; and accordingly we seldom, if ever, find that when the uterus yields the menstrual discharge, the milk is secreted in perfection, during the continuance of this discreted in perfection, during the continuance of this discreted in perfection. charge, nor do we ever find them both inflamed at the same time.

The uterus has not only this connexion with the breasts, but it has also a very particular sympathy with the stomach, which again sympathizes with the brain; and thus we see how a disorder of the uterus may induce an extensive series of affections, each dependent on the other.

The organs of generation in the male form likewise a little system, in which all the parts exhibit this sympathy with each other. They likewise give us a very good instance of the association of action, or sympathy, in the common acceptation of that word.

Sympathy is divided into, first, the sympathy of equilibrium, in which one part is weakened by the in-creased action of another; and, secondly, the sympa-thy of association, in which two parts act together at

the same time.

The sympathy of association is produced suddenly, and for a short time. The sympathy of equilibrium is produced more slowly, and continues to operate for a much longer time.

It is curious enough, that most, or at least many, of those organs, which seem to be connected by the sympathy of equilibrium, exhibit likewise more or less of the sympathy of association, when under the circum-

stances in which this can take place.

The sympathy of equilibrium is seen in the effects of inflammation of the end of the urethra on the testicle; which often diminishes its action, and produces a very disagreeable sensation of dulness, or, if this in-flammation be suddenly diminished, the action of the testicle is as suddenly increased, and swelling takes place. The same is seen in the connexion of the place.

tioned in all the dissertations on gonorrhoea. parts likewise affect the stomach greatly, increased action in them weakening that organ much. This is seen in the effects of swelled testicle, or excessive venery, or inflamed bladder, and in a stone; all which weaken the stomach, and produce dyspepsia. The same remark applies to the kidney; vomiting and flatu-

lence being produced by nephritis.

The sympathy of association, or an instance of sympathy in the common acceptation of the word, is likewise seen in the connexion between the glans and testicles in coition; but for this purpose, the action in the glans must be sudden, and of short duration; for, if continued long, weakness of the testicles, or diminished action, is induced. In those parts which exhibit this natural association of action, if the action of one part he suddenly and for a short time increased, the action of the sympathizing part will likewise be increased; as we see in the instance already given of coition, and likewise in paroxysms of the stone, in which the glans penis, after making water, becomes very painful.

But if the action be more slowly induced, and continued for a long time, then this association is set aside, by a stronger and more general principle of the equilibrium of action, and the sympathizing part is weakened. Hence violent inflammation of the end of the urethra produces a weakness and irritability of the

bladder, dulness of the testicle, &c.

There is also an evident sympathy of equilibrium between the stomach and lower tract of intestines; which two portions may be said in general to balance each other in the abdomen. When the action of the intestines is increased in diarrhoa, the stomach is often Weakened, and the patient tormented with nausea.

This will be cured, not so easily by medicines taken into the stomach, as by anodyne clysters, which will abate the action of the intestines. When the intestines are inflamed, as in strangulated hernia, vomiting is a never-failing attendant.

When again the stomach is inflamed, the intestines are affected, and obstinate costiveness takes place; even in hysterical affections of the stomach, the intes-tines are often deranged. Injections of cold water frequently relieve these affections of the stomach, by their

action on the intestines.

The liver and stomach are also connected with one another. When the liver is inflamed, or has its action increased, the stomach is weakened, and dyspeptic symptoms take place. When the stomach is weakened, as, for instance, by intoxication, then the action of the liver is increased, and a greater quantity than usual of bile is secreted. The same takes place in warm climates, where the stomach is much debilitated.

If the liver has its action thus frequently increased, If the liver has its action thus requently increased, it assumes a species of inflammation, or becomes, as it is called, scirrhous. This is exemplified in the habitual dram-drinkers, and in those who stay long in warm countries, and use freedoms with the stomach. The liver likewise sympathizes with the brain; for when this organ is injured, and its action much impaired, as in compression, inflammation and suppuration to the page in the liver. tion have been often known to take place in the liver.

Besides this connexion of the stomach with the liver, it is also very intimately dependent on the brain, being weakened when the action of the brain is increased; as we see in an inflammation of that organ. The brain again is affected with pain when the stomach is weakened by intoxication or other causes; and this pain will be often relieved by slowly renewing the action of the stomach by such stimuli as are natural to it, such as small quantities of soup frequently repeated. A slight increase of action in the stomach, at least if not of a morbid kind, affects the brain so as to produce sleep, diminishing its action. This we see in the effects of a full meal, and even of a draught of warm The stomach likewise sympathizes with the water. The stomach fixewise sympathizes with the throat, squeamishness and anorexia being often produced by inflammation of the tonsils. This inflammation is frequently abated by restoring or increasing the action of the stomach. Hence the throat, in slight inflammation, is frequently easier after dinner; hence, likewise, the effects of emetics in cynanche.

The extremities of bones and muscles also sympathize in the same manner. When one end of a bone is inflamed, the action of the other is lessened, and

thize in the same manner. When one end of a bone is inflamed, the action of the other is lessened, and pain is produced; for a painful sensation may result

wrethra with the bladder and prostate gland, as is mentioned in all the dissertations on gonorrhoea. These the tendon of a muscle is inflamed, the body of that the tendon of a muscle is inflamed, the body of that

muscle often is pained, and vice versa.

Lastly, the external skin sympathizes with the parts below it. If it be inflamed, as in erysipelas, the parts immediately beneath are weakened, or have their natural action diminished. If this inflammation affect the face, or scalp, then the brain is injured; and head-ache, stupor, or delirium supervene. If it attack the skin of the abdomen, then the abdominal viscera are affected, and we have vomiting and purging, or obatinate costiveness, according to circumstances. This is illustrated by the disease of children, which is called by the women the bowel-hive, in which the skin is inflamed, as they suppose, from some morbid matter within.

If the internal parts be inflamed, the action of the surface is diminished, and, by increasing this action, we can lessen or remove the disease below; as we see daily proved by the good effects of blisters. When the stomach, intestines, or kidney have been very irri-table, a sinapism has been known to act like a charm; and in the deep-seated inflammations of the breasts, bowels, or joints, no better remedy is known, after the

use of the lancet, than blisters.

The utility of issues in diseases of the lungs, the liver, and the joints, is to be explained on the same principle. In these cases we find that issues do little good unless they be somewhat painful, or be in the state of healthy ulcers. An indolent flabby sore, however large the discharge (which is always thin, and accompanied with little action), does no good, but only adds to the misery of the patient. We may, however, err on the other hand, by making the issues too painful, or by keeping them active too long; for after they have removed the inflammatory disease below, they will still operate on these parts, lessening their action and preventing the healing process from going on properly. This is seen in cases of curvature of the spine, where, at first, the inflammation of the vertebra is diminished by the issues; but if they be kept long open after this is removed, they do harm. We often see the patient recover rapidly after his surgeon has healed the issue in despair, judging that it could do no farther service, but only increase the weakness of his patient.

It is a well-established fact, that when any particular action disappears suddenly from a part, it will often speedily affect that organ which sympathizes most with the part that was originally diseased. This is best seen in the inflammatory action, which, as practi-cal writers have well observed, occasionally disappears quickly from the part first affected, and then shows

itself in some other.

From the united testimony of all these facts, Mr. Burns, of Glasgow, maintains the doctrine just deli-vered, and proposes to introduce it into pathological reasonings. In the whole of the animal economy, we discover marks of the wisdom of the Creator, but perhaps in no part of it more than in this, of the existence the sympathy of equilibrium; for, if a large part of the system were to have its action much increased, and all the other parts to continue acting in the same proportionate degree as formerly, the whole must be soon exhausted; (for increased action would require for its support an increased quantity of energy.)

But upon this principle, when action is much in-creased in one part, it is to a certain degree diminished in some other, the general sum or degree of action in the body is thus less than it otherwise would be, and

consequently the system suffers less.

SY'MPHYSIS. (From συν, together, and φυω, to grow.) Mediate connexion. A genus of the connexion of bones, in which they are united by means of an intervening body. It comprehends four species, viz. synchondrosis, syssarcosis, syncurosis, and syndermosis. desmosis

SYMPHYTUM. (From συμφυω, to unite; so called because it is supposed to unite and close the lips of wounds together.)

The name of a genus of plants in the Linnman system. Class, Pentandria; Order, Monogynia.
 The pharmacopæial name of the comfrey. See

Sumphytum officinale.

SYMPHYTUM MACULOSUM. See Pulmonaria officinalis.

SYMPHYTUM MINUS. See Prunella.

SYMPHYTUM OFFICINALE. The systematic name of

SYN SYN

the comfrey. Consolida major. This plant, Symphy-tum-foliis-ovatis lanceolatis decurrentibus, is admi-nistered where the althea cannot be obtained, its roots abounding with a viscid glutinous juice, whose virtues are similar to those of the althwa.

Symphytum Petræum. See Coris monspeliensis.

SYNA'NCHE. See Cynanche.
SYNA'NCHICA. (From συναγχη, the quinsey: so called from its uses in that disease.) Quinseywort.

SYNARTHRO'SIS. (From over, together, and approve, a joint.) Immoveable connexion. A genus of connexion of bones, in which they are united together by an immoveable union. It has three species, viz. suture, harmony, and gomphosis.

SYNASTOMO'SIS. This is used in the same sense

SYNCHONDRO'SIS. (From συν, with, and χονόρος, a cartilage.) A species of symphysis, in which one bone is united with another by means of an intervening cartilage; as the vertebræ and the bones of the

SYNCHONDROTO MIA. (From συνχονόρωσις, the symphysis of the pubes, and τεμνω, to cut.) The opera-

tion of dividing the symphysis of the pubes.

SY'NCHYSUS. (From συγχυω, to confound.) A solution of the vitreous humour into a fine attenuated aqueous fluid. In Cullen's Nosology, it is a variety of his species caligo pupilla.

SYNCIPUT. (Synciput vel sinciput, itis. n.)
The forepart of the head or cranium.
SY'NCOPE. (From συν, with, and κοπ τω, to cut, or strike down.) Animi deliquium; Leipothymia; SYNCOPE. (Flora deliquium; Lespocayma, Defectio animi; Dissolutio; Ezanimatio; Asphyxia; Virium lapsus; Apopsychia; Apsychia; Ecchysis. Fainting or swooning. A genus of Cullen, in which Fainting or swooning. A genus of disease in the Class Neuroses, and Order Adynamia, of Cullen, in which the respitation and action of the heart either cease, or become much weaker than usual, with paleness and coldness, arising from diminished energy of the brain, or from organic affections of the heart. Species: 1 Syncope cardiaca, the cardiac syncope, arising without a visible cause, and with violent palpitation of the heart, during the intervals, and depending generally on some organic affection of the heart or neighbouring vessels.

2. Syncope occasionalis, the exciting cause being

manifest.

The disease is sometimes preceded by anxiety about the præcordia, a sense of fulness ascending from the stomach towards the head, vertigo or confusion of ideas, dimness of sight, and coldness of the extremities. The attacks are frequently attended with, or end in, vomiting, and sometimes in epileptic or other convulsions. The causes are sudden and violent emotions of the mind, pungent or disagreeable odours, derangement of the primæ viæ, debility from preceding disorders, loss of blood spontaneous or artificial, the operation of paracentesis, &c. During the paroxysm the nostrils are to be stimulated with some of the preparations of ammonia, or these may be exhibited internally, if the patient is capable of swallowing; but when the disease has originated from large loss of blood, such stimulants must be used cautiously. When it is connected with a disordered state of the stomach, if an emetic can be given, or compliance excited by irritating the forces it will see or vomiting excited by irritating the fauces, it will pro-bably afford relief. Sometimes sprinkling the face with cold water will recover the patient. And when there is reason for supposing an accumulation about the heart, the disease not having arisen from debilitating causes, a moderate abstraction of blood may be made with propriety. Between the fits we should endeavour to strengthen the constitution, where debility appears concerned in producing them, and the several exciting causes must be carefully guarded against. When organic affections of the heart, and parts connected with it, exist, all that can be done is, to palliate the attacks of fainting; unless the primary disease can be removed, which is extremely care. removed, which is extremely rare.

SYNCOPE ANGINOSA. See Angina pectoris.

SYNDESMOLO'GIA. (From συνδεσμος, a ligament, and λογος, a discourse.) The doctrine of the ligaments. SYNDESMO-PHARYNGEUS. See Constrictor pharyngis medius.

bones in which they are united by ligament, as the

radius with the ulna.

SYNDE'SMUS: (From συνδεω, to bind together.)

SYNE CHIA. Σενεχία. A concretion of the iris with the cornea, or with the capsule of the crystalline lens. The proximate cause is adhesion of these parts, the consequence of inflammation. The remote causes are, a collapse of the cornea, a prolapse of the iris, a swelling or tumefied cataract, hypopium, or original formation. The species of this disorder are,

1. Synechia anterior totalis, or a concretion of the iris with the cornea. This species is known by inspecting the parts. The pupil in this species is dilated or coaretated, or it is found concreted; from whence various lesions of vision.

Synechia anterior partialis, when only some part of the iris is accreted. This concretion is observed in one or many places; from hence the pupil is variously disfigured, and an inordinate motion of the pupil is per-

3. Synechia anterior composita, when not only the whole iris, but also a prolapse of the crystalline lens,

unites with the cornea.

Syncchia posterior totalis, or a concretion of the whole uvea, with the ciliary processes and the capsule of the crystalline lens.

 Synechia posterior partialis, when only some part of the capsule of the crystalline lens is concreted with the uvea and cornea. This accretion is simplex, duthe uvea and cornea. This ac plex, triplex, or in many places.

6. Synechia complicata, with an amaurosis, cataract, mydriasis, myosis, or synizesis.

SYNEURO'SIS. (From συν, with, and νευρον, a nerve, because the ancients included membranes, ligaments, and tendons under the head of nerves.) A special tendon to the synited to an account of the synited to account cies of symphysis, in which one bone is united to another by means of an intervening membrane.

SYNGENESIA. (From συν, together, and γενεσις, generation.) The name of a class of plants, in the sexual system of Linnæus, consisting of plants in which the anthers are united into a tube, the filaments on which they are supported being mostly separate and distinct.

The flowers are compound.

SYNIZE'SIS. A perfect concretion and coarctation of the pupil. It is known by the absence of the pupil, and a total loss of vision. The species are,

1. Synizesis nativa, with which infants are sometimes born. In this case, by an error of the first conformation of the pupil, there is no perforation; it is very rarely found.

2. Synizesis accidentalis, a concretion of the pupil, from an inflammation or exulceration of the uvea or iris, or from a defect of the aqueous or vitreous hu-

mour.

3. Synizesis, from a secession of the iris or cornea. From whatever cause it may happen, the effect is certain, for the pupil contracts its diameter; the longitudinal fibres, separated from the circle of the cornea, cannot resist the orbicular fibres: from hence the pupil

is wholly or partially contracted.

4. Synizesis complicata, or that which is complicated with an amaurosis, synechia, or other occular disease. The amaurosis, or gutta serena, is known by the total absence of light to the retina. We can distinguish this not only by the pupil being closed, but likewise the eyelicide. lids; for whether the eyelids be open or shut, all is darkness to the patient. The other complicated cases are known by viewing the eye, and considering the parts anatomically.

5. Synizesis spuria, is a closing of the pupil by mu

cus, pus, or grumous blood.

SY'NOCHA. (From συνεχω, to continue.) Febris synocha. Inflammatory fever. A species of continued fever, characterized by increased heat; pulse frequent, strong, hard; urine high-coloured; senses not impaired. This fever is so named from its being attended with symptoms denoting general inflammation in the system, by which we shall always be able readily to distinguish it from either the nervous or putrid. It makes its at-tack at all seasons of the year, but is most prevalent in the spring; and it seizes persons of all ages and habits, but more particularly those in the vigour of life, with strong elastic fibres, and of a plethoric constitution. It SYNDESMO'SIS. (From συνδεσμος, a ligament.) is a species of fever almost peculiar to cold and tempo
That species of symphysis or mediate connexion of rate climates, being rarely, if ever, met with in very

SYN SYN

warm ones, except among Europeans lately arrived; and even then, the inflammatory stage is of very short duration, as it very soon assumes either the nervous or

putrid type.

The exciting causes are sudden transitions from heat to cold, swallowing cold liquors, when the body is much heated by exercise, too free a use of vinous and spirituous liquors, great intemperance, violent passions of the mind, the sudden suppression of habitual evacuations, and the sudden repulsion of cruptions. It may be doubted if this fever ever originates from personal infection; but it is possible for it to appear as an epidemic among such as are of a robust habit, from a peculiar state of the atmosphere. It comes on with a sense of lassitude and inactivity, succeeded by vertigo, rigors, and pains over the whole body, but more particularly in the head and back; which symptoms are shortly followed by redness of the face and eyes, great restlessness, intense heat, and unquenchable thirst, oppression of breathing, and nausea. The skin is dry and parched; the tongue is of a scarlet colour at the sides, and furred with white in the centre; the urine is red and scanty; the body is costive; and there is a quickness, with a fulness and hardness in the pulse, not much affected by any pressure made on the artery. If the febrile symptoms run very high, and proper means are not used at an early period, stupor and delirium come on, the imagination becomes much disturbed and hurried, and the patient rayer yielently. The disease usually goes through its raves violently. The disease usually goes through its course in about fourteen days, and terminates in a crisis, either by diaphoresis, diarrhœa, hæmorrhage from the nose, or the deposite of a copious sediment in the urine; which crisis is usually preceded by some variation in the pulse.

Our judgment as to the termination of the disease must be formed from the violence of the attack, and the nature of the symptoms. If the fever runs high, or continues many days with stupor or delirium, the event may be doubtful; but if to these are added, picking at the bed-clothes, startings of the tendons, involuntary discharges by stool and urine, and hiccups, it will then certainly be fatal. On the contrary, if the febrile heat abates, the other symptoms moderate, and there is a tendency to a crisis, we may then expect a recovery. In a few instances, this fever has been known to ter-

minate in mania.

On opening those who die of an inflammatory fever, an effusion is often perceived within the cranium, and now and then, topical affections of some of the viscera

The chief indication in synocha is to lessen the ex-The chief indication in synocha is to lessen the excessive vascular action by evacuations, and the antiphlogistic regimen. Of the former, by far the most important is blood-letting, which should be freely practised in this disease, making a large orifice into the vein, and taking from ten to twenty-four ounces of blood, according to the violence of the symptoms, and the strength of the patient. The disorder may sometimes be cut short at once by this active treatment in the beginning; but if it should continue urgent, and the strength of the pulse keep up, the repetition of it within strength of the pulse keep up, the repetition of it within more moderate limits will be from time to time advisable. Purging is next in efficacy, especially with those articles which produce copious serous discharges, and thoroughly clear out the intestines, as the saline cathartics, with infusion of senna, jalap with supertartrate of potassa, &c. As the disease advances, however, we must act less on this part, and attempt to promote the other discharges, particularly that by the skin: for which purpose calomel, antimonials, and the saline diaphoretics are to be exhibited. The antiphlogistic diapnoretics are to be exhibited. The antiphlogistic regimen consists in obviating stimuli of every kind, so far as this can be done safely; impressions on the senses, particularly the sight and hearing, bodily and mental exertion, &c. must be guarded against as much as possible. The diet should be of the most sparing kind; barley-water, or other mild liquid, with some acid, perhaps, added, or a little nitrate of potassa dissolved in it, taken in small quantities from time to time, chiefly to quench the thirst and coul the holy. time, chiefly to quench the thirst, and cool the body, will be the most proper; strictly interdicting animal food, fermented liquors, and the like. The stimulus of heat must be especially obviated by light clothing, or even exposing the body to the air, ventilating the apartment, sprinkling the floor with vinegar and water, &c. When the head is much affected, heaides the general treatment, it will be proper to take blood locally, have

the head shaved and cooled by some evaporating lotion, apply a blister to the neck, and, perhaps, stimulate the lower extremities. In like manner, any other organ being particularly pressed upon, may require additional means, which will be sufficiently understood by adverting to the several philegmasiæ.

ing to the several phlegmasiæ.

SY'NOCHUS. (From συνεχω, to continue.) A mixed fever. A species of continued fever, commencing with symptoms of synocha, and terminating in typhus; so that synocha and typhus, blended together in a slight degree, seem to constitute this species of fever, the former being apt to preponderate at its commencement, and the latter towards its termination.

Every thing which has a tendency to energate the

Every thing which has a tendency to enervate the body, may be looked upon as a remote cause of this fever; and accordingly we find it often arising from great bodily fatigue, too great an indulgence in sensual pleasures, violent exertion, intemperance in drinking, and errors in diet, and now and then likewise from the suppression of some long-accustomed discharge. tain passions of the mind (such as grief, fear, anxiety, and joy,) have been enumerated among the causes of fever, and in a few instances, it is probable, they may have given rise to it; but the concurrence of some other powers seems generally necessary to produce this effect. The most usual and universal cause of this fever is the application of cold to the body; and its morbid effect seem to depend partly upon certain cir-cumstances of the cold itself, and partly upon certain circumstances of the person to whom it is applied.

The circumstances which seem to give the application of cold due effect, are its degree of intensity, the length of time which it is applied; its being applied generally, or only in a current of air, its having a degree of moisture accompanying it, and its being a considerable or sudden change from heat to cold. The circumstances of persons rendering them more liable to be affected by cold, seem to be debility, induced either by great fatigue, or violent exertions, by long fasting, by the want of natural rest, by severe evacuations, by preceding disease, by errors in diet, by intemperance in drinking, by great sensuality, by too close an application to study, or giving way to grief, fear, or great anxiety, by depriving the body of part of its accustomed lething by exposing any one particular part of its clothing, by exposing any one particular part of it, while the rest is kept of its usual warmth, or by exposing it generally or suddenly to cold when heated much beyond its usual temperature; these we may, therefore, look upon as so many causes giving an effect to cold which it otherwise might not have produced. Another frequent cause of fever seems to be breathing air contaminated by the vapours arising either directly or originally from the body of a person labouring under the disease. A peculiar matter is supposed to generate in the body of a person affected with fever, and this floating in the atmosphere, and being applied to one in health, will no doubt often cause fever to take place

in health, will no doubt often cause fever to take place in him, which has induced many to suppose, that this infectious matter is produced in all fevers whatever, and that they are all, more or less, contagious.

The effluvia arising from the human body, if long confined to one place without being diffused in the atmosphere, will, it is well known, acquire a singular virulence, and will, if applied to the bodies of men become the cause of fever. Exhalations, arising from animal or vegetable substances in a state of putrefaction, have been looked upon as another general cause tion, have been looked upon as another general cause of fever: marshy or moist grounds, acted upon by heat for any length of time, usually send forth exhalations which prove a never-failing source of fever, but more particularly in warm climates. Various hypotheses have been maintained, with respect to the proximate cause of fever; some supposing it to be a lentor or viscidity prevailing in the mass of blood, and stagnating in the extreme vessels; others, that it is a noxious matter introduced into, or generated in, the body, and that the increased action of the heart and arteries is an effort of nature to expel the morbific matter; others, that it consisted in an increased secretion of bile; and others again, that it is to be attributed to a spasmodic

SYP SYN

and the skin over the whole surface of the body ap-pears constricted; he then perceives a sensation of

pears constricted; he then perceives a sensation of cold in his back, passing from thence over his whole frame; and this sense of cold continuing to increase, tremors in the limbs and rigors of the body succeed.

With these there is a loss of appetite, want of taste in the mouth, slight pains in the head, back, and loins, small and frequent respirations. The sense of cold and its effects after a little time becomes less violent, and are alternated with flushings, and at last, going off altogether, they are succeeded by great heat diffused generally over the whole body; the face looks flushed, the skin is dry, as likewise the tongue, universal restlessness prevails, with a violent pain in the head, opressness prevails, with a violent pain in the head, op-pression at the chest, sickness at the stomach, and an inclination to vomit. There is likewise a great thirst and costiveness, and the pulse is full and frequent, beating, perhaps, 90 or 100 strokes in a minute. When the symptoms run very high, and there is a consider-able determination of blood to the head, a delirium will arise. In this fever, as well as most others, there is generally an increase of symptoms towards evening.

If the disease is likely to prove fatal, either by its continuing a long time, or by the severity of its symptoms, then a starting of the tendons, picking at the bedclothes, involuntary discharges by urine and stool, coldness of the extremities, and hiccoughs, will be observed; where no such appearances take place, the

disease will go through its course.

As a fever once produced will go on, although its cause be entirely removed, and as the continued or fresh application of a cause of fever neither will increase that which is already produced, nor occasion a new one, there can be no certainty as to the duration of fever; and it is only by attending to certain appearances or changes, which usually take place on the approach of a crisis, that we can form any opinion or decision. The symptoms pointing out the approach of a crisis are, the pulse becoming soft, moderate, and near its natural speed; the tongue losing its fur and becoming clean, with an abatement of thirst; the skin being covered with a gentle moisture, and feeling soft to the touch; the secretory organs performing their several offices; and the urine depositing flaky crystals of a dirty red colour, and becoming turbid on being allowed to stand any time.

Many physicians have been of opinion, that there is something in the nature of all acute diseases, except those of a putrid kind, which usually determines them to be of a certain duration, and, therefore, that these terminations, when salutary, happen at certain periods of the disease rather than at others, unless disturbed in their progress by an improper mode of treatment, or the arising of some accidental circumstance. periods are known by the appellation of critical days; and from the time of Hippocrates down to the present, have been pretty generally admitted. The truth of them, Dr. Thomas thinks, can hardly be disputed, however they may be interrupted by various causes. A great number of phenomena show us, that both in the sound state and the discased, nature has a ten-dency to observe certain periods; for instance, the vicissitudes of sleeping and watching occurring with such regularity to every one; the accurate periods that the menstrual flux observes, and the exact time of pregnancy in all viviparous animals, and many other such instances that might be adduced, all prove this law

With respect to diseases, every one must have observed the definite periods which take place in regular intermittents, as well those universal as topical; in the course of true inflammation, which at the fourth, or at the farthest the seventh day, is resolved, or after this period changes into either abscess, gangrene, or scirrhus; in exanthematous eruptions, which, if they are favourable and regular, appear on a certain and definite day; for example, the small-pox about the fourth day. All these appear to be founded on immutable laws, according to which the motions of the body in health and in disease are governed.

The days on which it is supposed the termination of continued fevers principally happens, are the third, fifth, seventh, ninth, eleventh, fourteenth, seventeenth,

and twentieth. A simple continued fever terminates always by a

the face and extremities at the same time become pale, I the febrile matter falling on some particular parts, it excites inflammation, abscess, eruption, or destroys the patient.

Great anxiety, loss of strength, intense heat, stupor, delirium, irregularity in the pulse, twitchings in the fingers and hands, picking at the bed-clothes, startings of the tendous, hiccoughs, involuntary evacuations by urine and stool, and such like symptoms, point out the certain approach of death.

On the contrary, when the senses remain clear and distinct, the febrile heat abates, the skin is soft and moist, the pulse becomes moderate and is regular, and the urine deposites flaky crystals, we may then expect a speedy and happy termination of the disease.

The usual appearances which are to be observed on dissection of those who die of this fever, are an effusion within the cranium, and topical affections perhaps of

some viscera.

This disease being of a mixed nature, the treatment must be modified accordingly. In the beginning, the same plan is to be pursued as in synocha, except that we must be more sparing in the use of the lancet, in proportion as there is less power in the system, to main-tain the increased action of the heart and arteries; although if any important part should be much at-fected, we must act more vigorously, to prevent its disorganization, and the consequent destruction of life. When the character of the disease is changed, the means proper will be such as are pointed out under the

head of Typhus. SYNO VIA. (A term of no radical meaning, coined by Paracelsus.) coined by Paracelsus.) An unctuous fluid secreted from certain glands in the joint in which it is contained. Its use is to lubricate the cartilaginous surfaces of the

articulatory bones, and to facilitate their motions.

SYNOVIAL. Synovialis. Of or belonging to the synovia, or fluid of the joints.

SYNOVIAL GLANDS. Glandulæ synoviales. The assemblage of a fatty fimbriated structure within the Glandulæ synoviales. The cavities of some joints.

SYNTENO'SIS. (From συν, with, and τενων, a tendon.) A species of articulation where the bones are connected together by tendons.

SYNTE'XIS. (From συντηχω, to dissolve.) A marasmus or wasting of the body. SY'NTHESIS. (From συντιθημι, to compose.)

SY'NTHESIS. (From συντιθημι, to compose.)
Combination. See Analysis.
Syntheti's Mus. (From συνθεω, to concur.) The

reduction of a fracture.

Synulo'TICA. (From συνουλοω, to cicatrize.) Me-

dicines which heal wounds.

SY'PHILIS. (The name of a shepherd, who fed the flocks of king Alcithous, who, proud of their num-ber and beauty, insulted the sun; as a punishment for which, fable relates, that this disease was sent on earth; or from σιφλος, filthy.) Lues venerea; Morbus gallicus; Aphrodisius morbus; Morbus indicus; Morbus neapolitanus; Patursa. A genus of disease in the Class Cachexia, and Order Impetigines, of Cullen. Towards the close of the memorable fifteenth century, about the year 1494 or 1495, the inhabitants of Europe were greatly alarmed by the sudden ap-pearance of this disease. The novelty of its symptoms, and the wonderful rapidity with which it was propa-gated throughout every part of the known world, soon made it an important object of medical inquiry.

In common language, it is said a person has syphilis or is poxed, when the venereal poison has been re-ceived into, or is diffused through the system, and there produces its peculiar effects, as ulcers of the mouth or fauces, spots, tetters, and ulcers of the skin, pains, swelling, and caries of the bones, &c. But as long as the effects of the poison are local and confined to or near the genitals, the disorder is not called syphilis, lues venerea, nor pox; but distinguished by some par-ticular name, according to its different seat or appearance; such as gonorrhœa venerea, chancre, or bubo.

The venereal disease is always produced by a poison. Concerning the nature of this poison, we know no more than we do about that of the small-pox or any other contagion; we know only that it produces pecu-liar effects. The smallest particle of this poison is sufficient to bring on the most violent disorder over the whole body. It seems to spread and diffuse itself by a kind of fermentation and assimilation of matter; and, like other contagions, it requires some time after being regular crisis in the manner before mentioned, or from applied to the human body, before it produces that

effect. It is not known whether it has different degrees of acrimony and volatility, or whether it is always the same in its nature, varying only with regard to the particular part to which it is applied, or ac-cording to the different habit and constitution or particular idiosyncrasy of the person who receives the infection. We know that mercury possesses a certain and specific power of destroying the venereal virus; but we are quite uncertain whether it acts by a sedative, adstringent, or evacuant quality; or, which is not un-likely, by a chemical elective attraction whereby both substances uniting with one another are changed to a third, which is no more hurtful, but has some new properties entirely distinct from those which any of them had before they were united. The variolous miasma, we know, produces its effects in about twenty or twenty-four days after the infection is received from the atmosphere, and eight or ten days if by inoculation, but the venereal virus seems to keep no particular period. At some times, and, perhaps, in particular persons, Dr. Swediaur has seen chancres arise in the space of twelve hours, nay, in a still shorter time, indeed he mentions in a few minutes, after an impure coition; whereas in most cases, they make their ap-pearance only in so many days. The generality of men feel the first symptoms of a clap between the second and fifth days after an impure coltus; but there are instances where they do not appear till after as many weeks or months. Dr. S. was consulted by a young man, who was seized with a violent discharge from the glans along with a phimosis, but without any chancres, four weeks after coition; and during all the interval. he felt not the least symptom of the disease. Some years ago, a gentleman went out from London, in seemingly perfect health, to the East Indies; but on his arrival in that hot climate, after a voyage of four months, a violent clap broke out before he went on shore, though he could have received no infection during the voyage, as there was not a woman on board. There are instances which render it probable that the virusmay lie four, five, or six weeks, and perhaps longer, on the surface of the genitals before it is absorbed and were it not then to produce a chancre, might pro-bably not he absorbed at all. We see daily examples, where common women communicate the infection to different men in the space of several weeks, while they themselves have not the least symptom of syphilis local or universal, the poison lying all that time in the vagina harmless, and generally without being absorbed. How long the venereal virus may lurk in the body itself, after it has been absorbed into the mass of blood, before it produces any sensible effect, is a matter of equal uncertainty. There is scarcely a practitioner equal uncertainty. who has not observed instances of its remaining harmless for weeks or even months in the body. Dr. Swe-diaur had a case, where, after lying dormant for half a year, it broke out with unequivocal symptoms. But the following instance, if it be depended upon, is still more extraordinary:

Some years ago, says the above writer, I was consulted by a gentleman about a sore throat, which I declared to be venereal. My patient was astonished; and assured me that for nine years past he had not had the least venereal complaint, nor had be any reason to believe he had since received any infection; but that he had been in the East Indies, where he was affected with a violent clap. On his return to Europe, being to appearance in good health, he married, and conti-nued perfectly free of any such complaint ever since. By a mercurial course, however, the complaint for which he applied to me was completely removed. With regard to its effects, the venereal poison follows no constant rule; for though, in general, it affects first the throat, where it produces ulcerations, in others it exerts its virulence on the skin or bones. While the greatest part of mankind are thus easily affected by this poison, there are some few who seem to be altogether unsusceptible of the infection: as happens equally with the variolous contagion, though they go into infected places, and expose themselves to inocula-tion or every hazard by which the disease is generally communicated.

Some persons are more liable than others to be infected who are seemingly of the same habit; nay, the very same person seems to be more liable to be infected at one time than another, and those who have been once infected seem to be more liable to catch the infection a second time, than those who never were infected before with the disease. The climate, season, age, state of health, idiosyncrasy, are, perhaps, as in other diseases, the necessary predisposing causes. The same difference is observable in the progress made by the disease after the patient is infected. In some the progress is slow, and the disease appears scarcely to gain any ground; while in others it advances with the utmost rapidity, and speedily produces the most terrible symptoms. Whether the venereal poison can be abso.bed into the system, without a previous excoriation, or ulceration of the genitals, or some other parts of the surface of the body, is still a matter of doubt. Several cases, however, have occurred which render it highly probable, if not certain, that the poison really is now and then absorbed, without any previous excoriation or ulceration whatsoever, and thus produces buboes and other venereal symptoms in the body.

It has been asserted by the earliest and even by some late writers, that it may be caught by lying in the same bed or living in the same room with or after an infected person. What may have been the case at the commencement of the disease, rannot be said, but the most accurate observations and experiments, which have been made upon the subject, do not confirm this to be the case in our times. Nor are nurses infected in the Lock-Hospital, where they live night and day with patients in all stages of the distemper. The fact seems to be, that patients in our times are apt to impose upon themselves, or upon physicians and surgeons, with regard to this matter; and the above opinion easily gains ground among the vulgar, especially in countries where people are more influenced by prejudices, superstition, servile situation in life, or other circumstances. Hence, we sometimes hear the most ridiculous accounts given in those countries by friars and common soldiers, of the manner by which they came to this disorder; such as piles, gravel, colies, contusions, fevers, little-houses, lying in suspected beds, or lying in bed with a suspected person, retention of the semen, coition with a woman in menstruation, the use of cider, bad wine, or beer, &c.

of the semen, conton with a worker, the use of cider, had wine, or beer, &c.

Another question undecided is, whether the veneral poison ever infects any fluid of our body, besides real poison ever infects any fluid of our body, besides and lymphatic system. Does the venereal poison in an infected woman ever affect the milk, and consequently can the infection be conveyed to the infant by the milk alone, without any venereal ulcer on or about the nipples? It is equally a matter of uncertainty whether the venereal disease is ever conveyed from an infected father or mother, by coition, to the fœtus, provided their genitals are sound; or whether a child is ever affected with venereal symptoms in the uterus of an infected mother. Such infected infants as came under the observation of Dr. Swediaur, or of his friends, whose practice afforded them frequent opportunities of seeing new-born infants, seemed rather to militate against the opinion. Neither he nor any of them, have ever been able to observe ulcerations or other symptoms of a venereal kind upon newborn children; and such as make their appearance four, six, or eight, or more days afterward, on the genitals, anus, lips, mouth, &c. may rather be sup posed to arise by infection during the passage from ulcers in the vagina of the mother, the skin of the infant being then nearly in as tender a state as the glans penis, or the labia; and this perhaps at the time when an absorption of the venereal poison might more easily take place without a previous exceriation, or ulceration of the skin. All the ways, therefore, by which we see, in our days, the venereal poison communicated from an unhealthy to a healthy person, may be reduced to the following heads:

By the coition of a healthy person with another who is infected with venereal disease of the genitals.
 By the coition of a healthy person with another,

2. By the coition of a healthy person with another, apparently healthy, in whose genitals the poison lies concealed, without having yet produced any bad symptom. Thus, a woman who has perhaps received the infection from a man two or three days before, may during that time infect, and often does infect, the man or men who have to do with her afterward, without having any symptoms of the disease visible upon herself; and vice versā, a man may infect a woman in the same manner. Such instances occur in practice every day.

3. By sucking; in this case the nipples of the wet

331

nurse may be infected by venereal ulcers in the mouth | of the child: or, vice versd, the nipples of the nurse being infected, will occasion venereal ulcers in the child's nose, mouth, or lips. It is uncertain, as men-tioned above, whether the venereal poison was ever propagated by means of the milk from the breast.

4. By exposing to the contact of venereal poison any part of the surface of the body, by kissing, touching, &c. especially if the parts so exposed have been previously excoriated, wounded, or ulcerated by any cause whatever. In this manner we frequently see venereal ulcers arise in the scrotum and thighs; and there are some well-attested instances where the infection took place in the fingers of midwives or surgeons. Several instances are recorded of venereal ulcers in the nostrils, eyelids, and lips of persons who had touched their own genitals, or those of others, affected at the time with local venereal complaints, and then rubbed their nostrils, &c. with the fingers, without previously washhostris, &c. with the ingers, without previously wasning the hands. There was, a few years, ago in London, a melancholy example of a young lady, who, after having drawn a decayed tooth, and replaced it with one taken immediately from a young woman apparently in perfect health, was soon after affected with an ulcer in the mouth. The sore manifested symptoms of a venereal nature; but such was its obstinacy, that it resisted the most powerful mercurial remedies, terit resisted the most powerful mercurial remedies, terminating at last in a caries of the maxilla, with a most shocking erosion of the mouth and face, by which the unhappy patient was destroyed. During all this, however, we are informed that not the smallest venereal symptom was perceived in the woman from whom the sound tooth was procured.

5. By wounding any part of the body with a lancet or knife infected with the venereal virus. In this inor knife infected with the venereal virus. In this instance there is a similarity between the venereal poison and that of the small-pox. There are several examples of the latter being produced by bleeding with a lancet which had been previously employed for the purpose of inoculation, or of opening variolous pustules, without being properly cleaned afterward. In Moravia, in the year 1577, a number of persons who assembled in a house for bathing, had themselves, according to the custom of that time, scarified by the barber, were all of them infected with the venereal disease, and treated accordingly. Krato, the physidisease, and treated accordingly. Krato, the physician, and Jordan, who gave a description of this distemper, are both of opinion that it was communicated by means of the scarifying instrument. And Van Swieten relates several instances where the lues was communicated by a similar carelessness in cleaning the instrument used in bleeding or scarification.

The venereal poison applied to the urethra and va-gina produce a clap. See Gonorrhaa. Coming into contact with other parts, it produces a chancre or bubo and constitutional symptoms. Chancre is the primary and immediate consequence of inoculation with true venereal matter in any of the ways which have been mentioned, and may arise in any part of the human body: but it generally shows itself in the pudenda, because the infecting medium is there first taken up in the one sex, and communicated by contact to the other. It is not, however, peculiar to these parts, for whenever the same kind of fluid is applied to a scratch on the hand, finger, lip, or nipple, the same consequence will follow. There can be no doubt but that the slightest abrasion possible, or breach of the cuticle, is sufficient to give a speedy admission to this destructive poison. A chancre makes its appearance with a slight inflammation which afterward ulcerates, or there arises a small pimple or pustule filled with a transparent fluid, which soon breaks and forms into a spreading ulcer. The period at which it makes its appearance after infection is very various, being most commonly in five or six days, but in some cases not till after the expiration of as many weeks. There is both a local and general predisposition to chancres: Jews and Mahommedans, from the constant exposure of the glans and loss of the prepuce, have the cuticle of the glans penis of much firmer texture than those who have not been circumcised; and they are, from this circumstance, much less subject to chancres than the rest of mankind. For the same reason they who, from the shortness of the prepuce, generally keep the glans uncovered, are not so liable to the diseases as those who have long narrow preputia; for persons thus formed constantly keep the another, and the same happening several times, and at surface of the glans and prepuce moist and tender, length casting o

and almost at every cohabitation are liable to abrasions and to excoriations.

There is an intermediate state of the venereal disease between a local and constitutional affection, which arises from the absorption of venereal matter from some surface to which it has been applied. The glands situated nearest the parts thus affected are apt to be come swelled and inflamed, so as to give rise to what is termed bubo; and the parts of generation usually coming first in contact with the matter, so the glands in the groin generally afford this particular symptom. In most cases the venereal virus is absorbed from a chancre or an ulcer in the urethra; but instances have occurred where a bubo has arisen without either go norrhœa or any kind of ulceration, and where the mat-ter appears to have been absorbed, without any erosion

A bubo comes on with pain in the groin accompanied with some degree of hardness and swelling, and is at first about the size of a kidney bean, but continuing to increase, it at length becomes as large as an egg, accasions the person to experience some difficulty in occasions the person to experience some difficulty in walking, and is attended with a pulsation and throbbing in the tumour, and a great redness of the skin. In some cases the suppuration is quickly completed, in others it goes on very slow, and in others again the inflammatory appearances go off without any formation of pure. In a few instances the glane have been known. of pus. In a few instances the glans have been known to become scirrhous. The following are the characteristics of a venereal bubo. The swelling is usually confined to one gland, the colour of the skin where inflammation prevails is of a florid red, the pain is very acute, the progress from inflammation to suppuration and ulceration is generally very rapid, the suppuration is large in proportion to the size of the gland, and there is only one abscess.

A bubo is never attended with danger, where the inflamed gland proceeds on regularly to suppuration, but in particular cases it acquires an indolence after coming to a certain length, arising from a scrofulous taint, or by being combined with erysipelas it terminates in gangrene, and occasions a great loss of substance. This termination is, however, more frequently met with in hospitals than in private practice, and may partly be attributed to the contaminated state of the air of the

wards wherein venereal patients are lodged.

A constitutional taint is the third form under which it has been mentioned, that the venereal poison is apt to show itself, and which always arises in consequence of the matter being absorbed and carried into the circulating mass of fluids. The absorption of it may, however, take place in three ways

1st, It may be carried into the circulation, without producing any evident local effect on the part to which

it was first applied.

2dly, It may take place in consequence of some local affection, such as either gonorrhæa, chancre, or bubo.

3dly, It may ensue from an application of the matter to a common sore or wound, similar to what happens in inoculating for the small-pox.

The most general way, however, in which a constitutional taint is produced, is by an absorption of the matter, either from a chancre or a bubo.

When venereal matter gets into the system, some symptoms of it may often be observed in the course of six or eight weeks, or probably sooner; but in some cases, it will continue in the circulating mass of fluids for many months before any visible signs of its effects. for many months before any visible signs of its effects are produced. The system being completely contamiare produced. The system being completely contaminated, it then occasions many local effects in different parts of the body, and shows itself under a variety of forms, many of which put on the appearance of a distinct disease. We may presume that this variety depends wholly on the difference of constitution, the different kind of pages affected, and the different state these parts were in at the time the matter or poison was

The first symptoms usually show themselves on the skin and in the mouth or throat. When on the skin, reddish and brownish spots appear here and there on the surface, and eruptions of a copper colour are dispersed over different parts of the body, on the top of which there soon forms a thick scurf or scale. This scurf falls off after a short time, and is succeeded by

discharges an acrid foetid matter. When the matter is secreted in the glands of the throat and mouth, the tongue will often be affected so as to occasion a thickness of speech, and the tonsils, palate, and uvula will become ulcerated so as to produce a soreness and difficulty of swallowing, and likewise a hoarseness in the voice. In a venereal ulcer of the tonsil, a portion of it seems as if it was dug out; it is, moreover, very foul, and has a thick, white matter adhering to it, which cannot be washed off. By these characteristic marks it may, in general, readily be distinguished from any other species of ulceration in these parts.

If the disease affects the eyes, obstinate inflammation, and sometimes ulceration, will also attack these and has a thick, white matter adhering to it, which cannot be washed off. By these characteristic marks it may, in general, readily be distinguished from any other species of ulceration in these parts.

If the disease affects the eyes, obstinate inflammation, and sometimes ulceration, will also attack these

The matter sometimes falls on deep-seated parts, such as the tendons, ligaments, and periosteum, and occasions hard, painful swellings to arise, known by

the name of nodes.

When the disease is suffered to take its own course, and not counteracted by proper remedies, the patient will, in the course of time, be afflicted with severe pains, but more particularly in the night-time; his countenance will become sallow, his hair will fall off, he will lose his appetite, strength, and flesh, his rest will be much disturbed by night, and a small fever of the hectic kind will arise. The ulcers in the mouth and throat being likewise suffered to spread, and to occasion a caries of the bones of the palate, an opening will be made from the mouth of the nose; and the carti-lages and bones of the nose being at length corroded away, this will sink on a level with the face. Some constitutions will bear up for a considerable time against the disease, while others again will soon sink under a general weakness and irritation produced by it. If the disorder is recent, and the constitution not impaired by other diseases, a perfect cure may easily be affected; but where it is of long standing, and accompanied with the symptoms of irritation which have been mentioned, the cure will prove tedious, and in many cases uncertain, as the constitution and strength of the patient may not admit of his going through a course of medicine sufficient to destroy the poison; or his health may be in such a state, as that only a very small quantity of mercury can be administered even at considerable intervals.

The general appearances to be observed on dissection of those who die of lues, are, caries of the bones, but more particularly those of the cranium, often communicating ulceration to the brain itself, together with enlargements and indurations of the lymphatic glands, scirrhus of several of the organs, particularly the liver and lungs, and exostoses of many of the hardest

Syphilis indica. The yaws.

Syphilis polonica. A variety of venereal disease.

Syrix oleum. A fragrant essential oil, obtained by distilling the canary balsam-plant, or moldavica.

by distilling the canary balsam-plant, or moldavica.

Syrian herb mastich. See Teucrium marum.

SYRI'GMUS. See Paracusis.

SYRI'NGA. (From συριγζ, a pipe: so called because from its branches pipes were made after the removal of the pith.) The pipe-tree.

SYRI'NGMOS. See Paracusis.

SYRINGO'TOMUM. (From συριγζ, a fistula, and τεμνω, to cut.) An instrument to cut fistulas.

SY'RINX. (A Hebrew word.) A pipe. A syringe. A fistula.

A fistula. Syrmat's mus. (From συρμαίζω, to evacuate.) A gentle evacuation by vomit or stool.

gentle evacuation by vomit or stool.

SYRUP. See Syrupus.

Syrup of ginger. See Syrupus zingiberis.

Syrup of lemon. See Syrupus limonum.

Syrup of marsk-mallows. See Syrupus althew.

Syrup of mulberry. See Syrupus mori.

Syrup of orange. See Syrupus aurantii.

Syrup of poppy. See Syrupus papaveris.

Syrup of red poppy. See Syrupus rhwados.

Syrup of red poppy. See Syrupus rosw.

Syrup of saffron. See Syrupus croci.

Syrup of senna. See Syrupus sennw.

Syrup of Tolu. See Syrupus tolutanus.

SYRUPUS. (Serab, a potion, Arabian.) The name syrup is given to sugar dissolved in water; and in the present pharmacopæia this is termed simple syrup. See present pharmacopæia this is termed simple syrup. See Syrupus simplex.

Syrups are generally made with the juice of vegeta-

press out the liquor when cold. Set it by for 24 hours, that the feculencies may subside; then pour off the liquor, and having added the sugar, boil it down to a proper consistence. An emollient and demulcent; mostly given to aliay tickling coughs, hoarseness, &c. in conjunction with other remedies.

SYRUPUS AURANTII. Syrup of orange. corticis aurantii. Syrupus e corticibus aurantiorum. Syrupus de cortice aurantiorum. Take of fresh orangepeel, two ounces; boiling water, a pint; refined sugar, three pounds. Macerate the orange-peel in the water for 12 hours in a covered vessel; then pour off the liquor, and add the sugar. A pleasant bitter and sto-

machic.

SYRUPUS CARYOPHYLLI RUBRI. A warm and stimulating syrup.

SYRUPUS COLCHICI. An acrid and diuretic com-

pound given in dropsies.

SYRUPUS CORTICIS AURANTII. See Syrupus au-

Syrupus croct. Syrup of saffron. Take of saffron, an ounce; boiling water, a pound; refined sugar, two pounds and a half. Macerate the saffron in the water for 12 hours in a covered vessel, then strain the liquor, and add the sugar. This imparts a beautiful colour to liquids, and is sometimes employed as a cor-

colour to fiquids, and is sometimes employed as a cordial. Among the vulgar, syrup of saffron is in high
esteem in measles, small-pox, &c.

Syrupus Limonum. Syrup of lemon. Syrupus
succi limonis. Syrupus e succo limonum. Syrupus e
succo citrorum. Take of lemon-juice, strained, a pint;
refined sugar, two pounds. Dissolve the sugar in the
lemon-juice in the manner directed for simple syrup.
A very pleasant, cooling, and acid syrup which may be very pleasant, cooling, and acid syrup which may exhibited with advantage, in febrile and bilious affec-

Syrupus Mori. Syrup of mulberry. Syrupus mororum. Take of mulberry-juice, strained, a pint; refined sugar, two pounds. Dissolve the sugar in the mulberry-juice in the manner directed for simple syrup. Syrup of mulberries is very grateful and aperient, and may be given with such intentions to children.

dren.

Syrupus e meconio. Syrupus de meconio, sive diacodium.

Take of capsules of white poppy, dried and bruised, the seeds being separated, 14 ounces; refined sugar, two pounds; boiling water, two gallons and a half. Macerate the capsules in the water for 24 hours, then boil it down by means of a water-bath to one gallon, and press out the liquor strongly. Boil down the liquor again, after being strained, to two pints, and strain it while hot. Set it by for 12 hours, that the feculencies may subside: then boil down the clear liquor to a pint, and add the sugar in the manner directed for simple and add the sugar in the manner directed for simple syrup. It should be kept in stone bottles, and in a cel-lar. A useful anodyne preparation, which may be added with advantage to a vast variety of medicines against diseases of the bowels, coughs, &c.

SYRUPUS PAPAVERIS ERRATICI. See Syrupus rha-

SYRUPUS RHAMNI. Syrup of buckthorn. Take of the fresh juice of buckthorn-berries, four pints; gingerthe tresh juice of buckthorn-bernes, four pints; gingerroot, sliced, allspice, powdered, of each half an ounce;
refined sugar, three pounds and a half. Set by the
juice for three days, that the feculencies may subside,
and strain. To a pint of the clear juice add the ginger
and allspice; then maccrate in a gentle heat four hours,
and strain; boil down what remains to one pint and a half, mix the liquors, and add the sugar in the manner directed for simple syrup.

This preparation, in doses of three or four spoonfuls, operates as a brisk cathartic. The principal inconvenience attending it is, that it is very unpleasant, and

occasions a thirst and dryness of the mouth and fauces, and sometimes violent gripes. These effects may be prevented by drinking liberally of water-gruel, or other

warm liquids, during the operation.

Syrupus RHEADOS. Syrupus papaveris erratici.
Syrupus de papavere erratico. Syrup of red-poppy.
Take of red-poppy petals, fresh, a pound; boiling water, a pint and two fluid ounces; refined sugar, two pounds and a half. Having heated the water in a water-bath, add gradually the red-poppy petals, frequently stirring them; then having removed the vessel, macerate for twelve hours; next press out the liquor, and set it by to settle; lastly, add the sugar as directed for simple syrup. This is a very mild anodyne, and used more for the colour, than for its medical properties.

Syrurus ribis nigri. Syrup of black currants. Aperient and diuretic qualities are attributed to this

preparation.

Syrupus Rosæ. Syrup of roses. Syrupus rosarum solutivus. Syrupus e rosis siccis. Take of damask-rose petals, dried, seven ounces; refined sugar, six pounds; boiling water, four pints. Macerate the rose-petals in the water for twelve hours, and strain; then evaporate the strained liquor, by means of a water-bath, to two pints and a half; then add the sugar in the manner described for simple syrup. A useful laxative for children. From 3 j. to 3 ss.
Syrupus Rubi id. E. Syrup of raspberry. A plea-

sant aperient syrup for children.

Syrupus scillifficus. Expectorant and diuretic.

See Oxymel scilla.

SYRUPUS SENNÆ. Syrup of senna. Take of senna-leaves, two ounces; fennel-seed, bruised, an ounce; manna, three ounces; refined sugar, a pound; water, boiling, a pint. Macerate the senna-leaves and fennelseeds in the water for an hour, with a gentle heat; strain the liquor, and mix with it the manua and sugar; then boil to the proper consistence. A useful purgative for children.

Syrurus simplex. Syrupus. Simple syrup. Take of refined sugar, two pounds and a half; water, a pint. Dissolve the sugar in the water in a water-bath, then set it aside for twenty-four hours; take off the scum;

and if there be any feculencies, pour off the clear liquor from them.

SYRUPUS TOLUNTANUS. Syrup of Tolu. Take of balsam of Tolu, an ounce; water, boiling, a pint; refined sugar, two pounds. Boil the balsam in the water half an hour in a covered vessel, occasionally stirring it; strain the liquor when it is cold, and then add the sugar in the manner directed for simple syrup. A useful balsamic syrup, calculated to allay tickling coughs and hoarsenesses.

SYRUPUS VIOLE. A pleasant laxative for young

SYRUPUS ZINGIBERIS. Syrup of ginger. Take of ginger-root, sliced, two ounces; water, boiling, a pint; refined sugar, two pounds. Macerate the ginger-root in the water for twenty-four hours, and strain; then add the sugar in the manner directed for simple syrup. A carminative and stomachic syrup. Dose from one to three drachms.

SYSPASIA. (From συσπαω, contraho, convello.) The name of a genus of diseases in Good's Nosology. Class, Neurotica; Order, Systatica. Comatose spasm. It has three species, viz. Syspasia convulsio, hysteria,

cpilepsia.

SYSSARCO'SIS. (From συν, and σαρξ, flesh.) A species of union of bones, in which one bone is united to another by means of an intervening muscle. In this manner the os hyoides is connected with the ster-

this manner the os hyoides is connected with the sternum and other parts.

SYSTATICA. (From συνιστημι, congredior, consocio.) The name of an order of diseases in Class Neurotica, of Good's Nosology. Diseases affecting several, or all the sensorial powers simultaneously. Its genera are, Agrypnia, Dysphonia, Antipathia, Cephalæa, Dinus, Syncope, Syspasia, Caries.

System, absorbent. See Absorbents and Lymphatics. System, genital. The parts of generation.

System, nervous. See Nerve.

System, vascular. The arteries and veins.

SY'STOLE. (From συσερλω, to contract.) The contraction of the heart.

SYSTREMMA. (From συστρεφω, contorqueo, to

SYSTREMMA. (From συστρεφω, contorqueo, to wind about, or twist.) The cramp.

BANDAGE. A bandage so named from its figure. It is principally used for supporting the dressings, after the operation for fistula in ano, in diseases

of the perinsum, and those of the groins, anus, &c.

TABA'CUM. (From Tobago, the island from whence it was first brought.) Tobacco. See Nico-

TABASHEER. The silica found in the hollow stem of the bamboo cane is so called. Its optical properties are peculiar.

TABE'LLA. (Diminutive of tabula, a table.) A

TA'BES. (Tabes, is, f.; from tabesco, to consume or pine away.) A wasting of the body. A genus of disease in the Class, Cachexia; and Order, Marcores, of Cullen; characterized by emaciation and weakness, attended with hectic fever, but without any cough or spitting, which last symptoms distinguish it from phthisis. It has three species; 1. Tabes purulenta, from an ulcerous discharge: 2. Tabes scrofulosa, from a scrofulous habit: 3. Tabes venenata, from poison. See Atrophy.

poison. See Atrophy.

Tabes coxaria. A wasting of the thigh and leg from an abscess, or other cause in the hip.

Tabes dorsaris. Lordosis. A wasting of the body, attended at first with pain in the back or loins, and afterward also in the neck and head, caused by a too early or a too frequent use of venery. Dr. Cullen makes it a variety of atrophia inanitorum. Hippocrates calls it tabes ossis.

TABES OSSIS SACRI. See Tabes dorsalis. TABES PULMONALIS. See Phthisis.

Tabes renatis. A wasting away of the body from an abscess of the kidney.

TABULAR SPAR. Table spar. Schaalstein of

Werner. Prismatic augite of Jameson. A mineral of a grayish white colour, found in primitive rocks at

TACAMAHACCA. (Indian.) See Fagara oc-

TA'CTUS. See Touch.

TÆ'DA. ($\Delta a \iota \delta a$; from $\delta a \omega$, to burn.) A torch. A species of pine which burns like a torch. A medicated torch for fumigations.

TÆ'NIA. (Taivia, a Hebrew word, signifying a fillet: the name of a worm, from its resemblance to a fillet or tape.) The tape-worm. A genus of intestinal worms; characterized by a long, flat, and jointed body.

TAIL. See Cauda.
TALC. See Talcum.
TA'LCUM. (From talk, German.) Talc. Of this mineral, which is Jameson's sixth subgress of rhomburdal mice, there are two kinds. boidal mica, there are two kinds. 1. Common talc, of a greenish-white colour, greasy feel, breaks into curved plates or leaves, occurs in beds of mica slate, and clay slate, in several parts of Scotland. 2. Indurated talc, or talc slate, of a greenish-gray colour, found in Scotland, and abundantly on the Continent. It is used by carpenters, tailors, hat makers, and glaziers for draw-

Talc is composed of pure magnesia mixed with near twice its weight of silex and less than its weight of alumine. The greenish foliaccous Venice talc was formerly used medicinally, as possessing antacid and aperient qualities.

Tallow. See Fat.

TA'LPA. (From τυφλος, blind.) Talparia. A mole. Also, a tumour resembling a mole in cating, and creeping under the skin.

TA'LUS. See Astragalus
TALCITE. Nacrite of Jameson. Earthly tale of Werner. A greenish-white, scaly mineral found in

the mining district of Freyberg.

Tamalapa'tra. The Indian leaf is so termed by some authors. See Laurus cassia.

TAMARIND. See Tamarindus.

TAMARINDES. (Tamarindus, i, m.; from tamar, or tamarindi, which is, in the Arabian language, a synonyme of the dactylus or date.)

1. The name of a genus of plants. Class Manadelphia Order. Triangenus of plants. genus of plants. Class, Monadelphia; Order, Trian-dria. The tamarind-tree. dria. The tamarind-tree.
2. The pharmacopæial name of the tamarind. See

Tamarindus indica.

Tamarindus indica.

Tamarindus indica.

The systematic name of the tamarind-tree: Oxyphanicon; Siliqua arabica; Balampulli; Tamaraa zecla; oxyphanicia; Acacia indica. The pulp of the tamarind, with the seeds, connected together by numerous tough strings or fibres, are brought to us freed from the outer shell, and company preserved in syrup. According to Long, tamaring the language of the syrup. are brought to us freed from the outer shell, and com-monly preserved in syrup. According to Long, tama-rinds are prepared for exportation at Jamaica, in the following manner: "The fruit or pods are gathered in June, July, and August, when full ripe, which is known by their fragility or easy breaking on small pressure between the finger and thumb. The fruit taken out of the pod, and cleared from the shelly fragments, is placed in layers in a cask, and boiling syrup, just before it begins to granulate, is poured in, till the cask is filled: the syrup pervades every part quite down to the botthe syrup pervades every part quite down to the bottom, and, when cool, the cask is headed for sale." The tamarind is employed as a laxative, and for abating thirst or heat in various inflammatory complaints, and for correcting putrid disorders especially of a bilious kind, in which the cathartic, antiseptic, and refrigerant qualities of the fruit have been found equally useful. When intended marries are leavative, it may be of advantage. interest the trust have been found equally useful. When intended merely as a laxative, it may be of advantage (Dr. Woodville observes,) to join it with manna or purgatives of a sweet kind, by which its use is rendered safer and more effectual. Three drachms of the pulp are usually sufficient to open the body, but to prove moderately cathartic, one or two ounces are required. It is an ingredient in the confectio cassia, and confectio

TAMARI'SCUS. See Tamarix gallica.
TA'MARIX. (Tamarix, icis, f.; from Tamarik, abstersion, Heb.: named from its properties of cleansing and purifying the blood.) The name of a genus of plants. Class, Pentandria; Order, Digynia. The tamarisk-tree.

tamarisk-tree.

Tamarisk Gallica. The systematic name of the tamarisk-tree. Tamariscus. Tamarisk. The bark, wood, and leaves of this tree, were formerly employed medicinally, though seldom used at present. The former for its aperient and corroborant virtues in obstructions of the liver; the latter in ieterus, hæmoptysis, and some affections of the skin.

TAME-POISON. See Asclepias vincetoxicum.

TANACE TUM. (Tanacetum, i, n.; corrupted from tanasia, athanasia, the old name for tansy.) 1. The name of a genus of plants in the Linawan system. Class, Syngenesia; Order, Polygamia superflua. Tansy.

Tansy.

2. The pharmacopæial name of the tansy. See Ta-

nacetum vulgare.

TANACETUM BALSAMITA. The systematic name of the officinal alecost. Balsamita mas; Balsamita major; Tanacetum hortense; Costus hortorum. Costmary, or alecost. The plant which bears this name in the pharmaconomias is the Tanacetum halsemite. the pharmacopæias, is the Tanacetum balsamita; foliis ovatis, integris, serratis, of Linnæus. A fragrant smelling herb, somewhat like that of mint; formerly esteemed as a corroborant, carminative, and emmenagogue.

TANACETUM HORTENSE. See Balsamita mas.

TANACETUM VULGARE. The systematic name of the common tausy. Tanasia; Athanasia; Parthenium mas. Tanacetum—foliis bipinnatis incicis servatis, of Linnæus. The leaves and flowers of tausy have a strong, not very disagreeable smell, and a bitter somewhat aromatic taste. The virtues of tansy are tonic, stomachic, anthelmintic, emmenagogue, and resolvent. It has been much used as a vermifuge; and testimonies of its efficacy are given by many respectable physicians. Not only the leaves, but the seeds have been employed with this intention, and substituted for those of santonicum. We are told by Dr. Clark, that in TANACETUM VULGARE. The systematic name of the common tansy. Tanasia; Athanasia; Parthenium mas. Tanacetum—foliis bipinnatis incicis servatis, of Linnæus. The leaves and flowers of tansy have a strong, not very disagreeable smell, and a bitter somewhat aromatic taste. The virtues of tansy are tonic, stomachic, anthelmintic, emmenagogue, and resolvent. It has been much used as a vermifuge; and testimonies of its efficacy are given by many respectable physicians. Not only the leaves, but the seeds have been employed with this intention, and substituted for those of santonicum. We are told by Dr. Clark, that in 335

Scotland tansy was found to be of great service in various cases of gout; and Dr. Cullen, who afterward was informed of the effect it had produced upon those was informed of the effect it had produced upon those who had used the herb for this purpose, says, "I have known several who have taken it without any advantage, and some others who reported that they had been relieved from the frequency of their gout." Tansy is also recommended in the hysteria, especially when this disease is supposed to proceed from menstrual obstructions. structions.

This plant may be given in powder to the quantity of a drachm or more for a dose; but it has been more commonly taken in infusion, or drank in tea.

TANA'SIA. See Tanacetum.

TANNIN. This, which is one of the immediate principles of vegetables, was first distinguished by Seguin from the gallic acid, with which it had been confounded under the name of the astroget reverse. founded under the name of the astringent principle. He gave it the name of tannin, from its use in the tanning of leather; which it effects by its characteristic property, that of forming with gelatin a tough insoluble

It may be obtained from vegetables by macerating them in cold water; and precipitated from this solution, which contains likewise gallic acid and extractive matter, by hyperoxygenized muriate of tin. From this precipitate, immediately diffused in a large quantity of water, the oxide of tin may be separated by sulphuretted hydrogen gas, leaving the tannin in solution.

Professor Proust has since recommended another method, the precipitation of a description of galls by prove

thod, the precipitation of a decoction of galls by powdered carbonate of potassa, washing well the greenishgray flakes that fall down with cold water, and drying them in a stove. The precipitate grows brown in the air, becomes brittle and shining like a resin, and yet remains soluble in hot water. The tannin in this state,

he says, is very pure.

Sir H. Davy, after making several experiments on different methods of ascertaining the quantity of tannin in astringent infusions, prefers for this purpose the common process of precipitating the tannin by gelatin; but he remarks, that the tannin of different vegetables

requires different proportions of gelatin for its satura-tion; and that the quantity of precipitate obtained is influenced by the degree in which the solutions are con centrated.

Chenevix observed, that coffee-berries acquired by roasting the property of precipitating gelatin; and Hatchett has made a number of experiments, which show that an artificial tannin, or substance having its chief property, may be formed, by treating with nitric acid matters containing charcoal. It is remarkable that this tannin, when prepared from vegetable substances, as dry charcoal of wood, yields, on combustion, products analagous to those of animal matters. From his experiments it would seem, that tannin is, in reality, carbonnessess matter combined with oxygen; and the carbonaceous matter combined with oxygen; and the difference in the proportion of oxygen may occasion the differences in the tannin procured from different substances, that from catechu appearing to contain most.

Bouillon Lagrange asserts, that tannin, by absorbing

oxygen, is converted into gallic acid.

It is not an unfrequent practice, to administer medicines containing tannin in cases of debility, and at the same time to prescribe gelatinous food as nutritious. But this is evidently improper, as the tannin, from its chemical properties, must render the gelatin indi-

gestible.

TANSY. See Tanacetum.

Tansy, wild. See Potentilla.

TANTALUM. The metal, an account of which is given under the article columbic acid. See Columbic

TAPE-WORM. See Tania.
TAPIOCA. See Jatropha manihot.
TAPPING. See Paracentesis.

TARA'NTULA. (From Taranta, a city in Naples, where they abound.) A kind of venomous spider, whose bite is said to be cured by music.

TARA'XACUM. (From rapassus, to alter or change: because it alters the state of the blood.) See Leon-

TARA'XIS. (From ταρασσω, to disturb.) A slight inflammation of the eye.

TA'RCHON SYLVESTRIS. See Achillea ptarmica.
TARE. See Ervum.
TARRAS. Terras. A volcanic earth, used as a

TARSI EXTENSOR MINOR. See Plantaris.

ΤΑ'RSUS. Ταρσος. 1. The instep, or that part of the foot which is between the leg and metatarsus: it is composed of seven bones, viz. the astragalus, os calcis, os naviculare, os cuboides, and three ossa cuneiformia.

2. The thin cartilage situated at the edges of the eyelids to preserve their firmness and shape.

TARTAR. See Tartarum.

Tartar cream of. The popular name of the pulverized everytarte of potness.

rized supertartrate of potassa.

Tartar, emetic. See Antimonium tartarizatum.
Tartar, oil of. See Potassa subcarbonatis liquor.
Tartar, regenerated. See Potassa acetas.
Tartar, salt of. See Potassa subcarbonas.
Tartar, soluble. See Potassa tartras.

Tartar, spirit of. If the crystals of tartar be distilled by a strong heat, without any additional body, they furnish an empyreumatic acid, called the pyrotartareous acid, or spirit of tartar, and a very fætid empy-

umatic oil.
Tartar, vitriolated. See Potassæ sulphas.
TARTARIC ACID. Acidum tartaricum; Sal essentiale tartari; Acidum tartari essentiale. Tartareous acid. "The casks in which some kinds of wine are kept become incrusted with a hard substance, tinged with the colouring matter of the wine, and otherwise impure, which has long been known by the name of argal, or tartar, and distinguished into red and white according to its colour. This being purified by solution, filtration, and crystallization, was termed cream, or crystals of tartar. It was afterward discovered, that it consisted of a peculiar acid combined with potassa; and the supposition that it was formed during the fomentation of the wine, was disproved by Boerhaave, Neuman, and others, who showed that it existed ready formed in the juice of the grape. It has likewise been found in other fruits, particularly before they are too ripe; and in the tamarind, sumac, balm, carduus benedictus, and the roots of restharrow, germander, and sage. The sepa-ration of tartaric acid from this acidulous salt, is the ration of tartaric acid from this acidulous salt, is the first discovery of Scheele that is known. He saturated the superfluous acid, by adding chalk to a solution of the supertartrate in boiling water as long as any effer-vescence ensued, and expelled the acid from the precipitated tartrate of lime by means of the sulphuric. Or four parts of tartar may be boiled in twenty or twenty-four of water, and one part of sulphuric acid added gradually. By continuing the boiling, the sulphate of potassa will fall down. When the liquor is reduced to one-half, it is to be filtered; and if any more sulphate be deposited by continuing the boiling, the filtering must be repeated. When no more is thrown down, the liquor is to be evaporated to the consistence of a syrup; and thus crystals of tartaric acid, equal to half the weight of the tartar employed, will be obtained.

The tartaric acid may be procured in needly or laminated crystals, by evaporating a solution of it. Its taste is very acid and agreeable, so that it may supply the place of lemon-juice. It is very soluble in water. Burnt in an open fire, it leaves a coaly residuum; in close vessels it gives out carbonic acid and carburetted hydrogen gas. By distilling nitric acid off the crystals, they may be converted into oxalic acid, and the nitric

acid passes to the state of nitrous.

To extract the whole acid from tartar, Thenard recommends, after saturating the redundant acid with chalk, to add muriate of lime to the supernatant neutral tartrate, by which means it is completely decomposed. The insoluble tartrate of lime being washed with abundance of water, is then to be treated with three-fifths of its weight of strong sulphuric acid, diluted previously with five parts of water. But Fourcroy's process, as and projected into a red-hot crucible, it detonates, and

The desire of dancing which is produced by the bite of | improved by Vauquelin, seems still better. Tartar is treated with quicklime and boiling water in the proportion, by the theory of equivalents, of 100 of tartar to 30 of dry lime, or 40 of the slaked. A caustic magma is obtained, which must be evaporated to dryness, and gently heated. On digesting this in water, a solution of caustic potassa is obtained, while tartrate of lime remains; from which the acid may be separated by the equivalent quantity of oil of vitriol.

According to Berzelius, tartaric acid is a compound of 3.807 hydrogen + 35.980 carbon + 60.213 oxygen = 100; to which result he shows that of Gay Lussac and Thenard to correspond, when allowance is made for a certain portion of water, which they had omitted to estimate. The analysis of tartrate of lead, gives to estimate. The analysis of tartrate or lead, so to estimate. The analysis of tartrate or lead, so 8.384 for the acid prime equivalent; and it may be seen as 3 hydrogen = 0.375 4.48

made up of 3 hydrogen = 0.375 4 carbon = 3.000 5 oxygen = 5.000 35.82 59.70 100.00 8.375

The crystallized acid is a compound of 8.375 acid + 1.125 water = 9.5; or, in 100 parts, 88.15 acid + 11.85

The tartrates, in their decomposition by fire, comport themselves like all the other vegetable salts, except that those with excess of acid yield the smell of caromel when heated, and afford a certain quantity of the experience of the caroline and the caroline pyrotartaric acid. All the soluble neutral tartrates form, with tartaric acid, bitartrates of sparing solubility; while all the insoluble tartrates may be dissolved in an excess of their acid. Hence, by pouring gradually an excess of acid into barytes, strontites, and lime-wa-ters, the precipitates formed at first cannot fail to disappear; while those obtained by an excess of the same acid, added to concentrated solutions of potassa, soda, or ammonia, and the neutral tartrates of these bases, as well as of magnesia and copper, must be permanent. The first are always flocculent; the second always crystalline; that of copper alone is in a greenish-white powder. It likewise follows, that the greater number of acids ought to disturb the solutions of the alkaline neutral tartrates, because they transform these salts into bitartrates; and, on the contrary, they ought to affect the solution of the neutral insoluble tartrates, which indeed always happens, unless the acid cannot dissolve the base of the tartrate. The order of apparent affinities of tartaric acid are, lime, barytes, strontites, potassa, soda, ammonia, and magnesia. or ammonia, and the neutral tartrates of these base soda, ammonia, and magnesia.

The tartrates of potassa, soda, and ammonia are not only susceptible of combining together, but also with the other tartrates, so as to form double, or triple salts. We may thus easily conceive why the tartrates of potassa, soda, and ammonia do not disturb the so-lutions of fron and manganese; and, on the other hand, disturb the solutions of the salts of barytes, strontites, lime, and lead. In the first case, double salts are formed, however small a quantity of tartrate shall have been employed; in the second, no double salt is formed, unless the tartrate be added in very great

The tartrates of lime and barytes are white, pulve-rulent, and insoluble.

Tartrate of strontian, formed by the double decom-

position of muriate of strontian and tartrate of po-tassa, according to Vauquelin, is soluble, crystalliza-ble, and consists of 52.88 strontian, and 47.12 acid. That of magnesia forms a gelatinous or gummy

Tartrate of potassa, tartarized kali, and vegetable salt, of some, formerly called soluble tartar, because much more so than the supertartrate, crystallizes in oblong squares, bevelled at the extremities. It has a bitterish taste, and is decomposed by heat, as its solution is even by standing some time. It is used as a mild extraction is

mild purgative.

The supertartrate of potassa is much used as a cool ing and gently opening medicine, as well as in several chemical and pharmaceutical preparations. Dissolved in water, with the addition of a little sugar, and a slice or two of lemon-peel, it forms an agreeable cooling drink, by the name of imperial: and if an infusion of green balm be used, instead of water, it makes one of the pleasantest liquors of the kind with which we are acquainted. Mixed with an equal weight of nitre, and projected into a red-hot crucible, it detonates and

forms the white flux; treated in the same way, with half its weight of nitre, it forms the black flux; and simply mixed with nitre in various proportions, it is called raw flux. It is likewise used in dying, in hatmaking, in gilding, and in other arts.

The blanching of the crude tartar is aided by boiling

tis solution with one-twentieth of pipe-clay.

According to the analysis of Berzelius, it consists of 70.45 acid + 24.8 potassa + 4.75 water = 100; or,

2 primes acid, = 16.75 70.30 potassa, = 5.95

water, = 1.125 4.75 23.825 100.00

24.95

60 parts of water dissolve 4 of bitartrate, at a boiling heat; and only I at 60° Fahr. It is quite insoluble in alkohol.

By saturating the superfluous acid, in this superfartrate, with soda, a triple salt is formed, which crystallizes in larger regular prisms of eight nearly equal sides, of a bitter taste, efflorescent, and soluble in about five parts of water. It consists, according to Vauquelin, of 54 parts tartrate of potassa and 46 tartrate of soda; and was once in much repute as a pur-

gative, by the name of Rochelle salt, or Sel de Seignette. The tartrate of soda is much less soluble than this triple salt, and crystallizes in slender needles or thin

plates.

The tartrate of ammonia is a very soluble, bitter salt, and crystallizes easily. Its solution is sponta-

neously decomposable.

This too forms, with tartrate of potassa, a triple salt, the solution of which yields, by cooling, fine pyra-midal or prismatic efflorescent crystals. Though both the neutral salts that compose it are bitter, this is not,

but has a cooling taste.

Take of the supertartrate of potassa, two pounds and a half; three gallons of boiling-hot water; one pound of prepared chalk; one pound of sulphuric acid. Boil the cream of tartar in two gallons of the water, and gradually throw in the chalk, until all effervescence ceases; set the liquor aside, that the tartrate of lime may subside; pour off the liquor, and wash the tartrate of lime repeatedly with distilled water, until it is tasteless. The pour on it the sulphuric acid, diluted with the remaining gallon of boiling water, and set the whole aside for twenty-four hours, stirring it well now and then. Strain the liquor, and evaporate in a water-bath until crystals form. The virtues of this acid are antiseptic, refrigerant, and diuretic. used in acute fevers, scurvy, and hamorrhage."-Ure's

TARTARINE. The name given by Kirwan to the

vegetable alkali. TA'RTARUM.

TA'RTARUM. (Tartarum, i, n.; from ταο/αρος, infernal: because it is the sediment or dregs.) Tartar.

1. The concretion which fixes to the inside of hogsheads containing wine. It is alloyed with much extractive and colouring matter, from which it is purified by decoction with argillaceous earths and subsequent crystallization. By this means it becomes perfectly white, and shoots out crystals of tartar, consisting of a peculiar acid called acid of tartar, imperfectly saturated with potassa; it is therefore a supertartrate of that alkali, which, when powdered, is the cream of tartar of the shops. Its virtues are eccoprotic, diuretic, and refrigerant, and it is exhibited in abdominal physconia, dropsy, inflammatory and bilious fevers, dyspep-sia from rancid or fat substances, bilious diarrhea and colic, hæmorrhoids and obstipation.

2. A name heretofore given to many officinal preparations, containing the acid of tartar; but in consequence of recent changes in the chemical nomenclature, superseded by appellations more expressive of

the respective compositions.

3. The name of the concretion which so frequently incrusts the teeth, and which is apparently phosphate of lime.

TARTARUS CHALYBEATUS. See Ferrum tartari-

TARTRAS. (Tartras, atis, m; the tartaric being

its acid base.) A tartrate, or salt, formed by the com-bination of tartaric acid with salifiable bases; as tar-

trate of soda, potassa, &c.

TARTRAS AMMONIA. Alkali volatile tartarizatum, of Bergman. Salammoniacum tartareum; Tartarus ammonia. A salt composed of tartaric acid and am-monia; its virtues are diaphoretic, diuretic, and deobstruent. It is prescribed in fevers, atonic exanthe-mata, catarrh, arthritic and rheumatic arthrodynia, hysteric spasms, &c.

TARTRAS POTASSE. See Potasse tartras.

TARTRAS POTASSE ACIDULUS. Cream of tartar.

See Potassa supertartras.

TARTRAS POTASS & ACIDULUS FERRATUS. Globuli martiales; Tartarus chalybeatus; Mars solubilis; Ferrum potabile. Its virtues are adstringent. It is principally used externally in the form of fomentations or bath in contusions, distortions, and luxitions.

TARTRAS POTASSÆ ACIDULUS STIBIATUS. See An-

timonium tartarizatum.

TARTRAS SODE. See Soda tartarizata.

TASTE. Gustus. "Savours are only the impression of certain bodies upon the organ of taste. Bodies which produce it are called sapid.

It has been supposed that the degree of sapidity of a body could be determined by that of its solubility; but certain bodies, which are insoluble, have a very strong taste, while other bodies very soluble have scarcely The sapidity appears to bear relation to the che mical nature of bodies, and to the peculiar efforts which they produce upon the animal economy.

Tastes are very numerous, and very variable. have been numerous endeavours made to class them, though without complete success; they are better un-derstood, however, than the odours, no doubt owing to the impressions received by the sense of taste being less fugitive than those received by the smell. Thus

we are sufficiently understood, when we speak of a body having a taste that is bitter, acid, sour, sweet, &c.

There is a distinction of tastes which is sufficiently established, it being founded on the organization: that of agreeable and disagreeable. Animals establish it instinctively. This is the most important distinction; for those things which have an agreeable taste are generally useful for nutrition, while those whose sa-

generally useful for nutrition, while those whose savour is disagreeable, are, for the most part, hurtful.

Apparatus of taste.—The tongue is the principal organ of taste; however, the lips, the internal surface of the cheeks, the palate, the teeth, the velum pendulum palati, the pharynx, asophagus, and even the stomach, are susceptible of receiving impressions by

the contact of sapid bodies.

The salivary glands, of which the excretory ducts open into the mouth; the follicles which pour into it the mucus, which they secrete, have a powerful effect in forming the taste. Independently of the mucous follicles that the superior surface of the tongue presents, and which form upon it fungous papilla, there are also little inequalities seen, one sort of which, very numerous, are called villous papille; the others, less numerous, and disposed on two rows on the sides of

the tongue, are called conical papilla.

All the nerves with which those parts are provided that are intended to receive the impressions of sapid bodies may be considered as belonging to the apparatus of taste. Thus the inferior maxillary nerves, many branches of the superior, among which it is necessary to notice the threads which proceed from the sphenopalatine ganglion, particularly the naso-palatine nerve of Scarpo, the nerve of the ninth pair, glosso pharyn-gens, appear to be employed in the exercise of taste.

The lingual nerve of the fifth pair is that which anatomists consider the principal nerve of taste; and as a reason they say that its threads are continued into the

villous and conical papilla of the tongue.

Mechanism of taste.-For the full exercise of taste, the mucous membrane which covers the organs of it must be perfectly uninjured; it must be covered with mucous fluid, and the saliva must flow freely in the mouth. When the mouth becomes dry, the powers of taste cannot be excited.

It is also necessary that these liquids undergo no change: for if the mucous become thick, yellow, and the saliva acid, bitter, &c., the taste will be exerted but very imperfectly.

Some authors have assured us that the papilla of

TEE TEA

the tongue become really erect during the time that the taste is exerted. This assertion I believe to be entirely without foundation.

It is quite enough that a body be in contact with the organs of taste, for us to appreciate its savour immediately; but if it is solid, in most cases it is necessary to dissolve in the saliva to be tasted; this condition is not

necessary for liquids and gases.

There appears to be a certain chemical action of sapid bodies upon the epidermis of the mucous membrane of the mouth; it is seen evidently at least in some, as vinegar, the mineral acids, a great number of salts, &c. In these different cases the colour of the epidermis is changed, and becomes white, yellow, &c. By the same causes, like effects are produced upon dead bodies. Perhaps to this sort of combination may be attributed the different kinds of impressions made by sapid bodies, as well as the variable duration of

those impressions.

Hitherto no one has accounted for the faculty possessed by the teeth of being strongly influenced by cersessed by the teeth of being strongly influenced by certain sapid bodies. According to the researches of Miel, a distinguished dentist of Paris, this effect ought to be attributed to imbibition. The researches of Miel prove that the teeth imbibe very quickly liquids with which they are placed in contact. Different parts of the mouth appear to possess different degrees of sensibility for sapid bodies; for they act sometimes on the tongue, on the gums, on the teeth; at other times they have an explusive action on the palate, on the placety. have an exclusive action on the palate, on the pharynx, &c. Some bodies leave their taste a long time in the mouth; these are particularly the aromatic bodies. This after-taste is sometimes felt in the whole mouth, sometimes only in one part of it. Bitter bodies, for example, leave an impression in the pharynx: acids upon the lips and teeth: peppermint leaves an impression which exists both in the mouth and pharynx.

Tastes, to be completely known, ought to remain some time in the mouth; when they traverse it rapidly, they leave scarcely any impression; for this reason we swallow quickly those bodies which are disagreeable to us; on the contrary, we allow those that have an agreeable savour to remain a long-time in the mouth.

When we taste a body which has a very strong and pertinacious taste, such as a vegetable acid, we become insensible to others which are feeble. This observation has been found valuable in medicine, in administering disagreeable drugs to the sick. We are capable of distinguishing a number of tastes at the same time. as also their different degrees of intensity; this is used by chemists, tasters of wine, &c. By this means we arrive sometimes at a tolerably exact knowledge of the chemical nature of bodies; but such delicacy of taste is not acquired until after long practice.

Is the lingual nerve that which is essential to taste? Nothing is known which can make us attribute this

property entirely to it.

The choice of food depends entirely on the taste; joined to smell, it enables us to distinguish between substances that are hurtful and those that are useful. It is this sense which gives us the most correct know-ledge of the composition of chemical bodies."

TA'XIS. An operation, by which those parts which have quitted their natural situation are replaced by the hand without the assistance of instruments, as in reducing hernia, &c.

See Thea.

TEAR. Lachryma The limpid fluid secreted by the lachrymal glands, and flowing on the surface of

The organ which secretes this liquid is the lachrymal gland, one of which is situated in the external canthus of each orbit, and emits six or seven excretory ducts which open on the internal surface of the upper eyelid above its tarsus, and pour forth the tears. The tears have mixed with them an arterious roscid vapour, which exhales from the internal surface of the eyelids, and external of the tunica conjunctiva, into the eye. Perhaps the aqueous humour also transudes through the pores of the cornea on the surface of the eye. A certain part of this aqueous fluid is dissipated in the air; but the greatest part, after having performed its office, is propelled by the orbicular muscle, which so closely constringes the eyelid to the ball of the eye as to leave no space between, unless in the internal angle, where the tears are collected. From this collection the tears are absorbed by the orifices of the puncta

lachrymalia; from thence they are propelled through the lachrymal canals, into the lachrymal sac, and flow through the ductus nasalis into the cavity of the nostrils, under the inferior concha nasalis. The lachrytrils, under the inferior concha nasalis. mal sac appears to be formed of longitudinal and transverse muscular fibres; and its three orifices furnished with small sphincters, as the spasmodic contriction of the puncta lachrymalia proves, if examined with a probe

The tears have no smell but a saltish taste, as people They are of a transparent colour who cry perceive.

and aqueous consistence.

The quantity, in its natural state, is just sufficient to moisten the surface of the eye and eyelids; but from sorrow, or any kind of stimulus applied to the surface of the eye, so great is the quantity of tears secreted that the puncta lachrymalia are unable to absorb them Thus the greatest part runs down from the internal angle of the eyelids, in the form of great and copious drops upon the cheeks. A great quantity also descends, through the lachrymal passages, into the nostrils; hence those who cry have an increased discharge from the nose

Use of the tears .- 1. They continually moisten the surface of the eye and eyelids, to prevent the pellucid cornea from drying and becoming opaque, or the eye from concreting with the eyelids. 2. They prevent that pain, which would otherwise arise from the friction of the eyelids against the bulb of the eye from continually winking. 3. They wash and clean away the dust of the atmosphere, or any thing acrid that has fallen into the eye. 4. Crying unloads the head of

congestions.

TECTUS. Covered: applied as opposed to nudus, or naked; as to the seeds of the angiosperm plants.

TEETH. (Dens, a tooth; quasi edens, from edo, to eat.) Small bones fixed in the alveoli of the upper and under jaw. In early infancy Nature designs us for the softest aliment, so that the gums alone are then sufficient for the purpose of manducation; but as we advance in life, and require a different food, she wisely provides us with teeth. These are the hardest and whitest of our bones, and, at full maturity, we usually find thirty-two in both jaws; viz. sixteen above, and as many below. Their number varies indeed in different subjects; but it is seldom seen to exceed thirty-two, and it will very rarely be found to be less than twenty eight. twenty eight.

Each tooth may be divided into two parts; viz. its body, or that part which appears above the gums; and its fancs or root, which is fixed into the socket. The its fangs or root, which is fixed into the socket. The boundary between these two, close to the edge of the gum, where there is usually a small circular depression, is called the neck of the tooth. The teeth of each jaw are commonly divided into three classes; but before each of these is treated of in particular, it will be right

to say something of their general structure.

Every tooth is composed of its cortex or enamel, and its internal bony substances. The enamel, or, as it is sometimes called, the vitreous part of the tooth, is a very hard and compact substance, of a white colour, and peculiar to the teeth. It is found only upon the body of the tooth, covering the outside of the bony or internal substance. When broken it appears fibrous or striated; and all the striæ are directed from the circumference to the centre of the tooth. This enamel is thickest on the grinding surface, and on the cutting edges or points of the teeth, becoming gradually thinner as it approaches the neck, where it terminates insensibly. Some writers have described it as being vascular; but it is certain that no injection will ever reach this substance, that it receives no tinge from madder, and that it affords no appearance of a circulation of fluids. The bony part of a tooth resembles other bones in its structure, but is much harder than the most compact part of bones in general. It composes the inner part of the body and neck, and the whole of the root of the tooth. This part of a tooth, when completely formed, does not, like the other bones, receive a tinge from madder, nor do the minutest injections penetrate into its substance, although many writers have asserted the contrary. Mr. Hunter has been, therefore, induced to deny its being vascular, although he is aware that the teeth, like other bones, are liable to swellings, and that they are found anchylosed with their sockets. He supposes, however, that both these may be original formations; and, as the most convincing proof of their

not being vascular, he reasons from the analogy be-tween them and other bones. He observes, for instance, that in a young animal that has been fed with madder, the parts of the teeth which were formed before it was put on madder diet will appear of their natural colour, but that such parts as were formed while the animal was taking the madder, will be of a red colour; whereas, in other boncs, the hardest parts are susceptible of the dye, though more slowly than the parts which are growing. Again he tells us, that if you leave off feeding the animal with madder a considerable time before you kill it, you will find the above appearances still subsisting, with this addition, that all the parts of the teeth which were formed after leaving off the madder will be white. This experiment proves that a tooth once tinged does not lose its colour; whereas other bones do (though very slowly) return again to their natural appearance; and, as the dye in this case must be taken into the habit by absorbents, he is led to suspect that the teeth are without absorbents as well as other vessels. These arguments are very ingenious, but they are far from being satisfac-The facts adduced by Mr. Hunter are capable of a different explanation from that which he has given them; and when other facts are added relative to the same subject, it will appear that this bony part of a tooth has a circulation through its substance, and even lymphatics, although, from the hardness of its structure, we are unable to demonstrate its vessels. The facts which may be adduced are, 1st, We find that a tooth recently drawn and transplanted into another socket, becomes as firmly fixed after a certain time, and preserves the same colour as the rest of the set whereas a tooth that has been long drawn before it is transplanted, will never become fixed. Mr. Hunter, indeed, is aware of this objection, and refers the success of the transplantation, in the first instance, to the living principle possessed by the tooth, and which he thinks may exist independent of a circulation. But however applicable such a doctrine may be to zoophytes, it is suspected that it will not hold good in man, and others of the more perfect animals: and there does not appear to be any doubt but that, in the case of a transplanted tooth, there is a real union by vessels. 2dly, The swellings of the fangs of a tooth, which in many instances are known to be the effects of disease, and which are analogous to the swelling of other bones, are a clear proof of a similarity of structure, especially as we find them invested with a periosteum. 3dly, It is a curious fact, though as yet perhaps not generally known, that, in cases of phthisis pulmonalis, the teeth become of a milky whiteness, and, in some degree, transparent. Does not this prove them to have absor-

Each tooth has an inner cavity, which, beginning by a small opening at the point of the fang, becomes larger and terminates in the body of the tooth. This cavity is supplied with blood-vessels and nerves, which pass through the small hole in the root. In old people this hole sometimes closes, and the tooth becomes then in-

The teeth are invested with periosteum from their fangs to a little beyond their bony sockets, where it is attached to the gums. This membrane seems to be common to the tooth which it encloses, and to the sockets which it lines. The teeth are likewise secured in their sockets by a red substance called the gums, which every where covers the alveolar processes, and has as many perforations as there are teeth. The gums are exceedingly vascular, and have something like carti-laginous hardness and elasticity, but do not seem to have much sensibility. The gums of infants, which perform the offices of teeth, have a hard ridge extend-The gums of infants, which ing through their whole length; but in old people, who have lost their teeth, this ridge is wanting. The three classes into which the teeth are commonly divided are,

incisores, canini, and molares or grinders.

The incisores are the four teeth in the forepart of each jaw; they derive their name from their use in dividing and cutting the food in the manner of a wedge, and have each of them two surfaces, which meet in a sharp edge. Of these surfaces, the anterior one is convex, and the posterior one somewhat concave. In the upper jaw they are usually broader and thicker, espe-cially the two middle ones, than those of the under jaw, over which they generally fall by being placed a little obliquely

The canini or cuspidati are the longest of all the teeth, deriving their name from their resemblance to a dog's tusk. There is one of these teeth on each side of the incisores, so that there are two in each jaw. They are the longest of all the teeth. Their fangs differ from that of the incisores only in being much larger, and their shape may be easily described to be that of an incisor with its edge worn off, so as to end in a narrow point instead of a thin edge. The canini not being calculated for dividing like the incisores, or for grinding, seem to be intended for laying hold of substances. Mr. Hunter remarks of these teeth, that we may trace in them a similarity in shape, situation, and use, from the most imperfect carnivorous animal, which we believe to be the human species, to the lion, which is the most

perfectly carnivorous. .

The molares or grinders, of which there are ten n each jaw, are so called, because from their size and figure they are calculated for grinding the food. The canini and incisores have only one fang, but the last three grinders in the under jaw have constantly two fangs, and the same teeth in the upper jaw three fangs. Sometimes these fangs are divided into two points near their base, and each of these points has, perhaps, been sometimes considered as a distinct fang. The grinders likewise differ from each other in their appearance. The first two on each side, which Mr. Hunter appears to have distinguished very properly by the name of bicuspides, seem to be of a middle nature between the incisores and grinders; they have in general only one root, and the body of the tooth terminates in two points, of which the anterior one is the highest, so that the tooth has in some measure the appearance of one of the canini. The two grinders beyond these, on each side, are much larger. Their body forms almost a square with rounded angles; and their grinding surface has commonly five points or protuberances, two of which are on the inner, and three on the outer part of the tooth. The last grinder is shorter and smaller than the rest, and, from its coming through the gums later than the rest, and sometimes not appearing till late in life, is called dens sapientia. The variation in the number of teeth usually depends on these dentes sapientiæ.

Having thus described the appearance of the teeth in the adult; the manner of their formation and growth in the fætus is next to be considered. We shall find that the alveolar process, which begins to be formed at a very early period, appears about the fourth month only as a shallow longitudinal groove, divided by sligh only as a shallow longitudinal government of intermediate depressions ridges into a number of intermediate depressions and control of the con pressions are at first filled with small pulpy substances included in a vascular membrane; and these pulpy substances are the rudiments of the teeth. As these advance in their growth, the alveolar processes become gradually more completely formed. The surface of the pulp first begins to harden: the ossification proceeding from one or more points, according to the kind of tooth that is to be formed. Thus in the incisores and canini, it begins from one point; in the bicuspides, from two points, corresponding with the future shape of those teeth; and in the molares from four or five points. As teeth; and in the molares from four or five points. As the ossification advances, the whole of the pulp is gradually covered with bone, excepting its under surface, and then the fang begins to be formed. Soon after the formation of this bony part, the tooth begins to be incrusted with its enamel; but in what manner this is deposited we are as yet unable to explain.—Perhaps the vascular membrane which encloses the pulp, may serve to secrete it. It gradually crystallizes upon the surface of the hony part, and continues to increase in thick of the bony part, and continues to increase in thickness, especially at the points and basis of the tooth, till some time before the tooth begins to pass through the gum; and when this happens, the enamel seems to be as hard as it is afterward, so that the air does not ap-pear to have the least effect in hardening it, as has been sometimes supposed. While the enamel is thus forming, the lower part of the pulp is gradually lengthened out and ossified, so as to form the fang. In those teeth which are to have more than one fang, the ossification begins at different parts of the pulp at one and the same time. In this manner are formed the incisores, the canini, and two molares on each side, making in the whole twenty teeth, in both jaws, which are sufficient for the purposes of manducation early in life. As the fangs of the teeth are formed, their upper part is gradu-

TEL

ally pushed upwards, till at length, about the seventh, eighth, or ninth month after birth, the incisores, which are the first formed, begin to pass through the gum. The first that appears is generally in the lower jaw. The canini and molares not being formed so soon as the incisores, do not appear till about the twentieth or twenty-fourth month. Sometimes one of the canini, but more frequently one of the molares, appears first.

The danger to which children are exposed, during the time of dentition, arises from the pressure of the teeth in the gum, so as to irritate it, and excite pain and inflammation. The effect of this irritation is, that the gum wastes, and becomes gradually thinner at this part, till at length the tooth protrudes. In such cases, therefore, we may, with great propriety, assist nature by cutting the gum. These twenty teeth are called temporary or milk teeth, because they are all shed between the age of seven and fourteen, and are supplied by others of a firmer texture, with large fangs which remain till they become affected by disease, or fall out in old age, and are therefore called the permanent or adult teeth. The rudiments of these adult teeth begin to be formed at different periods. The pulp of the first adult incisor, and of the first adult grinder, may be perceived in a fætus of seven or eight months, and the ossification begins in them about six months after birth. Soon after birth the second incisor, and canine tooth on each side, begin to be formed. About the fifth or sixth year the first bicuspis, and about the seventh the second bicuspi begin to ossify. These bicuspides are destined to replace the temporary grinders. All these permanent teeth are formed in a distinct set of alveoli; so that it is not by the growing of one touth and so that it is not by the growing of one tooth under another in the same socket, that the uppermost tooth is gradually pushed out, as is commonly imagined; but the temporary teeth, and those which are to succeed them, being placed in separate alveoli, the upper sockets gradually disappear, as the under ones increase in size, till at length the teeth they contain, having no longer any support, consequently fall out. But, besides these twenty teeth, which succeed the temporary ones, there are twelve others to be added to make up the number These twelve are three grinders on each side in both jaws; and in order to make room for this addition, we find the jaws grow as the teeth grow, so that they appear as completely filled with twenty teeth, as they are afterward with thirty-two. Hence, in children the face is flatter and rounder than in adults. Hence, in The first adult grinder usually passes through the gum about the twelfth year; the second, which begins to be formed in the sixth or seventh year, cuts the gum about the seventeenth or eighteenth; and the third, or dens sapientiæ, which begins to be formed about the twelfth year, passes through the gum between the age of twenty and thirty. The dentes sapientize have, in some instances, been cut at the age of forty, fifty, sixty, and even eighty years; and it sometimes happens, that they do not appear at all. Sometimes likewise it happens that a third set of teeth appear about the age of sixty or seventy. Diemerbroek tells us that he himself, at the age of fifty-six, had a fresh canine tooth in the place of one he had lost several years before; M. du Fay saw two incisores and two canini cut the gum in a man aged eighty-four; Mr. Hunter has seen two foreteeth shoot up in the lower jaw of a very old person; and an account was lately published of a man who had a com-plete set of teeth at the age of sixty. Other instances of the same kind are to be met with in authors. The circumstance is curious, and from the time of life at which it takes place, and the return of the catamenia, which sometimes happens to women at the same age, it has been very ingeniously supposed, that there is some effort in nature to renew the body at that period. The teeth are subject to a variety of accidents.

Sometimes the gums become so affected as to occasion them to fall out, and the teeth themselves are frequently rendered carious by causes which have not hitherto been satisfactorily explained. The disease usually begins on that side of the tooth which is not exposed to pressure, and gradually advances till an opening is made into the cavity: as soon as the cavity is exposed, the tooth becomes liable to considerable pain, from the air coming into contact with the nerve. Besides these accidental means by which the teeth are occasionally affected, old age seldom fails to bring with it sure and natural causes for their removal. The alveoli fill up, and the teeth consequently fall out. The gums then

no longer meet in the forepart of the mouth, the chin projects forwards, and the face being rendered much shorter, the whole physiognomy appears considerably altered. Having thus described the formation, structure, growth, and decay of the teeth, it remains to speak of their uses; the chief of which we know to be in And here we cannot help observing the great variety in the structure of the human teeth, which hts us for such a variety of food, and which, when compared with the teeth given to other animals, may in ome measure enable us to explain the nature of the aliment for which man is intended by Nature. Thus, in ruminating animals, we find incisores only in the lower jaw, for cutting the grass, and molares for grinding it; in graminivorous animals, we see molares alone; and in carnivorous animals, canine teeth for catching at their prey, and incisores and molares for cutting and dividing it. But, as man is not designed to catch and kill his prey with his teeth, we observe that our canini are shaped differently from the langs of beasts of prey, in whom we find them either longer than the rest of the teeth, or curved. The incisores likewise are sharper in those animals than in man. Nor are the molares in the human subject similar to the molares of carnivorous animals; they are flatter in man than in these animals; and, in the latter, we likewise find them sharper at the edges, more calculated to cut and tear food, and by their greater strength, capable of breaking the bones of animals. From these circumstances, therefore, we may consider man as partaking of the nature of these different classes; as approaching more to the carnivorous than to the herbivorous tribe of animals; but upon the whole, formed for a mixed aliment, and fitted equally to live upon flesh and upon vegetables. Those philosophers, therefore, who would confine a man wholly to vegetable food, do not seem to have studied nature. As the molares are the last teeth that are formed, so they are usually the first that fall out; this would seem to prove, that we require the same kind of aliment in old age as in infancy. Besides the use of the teeth in mastication, they likewise serve a secondary purpose, by assisting in the articulation of

TEETHING. See Dentition and Teeth.

TEGUMENTS. Under the term common integuments, anatomists comprehended the cuticle, rete mucosum, skin, and adipose membrane, as being the covering to every part of the body except the nails. Sec Skin. TE'LA.

A web of cloth. The cellular membrane is so called from its likeness to a fine web. See Cellular membrane.

TELE PHIUM. (Because it heals old ulcers, such as that of Telephus, made by Ulysses.) See Sedum

TELESIA. Sapphire.

TELLURETTED HYDROGEN. A combination of tellurium and hydrogen. To make this compound, hydrate of potassa and oxide of tellurium are ignited with charcoal, and the mixture acted on by dilute sulphuric acid, in a retort connected with a mercurial pneumatic apparatus. An elastic fluid is generated, consisting of hydrogen holding tellurium in solution. It is possessed of very singular properties. It is soluble in water, and forms a claret-coloured solution. It combines with the alkalies. It burns with a bluish flame, depositing oxide of tellurium. Its smell is very strong and peculiar, not unlike that of sulphuretted hydrogen. This elastic fluid was discovered by Sir H. Davy, in 1809. TELLURIC ACID.

Acidum telluricum. oxide of tellurium combines with many of the metallic oxides, acting the part of an acid, and producing a class

of compounds which have been called tellurates.

TELLU'RIUM The name given by Klaproth to a metal extracted from several Transylvanian ores.

Pure tellurium is of a tin-white colour, verging to lead-gray, with a high metallic lustre; of a foliated fracture; and very brittle, so as to be easily pulverized. Its sp. gr. is 6.115. It melts before ignition, requiring little higher heat than lead, and less than antimony; and, according to Gmelin, is as volatile as arsenic. When cooled without agitation, its surface has a crystallized appearance. Before the blowpipe on charcoal, it burns with a vivid blue light, greenish on the edges.

TEM TEM

and is dissipated in grayish-white vapours, of a pun-gent smell, which condense into a white oxide. This gent smell, which condense into a white oxide. This oxide heated on charcoal is reduced with a kind of explosion, and soon again volatilized. Heated in a glass retort, it fuses into a straw-coloured striated mass. It appears to contain about 16 per cent. of oxygen.

Tellurium is oxidized and dissolved by the principal

acids. To sulphuric acid it gives a deep purple colour. Water separates it in black flocculi, and heat throws

it down in a white precipitate.

With nitric acid it forms a colourless solution, which remains so when diluted, and affords slender denditric

remains so when discovered and crystals by evaporation.

The muriatic acid with a small portion of nitric, forms a transparent solution, from which water throws a white submuriate. This may be redissolved to the control of water. Alkoalmost wholly by repeated affusions of water. Alkohol likewise precipitates it.

Sulphuric acid, diluted with two or three parts of water, to which a little nitric acid has been added,

dissolves a large portion of the metal, and the solution is not decomposed by water.

The alkalies throw down from its solutions a white precipitate, which is soluble in all the acids, and by an excess of the alkalies or their carbonates. They are not precipitated by prussiate of potassa. Tincture of not precipitated by prussiate of potassa. Tincture of galls gives a yellow flocculent precipitate with them. l'ellurium is precipitated from them in a metallic state

by zinc, iron, tin, and antimony.

Tellurium fused with an equal weight of sulphur, in a gentle heat, forms a lead-coloured striated sulphuret. Alkaline sulphurets precipitate it from its solutions of a brown or black colour. In this precipitate, either the metal or its oxide is combined with sulphur. Each of these sulphurets burns with a pale blue flame, and white smoke. Heated in a retort, part of the sulphur is sublimated, carrying up a little of the metal with it.

It does not easily amalgamate with quicksilver.

TEMPERAME'NTUM. (From tempero, to mix together.) The peculiar constitution of the humours.

Temperaments have been variously distinguished: the division most generally received is into the sanguineous,

phlegmatic, choleric, and melancholic.
TEMPERATURE. A definite degree of sensible heat, as measured by the thermometer. Thus we say, a high temperature, and a low temperature, to denote a manifest intensity of heat or coid; the temperature of boiling water, or 212° Fahr.; and a range of temperature, to designate the intermediate points of heat between two distant terms of thermometric indication.

TEMPLE. (Tempora, um, n.; and tempus, oris, n.)
The lateral and flat parts of the head above the ears. TEMPORAL. (Temporalis; from tempus.) Be-

longing to the temple.

TEMPORAL ARTERY. Arteria temporakis. A branch of the external carotid, which runs on the temples, and

gives off the frontal artery.

Temporal bone. Os temporis. Two bones situated one on each side of the head, of a very irregular figure. They are usually divided into two parts, one of which, from the manner of its connexion with the neighbouring bones, is called os squamosum, and the other os petrosum, from its irregularity and hardness.

In both these parts there are processes and cavities to be described. Externally there are three processes; one anterior, called zygomatic process, which is stretched forwards to join with the os malæ, and thus forms the bony jugum under which the temporal muscle passes; one posterior, called the mastoid or mamillary process, from its resemblance to a nipple; and one inferior, called the styloid process, from its shape, which is said to resemble that of the ancient stylus scriptorius. In young subjects, this process is united with the bone by an intermediate cartilage, which sometimes, even in adults, is not completely ossified. Three muscles have their origin from this process, and borrow half of their names from it, viz. stylo-glossus, stylo-byoideus, and stylo-pharyngeus. Round the root of this process there is a particular rising of the os petrosum, which some writers describe as a process, and, from its appearance with the styloid, have named it vaginalis. Others describe the semicircular ridge of the meatus auditorius externus as a fifth process, to which they give the name of auditory. The depressions and cavities are, I. A large fossa, which serves for the articulation of the lower jaw; it is situated between the zygomatic auditory and vaginal processes,

and is separated in its middle by a fissure, into which the ligament that secures the articulation of the lower jaw with this bone is fixed. The forepart of this The forepart of this cavity, which seceives the condyle of the jaw, is covered with cartilage; the back part only with the periosteum. 2. A long fossa behind the mastoid pro-cess, where the digastric muscle has its origin. 3. The meatus ouditorius externus, the name given to a large funnel-like canal that leads to the organ of hearing. The stylo-mastoid hole, so called from its situation between the styloid and mastoid processes. It is likewise called the aqueduct of Fallopius, and affords a passage to the portio dura of the auditory, or seventh pair of nerves. 5. Below and on the forepart of the last foramen, we observe part of the jugular fossa, a thimble-like cavity, in which the beginning of the internal jugular vein is lodged. 6. Before and a little above this fossa is the orifice of a foramen, through which pass the internal carotid artery and two filaments of the intercostal nerve. This conduit runs first upward and then forward, forming a kind of elbow, and terminates at the end of the os petrosum. 7. At this part of the ossa temporum we observe the orifice of a canal which runs outwards and backwards in a horizontal direction, till it terminates in a cavity of the ear called tympanum. This canal, which in the recent subject is continued from the ear to the mouth, is called the Eustachian tube. 8. A small hole behind the mastoid process, which serves for the trans mission of a vein to the lateral sinus. But this, like other foramina in the skull that serves only for the transmission of vessels, is neither uniform in its situation, nor to be met with in every subject. The internal surface of these bones may easily be divided into three parts. The first, uppermost, and largest is the squamous part, which is slightly concave from the impressions of the best sion of the brain. Its semicircular edge is sloping, so that the external lamella of the bone advances farther than the internal, and thus rests more securely on the parietal bones. The second and middlemost, which is the petrous part of the bone, forms a hard, craggy protuberance, nearly of a triangular shape. On its posterior side we observe a large foramen, which is the meatus auditorius internus; it receives the double nerve of the seventh pair, viz. the portio dura and portio mollis of that pair. About the middle of its anterior surface is a small foramen, which opens into the aqueduct of Fallopius, and receives a twig of the portio dura of the seventh pair of nerves. This fora-men having been first described by Fallopius, and by him named hiatas, is sometimes called hiatus Fallopii. Besides these, we observe other smaller holes for the transmission of blood-vessels and nerves. Below this craggy protuberance is the third part, which, from its shape and connexion with the os occipitis by means of the lambdoidal suture, may be called the lambdoidal angle of the temporal bone. It is concave from the impression of the brain; it helps to form the posterior and inferior fossæ of the skull, and has a considerable furrow, in which is lodged part of the lateral sinus. The temporal bones differ a little in their structure from the other bones of the cranium. At their upper parts they are very thin, and almost without diploe, but below they have great strength and thickness. In the feetus, the thin upper part, and the lower craggy part, are separated by a cartilaginous substance; there is no appearance either of the mastoid or styloid processes, and, instead of a long funnel-like meatus auditorius externus, there is only a smooth bony ring, within which the membrana tympani is fastened. Within the petrous part of these bones there are several cavities, processes, and bones, which bolong altogether to the ear, do not enter into the formation of the cranium, and are described under the article Ear. The ossa temporum are connected by suture with the ossa parietalia, the os occipitis, the ossa malarum, and the os sphenoides, and are articulated with the lower TEMPORA'LIS. (From tempus, the temple.) 1

See Temporal.

2. A muscle of the lower jaw, situated in the temple. Arcardi-temporo-mazillaire, of Dumas. Crota phites, of Winslow. It arises fleshy from the lower lateral, and anterior part of the parietal bone; from all the squamous portion of the temporal bone; from the lower and lateral part of the os frontis; from the posterior surface of the os malæ; from all the temporal pro-

at the lower part of this process. This latter portion, however, is often common to this muscle and the pterygoideus externus. It is of a semicircular shape, and its radiated fibres converge, so as to form a strong middle tendon, which passes under the jugum, and is inserted into the coronoid process of the lower jaw, to which it adheres on every side, but more particularly at its forepart, where the insertion is continued down to the body of the bone. This muscle is covered by a pretty strong fascia, which some writers have erroneously described as a part of the aponeurosis of the occipito-frontalis. This fascia adheres to the bones, round the whole circumference of the origin of the muscle, and, descending over it, is fixed below to the ridge where the zygomatic process begins, just above the meatus auditorius, to the upper edge of the zygomatic process itself, and anteriorly to the os male. This fascia serves as a defence to the muscles, and likewise gives origin to some of its fleshy fibres. The likewise gives origin to some of its fleshy fibres. principal use of the temporal muscle is to draw the lower jaw upwards, as in the action of biting; and as it passes a little forwards to its insertion, it may at the same time pull the condyle a little backwards, though not so much as it would have done if its fibres had passed in a direct line from their origin to their insertion, because the posterior and lower part of the muscle passes over the root of the zygomatic process, as over a polley.

TENDO. See Muscle.

TENDO ACHILLIS. See Achillis tendo. TENDON. (From tendo, to stretch.) The white and glistening extremity of a muscle. See Muscle.

TENDRIL. See Cirrus.
TENE'SMUS. (From τεινω, to constringe: so called from the perception of a continual constriction or bound state of the part.) A continual inclination to go to stool, without a discharge.

TENNANTITE. A variety of gray copper ore found in Cornwall, in copper veins, that intersect granite and clay slate, associated with copper pyrites. It is of a lead-gray or iron black colour, and consists of copper, sulphur, arsenic, iron, and silica.

TE NSOR. (From tendo, to stretch.) A muscle, the office of which is to extend the part to which it is

fixed.

TENSOR PALATI. See Circumflexus.

TESSOR TYMPANI. Internus auris, of Douglas and Cowper. Internus mallei, of Winslow; and salpingomallecn, of Dumas. A muscle of the ear, which pulls the malleus and the membrane of the tympanum towards the petrous portion of the temporal bone, by which the membrana tympani is made more concave and tense.

TENSOR VAGINÆ FEMORIS. Fascialis. Membra-Tensor Vagina: Pemoris. Fascialis. Memoranosus, of Douglas. Membranus vel fascia làta, of Cowper; and Ilio aponeurosi femoral, of Dumas. Musculus aponeurosis, vel fascia lata, of Winslow. A muscle situated on the outside of the thigh, which stretches the membranous fascia of the thigh, assists in the abduction of the thigh, and somewhat in its rota-tion inwards. It arises by a narrow, tendinous, and fleshy beginning from the external part of the anterior, superior, spinous process of the ilium, and is inserted a little below the great trochanter into the membranous

TENT. A roll of lint for dilating openings, sinuses,

c. See Spongia praparata.
TENTO RIUM. A process of the dura mater, separating the cerebrum from the cerebellum. It exteads from the internal horizontal spine of the occipital bone, directly forwards to the sella turcica of the sphenoid bone.

TEREBE'LLA. (Diminutive of terebra, a piercer or gimlet.) A trepan or instrument for sawing out cir-cular portions of the skull. A trephine.

TEREB! NTHINA. (From τερεβενθος, the turpentine-tree.) Turpentine, the produce of pine-trees. See

Turpentine.

TEREBUNTHINA ARGENTORATENSIS. Strasburg tur-This species is generally more transparent pentine. and less tenacious than either the Venice or Chio turpentines. It is of a yellowish-brown colour, and of a more agreeable smell than any of the turpentines, except the Chio. It is extracted in several parts of Germany, from the red and silver fir, by cutting out successively narrow strips of the bark. In some

cess of the sphenoid bone; and sometimes from a ridge | places a resinous juice is collected from under the bark, called Lachryma abiegna, and Oleum abietinum.

TEREBINTHINA CANADENSIS. Canada turpentine. See Pinus balsamea.

TEREBINTHINA CHIA. The resin obtained from the Pistacia terebinthus.

TEREBINTHINA COMMUNIS. Common turpentine. See Pinus sylvestris.

TEREBINTHINA CYPRIA. Cyprus turpentine. See Pistacia terebinthus.

TEREBINTHINA VENETA. Venice turpentine: so called because we are supplied with it from the Venetians. See Pinus larix.

TEREBINTHINA VULGARIS. Common turpentine. The liquid resin of the Pinus sylvestris.

TEREBINTHINE OLEUM. The oil distilled from the liquid resin of the Pinus sylvestris.

TE'RES. Round, cylindrical.

The name of some muscles and ligaments.

2. The name of the ascaris lumbricoides, or round

worm, which infests the intestines. See Worms.

2. Applied to roots, stems, leaves, leafstalks, seeds, &c.

TERES LIGAMENTUM. The ligament at the bottom

of the socket of the hip-joint.

TERES MAJOR. Riolanus, who was the first that distinguished this and the other muscles of the scapula by particular appellations, gave the name of teres to this and the following muscle, on account of their long and round shape. Anguli-scapulo-humeral, of Dumas This muscle, which is longer and thicker than the teres minor, is situated along the inferior costa of the scapula, and is in part covered by the deltoides.

It arises fleshy from the outer surface of the inferior angle of the scapula, (where it covers some part of the infra-spinatus and teres minor, with both which its fibres intermix,) and likewise from the lower and posterior half of the inferior costa of the scapula. Ascending obliquely towards the os humeri, it passes under the long head of the triceps brachii, and then becomes thinner and flatter to form a thin tendon of about an inch in breadth, and somewhat more in length, which runs immediately behind that of the latissimus dorsi, and is inserted along with it into the ridge at the inner side of the groove that lodges the long head of the biceps. These two tendons are included in the common capsula, besides which the tendon of this muscle adheres to the os humeri by two other capsulæ which we find placed one above the

This muscle assists in the rotatory muscle of the arm, and likewise in drawing it downwards and backwards; so that we may consider it as the congener of the latissimus dorsi.

TNOR. Marginisus-scapule-trochiterien, This muscle seems to have been first de-TERES MINOR. of Dumas. scribed by Fallopius. The teres minor is a thin fleshy muscle, situated along the inferior edge of the infraspinatus, and is in part covered by the posterior part

It arises fleshy from all the convex edge of the inferior costa of the scapula; from thence it ascends obliquely upwards and forwards, and terminates in a flat tendon, which adheres to the lower and posterior part of the capsular ligament of the joint, and is inserted into the lower part of the great tuberosity of the os humeri, a little below the termination of the infra-spinatus.

The tendinous membrane, which is continued from the infra-spinatus, and spread over the teres minor, likewise forms a thin septum between the two muscles. In some subjects, however, they are so closely united, as to be with difficulty separated from each other. Some of the fibres of the teres minor are intermixed with those of the teres major and subscapularis.

The uses of this muscle are similar to those of the infra-spinatus

TE RETRUM. (From τερεω, to pierce.) The tre-

TERMINALIS. Terminal: applied to flower-stalk when it terminates a stem or branch; as in Centaurea

TERMI'NTHUS. (From τερμινθος, the turpentine-tree: so called from their resemblance to the fruit of the turpentine-tree.) Albatis. Black and ardent pustules, mostly attacking the legs of females.

TERNARY. Consisting of the number three, which

some chemical and mystical writers have made strange work with; but the most remarkable distinction of this kind, and the only one worth notice, is that of Hippocrates, who divides the parts of a human body into con-tinentes, contenta, and impetum facientes, though the latter is resolvable into the mechanism of the two for-

mer, rather than any thing distinct in itself.
TERNATUS. Ternate: applied in botany to a leaf
which consists of three leaflets, as that of the trefoil.

TERNUS. Ternate: applied to leaves, when there are three together; as in many of the plants of Chili and Peru, which seem particularly disposed to this arrangement, and in Verbena triphylla.

E'RRA. See Earth.

TERRA CARIOSA. Rotten stone, a species of noneffervescent chalk, of a brown colour.

TERRA CATECHU. See Acacia catechu.
TERRA DAMNATA. See Caput mortuum.
TERRA FOLIATA TARTARI. The acetate of potassa.

TERRA JAPONICA. Japan earth. See Acacia catechu. TERRA LEMNIA. See Bole.

TERRA LIVONICA. See Bole.
TERRA LIVONICA. The curcuma, or turmeric-root, is sometimes so called.

Terra mortua. See Caput mortuum.

TERRA PONDEROSA. The heavy spar.

TERRA PONDEROSA SALITA. See Murias baryta. TERRA SIENNA. A brown ochre found at Sienna, in

Italy, used in painting, both raw and burnt. TERRA SIGILLATA. See Bole. TERRA SIGILLATA.

TERRA VERTE. An ore used in painting, which contains iron in some unknown state mixed with clay, and sometimes with chalk and pyrites.

TERRE OLEUM. See Petroleum.

Terrea absorbentia. Absorbent earths, distinguishable from other earthy and stony substances by their solubility in acids; as chalk, crabs' claws, oyster-

shells, egg-shells, pearl, coral, &c.
TERRENUS. Terrene; earthy: applied to plants which grow in the earth only, in opposition to those

which live only in water.
Τκ'πτιπα. (From τερθρον, a crane.) The middle

and lateral parts of the neck.
TERTIAN. A third-day ague. See Febris intermittens.

Tertian ague. See Febris intermittens. TERTIA'NA. See Febris intermittens. TERTIANA DUPLEX. A tertian fever that returns

every day; but the paroxysms are unequal, every other fit being alike.

Terriana duplicata. A tertian fever returning every other day; but there are two paroxysms in one

TERTIANA PERRIS. See Febris intermittens.

TERTIANA TRIPLEX. A tertian fever returning every day, every other day there are two paroxysms, and but one in the intermediate one.

TERTIANA'RIA. (From tertiana, a species of intermittent fever, which is said to be cured by this plant.) See Scutcllaria galericulata.

TER THUM SAL. (From tertius, third.) A neutral salt, as being the product of an acid and an alkali, making a third body different from either.

TE'SSERA. (From τεσσαρα, four.) A four square

one. The cuboid bone.
TEST. Any reagent which, added to a substance, teaches us to discover its chemical nature or composi-

on. See Reagent.
TE'STA. (Quasi tosta; from torres, to burn.)
A shell. The oyster-shell.

 A shell. The oyster-such.
 In botany, it is the name of the skin which contains all the parts of a seed, as the embryo, the lobes, the vitellus, and albumen, and which gives shape to the seed, for the skin is perfectly formed while they are but a homogeneous liquid. The testa differs in thickness and texture in different plants. It is sometimes single, but more frequently lined with a finer and very delicate film, called by Gærtner membrana, as may be seen in a walnut, and the kernel of a peach, almond, or

Testa probatrix. A cupel or test. A pot for sepa-

rating baser metals from gold and silver.
TESTA'DO. (From testa, a shell: because it is covered with a shell.)

 A tortoise, also a snail.
 An ulcer, which, like a snail, creeps under the skin.

TESTE PREPARATE. Prepared oyster-shells. Wash the shells, previously cleared of dirt, with boiling water, then prepare them as is directed with chalk.

TESTES CEREBRI. See Tubercula quadrigemina.
TESTICLE. See Testis.
Testicle, swelled. See Orchitis.
TESTICULUS. (Testiculus, diminutive of testis.) A small testicle.

2. The orchis plant: so named from the resemblance of its roots to a testicle.

TESTICULUS CANINUS. See Orchis mascula. TE'STIS. (Testis, is, m.; a witness, the testes being the witnesses of our manhood.) The testicle. Orchis. They are also called didymi, and by some Orchis. They are also called didymi, and by some perin. Two little oval bodies situated within the scrotum, and covered by a strong, white, and dense coat, called tunica albuginea. Each testicle is composed of small vessels, bent in a serpentine direction, arising from the spermatic artery, and convoluted into little heaps, separated from one another by cellular partitions. In each partition there is a duct receiving semen from the small vessels; and all the ducts constitute a net which is attached to the tunica albuginea. From this net-work twenty or more vessels arise, all of which are variously contorted, and, being reflected, ascend to the posterior margin of the testis, where they unite into one common duct, bent into serpentine windings, and forming a hard body called the cpididymis. The spermatic arteries are branches of the aorta. The spermatic veins empty themselves into the vena cava and emulgent vein. The nerves of the testicle are branches of the lumbar and great intercostal nerve. The use of the testicle is to secrete the semen.

TETANIC. Tetanicus. Appertaining to tetanus

or cramp.

TETANO MATA. (From τετανοω, to smooth.) Teta-nothra. Medicines which smooth the skin, and remove

TE TANUS. (Tetanus, i, m.; from τεινω, to stretch.) Spasm with rigidity. Convulsio indica; Holotonicos; Rigor nervosus. A genus of disease in the Class Neuroses, and Order Spasmi, of Cullen; characterized by a spasmodic rigidity of almost the whole body. The varieties of tetanus are, 1. Opisthotonos, where the body is thrown back by spasmodic contractions of the muscles. muscles. 2. Emprosthotonos, the body being bent forwards. 3. Trismus, the locked jaw. Tetanus is often symptomatic of syphilis and worms.

These affections arise more frequently in warm climates than in cold ones, and are very apt to occur when much rain or moisture quickly succeeds excessively dry and sultry weather. They attack persons of all ages, sexes, temperaments, and complexions, but the male sex more frequently than the female, and those of a robust and vigorous constitution than those of a weak habit. An idea is entertained by many, Dr. Thomas observes, that negroes are more predisposed to attacks of tetanus than white people; they certainly are more frequently affected with it, but this circumstance does not arise from any constitutional predisposition, but from their being more exposed to punctures and wounds in the feet, by nails, splinters of wood, pieces of broken glass, &c. from usually going bare-footed.

Tetanic affections are occasioned either by exposure to cold, or by some irritation of the nerves, in consequence of local injury by puncture, incision, or laceration. Lacerated wounds of tendinous parts prove, in warm climates, a never-failing source of these complaints. In cold climates, as well as in warm, the locked jaw frequently arises in consequence of the

amputation of a limb. When the disease has arisen in consequence of a puncture, or any other external injury, the symptoms show themselves generally about the eighth day; bu when it proceeds from exposure to cold, they generally

make their appearance much sooner. In some instances it comes on suddenly, and with great violence; but it more usually makes its attack in a gradual manner; in which case, a slight stiffness is at first perceived in the back part of the neck, which, after a short time, becomes considerably increased, and

at length renders the motion of the head both difficult and painful.

With the rigidity of the head there is likewise an uneasy sensation at the root of the tongue, together with some difficulty in swallowing, and a great tightness is perceived about the chest, with a pain at the extremity

TEU TET

is termed the locked jaw, or trismus

In some cases, the spasmodic affection extends no further. In others the spasms at this stage of the disease, returning with great frequency become likewise more general, and now affect not only the muscles of the neck and jaws, but likewise those of the whole spine, so as to bend the trunk of the body very forcibly backwards, and this is what is named opisthotonos. Where the body is bent forwards the disease is called emprosthotonos.

During the whole course of the disorder, the abdominal muscles are violently affected with spasm, so that the belly is strongly retracted, and feels very hard, most obstinate costiveness prevails, and both the flexor and extensor muscles of the lower extremities are commonly affected at the same time so as to keep the limbs rigidly

extended.

The flexors of the head and trunk become at length so strongly affected, as to balance the action of the extensor, and to keep the head and trunk so rigidly extended and straight, as to render it incapable of being moved in any direction. The arms, which were little moved in any direction. The arms, which were little affected before, are now likewise rigidly extended, the tongue also becomes affected with spasm, and, being convulsively darted out, is often much injured by the teeth at that moment snapping together. It is to this state of the disease that the term tetanus has been strictly applied.

The disorder continuing to advance, every organ of voluntary motion becomes affected; the eyes are rigid and immoveable, the countenance is hideously distorted, and expresses great distress; the strength is exhausted, and the pulse becomes irregular, and one universal spasm puts a period to a most miserable state of

Attacks of tetanus are seldom attended with any fever, but always with violent pain, and the spasms do not continue for a constancy, but the muscles admit of some remission in their contraction, which is frequently renewed, especially if the patient makes the least attempt to speak, drink, or alter his position.

When tetanic affections arise in consequence of a wound, puncture, or laceration, in warm climates, Dr. Thomas observes, they are almost sure to prove fatal. The locked jaw in consequence of an amputation, likewise proves usually fatal. When these affections are produced by an exposure to cold, they may in most cases be removed by a timely use of proper remedies, although a considerable space will probably elapse before the patient will be able to recover his former strength.

On dissections of this disease, slight effusions within the cranium have been observed in a few instances: but in by far the greater number, nothing has been dis-

covered, either in the brain, or any other organ.

The general indications are, 1. To remove any local irritation, which may appear to have excited the dis-ease; 2. To lessen the general irritability, and spas-modic tendency; 3. To restore the tone of the system. If a thorn, or other extraneous substance, be lodged in any part, it must be extracted; any spicula of bone, which may have brought on the disease after amputation, should be removed; a punctured wound ought to he dilated, &c. Some have proposed dividing the nerve going to the part, or even amputating this, to cut off the irritation; others paralyzing the nerves by powerful sedatives, or destroying them by caustics; others again exciting a new action in the part by active stimulants; but the efficacy, and even propriety of such measures, is doubtful. To fulfil the second indication, various means have been proposed. The abstraction of blood, recommended by Dr. Rush, might perhaps appear advisable in a vigorous plethoric-habit in the beglining of the disease, but it has generally proved of little utility, or even hurtful, and is rather contra-indicated by the state of the blood. Purging is a less questionable measure, as costiveness generally attends the disease, and in many cases it has appeared very beneficial, especially when calomel was employed. been found also, that a salivation, induced by mercury, has sometimes greatly relieved the disorder; but in other instances it has failed altogether. The remedy which has been oftenest employed, and with the most | are then preferable to the leaves. When dry, the dose

of the sternum, shooting into the back. A stiffness also takes place in the jaws, which soon increases to such a height, that the teeth become so closely set together, as not to admit of the smallest opening. This is whatlence of the symptoms is renewed; and where the patient cannot swallow, it may be tried in glyster, or freely rubbed into the skin. Other sedative and antispasmodic remedies, have been occasionally resorted to, as fiemlock, tobacco, musk, camphor &c. but for the most part with less satisfactory results. The warmbath has sometimes proved a useful auxiliary in cold climates; but the cold-bath is much more relied upon, especially in the West Indies, usually in conjunction with the liberal use of opium. In Germany, alkaline baths, and the internal use of the same remedies, are stated to have been decidedly serviceable. Others have advised the large use of bark and wine, which seem, however, rather calculated to be preventives, or to fulfil the third indication; yet wine may be employed rather as nourishment, since in severe cases of the dis ease little else can be taken. Electricity seems too hazardous a remedy to be tried in a general affection, especially in the muscles of respiration; but if confined to the jaw, it may be useful in a mild form. the period of convalescence the strength must be re-stored by suitable diet and medicines, the cold-bath, regular exercise, &c.; and removing the patient from the West Indies to a colder climate, till the health is fully established, would be a very proper precaution.

TETARTE'US. (Τεταρταιος, fourth.) Aquartan fever.
ΤΕΤΚΑΝΙΑΝΑΜΙΑ. (From τεσσαρες, four, and δυναμες, power.) The name of a class of plants in the sexual system of Linnæus, containing hermaphrodite flowers, with six stamens, four of which are long, and

TETRAGONUS. Quadrangular, square: applied to several parts of plants, as Caulis tetragonus, in that of the Lamium album, and a multitude of plants; Fo lium tetragonium, with four edges, or prominent angles, as that of Iris tuberesa

TETRAGYNIA. (From τεσσαρες, four, and γυνη, wife.) The name of an order of plants in several of the classes of the sexual system of Linnæus, con sisting of plants which, to the classic character, what ever it is, add the circumstance of having four pistils.

TETRAMY RUM. (From τετρας, four, and μυρον, an nument.) An ointment of four ingredients.

ointment.) An ointment of four ingredients.

TETRANDRIA. (From τισσαρις, four, and ανηρ, a husband.) The name of a class of plants in the sexual system of Linnæus. To it belong those which have hermaphrodite flowers with four stamina of equal

TETRANGU'RIA. (From τετρας four, and αγγος, a cup: so called because its fruit resembles a cup divided into

The citrul. four parts.)

TETRAPETALOUS. Four-petalled: applied to the flower that consists of four single petals or leaves placed around the pistil.

TETRAPHA'RMACUM. (From τετρας, four, and φαρμακον, a drug.) A medicine composed of four in-

TETRAPHYLLUS. (From τετρας, four, and φυλλον,

TETRAPHYLLUS. (From 727pas, rour, and \$\psi\text{Adv}\$, a leaf.) Four-leaved.

TETTER. See Herpes.

TEUCRIUM. (Teucrium, ii, n.; from Teucer, who discovered it.) The name of a genus of plants in the Linnwan system. Class, Didynamia; Order, Gymnospermia. The herb speedwell.

TEUCRIUM CAPITATUM. The systematic name of the polecy mountain of Montrellier. Policy menta-

the poley mountain of Montpellier. Polium monta-This plant bears the winter of our climate, and

is generally substituted for the candy-species.

TEUCRIUM CHAMÆDRYS. The systematic name of the common germander. Chamædrys; Chamædrys minor repens, vulgaris; Quercula calamandrina; Trissago; Chamædrops, of Paulus Ægineta, and Ori basius. This plant, called creeping germander, small germander, and English treacle; Teucrium—foliss cu-neiformi-ovatis, incisis, crenatis, petiolatis; floribus ternis; caulibus procumbentibus, subpilosis, of Lin-næus, has a moderately bitter and somewhat aromatic It was in high repute among the ancients in in termittent fevers, rheumatism, and gout; and where an aromatic bitter is wanting, germander may be ad-ministered with success. The best time for gathering this berb is when the seeds are formed, and the tops

is from 3 ss. to 3 j. Either water or spirit will extract their virtue; but the watery infusion is more bitter. This plant is an ingredient in the once celebrated powder called from the Buke of Portland, Portland powder.

TEUCRIUM CHAMPEPITYS. The systematic name of the ground-pine. Chamepitys; Arthetica; Arthretica; Ajuga; Abiga; Ica arthritica; Holocyron; Ionia; Sideritis. Common ground-pine. This low hairy plant, Teucrium—foliis trifidis, linearibus, integerrimis; floribus sessilibus, lateralibus, solitariis; caule diffuso, of Linnæus, has a moderately bitter taste, and a resinous, not disagreeable smell, somewhat like that of the pine. The tops of leaves are recommended as aperients and corroborants of the nervous system, and said to be particularly serviceable in female obstructions and paralytic disorders.

TEUCRIUM CRETICUM. The systematic name of the poley mountain of Candy. Polium creticum. The tops and whole herb enter the antiquated compounds mithridate and theriaca. The plant is obtained from the island of Candy; has a moderately aromatic smell, and a nauseous bitter taste. It is placed among the

aperients and corroborants. TEUCRIUM IVA. Chamapitys moschata; Iva moschata monspeliensium; Chamapitys anthyllus. French ground-pine. It is weaker, but of similar virtues to

Chamæpitys.

TEUCRIUM MARUM. The systematic name of the Marum syriacum; Marum creticum; Majorana syriacd; Marum verum; Marum cortusi; Chamedrys incana maritima; Marum germander, or Syrian herb mastich. This shrub is the Teucrium—folis integerrimis ovatis acutis petiolatis, subtus tomentosis; floribus racemosis secundis, of Linneus. It grows plentifully in Greece, Egypt, Crete, and Syria. The leaves
and younger branches, when recent, on being rubbed
between the fingers, emit a volatile aromatic smell,
which readily excites sneezing; to the taste they are bitterish, accompanied with a sensation of heat and acrimony. Judging from these sensible qualities of the plant, it may be supposed to possess very active powers. It is recommended as a stimulant aromatic, and deobstruent; and Linnæus, Rosenstein, and Bergius, speak highly of its utility. Dose, ten grains to half a drachm of the powdered leaves, given in wine. At present, however, marum is chiefly used as an errhine.

TRUCKIUM MONTANUM. The systematic name of the

Common poley mountain.

The systematic name of the

golden poley mountain.

TEUGRIUM SCORDIUM. The systematic name of the Scordium. Trissago palustris; Chamadrys palustris; Allium redolens. Water germander. The leaves of this plant have a smell somewhat of the garlic kind, from which circumstance it is supposed to take its name. to the taste they are bitterish and slightly pun-gent. The plant was formerly in high estimation, but is now justly fallen into disuse, although recommended by some in antiseptic cataplasms and fomentations. TEUTHRUM. Τευθρον. The herb polium.

Tευθρον. The herb polium. See

Teucrium polium.

THA'LAMUS. (Θαλαμος; Thalamus, i, m. a bed.)

A bed: the term applied to what is supposed to be the origin of the optic nerve; and to the receptacle of parts of fructification of plants. See Receptaculum.
THALAMUS NERVI OPTICI. Two bodies which form

in part the optic nerve, placed near to each other, in appearance white, protruding at the base of the lateral ventricles, and running in their direction inwards, a little downwards, and upwards, are called the Tha-

Thallsometric composed of sea-water and honey.

Thallsometric (From θαλασσα, the sea, and μελι, honey) A medicine composed of sea-water and honey.

Thall CTRUM. (Thalictrum, ri, n.; from θαλλω, to flourish.) 1. The name of a genus of plants in the Linnæan system. Class, Polyandria; Order, Poly-

gynia.

2. The pharmacopæial name of the poor man's rhubarb. See Thalictrum flavum.

Thalictrum flavum. The systematic name of the poor man's rhubarb. The root of this plant is said to be aperient and stomachic, and to come very near in its virtues to rhubarb. It is a common plant in this country, but seldom used medicinally. THALLITE. Epidote, or Pistacite. THALLUS. (From βαλλος, an olive bud, or green bough; from βαλλω, to be verdant, to shoot forth, or spread abroad. A term applied by Acharius, for the frond or foliage of a lichen, whether that part be of a leafy, fibrous, scaly, or crustaceous nature.

leafy, fibrous, scaly, or crustaceous nature.

THA PSIA. (From Thapsus, the island where it was found.) The name-of a genus of plants in the Linnman system. Class, Pentandria; Order, Digynia Thapsia asclepias. The deadly carrot. The root

operates violently both upwards and downwards, and

operates violently both upwards and downwards, and is not used in the present practice.

THA'PSUS. (From the island Thapsus.) The great white mullein, or cows' lungwort.

THE'A. Tea. The dried leaves of the tea-tree, of which there are two species, viz. 1. The Thea nigra, bohea, or black tea; and 2. The viridis, or green tea; both of which are natives of China or Japan, where they attain the height of five or six feet.

Great pairs are taken in collecting the leaves civaly

Great pains are taken in collecting the leaves singly, at three different times, viz. about the middle of February, in the beginning of March, and in April. Although some writers assert, that they are first exposed to the steam of boiling water, and then dried on copperplates; yet it is now understood that such leaves are simply dried on *iron* plates, suspended over a fire, till they become dry and shrivelled; when cool, they are packed in tin boxes to exclude the air, and in that state

exported to Europe.

Teas are divided in Britain into three kinds of green,

and five of bohea. The former class includes,

1. Imperial or bloom tea, having a large leaf, a faint smell, and being of a light green colour.

2. Hyson, which has small curled leaves, of a green shade inclining to blue.

3. Singlo tea, thus termed from the place where it is cultivated.

The boheas comprehend,

1. Souchong, which, on infusion, imparts a yellowish

2. Camho, a fine tea, emitting a fragrant violet smell, and yielding a pale shade; it receives its name from the province where it is reared.

3. Pekoe tea is known by the small white flowers that

are mixed with it.

are mixed with it.

4. Congo has a larger leaf than the preceding variety, and yields a deeper tint to water; and,

5. Common bohea, the leaves of which are of a uniform green colour. There are besides other kinds of tea, sold under the names of gunpowder tea, &c. which differ from the preceding only in the minuteness of their leaves, and being dried with additional care.

The following interesting results of experiments on

The following interesting results of experiments on tea by Brande, have been published by him in his

Journal.

One hundred parts of Tea.	in	Soluble in Alkohol.	with	Inert Residue.
Green Hyson,	41 34 36 36 31 35 34 37 36 36 37	44 43 43 42 41 36 37 35 35 31	31 33 35 34 34 38 38 38 38 38 38 38 38 38 38 38 38 38	56 57 57 58 59 64 63 63 64 65

Much has been said and written on the medicinal properties of tea; in its natural state it is a narcotic properties of tea; in its natural state it is a narcotic plant, on which account the Chinese refrain from its use till it has been divested of this property by keeping it at least for twelve months. If, however, good tea be drunk in moderate quantities, with sufficient milk and sugar, it invigorates the system, and produces a temporary exhilaration; but when taken too copiously, it is apt to occasion weakness, tremor, palsies, and various other symptoms arising from narcotic plants, while it contributes to aggravate hysterical and hypochondriacal complaints. Tea has also been supposed to possess considerable diuretic and sudorific virtues, which, however, depend more on the quantity of warm water employed as a vehicle, than the quantity of tea itself. Lastly, as infusions of these leaves are the safest refreshment after undergoing great bodily fatigue or mental exertion, they afford an agreeable beverage to those who are exposed to cold weather; at the same time tending to support and promote perspiration, which is otherwise liable to be impeded.

THEA GERMANICA. Fluellin or male speedwell.

See Veronica officinalis.

THEBAICA. (A Thebaide regione, from the country about the ancient city of Thebes in Egypt, where it flourished.) The Egyptian poppy.

THEBESI FORAMINA. The orifices of veins in the

cavities of the heart.

THE CA. (From τιθημι, to place.) A case, sheath,
or box. 1. The canal of the vertebral column.
2. The capsule or dry fructification adhering to the

apex of a frondose stem.

THECA VERTEBRALIS. The vertebral canal. See

THELY PTERIS. (From θηλυς, female, and πτερις, fern.) The female fern.

THE NAR. See Flexor brevis pollicis manus.

THEORRO'MA. (Theobroma, ω, f.; from θερι, the gods, and βρωμα, food: so called from the deliciousness of its fruit.) The name of a genus of plants. Class, Polyadelphia; Order, Decandria.
Theorems cacao. The systematic name of the

tree which affords cocoa and chocolate.

Theodo'Ricum. (From θεσε, the gods, and δωρον, a

 The pompous name of some antidotes.
 THERAPEI'A. (From θεραπενω, to heal.) The art of healing diseases. rapia. See Thera-

peutica.

THERAPEUTICA. (From Θεραπενω, to cure.)

Therapia. Methodus medendi. Therapeutics. That
branch of medicine which treats of the operation of the different means employed for curing diseases, and of the application of these means.

THERI'ACA. (From 3ηρ, a viper, or venomous wild beast.) 1. Treacle, or molasses.

2. A medicine appropriated to the cure of the bites

of venomous animals, or to resist poisons.

THERIACA ANDROMACHI. The Venice or Mithridate treacle; a composition of sixty-one ingredients, prepared, pulverized, and with honey formed into an electuary.

THERIACA COLLESTIS. Liquid laudanum.
THERIACA COMMUNIS. Common treacle, or mo-

THERIACA DAMOCRATIS. The same preparation as mithridate. See Mithridatium.

THERIACA EDINENSIS. Edinburgh theriaca. The

Confectio opii.

THERIACA GERMANORUM. A rob of juniper-ber-

THERIACA LONDINENSIS. A cataplasm of cummin-seed, bay-berries, germander, snake-root, cloves, and

THERIACA RUSTICORUM. The roots of the common

garlic were so called. See Allium satirum.

THERIO'MA. (From θηριοώ, to rage like a wild A malignant ulcer.

THE'RMA. A warm-bath or spring. See Mineral

THERMOMETER. (Thermometrum; from θερμη, heat, and μετρον, a measure.) An instrument for measuring the degrees of heat. A thermometer is a hollow tube of glass, hermetically sealed, and blown at one end in the shape of a hollow globe. The bulb and part of the tube are filled with mercury, which is the only fluid that expands equally. When we immerse the 346

expands, and of course rises in the tube; but when we plunge it into a cold body, the mercury contracts,

and of course falls in the tube.

The rising of the mercury indicates, therefore, an increase of heat; its falling, a diminution of it; and the quantity which it rises or falls, denotes the proportion of increase or diminution. To facilitate observation, the tube is divided into a number of equal parts, called degrees.

Further, if we plunge a thermometer ever so often into melting snow or ice, it will always stand at the same point. Hence we learn that snow or ice always

begins to melt at the same temperature.

If we plunge a thermometer repeatedly into water kept boiling, we find that the mercury rises up to a certain point. This is therefore the point at which water always boils, provided the pressure of the atmosphere be the same.

There are four different thermometers used at present in Europe, differing from each other in the number of degrees into which the space between the freezing and boiling points is divided. These are Fahrenheit's boiling points is divided. These Reaumur's, Celsius's, and Delisle's.

The thermometer uniformly used in Britain, is Fahrenheit's; in this the freezing point is fixed at 320—the boiling point, at 2120 above 00—or the part at which both the ascending and descending series of numbers commence.

In the thermometer which was first constructed by Reaumur, the scale is divided into a smaller number of degrees upon the same length, and contains not more than 800 between the freezing and the boiling points. The freezing point is fixed in this thermometer precisely at 0°, the term between the ascending and the descending series of numbers. Again, 100 is the number of the degrees between the freezing and the boiling points in the scale of Celsius; which has been intro-duced into France, since the revolution, under the name of the Centigrade thermometer; and the freez-ing point is in this, as in the thermometer of Reaumur, fixed at 0°. One degree on the scale of Fahrenheit appears, from this account, to be equal to 4.9ths of a degree on that of Reaumur, and to 5-9ths of a degree on that of Celsius.

The space in Delisle's thermometer between the freezing and boiling points is divided into 1500, but the reczing and boiling points is divided into 150°, but the graduation begins at the boiling point, and increases towards the freezing point. The boiling point is marked 0, the freezing point 150. Hence 180 F. = 150 D., or 6 F. = 5 D. To reduce the degrees of Delisle's thermometer under the boiling point to those of Fahrenheit, we have $F_{-} = 212 - 6.5$ D.; to reduce those above the boiling, point $F_{-} = 212 + 6.5$ D. Upon the knowledge of this proportion it is easy for the student knowledge of this proportion it is easy for the student to reduce the degrees of any of these thermometers into the degrees of any other of them.

Thieves-vinegar. See Acctum aromaticum.

THIGH. See Femur.

THIGH-BONE. See Femur.
THIRST. Sitis. The sensation by which we experience a desire to drink. It is variable according to individuals, and it is rarely uniform in the same per-son. Generally speaking, it consists of a feeling of dryness, of heat, and constriction, which reigns in the back part of the mouth, the pharynx, æsophagus, and sometimes the stomach. Though thirst continue but for a short time, these parts swell and become red, the mucous secretion ceases almost entirely; that of the follicles changes, becomes thick and tenacious; the flowing of the saliva diminishes, and its viscosity is sensibly augmented.

These phenomena are accompanied by a vague inquietude, by a general heat; the eyes become red, the mind is troubled, the motion of the blood is accelerated, the respiration becomes laborious, the mouth is frequently opened wide, in order to bring the external air into contact with the irritated parts, and thus to pro-

duce a momentary ease.

For the most part, the inclination to drink is developed, when by some cause, for example, heat and dryness of the atmosphere, the body has lost a great deal of fluid; but it appears under a great many different circumstances, such as having spoken long, having eaten certain sorts of food, or swallowed a substance which remains in the esophagus, &c. The vicious habit of frequently drinking, and the desire of tasting bulb of the thermometer in a hot body, the mercury some liquids, such as brandy, wine, &c., cause the developement of a feeling which has the greatest

analogy with thirst.

There are people who never felt thirst, who drink from a sort of sympathy, but who could five a long time without thinking of it, or without suffering from the want of it; there are other persons in whom thirst is often renewed, and becomes so strong as to make them drink from forty to sixty pints of liquid in twenty four hours; in this research great individual different pours. four hours; in this respect, great individual differences are remarked.

Thirst is an internal sensation, an instinctive feeling; it belongs essentially to the organization, and ad-

mits of no explanation.

mits of no explanation.

THISTLE. See Carduus.

Thistle, carline. See Carlina acaulis.

Thistle, holy. See Centaurea benedicta.

Thistle, pine. See Carlina gummifera.

THLA SPL (Thlaspi, n.; indeclinable: from θλαω, to break; because its seed appears as if it were broken or bruised.)

1. The name of a genus of plants in the linnean system. Class. Tetradunamia: Order, Sili-Linnæan system. Class, Tetradynamia; Order, Sili-

2. The pharmaceutical name of the herb penny-cress. Two species of thlaspi are directed in some pharmacopaias for medicinal use:—the Thlaspi arceuse, of Linnæus, or treacle mustard; and Thlaspi campestre, of Linnæus, or mithridate mustard. The seeds of both have an acrid biting taste, approaching to that of common mustard, with which they agree nearly in their pharmaceutic qualities. They have also an unpleasant flavour, somewhat of the garlic or onion

THEASPI ARVENSE. The systematic name of the

THEASPI CAMPESTRE. The systematic name of the treacle mustard. See Thlaspi.

THEASPI CAMPESTRE. The systematic name of the mithridate mustard. See Thlaspi.

THORACIC. (Thoracicus; from thorax, the chest.)

Belonging to the thorax, or chest.

THORACIC DUCT. Ductus thoracicus. Pecquettii. The trunk of the absorbents; of a serpentine form, and about the diameter of a crow-quill. It lies upon the dorsal vertebræ, between the aorta and vena azygos, and extends from the posterior opening of the diaphragm, to the angle formed by the union of the left subclavian and jugular veins, into which it opens and evacuates its contents. In this course, the thoracic duct receives the absorbent vessels from al-

most every part of the body.

THORAX. (Thorax, acis, f.; from ξορεω, to leap: because in it the beart leaps.) The chest. That part of the body situated between the neck and the abdomen. The external parts of the thorax are, the common integuments, the breasts, various muscles, and the bones of the thorax. (See Bone, and Respiration.) The parts within the cavity of the thorax are, the pleura and its productions, the lungs, heart, thymus gland, æsophagus, thoracic duct, arch of the aorta, part of the vena cava, the vena azygos, the eighth pair of nerves, and part of the great intercostal nerve.

THORINA. An earth discovered in 1816 by Ber-zelius. He found it in small quantities in the gadolinite of Korarvet, and two new minerals which he calls the deutofluate of cerium, and the double fluate of cerium

and yttria. It resembles zirconia.

To obtain it from those minerals that contain protoxide of cerium and yttria, we must first separate the oxide of iron by succinate of ammonia. The new earth, indeed, may, when alone, be precipitated by the succinates; but in the analytical experiments in which he has obtained it, it precipitated in so small a quantity along with iron, that he could not separate it from that oxide. The deutoxide of cerium is then precipitated by the subplicate of notaces a color which the entire tated by the sulphate of potassa; after which the yttria and the new earth are precipitated together by caustic ammonia. Dissolve them in muriatic acid. Evaporate the solution to dryness, and pour boiling water on the residue, which will dissolve the greatest part of the yttria; but the undissolved residue still contains a portion of it. Dissolve it in muriatic or nitric acid, and evaporate it till it becomes as exactly neutral as possible. Then pour water upon it, and boil it for an instant. The new earth is precipitated, and the liquid contains disengaged acid. By saturating this liquid, and boiling it a second time, we obtain a new precipitate of the new earth.

This earth, when separated by the filter, has the appearance of a gelatinous, semitransparent mass. When

washed and dried, it becomes white, absorbs carbonle acid, and dissolves with effervescence in acids. Though calcined, it retains its white colour; and when the heat to which it has been exposed was only moderate, it dissolves readily in muriatic acid; but if the heat has been violent, it will not dissolve till it be digested in strong muriatic acid. This solution has a yellowish colour; but it becomes colourless when diluted with water, as is the case with glucina, yttria, and alumina. If it be mixed with yttria, it dissolves more readily after having been exposed to heat. The neutral solutions of this earth have a purely astringent taste, which is neither sweet, nor saline, nor bitter, nor metallic. In this property it differs from all other species of earths, except zirconia.

When dissolved in sulphuric acid with a slight excess of acid, and subjected to evaporation, it yields transparent crystals, which are not altered by exposure to the air, and which have a strong styptic taste.

This earth dissolves very easily in nitric acid; but after being heated to redness, it does not dissolve in it except by long boiling. The solution does not crystalize, but forms a mucilaginous mass, which becomes more liquid by exposure to the air, and which, when evaporated by a moderate heat, leaves a white, opaque mass, similar to enamel, in a great measure insoluble in water.

It dissolves in muriatic acid, in the same manner as in nitric acid. The solution does not crystallize. When evaporated by a moderate heat, it is converted into a syrupy mass, which does not deliquesce in the air, but dries, becomes white like enamel, and afterward dissolves only in very small quantity in water, leaving a subsalt undissolved; so that by spontaneous evapora-tion it lets the portion of muriatic acid escape to which it owed its solubility.

This earth combines with avidity with carbonic acid. The precipitates produced by caustic ammonia, or by boiling the neutral solutions of the earth in acids, absorb carbonic acid from the air in drying. kaline carbonates precipitate the earth combined with the whole of their carbonic acid.

The ferruginous prussiate of potassa poured into a solution of this earth, throws down a white precipitate, which is completely redissolved by muriatic

Caustic potassa and ammonia have no action on this earth newly precipitated, not even at a boiling

temperature.

The solution of carbonate of potassa, or carbonate of ammonia, dissolves a small quantity of it, which precipitates again when the liquid is supersaturated with an acid, and then neutralized by caustic ammonia; but this earth is much less soluble in the al-kaline carbonates than any of the earths formerly known that dissolve in them.

Thorina differs from the other earths by the follow-Thorma differs from the other earths by the following properties:—From alumina, by its insolubility in hydrate of potassa; from glucina, by the same property; from yttria, by its purely astringent taste, without any sweetness, and by the property which its solutions possess of being precipitated by boiling when they do not contain too great an excess of acid. It differs from zirconia by the following properties:—1. After being heated to reduce it is still capable of being dissolved in acide. to redness, it is still capable of being dissolved in acids 2. Sulphate of potassa does not precipitate it from its solutions, while it precipitates zirconia from solutions containing even a considerable excess of acid. 3. It is containing even a considerable excess of acid. 3. It is precipitated by oxalate of ammonia, which is not the case with zirconia. 4. Sulphate of thorina crystallizes readily, while sulphate of zirconia, supposing it free from alkali, forms, when dried, a gelatinous, transparent mass, without any trace of crystallization.

THORINUM. The supposed metallic basis of thorina, not hitherto extracted.

THORN. See Prynus spinosa.

THORN. See Prunus spinosa.

Thorn, Egyptian. See Acacia vera. THORN-APPLE. See Datura stramonium. [THOROUGHWORT. See Eupatorium perfolia-

m. A.]
THROMBOSIS. (Thrombosis, is, f.; from θρομβος.)

The same as thrombus.

The OMBUS. (Thrombus, i, m.; from θροςω, to disturb.) A small tumour which sometimes arises after bleeding, from the blood escaping from the vein into the cellular structure surrounding it.

THRUSH. See Aphtha.

TIB THY

THULITE. A hard, peach-blossom coloured mineral, found at Souland, in Tellemark, in Norway.

THUMERSTONE. See Aximite.

THU'RIS CORTEX. The cascarilla and elutheria THU'RIS CORTEX. The cascarilla and parks were so called. See Croton cascarilla.

THUS. (From Ψυω, to sacrifice: so called from its great use in sacrifices.) See Juniperus lycia, and Pinus abies.

THUS JUDEORUM. See Thymiama.
THUS MASCULUM. See Juniperus lycia.

THUY'A. (From \(\theta voy\), odour: so named from its fragrant smell.) Thuja. The name of a genus of plants.

Class, Monacia; Order, Monadelphia.

They a occidentalis. The systematic name of the tree of life. Arbor vita. Thuya—strobilis lavibus; squamis obtusis, of Linnaus. The leaves and wood were formerly in high estimation as resolvents, sudorifics, and expectorants, and were given in phthisical affections, intermittent fevers, and dropsies.

Thylaci'tis. (From θυλακος, a seed-vessel: so called from its large head.) The white garden poppy. THY'MBRA. (A name borrowed from Dioscorides, whose real θυμβρα, however, is a species of Saturcia.) I. The name of a genus of plants. Class, Didynamia; Order, Gymnospermia.

2. See Saturcia hortensis.

THYMBRA HISPANICA. The name given by Tournefort to the common herb mastich. See Thymus mas-

THYME. Sec Thymus.

Thyme, lemon. See Thymus scrpyllum.
Thyme, mother of. See Thymus scrpyllum.
Thymeια' A. (From θυρος, thyme, and ελαια, an olive; the first alluding to the leaf, and the latter to the shape and oiliness of the fruit.) See Daphne

gnidium.

THYMIA'MA. (From θυμα, an odour: so called from its odoriferous smell.) Muskwood. Thus judα-orum. A bark in small brownish gray pieces, intermixed with bits of leaves, seeming as if the bark and leaves had been bruised and pressed together; brought from Syria, Cilicia, &c. and supposed to be the produce of the liquid storax-tree. This bark has an agreeable balsamic smell, approaching to that of liquid storax, and a sub-acrid bitterish taste, accompanied with some slight adstringency.

elight adstringency.

Thy'mtum. (From θυμος, thyme; because it is of the colour of thyme.) A small wart upon the skin.

Thymoxa'lme. (From θυμος, thyme, οξυς, acid, and aλς, salt.) A composition of thyme, vinegar, and salt.

THY'MUS. (Thymus, i, m. Απο του θυμω, because it was used in faintings; or from θυμα, an odour, because of its fragrant smell.) 1. The name of a genus of plants in the Linneau system.

of plants in the Linnean system. Class, Didynamia; Order, Gyanospermia. Thyme. 2. The pharmacopæial name of the common thyme.

See Thymus vulgaris.

3. A small indolent carnous tubercle like a wart arising about the anus, or the pudenda, resembling the

flowers of thyme, from whence it takes its name.

Thymus citratus. See Thymus serpyllum.

Thymus creticus. See Satureia capitata.

Thymus gland. Θυμος. A gland of considerable size in the fietus, situated in the anterior duplicature or space of the mediastinum, under the superior part of the sternum. An excretory duct has not yet been

detected, but lymphatic vessels have been from it to the thoracic duct. Its use is unknown.

Thymus mastichina. The systematic name of the common herb mastich. Marum vulgare; Sampsudium mastichina gallorum; Thymbra chus; Clinopodium mastichina gallorum; Thymbra hyspanica; Jaca indica. A low shrubby plant, a native of Spain, which is employed as an errhine. It has a strong agreeable smell, like mastich. Its virtues are similar to those of the Marum syriacum, but less

Description of the Scrpyllum; Scrpyllum; Gilarum; Scrpyllum vulgare minus. Wild or mother of thyme. Thymus—floribus capitatis, caulibus repentibus, foliis planis obtusis basi ciliatis, of Linnæus. This plant has the same sensible qualities as those of the garden thyme, but has a milder and rather more grateful flavour. Lemon thyme, the Serpyllum citratum, is merely a variety of

THRY'PTICA. (From θρυπτω, to break.) Medicines which are said to have the power of destroying stones in the bladder.

THULITE. A hard, peach-blossom coloured mineral, found at Souland, in Tellemark, in Norway.

THUMERSTONE. See Azinite.

The secondary of Linear control of the common thyme. This herb, the Thymus—erectus foliis revolutis ovatis, floribus verticillato spicatis, of Linear control of the common thyme. This herb, the Thymus—erectus foliis revolutis ovatis, floribus verticillato spicatis, of Linear control of the common thyme. This herb, the Thymus—erectus foliis revolutis ovatis, floribus verticillato spicatis, of Linear control of the common thyme. pungent taste. Its virtues are said to be resolvent, em menagogue, tonic, and stomachic; yet there is no disease mentioned in which its use is particularly recom-

mended by any writer on the materia medica.

THYRO. Names compounded with this word belong to muscles which are attached to the thyroid car

THYRO ARYTENOIDEUS. A muscle situated about the glottis, which pulls the arytenoid cartilage forward nearer to the middle of the thyroid, and consequently shortens and relaxes the ligament of the larynx.

THYRO-HYOIDEUS. A muscle situated between the os hyoides and trunk, which pulls the os hyoides downwards, and the thyroid cartilage upwards.

THYRO-PHARYNGEUS. See Constrictor pharyngis

THYRO-PHARYNGO-STAPHILINUS. See Palato pha-

THYRO STAPHILINUS. See Palato pharyngeus.
THYROID. (Thyroideus; from θυρεος, a shield, and ειδος, resemblance; from its supposed resemblance to a shield.) Resembling a shield.

Thyroid Captillage. Cartilago thyroidea; Carti

THYROID CARTILAGE. Cartilago thyroidea; Cartilago scutiformus. Scutiform cartilage. The cartilage which is placed perpendicular to the cricoid cartilage of the larynx, constituting the anterior, superior, and largest part of the larynx. It is harder and more prominent in men than in women, in whom it forms the omum adami.

THYROID GLAND. Glandula thyroidea. A large gland situated upon the cricoid cartilage, trachea, and horns of the thyroid cartilage. It is uncertain whether it be conglobate or conglomerate. Its excretory duct has never been detected, and its use is not yet known.

THYRSUS (Thyrsus, i, m. : a young sprout.) In botany, a bunch, or dense and close pannicle, more or less of an ovate form. It is oblong in Tussilago hybrida,

and ovate in Tussilago petasites.
TIBIA. (Tibia, the hautboy; qu. tubia, from tuba, a tube: so called from its pipe-like shape.) majus; Arundo-major; Fosilus; and, from its resemblance to an old musical instrument, Canna major; Canna-domestica cruris. The largest bone of the leg. It is of a long, thick, and triangular shape, and is situated on the internal part of the leg. Its upper extremity is large, and flattened at its summit, where we observe two articulating surfaces, a little concave, and sepa-rated from each other by an intermediate irregular protuberance. Of these two cavities, the internal one is deepest, and of an oblong shape, while the external one is rounded, and more superficial. Each of these, in the recent subject, is covered by a cartilage, which extends to the intermediate protuberance, where it termediate protuberance is the conductor of the protuberance of the protuberance is the protuberance of the protuberance o minates. These two little cavities receive the condyles of the os femoris, and the eminence between them is admitted into the cavity which is seen between the two condyles of that bone; so that this articulation affords a specimen of the complete ginglymus. Behind the in-termediate protuberance, or tubercle, is a pretty deep depression, which serves for the attachment of a ligament, and likewise to separate the two cavities from each other. Under the edge of the external cavity is a circular flat surface, covered with cartilage, which serves for the articulation of the fibula; and at the forepart of the bone is a considerable tuberosity of an inch and a half in length, to which the strong ligament of the rotula is fixed.

The body of the tibia is smaller than its extremities, and, being of a triangular shape, affords three surfaces. Of these, the external one is broad, and slightly hol-lowed by muscles above and below; the internal surface is broad and flat, and the posterior surface is narrower than the other two, and nearly cylindrical. This last has a slight ridge running obliquely across it, from the outer side of the upper end of the bone to about one-third of its length downwards. A little below this we observe a passage for the medullary vessels, which is pretty considerable, and slants obliquely downwards. Of the three angles which separate these surfaces, the anterior one, from its sharpness, is called the spine or shin. This ridge is not straight, but describes a figure

tike an Italic f, turning first Inwards, then outwards, and lastly inwards again. The external angle is more rounded, and serves for the attachment of the interosseous ligament; and the internal one is more rounded

still by the pressure of muscles.

The tibia enlarges again at its lower extremity, and terminates in a pretty deep cavity, by which it is arti-culated with the uppermost bone of the foot. This cavity, in the recent subject, is lined with cartilage. Its internal side is formed into a considerable process, called malleolus internus, which, in its situation, resem-bles the styloid process of the radius. This process is broad, and of considerable thickness, and from its ligaments are extended to the foot. At its back part we find a groove, lined with a thin layer of cartilage, in which slide the tendons of the flexor digitorum longus, and of the tibialis posticus; and a little behind this is a smaller groove, for the tendon of the flexor longus pollicis. On the side opposite to the malleolus internus, the cavity is interrupted, and immediately internus, the cavity is interrupted, and immediately above it is a rough triangular depression, which is furnished with cartilage, and receives the lower end of the

The whole of this lower extremity of the bone seems to be turned somewhat outwards, so that the malleolus internus is situated more forwards than the inner border of the upper extremity of the bone.

In the fætus, both ends of the tibia are cartilaginous,

and become afterward epiphyses.

and become afterward epiphyses.

TIBIAL. (Tibialis; from tibia, the bone of the leg, so called.) Belonging to the tibia.

TIBIAL ARTERY. Arteria tibialis. The two principal branches of the popliteal artery: the one proceeds forwards, and is called the anterior tibial; the other backwards, and is called the posterior tibial; of which he external tibial, the fibular, the external and internal plantar, and the plantal arch, are branches.

TIBIALIS. See Tibial.

TIBIALIS. ANTICUS. Tibio-sus-metatarsien, of Du-

Tibialis anticus. Tibio-sus-metatarsien, of Du-mas. A flexor muscle of the foot, situated on the leg, which bends the foot by drawing it upwards, and at the same time turns the toes inwards.

TIBIALIS GRACILIS See Plantaris.

TIBIALIS POSTICUS. Tibio-tarsien, of Dumas. A flexor muscle of the foot, situated on the leg, which ex-

tends the foot, and turns the toes inwards.

A painful affection of a TIC DOULOUREUX. nerve, so called from its sudden and momentary excruciating stroke. The more appropriate name is neuralgia. It mostly attacks the face, particularly that branch of the fifth pair, which comes out of the infraorbitary foramen.

Ti GLIA GRANA. See Croton tiglium.
TILBURY. A small town in Essex, celebrated for its fort. A mineral water is found at West Tilbury. It is an aperient and chalybeate now seldom used medici-

TILE ORE. A species of octohedral red copper ore.
TILIA. (Tilia, σ, f.; Π7ελεα, utmus, the elm-tree.)

1. The name of a genus of plants in the Linnæan system. Class, Polyandria; Order, Monogynia.

2. The pharmacopæial name of the lime, or linden-

See Tilia curopæa.

The systematic name of the lime-TILIA EUROPÆA. tree. The flowers of this tree are supposed to possess anodyne and antispasmodic virtues. They have a moderately strong smell, in which their virtue seems to consist, and abound with a strong mucilage. They are in high esteem in France. See Tilia.

TILLI GRANA. See Croton tiglium.
TI'LMUS. (From τιλλω, to pluck.) Floccitatio, or picking of bed-clothes, observable in the last stages of

some disorders.

[TILTON, James, M.D. was born in the county of Kent, in the state of Delaware, in June, 1745. His father, dying when he was very young, left him to the care of his mother, with very slender means. Notwithstanding this, he found means to study a profession, and obtained his degree of doctor in medicine from the University of Pennsylvania. He then commenced practice in his native State, and was successful in establishing himself, but the troubles of the revolution establishing himself, but the troubles of the revolution soon commenced, and in 1776 he joined the army of the United States as a surgeon, and was afterward promoted to the grade of hospital surgeon. After the successful termination of the revolutionary contest, when Dr. Tilton saw his country free and independent,

he once more retired to his native state, and recom-menced the practice of his profession, which he conmenced the practice of his profession, which he continued for many years with distinguished reputation and abilities. In 1812, he had retired to his country-seat in the neighbourhood of Wilmington, when he was again called to take an active part in a new contest with our old enemy. After the declaration of war against Great Britain, Dr. Tilton was appointed by the light of the United States. Physician and Surgeon General of the United States Army, and continued to act in that capacity during the three years of the war.

As a physician Dr. Tilton was bold and decided; he never temporized with disease. His remedies were few in number, but generally of an active kind. He died in May, 1822, nearly 77 years old. His publica-tions were few, but valuable and useful. His friend,

Dr. McLane, in a eulogy to his memory, gives the following summary of his character:

"In whatever view we may consider the character "In whatever view we may consider the character of Dr. Tilton, we shall find many traits to distinguish him from other men. He was in many respects an original; wholly unlike most other men in person, countenance, manners, speech, gesture, and habits. His height was about six feet and a half, and his structure slender. Whether he walked or sat still; whether in conversation or mute; whether he ate, drank, or smoked; whether in a grave mood or indulging in his loud laugh, all was in a style peculiar to himself, and most remarkable. For honesty and frankness he was proverbial; in these important points he had few equals, certainly no superiors. His whole life afforded a luminous example of the effects of deep-rooted principles and moral rectitude upon the conduct of men; and we have the fullest assurance to believe that he has reached those realms of peace and happiness, from

which he can never be separated; and has become the 'just may made perfect.'"—Thach. Med. Biog. A.]

TIMAC. The name of a root imported from the East Indies, which is said to possess diuretic virtues, and therefore exhibited in dropsies. It is not known from what plant it is obtained.

what plant it is obtained.

TIN. Stannum. Jupiter of the alchemists. It has been much doubted whether this metal is found native. In the opinion of Kirwan, there are sufficient authorities to determine the question in the affirmative. The native oxide of tin, or tin stone, occurs both massive and crystallized. Its colour is a dark brown, sometimes yellowish-gray. When crystallized, it is somewhat yellowish-gray. When crystallized, it is somewhat transparent. The wood tin ore is a variety of the native oxide, termed so from its fibrous texture. This variety has hitherto been found only in Cornwall. It occurs in fragments which are generally round, and its colour is brown, sometimes inclining to yellow. Tin is also found mineralized by sulphur, associated always with a portion of copper, and often of iron. is called tin pyrites. Its colour is yellowish-gray. It has a metallic lustre, and a fibrous or lamellated texture; sometimes it exhibits prismatic colours. comparatively a rare metal, as it is not found in great quantity any where but in Cornwall or Devonshire; though it is likewise met with in the mines of Bohemia, Saxony, the island of Banca, the peninsula of Malacca, and in the East Indies.

Tin is a metal of a yellowish-white colour, considerably harder than lead, scarcely at all sonorous, very malleable, though not very tenacious. Under the hammer it is extended into leaves, called tin-foil, which are about one thousandth of an inch thick, and might easily be beaten to less than half that thickness, if the pur-poses of trade required it. Its specific gravity is 7.29. It melts at about the 442° of Fahrenheit's thermometer: and by a continuance of the heat it is slowly converted into a white powder by oxidation. Like lead, it is brittle when heated almost to fusion, and exhibits a grained or fibrous texture if broken by the blow of a hammer. It may also be granulated by agitation at the time of its transition from the fluid to the solid the time of the state. The oxide of tin resists fusion more strongly than that of any other metal; from which property it is useful to form an opaque white enamel when mixed with pure glass in fusion. The brightness of its surface, when scraped, soon goes off by exposure to the air; but it is not subject to rust or corrosion by exposure to the weather.

To obtain pure tin, the metal should be boiled in nitric acid, and the oxide which falls down reduced by heat in contact with charcoal, in a covered crucible

TIN TIN

oxygen. The first or protoxide is gray: the second or peroxide is white. The first is formed by heating tin in the air, or by dissolving tin in muriatic acid, and adding water of potassa to the solution while recent, and before it has been exposed to air. The precipitate, after being heated to whiteness to expel the water of the hydrate, is the pure protoxide. It is convertible into the peroxide by being boiled with dilute nitric acid,

dried and ignited.

There are also two chlorides of tin. When tin is burned in chlorine, a very volatile clear liquor is formed, a non-conductor of electricity, and which, when mixed with a little water, becomes a solid crystalline substance, a true muriate of tin, containing the peroxide of the metal. This, which has been called the liquor of Libavius, may be also procured by heating together tin-filings and corrosive sublimate, or an amalgam of tin and corrosive sublimate. The other compound of tin and chlorine is a gray semitransparent crystalline solid. It may be procured by heating together an amalgam of tin and calomel. It dissolves in water, and forms a solution, which rapidly absorbs oxygen from the air, with deposition of peroxide of tin.

There are two sulphurets of tin. One may be made by fusing tin and sulphur together. It is of a bluish colour, and lamellated texture. It consists of 7.35 tin + 2 sulphur. The other sulphuret, or the bisulphuret, is made by heating together the peroxide of tin and sulphur. It is of a beautiful gold colour, and appears

in fine flakes.

The salts of tin are characterized by the following

general properties:

1. Ferro-prussiate of potassa gives a white precipi-

- 2. Hydrosulphuret of potassa, a brownish black with the protoxide; and a golden yellow with the peroxide. 3. Galls do not affect the solutions of these salts.
- 4. Corrosive sublimate occasions a black precipitate with the protoxide salts; a white with the peroxide

5. A plate of lead frequently throws down metallic tin, or its oxide, from the saline solutions.

Muriate of gold gives, with the protoxide solutions, the purple precipitate of Cassius.

Muriate of platinum occasions an orange preci-

pitate with the protoxide salts.

Concentrated sulphuric acid, assisted by heat, dis-solves half its weight of tin, at the same time that sul-phurous gas escapes in great plenty. Nitric acid and tin combine together very rapidly

without the assistance of heat.

The muriatic acid dissolves tin very readily, at the same time that it becomes of a darker colour, and ceases to emit fumes.

Aqua regia, consisting of two parts nitric and one muriatic acid, combines with tin with effervescence,

and the developement of much heat.

The acetic acid scarcely acts upon tin. The operation of other acids upon this metal has been little inquired into. Phosphate, fluate, and borate of tin have been formed by precipitating the muriate with the re-

spective neutral salts.

If the crystals of the saline combination of copper with the nitric acid be grossly powdered, moistened, nd rolled up in tinfoil, the salt deliquesces, nitrous fumes are emitted, the mass becomes hot, and suddenly takes fire. In this experiment, the rapid transition of the nitric acid to the tin is supposed to produce or de-velope heat enough to set fire to the nitric salts; but by what particular changes of capacity, has not been shown.

If small pieces of phosphorus be thrown on tin in fusion, it will take up from 15 to 20 per cent., and form a silvery white phosphuret of a foliated texture, and soft enough to be cut with a knife, though but little This phosphuret may be formed likewise

by fusing tin filings with concrete phosphoric acid.

Tin unites with bismuth by fusion, and becomes harder and more brittle in proportion to the quantity of that metal added. With nickel it forms a white brilliant mass. It cannot easily be united in the direct way with arsenic, on account of the volatility of this metal; but by heating it with the combination of the arsenical acid and potassa, the salt is partly decomposed; and the tin combining with the acid, becomes converted into a brilliant brittle compound, of a plaited It has been said, that all tin contains arsenic;

There are two definite combinations of tin and and that the crackling noise which is heard upon bend ing pieces of tin, is produced by this impurity; but from the experiment of Bayen, this appears not to be the fact. Cobalt unites with tin by fusion, and forms a grained mixture of a colour slightly inclining to violet. Zinc unites very well with tin, increasing its hardness, and diminishing its ductility, in proportion as the quantity of zinc is greater.

This is one of the principal additions used in making pewter, which consists for the most part of tin.

Antimony forms a very brittle, hard mixture with tin. Tungsten fused with twice its weight of tin, affords a

Tringsten fused with twice its weight of the anores a brown spongy mass, which is somewhat ductile.

The uses of tin are very numerous, and so well known, that they scarcely need be pointed out. The tinning of iron and copper, the silvering of looking-glasses, and the fabrication of a great variety of vessels and utensils for domestic and other uses, are among

the advantages derived from this metal.

TINCA. (Tinca, \(\pi_\), \(\text{i}, \(\pi_\), quasi tincta: so called, because it appears as if it were dyed.) The name of a genus of fishes. The tench.

Tinc\(\tilde{x} \) os. The mouth of the uterus is so called by

some writers from its resemblance to a tenche's mouth. TINCAL. Crude borax, as it is imported from the

East Indies in yellow greasy crystals. See Boraz.

TINCTO'RIUS. (From tingo, to dye.) An epithet of a species of broom used by dyers. The genista

tinctoria of Linnæus.

TINCTU'RA. (From tingo, to dye.) A t
A solution of any substance in spirit of wine. fied spirit of wine is the direct menstruum of the resins, and essential oils of vegetables, and totally extracts these active principles from sundry vegetable matters, which yield them to water not at all, or only in part. which yield them to water not at all, or only in part. It dissolves likewise the sweet saccharine matter of vegetables, and generally those parts of animal bodies in which their peculiar smell and taste reside.

The virtues of many vegetables are extracted almost equally by water and rectified spirit; but in the watery and spirituous tinctures of them there is this difference.

ence, that the active parts in the watery extractions are blended with a large proportion of inert gummy matter, on which their solubility in this menstruum in a great measure depends, while rectified spirit extracts them almost pure from gum. Hence, when the spirit-uous tinctures are mixed with watery liquors, a part of what the spirit had taken up from the subject generally separates and subsides, on account of its having been freed from that matter, which, being blended with it in the original vegetable, made it soluble in water. This, however, is not universal, for the active parts of some vegetables, when extracted by rectified spirits, are not precipitated by water, being almost soluble in both menstrua.

Rectified spirit may be tinged by vegetables of all clours, except blue. The leaves of plants, in general, colours, except blue. will give out little of their natural colour to watery liquors, but communicate to spirit the whole of their green tincture, which for the most part proves elegant,

though not very durable.

Fixed alkaline salts deepen the colour of spiritnous tinctures; and hence they have been supposed to promote the dissolving power of the menstruum, though this does not appear from experience. In the trials which have been made, no more was found to be taken up in the deep-coloured tinctures than in the paler ones, and often not so much. If the alkali be added after the extraction of the tincture, it will heighten the co-lour as much as when mixed with the ingredients at first. The addition of these salts in making tinctures is not only needless but prejudicial, as they generally injure the flavour of aromatics, and superadd a quality sometimes contrary to the intention of the medicine.

Volatile alkaline salts, in many cases, promote the action of the spirits. Acids generally weaken it; unless when the acid has been previously combined with the vinous spirit into a compound of new qualities,

called dulcified spirit.

TINCTURA ALOES. Tincture of aloes. Take of the extract of spike aloe, powdered, half an ounce; extract of liquorice, an ounce and a half; water, a pint; rectified spirit, four fluid ounces. Macerate in a sandbath until the extracts are dissolved, and then strain. This preparation possesses stomachic and purgative qualities, but should never be given where there is a tendency to hæmorrhoids. In chlorotic cases and strain. amenorrhœa, it is preferred to other purges. The dose spasm

is from half to a whole fluid ounce.

TINCTURA ALOES COMPOSITA. Compound tincture of aloes, formerly called Elixir aloes; Elixir proprietatis. Take of extract of spiked aloe, powdered saffron, of each three ounces; tincture of myrrh, two pints. Macerate for fourteen days, and strain. A more stimulating compound than the former. It is a useful application to deliver the strain of the stra application to old indolent ulcers. The dose is from half a fluid drachm to two.

TINCTURA ALORS VITRIOLATA. With the bitter infusion, a drachm or two of this elegant tincture is extremely serviceable against gouty and rheumatic affec-tions of the stomach and bowels, and also in the weaknesses of those organs which frequently attended

TINCTURA ASSAFŒTIDÆ. Tincture of assafætida, formerly known by the name of tinctura fatida. Take of assafætida, four ounces; rectified spirit, two with water, this is mostly given in all kinds of fits, by the vulgar. It is a useful preparation as an antispas-modic, especially in conjunction with sulphate of zinc. The dose is from half a fluid drachm to two.

TINCTURA AURANTII. Tincture of orange-peel, formerly tinctura corticis aurantii. Take of fresh Take of fresh orange-peel, three ounces; proof spirit, two pints. Macerate for fourteen days, and strain. A mild and

pleasant stomachic bitter.

TINCTURA BENZOINI COMPOSITA. Compound tincture of benzoin, formerly known by the names of tinctura benzoes composita, and balsamum traumati-Take of benzoin, three ounces; thorax balsam, strained, two ounces; balsam of Tolu, an ounce; extract of spiked aloe, half an ounce; rectified spirit, two pints. Macerate for fourteen days, and strain. This tincture is more generally applied externally to ulcers and wounds than given internally, though possessing expectorant, antispasmodic, and stimulating powers. Against coughs, spasmodic affections of the stomach and bowels, and diarrhea, produced by ulcerations of those parts, it is a very excellent medicine. The dose, when given internally, is from half a flaid deacher to two fluid drachm to two.

TINCTURA CALUMBÆ. Tincture of calumba, formerly called tinctura columbæ. Take of calumbaroot, sliced, two ounces and a half; proof spirit, two pints. Macerate for fourteen days, and strain. This tincture contains the active part of the root, and is generally given with the infusion of it, as a stomachic

and adstringent.

TINCTURA CAMPHORÆ COMPOSITA. tineture of campbor, formerly called tinctura opii camphorata, and elixir paregoricum. Take of camphor, two scruples; opium, dried and powdered, benzoic acid, of each a drachm; proof spirit, two pints. Macerate for fourteen days, and strain. The London college has changed the name of this preparation, because it was occasionally the source of mistakes under its old one, and tincture of opium was sometimes substituted for it. It differs also from the former preparation in the omission of the oil of aniseed, which was often complained of as disagreeable to the palate, and to which, as an addition, no increase of power could be affixed. The dose is from half a fluid drachm to half a fluid ounce.

TINCTURA CANTHARIDIS. Tincture of blistering fly.
Formerly called Tinctura lytta; Tinctura cantharidum. Take of blistering flies, bruised, three drachms; proof spirit, two pints. Macerate for fourteen days, and strain. In the last edition of the London Pharmacopæia, the colouring matter of the former preparation is omitted as useless, and the proportion of the fly increased. It is a very acrid, diuretic, and stimulating preparation, which should always be administered with great caution from its known action on the parts of generation. In chronic eruptions on the skin, and dropsical diseases of the aged, it is often very useful when other medicines have been inert. The dose is from half a fluid drachm to two.

TINCTURA CAPSICI. Tincture of capsicum. Take of capsicum-berries, an ounce; proof spirit, two pints.

Macerate for fourteen days, and strain.

TINCTURA CARDAMOMI. Tincture of cardamom. Take of cardamom-seeds, bruised, three ounces; proof spirit, two pints. Macerate for fourteen days, and

strain. A powerful stimulating carminative. In spasm of the stomach, an onnce, with some other diluted stimulant, is given with advantage. The dose may vary according to circumstances, from half a drachm to an ounce and upwards.

TINCTURA CARDAMOMI COMPOSITA. Compound tincture of cardamom, formerly called tinctura stomackica. Take of cardamom-seeds, carraway-seeds, cochineal, of each, powdered, two drachms; cinnamon-bark, bruised, half an ounce; raisins, stoned, four ounces; proof spirit, two pints. Macerate ifor fourteen days, and strain. A useful and elegant carminative and cardial. The descript half a fail describe to half a cordial. The dose from half a fluid drachm to half a fluid ounce and upwards.

TINCTURA CASCARILLE. Tincture of cascarilla. Take of cascarilla-bark, powdered, four ounces; proof spirit, two pints. Macerate for fourteen days, and strain. A stimulating aromatic tonic, that may be exhibited in debility of the bowels and stomach, and in those cases of fever in which the Peruvian bark proves The dose from half a drachm to two

TINCTURA CASTOREL. Tincture of castor. Take of castor, powdered, two ounces; rectified spirit, two pints. Macerate for seven days, and strain. A powerful stimulant and antispasmodic, mostly exhibited in hysterical affections in a dilute form. The dose is

hysterical affections in a successful affections in a successful affection of two.

The carrier of catechu, for the c merly known by the name tinctura japonica. of extract of catechu, three ounces; cinnamon-bark, bruised, two ounces; proof spirit, two pints. Macerate for fourteen days, and strain. An aromatic adstringent, mostly given in protracted diarrhæa. The dose is from half a fluid drachm to two.

TINCTURA CINCHONE. Tincture of cinchona. Formerly known by the name of tinctura corticis peruviani simplex. Take of lance-leaved cinchona-bark, powdered, seven ounces; proof spirit, two pints. Macerate for fourteen days, and strain. The dose is from a fluid drachm to half a fluid ounce. For its virtues, sec Cinchona.

TINCTURA CINCHONÆ AMMONIATA. Ammoniated tincture of cinchona. Volatile tincture of bark. Take of lance-leaved cinchona-bark, powdered, four ounces aromatic spirit of ammonia, two pints; macerate for

ten days, and strain.

Tinctura cinchonæ composita. Compound tincture of cinchona. Take of lance-leaved cinchonabark, powdered, two ounces; orange peel, dried, an ounce and a half; serpentary-root, bruised, three drachms; saffron, a drachin; cochineal, powdered, two scruples; proof spirit, twenty fluid ounces. Macerate for fourteen days, and strain. The dose is from one fluid drachm to half a fluid ounce. For its virtues, see

Cinchona.

Tinctura cinnamoni. Tincture of cinnamon Formerly called aqua cinnamomi fortis. Take of cinnamon-bark, bruised, three ounces; proof spirit, two process. Maccanto for fourteen days, and strain. The dose is from a fluid drachm to three or more.

TINCTURA CINNAMONI COMPOSITA. Compound tincture of cinnamon. Formerly called tinctura aromatica. Take of cinnamon-bark, bruised, six drachms; cardamom-seeds, bruised, three drachms; long pepper, powdered, ginger-root, sliced, of each two drachms; proof spirit, two pints. Macerate for fourteen days, and The dose is from half a fluid drachm to two strain. or more.

TINCTURA DIGITALIS. Tincture of fox-glove. of fox-glove leaves, dried, four ounces; proof spirit, two pints. Macerate for fourteen days, and strain. This tincture is introduced in the London Pharmacopæia as possessing the properties of the plant in a con venient, uniform, and permanent form; it is a saturated tincture, and in the same proportions has been long used in general practice. The dose is from ten to forty minims. For its virtues, see Digitalis.

TINCTURA FERRI ACETATIS. This preparation is

TINCTURA FERRI ACETATIS. This preparation is directed in the Dublin Pharmacopæia, with acetate of potassa, two ounces; sulphate of iron, one ounce; and

rectified spirit, two pints.

TINCTURA FERRI AMMONIATI. Tincture of ammoniated iron, formerly called tinctura ferri ammoniacalis; tinctura florum martialium; tinctura martis myn-sichti. Take of ammoniated iron, four ounces; proof spirit, a pint. Digest and strain. This is a most 351

TIN TIN

excellent chalybeate in all atonic affections, and may be | given with cinchona in the cure of dropsical and other cachectic diseases. The dose is from half a fluid drachm to two.

TINCTURA FERRI MURIATIS. Tincture of muriate of iron Formerly called tinctura martis in spiritu salis; tinctura martis cum spiritu salis; and lately known by the name of tinctura ferri muriati. Take known by the name of tractura ferri muriati. Take of subcarbonate of iron, half a pound; muriatic acid, a pint; rectified spirit, three pints. Pour the acid upon the subcarbonate of iron in a glass vessel, and shake it occasionally for three days. Set it by that the fæces, if there be any, may subside; then pour off the solution, and add the spirit. Cline strongly recommends this in ischuria and many diseases of the kidneys and urinary passages. The dose is from ten to twenty drope. It is passages. The dose is from ten to twenty drops. It is a good chalybeate, and serviceable against most dis-eases of debility without fever.

TINCTURA GENTIANÆ COMPOSITA. Compound tincture of gentian. Formerly called tinctura amara. Take of gentian-root, sliced, two ounces; orange-peel, dried, an ounce; cardamom-seeds, bruised, half an ounce; proof spirit, two pints. Macerate for fourteen

days, with a gentle heat, and strain. The dose is from one fluid drachm to two. For its virtues, see Gentiana.

Tinctura gualact. Tincture of guaiacum. Take of guaiacum resin, powdered, half a pound; rectified spirit, two pints. Macerate for fourteen days, and strain. This tincture, which possesses all the active parts of this peculiar vegetable matter, is now first introduced into the London Pharmacopæia. The dose is from one fluid drachm to two. For its virtues, see is from one fluid drachm to two. For its virtues, see Guaiacum.

TINCTURA GUAIACI AMMONIATA. Ammoniated tincture of guaiacum. Formerly called tinctura guaiacina volatilis. Take of guaiacum resin, powdered, four ounces; aromatic spirit of ammonia, a pint and a half. Macerate for fourteen days, and strain. The dose is from one fluid drachm to two.

TINCTURA HELLEBORI NIGRA. Tincture of black hellebore. Formerly called tinctura melampodii.
"Take of black hellebore-root, sliced, four ounces; proof spirit, two pints. Macerate for fourteen days, and strain." The dose is from half to a whole fluid

and strain." The dose is from half to a whole fluid drachm. For its virtues, consult Helleborus niger.

Tinctura humuli. Tincture of hop. Take of hops, five ounces; proof spirit, two pints. Macerate for fourteen days, and strain. Various modifications of the preparations of this bitter have lately been strongly recommended by Freke (Observations on Human). mulus Lupulus), and employed by many practitioners, who believe that it unites sedative and tonic powers, and thus forms a useful combination. from half to a whole fluid drachm. See Humulus.

TINCTURA HYOSCYAMI. Tincture of henbane. Take of henbane-leaves, dried, four ounces; proof spirit, two pints. Macerate for fourteen days, and strain. That the henbane itself is narcotic is abundantly proved, that the same power is also found in its tincture is also certain, but to produce the same effects requires a much larger dose. In some of the state-ments made to the College of Physicians of London, a different opinion has been given, and twenty-five drops have been considered as equivalent to twenty of tincture of opium: it does not produce costiveness, or the subsequent confusion of head which follows the use of opium, and will therefore be, even if its powers be weaker of considerable use. The dose is from ten weaker, of considerable use. minims to one fluid drachm.

TINCTURA JALAPÆ. Tincture of jalap, formerly called tinctura jalapii. Take of jalap-root, powdered, eight ounces: proof spirit, two pints. Macerate for fourteen days, with a gentle heat, and strain. The dose is from one fluid drachm to half a fluid ounce.

For its virtues, see Convolvaius jalapa.

TINCTURA KINO. Tincture of kino. Take of kino, powdered, three ounces; proof spirit, two pints. Macerate for fourteen days, and strain. All the astringency of kino is included in this preparation. The dose is from half a fluid drachm to two. See Kino.

TINCTURA LYTTE. See Tincture cantharidis.
TINCTURA MYRRHE. Tincture of myrrh. Take of myrrh, bruised, four ounces; rectified spirit, two pints; water, a pint. Macerate for fourteen days, and strain. The dose is from half to a whole fluid drachm. For its virtues, sec Myrrha.

TINCTURA OPH. Tincture of opium: Take of hard

opium, powdered, two ounces and a half; proof spirit, two pints. Macerate for fourteen days and strain. The dose is from ten minims, or twenty drops, to half a fluid drachm. For its virtues, see Opium.

TINCTURA RHEI. Tincture of rhubarb. Formerly known by the names of Tinctura rhabarbari, and

Tinctura rhabarbari spirituosa. Take of rhubarb-root sliced, two ounces; cardamom-seeds, bruised, half an ounce; saffron, two drachms; proof spirit, two pints. Macerate for fourteen days, with a gentle heat, and strain. The dose is from half a flui and a half. For its virtues, see Rheum. The dose is from half a fluid ounce to one

TINCTURA RHEI COMPOSITA. Compound tincture of rhubarb. Formerly called Tinctura rhabarbari com-posita. Take of rhubarb-root, sliced, two ounces; liquorice-root, bruised, half an ounce; ginger-root, sliced, saffron, of each two drachms; proof spirit, a pint; water, twelve fluid ounces. Macerate for four-teen days, with a gentle heat, and strain. This is a mild stomachic aperient. The dose is from half a fluid

ounce to one and a half.

TINCTURA SCILLÆ. Tincture of squill. Take of squill-root, fresh dried, four ounces; proof spirit, two pints. Macerate for fourteen days, and strain. The virtues of this squill (see Scilla) reside in the tincture, which is administered in doses of from twenty drops to a fluid drachm.

TINCTURA SENNÆ. Tincture of senna. Formerly called Elizir salutis. Take of senna-leaves, three ounces; carraway-seeds, bruised, three drachms; car-damom-seeds, bruised, a drachm; raisins, stoned, four ounces; proof spirit, two pints. Macerate for fourteen days, with a gentle heat, and strain. A carminative, aperient, and purgative, in doses from two fluid drachms to a fluid ounce. See Cassia senna.

TINCTURA SERPENTARIA. Tincture of serpentary. Formerly called Tinctura serpentaria virginiana. Take of serpentary-root, three ounces; proof spirit, two

Take of serpentary-root, three ounces; proof spirit, two pints. Macerate for fourteen days, and strain. This tincture possesses, in addition to the virtues of the spirit, those of the serpentaria. The dose is from half a fluid drachm to two. See Aristolochia serpentaria. Tinctura valerianæ. Tinctura valerianæ formerly called Tinctura valerianæ simplex. Take of valerian-root, four ounces; proof spirit, two pints. Macerate for fourteen days, and strain. A useful antispasmodic in conjunction with others. The dose is from half a fluid drachm to two. See Valeriana. is from half a fluid drachm to two. See Valeriana.

TINCTURA VALERIANE AMMONIATA. Ammoniated tincture of valerian. Formerly called *Tinctura valerianæ volatilis*. Take of valerian-root, four ounces; aromatic spirit of ammonia, two pints. Macerate for fourteen days, and strain. A strong antispasmodic and stimulating tincture. The dose is from half a fluid drachm to two.

TINCTURA VERATRI. A very active alterative, re-commended in the cure of epilepsy and cutaneous crup tions. Its administration requires great caution; the

white hellebore being a powerful poison.

Tinctura zingiberis. Tincture of ginger. Take
of ginger-root, sliced, two ounces; proof spirit, two pints. Macerate for fourteen days, and strain. A strmulating carminative. The dose is from a fluid drachm to three.

Tincture. See Tinctura. Tincture of assafatida. See Tinctura assafatida. Tincture of black hellebore. See Tinctura hellebori

Tincture of blistering fly. See Tinctura lyttæ. Tincture of calumba. See Tinctura calumbæ. Tincture of capsicum. See Tinctura capsici. Tincture of cardamom. See Tinctura cardamomi. tianæ composita. Tincture, compound, of rhubarb. See Tinctura rhei

Tineture, composita.

Tinea: (Tinea; from teneo, to bold.) Tinea capitis. The scald head. A genus of diseases in the Class Locales, and Order Dialyses, of Cullen; characterized by small ulcers at the root of the hairs of the head, which produce a friable white crust.

Timelass. See Bismuth.

Tin-glass. See Bismuth.
TINNITUS. (Tinnitus, us, m.; a ringing.) A ringing or tingling noise.

Tinnitus aurium. A noise like ringing or tingling in the ears. A species of paracusis. See Paracusis.

TISSUE. A term introduced by the French anatomists to express the textures which compose the different organs of animals. These have chemical and physical properties which it is important to study on the dead subject and in the living animal. We find in the dead subject and in the living animal. We find in them almost all the physical qualities which are observed in inorganic bodies; different degrees of consistence from extreme hardness to fluidity, elasticity, transparency, refractiveness, &c.; but we are particularly attracted by certain qualities which have been named the properties of tissue. These are the extensibility and contractility of tissue, the contractility of the properties of the contraction. sibility and contractility of tissue; the contractility par racornissement; from crispation. Independently of these physical qualities, the tissues have been studied in respect of their composition, and it has been found that some are principally composed of gelatine, others of albumen, others of phosphate of lime, others of fibrine, and so on. These various textures present the interest of the principal control to the limit of the limit and account of the limit o also, in the living animal, certain phenomena which have not failed to attract the attention of physiologists.

have not failed to attract the attention of physiologists.

TITANITES. A name given to certain ores of titanium which contain that metal in a state of oxide.

TITA'NIUM. This is a lately discovered metal. It was first noticed by Macgregor as existing in the state of an oxide mixed with iron, manganese, and silex, in a grayish-black sand found in the vale of Menachan, in Cornwall, and thence named menachanite, or oxide of titanium, combined with iron. It has since been distitanium, combined with iron. It has since been discovered by Klaproth, in an ore named titanite, or oxide of titanium, combined with lime and silex. is generally met with crystallized in four-sided prisms, is generally met with crystallized in four-sided prisms, not longer than a quarter of an inch. Its colour is a yellowish-red, or blackish-brown; it is opaque, and of an imperfect fustre. It breaks with a foliated, uneven, or conchoidal fracture. It exists also in an ore called red schorl, of Hungary, or red oxide of titanium. This ore, which is found generally crystallized in rectangular prisms is of a brownish red colour, of the specific lar prisms, is of a brownish-red colour, of the specific gravity 4.2, and its texture foliated. In all these ores

gravity 4.2, and its texture foliated. In all these ores titanium exists in the state of an oxide.

Properties of titanium.—Titanium has been only obtained in very small agglutinated grains. It is of a red-yellow and crystalline texture, brittle, and extremely refractory. When broken with a hammer, while yet hot from its recent reduction, it shows a change of colours of purple, violet, and blue. In a very intense heat it is volatilized. Most of the acids have a striking action on this metal: though nitric have a striking action on this metal: though nitric acid has little effect upon it. It is very oxidable by the muriatic acid. It is not attacked by the alkalies. Nitro-murtatic acid converts it into a white powder. Sulphuric acid, when boiled upon it, is partly decom-

It is one of the most infusible metals. It does not combine with sulphur, but it may be united to phosphorus. It does not alloy with copper, lead, or arse-

phorus. It does not alloy with copper, lead, or arsenic, but combines with iron.

Method of obtaining titanium.—It is extremely difficult to reduce the oxide of titanium to the metallic state. However, the experiments of Klaproth, Hecht, and Vauquelin have proved its reducibility. According to the two latter, one part of oxide of tetanium is to be melted with six of potassa; the mass, when cold, is to be dissolved in water. A white precipitate will be formed which is carbonate of titanium. This carbe formed which is carbonate of titanium. This carbonate is then made into a paste with oil, and the mix-ture is put into a crucible filled with charcoal powder and a little alumine. The whole is then exposed for a few hours to the action of a strong heat. The metal-lic titanium will be found in the form of a blackish puffed-up substance, possessing a metallic appear-

[A very curious ore of titanium, one of the newly discovered metals, has been found to exist in New-Jersey. A specimen of considerable size had been presented, several years ago, by Mr. Alber to Dr. Mitchill, as an ore of zinc. But it not appearing to him to be an ore of zinc, and indeed, his mind remaining rather uncertain as to what it truly was, he laid it ing rather uncertain as to what it truly was, he laid it aside in his cabinet, and at length furnished Professor Bruce with a part of it. This able mineralogist has not only made it a subject of experiment himself, but has taken the opinion of some of his chemical correspondents in Europe upon it; and it is their united opinion that it is composed chiefly of the oxide of titanium, combined with the other form of the metal, which, from its having been found in the valley of Menachan, in Cornwall, England, has been called Menachan, in Cornwall, England, has been called Menachanite.

A further account of this remarkable substance is contained in a letter, from Professor Woodhouse to

Senator Mitchill.

"The following experiments were performed upon the mineral found in New-Jersey, which I received from you in the year 1805, which was then supposed, by the person who presented it to you, to be an ore of zinc, and which Count Bournon has declared to be composed of iron and titanium.

"The specific gravity of this mineral is 5.28. viewed, it has the appearance of black spots, the size of duck shot, surrounded by a red substance; and streaks of a white powder, (which is lithormarge,) are dispersed through it. Upon looking through a microscope, a crystal of titanium was seen adhering to it. One hundred grains of it, reduced to an impalpable powder, and exposed one hour to the intense heat of an air furnace, lost fifteen grains in weight, and from a brown was turned to a black colour.

" One hundred grains of it, submitted to heat in the same manner with charcoal, produced a great number of small globules of pure iron. This metal can be separated from the powder by a magnet.

"One hundred grains of it, boiled in aqua regia, was totally soluble in this agent, which proves it contains

"The prussiate of potash, added to this solution, yielded a blue precipitate, which, when dried, weighed three bundred grains. Now, if we divide this sum by six, we shall have the quantity of metallic iron in the hundred grains of the ore, which is fifty.

"A portion of lime was thrown down from a solu-

tion of the mineral in aqua regia, by the oxalate of potash. Carbonate of ammonia, and a solution of potash produced a copious white and gelatinous pre-

cipitate

"One hundred grains of it were mixed with six hundred of potash, and submitted to intense heat one hour, in a blacklead crucible. The part remaining in the crucible was powdered, boiled in water, and filthe crucible was powdered, boiled in water, and fil-tered. Upon adding a small portion of muriatic acid to the water, a white precipitate was thrown down, which was supposed to be the titanium. Upon col-lecting it, and mixing it with a small portion of sper-maceti oil and charcoal, it was exposed to the heat of a blacksmith's forge, when nothing was obtained but a shining, heavy, black substance, of the appearance of

glass. "When the muriatic acid was added in excess to the filtered water obtained, by boiling the residue, which remained in the crucible, in water, no precipi-

TOR TON

to neutralize the acid.

"The solution of the mineral in nitric acid is as-

tringent to the taste.

"The ore appears to be composed of iron, titanium, lime, alumina, and no silictous earth."—Med. Repos.

From the above it appears that the ores of titanium are of very frequent occurrence within the United States. The locality of the specimens described, as far as could be ascertained, tend to confirm the opinion of Werner, as to titanium being one of the oldest of metals. Should this metal bereafter be applied extensively to the arts, it is presumed that the United States will be enabled to furnish any quantity required.—

Min. Jour. A.)

TITHY'MALUS. (From τιθος, a dug, and μαλος, tender: so, called from its smooth leaves and milky juice.) Spurge. Two plants are directed for medicinal purposes by this name. See Euphorbia paralias,

and Esula minor.

TITHYMALUS CYPARISSIUS. See Esula minor.
TITHYMALUS PARALIOS. See Euphorbia paralias.
TITHYMALYS PARALIOS. See Euphorbia paralias.
TITHYMELE'A. See Daphne gnidium.
TITI'LLICUM. (From titillo, to tickle: so called from its being easily tickled,) The arm-pit.
TOAD-FLAX. See Antirrhinum linaria.
TOBACCO. See Nicotiana.

Tobacco, English. See Nicotiana rustica.
Tobacco, Virginian. See Nicotiana.
TOE. Digitus pedis. The toes consist of three distinct bones disposed in rows, called phalanges, or rank of the toes. The great toe has but two phalanges; the others have three ranks of bones, which have nothing particular, only the joints are made round and free, formed by a round head on one bone, and by a

pretty deep hollow for receiving it, in the one above it.

Toffania aqua. (Toffana, or Tophania: the name of an infamous woman, who resided at Palermo, and afterward at Naples, who sold this poison.) See

Aquetta. Tolu balsam.

Tolu balsam. See Toluifera balsamum.
TOLUI'FERA. (So called because it produces the balsam of Peru.) The name of a genus of plants in the Linnman system. Class, Decandria; Order,

Monogynia.

Toluivera balsamum. The systematic name of the tree which affords the Tolu balsam. Balsamum tolutanum. Balsam of Tolu. It grows in South America, in the province of Tolu, behind Carthagena, whence we are supplied with the balsam, which is brought to us in little gourd-shells. The balsam is obtained by making incisions into the bark of the tree, and is collected into spoons, which is made of black wax. from which it is poured into proper vessels. It thickens, and in time becomes concrete: it has a fragrant colour, and a warm, sweetish taste. It disolves entirely in alkohol, and communicates its odour and taste to water, by boiling. It contains acid of benzoin. This is the mildest of all the balsams. It has been used as an expectorant; but its powers are very inconsiderable, and it is at present employed principally on account of its flavour, somewhat resembling that of lemons. It is directed, by the pharmacopæias, in the Syrupus solutanus, Tinctura tolutana, and Syrupus balsamicus.

Syrupus balsamicus.

Tolutanum Balsamum. See Toluifera balsamum.
TOMATUM. Love apple. See Solanum lycoper-

TOMBAC. A white alloy of copper with arsenic. Tomber'um. (From τεμνω, to cut.) An incision-

TOMENTI'TIA. (From tomentum, a flock of wool; so called from its soft coat.) Cotton-weed.

TOMENTOSUS. Downy. Applied to stems, leaves, &c. as the stem of the Geranium rotundifolium.

TOME'NTUM. (Tomentum, i. n.; a flock of wool.)

This term is used in anatomy to the small vessels of the beat made and the present the the brain, which appear like wool.

2. In botany, a species of pubescence, very soft to the touch, of a white, or ferruginous colour, giving the surface a downy appearance, and so thick that they

cannot be seen separately.

Tomentum cerebri. The small vessels that penetrate the cortical substance of the brain from the pia mater, which, when separated from the brain, and adhering to the pia mater, give it a flocky appearance.

TONGUE. Lingua. A soft, fleshy viscus, very

tate was produced, until a solution of potash was added | moveable in every direction, situated inferiorly in this cavity of the mouth, and constituting the organ of taste. It is divided into a base, body, and back, an inferior surface, and two lateral parts. It is composed of muscular fibres, covered by a nervous membrane, on which are a great number of nervous papillae, paron which are a great number of nervous papins, particularly at the apex, and lateral parts, the rete mucosum, and epidermis. The arteries of the tongue are branches of the ramine and labial. The veins empty themselves into the great linguals, which proceed to the external jugular. The nerves come from the eighth, ninth, and fifth pair. The use of this organ is for chewing, swallowing, sucking, and tasting. See also Taste. also Taste.

Tongue-shaped. See Lingulatus.
TONIC. (Tonicus, Torexos; from τεινω, to pull or draw.) 1. A rigid contraction of the muscles, without relaxation, as in trismus, tetanus, &c. See Te-

tanus.

(From τονοω, to strengthen.) Medicines which increase the tone of the muscular fibre, such as vege-

table bitters; also stimulants, adstringents, &c.
TONSIL. (Tonsille, arum, f.) Amygdala; Tola;
Totes; Tolles. An oblong, suboval gland, situated on each side of the fauces, and opening into the cavity of the mouth by twelve or more large excretory ducts.

TOOTH. See Teeth.

TOOTHACHE. See Odontalgia.

Tooth-shaped. See Dentatus.

TOPAZ. According to Jameson this mineral species

contains three subspecies common topaz, schorlite,

and physalite.

and physalite.

Common topaz is of a wine-yellow colour, in granular crystallized concretions, harder than emerald. It comes from the Brazils, Siberia, Asia Minor, and Saxony. It forms an essential constituent of the topaz-rock.

TOPAZOLITE. A variety of precious garnet found at Mussa, in Piedmont.

TO PHUS. (Toph, Hebrew.) A toph. Epiporoma, a soft swelling on a bone.) The concretion on the teeth or in the joints of gouty people. Also gravel.

the teeth or in the joints of gouty people. Also gravel.

TO PICAL. (From roπos, a place.) Medicines applied to a particular place.

Topina'ria. A species of tumour in the skin of the

TO'RCULAR. (From torqueo, to twist.) The tour niquet: a bandage to check hæmorrhages after wounds or amputations.

TORCULAR HEROPHILL Lechenon; Lenos. The press of Herophilus. That place where the four sinuses of the dura mater meet together, first accurately described by Herophilus, the anatomist.

TORDY'LIUM. (Tordylium, ii. n. Quasi tortilium; from torqueo, to twist: so named from its tortuous branches, or from the neat orbicular figure of its seed, which seem as if artificially wrought or turned.) Che name of a genus of plants in the Linnaan system.

Tlass, Pentandria; Order, Digynia
TORDYLIUM OFFICINALE. The systematic name of
the officinale seseli creticum. The seeds are said to be

diuretic.

TORMENTIL. See Tormentilla. TORMENTI'LLA. (From tormentum, pain; because it was supposed to relieve pain in the teeth.)

1. The name of a genus of plants in the Linnæan system. Class, Icosandria; Order, Monogynia.

2. The pharmacopæial name of the upright stepfoil. See Tormentilla crecta.

Tormentilla erecta. The systematic name of the upright stepfoil. Heptaphyllum; Consolida rubra; Tormentilla—caule erectiusculo, foliis sessilibus, of Linnæus. The root is the only part of the plant which is used medicinally; it has a strong styptic taste, but imparts no peculiar sapid flavour: it has been long held in estimation as a powerful adstringent; and, as a proof of its efficacy in this way, it has been substituted for oak bark in the tanning of skins for leather. Tormentil is ordered in the pulvis cretærempositus, of the London Pharmacopcia. TORMENTILLA ERECTA. The systematic name of

leather. Tormentil is ordered in the pulvis cretæ compositus, of the London Pharmacopæia.

TO'RMINA. Severe pains.

TO'RPOR. A numbness, or deficient sensation.

TORTICO'LLIS. (From torqueo, to twist, and collum, the neck.) The wry neck.

TORTULOSUS. A little swelling out. Applied to the knotty pod of the Rhaphanus sativus.

TORTU'RA OSSIS. The locked jaw.

TOTA BORA. See Chenopodium bonus henricus.
TOUCH. Tactus. "By touch we are enabled to know the properties of bodies; and as it is less subject

to deception than the other senses, enabling us in cer-tain cases to clear up errors into which the others have led us, it has been considered the first and the most excellent of all the senses; but several of the advantages which have been attributed to it by physiologists and metaphysicians should be considerably limited.

We ought to distinguish tact from touch. Tact is, with some few exceptions, generally diffused through all our organs, and particularly over the cutaneous and mucous surfaces. It exists in all animals; while touch is exerted evidently only by parts that are intended particularly for this use. It does not exist in all animals, and it is nothing else but tact united to muscular contractions directed by the will.

In the exercise of tact, we may be considered as We ought to distinguish tact from touch.

In the exercise of tact, we may be considered as passive, while we are essentially active in the exercise

of touch.

Physical properties of bodies which employ the action of touch. Almost all the physical properties of bodies are susceptible of acting upon the organs of touch; form, dimensions, different degrees of consistence, weight, temperature, locomotion, vibration, &c. are all so many circumstances that are exactly appreciated by the touch.

The organs destined to touch do not alone exercise this function; so that in this respect the touch differs much from the other senses. As in most cases it is the skin which receives the tactile impressions produced by the bodies which surround us, it is necessary to say

something of its structure.

The skin forms the envelope of the body; it is lost in the mucous membranes at the entrance of all the cavities; but it is improper to say that these membranes are a continuation of it.

The skin is formed principally by the cutis vera, a fibrous layer of various thickness, according to the part which it covers; it adheres by a cellular tissue, more or less firm, at other times by fibrous attach-ments. The cutis is almost always separated from the subjacent parts by a layer of a greater or less thick-ness, which is of use in the exercise of touch.

The external side of the cutis vera is covered by the epidermis, a solid matter secreted by the skin. ought not to consider the epidermis as a membrane; it is a homogeneous layer, adherent by its internal face to the chorion, and full of a great number of holes, of which the one sort are for the passage of the hair, and the other for that of cutaneous perspiration; they serve at the same time for the absorption which takes place by the skin. These last are called the pores of

It is necessary to notice, with regard to the epidermis, that it is void of feeling; that it possesses none of the properties of life; that it is not subject to putrefaction; that it wears and is renewed continually; that its thickness augments or lessens as it may be necessary: it is even said to be proof to the action of the digestive

The connexion of the epidermis to the cutis vera is very close; and yet it cannot be doubted that there is a particular layer between these two parts, in which certain particular phenomenatake place. The organization of this layer is yet little known. Malpighi believed it to be formed of a particular mucus, the existence of which has been long admitted, and which bore the name of the corpus mucosum of Malpighi Ches authors have considered it more justly as a variety. Other authors have considered it, more justly, as a vascular net-work. Gall makes it similar to the gray matter which is seen in many parts of the brain.

Gantier, in examining attentively the external surface of the true skin, has noticed some small reddish projections, disposed in pairs; they are easily perceived when the skin is laid bare by a blister. These little bodies are regularly disposed upon the palm of the hand, and on the sole of the foot. They are sensible, and are reproduced when they have been torn out.

They appear to be essentially vascular. These bodies, without being understood, have been long called the papille of the skin. The epidermis is piecced by little holes, opposite their tops, through which small drops of sweat are seen to issue, when the skin is exposed to an elevated temperature. The skin contains a great number of sebaceous follicles; it receives a great number of vessels and nerves, particularly at the Ggg2

points where the sense of touch is more immediately exercised. The mode in which the nerves are terminated in the skin is totally unknown; all that has been said of the cutaneous nervous papille is entirely hypothetical.

The exercise of tact and of touch is facilitated by the thinness of the cutis vera, by a gentle elevation of temperature, by an abundant cutaneous perspiration, as well as by a certain thickness and flexibility of the epidermis; when the contrary dispositions exist, the tact and the touch are always more or less im-

perfect.

Mechanism of tact .- The mechanism of tact is extremely simple; it is sufficient that bodies be in contact. with the skin to furnish us with data, more or less exact, of their tactile properties. By tact we judge particularly of the temperature. When bodies deprive us of caloric, we call them cold; when they yield it to us, we say they are hot; and according to the quantity of caloric which they give or take, we determine their different degrees of heat or cold. The notions that we have of temperature are, nevertheless, far from being exactly in relation to the quantity of caloric that bodies yield to us, or take from us; we join with it unawares a comparison with the temperature of the atmosphere, in such a manner that a body colder than ours, but hotter than the atmosphere, appears hot, though it really deprive us of caloric when we touch it. On this account, places which have a uniform temperature, such as cellars or wells, appear cold in summer, and hot in winter. The capacity also of bodies for caloric has a great influence upon us with regard to temperature; as an example of this, we have only to notice the great difference of sensation produced by iron and wood, though the temperature of both be the same. A body which is sufficiently hot to cause a chemica.

decomposition of our organs produces the sensation of burning. A body whose temperature is so low as to absorb quickly a great portion of the caloric of any part, produces a sensation of the same sort nearly; this may be proved in touching frozen mercury. The bodies which have a chemical action upon the

epidermis, those that dissolve it, as the caustic alka-lies, and concentrated acids, produce an impression which is easy to be recognised, and by which these

bodies may be known.

Every part of the skin is not endowed with the same sensibility; so that the same body applied to different points of the skin in succession will produce a series of different impressions.

The mucous membranes possess great delicacy of tact. Every one knows the great sensibility of the lips, the tongue, of the conjunctiva, the pituitary membrane, of the mucous membrane, of the trachea, of the urethra, of the vagina, &c. The first contact of bodies, which are not destined naturally to touch these membranes, is painful at first, but this soon wears off.

Mechanism of touch.—In man, the hand is the prin-cipal organ of touch; all the most suitable circumstances are united in it. The epidermis is thin, smooth, flexible; the cutaneous perspiration abundant, as well as the oily secretion. The vascular eminences are more numerous there than any where else. The cutis vera has but little thickness; it receives a great number of vessels and nerves; it adheres to the subja-cent aponeuroses by fibrous adhesions; and it is sustained by a highly elastic cellular tissue. The extremities of the fingers possess all these properties in the highest degree: the motions of the hand are very

numerous, and performed with facility, and it may be applied with ease to any body of whatsoever form.

As long as the hand remains immoveable at the surface of a body, it acts only as an organ of tact. To exercise touch, it must move, either by passing over the surface, to examine form, dimensions, &c., or to press it for the purpose of determining its consistence,

elasticity, &c.

We use the whole hand to touch a body of considerable dimensions; if, on the contrary, a body is very small, we employ only the points of the fingers. This delicacy of touch in the fingers has given man a great advantage over the animals. His touch is so delicate, that it has been considered the source of his intelli-

From the highest antiquity the touch has been considered of more importance than any of the other senses; it has been supposed the cause of human

TOU TRA

reason. This idea has continued to our times; it has dical Faculty at Paris; and was likewise decorated been even remarkably extended in the writings of with the Order of St. Michael. He published about Condillac, of Buffon, and other modern physiologists. Buffon, in particular, gave such an importance to the touch, that he thought one man had little more ability than another, but only in so far as he had been in the habit of making use of his hands. He said it would be well to allow children the free use of their hands from the moment of their birth.

The touch does not really possess any prerogative over the other senses; and if in certain cases it assists the eye or the ear, it receives aid from them in others, and there is no reason to believe that it excites ideas in the brain of a higher order than those which are

produced by the action of the other senses.

Of internal sensations .- All the organs, as well as the skin, possess the faculty of transmitting impressions to the brain, when they are touched by bodies, or when they are compressed, bruised, &c. It may be said, that they generally possess tact. There must be an exception made of the bones, the tendons, the aponeuroses, the ligaments, &c.; which in a healthy state are insensible, and may be cut, burned, torn, without any thing being felt by the brain.

This important fact was not known to the ancients; they considered all the white parts as nervous, and attributed to them all those properties which we now know belong only to the nerves. These useful results, which have had a great influence upon the recent progress of surgery, we owe to Haller and his disciples.

All the organs are capable of transmitting spontaneously a great number of impressions to the brain without the intervention of any external cause. They without the intervention of any external cause. are of three sorts. The first kind take place when it is necessary for the organs to act; they are called wants, instinctive desires. Such are hunger, thirst, the necessity of making water, of respiration, the venereal impulse, &c. The second sort take place venereal impulse, &c. The second sort take place during the action of the organs; they are frequently obscure, sometimes very violent. The impressions which accompany the different excretions, as of the semen, the urine, are of this number.

Such are also the impressions which inform us of our motions, of the periods of digestion :- even thought

seems to belong to this kind of impression.

The third kind of internal sensations are developed when the organs have acted. To this kind belongs the feeling of fatigue, which is variable in the different sorts of functions.

The impressions which are felt in sickness ought to be added to these three sorts: these are much more numerous than the others. The study of them is

absolutely necessary to the physician.

All those sensations which proceed from within, and which have no dependence upon the action of exterior bodies, have been collectively denominated internal sensations, or feelings."—Magendie's Physiology.

TOUCH-ME-NOT. See Noli me tangere.

TOUCHSTONE. Lydian stone. A variety of

TOUCHWOOD. See Agaricus.
TOURMALINE. Rhomboidal tourmaline is divided into two subspecies, schorl and tourmaline. The latter mineral is of a green, brown, and red colour, in pris-

matic concretions, rolled pieces, but generally crystallized. It occurs in gueiss, mica slate, tale slate, &c.

TOURNEFORT, JOSEPH PITTON DE, was born at
Aix, in Provence, in 1656. He was destined for the
church, but a taste for natural knowledge led him, at his father's death, to change for the profession of physic. He therefore qualified himself thoroughly in anatomy, chemistry, and other branches of medical study, and likewise distinguished himself as an elegant writer and lecturer; but he displayed especially an ardent devotion to botany, which ever after made the chief object of his life. His zeal in this pursuit led him to encounter considerable danger in exploring the Alps, Pyrenees, &c. during several seasons, passing the intermediate winters at Montpellier; but he is said to have graduated at Orange. His merits as a botanist, soon became conspicuous at Paris, and the superintendence of the royal garden was resigned to him by Fagon. In this school he soon drew together a crowd of students; but anxious for farther improvements, he travelled into the neighbouring countries, and thus greatly enriched his collections. He was admitted a member of the Academy of Sciences, and of the Me- of very clastic ligamentous fib:es; and are enabled by

the same period several botanical works, of which the In the year 1700, he set out, under royal patronage, on a voyage to the Levant, with the view of investigating the plants of ancient writers, and making new discoveries; and on his return, after two years, he wrote a very interesting and valuable account of the expedition in French, which was not published, however, till after his death. This took place in 1708, in consequence of a hurt in the breast, which he received from a car-riage. He left his collection of plants to the king, who bestowed in return a pension of a thousand livres on his nephew. Besides the botanical works published by him, he is said to have left several others in manu One object, which had occupied much of his attention, was to determine the medical virtues of plants by a chemical analysis; but the loss of these labours is not to be regretted, as those of Geoffroy, on the same plan, turned out to be without any solid advantage. The elegance and facility of Tournefort's botanical method gained him many followers at first; but it has since been superseded by that of Linnæus, which is much more systematic and comprehensive. Still, however, it must be acknowledged, that the generic distinctions established by the former botanist, and most accurately delineated, have been the principal foundation of subsequent improvements.
TOURNIQUET. (French; from town

(French; from tourner, to turn.) An instrument used for stopping the flow of blood into

a limb.

TOXICA'RIA. (Toxicaria, &, f.; from τοξικον, a poison: so called from its poisonous quality.) The name of a plant.

An Indian poison TOXICARIA MACASSARIENSIS. obtained from a tree hitherto undescribed by any medical botanist, known by the name of Boas-upas; a native of Southern Asia. Concerning this plant, various and almost incredible particulars have been related, both in ancient and modern times; some of them true, others probably founded on superstition. Rumphius testifies that he had not met with any other more dreadful product from any vegetable. And he adds, that this poison, of which the Indians boast, was much more terrible to the Dutch than any warlike instrument. He likewise says, it is his opinion, that it is of the same natural order, if not of the same genus,

TOXICODE'NDRUM. (From τοξικον, a poison, and δενδρον, a tree.) The poison-tree, which is so noxious that no insects ever come near it. See Rhus

TOXICOLOGY. (Toxicologia; from τοξον, an arrow or how; because the darts of the ancients were TOXICOLOGY. usually besmeared with some poisonous substance; and loyos, a discourse.) A dissertation on poisons See Poison

TO'XICUM. (From τοξον, an arrow, which was sometimes poisoned.) A deadly poison. See Poison. Τοχιτε'sια. The artemisia or mugwort.

TRABE CULA. (Trabecula, a small beam.) This word is mostly applied by anatomists to the small medullary fibres of the brain, which constitute the com-

TRA'CHEA. (So called from its roughness; from τραχυς, rough.) The windpipe. The trachea is a cartilaginous and membranous canal, through which The windpipe. The trachea is a cartilaginous and membranous canal, through which the air passes into the lungs. Its upper part, which is called the larynx, is composed of five cartilages. The uppermost and smallest of these cartilages is placed over the glottis or mouth of the larynx, and is called epiglottis, as closing the passage to the lungs in the act of swallowing. The sides of the larynx are composed of the two arytenoid cartilages, which are of a very complex figure, not easy to be described of a very complex figure, not easy to be described. The anterior and larger part of the larynx is made up of two cartilages, one of which is called thyroides or scutiformis, from its being shaped like a buckler; and the other cricoides or annularis, from its resembling a ring. Both these cartilages may be felt immediately under the skin, at the forepart of the thorax; and the thyroides, by its convexity, forms an eminence called the pomum adami, which is usually more considerable in the male than in the female subject.

All these cartilages are united to each other by means

the assistance of their several muscles, to dilate or contract the passage of the larynx, and to perform that variety of motion which seems to point out the larynx as the principal organ of the voice; for when the air passes through a wound in the trachea, it produces little or no sound.

These cartilages are moistened by a mucus, which seems to be secreted by minute glands situated near them. The upper part of the trachea, and the cricoid and thyroid cartilages, are in some measure covered anteriorly by a considerable body, which is supposed to be of a glandular structure, and from its situation is called the thyroid gland, though its excretory duct has not yet been discovered, or its real use ascertained. The glottis is entirely covered by a very fine membrane, which is moistened by a constant supply of watery fluid. From the larynx the canal begins to take the name of trachea, or aspera arteria, and ex-tends from thence as far down as the fourth or fifth vertebræ of the back, where it divides into two branches, which are the right and left bronchial tube. Each of these bronchia ramifies through the substance of that lobe of the lungs, to which it is distributed by an infinite number of branches, which are formed of cartilages separated from each other like those of the trachea, by an intervening membranous and ligamentary substance. Each of these cartilages is of an annular figure; and as they become gradually less and less in their diameter, the lower ones are in some measure received into those above them, when the lungs, after being inflated, gradually collapse by the air being pushed out from them in expiration. As the branches of the bronchia become more minute, their cartilages become more and more annular and membranous, till at length they become perfectly membranous, and at last become invisible. The trachea is furnished with fleshy or muscular fibres, some of which pass through its whole extent longitudinally, while the others are carried round it in a circular direction, so that by the contraction or relaxation of these fibres, it is enabled to shorten or lengthen itself, and likewise to dilate or contract the diameter of its passage. The trachea and its branches, in all their ramifications, are furnished with a great number of small glands which are lodged in their cellular substance, and discharge a mucous fluid on the inner surface of these tubes.

The cartilages of the trachea, by keeping it constantly open, afford a free passage to the air which we are obliged to be incessantly respiring; and its membranous part, by being capable of contraction or dilatation, enables us to receive and expel the air in a greater or less quantity, and with more or less velocity, as may be required in singing and declamation. This membranous structure of the trachea posteriorly, seems likewise to assist in the descent of the food, by preventing that impediment to its passage down the eso-phagus, which might be expected, if the cartilages were complete rings. The trachea receives its arteries from complete rings. The trachea receives its arteries from the carotid and subclavian arteries, and its veins pass into the jugulars. Its nerves arise from the recurrent branch of the eighth pair, and from the cervical plexus.

TRACHELA'GRA. (Trachelagra, æ, f.; from τραχηλος, the throat, and αγρα, a seizure.) The gout

TRACHE'LIUM. (Trackelium, ii, n.; from τρα-χηλος, the throat: so called from its efficacy in diseases of the throat.) The Campanula trackelium, of Lin-næus, or herb throat-wort. TRACHELO. (From τραχηλος, the neck.) Names compounded of this word belong to muscles, &c. which

are a tached to the neck; as Trackelo-mastoideus.

TRACHELOCE'LE. (From τραχεια, the wind-

pipe, and κηλη, a tumour). A tumour upon the trachea. A bronchocele.

TRACHELO-MASTOIDEUS. A muscle situated on the neck, which assists the complexus, but pulls the head more to one side. It is the complexus minor seu mastoideus lateralis, of Winslow. Trachelo-mastoidien, of Dumas. It arises from the transverse processes of the five inferior cervical vertebra, where it is connected with the transversalis cervicis, and of the three superior dorsal, and it is inserted into the middle of the posterior part of the mastoid proces

TRACHELO'PHYMA. (From τραχηλος, the throat, and φυμα, a tumour.) A swelling of the bronchial gland.
TRACHE'LOS. (From τραχυς, rough; because of the rough cartilages.) The wind-pipe. See Trachea.

TRACHEOTOMY. TRACHEOTOMY. (Tracheotomia, &, f.; from τραχεια, the trachea, and τεμνω, to cut.) See Bron-

TRACHO'MA. (Trachoma, atis, n.; from reaxes, rough.) An asperity in the internal superficies of the eyelid. The effects are a violent ophthalmia, and a severe pain, as often as the eyelid moves. The species

1. Trackoma sabulosum, from sand falling between the eye and the eyelid of persons travelling, blown by a high wind; this happens chiefly in sabulous situations, and may be provented by spectacles for the pur-pose, or by guarding against the flights of sand by covering the eyes.

2. Trachoma carunculosum, which arises from caruncles, or fleshy verrucæ, growing in the internal superficies of the eyelid. This species of the trachoma is called morum palpebræ internæ, because the tubercu-

lous internal superficies appears of a livid red like a mulberry. Others call these carunculæ pladorotes.

3. Trachoma herpeticum, which are hard pustules in the internal superficies of the eyelids. This is also called ficosis, and palpebra ficosa, from its resemblance to the granulated substances in a cut fig. With the Greeks, it is denominated atomablepharon, or prop-

TRACHYTE. A rock of igneous origin, principally composed of felspar. It has generally a porphyritic structure.

TRAGACANTH. See Astragalus.
TRAGACA'NTHA. (Tragacantha, æ, f.; from τραγος, a goat, and ακανθα, a thorn: so called from its pods resembling a goat's beard.) See Astragalus tragacantha

gacantha.

TRA'GICUS. A proper muscle of the ear, which pulls the point of the tragus a little forward.

TRA'GIUM. (From τραγος, a goat: so named from its filthy smell.) 1. The name of a genus of plants. Class, Pentandria; Order, Digynia.

2. The bastard dittany, or Dictamnus albus.

TRAGO'CERUS. (From τραγος, a goat, and κερας, a horn: so named from the supposed resemblance of its leaves to the horn of a goat.) The aloe.

TRAGOPO'GON. (Tragopogon, onis, m.; from τραγος, a goat, and πωγων, a beard: so called because its downy seed, while enclosed in the calyx, resembles a goat's beard.) 1. The name of a genus of plants in the Linnæan system. Class, Syngenesia; Order, Pothe Linnaan system. Class, Syngenesia; Order, Po-

lygamia.

2. The pharmacopæial name of the common goat's

TRAGOPOGON PRATENSE. The systematic name of the common goat's beard. The young stems of this plant are eaten like asparagus, and are a pleasant and wholesome food. The root is also excellent, and was formerly used medicinally as a diuretic.

TRAGOPY RUM. (Tragopyrum, i, n.; from τραγος, a goat, and πυρον, wheat: so named from its beard.)

Buck-wheat.

TRAGO'RCHIS. (Tragorchis, is, m.; from τραγος, a goat, and ορχις, a testicle: so named from the supposed resemblance of its roots to the testicles of a goat.)

A species of orchis.

TRAGORI'GANUM. (Tragoriganum, i, n.; from τραγος, a goat, and οριγανον, marjoram: so called be-cause goats are fond of it.) A species of wild mar-

TRAGOSELI'NUM. (Tragosclinum, i, n.; from τραγος, a goat, and σελινον, parsley: named from its hairy coat like the beard of a goat.) The burnet saxi-

TRA'GUS. (Teayor. Tragus, i, m.; a goat: so called from its having numerous little hairs, or from its being hairy like the goat.) 1. In anatomy. A small cartilaginous eminence of the auricular or external ear, placed anteriorly, and connected to the anterior extre-mity of the helix. It is beset with numerous little hairs, defending, in some measure, the entrance of the external auditory passage.

2. In botany. This name has been variously ap-

plied, by Dioscorides, to meal or flour, and to a mari-

time shrub.

TRALLIAN. ALEXANDER, a learned and ingenious physician, who was born at Tralles, in Lydia, and flourished at Rome under the emperor Justinian, about the middle of the sixth century. Like Hippo crates, he travelled over various countries to improve

his knowledge. Besides improving upon many of the compositions then employed, he invented several others; and particularly introduced the liberal use of the preparations of iron. He principally followed the practice of Hippocrates and Galen, but not indiscriminately. He appears, however, to have had too great faith in charms and anulets, which was the common error of the

age in which he lived.

TRA'MIS. Tpauts. The line which divides the scrotum, and runs on to the anus. See Raphe.

TRANSFUSION. (Transfusio; from transfundo, to pour from one vessel into another.) The transmission of blood from one living animal to another by means of a canula. "Harvey was thirty years before the could get his discovery admitted though the most he could get his discovery admitted, though the most evident proofs of it were every where perceptible; but as soon as the circulation was acknowledged, people's minds were seized with a sort of delirium: it was thought that the means of curing all diseases was found, and even of rendering man immortal. The cause of all cur evils was attributed to the blood; in order to cure them, nothing more was necessary but to remove the bad blood, and to replace it by pure blood, drawn from a round animal from a sound animal.

The first attempts were made upon animals, and they had complete success. A dog having lost a great part of its blood, received, by transfusion, that of a sheep, and it became well. Another dog, old and deaf, regained, by this means, the use of hearing, and seemed to recover its youth. A horse of twenty-six years having received in his veins the blood of four lambs, he

recovered his strength.

Transfusion was soon attempted upon man. Denys and Emerez, the one a physician, the other a suggeon of Paris, were the first who ventured to try it. They introduced into the veins of a young man, an idiot, the blood of a calf, in greater quantity than that which had been drawn from them, and he appeared to recover his reason. A leprous person, and a quartan ague, were also cured by this means; and several other transfusions were made upon healthy persons without any disagreeable result.

However, some sad events happened, to calm the general enthusiasm caused by these repeated successes. The young idiot we mentioned fell into a state of madness a short time after the experiment. He was submitted a second time to the transfusion, and he was immediately seized with a hamaturia, and died in a state of sleepiness and torpor. A young prince of the blood royal was also the victim of it. The parliament of Paris prohibited transfusion. A short time after, G. Riva, having, in Italy, performed the transfusion upon two individuals, who died of it, the pope prohibited it also.

From this period, transfusion has been regarded as

From this period, transfusion has been regarded as useless, and even dangerous."

TRANSPARENCY. Diaphaneity. A quality in certain bodies, by which they give passage to the rays of light. It is opposed to opacity; hence Cornea transparens, and Cornea opace.

TRANSPIRATION. (Transpiratio; from trans, through, and spiro, to breathe.) See Perspiration.

TRANSUDATION. Transudatio. The passing through the cells or pores of any thing. The term should be distinguished from perspiration, which implies a function, by which the perspired fluid is secreted from the blood, whereas, by transudation, the blood or other fluid merely passes or oozes through unaltered.

TRANSVERSA'LIS. Transverse.

TRANSVERSA'LIS. Transverse.

Transversalis abdominis. A muscle situated on the anterior part of the abdomen: so named from its direction. It arises internally or posteriorly from the cartilages of the seven lower ribs, being there connected with the intercostals and diaphragm, also from the transverse process of the last vertebra of the back, from those of the four upper vertebræ of the loins, from the inner edge of the crista ilii, and from part of Poupart's ligament, and it is inserted into the inferior bone of the sternum, and almost all the length of the linea alba. Its use is to support and compress the abdominal

TRANSVERSALIS ANTICUS PRIMUS. See Rectus capi-

tis lateralis.

Transversalis cervicis. See Longissimus dorsi.
Transversalis colli. A muscle, situated on the posterior part of the neck, which turns the neck obliquely backwards, and a little to one side.

358

TRANSVERSALIS DORSI. See Multifidus spina. TRANSVERSALIS MAJOR COLLI. See Longissimus

TRANSVERSALIS PEDIS. A muscle of the foot, which it contracts, by bringing the great toe and the two outer-

Transverse suture. Sutura transversalis. This suture runs across the face, and sinks down into the orbits, joining the bones of the skull to the bones of the face; but with so many irregularities and interruptions, that it can scarcely be recognised as a suture.

TRANSVERSO-SPINALES. See Multifidus spinæ.
TRANSVERSUS AURIS. A muscle of the external ear,
which draws the upper part of the concha towards the

TRANSVERSUS PERINAL. (Musculus transversus which sustains and keeps the perinæum in its proper

TRANSVERSUS PERINEI ALTER. Prostaticus infe-rior, of Winslow. A small muscle occasionally found

accompanying the former.

TRAP. This term is derived from the Swedish word trappa, a stair. It is applied in geology to rocks principally characterized by the presence of hornblende and black iron clay.

TRAPA (A term given by Linnaus where identically)

TRAPA. (A term given by Linnæus, whose idea is certainly taken from the warlike instrument called caltrop, the tribulus of the ancients, which consisted of four iron radiated spikes, so placed, that one of them must always stand upwards, in order to wound the feet of the passengers. Such is the figure of the singular fruit of this genus; hence named by Tournefort, tribuloides. Calcitrapa, an old botanical term of similar meaning to tribulus, is compounded, perhaps, of calco, to tread or kick, and $\tau \rho \varepsilon \pi \omega$, to turn, because the caltrops are continually kicked over if they fail of their intended mischief: here we have the immediate origin of trapa.) The name of a genus of plants, Class, Tetrandria; Order, Monogynia.
TRAPA NATANS. The systematic name of the plant

which affords the nux aquatica. Tribulus aquaticus. Caltrops. The fruit is of a quadrangular and somewhat oval shape, including a nut of a sweet farina-ceous flavour, somewhat like that of the chesnut, which is apt to constipate the bowels, and produce disease; however, it is said to be nutritious and demulcent, and to be useful in diarrhoas from abraded bowels, and against calculus. Likewise a poultice of these nuts is said to be efficacious in resolving hard and

TRAPE ZIUM. (A four-sided figure: so called from its shape.) The first bone of the second row of

TRAPE ZIUS. (From τραπεζιος, four-square: so named from its shape.) Cucultaris. A muscle situated immediately under the integuments of the posterior part of the neck and back. It arises by a thick, round, and short tendon, from the lower part of a protuberance in the middle of the occipital bone backwards, and from the rough line that is extended from thence towards the mastoid process of the os temporis, and by a thin membranous tendon, which covers part of the complexus and splenius. It then runs down-wards along the nape of the neck, and rises tendinous wards along the nape of the neck, and rises tendinous from the spinous processes of the two lowermost vertebræ of the neck, and from the spinous processes of all the vertebræ of the back, being inseparably united to its fellow, the whole length of its origin, by tendinous fibres, which, in the nape of the neck, form what is called ligamentum colli, or the cervical ligament. It is inserted fleshy into the broad and posterior half of the clavicle, tendinous and fleshy into one-half of the acromion, and into almost all the spine of the scapula.

This muscle serves to move the scapula in different directions. Its upper descending fibres pull it obliquely upwards; its middle transverse ones pull it directly backwards; its inferior fibres, which ascend obliquely upwards, draw it obliquely downwards and backwards.

The upper part of the muscle acts upon the neck and head, the latter of which it draws backwards, and turns upon its axis. It likewise concurs with other muscles in counteracting the flexion of the head for-

TRAPEZOIDES OS. The second bone of the

second row of the carpus: so called from its resemblance to the trapezium, or quadrilateral geometrical figure.
TRAUMATIC. (From τραυμα, a wound.)

thing relating to a wound.

TRAVELLER'S JOY. See Clematis vitalba.

TREACLE. See Theriaca.

Treacle, mustard. See Theriaca.
Treacle, mustard. See Thlaspi.
TREFOIL. (So called because the leaf is formed of three leaflets.) See Trifolium.
Trefoil marsh. See Menyanthes trifoliata.
TREMOLITE. A subspecies of straight edged augite. There are three kinds, the asbestous, common, and starse.

and glassy.

TRE MOR. An involuntary trembling.

TREPAN. Trephine. An instrument used by surgeons to remove a portion of bone from the skull.

TREPHINE. See Trepan.
TREW, Christopher James, was born at Lauffen, in Franconia, in 1695; and settled as a physician at Nuremburg, where he gained so much reputation, as to be made director of the academy "Naturae Curioso-rum." He also contributed much towards establishing a society under the title of "Commercium Literarium Noricum," for the advancement of medical and natural knowledge, which published some valuable memoirs. To these societies he communicated several papers, and he also published some splendid works in anatomy and botany. He died in 1769. TRIANGULA'RIS.

TRIANGULA'RIS. Trigonus. Triangular: a term very generally used in the different departments

of science, to parts of animals, vegetables, minerals, &c., from their form. See Caulis, Folium, &c.

TRI BULUS. (Τριβολος; from τριδω, to tear or injure: an instrument of war to be thrown in the way to annoy the enemy's horse: hence the name of an herb from its resemblance to this instrument.)

1. The name of a genus of plants. Class, Decan-

dria; Order, Monogynia.
2. See Trapa natans.

TRIBULUS AQUATICUS. See Trapa natans.
TRICA. (Trica, ω, f.; from θριξ, τριχος, a hair: because they seem composed of a horse hair rolled, or partly folded, into a little, round, black head.) A term applied by Dr. Acharius to the black filaments, resembling a curled horse hair, in the Gyrophora and Umbilicaria of Hoffman.

TRICAUDA'LIS. (From tres, three, and cauda, a

tail.) A muscle with three tails.
TRICEPS. (From tres, three

(From tres, three, and caput, a head.)

Three-headed.

TRICEPS ADDUCTOR FEMORIS. Under this apption are comprehended three distinct muscles. Under this appella-Adductor brevis, longus, and magnus femoris.
TRICEPS AURIS. See Retrahentes auris.

TRICEPS AURIS. See Retrakentes auris.

TRICEPS EXTENSOR CUBITI. This muscle, which occupies all the posterior part of the os humeri, is described as two distinct muscles by Douglas, and as three by Winslow. The upper part of its long head is covered by the deltoides: the rest of the muscle is situated immediately under the integuments.

It arises, as its name indicates, by three heads. The first, or long head, (the long head of the biceps externus, of Douglas; anconcus major, of Winslow, as it is called,) springs, by a flat tendon of an inch in breadth, from the anterior extremity of the inferior costa of the scapula, near its neck, and below the origin of the teres minor. The second head, (the short head of the biceps externus, of Douglas; anconeus externus, of Winslow), arises by an acute, tendinous, and fleshy beginning, from the upper and outer part of the os humeri, at the bottom of its great tuberosity. The third head, (brachialis externus of Douglas; anconeus in-ternus, of Winslow,) which is the shortest of the three, originates by an acute fleshy beginning, from the back part of the os humeri, behind the flat tendon of back part of the os humeri, behind the flat tendon of the latissimus dorsi. These three portions unite about the mlddle of the arm, so as to form one thick and powerful muscle, which adheres to the os humeri to within an inch of the elbow, where it begins to form a broad tendon, which, after adhering to the capsular ligament of the elbow, is inserted into the upper and outer part of the olecranon, and sends off a great number of fibres, which help to form the fascia on the outer part of the forcarm. The use of this muscle is to extend the forearm. to extend the forearm.

TRICHIA. (From θριξ, a hair.) A disease of the

hair. See Trichoma.

TRICHI'ASIS. (From $\theta_{\rho i}\xi$, a hair.) Trichosis.

1. A disease of the eye-lashes, in which they are turned in towards the bulb of the eye.

2. A disease of the hair. See Trichoma. TRICHI'SMUS. (From $\theta p \epsilon \xi$, a hair.) A species of fracture which appears like a hair, and is almost imperceptible. TRICHO'MA. (From τριχες, the hair.) The plaited

hair. See Plica.
TRICHOMANES. (From τριχες, hair, and μανοςι thin, lax: so called because it resembles fine hair.) See

thin, lax: so called because it rescribes and asplenium trichomanes.

Asplenium trichomanes.

TRICHOSIS. (Τριχωσις, pilare malum; from θρίξ, a hair.) Under this name Good makes a genus of disease in the Class Eccritica, Order Acrotica, of his Nosology. Morbid hair. It has eight species, viz.

Trichosis setosa, plica, hirsutus, distriz. See Plica.

TRICHU'RIS. (From θρίξ, a hair.) The long hair-

orm. See Worms.
TRICOCCUS. (From τρεις, three, and κοκκος, a

grain.) Three-seeded.
Tracoccæ. The name of an order in Linnæus's Fragments of a Natural Method, consisting of those

which have a triangular capsule with three seeds.

TRICUSPID. (Tricuspis; from tres, three, and cuspis, a point: so called from their being three-point ed.) Three-pointed.

TRICUSPID VALVE. The name of the valve in the right ventricle.

Trifoil, water. See Menyanthes trifoliata.
TRIFO'LIUM. (From tres, three, and folium, a leaf: so called because it has three leaves on each stalk.) The name of a genus of plants in the Linnaran system. Class, Pentandria; Order, Monogynia.

TRIFOLIUM ACETOSUM. The wood-sorrel was so

called

illed See Oxalis acetosella.
Tripolium aquaticum. See Menyanthes trifo-

TRIFOLIUM ARVENSE. Hare's foot trefoil.
TRIFOLIUM AUREUM. Herb trinity; noble liver-

TRIFOLIUM CABALLINUM. Melilotus.
TRIFOLIUM CARULEUM. Sweet trefoil.
TRIFOLIUM FALCATUM. The Auricula muris. See

Hieracium pilosella.

Hieracium pilosella.

TRIFOLIUM FIBRINUM. See Menyanthes trifoliata.
TRIFOLIUM HEFATICUM. See Anemone hepatica.
TRIFOLIUM MELLLOTUS OFFICINALIS. The systematic name of the officinal melilot; Melilotus; Lotus sylvestris; Seratula campana; Trifolium caballinum; Coroda regia; Trifolium odoratum. This plant has been said to be resolvent, emollient, anodyne, and to participate of the virtues of chamomile. Its taste is unpleasant, subacrid, subsaline, but not bitter; when fresh it bus scarcely any smell; in drying, it acquires a pretty strong one of the aromatic kind, but not agree. pretty strong one of the aromatic kind, but not agree-able. The principal use of melilot has been in clys-

ters, fomentations, and other external applications.

Trifolium odoratum. See Trifolium melilotus

officinalis.

TRIFOLIUM PALUDOSUM. See Menyonthes trifoliata. TRIGE MINI. (Trigeminus, from tres, three, and geminus, double; three fold.) Nervi innominati. The fifth pair of nerves, which arise from the crura of the cerebellum, and are divided within the cavity of the cranium into three branches, viz. the orbital, superior, and inferior mazillary. The orbital branch is divided into the frontal, lachrymal, and masal nerves; the superior maxillary into the spheno-palatine, poste-rior alveolar, and infra-orbital nerves; and the inferior

maxillary into two branches, the internal lingual, and one more properly called the inferior maxillary.

TRIGONE'LLA. (A diminutive of trigona, three-sided, alluding to its little triangular flower.) The name of a genus of plants. Class, Diadetphia; Order,

Decandria.

TRIGORELLA FENUM GRÆCUM. The systematic name of the fænugreek. Fænum græcum; Buceras; Ægoceras. Trigonella—leguminibus sessilibus strictis erectiusculis subfalcatis acuminatis, caule erecto, of Linnæus. A native of Montpellier. The seeds are brought to us from the southern parts of France and Germany: thus have a strong disagreeable small. Germany; they have a strong disagreeable smell, and an unctuous farinaceous taste, accompanied with a a slight bitterness. They are esteemed as assisting the formation of pus, in inflammatory tumours; and the

TRO TRO

TRIGONUS. See Triangularis.
TRIHILATÆ. (From tres, three, and hilum, the scar or external mark on the seed.) The name of a class of plants in Linnaus's Fragments of a Natural Method, consisting of plants, the seeds of which have the scar well marked; the style has three stigmas. TRILOBUS. Three-lobed. Applied to parts of

animals and plants which are so shaped.

TRINERVIS. Three-nerved. In botany, threeribbed; as applied to leaves, &c.

TRINITA'TIS HERBA. See Anemone hepatica.
TRINITY-HERB. See Anemone hepatica.
["TRIOSTEUM. The triosteum perfoliatum is a

native plant, the root of which is cathartic in the dose of thirty or thirty-five grains. It sometimes operates as an emetic in the same doses. The strength is some-

what impaired by keeping, so that the stock should be renewed every year."—Big. Mat. Med. A.]

TRIPARTITUS. Tripartite: divided into three.

TRIPA'STRUM APELLIDIS. 'Tripastrum archimedis.

A surgical instrument for extending fractured limbs; so named because it resembled a machine invented by Apellides or Archimedes, for the launching of ships, and because it was worked with three cords.

and because it was worked with three cords.

TRIPHANE. See Spodumene.

TRIPHYLLUS. (From τρεις, three, and φυλλον, a leaf.) Three-leaved.

TRIPLINERVIS. Triply-ribbed: applied to a leaf, which has a pair of large ribs branching off from a main one above the base, which is the case in every species of sunflower, and the Blakea triplinervis.

TRIPOLI. Rottenstone. A grayish yellow-coloured mineral used for polishing.

TRIQUETRA. (Triguetrus; from tres, three.)

TRIQUETRA. (Triquetrus; from tres, three.)
Ossicula xormiana. The triangular-shaped bones, which are found mostly in the course of the lambdoidal suture of the skull.

TRIQUETRUS. Three-sided. Applied to some parts of plants; as the stems, flowerstalk, leaves,

Spastic rigidity of the under jaw. Capistrum, of Vogel. Dr. Cullen makes two species. 1. Trismus vogel. Dr. Cullen makes two species. 1. Trismus nascentium, attacking infants during the first two weeks from their birth. 2. Trismus traumaticus, attacking persons of all ages, and arising from cold or a wound. See Tetanus.

TRISSA'GO. (Quasi tristago; from tristis, sad: because it dispels sadness.) The common germander is sometimes so called. See Teucrium chamadrys.

TRISSAGO PALLUSTRIS. The water-germander was so called. See Teucrium scordium.

so called. See Tencrium scordium.

TRITÆO'PHYA. (From τισ]αιος, tertian, and φνω, importing a like nature or original.) Tritæus. A fever much of a nature with a tertian, and taking its rise from it. Some call it a continued tertian. It is remittent or intermittent.

TRITEOPHYA CAUSUS. The fever called causus by

TRITE'US. See Tritaophya.
TRITE'US. See Tritaophya.
TRITICUM. (From tero, to thresh from the husk.)
The name of a genus of plants. Class, Triandria;
Order, Digynia. See Wheat.

Order, Digyma. See Wheat.

TRITICUM REPENS. Gramen caninum; Gramen Dioscoridis; Gramen repens; Loliaceum radice revente. Dog's grass; Couch grass. A very common grass, the roots of which are agreeably sweet, and possess aperient properties. The expressed juice is recommended to be given largely.

TRITO'RIUM. (From tritus, beat small.) 1. A

mortar.

2. A glass for separating the oil from the water in distilling.

TRITURATION. (Trituratio; from tero, to rub or grind.) Tritura; Tritus. The act of reducing a or grind.) Tritura; Tritus. The act of reducing a solid body into a subtile powder; as woods, barks, &c. It is performed mostly by the rotary motion of a pestle in metallic, glass, or Wedgewood mortars.

TROCAR. (Corrupted from un trois quart, French, a three-quarters; from the three sides with which the point is made.) The name of an instrument used in tapping for the dropsy.

TROCHA'NTER. (From τρεχω, to run: because the muscles inserted into them perform the office of

the muscles inserted into them perform the office of The name of two processes of the thigh-

meal, with that intention, is made into a poultice with | bone, which are distinguished into the greater and

ss. See Femur. TROCHI'SCUS. TROCHI'SCUS. (Diminutive of τροχος, a wheel.) A troch or round tablet: Troches and lozenges are composed of powders made up with glutinous substances into little cakes, and afterward dried. This form is principally used for the more commodious exhibition of certain medicines, by fitting them to dissolve slowly in the mouth, so as to pass by degrees into the stomach; and hence these preparations have generally a considerable portion of sugar or other materials grateful to the palate. Some powders have likewise been reduced into troches, with a view to their preparation, though possibly for no very good reasons: for the moistening them, and afterward drying them in the air, must on this account be of greater injury, than any advantage accruing from this form can counterbalance. General rules for making troches:

1. If the mass proves so glutinous as to stick to the fingers in making up, the hands may be anointed with any sweet or aromatic oil; or else sprinkled with

starch, or liquorice powder, or with flour.

2. In order to thoroughly dry the troches, put them on an inverted sieve, in a shady, airy place, and fre-

quently turn them.

3. Troches are to be kept in glass vessels, or in

carthen ones well glazed.

TRO CHLEA. (Τροχλεα, a pulley; from τρεχω, to run.) A kind of cartilaginous pulley, through which the tendon of one of the muscles of the eye passes.

TROCHLEA'RIS. See Obliques superior oculi. TROCHLEATO'RES. The fourth pair of nerves are so called, because they are inserted into the mus-

culus troclearis of the eye. See Pathetici.
TROCHOI'DES. (From τροχος, a wheel, and ειδος, resemblnace.) Axea commissura. A species of diarthrosis, or moveable connexion of bones, in which one bone rotates upon another; as the first cervical vertebra upon the odontoid process of the second.

TRONA. The African name for the native car-

bonate of soda found near Fezzan.

["The carbonate of soda, strictly so called, is found in the province of Sukena, two days' journey from Fezzan, in Africa. It appears in crusts, composed of minute crystals, at the foot of a mountain. It is there called Trona, and transported to Egypt, Tripoli, &c. This variety is also found near Buenos Ayres in considerable quantities, whence it has been transported to England. It there exists in stratified masses from two to six inches thick, resting on clay, which is strongly impregnated with common salt. It has a light yellowish-gray colour, a granular texture, is easily broken, and does not effloresce in the air."—Cleav. Min. A.]

TRONCHIN, THEODORE, was born at Geneva, in 1709, and went to study under Boerhaave, at Leyden, where he graduated in 1730. He then settled at Amsterdam, became a member of the College of Physicians, and an inspector of hospitals; and distinguished himself as a zealous promoter of inoculation. In 1754, he returned to Geneva, and ranked among the most eminent practitioners in Europe; a chair of medicine was instituted in his favour, and the Society of Pastors admitted him into their body. He was employed by the Duke of Orleans, and other persons of rank at Paris, to inoculate their children; and performed the same office for the Duke of Parma. In rank at Paris, to inoculate their children; and performed the same office for the Duke of Parma. In 1766, he accepted the appointment of principal physician to the Duke of Orleans; though he had previously declined an invitation from the Empress of Russia. His practice appears to have been simple and judicious, and his conduct marked by humanity and charity. He had little time for writing; but besides his inaugural dissertation, he published a treatise on the Colica Pictonum, in 1757, and contributed several articles to the Encyclopedia, and to the Memoirs of the Academy of Surgery: and to an edition of the works of Baillou he gave a Preface on the State of Medicine. He had the honour of being a member of the chief medical and scientific societies in Europe. His death happened in 1781.

TROPÆOLUM. (A diminutive of tropæum, or τρωπαιον, a warlike trophy. This fanciful but elegant name was chosen by Linnæus for this singular and striking genus, because he conceived the shield-like leaves and the brilliant flowers, shaped like golden helmets, pierced through and through, and stained with blood, might well justify such an allusion.) The name

TROPEOLUM MAJUS. The systematic name of the Indian cress. Nasturtium indicum; Acriviola; Flos sanguincus monardi; Nasturtium peruvianum; Car-damindum minus. Greater Indian cress, or Nastur-tium. This plant is a native of Peru; it was first tium. This plant is a native of Peru; it was first brought to France in 1684, and there called La grande capucine. In its recent state this plant, and more especially its flowers, have a smell and taste resembling those of water-cress; and the leaves, on being bruised in a mortar, emit a pungent odour, somewhat like that of horse-radish. By distillation with water, they impregnate the fluid in a considerable degree with the smell and flavour of the plant. Hence the antiscorbutic character of the nasturtium seems to be well founded, at least as far as we are able to judge from its sensible qualities: therefore, in all those cases where the warm and antiscorbutic vegetables are recom-mended, this plant may be occasionally adopted as a pleasant and effectual variety. Patients to whom the nauseous taste of scurvy-grass is intolerable, may find a grateful substitute in the nasturium. The flowers are frequently used in salads, and the capsules are by many highly esteemed as a pickle. The flowers, in the warm summer months, about the time of sunset, have been observed to emit sparks like those of the electrical kind.

TROPHIS AMERICANA. Red fruited bucephalon. The fruit of the plant is a rough red berry, which is eaten in Jamaica, though not very pleasant.

TRUFFLE. See Lycoperdon tuber.
TRUNCATUS. Truncate. Used in botany. truncate leaf is an abrupt one, which has the extremity cut off, as it were, by a transverse line; as in Lirio

dendrum tulipifera, and the petals of Hura crepitans.
TRUNCUS. (Truncus, i, m.) The trunk.

1. In anatomy, applied to the body strictly so called.
It is divided into the thorax or chest, the abdomen or

belly, and the *pelvis*.

II. In *botany*, that part of a plant which emerges from the root, and sustains all other parts. The genera of trunks are,

1. Truncus: applied to trees and shrubs, which are thick and woody

2. Caulis: the stem of heros. Calmus: the stem of grasses.

Stipes: the trunk of funguses, ferns, and palms.
 Scapus: which is not a trunk, but a flower-stalk,

emerging from the root.

[TRUSS. This is an instrument employed by surgeons to retain the intestines in their proper place, when they have been forced out of their natural position, forming the disease which is called a rupture or hernia. A hernia is reducible or not. When not re-ducible, it becomes a strangulated hernia, requiring a surgical operation, before the intestines can be restored to their proper position. When not strangulated, ruptures are liable to become so by accident, and hence trusses were invented to keep the intestines in their place, and if possible to cure the disease, by closing the opening through which the bowels protruded. Trusses have heretofore been considered as a palliative remedy, rather than the means of effecting a radical cure. This has arisen from the manner of constructing them; and although they sometimes effected the desired object. yet they more generally failed, because the pads of all the trusses heretofore applied, were made convex. The intention of this shape of the instrument was to press into the opening through which the gut descended, and to keep it well into its place; but while it had this effect, it tended to keep the opening from healing, and even to enlarge it. This evil was not fully remedied until Dr. Amos G. Hull, of New-York, turned his atuntil Dr. Amos G. Hull, of New-York, turned his attention to the subject, and by his improvements in the construction of trusses, has rendered it certain that all recent ruptures, and those of children, may be permanently cured, and those of old people and of long standing may, in many cases, also be remedied. The pad of Dr. Hull's truss is concave, and not convex; and hence the raised circular margin, by proper adaptation, presses upon the sides of the hermial opening, and tends

of a genus of plants. Class, Octandria; Order, Monogynia.

Tropeolum majus. The systematic name of the proportion of cures it has effected is altogether unparalleled. It may, perhaps, be an interesting inquiry to some, how this instrument produces its effects: and we think, after considering its construction, this question can be answered to the satisfaction of every rational mind. It will be observed, that this truss presents a concave surface to the rupture opening. The concavity of the plate is occupied by an elastic cushion, the resistance of which is sufficient to reduce the intruding intestine while it is prevented escaping to any consider able distance by the pressure of the metallic plate; which pressure being greatest at the circumference and diminishing towards the centre, tends constantly to approximate the hernial parietes, and afford them rest and mechanical support. It is therefore obvious that nothing is suffered to intervene between the lips of the opening, as is the case when the intestine protrudes, or opening, as is the case which the interaction produced is applied, but a fair opportunity is presented for the fibres to recover their tone, or to heal, when any laceration has been produced by violence done to the parts. It is a law of the animal economy, particularly noticed by Dorsey, that all hollow parts of the body have a tendency to adapt themselves to their contents.

"For the cure of hernia, then, it is only necessary to remove every obstacle which counteracts this tendency This indication is certainly very far from being answered by the convex pad, and we think it can only be fulfilled by one which shall reduce the bowel without dilating the ring: with this view, we have applied the concave pad, which has more than answered our expectations, in preventing a descent of the gut, and in restoring the fibres, which it undoubtedly greatly facilitates by its constant and uniform pressure. But without tates by its constant and uniform pressure. But without investigating the modus operandi, it is sufficient for the patient, and for all practical purposes, for the physician to know, that with this instrument hernia may always be secured. If applied in cases of umbilical or congenital hernia in children, it will, in every instance, remove the necessity of an operation. In cases of congenital hernia, it should be applied before adhesion takes place, but not until the testicle has made its descent. If this particular period should be more carefully observed by surgeons, and the application of the truss (instead of being abandoned to mechanics) receive a greater share of their attention, they might be instrumental in obvinting much of the distress which be instrumental in obviating much of the distress which has been entailed upon the world.

"The distinctive merits of this truss Dr. Hull sums up

under the following heads:-" First .- The concave internal surface of the rup-

ture pad, from its pressure being greatest at the circum-ference, tends constantly to approximate the hernial parietes, affording them rest and mechanical support. "Secondly.—The combined hinge and pivot mode of connexion between the spring and pad, by means of a tenon and mortice, so constructed as to preserve a

double hinge and limited joint, acting in every direc-tion, thereby securing the uniform pressure of the spring on the pad, and sustaining the same nice coapta-tion of the pad and rupture opening, as well under the varied ordinary desultory muscular actions, as when

the body is in a recumbent posture.

' Thirdly .- The graduating power and fixture of the pad to the spring, rendering, as will be readily per-ceived, the condition of the pad perfectly controllable, even to nameless minuteness. Also resulting from this mechanism, is the advantage of accommodating a large truss to a small person; hence the facility of sup-plying, without disappointment, persons at a great

distance "Fourthly.-The double inguinal truss, being simply the addition of another pad, attached to a short elastic metallic plate: this plate with its pad move on the main metallic plate: this plate with its pad move on the main spring by the same power of adjustment and fixture as the first pad, the pressure of the pads being graduated at pleasure by an intervening cork wedge." A.]

TUBA. (From tubus: any hollow vessel.) 1. A tube.

2. In botany, the inferior part of a monopetalous corol. It is the cylindrical part which is enclosed in

presses upon the sides of the hernial opening, and tends to close the aperture and cure the hernia.

The following particulars of this invention, and its application to the cure of hernia, we take from the New-York Medical and Physical Journal, vol. 4.

"The qualities we have united in the truss, are the calvx of the primrose. See Corolla. Tuba aristotelica; Aquaductus; Aquaductus fallopii; Meatus siccus; Palatinus ductus; Ductus auris palatinus. The auditory tube The Eustachian tube, so called because it was first

described by Eustachius, arises in each ear from the anterior extremity of the tympanum by means of a bony semi-canal; runs forwards and inwards, at the same time becoming gradually smaller; and after persame time becoming gradually smaller; and after per-forating the petrous portion of the temporal bone, terminates in a passage, partly cartilaginous and partly membranous, narrow at the beginning, but becoming gradually larger, and ending in a pouch behind the soft It is through this orifice that the pituitary membrane of the nose enters the tympanum. It is always open, and affords a free passage for the air into the tympanum; hence persons hear better with their mouth open.

TUBA FALLOPIANA. scribed by Fallopius. The Fallopian tube first described by Fallopius. The uterine tube. A canal included in two laminæ of the peritonæum, which arises at each side of the fundus of the uterus, passes transversely, and ends with its extremity turned downwards at the ovarium. Its use is to grasp the ovum, and convey the prolific vapour to it, and to conduct the

fertilized ovum into the cavity of the uterus.

TUBER. (Tuber, eris, n.; from tumeo, to swell.)

An old name for an excrescence.

1. In anatomy, applied to some parts which are rounded; as tuber annulare, &c.

2. In surgery, a knot or swelling in any part.

3. In botany, applied to a kind of round turgid root,

as a turnip; hence these are called tuberose roots.

4. The name of a genus of plants in the Linnwan system. Class, Cryptogamia, Order, Fungi.

Tuber Cibarum. The common truffle. See Lyco-

perdon tuber.

Tubercula quadrigemina. Corpora quadrigemina; Eminentiæ quadrigeminæ; Natulæ. Four white oval tubercles of the brain, two of which are situated on each side over the posterior orifice of the third ventricle and the aqueduct of Sylvius. The ancients called

them nates and testes, from their supposed resemblance.

TUBE'RCULUM. (Tuberculum, i, n. diminutive
of tuber.) A tubercle. In anatomy, applied to several
elevations, and in morbid anatomy to a diseased structure, which consists of a solid roundish substance; as In botany, it is applied to the hemispherical projections, as the fruit of the Lichen caninus.

Tuberculum annulare. The commencement of

the medulla oblongata.

Tuberculum lowers. An eminence in the right auricle of the heart where the two venæ cavæ meet: so called from Lower, who first described it.

Tuberosus. Tuberose, knobbed: applied to parts of plants. The root so called is of many kinds. The most genuine consists of fleshy knobs, various in form, connected by common stalks or fibres; as the potato, and Jerusalem artichoke.

TUBULARIS. Tubular. In Good's Nosology used

in which membrane-like tubes pass with the motions.

TUBULOSUS. Tubulose. A leaf is so called which is hollow within, as that of the common onion. The florets of a compound flower are called tubulosi,

tubular or cylindrical, to distinguish them from such as

TUBULUS. A small tube or duct.

TUBULUS. A small tube or duct.

TUBULI LACTIFERI. The ducts or tubes in the nipple, through which the milk passes.

TUFT. See Capitalum.

TULP, Nicholas, was the son of an opulent merchant, and born at Amsterdam, in 1593. Having studied and graduated at Leyden, he settled in his native city, and rose to a high rank, not only in his profession, but also as a citizen. He was made burgomaster in 1652, and in that station resisted the invasion of Holland by Lewis XIV. twenty years after, and thus saved his country; on which occasion a medal was struck to his honour. He died in 1674. His three books of Medical Observations have been several times reprinted, and contain many valuable physiological remarks. He is said to have been among the first who observed the lacteal vessels.

TUMITE. See Thummerstone. TU'MOUR. (Tumor; from tu (Tumor; from tumeo, to swell.) A

Tumo'res. Tumours. An order in the Class, Locales, of Cullen's Nosology, comprehending partial swellings without inflammation.

TUNBRIDGE. Tunbridge wells is a populous vil-

and therefore afford an abundant supply for the numerous invalids who yearly resort thither. The analysis of Tunbridge spring proves it to be a very pure water, as to the quantity of solid matter; and the saline contents (the iron excepted) are such as may be found in almost any water that is used as common drink. It is only as a chalybeate, and in the quantity of carbonic acid, that it differs from common water. Of this acid it contains one twenty-second of its bulk. The general operation of this chalybeate water is to increase the power of the secretory system in a gradual, uniform manner, and to impart tone and strength to all the functions; hence it is asserted to be of eminent service in irregular digestion, flatulency, in the incipient stages of those chronic disorders which are attended with great debility, in chlorosis, and numerous other complaints incident to the female sex. The prescribed method of using the Tunbridge water, observes Dr. Saunders, is judicious. The whole of the quantity Saunders, is judicious. The whole of the quantity daily used, is taken at about two or three intervals, beginning at eight o'clock in the morning, and finishing about noon. The dose at each time varies from about one to three quarters of a pint; according to the age, sex, and general constitution of the patient, and especially the duration of the course; for it is found that these waters lose much of their effect by long habit.

TUNGSTATE. Tunstas. A salt formed by the combination of the tungstic acid, with salifiable bases;

as tungstate of lime, &c. TUNGSTENUM. ((Tungsten, Swed. ponderous stone.) A metal, never found but in combination, and by no means common. The substance known to mineoy no means common. The substance known to mineralogists, under the name of tungsten, was, after some time, discovered to consist of lime, combined with the acid of this metal. This ore is now called tungstate of lime, and is exceedingly scarce. It has been found in Sweden and Germany, both in masses and crysta!lized, of a yellowish-white or gray colour. It nas a sparry appearance, is shining, of a lamellated texture, and semitransparent. The same metallic acid is like semitransparent. found united to iron and manganese; it then forms the ore called Wolfram, or tungstate of iron and manga-nese. This ore occurs both massive and crystallized, and is found in Cornwall, Germany, France, and Spain. Its colour is brownish-black, and its texture foliated. It has a metallic lustre, and a lamellated texture; it is brittle and very heavy; it is found in solid masses, in the state of layers interspersed with quartz. These two substances are therefore ores of the same metal.

Properties.—Tungstenum appears of a steel-gray colour. Its specific gravity is about 176. It is one of the hardest metals, but it is exceedingly brittle; and it is said to be almost as infusible as platina. Heated in the air it becomes converted into a yellow pulverulent oxide, which becomes blue by a strong heat, or when exposed to light. Tungstenum combines with phosphorus and sulphur, and with silver, copper, iron, lead, tin, antimony, and bismuth; but it does not unite with gold and platina. It is not attacked by sulphuric, nitric, or muriatic acids; nitro-muriatic acid acts upon it very slightly. It is oxidizable and acidifiable by the nitrates and hyperoxymuriates. It colours the vitrified earths or the vitreous fluxes, of a blue or brown colour. It is not known what its action may be on water and different oxides. Its action on the alkalies is likewise un-known. It is not employed yet, but promises real utility, on account of its colouring property, as a basis for pigment, since the compounds it is said to form with or pigment, since the compounds it is said to form with vegetable colouring matter, afford colours so permanent, as not to be acted on by the most concentrated oxymuriatic acid, the great enemy of vegetable colours.

Methods of obtaining tungstenum.—The method of obtaining metallic tungstenum is a problem in chemistry. Scheele, Bergman, and Gmelin did not succeed in their strengts to procure it. Elegants to the second of the second

attempts to procure it. Klaproth tried to reduce the yellow oxide of this metal with a variety of combustible substances, but without success. Ruprecht and Tondy say they have obtained this metal by using combustible substances alone: and by a mixture of com-

bustible and alkaline matter.

The following process is recommended by Richter, an ingenious German chemist. Let equal parts of tungstic acid and dried blood be

exposed for some time to a red heat in a crucible; press able in chronic rheumatism and paralysis. Turpen. the black powder which is formed into another smaller crucible, and expose it again to a violent heat in a forge, for at least half an hour. Tungstenum will then be found, according to this chemist, in its metallic state in the crucible. There are two oxides of tungstenum the recommend the religious content and the religious con state in the crucible. There are two oxides of un stenum, the brown and the yellow, or tungstic acid.

TUNGSTIC ACID has been found only in two minerals; one of which, formerly called tungsten, is a tungstate of lime, and is very rare; the other, more common, is composed of tungstic acid, oxide of iron, and a little oxide of manganese. The acid is separated from the latter in the following way:—The wolfrated from the latter in the following way:—The wolfram cleared from its silicious gangue, and pulverized, is heated in a matrass with five or six times its weight of muriatic acid for half an hour. The oxides of iron and manganese being thus dissolved, we obtain the tungstic acid under the form of a yellow powder. After washing it repeatedly with water, it is then digested in an excess of liquid ammonia, heated, which dissolves it completely. The liquor is filtered and evaporated to dryness in a capsule. The dry residue being ignited, the ammonia flies off, and pure tungstic acid remains. If the whole of the wolfram has not been decomposed If the whole of the wolfram has not been decomposed in this operation, it must be subjected to the muriatic acid again.

It is tasteless, and does not affect vegetable colours. The tungstates of the alkalies and magnesia are soluble and crystallizable, the other earthy ones are insoluble, as well as those of the metallic oxides. The acid is composed of 100 parts metallic tungsten, and 25 or 26.4

TUNGSTOUS ACID. What has been thus called appears to be an oxide of tungsten.

Tunic of a seed. See Arillus.

TU'NICA. (A tuendo corpore, because it defends the body.) A membrane or covering; as the coats of the eye, &c.

TUNICA ACINIFORMIS. The uvea, or posterior lamella

TUNICA ALBUGINEA OCULL. See Adnata tunica.

TUNICA ALBUGINEA TESTIS. See Albuginea testis. TUNICA ARACHNOIDEA. See Arachnoid membrane. TUNICA CELLULOSA RUYSCHII. The second coat of the intestines.

TUNICA CHOROIDEA. See Choroid membrane.

TUNICA CONJUNCTIVA. See Conjunctive membrane.

TUNICA CONJUNCTIVA. See Conjunctive membrane.
TUNICA CORNEA. See Cornea.
TUNICA FILAMENTOSA. The false or spongy chorion.
TUNICA RETINA. See Retina.
TUNICA VAGINALIS TESTIS. A continuation of the
peritonæum through the inguinal ring, which loosely
invests the testicle and spermatic cord. See Testis.
TUNICA VILLOSA. The villous, or inner folding coat

of the intestines.

Turbeth mineral. See Hydrargyrus vitriolatus.

Turbeth-root. See Convolvulus turpethum. TURBINATE. (Turbinatus; from tur TURBINATE. (Turbinatus; from turbino, to sharpen at the top, shaped like a sugar-loaf.) Shaped like a sugar-loaf.

TURBINATED BONES. The superior spongy portion of the ethmoid bone, and the inferior spongy bones, are so called by some writers. See Spongiosa ossa.

TURBINATUM. The pineal gland.

TURBINATUS. Turbinate, or sugar-loaf form.

Applied to the fig, &c.

Turbith. A cathartic eastern bark; a species of

cicely.

Turkeystone. See Whatslate.
TURMERIC. See Curcuma.
TURNHOOF. A vulgar name of the ground ivy.

TURNHOOF. A vulgar name of the ground ivy.
See Glecoma hederacea.

TURNIP. See Brassica rapa.
Turnip, French. See Brassica rapa.
TURNSOLE. See Heliotropium.
TURPENTINE. Terebinthina. There are many kinds of turpentine. Those employed medicinally are,
1. The Chian or Cyprus turpentine. See Pistacia terebinthus. terebinthus.

2. The common turpentine. See Terebinthina com-

3. The Venice turpentine. See Pinus lariz.
All these have been considered as hot, stimulating corroborants and detergents; qualities which they possess in common. They stimulate the primæ viæ, and prove laxative; when carried into the blood-vessels they excite the whole system, and thus prove service
TY'MPANUM. ($Tv\mu\pi\alpha\nu\nu\nu$. A drum.) The drum or barrel of the ear. The hollow part of the ear in which are lodged the bones of the ear. It begins behind the membrane of the tympanum, which terming the provided that the membrane of the tympanum, which terming the provided that the membrane of the tympanum, which terming the provided that the p

able in chronic rheumatism and paralysis. Turpentine readily passes off by urine, which it imbues with a peculiar odour; also by perspiration and by exhalation from the lungs; and to these respective effects are ascribed the virtues it possesses in gravelly complaints, scurvy, and pulmonic disorders. Turpentine is much used in gleets, and fluor albus, and in general with much success. The essential oil, in which the virtues of turpentine reside, is not only preferred for external use, as a rubefacient, but also internally as a diuretic and styptic; the latter of which qualities it possesses and styptic; the latter of which qualities it possesses in a very high degree. Formerly, turpentine was much used as a digestive application to ulcers, &c.; but in the modern practice of surgery, it is almost wholly exploded.

Tarpeth mineral. See Hydrargyrus vitriolatus.

TURPE THUM. (From Turpeth, Indian turbeth.)

See Convolvulus turpethum.

TURPETHUM MINERALE. See Hydrargyrus vitrio-

TURQUOIS. Calaite. A much-esteemed orna-mental stone brought from Persia, of a smalt-blue and apple green colour.

TURU'NDA. (A terendo, from its being rolled up.)

TURU NDA. (A terenao, from its being rolled up.)
A tent, or suppository.
TUSSILA'GO. (Tussilago, inis, f.; from tussis, a cough; because it relieves coughs.) 1. The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Polygamia superflua.

2. The pharmacopeial name of the coltsfoot. See

Tussilago farfara.

Tussilago farfara.

Tussilago farfara.

Tussilago farfara. The systematic name of the Bechium; Bechion; Calceum equinum; Chamaeleuce; Filius antepatrem; Farfarella; Farfara; Tussilago vulgaris; Farfara bechium; Ungulacaballina. Coltsfoot. Tussilago farfara—scapo uniforo imbricato, foliis subcordatis angulatis denticulatis. The sensible qualities of this plant are very inconsiderable; it has a rough mucilaginous taste, but no remarkable smell. The leaves have always been esteemed as possessing demulcent and pectoral virtues; and hence they have been exhibited in pulmonary consumptions, coughs, asthmas, and catarrhal affections. It is used coughs, asthmas, and catarrhal affections. It is used as tea, or given in the way of infusion with liquoriceroot or honey.

Tussilago petasites. The systematic name of the butter-bur. Petasites. Pestilent-wort. The roots of this plant are recommended as aperient and alexipharmic, and promise, though now forgotten, to be of considerable activity. They have a strong smell, and a bitterish acrid taste, of the aromatic kind, but not

agreeable. TU'SSIS. TU'SSIS. A cough, a sonorous concussion of the breast, produced by the violent, and for the most part involuntary motion of the muscles of respiration. It is symptomatic of many diseases.

Tussis convulsiva. See Pertussis.

Tussis exanthematica. A cough attendant on an eruption.

TUSIS FERINA. See Pertussis.

TUTENAG. 1 The Indian name for zinc.
2. A metallic compound brought from China.

TU'TIA. (Persian.) Pompholyz; Cadmia. Tutty.

A gray oxide of zinc; it is generally formed by fusing brass or copper, mixed with blende, when it is incrusted in the chimneys of the furnace. Mixed with any compound of the co mon cerate, it is applied to the eye, in debilitated states of the conjunctive membrane.

TUTIA PREPARATA. Prepared tutty is often put into

TUTTY. See Tutia.

TYLO'SIS. (From τυλος, a callus.) Tyloma. An induration of the margin of the eyelids.

TYMPANI MEMBRANA. See Membrana tympani.

TYMPANI'TES. (From τυμπανον, a drum: so called because the belly is distended with wind, and called because the belly is distended with wind, and sounds like a drum when struck.) Tympany. Drumbelly. An elastic distention of the abdomen, which sounds like a drum when struck, with costiveness and atrophy, but no fluctuation. Species: 1. Tympanites intestinalis, a lodgment of wind in the intestines, known by the discharge of wind giving relief

2. Tympanites abdominalis, when the wind is in the cavity of the abdomen.

TY'MPANUM. ($Tv\mu\pi\alpha\nu\nu\nu$. A drum.) The drum or barrel of the ear. The hollow part of the ear in which are lodged the bones of the ear. It begins behind the membrane of the tympanum, which terms

TYP

nates the external auditory passage, and is surrounded | have been effected under the most unpromising appear-by the petrous portion of the temporal bone. It terminates at the cochlea of the labyrinth, and has opening into it four foramina, viz. the orifices of the Eustachian tube and mastoid sinus, the fenestra ovalis, and ro-tunda. It contains the four ossicula auditus.

TY'PHA. (From τεφος, a lake; because it grows in marshy places.) The name of a genus of plants in

the Linnean system. The cat's tail.

Typha aromatica. See Acorus calamus.

Typha Latifolia. The broad leaved cat's tail, or bull-rush. The young shoots, cut before they reach the surface of the water, eat like asparagus when boiled.

TYPHOMA'NIA, A'NIA, (From τυφος, to burn, and μανια, A complication of phrensy and lethargy delirium.)

TY'PHUS. (From rupos, stupor.) A species of continued fever, characterized by great debility, a tendency in the fluids to putrefaction and the ordinary symptoms of fever. It is to be readily distinguished from the inflammatory by the smallness of the pulse, and the sudden and great debility which ensues on its first attack; and, in its more advanced stage, by the petechiæ, or purple spots, which come out on various parts of the body, and the fætid stools which are discharged; and it may be distinguished from a nervous fever by the great violence of all its symptoms on its first coming on.

The most general cause that gives rise to this disease, is contagion, applied either immediately from the body of a person labouring under it, or conveyed in clothes, or merchandise, &c.; but it may be occasioned by the effluvia arising from either animal or vegetable substances in a decayed or putrid state: and hence it is, that in low and marshy countries it is apt to be prevatent when intense and sultry heat quickly succeeds any great inundation. A want of proper cleanliness and confined air are likewise causes of this fever; hence it prevails in hospitals, jails, camps, and on board of ships, especially when such places are much crowded, and the strictest attention is not paid to a free ventilaand the strictest attention is not paid to a free ventila-tion and due cleanliness. A close state of the atmos-phere, with damp weather, is likewise apt to give rise to putrid fever. Those of lax fibres, and who have been weakened by any previous debilitating cause, such as poor diet, long fasting, hard labour, continued want of sleep, &c. are most liable to it.

On the first coming on of the disease, the person is seized with languor, dejection of spirits, amazing deseized with languor, dejection of spirits, amazing de-pression and loss of muscular strength, universal wea-riness and soreness, pains in the head, back, and extre-mities, and rigors; the eyes appear full, heavy, yellow-ish, and often a little inflamed; the temporal arteries throb violently, the tongue is dry and parched, respira-tion is commonly laborious, and interrupted with deep inhight the health is lost and interrupted. sighing; the breath is hot and offensive, the urine is crude and pale, the body is costive, and the pulse is usually quick, small, and hard, and now and then flut-tering and unequal. Sometimes a great heat, load, and pain are felt at the pit of the stomach, and a vomiting

of bilious matter ensues.

As the disease advances, the pulse increases in frequency (beating often from 100 to 130 in a minute); requency (beating often from 100 to 130 in a minute); there is vast debility, a great heat and dryness in the skin, oppression at the breast, with anxiety, sighing, and moaning; the thirst is greatly increased; the tongue, mouth, lips, and teeth are covered over with a brown or black tenacious fur; the speech is inarticulate, and scarcely intelligible; the patient mutters much, and delirium ensues. The fever continuing to increase still more in violence, symptoms of putrefer. increase still more in violence, symptoms of putrefaction show themselves; the breath becomes highly offensive; the urine deposites a black and feetid sedi-ment; the stools are dark, offensive, and pass off insensibly; hæmorrhages issue from the gums, nostrils, mouth, and other parts of the body; livid spots or petechiæ appear on its surface; the pulse intermits and sinks; the extremities grow cold; hiccoughs ensue; and death at last closes the tragic scene.

When this fever does not terminate fatally, it gene-

When this fever does not terminate fatally, it generally begins, in cold climates, to diminish about the commencement of the third week, and goes off gradu-ally towards the end of the fourth, without any very evident crisis; but in warm climates it seldom con-

tinues above a week or ten days, if so long.

Our opinion, as to the event, is to be formed by the degree of violence in the symptoms, particularly after petechiæ appear, although in some instances recoveries 364

gentle moisture diffused equally over the whole sur face of the body, loose stools, turbid urine, rising of the pulse, and the absence of delirium and stupor, may be regarded in a favourable light. On the con trary, petechia, with dark, offensive, and involuntary discharges by urine and stool, fætid sweats, bæmorrhages, and hiccoughs, denote the almost certain dissolution of the patient.

The appearances usually perceived on dissection, are inflammations of the brain and viscera, but more particularly of the stomach and intestines, which are now and then found in a gangrenous state. In the muscular fibres there seems likewise a strong tendency to gan

In the very early period of typhus fever, it is often possible, by active treatment, to cut short the disease at once; but where it has established itself more firmly, we can only employ palliative measures to diminish its violence, that it may run safely through Among the most likely means of accomits course. plishing the first object is an emetic; where the fever runs high, we may give antimonials in divided doses at short intervals till full vomiting is excited; or if there be less strength in the system, ipecacuanha in a full dose at once. Attention should next be paid to clear out the bowels by some sufficiently active form of medicine; and as the disease proceeds, we must keep up this function, and attempt to restore that of the skin, and the other secretions, as the best means of moderating the violence of vascular action. Some of the preparations of mercury, or if there be tolerable strength, those of antimony, assisted by the saline compounds, may be employed for this purpose. The general antiphiogistic regimen is to be observed in the carly part of the disease, as explained under synocha. In cases where the skin is uniformly very hot and dry, the abstraction of caloric may be more actively made by means of the cold affusion, that is, throwing a quantity of cold water on the naked body of the patient; which measure has sometimes arrested the disease in its first stage; and when the power of the system is less, sponging the body occasionally with cold water, medicated, perhaps, with a little salt or vinegar, may be substituted as a milder proceeding. But where the evolution of heat is even deficient, such means would be highly improper; and it may be sometimes advisable to employ the tepid bath, to promote the operation of the diaphoretic medicines. If under the use of the measures already detailed, calculated to lessen the violence of vascular action, the vital powers should appear materially falling off, recourse must then be had to a more nutritious diet, with a moderate quantity of wine, and cordial, or tonic medi-cines. There is generally an aversion from animal food, whence the mucilaginous vegetative same as arrow-root, &c., rendered palatable by spice, or a little wine, or sometimes mixed with milk, may be little wine, or sometimes and easy of digestion. If, however, there be no marked septic tendency, and the however, there be no marked septic tendency, and the patient cloyed with these articles, the lighter animal preparations, as calves-foot jelly, veal broth, &c., may be allowed. The extent to which wine may be carried, must depend on the urgency of the case, and the previous habits of the individual; but it will commonly not be necessary to exceed half a pint, or a pint at most, in the twenty-four hours; and it should be given in divided portions, properly diluted, made, perhaps, into negus, whey, &c., according to the liking of the patient. The preference should always be given to that which is of the soundest quality, if agreeapatient. The preference should always be given to that which is of the soundest quality, if agreeable: but where wine cannot be afforded, good malt liquor, or mustard whey, may be substituted. Some moderately stimulant medicines, as ammonia, aromatics, serpentaria, &c., may often be used with advantage, to assist in keeping up the circulation: also those of a tonic quality, as calumba, cusparia, cinchona, &c., occasionally in their lighter forms; but more especially the acids. These are, in several respects, useful; by promoting the secretions of the prime viæ, &c., they quench thirst, remove irritation, and manifestly cool the body; and in the worst forms of typhus, where the putrescent tendency appears, they are particularly indicated from their antiseptic power; they are also decidedly tonic, and indeed those from the mineral kingdom powerfully so. These may

be given freely as medicines, the carbonic acid also in | the form of brisk fermenting liquors; and the native vegetable acids, as they exist in ripe fruits, being generally very grateful, may constitute a considerable part of the diet. In the mean time, to obviate the septic tendency, great attention should be paid to cleanliness and ventilation, and keeping the bowels regular by mild aperients, or clysters of an emollient or antiseptic nature: and where aphthæ appear, acidulated gargles should be directed. If the disease inclines more to the nervous form, with much mental anxiety, tremors, and other irregular affections of the muscles, or organs of sense, the antispasmodic medicines may be employed with more advantage, as æther, camphor, musk, &c., but particularly opium; which camphor, musk, &c., but particularly opium; which should be given in a full dose, sufficient to procure sleep, provided there be no appearances of determination of blood to the head; and it may be useful to call a greater portion of nervous energy to the lower extremities by the pediluvium, or other mode of applying warmth, or occasionally by sinapisms, not allowing these to produce vesication. But if there should be much increased vascular action in the brain, more active means will be required, even the local abstraction of blood, if the strength will permit; and it will

be always right to have the head shaved, and kept cool by some evaporating lotion, and a blister applied to the back of the neck. In like manner, other important parts may occasionally require local means of relief. Urgent vomiting may, perhaps, be checked of relief. Urgent vomiting may, perhaps, be checked by the effervescing mixture; a troublesome diarrhea by small doses of opium, assisted by aromatics, chalk, and other astringents, or sometimes by small doses of and other astringents, or sometimes by small doses of ipecacuanha; profuse perspirations by the infusum rose, a cooling regimen, &c.

Typhus &gyptiacus. The plague of Egypt.
Typhus carcerum. The jail-fever.
Typhus castrensis. The camp-fever.
Typhus Gravior. The most malignant species of typhus. See Typhus.

Typhus litterodes.
Typhus with symptoms of jaindice. See Typhus.
Typhus mittor. The low-fever.

Typhus mition. The low-fever.

Typhus metror. The low-fever.

Typhus mervous. The nervous-fever.

Typhus petechialis. Typhus with purple spots.

TYRI'ASIS. Tuphasis. A species of leprosy in which the skin may be easily withdrawn from the flesh.

TYRO'SIS. (From repow, to coagulate.) A dis-order of the stomach from milk curdled in it.

ULCER. (Ulcus, eris, n.: from ελκος, a sore.) A purulent solution of continuity of the soft parts of an animal body. Ulcers may arise from a variety of causes, as all those that produce inflammation, from causes, as all those that produce inflammation, from wounds, specific irritation of the absorbents, from scurvy, cancer, the venereal or scrofulous virus, &c. The proximate or immediate cause is an increased action of the absorbents, and a specific action of the arteries, by which a fluid is separated from the blood upon the ulcerated surface. They are variously denominated; the following is the most frequent division: division

1. The simple ulcer, which takes place generally

from a superficial wound.

2. The sinuous, that runs under the integuments, and the orifice of which is narrow, but not callous.

3. The fistulous ulcer, or fistula, a deep ulcer with a narrow and callous orifice.

The fungous vicer, the surface of which is covered with fungous flesh.

5. The gangrenous, which is livid, fætid, and gan-6. The scorbutic, which depends on a scorbutic

acrimony. The venereal, arising from the venereal disease.

8. The cancerous ulcer, or open cancer. See Cancer.
9. The carious ulcer, depending upon a carious bone.
10. The inveterate ulcer, which is of long continu-

ance, and resists the ordinary applications.

11. The scrofulous ulcer, known by its having arisen from indolent tumours, its discharging a viscid, glairy matter, and its indolent nature.

glairy matter, and its indolent nature.

ULCERA SERPENTIA ORIS. See Aphtha.

Ulcerated sore throat. See Cynanche.

ULLA. The common diminutive ulla, or illa, is, according to Dr. Good, most probably derived from the Greek, υλη, ule or ile, materia, materies, of the matter, make, or nature of; thus, papula or papilla, of the matter or nature of pappus; lupula, of the matter or nature of lupus; pustula, of the matter or nature of pus; and so of many others.

ULMARIA. (From ulmus, the clm; so named be.

pus; and so of many others.

ULMA'RIA. (From ulmus, the elm: so named because it has leaves like the elm.) See Spiræa ulmaria.

ULMIN. Dr. Thomson has given this temporary name to a very singular substance lately examined by Klaproth. It differs essentially from every other known body, and must therefore constitute a new and peculiar vegetable principle. It exuded spontaneously from the trunk of a species of elm, which Klaproth conjectures to be the ulmus nigra, and was sent to him from Palermo in 1802. lermo in 1802.

1. In its external characters it resembles gum. was solid, hard, of a black colour, and had considerable

lustre. Its powder was brown. It dissolved readily

in the mouth, and was insipid.

2. It dissolved speedily in a small quantity of water. The solution was transparent, of a blackish-brown colour, and, even when very much concentrated by evaporation, was not in the least mucilaginous or ropy; nor did it answer as a paste. In this respect ulmin dif-

as the sessentially from gum.

3. It was completely insoluble both in alkohol and ather. When alkohol was poured into the aqueous solution, the greater part of the ulmin precipitated in light brown flakes. The remainder was obtained by evaporation, and was not sensibly soluble in alkohol. The alkohol by this treatment acquired a sharpish taste.

4. When a few drops of nitric acid were added to the aqueous solution, it became gelatinous, lost its blackish-brown colour, and a light brown substance precipitated. The whole solution was slowly evaporated to dryness, and the reddish-brown powder which remained was treated with alkohol. The alkohol assumed a golden yellow colour; and, when evapo-rated, left a light brown, bitter, and sharp resinous substance.

5. Oxymuriatic acid produced precisely the same effects as nitric. Thus it appears that ulmin, by the effects as nitric. Thus it appears that unnin, by the addition of a little oxygen, is converted into a resinous substance. In this new state it is insoluble in water. This property is very singular. Hitherto the volatile oils, were the only substances known to assume the form of resins. That a substance soluble in water form of resins. That a substance soluble in water should assume the resinous form with such facility, is very remarkable.

6. Ulmin when burned emitted little smoke or flame and left a spongy but firm charcoal, which, when burned in the open air, left only a little carbonate of potassa be-

U'LMUS. 1. The name of a genus of plants in the Linnwan system. Class, Pentandria; Order, Digynia. 2. The pharmacopæial name of the common elm.

See Ulmus campestris.

ULMUS CAMPESTRIS. The systematic name of the common elm. Ulmus—foliis duplicato-serratis, basi inaqualibus, of Linnæus. The inner tough bark of this tree, which is directed for use by the pharmacopæias, has no remarkable smell, but a bitterish taste, and abounds with a slimy juice, which has been recommended in nephritic cases, and externally as a useful application to burns. It is also highly recommended in some cutaneous affections allied to herpes and lepra. It is mostly exhibited in the form of decoction, by boiling four ounces in four pints of water to two pints; of which from four to eight ounces are given two or three times a day.

A THE RESERVED OF A STAND

I" ULMUS FULVA. elm, inhabits the northern and western parts of the United States, from Canada to Pennsylvania. The inner bark of this tree is charged with a gummy substance in great quantity, so that if a small piece is chewed in the mouth, it almost instantly fills it with a thick, viscid mucilage. This bark, both in substance and decoction, is a valuable demulcent in dysentery, and in strangury, either produced by cantharides or resulting from other causes. Elm-bark has been used as food, and been found capable of supporting life in cause of emergency. Externally, it is employed as an cases of emergency. Externally, it is employed as an emollient application, to promote suppuration, and to answer the different ends to which common poultices are applicable. For this purpose, either the green bark should be bruised, or the dried bark cut into shreds

and boiled. Internally, it proves most palatable in the infusion."—Big. Mat. Med. A.]

U'LNA. (From ωλενη, the ulna, or cubit.) Cubitus.

The larger bone of the forearm. It is smaller and shorter than the os humeri, and becomes gradually smaller as it descends to the wrist. We may divide it into its upper and lower extremities, and its body or middle part. At its upper extremity are two considerable processes, of which the posterior one and largest is named olecranon, and the smaller and interior one the coronoid process. Between these two processes, the extremity of the bone is formed into a deep articulating cavity, which, from its semicircular shape, is called the greater sigmoid cavity, to distinguish it from another, which has been named the less sigmoid cavity. The olecranon, called also the anconoid process, begins by a considerable tuberosity, which is rough, and serves for the insertion of muscles, and terminates in a kind of hook, the concave surface of which moves upon the pulley of the os humeri. This process forms the point of the elbow. The coronoid process is sharper at its extremity than the olecranon, but is much smaller, and does not reach so high. In bending the arm, it is received into the fossa at the forepart of the pulley. At the external side of the coronoid process is the less sigmoid cavity, which is a small, semilunar articulating surface, lined with cartilage, on which the round head of the radius plays. At the forepart of the coronoid process we observe a small tuberosity, into which the tendon of the brachialis internus is inserted. The greater sigmoid cavity, the situation of which we just now mentioned, is divided into four surfaces by a pro-minent line which is intersected by a small sinuosity that serves for the lodgment of mucilaginous glands. The whole of this cavity is covered with cartilage. The body, or middle part of the ulna, is of a prismatic or triangular shape, so as to afford three surfaces and as many angles. The external and internal surfaces are flat and broad, especially the external one, and are separated by a sharp angle, which, from its situation, may be termed the internal angle. This internal angle, which is turned towards the radius, serves for the attachment of the ligament that connects the two bones, and which is therefore called the *interosscous* ligament. The posterior surface is convex, and corligament. The posterior surface is convex, and cor-responds with the olecranon. The borders, or angles, which separate it from the other two surfaces, are somewhat rounded. At about a third of the length of this bone from the top, in its forepart, we observe a channel for the passage of vessels. The lower extre-mity is smaller as it descends, nearly cylindrical, and slightly curved forwards and outwards. Just before it terminates, it contracts, so as to form a neck to the small head with which it ends. On the outside of this little head, answering to the olegranon, a small pro-cess, called the styloid process, stands out, from which a strong ligament is stretched to the wrist. The head has a rounded articulating surface, on its internal side, which is covered with cartilage, and received into a semilunar cavity formed at the lower end of the radius. Between it and the os cuneiforme, a moveable cartilage is interposed, which is continued from the cartilage that covers the lower end of the radius, and is con-nected by ligamentous fibres to the styloid process of the ulna. The ulna is articulated above with the lower end of the os humeri. This articulation is of the spe-cies called ginglymus; it is articulated also both above and below to the radius, and to the carpus at its lowest extremity. Its chief use seems to be to support and regulate the motions of the radius. In children, both extremities of this bone are first cartilaginous, and after-

The Ulmus fulva, or slippery | ward epiphyses, before they are completely united to thern and western parts of the the rest of the bone.

ULNAR. (Ulnaris; from ulna, the bone so named.) Belonging to the ulna.

Beionging to the ulma.

ULNAR ARTERY. See Cubital artery.

ULNAR NERVE. See Cubital nerve.

ULNA'RIS EXTERNUS. See Extensor carpi ulnaris.

ULNA'RIS INTERNUS. See Flexor carpi ulnaris.

ULTRAMARINE. See Lapis lazuli.

UMBELLA. (Umbella, a, f.; a little shade, or umbrella.) An umbel; the rundie of some authors. A species of inflorescence in which several flower-stalks of rays, nearly equal in length, spread from one common centre, their summits forming a level, convex, or

even globose surface, more rarely a concave one.

From the insertion of the umbel, it is distinguished into pedunculate and sessile. The former implies that the rays or flower-stalks come from one; and the latter, that the rays or stalklets come, not from a common peduncle, but from the stem or branch of the plant; as

peduncle, but from the stem or branch of the plant; as in Sium nodiflorum, and Prunus aviam.

From the division of the umbel it is said to be simple, when single-flowered; as in Allium ursinum: and compound, when each ray or stalk bears an umbellula, or partial umbel; as in the Anethum faniculum.

The umbella involucrata is supplied with involucra.

UMBELLULA. A partial or little umbel. See

UMBER. An ore of iron.
UMBILI'CAL. (Umbilicalis; from umbilicus, the navel.) Of or belonging to the navel.

UMBILICAL CORD. Funis umbilicalis; Funiculus umbilicalis. The navel-string. A cord-like substance of an intestinal form, about half a yard in length, that proceeds from the navel of the fœtus to the centre of the placenta. It is composed of a cutaneous sheath, cellular substance, one umbilical vein, and two umbili-cal arteries; the former conveys the blood to the child from the placenta, and the latter return it from the child to the placenta.

Umbilical hernia. See Hernia umbilicalis. Umbilical region. Regio umbilicalis. The part of the abdominal parietes about two inches all round the navel.

UMBILI'CUS. The navel.

UMBILITUS. The navel.

UMBILITUS MARINUS. Cotyledon marina; Andro sace; Acetabulum marinum; Androsace matthioli; Fungus petraus marinus. A submarine production found on rocks and the shells of fishes, about the coast of Montpellier, &c. It is said to be, in the form of powder, a useful anthelminitic and diuretic.

UMBO. (The top of a buckler.) The knob or more prominent part in the centre of the hat or pilus of the

UNCEOLA ELASTICA. This plant affords a juice which

becomes an elastic gum. See Caoutchouc.

UNCIFORM. (Unciformis; from uncus, a hook, and forma, a likeness.) Hook-like: applied to bones, &c.

UNCIFORM BONE. The last bone of the second row of the carpus or wrist: so named from its hook-like process, which projects towards the palm of the hand, and gives origin to the great ligament by which the tendons of the wrist are bound down.

UNCINATUS. (From uncus, a hook.) Uncinate or hooked: applied to the stigma of the Lantana.
UNDERSTANDING. Intellectus See Ideology.
UNDULATUS. Undulated: applied to a leaf when the disk near the margin is waved obtusely up and down; as in Reseda lutea.

UNEDO PAPVRACEA. See Arbutus unedo.
UNGUE'NTUM. (Unguentum, i, n.; from ungo, to anoint.) An ointment. The usual consistence of ointments is about that of butter. The following are among the best formulæ.

Unquentum apostolorum. Dodeca pharmicum. The apostles' ointment: so called because it has twelve ingredients in it exclusive of the oil and vinegar. Not

Unguentum cantharidis. Unguentum lyttæ. Ointment of the blistering-fly. Take of the blisteringfly, rubbed to a very fine powder, two ounces; distilled water, eight fluid ounces; resin cerate, eight ounces. Boil the water with the blistering-fly to one-half, and strain; mix the cerate with the liquor, and then let it avanorate to the proper consistence. This is some times used to keep a blister open , but the savine cerate is to be preferred.

Unquentum crtacel. Ointment of spermaceti, formerly called linimentum album, and latterly, unguentum spermaceti. Take of spermaceti, six drachms; white wax, two drachms; olive oil, three fluid ounces. Unquentum resine flave. Yellow basilicon is in general use as a stimulant and detersive; it is an all and detersive in the specific of the specific o Having melted them together over a slow fire, constantly stir the mixture until it gets cold. A simple

emollient ointment.

UNGUENTUM CICUTÆ. Hemlock ointment. of the fresh leaves of hemlock, and prepared hog's lard, of each four ounces. The hemlock is to be bruised in a marble mortar, after which the lard is to be added, and the two ingredients thoroughly incorporated by beating. They are then to be gently included over the fire, and after being strained through a cloth, and the fibrous parts of the hemlock well pressed, the ointment is to be stirred till quite cold. To cancerous or scrofulous sores this ointment may be applied with a prospect of success.

UNGUENTUM ELEMI COMPOSITUM. Compound oint-ment of elemi, formerly called linimentum arcai, and unguentum e gummi elemi. Take of elemi, a pound; common turpentine, ten ounces; prepared suet, two pounds; olive oil, two fluid ounces. Melt the elemi with the suet, then remove it from the fire, and immediately mix in the turpentine and oil, then strain the mixture through a linen cloth. Indolent ulcers, chilblains, chronic ulcers after burns, and indolent tumours

are often removed by this ointment.

Unquentum hydrargyri fortius. curial ointment, formerly called unguentum caruleum fortius. Take of purified mercury, two pounds; prepared lard, twenty-three ounces; prepared suet, an ounce. First rub the mercury with the suet and a little of the lard, until the globules disappear; then add the remainder of the lard, and mix. In very general use for mercurial frictions. It may be employed in almost all cases where mercury is indicated.

Mild mercurial UNGUENTUM HYDRARGYRI MITIUS. ointment, formerly called unguentum caruleum mitius.

Take of strong mercurial ointment, a pound; prepared lard, two pounds. Mix. Weaker than the

former.

UNGUENTUM HYDRARGYRI NITRATIS. hydrargyri nitrati. Ointment of nitrate of mercury. Take of purified mercury, an ounce; nitric acid, eleven fluid drachms; prepared lard, six ounces; olive oil, four fluid ounces. First dissolve the mercury in the acid, then, while the liquor is hot, mix it with the lard and oil melted together. A stimulating and deter-gent ointment. Tinea capitis, psorophthalmia, indo-lent tumours on the margin of the eyelid, and ulcers in the urethra, are cured by its application.

UNGUENTUM HYDRARGYRI NITRATIS MITIUS. Weak-

er only than the former.

UNGUENTUM HYDRARGYRI NITRICO-OXIDI. Ointment of nitric oxide of mercury. Take of nitric oxide of mercury, an ounce; white wax, two ounces; prepared lard, six ounces. Having melted together the wax and lard, add thereto the nitric oxide of mercury in very fine powder, and mix. A most excellent sti-mulating and escharotic ointment.

UNQUENTUM HYDRARGYRI PRÆCIPITATI ALBI. Ointunguentum calcis hydrargyri albæ. Take of white precipitate of mercury, formerly called unguentum calcis hydrargyri albæ. Take of white precipitate of mercury, a drachm; prepared lard, an ounce and a half. Having melled the lard over a slow fire, add the precipitated mercury and mix. A useful ointment to destroy verminin the head, and to assist in the removal of scald head, venereal ulcers of children,

and cutaneous eruptions.

UNGUENTUM LYTTE. See Unguentum cantharidis.

UNGUENTUM OPETHALMICUM. Ophthalmic ointment
of Janin. Take of prepared log's-lard, half an ounce; prepared tutty, Armenian bole, of each two drachms; white precipitate one drachm. Mix. This celebrated outment may be used for the same diseases of the eye and eyelid as the ung. hydrarg. nitratis. It must be at first weakened with about twice its quantity of hog's-

land.

UNGUENTUM PICIS ARIDÆ. See Unguentum resinæ

nigræ.

Unguentum picis liquidæ. Tar ointment, formerly called unguentum picis; unguentum e pice.

Take of tar, prepared suct, of each a pound. Melt them together, and strain the mixture through a linen cloth. This is applicable to cases of tinea capitis, and

UNGUENTUM RESINE FLAVE. Yellow basilicon is in general use as a stimulant and detersive; it is an elegant and useful form of applying the resin.

Unguentum resine nigre. Unguentum picis

Unguentum RESINE NIGRE. Unguentum picis arida. Pitch ointment, formerly called unguentum basilicum nigrum, vel tetrapharmacum. Take of pitch, yellow wax, yellow resin, of each nine ounces; olive oil, a pint. Meltthem together, and strain the mixture through a linen cloth. This is useful for the same purposes as the tar ointment.

UNQUENTUM SAMBUCI. Elder ointment, formerly called unguentum sambucinum. Take of elder flowers, two pounds; prepared lard, two pounds. Boil the elder flowers in the lard until they become crisp, then strain the ointment through a linen cloth. A cooling

and emollient preparation.

Sulphur ointment, for-UNGUENTUM SULPRURIS. merly called unguentum e sulphure. Take of sublimed sulphur, three ounces; prepared lard, half a pound. Mix. The most effectual preparation to destroy the itch. It is also serviceable in the cure of other cuta-

neous eruptions.

UNGUENTUM SULPHURIS COMPOSITUM. Compound sulphur ointment. Take of sublined sulphur, half a pound; white hellebore-root, powdered, two ounces; nitrate of potassa, a drachm; soft soap, half a pound; prepared lard, a pound and a half. Mix. This preparation is introduced into the last London Pharmaco-paraign as a more officacions remedy for italy they come pæia as a more efficacious remedy for itch than common sulphur ointment. In the army, where it is generally used, the sulphur vivum, or native admixture of sulphur with various heterogeneous matters, is used

instead of sublimed sulphur.

UNGUENTUM VERATEL. White hellebore ointment, formerly called unguentum hellebori albi. Take of white hellebore-root, powdered, two ounces: prepared lard, eight ounces: oil of lemons, twenty minims.

Mix.

Unguentum zinci. Zinc ointment. Take of the oxide of zinc, an ounce; prepared lard, six ounces.

Mix. A very useful application to chronic ophthalmia and relaxed ulcers.

U'NGUIS. (Unguis, is, m.; from ovel, a hook.)

1. The nail. The nails are horny lamina situated at the extremities of the fingers and toes; composed of

coagulated albumen, and a little phosphate of lime.

2. An abscess or collection of pus between the lamella of the cornea transparens of the eye; so called from its resemblance to the lunated portion of the nail of the finger.

3. The lachrymal bone is named os unguis, from its

resemblance to a nail of the finger.

resemblance to a nail of the finger.

4. In botany, unguis, or the claw: applied to the thin part of the petal of a polypetalous corolla.

U'NGULA CABALLINA. See Tussilago.

UNIFLORUS. Bearing one flower.

UNIO. (Unio, pl. uniones; from unus, one: so called because there is never more than one found in the cape chall. the same shell, or, according to others, for that many

the same shell, or, according to others, for that many being found in one shell, not any one of them is like the other.) The pearl. See Margarita.

URACHUS. (From συρου, urine, and εχω, to contain.) Urinaculum. The ligamentous cond which it runs, and terminates in the umbilical cord. In the focuses of brute animals which the ancients mostly. fœtuses of brute animals, which the ancients mostly dissected, it is a hollow tube, and conveys the urine to the allantoid membrane.

URA'GIUM. (From oupayos, the hinder part of an

army.) The apex or extreme point of the heart. URANGLIMMER. Green mica. Chalcolite. ore of uranium.

(From ovpavos, the firmament: so URANIS'CUS.

URANIS'CUS. (From ovpavos, the firmament: so called from its arch.) The palate.

URANITE. See Uranium.

URA'NIUM. Uranite This metal was discovered by Klaproth, in the year 1789. It exists combined with sulphur, and a portion of iron, lead, and silex, in the mineral termed Pechblende, or oxide of uranium. Combined with carbonic acid it forms the chalcolite, or green mica: and mixed with oxide of iron, it constitutes the uranitic ochre. It is always found in the stitutes the uranitic ochre. It is always found in the state of an oxide with a greater or smaller portion of iron, or mineralized with sulphur and copper. The oresof uranium are of a blackish colour, inclining to a

URI URE

dark iron-gray, and of a moderate splendour; they are of a close texture, and when broken present a somewhat uneven, and in the smallest particles a conchoidal surface. They are found in the mines of

Properties of uranium.-Uranium exhibits a mass of small metallic globules, agglutinated together. Its colour is a deep gray on the outside, in the inside it is a pale brown. It is very porous, and is so soft, that it may be scraped with a knife It has but little lustre. Its specific gravity is between eight and nine. more difficult to be fused than even manganese. W intensely heated with phosphate of soda and ammonia, or glacial phosphoric acid, it fuses with them into a grass-green glass. With soda or borax it melts only into a gray, opaque, scoriaceous bead. It is soluble in sulphuric, nitric, and muriatic acids. It combines with sulphur and phosphorus, and alloys with mercury. It has not yet been combined with other combustible bodies. It decomposes the nitric acid and becomes converted into a yellow oxide. The action of uranium alone upon water, &c. is still unknown, probably on account of its extreme scarcity.

Method of obtaining uranium.—In order to obtain uranium, the pechblende is first freed from sulphur by heat, and cleared from the adhering impurities as carefully as possible. It is then digested in nitric acid; the metallic matter that it contains is thus completely dissolved, while part of the sulphur remains undissolved, and part of it is dissipated under the form of sulphuretted hydrogen gas. The solution is then precipitated by a carbonated alkali. The precipitate has a lemonyellow colour when it is pure. This yellow carbonate is made avroused to a violent fully as possible. It is then digested in nitric acid; the is made into a paste with oil, and exposed to a violent heat, bedded in a crucible well lined with charcoal.

Klaproth obtained a metallic globule 28 grains in weight, by forming a ball of 50 grains of the yellow carbonate, with a little wax, and by exposing this ball in a crucible lined with charcoal to a heat equal to 179° of Wedgewood's pyrometer. Richter obtained in a single experiment 100 grains of this metal, which seemed to be free from all admixture. There are probably two evides of warnium the arctavide which is a bably two oxides of uranium, the protoxide, which is a grayish black; and the peroxide, which is yellow.

URANOCHRE. An ore of uranium.

URATE. Uras. A compound of uric or lithic acid,

with a salifiable basis.

URCE'OLA. (From urceolus, a small pitcher: so named from its uses in scouring glazed vessels.)

herb feverfew.

UREA. A constituent of urine. The best process for preparing it is to evaporate urine to the consistence of syrup, taking care to regulate the heat towards the end of the evaporation; to add very gradually to the syrup its volume of nitric acid (24º Baumé) of 1.20; to stir the mixture, and immerse it in a bath of iced water, to harden the crystals of the acidulous nitrate of urea which precipitate; to wash these crystals with ice-cold water, to drain them, and press them between the folds of blotting paper. When we have thus separated the adhering heterogeneous matters, we redissolve the captering neerogeneous maters, we re-dissolve the crystals in water, and add to them a suf-ficient quantity of carbonate of potassa, to neutralize the nitric acid. We must then evaporate the new liquor, at a gentle heat, almost to dryness, and treat the residuum with a very pure alkohol, which dis-solves only the urea. On concentrating the alkoholic solution, the urea crystallizes.

The preceding is Thenard's process, which Dr. Prout has improved. He separates the nitrate of potassa by crystallization, makes the liquid urea into a paste with animal charcoal, digests this with cold water, filters, concentrates, then dissolves the new colourless urea in

alkohol, and lastly, crystallizes.

Urea crystallizes in four-sided prisms, which are transparent and colourless, with a slight pearly lustre. It has a peculiar, but not urinous odour; it does not affect litmus or turmeric papers; it undergoes no change affect litmus or turmeric papers; it undergoes no change from the atmosphere, except a slight deliquescence in very damp weather. In a strong heat it melts, and is partly decomposed and partly sublimed without change. The spec. grav. of the crystals is about 1.35. It is very soluble in water. Alkohol, at the temperature of the atmosphere, dissolves about 20 per cent.; and, when boiling, considerably more than its own weight, from which the uses separates, on cooling, in its crystalline which the urea separates, on cooling, in its crystalline form. The fixed alkalies and alkaline earths decom-

pose it. It unites with most of the metallic oxides, and forms crystalline compounds with the nitric and oxalic acids.

Urea has been recently analyzed by Dr. Prout and Berard. The following are its constituents :-

Hydrogen Carbon Oxygen Azote	10.80 19.40 26.40	per cent. 6.66 19.99 26.66 46.66	per atom. 2 = 2.5 1 = 7.5 1 = 10.0 1 = 17.5
	100.00	100.00	37.5

Uric, or lithic acid, is a substance quite distinct from urea in its composition. This fact, according to Dr. Prout, explains, why an excess of urea generally accompanies the phosphoric diathesis, and not the lithic. He has several times seen urea as abundant in the urine of a person where the phosphoric diathesis prevailed, as to crystallize spontaneously on the addition of nitric acid, without being concentrated by evapo-

As urea and uric acid, says Berard, are the most azotized of all animal substances, the secretion of urine appears to have for its object the separation of the excess of azote from the blood, as respiration sepa-

rates from it the excess of carbon.

URE DO. (From uro, to burn.) An itching or burning sensation of the skin, which accompanies many diseases. The nettle-rash is also so called.

URET. The compounds of simple inflammable

bodies with each other, and with metals, are commonly designated by this word; as sulphuret of phosphorus, carburet of iron, &c. The terms bisulphuret, bisulphate, &c. applied to compounds, imply that they contain twice the quantity of sulphur, sulphuric acid, &c. existing in the respective sulphuret, sulphate, &c.

URETER. (Ureter, eris, m.; from oupon, urine.)
The membranous canal which conveys the urine from the kidney to the urinary bladder. At its superior part it is considerably the largest, occupying the greatest portion of the pelvis of the kidney; it then contracts to the size of a goose quill, and descends over the psoas magnus muscle and large crural vessels into the pelvis, in which it perforates the urinary bladder very obliquely. Its internal surface is lubricated with mucus to defend it from the irritation of the urine in passing.

URETERITIS. (From ουρητηρ, the ureter.) An

inflammation of the ureter.

URE THRA. (From ovpov, the urine: because it is the canal through which the urine passes.) A membranous canal running from the neck of the bladder through the inferior part of the penis to the extremity of the glans penis, in which it opens by a longitudinal orifice, called meatus urinarius. In this course, it first passes through the prostate gland, which portion is distinguished by the name of the prostatical wrethra; it then becomes much dilated, and is known by the name of the bulbous part, in which is situated a cutaneous eminence called the caput gallinaginis or verumentanum, around which are ten or twelve orifices of the excretory ducts of the prostate gland, and two of the spermatic vessels. The remaining part of the urethra contains a number of triangular mouths, which are the lacuna, or openings of the excretory duets of the mucous glands of the urethra.

URETHRITIS. (From ουρηθρα, the urethra.) An inflammation in the urethra. See Gonorrhaa.

URE'TICA. (From ουρου, urine.) Medicines which promote a discharge of urine.

promote a discharge of urine.

U'RIAS. (From super, urine.) URIC ACID. See Lithic acid. URI'NA. See Urine. The urethra.

URI'NA. See Orine.
URINA'CULUM. See Urachus.
URI'NE ARDOR. See Dysuria.
URINA'RIA. (From urina, urine: so named from a diuretic qualities.) The herb dandelion. See its diuretic qualities.)

Leontodon tarazacum.
URINARY. (Urinarius; from urina, urine.) Appertaining to urine.

URINARY BLADDER. Vesica urinaria. The bladder is a membranous pouch, capable of dilatation and contraction, situated in the lower part of the abdomen, immediately behind the symphysis pubis, and opposite to the beginning of the rectum. Its figure is nearly that of a short oval. It is broader on the fore and back than on the lateral parts; rounder above than below,

when empty; and broader below than above, when full. It is divided into the body, neck, and fundus, or upper part; the neck is a portion of the lower part, which is contracted by a sphincter muscle. This organ is made up of several coats; the upper, posterior, and lateral parts are covered by a reflection of the broader of the present the present of the present the present of the present the present of the p the peritoneum, which is connected by cellular substance to the muscular coat. This is composed of several strata of fibres, the outermost of which are mostly longitudinal, the interior becoming gradually more transverse, connected together by reticular menibrane. Under this is the cellular coat, which is nearly of the same structure with the tunica nervosa of the stomach. Winslow describes the internal or villous coat as somewhat granulated and glandular; but this has been disputed by subsequent anatomists. ever, a mucous fluid is poured out continually from it. which defends it from the acrimony of the urine. Sometimes the internal surface is found very irregular, and full of rugæ, which appear to be occasioned merely by the strong contraction of the muscular fibres, and may be removed by distending it. The sphincter does not seem to be a distinct muscle, but merely formed by the transverse fibres being closely arranged about the neck. The urine is received from the ureters, which enter the posterior part of the biadder obliquely; and when a certain degree of distention has occurred, the muscular fibres are voluntarily exerted to expel it.

URINE. (Urina, &, f. Oupov; from opovw, to sh out.) The saline liquid, secreted in the kidneys, rush out.) and dropping down from them, guttatim, through the ureters, into the cavity of the urinary bladder. sccretory organ is composed of the arterious vessels of the cortical substance of the kidneys, from which the urine passes through the uriniferous tubuli and renal papillæ into the renal pelvis; whence it flows, drop by drop, through the ureters, into the cavity of the urinary bladder; where it is detained some hours, and at length, when abundant, climinated through the urethra.

Few of the apparatus of secretion are so complicated as that of the urine; it is composed of the two kidneys, of the ureters, of the bladder, and the urethra; besides, the abdominal muscles contribute to the action of these different parts, among which the kidneys alone form urine; the others serve in its transportation

and expulsion.

Situated in the abdomen, upon the sides of the vertebral column, before the last false ribs and the quadratus lumborum, the kidneys are of small volume relatively to the quantity of fluid they secrete. are generally surrounded with a great deal of fat. Their parenchyma is composed of two substances; the one exterior, vascular, or cortical, the other tubular, disposed in a certain number of cones, the base of which corresponds to the surface of the organ, and their summits unite in the membranous cavity called petris. Its cones appear formed by a great number of small hollow fibres, which are excretory canals of a particular kind, and which are generally filled with

In respect of its volume, no organ receives so much blood as the kidney. The artery which is directed there is large, short, and proceeds immediately from the aorta; it has easy communication with the veins and the tubulous substance, as may easily be ascertained by means of the most coarse injections, which, being thrown into the renal artery, pass into the veins and into the pelvis, after having filled the cortical sub-

The filaments of the great sympathetic alone are dis-tributed to the kidneys. The calices, pelvis, and ureter form together a canal which commences in the kidneys, where it embraces the top of the mamillary processes, and, placed at the sides of the vertebral column, it goes in the bottom of the pelvis to the bladder, where it terminates. This last organ is an extensible and contractile sac, intended to hold the fluid secreted by the kidneys, and which communicates with the exterior by a canal of considerable length in man, but very short in woman, called urethra.

The posterior extremity of the urethra is, only in man, surrounded by the prostate gland, which is considered by certain anatomists as a collection of mucous follicles. Two small glands placed before the anus pour a particular fluid into this canal. Two muscles, which descend from the pubis towards the rectum, pass upon the sides of the part of the bladder which ends in | H h h

URI

carries it more or less upwards.

If the pelvis is cut open in a living animal, the urine the kidney, and then by little and little it enters into the ureter, through the whole length of which it passes. It thus arrives at the bladder, into which it penetrates by a constant exudation or dribbling.

A stight compression upon the uriniferous cones makes the urine pass out in considerable quantity: but instead of being limpid; as when it passes out naturally, it is muddy and thick. It appears then to be filtered by the hollow fibres of the tubular substance.

Neither the pelvis nor the ureter being contractile, probably the power which produces the motion of the urine is, on the one hand, that by which it is poured into the pelvis; and on the other, the pressure of the abdominal muscles, to which may be added, when we stand upright, the weight of the liquid.

Under the influence of these causes, the urine passes into the bladder, and slowly distends this organ, sometimes to a considerable degree; this accumulation being permitted by the extensibility of different organs.

How does the urine accumulate in the bladder? Why

does it not flow immediately by the urethra? and why does it not flow back into the ureter? The answer is easy for the ureters. These conduits pass a considera-ble distance into the sides of the bladder. In proportion as the urine distends this organ, it flattens the ureters, and shuts them so much more firmly as it is more abundant. This takes place in the dead body as well as in the living; also, a liquid, or even air, injected into the bladder, by the urethra, never enters the ureters. It is, then, by a mechanism analagous to that of certain valves, that the urine does not return towards the kidneys.

It is not so easy to explain why the urine does not flow by the urethra. Several causes appear to contri-bute to this. The sides of this canal, particularly to-wards the bladder, have a continual tendency to con tract, and to lessen the cavity; but this cause alone would be insufficient to resist the efforts of the urine to escape, when the bladder is full. In the dead body, in which the canal contracts nearly in the same manner, it has but a very weak resistance, and does not prevent the passage of the liquid outwards, though the bladder

be very little compressed.

The angle of the bladder with the urethra, when it is strongly distended, may also present an obstacle to the passage of the urine; but the principal cause, most probably, is the contraction of the elevating muscles of the anus, which, either by the disposition to contraction of the muscular fibres, or by their contraction under the influence of the brain, press the urethra upwards, compress its sides with more or less force against each other, and thus shut its posterior orifice.

Exerction of urine.—As soon as there is a certain quantity of urine in the bladder, we feel an inclination to discharge it. The mechanism of this expulsion deserves particular attention, and has not always been

well understood.

If the urine is not always expelled, this ought not to be attributed to the want of contraction in the bladder, for this organ always tends to contract; but, by the influence of the causes that we have noticed, the internal orifice of the urethra resists with a force that the contraction of the bladder cannot surmount. The will produces this expulsion, 1st, by adding the contraction of the abdominal muscles to that of the bladder; 2dly by relaxing the *levatores ani*, which shut the urethra. The resistance of this canal being once overcome, the contraction of the bladder is sufficient for the complete expulsion of the urine it contained; but the action of the abdominal muscles may be added, and then the urine passes out with much greater force. We may also stop the flowing of the urine all at once, by contracting the levators of the anus

The contraction of the bladder is not voluntary, though by acting on the abdominal muscles, and the levators of the anus, we may cause it to contract when

The urine that remains in the urethra after the bladder is empty, is expelled by the contraction of the mus-cles of the perinaum, and particularly by that of the acceleratores urina.

Though the quantity of urine is very copious, and though it contains several proximate principles which are not found in the blood, and consequently a chemical action takes place in the kidneys, the secretion of the

urine is nevertheless very rapid.

The physical properties of the urine are subject to If rhubarb or madder has been used, great variations. it becomes of a deep yellow, or blood red; if one has breathed an air charged with vapours of oil or turpentine, or if a little rosin has been swallowed, it takes a violet colour. The disagreeable odour that it takes by the use of asparagus, is well known.

Its chemical composition is not less variable. The more use that is made of watery beverages, the more considerable the total quantity and proportion of water becomes. If one drinks little, the contrary happens.

The uric acid becomes more abundant when the regimen is very substantial, and the exercise trifling-This acid diminishes, and may even disappear altogether, by the constant and exclusive use of unazotized food, such as sugar, gum, butter, oil, &c. Certain salts, carried into the stomach, even in small quantity, are found in a short time in the urine.

The extreme rapidity with which this translation takes place, has made it be supposed there is a direct communication between the stomach and the bladder. Even now there are considerable numbers of partisans

in favour of this opinion.

It is not yet long since a direct canal from the stomach to the bladder was supposed to exist, but this passage has no existence. Others have supposed, without giving any proof, that the passage took place by the cellular tissue, by the anastomoses of the lymphatic vessels, &c.

Darwin having given to a friend several grains of nitrate of potassa, in half an hour he let blood of him, and collected his urine. The salt was found in the urine, but not in the blood. Brande made similar observations with prussiate of potassa. He concluded from it that the circulation is not the only means of communication between the stomach and the urinary organs, but without giving any explanation of the existing means. Sir Everard Home is also of this opinion.

I have made experiments in order to clear up this important question, and I have found, 1st, That whenever prussiate of potassa is injected into the veins, or absolved in the intestinal canal, or by a serous membrane, it very soon passes into the bladder, where it is easily recognised among the urine. 2dly, that if the quantity of prussiate injected is considerable, the tests can discover it in the blood; but if the quantity is small, its presence cannot be recognised by the usual means. 3dly, That the same result takes place by mixing the prussiate and blood together in a vessel. 4thly, That the same salt is recognised in all proportions in the urine. It is not extraordinary, then, that Darwin and Brande did not find in the blood the substance that they distinctly perceived in the urine.

With regard to the organs that transport the liquids of the stomach and intestines into the circulating system, it is evident, according to what we have said, in speaking of the chyliferous vessels, and the absorption of the veins, that these liquids are directly absorbed by the veins, and transported by them to the liver and the heart; so that the direction which these liquids follow, in order to reach the veins, is much shorter than is generally admitted, viz. by the lymphatic vessels, the mesenteric glands, and the thoracic duct."—Magendie's

Phusiology.

The urine of a healthy man is divided in general

1. Crude, or that which is emitted one or two hours after eating. This is for the most part aqueous, and often vitiated by some kinds of food.

 Cocted, which is eliminated some hours after the digestion of the food, as that which is emitted in the morning after sleeping. This is generally in smaller quantity, thicker, more coloured, more acrid than at any other time. Of such cocted urine, the colour is usually citrine, and not unhandsome.

The degree of heat agrees with that of the blood. Hence in atmospheric air it is warmer, as is perceived if the hand be washed with urine. The specific gravity is greater than water, and that emitted in the morning is always heavier than at any other time. 'Inc smell of fresh urine is not disagreeable. The

what thicker than water. The quantity depends on that of the liquid drink, its diuretic nature, and the temperature of the air.

Changes of urine in the air .- Preserved in an open vessel, it remains pellucid for some time, and at length there is perceived at the bottom a nubecula, or little cloud, consolidated as it were from the gluten. This nubecula increases by degrees, occupies all the urine, and renders it opaque. The natural smell is changed into a putrid cadaverous one; and the surface is now generally covered with a cuticle, composed of very minute crystals. At length, the urine regains its transparency, and the colour is changed from a yellow to a prown; the cadaverous small assets from a yellow to a parency, the cadaverous smell passes into an alkaline; and a brown, grumous sediment falls to the bottom, filled with white particles, deliquescing in the air, and so conglutinated as to form, as it were, little soft calculi.

Thus two sediments are distinguishable in the urine; the one white and gelatinous, and separated in the beginning; the other brown and grumous, deposited

by the urine when putrid.

Spontaneous degeneration .- Of all the fluids of the body, the urine first putrifies. In summer, after a few hours it becomes turbid, and sordidly black; then deposites a copious sediment, and exhales a fetor like that of putrid cancers, which at length becomes cada-verous. Putrid urine effervesces with acids, and, if distilled, gives off, before water, a urinous volatile

The properties of healthy urine are,
1. Urine reddens paper stained with turnsole and with the juice of radishes, and therefore contains an This acid has been generally considered as the phosphoric, but Thenard has shown that in reality it is the acetic.

2. If a solution of ammonia be poured into fresh urine, a white powder precipitates, which has the pro-

perties of phosphate of lime.

3. If the phosphate of lime precipitated from urine be examined, a little magnesia will be found mixed with it. Fourcroy and Vauquelin have ascertained that this is owing to a little phosphate of magnesia which urine contains, and which is decomposed by the alkali employed to precipitate the phosphate of lime.

4. Proust informs us that carbonic acid exists in urine, and that its separation occasions the froth which appears during the evaporation of urine,

5. Proust has observed, that urine kept in new casks deposites small crystals, which effloresce in the air, and fall to powder. These crystals possess the properties of the carbonate of lime.

6. When fresh urine cools, it often lets fall a brick coloured precipitate, which Scheele first ascertained to be crystals of uric acid. All urine contains this acid, even when no sensible precipitate appears when it

7. During intermitting fevers, and especially during diseases of the liver, a copious sediment of a brick-red colour is deposited from urine. This sediment contains the rosacic acid of Proust.

8. If fresh urine be evaporated to the consistence of a syrup, and muriatic acid be then poured into it, a precipitate appears which possesses the properties of

benzoic acid.
9. When an infusion of tannin is dropped into urine, a white precipitate appears, having the properties of the combination of tannin and albumen, or gelatine. Their quantity in healthy urine is very small, often indeed not sensible. Cruickshanks found that the precipitate afforded by tannin in healthy urine amounted

to 1-240th part of the weight of the urine.

10. If urine be evaporated by a slow fire to the consistence of a thick syrup, it assumes a deep brown colour, and exhales a fætid ammoniacal odour. When allowed to cool, it concretes into a mass of crystals, composed of all the component parts of urine. If four times its weight of alkohol be poured into this mass, at intervals, and a slight heat be applied, the greatest part is dissolved. The alkohol which has acquired a brown colour is to be decanted off, and distilled in a retort in a sand heat till the mixture has boiled for some time, and acquired the consistence of a syrup. By this time the whole of the alkohol has passed off, and the matter, on cooling, crystallizes in quadrangular plates, which intersect each other. This substance is urea, which composes 9-20ths of the urine, provided the watery part be excluded. It is this substance which characterizes urine, and constitutes it what it is, and to | nates many morbid and acrid substances with the which the greater part of the very singular phenomena

of urine are to be ascribed.

11. According to Fourcroy and Vauquelin, the colour of urine depends upon the urea; the greater the pro-portion of urea the deeper the colour. But Proust has detected a resinous matter in urine similar to the resin of bile, and to this substance he ascribes the colour of

12. If urine be slowly evaporated to the consistence of a syrup, a number of crystals make their appearance on its surface; these possess the properties of the muri-

ate of soda.

13. The saline residuum which remains after the separation of urea from crystallized urine by means of alkohol, has been long known by the names of fusible salt of urine, and microcosmic salt. When these salts are examined, they are found to have the properties of phosphates. The rhomboidal prisms consist of phosphate of ammonia united to a little phosphate of soda, the rectangular tables, on the contrary, are phosphate of soda united to a small quantity of phosphate of ammonia; urine then contains phosphate of soda, and phosphate of ammonia. 14. When urine is cautiously evaporated a few cubic

crystals are often deposited among the other salts; these crystals have the properties of muriate of am-

15. When urine is boiled in a silver basin, it blackens the basin, and if the quantity of urine be large, small crusts of sulphuret of silver may be detached. Hence we see that urine contains sulphur.

Urine then contains the following substances: 10. Albumen. 11. Urea.

1. Water.

 Acetic acid.
 Phosphate of lime. Phosphate of lime. 12. Resin
 Phosphate of magnesia. 13. Muriate of soda.

5. Carbonic acid.

6. Carbonate of lime. Uric acid. 8. Rosacic acid.

14. Phosphate of soda. 15. Phosphate of ammonia.

16. Muriate of ammonia. 17. Sulphur.

9. Benzoic acid.

9. Benzoic acid.

According to Berzelius, healthy human urine is composed of, water 933, urea 30.10, sulphate of potassa 3.71, sulphate of soda 3.16, phosphate of soda 2.94, muriate of soda 4.45, phosphate of ammonia 1.65, muriate of ammonia 1.50, free acetic acid, with lactate of ammonia, animal matter soluble in alkohol, urea adhering to the preceding, altogether 17.14, earthy phosphates with a trace of fluate of lime 1.0, uric acid 1, mucus of the bladder 0.32, silica 0.03, in 1000.0

No liquor in the human body, however, is so variable, in respect to quantity and quality, as the urine; for it varies,

for it varies,

In respect to age: in the fatus it is inodorous, insipid, and almost aqueous; but as the infant grows, it becomes more acrid and fætid; and in old age more

2. In respect to drink: it is secreted in greater quantity, and of a more pale colour, from cold and copious draughts. It becomes green from an infusion of Chi-

nese tea.

 In respect to food: from eating the heads of asparagus, or olives, it contracts a peculiar smell; from the fruit of the opuntia, it becomes red; and from fasting, turbid.

 In respect to medicines: from the exhibition of rhubarb-root, it becomes yellow; from cassia-pulp, green; and from turpentine it acquires a violet odour.

5. In respect to the time of the year: in the winter the urine is more copious and aqueous; but in the summer, from the increased transpiration, it is more sparing, higher coloured, and so acrid that it sometimes occasions strangury. The climate induces the same difference.

6. In respect of the muscular motion of the body; it is secreted more sparingly, and concentrated by motion; and is more copiously diluted, and rendered more crude by rest.

7. In respect of the affections of the mind: thus fright makes the urine pale.

Use.—The urine is an excrementitious fluid, like lixivium, by which the human body is not only liberated from the superfluous water, but also from the superfluous salts, and animal earth; and is defended from corruption

Lastly, the vis medicatrix nature sometimes elimi-

urine; as may be observed in fevers, dropsies, &c.

URINE, RETENTION OF. A want of the ordinary secretion of urine. In retention of urine there is none secreted: in a suppression, the urine is secreted but cannot be avoided.

Urine, suppression of. See Ischuria.
UROCRI'SIA. (From ουρου, urine, and κρενω, to judge. The judgment formed of diseases by the inspection of urine.

URORRHÆ'A. (From ουρόν, the urine, and ρεω, to flow.) A discharge of the urine.

UROSCO'PIA. (From ουρόν, the urine, and σκοπεω, to inspect.) Inspection of urine, that a judgment of diseases may be made from its appearance

URSI'NA RADIX. The root of the plant called baldmoney. See Athus a meum.
URSINE. Ursinus. Of or belonging to the bear.
URSUS. 1. The bear.

URSUS. 1. The bear.

2. The name of a genus of animals. Class, Mammalia; Order, Ferw. It comprehends the several kinds of bears, the badger, and racoon.

URTICA. (Ab urendo; because it excites an itching and pustules like those produced by fire.) 1. The name of a genus of plants in the Linnwan system. Class Monacia; Order, Tetrandria. The nettle.

2. The pharmacopæial name of the common nettle. See Urtica divisa.

See Urtica divica.

URTICA DIOICA. The systematic name of the common stinging-nettle. This plant is well known, and though generally despised as a noxious weed, has been long used for medical, culinary, and economical The young shoots in the spring possess diu-

retic and antiscorbutic properties, and are with these intentions boiled and eaten instead of cabbage greens.

URTICA MORTUA. See Lamium album.

URTICA PILULIFERA. The systematic name of the pillbearing nettle. Urtica romana. The seed was formerly given against diseases of the chest, but is now the content of the pillbearing nettle. deservedly forgotten. To raise an irritation in paralytic limbs, the fresh plant may be employed as producing a more permanent sting than the common nettle.

nettle.

URTICA ROMANA. See Urtica pilulifera.

URTICA URENS. The systematic name of a less nettle than the dioica, and possessing similar virtues.

URTICA'RIA. (From urtica, a nettle.) Febris urticata; Uredo; Purpura urticata; Scarlatina urtica. The nettle-rash. A species of exanthematous fever, known by pyrexia and an eruption on the skin like that produced by the sting of the nettle. The little elevations, called the nettle-rash, often appear instantaneously, especially if the skin be rubbed or scratched, and seldom stay many hours in the same place, and and seldom stay many hours in the same place, and sometimes not many minutes. No part of the body is exempt from them; and where many of them rise together, and continue an hour or two, the parts are often considerably swelled, which particularly happens in the arms, face, and hands. These cruptions will continue to infest the skin, sometimes in one place and sometimes in another, for one or two hours together. sometimes in another, for one or two hours together, two or three times a day, or perhaps for the greatest part of twenty-four hours. In some constitutions they last only a few days, in others many months.

URTICA'TIO. (From wrtica, a nettle.) The whipping a paralytic or benumbed limb with nettles,

in order to restore its feeling.

U'SNEA. See Lichen saxatilis.

U'SNEA. See Lichen saxatilis.

UTERA'RIA. (From uterus, the womb.) Medicines appropriated to diseases of the womb.

UTERINE. Uterinus. Appertaining to the uterus. Uterine fury. See Nymphomania.

U'TERUS. Yotepa. Matrix; Ager natura; Hystera; Metra; Utriculus. The womb. A spongy receptacle resembling a compressed pear, situated in the cavity of the pelvis, above the vagina, and between the urinary bladder and rectum.

The form of the uterus resembles that of an oblong pear flattened, with the depressed sides placed towards the ossa pubis and sacrum; but, in the impregnated state, it becomes more oval, according to the degree of its distention. For the convenience of description, and for some practical purposes, the uterus is distinguished into three parts. The fundus, the body, and the cervix; the upper part is called the fundus, the lower the cervix; the space between them, the extent of which is undefined, the body. The uterus is about UTE

three inches in length, about two in breadth at the fundus, and one at the cervix. Its thickness is dif-ferent at the fundus and cervix, being at the former usually rather less than half an inch, and at the latter somewhat more; and this thickness is preserved throughout pregnancy, chiefly by the enlargement of the veins and lymphatics; there being a smaller change in the size of the arteries. But there is so great a variety in the size and dimensions of the uterus in different women, independent of the states of virginity, marriage, or pregnancy, as to prevent any very ac-curate mensuration. The cavity of the uterus corres-ponds with the external form; that of the cervix leads from the os uteri, where it is very small, in a straight direction, to the fundus, where it is expanded into a triangular form, with two of the angles opposed to the entrance into the Fallopian tubes; and at the place of junction between the cervix and the body of the uterus, the cavity is smaller than it is in any other part. is a swell or fulness of all the parts towards the cavity, which is sometimes distinguished by a prominent line running longitudinally through its middle. The villous coat of the vagina is reflected over the os uteri, and is continued into the membrane which lines the cavity of the uterus. The internal surface of the uterus is corrugated in a beautiful manner, but the ruge, or wrinkles, which are longitudinal, lessen as they advance into the uterus, the fundus of which is smooth. In the intervals between the rugæ are small orifices, like those in the vagina, which discharge a mucus, serving, besides other purposes, that of closing the os uteri very curiously and perfectly during pregnancy. The substance of the uterus, which is very firm, is composed of arteries, veins, lymphatics, nerves, and muscular fibres, curiously interwoven and connected together by cellular membrane. The muscular fibres are of a pale colour, and appear also in their texture somewhat different from muscular fibres in other parts of the body. The arteries of the uterus are the sper-matic and hypogastric. The spermatic arteries arise from the anterior part of the aorta, a little below the emulgents, and sometimes from the emulgents. pass over the psoc muscles behind the peritonaum, enter between the two laminæ or duplicatures of the peritonæum which form the broad ligaments of the uterus, and proceed to the uterus, near the fundus of which they insinuate themselves, giving branches in their passage to the ovaria and Fallopian tubes. The hypogastric arteries are on each side a considerable branch of the internal iliacs. They pass to the sides of the body of the uterus, sending off a number of smaller branches, which dip into its substance. Some branches also are reflected upwards to the fundus uteri, which anastomose with the spermatic arteries, and others are reflected downwards, supplying the vagina. The veins which reconduct the blood from the uterus are very numerous, and their size in the unimpregnated state is proportioned to that of the arteries; but their enlargement during pregnancy is such, that the orifices of some of them, when divided, will admit even of the end of a small finger. The veins anastomose in the manner of the arteries which they accompany out of the uterus, and then. baving the same names with the arteries, spermatic and hypogastric, the former proceeds to the vena cava on the right side, and on the left to the emulgent vein; and the latter to the internal

From the substance and surfaces of the uterus an infinite number of lymphatics arise, which follow th course of the hypogastric and spermatic blood-vessels. The first pass into the gland of the internal iliac plexus, and the other into the glands which are situated near the origin of the spermatic arteries. Of these Nuck

first gave a delineation.

The uterus is supplied with nerves from the lower mesocolic plexus, and from two small flat circular ganglions, which are situated behind the rectum. These ganglions are joined by a number of small branches from the third and fourth sacral nerves. The ovaria derive their nerves from the renal plexus. By the great number of nerves, these parts are rendered very irritable, but it is by those branches which the uterus receives from the intercostal, that the intimate consent netween it and various other parts is chiefly preserved. The muscular fibres of the uterus have been described in a very different mainer by anatomists, some of whom have asserted that its substance was chiefly

muscular, with fibres running in transverse, orbicular, or reticulated order, while others have contended that there were no muscular fibres whatever in the uterus. In the unimpregnated uterus, when boiled for the purpose of a more perfect examination, the former seems to be a true representation; and when the uterus is distended towards the latter part of pregnancy, these fibres are very thinly scattered; but they may be dis-covered in a circular direction, at the junction between the body and the cervix of the uterus, and surrounding the entrance of each Fallopian tube in a similar order. Yet it does not seem reasonable to attribute the time of labour to its muscular fibres only, if we are to judge of the power of a muscle by the number of fibres of which it is composed, unless it is presumed that those of the uterus are stronger than in common muscles. With respect to the glands of the uterus, none are discoverable dispersed through its submance upon the inner surface of the cervix; between the rugæ there are lacunæ which secrete mucus, and there are small follicles at the edge of the os uteri. These last are only observable in a state of pregnancy, when they are much enlarged. From the angles at the fundus of the uterus, two processes of an irregular round form ori-ginate, called from the name of the first describer, the Fallopian tubes. They are about three inches in length, and, becoming smaller in their progress from the uterus, have an uneven, fringed termination, called The canal which passes through these the fimbriæ. tubes is extremely small at their origin, but it is gradually enlarged, and terminates with a patulous orifice, the diameter of which is about one-third of an inch, surrounded by the fimbriæ. It is also lined by a very fine vascular membrane, formed into serpentine plice. Through this canal the communication between the uterus and ovaria is preserved. The Fallopian tubes are wrapped in duplicatures of the peritonæum, which are called the broad ligaments of the uterus; but a portion of their extremities, thus folded, hang loose on each side of the pelvis. From each lateral angle of the uterus, a little before and below the Fallopian tubes, the round ligaments arise, which are composed of arteries, veins, lymphatics, nerves, and a fibrous structure. These are connected together by cellular membrane, and the whole is much enlarged during pregnancy. They receive their outward covering from the peritoneum, and pass out of the pelvis through the ring of the external oblique muscle to the groin, where the vessels subdivide into small branches, and terminate at the mons veneris and contiguous parts. From the insertion of these ligaments into the groin, the reason appears why that part generally suffers in all the diseases and affections of the uterus, and why the inguinal glands are in women so often found in a morbid or enlarged state. The duplicatures of the peritonæum, in which the Fallopian tubes and ovaria are involved, are called the broad ligaments of the uterus. These prevent the entanglement of the parts, and are conductors of the vessels and nerves, as the mesentery is of those of the intestines. Both the round and broad ligaments alter their position during pregnancy, appearing to rise lower and more forward than in the unimpregnated state. Their use is supposed to be that of preventing the descent of the uterus, and to regulate its direction when it ascends into the cavity of the abdomen; but whether they answer these pur poses may be much doubted. The use of the womb is for menstruation, conception, nutrition of the fœtus, and parturition. The uterus is liable to many diseases, the principal of which are retroversion and its falling and parturition. The uterus is liable to many diseases, the principal of which are retroversion and its falling down, hydatids, dropsy of the uterus, moles, polypes, ulceration, cancer, &c.

Uterus, retroversion of. By the term retroversion, such a change of the position of the uterus is understood, that the fundus is turned backwards and downwards upon its cervix, between the vagina and rectum, and the os uteri is turned forwards to the pubis, and upwards, in proportion to the descent of the fundus, so that hy an examination per vaginam, it cannot be felt, or not without difficulty, when the uterus is retroverted. By the same examination there may also be perceived a large round tumour, occupying the inferior part of the cavity of the pelvis, and pressing the vagina towards the pubes. By an examination per anum, the same tumour may be felt, pressing the rectum to the heliow of the sacrum, and if both these examinations are made at the same time, we may

readily discover that the tumour is confined within the Besides the knowledge of the vagina and rectum. retroversion which may be gained by these examina-tions, it is found to be accompanied with other very distinguishing symptoms. There is in every case, together with extreme pain, a suppression of urine; and by the continuance of this distention of the bladder, the tumour formed by it in the abdomen often equals in size, and resembles in shape the uterus in the sixth or seventh months of pregnancy; but it is necessary to observe, that the suppression of urine is frequently absolute only before the retroversion of the uterus, or during the time it is retroverted; for when the retroversion is completed, there is often a discharge of urine, so as to prevent an increase of the distention of the bladder, though not in a sufficient quantity to remove it. There is also an obstinate constipation of the bowels, produced by the pressure of the retroverted uterus upon the rectum, which renders the injection of a clyster very difficult, or even impossible. But it appears that all the painful symptoms are chiefly in consequence of the suppression of urine; for none of those parts which are apt to sympathize in affections or diseases of the uterus are disturbed by its retrover-The retroversion of the uterus has generally occurred about the third month of pregnancy, and sometimes afterdelivery it may likewise happen, where the uterus is, from any cause, enlarged to the size it acquires about the third month of pregnancy, but not with such facility as in the pregnant state, because the enlargement is then chiefly at the fundus. If the uterus is but little enlarged, or if it be enlarged beyond a certain time, it cannot well be retroverted; for, in the first case, should the cause of a retroversion exist, the weight at the fundus would be wanting to produce it; and in the latter the uterus would be raised above the projection of the sacrum, and supported by the

UTRICA'RIA. (From uter, a bottle: so called from its appendages at the end of the leaves resembling bot-

tles, to contain water.) A name of the nepenthes, or wonderful plant."
UTRI'CULUS.

. (Dim. of uter, a bottle: so called 1. The womb.

from its shape.)

2. A little bladder. Applied by botanists to a species of capsule, which varies in thickness, never opens by any valve, and falls off with the seed. Sir J. Smith believes it never contains more than one seed, of which it is most commodiously, in botanical language, called an external coat, rather than a capsule. Gærtner ap-plies it to Chænopodium and Clematis: in the tormer it seems to be pellicula; in the latter, testa.—Smith.
U'VA. (Uva, &, f.; Quasi uvida, from its juice.)

1. An unripe grape.

2. A tumour on the eye resembling a grape.
UVA GRUINA. Crane-berries. The berries of the
Oxycoccos crythrocarpus. They are brought from New-England, and are reckoned antiscorbutic.

Uva Passa Major. The raisin. See Vitis vinifera. Uva Passa Minor. The dried current. See Vitis

corinthica. Uva ursi. Bear's whortle-berry. See Arbutus uva

U'VEA. (From uva, an unripe grape: so called because, in beasts, which the ancients chiefly dissected, it is like an unripe grape.) The posterior lamina of the iris. See Choroid membrane.

U'VULA. (Dim. of uva, a grape.) Cion; Gargareon; Columna oris; Gurgulio; Inter-septum. The small conical fleshy substance banging in the middle of the velum pendulum palati, over the root of the tongue. It is composed of the common membrane of the mouth, and a small muscle resembling a worm which arises from the union of the palatine bone, and descends to the tip of the uvula. It was called Palato staphilinus, by Douglas, and Staphilinus epistaphilinus, by Winslow. By its contraction, the uvula is raised up.

UVULA'RIA. (From wvula; because it cured diseases of the uvula.) See Ruscus hypoglossum.

VA'CCA. The cow. See Milk.
VACCA'RIA. (From vacca, a cow; because it is coveted by cows.) The herb cow's-basil.
VACCINATION. The insertion of the matter to produce the cow-pox. See Variola vaccina.
VACCINIA. See Variola vaccina.

VACCINIA. See Variola vaccina.

VACCINIUM. (Quasi baccinium, from its berry.)
The name of a genus of plants in the Linnwan system.
Class, Octandria; Order, Monogynia.
Vaccinium myrtillus. The systematic name of the myrtle-berry. The berries which are directed in pharmacopæias by the name of bacca myrtillorum, are the fruit of this plant. Prepared with vinegar they are esteemed as antiscorbutics, and when dry possess. are esteemed as antiscorbutics, and when dry possess astringent virtues.

VACCINIUM OXYCOCCOS. The systematic name of the cranberry plant. Ozycoccos palustris; Vaccinia palustris; Vitis idea palustris. Moor-berry. Cranberry. These berries are inserted in some pharmaco-They are about the size of our haws, and are pleasantly acid, and cooling, with which intention they are used medicinally in Sweden. In this country they

are used medicinally in Sweden. In this country they are mostly preserved and made into tarts.

Vaccinium vitis idæa. The systematic name of the red whortleberry. Vitis idæa. The leaves of this plant, vaccinium vitis idæa, of Linnæus, are so adstringent as to be used in some places for tanning. They are said to mitigate the pain attendant on calculous diseases. when given internally in the form of decoction. ripe berries abound with a grateful acid juice; and are esteemed in Sweden as aperient, antiseptic, and refri-gerant, and often given in putrid diseases.

VAGINA. Vagina uteri. The canal which leads from the external orifice of the female pudendum to the uterus. It is somewhat of a conical form, with the narrowest part downwards, and is described as being five or six inches in length, and about two in diameter. But it would be more proper to say, that it is capable of being extended to those dimensions; for in its com-

mon state, the os uteri is seldom found to be more than three inches from the external orifice, and the vagina is contracted as well as shortened. The vagina is is contracted as wen as shortened. The vagina is composed of two coats, the first or innermost of which is villous, interspersed with many excretory ducts, and contracted into plicæ, or small transverse folds, particularly at the fore and back part, but, by child-bearing, these are lessened or obliterated. The second coat is composed of a firm membrane, in which muscular fibres are not distinctly observable, but which are endowed to a certain degree with contractile necessariandegrees. dowed, to a certain degree, with contractile powers like a muscle. This is surrounded by cellular mem-brane, which connects it to the neighbouring parts. A portion of the upper and posterior part of the vagina is also covered by the peritonæum. The entrance of the vagina is constricted by muscular fibres, originating from the rami of the pubis, which run on each side of the pudendum, surrounding the posterior part, and executing an equivalent office, though they cannot be said to form a true sphinter.

executing an equivalent office, though they cannot be said to form a true sphincter.

The upper part of the vagina is connected to the circumference of the os uteri, but not in a straight line, so as to render the cavity of the uterus a continuation of that of the vagina. For the latter stretches beyond the former, and, being joined to the cervix, is reflected over the os uteri, which by this mode of union, is suspended with protuberant line in the vagina and protube pended with protuberant lips in the vagina, and permitted to change its position in various ways and direc-When, therefore, these parts are distended and unfolded at the time of labour, they are continued into each other, and there is no part which can be considered as the precise beginning of the uterus or termination of

the vagina.

the vagina.

The diseases of the vagina are, first, such an abbreviation and contraction as render it unfit for the uses for which it was designed: secondly, a cohesion of the sides in consequence of preceding ulceration: thirdly, cicatrices after an ulceration of the parts; fourthly, excrescences; fifthly, fluor albus. This abbreviation and

contraction of the vagina, which usually accompany each other, are produced by original defective forma-tion, and they are seldom discovered before the time of marriage, the consummation of which they sometimes prevent. The curative intentions are to relax the parts by the use of emollient applications, and to dilate them to their proper size by sponge, or other tents, or, which are more effectual, by bougies gradually enlarged. But the circumstances which attend this disorder, are sometimes such as might lead us to form an erroneous opinion of the disease. A case of this kind, which was under Dr. Denman's care, from the strangury, from the heat of the parts, and the profuse and inflammatory discharge, was suspected to proceed from venereal infection; and with that opinion the patient had been put upon a course of medicine composed of quicksilver, for several weeks, without relief. When she applied to the Doctor, he prevailed upon her to submit to an examination, and found the vagina rigid, so much contracted as not to exceed half an inch in diameter, nor more than one inch and a half in length. The repeated, though fruitless attempts which had been made to complete the act of coition, had occasioned a considerable inflammation upon the parts, and all the suspicious appearances before mentioned. To remove the inflammation she was bled, took some gentle purgative medicines, used an emollient fomentation, and afterward some unctuous applications; she was also advised to live separate from her husband for some time. inflammation being gone, tents of various sizes were introduced into the vagina, by which it was distended, though not very amply. She then returned to her husband, and in a few months became pregnant. Her labour, though slow, was not attended with any extra-ordinary difficulty. She was delivered of a full-sized child, and afterward suffered no inconvenience. Another kind of constriction of the external parts sometimes occurs, and which seems to be a mere spasm. By the violence or long continuance of a labour, by the morbid state of the constitution, or by the negligent and improper use of instruments, an inflammation of the external parts, or vagina, is sometimes produced in such a degree as to endanger a mortification. By careful management this consequence is usually prevented; but in some cases, when the constitution of the patient was prone to disease, the external parts have sloughed away, and in others, equal injury has been done to the vagina. But the effect of the inflammation is usually confined to the internal or villous coat, which is sometimes cast off wholly or partially. An ulcerated surface being thus left, when the disposition to heal has taken place, cicatrices have been formed of different kinds, according to the depth and extent of the ulceration, and there being no counteraction to the contractile state of the parts, the dimensions of the vagina be-come much reduced, or, if the ulceration should not be healed, and the contractibility of the parts continue to operate, the ulcerated surfaces, being brought together, may cohere, and the canal of the vagina be perfectly

Cicatrices in the vagina very seldom become an imediment to the connexion between the sexes; when they do, the same kind of assistance is required as was recommended in the natural contraction or abbreviation of the part; they always give way to the pressure of the head of the child in the time of labour, though in many cases with great difficulty. Sometimes the appearances may mislead the judgment; for the above author was called to a woman in labour, who was thought to have become pregnant, though the hymen remained unbroken; but, on making very particular inquiry, he discovered that this was her second labour, and that the part, which, from its form and situation was supposed to be the hymen, with a small aperture, was a cicatrice, or unnatural contraction of the entrance into the vagina, consequent to an ulceration of the part after her former labour. Fungous ex-crescences arising from any part of the vagina or uterus, have been distinguished, though not very properly, by the general term polypus. See Polypus.

VAGINA OF NERVES. The outer covering of nerves. By some it is said to be a production of the pia mater only, and by others of the dura mater, because it

Vagina of Tendons. A loose membranous sheath, formed by cellular membrane, investing the tendons and containing an unctuous juice, which is secreted by

the vessels of its internal surface. Ganglions are nothing more than an accumulation of this juice.

VAGINA'LIS TUNICA. See Tunica vaginalis

VAGINANS. Sheathing: applied to parts of animals and plants, as the tunica vaginalis or testicle; to leaves which sheath the stem, or each other, as in grasses; and to the leafstalk of the Canna indica, which surrounds the stem like a sheath; hence petiolus

vaginans. VAGITUS. The cry of young children; also the

distressing cry of persons under surgical operation.
VA'GUM, PAR. See Par vagum.
VALERIAN. See Valeriana. Valerian, celtic. See Valeriana celtica. Valerian, garden. See Valeriana major, Vaierian, great. See Valeriana major. Valerian, less. See Valeriana. VALERIA'NA. (From Valerius, who

VALERIA'NA. (From Valerius, who first par-ticularly described it.) 1. The name of a genus of plants in the Linnwan system. Class, *Triandria*; Order, *Monogynia*. Valerian.

2. The pharmacopæial name of the wild valerian.

See Valeriana officinalis.

The systematic name of the VALERIANA CELTICA. Nardus celtica. Spica celtica dioscoridis. Celtic nard. The root of this plant, a native of the Alps, has been recommended as a stomachic, carminative, and diuretic. At present it is only used in this country in the theriaca and mithridate, though its sensible qualities promise some considerable medicinal powers. a moderately strong smell, and a warm, bitterish, subacrid taste.

VALERIANA LOCUSTA. Album olus. Corn salad. This is cultivated in our gardens for an early salad. It is a wholesome, esculent plant, generally aperient

and antiscorbutic.

VALERIANA MAJOR. See Valeriana phu.

VALERIANA MINOR. See Valeriana officinalis.

VALERIANA OFFICINALIS. The systematic name of the Valeriana minor. Valeriana sylvestris; Leuco lachanum. Officinal valerian; Wild valerian. Valeriana—floribus triandris, foliis omnibus pinnatis, of Linnæus. The root of this plant has been long extolled as an efficacious remedy in epilepsy, which caused it to be exhibited in a variety of other complaints termed nervous, in which it has been found highly serviceable. It is also in very general use as an antispas-modic, and is exhibited in convulsive hysterical dis-eases. A simple and volatile tincture are directed in the pharmacopæias.

VALERIANA PHU. The systematic name of the gar-den valerian. Valeriana major. The root of this plant is said to be efficacious in removing rheumatism,

VALERIANA SYLVESTRIS. See Valeriana officinalis.
Va'LLUM. (From vallus, a hedge stake: so called from the regular trench-like disposition of the hairs.)

The eyebrows

VALSALVA, ANTON. MARIA, was born at Imola, in 1666, and placed at a proper age under Malpighi, at Bologna, where he applied so closely as to impair his health. He took his degree at the age of twenty-one, and connecting surgery with physic, acquired high reputation. He simplified the instruments in use, banished the practice of cauterizing the arteries after amputation, and employed manual operations in the cure of deafness. In 1697, he was chosen professor of anatomy in the university; and under his direction the school acquired great celebrity, among other dis-tinguished pupils of his, Morgagni must be reckoned, whose chief work, "De Sedibus et Causis Morborum," contains any dissections by Valsalva. As he advanced in life he became corpulent and lethargic, and in 1723 was carried off by an apoplectic stroke. His museum was bequeathed to the institute of Bologna, and his surgical instruments to the Hospital for Incurables. The principal of his works is a treatise, "De Aure Humana;" and after his death, three of his dissertations on anatomical subjects were printed by Morgagni.

VALVA. (Valva; from valves, to fold up.) A thin and transparent membrane situated within certain vessels, as arteries, veins, and absorbents, the office of which appears to be to prevent the contents of the vessel from flowing back.

Valve of the colon. See Intestine. Valve, semilunar. See Semilunar valves.

Valve, tricuspid. See Tricuspid valves.
Valve, triglochin. See Tricuspid valves.
VALVULA. (From valva, a valve, of which it is diminutive.) A little valve. a diminutive.)

1. Applied to the valves of the venal and lymphatic system of animals.

In botany, to the parts or halves of a capsule, which split open when the seed is ripe.

VALVULA COLI. Sce Intestine.

VALVULA EUSTACHII. A membranous semilunar valve, which separates the right auricle from the in-

ferior vena cava, first described by Eustachius.

Valvula mitralis. See Mitral valves.

Valvula semilunaris. See Semilunar valves.

Valvula triglochinis. See Tricuspid valves.

VALVULA TULPII. See Intestine.

VALVULE CONSIDENTES. The semilunar folds formed of the villous coat of the intestinum duodenum, and jejunum. Their use appears to be to increase the in-ternal surface of the intestines.

VANELLOE. See Epidendrum vanilla. VANILLA. See Epidendrum vanilla. VAPORA'RIUM. (From vapor, vapour.) A va-

pour-bath.

VAPRECULÆ. The name of an order of plants in Linnaus's Fragments of a Natural Method, consisting of such as are, and have a monophylous calyx, like a coloured corolla.

Varec. The French name for kelp. Va'ria. (From varius, changeabl (From varius, changeable.) The small-

variation of the small red pinples in the face.

VARICE LLA. (Dim. of varia, the small-pox: so called from its being changeable.) Variola lymphatica. The chicken-pox. A genus of disease in the Class Pyrexia, and Order Exanthemata, of Cullen, known by moderate synocha, pimples bearing some resem-blance to the small-pox, quickly forming pustules, which contain a fluid matter, but scarcely purulent, and after three or four days from their first appearance, desquamate:

VARICOCE LE. (From varix, a distended vein, and κηλη, a tumour.) A swelling of the veins of the scrotum, or spermatic cord; hence it is divided into the scrotal varicoccle, which is known by the appearance of livid and tumid veins on the scrotum; and paricoccle of the spermatic cord, known by feeling hard vermitorm vessels in the course of the spermatic cord. Varicoccle mostly arises from excessive walking, running, jumping, wearing of trusses, and the like, producing at first a slight uneasiness in the part, which, of not remedied; continues advancing towards the loins.

VARIEGATUS. Variegated: applied to an intermixture of colours; as in the leaves of some plants,

Mentha rotundifolia, &c.

VARI'OLA. (From varius, changing colour, because it disfigures the skin.) The small-pox. A genus of disease in the Class Pyrexia, and Order Exanthemata, of Cullen, distinguished by synocha, eruption of red pumples on the third day, which on the eighth day contain pus, and afterward drying, fall off in crusts.

It is a disease of a very contagious nature, supposed to have been introduced into Europe from Arabia, and in which there arises a fever, that is succeeded by a number of little inflammations in the skin, which proceed to suppuration, the matter formed thereby being capable of producing the disorder in another per-son. It makes its attack on people of all ages, but the young of both sexes are more habie to it than those who are much advanced in life; and it may prevail at all seasons of the year, but is most prevalent in the spring and summer.

The small-pox is distinguished into the distinct and confluent, implying that in the former the eruptions are perfectly separate from each other, and that in the

latter they run much into one another.

Both species are produced either by breathing air impregnated with the effluvia arising from the bodies of those who labour under the disease, or by the introduction of a small quantity of the variolous matter into the habit of inoculation; and it is probable, that the difference of the small-pox is not owing to any dif-ference in the contagion, but depends on the state of the person to whom it is applied, or on certain circumstances concurring with the application of it.

A variety of opinions have been entertained respecting the effect of the variolous infection on the fœtus in utero: a sufficient number of instances, however, has

been recorded, to ascertain that the disease may be communicated from the mother to the child. In some cases, the body of the child, at its birth, has been covered with pustules, and the nature of the disease has been most satisfactorily ascertained by inoculating with matter taken from the pustules. In other cases, there has been no appearance of the disease at the birth, but an eruption and other symptoms of the disease have appeared so early, as to ascertain that the infection must have been received previously to the removal of the child from the userus removal of the child from the uterus.

Four different states, or stages, are to be observed in the small-pex: first, the febrile; second, the eruptive; third, the maturative; and fourth, that of the declination or scabbing. When the disease has arisen naturally, and is of the distinct kind, the eruption is commonly preceded by a redness in the eyes, soreness in the throat, pains in the head, back, and loins, weariness and faintness, alternate fits of chilliness and heat, thirst, nausea, inclination to vomit and a quick pulse. thirst, nausea, inclination to vomit, and a quick pulse. .

In some instances, these symptoms prevail in a high degree, and in others they are very moderate and tri-fling. In very young children, startings and convul-sions are apt to take place a short time previous to the appearance of the eruption, always giving great alarm to those not conversant with the frequency of the

About the third or fourth day from the first seizure, the eruption shows itself in little red spots on the face, neck, and breast, and these continue to increase in number and size for three or four longer, at the end of which time they are to be observed dispersed over several parts of the body.

If the pustules are not very numerous, the febrile symptoms will generally go off on the appearance of the eruption, or then will become very moderate. It sometimes happens, that a number of little spots of an erysipelatous nature are interspersed among the pussupportation commences, which is usually about the fifth or sixth day, at which period, a small vesicle, containing an almost colourless fluid, may be observed upon the top of each pimple. Should the pustules be perfectly distinct and separate from each other, the suppuration will probably be completed about the eighth or ninth day, and they will then be filled with a thick yellow matter; but should they run much into each other, it will not be completed till some days later.

When the pustules are very thick and numerous on the face, it is apt about this time to become much swelled, and the eyelids to be closed up, previous to which, there usually arises a hoarseness, and difficulty of swallowing, accompanied with a considerable discharge of viscid saliva. About the eleventh day, the swelling of the face usually subsides, together with the affection of the fauces, and is succeeded by the same in the hands and feet, after which the pastules break, and discharge their contents: and then becoming dry, they fall in crusts, leaving the skin which they covered of a brown-red colour, which appearance continues for many days. In those cases where the pustules are large, and are late in becoming dry and falling off, they are very apt to leave pits behind them; but where they are small, suppurate quickly, and are few in number, they neither leave any marks behind them, nor do they occasion much affection of the system.

In the confluent small-pox, the fever which precedes the eruption is much more violent than in the distinct, being attended usually with great anxiety, heat, thirst, nausea, vomiting, and a frequent and contracted pulse, and often with come or delirium. In infants, convul-sive fits are apt to occur, which either prove fatal before any eruption appears, or they usher in a malignant species of the disease.

The eruption usually makes its appearance about the third day, being frequently preceded or attended with a rosy efflorescence, similar to what takes place in the measles; but the fever, although it suffers some slight remission on the coming out of the eruption, does not go off as in the distinct kind; on the contrary, it be-comes increased after the fifth or sixth day, and continues considerable throughout the remainder of the disease.

As the eruption advances, the face, being thickly beset with pustules, becomes very much swelled, the eyelids are closed up, so as to deprive the patient of sight, and a gentle salivation ensues, which towards

the eleventh day, is so viscid as to be spit up with great In children, a diarrhœa usually attends this stage of the disease instead of a salivation, which is to be met with only in adults. The vesicles on the top of the pimples are to be perceived sooner in the confluent small-pox than in the distinct; but they never rise to an eminence being usually flatted in; neither do they arrive to proper suppuration, as the fluid contained in them, instead of becoming yellow, turns to a brown

About the tenth or eleventh day, the swelling of the face usually subsides, and then the hands and feet begin to puff up and swell, and about the same time the vesicles break, and pour out a liquor that forms into brown or black crusts, which, upon falling off, leave deep pits behind them that continue for life; and where the pustules have run much into each other, they then disfigure and scar the face very considerably

Sometimes it happens that a putrescency of the fluids takes place at an early period of the disease, and shows · itself in livid spots interspersed among the pustules, and by a discharge of blood by urine, stool, and from various

parts of the body.

In the confluent small-pox, the fever which, perhaps had suffered some slight remission from the time the eruption made its appearance to that of maturation, is often renewed with considerable violence at this lastmentioned period, which is what is called the secondary fever, and this is the most dangerous stage of the disease. It has been observed, even among the vulgar, that the small-pox is apt to appear immediately before or after the prevalence of the measles. Another curious observation has been made relating to the symptoms of these complaints, namely, that if, while a patient labours under the small-pox, he is seized with the measles, the course of the former is retarded till the eruption of the measles is finished. The measles The measles appear, for instance, on the second day of the eruption of small-pox; the progress of this ceases, till the measles terminate by desquamation, and then it goes on in the usual way. Several cases are, however, recorded in the Medical and Physical Journal, as likewise in the third volume of the Medical Commentaries, in which a concurrence of the small-pox and measles took place without the progress of the former being retarded. distinct small-pox is not attended with danger, except when it attacks pregnant women, or approaches nearly in its nature to that of the confluent; but this last is always accompanied with considerable risk, the degree of which is ever in proportion to the violence and per-manence of the fever, the number of pustules on the face, and the disposition to putrescency which pre-

When there is a great tendency this way, the disease usually proves fatal between the eighth and eleventh day, but, in some cases, death is protracted to the fourteenth or sixteenth. The confluent small-pox, although it may not prove immediately mortal, is very apt to

induce various morbid affections.

Both kinds of small pox leave behind them a predisposition to inflammatory complaints, particularly to opthalmia and visceral inflammations, but more especially of the thorax; and they not unfrequently excite scrofula into action which might otherwise have lain dormant in the system.

The regular swelling of the hands and feet upon that of the face subsiding, and its continuance for the due time, may be regarded in a favourable light.

The dissections which have been made of confluent small-pox, have never discovered any pustules inter-nally on the viscera. From them it also appears that variolous pustules never attack the cavities of the body, except those to which the air has free access, as the nose, mouth, trachea, the larger branches of the bronchia, and the outermost part of the meatus auditorius. In cases of prolapsus ani, they likewise frequently attack that part of the gut which is exposed to the air. They have usually shown the same morbid appearances inwardly, as are met with in putrid fever, where the disease has been of the malignant kind. Where the febrile symptoms have run high, and the head has been much affected with coma or delirium, the vessels of the brain appear, on removing the cranium and dura mater, more turgid, and filled with a darker coloured blood than usual, and a greater quantity of serous fluid is found, particularly towards the base of the brain. Under similar circumstances, the lungs

have often a darker appearance, and their moisture is more copious than usual. When no inflammatory affection has supervened, they are most usually sound.

affection has supervened, they are most usually sound.

The treatment of small-pox will differ materially according to the species of the disease. In the distinct, ushered in by synochal pyrexia, it may be occasionally proper, in persons of a middle age, good constitution, and plethoric habit, to begin by taking away a moderate quantity of blood; the exhibition of an emetic will be generally advisable, provided there be no material tenderness of the stomach; the bowels must then be cleared, antimonial and other displacetics employed. cleared, antimonial and other diaphoretics employed, and the antiphlogistic regimen strictly enforced. It is particularly useful in this disease during the eruptive fever to expose the patient freely to cold air, as taught by the celebrated Sydenham; and even the cold affusion may be proper, where there is much heat and redness of the skin, unless the lungs be weak. After the cruption has come out, the symptoms are usually so much mitigated, that little medical interference is necessary. But the confluent small-pox requires more manage-ment: after evacuating the primæ viæ, and employing other means to moderate the fever in the beginning, the several remedies adapted to support the strength and counteract the septic tendency, must be resorted to, as the disease advances, such as have been enumerated under typhus. The chief points of difference are, that bark may be more freely given to promote the process of suppuration, and opium to relieve the irritation in the skin; when the cruption has come out, it will be generally proper to direct a full dose of this remedy every night to procure rest, using proper precautions to obviate its confining the bowels, or determining to the head. Where alarming convulsions occur also, opium is the medicine chi fly to be relied upon, taking care subsequently to remove any source of irritation from the primæ viæ. Sometimes the tepid-bath may be useful under these circumstances, and favour the appearance of the eruption, where the skin is pale and cold, the pulse weak, &c. Where at a more advanced appearance of the eruption, where the skin is pair and cold, the pulse weak, &c. Where at a more advanced period the pustules flatten, and alarming symptoms follow, the most powerful cordial and antispasmodic remedies must be tried, as the confectio opii, wther, wine, &c. For the relief of the brain, or other important part, particularly affected, local means may be used, as in typhus. To prevent the eyes being injured, a cooling lotion may be applied, and blisters behind the a cooling lotion may be applied, and blisters behind the ears, or even leeches to the temples VARIOLA VACCINA. Vaccinia.

Vaccinia. The cow-pox. pustulous disease affecting the cow, may be called the cow-pox: whether it arises from an over-distention of the udder, in consequence of a neglect in milking the cow, or from the sting of an insect, or any other casse. But the species which claims our particular attention, is that which was recommended to the world by Dr. Jenner, in the year 1798, as a substitute for the small-This, which originates from the grease in the horse's heel, is called the genuine cow-pox; all other

kinds are spurious.

That the vaccine fluid, fraught with such unspeakable benefits to mankind, derives its origin from this humble source, however it may mortify human pride, or medical vanity, is confirmed by the observations and experiments of competent judges. For proofs of this assertion, the reader may consult the works of Dr. Jenner; the Medical and Physical Journal; and a treatise on the subject by Dr. Loy, of which an analysis is given in the Aurela of Medical and Physical Formal Control of the State lysis is given in the Annals of Medicine for the year 1801; and Mr. Ring's work on this disease, which contains the whole mass of evidence that has appeared concerning it.

The genuine cow-pox appears on the teats of the The genuine cow-pox appears on the teats of the cow, in the form of vesicles, of a blue colour approaching to livid. These vesicles are elevated at the mar gin, and depressed at the centre. They are surrounded with inflammation. The fluid they contain is limpid. The animals are indisposed; and the secretion of milk is lessened. Solutions of the sulphates of zinc and copper are a speedy remedy for these pustules; otherwise they degenerate into ulcers, which are extremely wise they degenerate into ulcers, which are extremely troublesome. It must, however, be recollected, that much of the obstinacy attending these cases is owing to the friction of the pustules, in consequence of milking. It is probable, that a solution of the superacetate

of lead would be preferable to irritating applications.

Similar effects are produced in the hands of the milkers, attended with febrile symptoms, and some-

times with tumours in the axilla. Other parts, where | gone the vaccine disease, their apparent security was the cuticle is abraded, or which are naturally destitute of that defence, are also liable to the same affection, provided active matter is applied. It even appears that, in some instances, pustules have been produced by the application of vaccine virus to the sound cu-ticle. One case of this kind may be found in a letter from Dr. Fowler, of Salisbury, to Dr. Pearson, published in the first work of Dr. Pearson on this subject.

The spurious cow-pox is white; and another crite-rion is, that both in the brute animal and in the human subject, when infected with the casual cow-pox, the sores occasioned by the genuine species are more difficult to heal than those which are occasioned by the spurious kind. It is of the utmost importance to dis-tinguish the genuine from the spurious sort, which is also, in some degree, infectious; since a want of such discrimination would cause an idea of security against

the small-pox, which might prove delusive.

Dr. Jenner has elucidated one point of the first importance, relative to the genuine cow-pox itself. had frequently been observed, that when this disorder prevailed in a farm, some of the persons who contracted it by milking were rendered insusceptible of the small-pox, while others continued liable to that infection. This is owing to the different periods at which the disease was excited in the human subject; one person, who caught the disease while the virus was in an active state, is rendered secure from variolous contagion; while another, who received the infection of the cow pox when it had undergone a decomposition, is still susceptible of the small-pox. This uncertainty is still susceptible of the small-pox. This uncertainty of the prevention, the value of which is beyond all calculation, is probably the reason why it was not before introduced into practice.

From the violent opposition which vaccine inoculation has met with, in consequence of certain apparent failures in the casual way, it may be doubted whether the public would ever have adopted the practice, had not this fallacy been detected by Dr. Jenner. To him also we are indebted for another discovery of the first importance; namely, that the pustule excited in the human subject by vaccine matter, yields a fluid of a similar nature with that which was inserted. This experiment, so essential to the general propagation of the practice, and so happy in its result, was never before attempted. It was reserved to crown the labours of Dr. Jenner.

A considerable number of instances are on record, to prove that farriers and others who receive infection from the heel of a horse, are either partly or totally deprived of the susceptibility of the small-pox. Dr. Jenner first published an account of his discoveries, this point was enveloped in some degree of obscurity. He then conceived, that the matter of grease was an imperfect preservative against the small-pox. This opinion was founded on the following circumstance: It had been remarked, that farriers either wholly escaped the small-pox, or had that distemper in a milder manner than other people. This, however, is easily reconcileable to reason, if we only suppose, that in some cases the infection is communicated when the virus possesses all its prophylactic virtue; and in others, when its specific quality is in some measure

This variation in the effects produced by the virus of the horse, inclined Dr. Jenner to believe that it was modified, and underwent some peculiar alteration in the teats of the cow. He now concludes, that it is perfect when it excites the genuine disease in the cow; yet a considerable advantage is derived from its being transferred to the latter animal, the nipples of which furnish a more obvious and a more abundant source of this inestimable fluid, than its original element the

This theory, that the preservative against variolous contagion is perfect when it issues from the fountainhead, and comes immediately from the hands of Nature, is consonant with reason, and consistent with Thus, one obstacle more to the universal adoption of the practice is removed.

Another point respecting vaccine inoculation, which has been much controverted, is the permanency of its effect. Instances have been known where persons have escaped the small-pox for a number of years, and yet have ultimately proved not insusceptible of its in-fection. When such persons had previously under-

erroneously ascribed to that cause; but we have not even a shadow of proof, that the cow-pox possesses in the least degree the property of a temporary prophylactic, since it appears not even to retard the eruption of the small-pox, where previous infection has been received.

By this remark, it is not meant to be asserted, that it never supersedes or modifies the small-pox, for we have great reason to believe that such beneficial effects often flow from vaccination; but where an eruption of the small-pox actually takes place after vaccine inoculation, the two diseases frequently co-exist, without retarding each other in the smallest degree. therefore, contrary to all reason and analogy, to consider the cow-pox as a mere temporary preservative: it is nothing less than a perfect and permanent security against that terrible disease.

A number of cases are recorded by Dr. Jenner, and other authors, who have written on this subject, in which persons who have received the cow-pox by casual infection, twenty, thirty, forty, and fifty years before, still continued insusceptible of variolous contagion, in whatever form it was applied.

As the cow-pox destroys the susceptibility of the small-pox, so the small-pox destroys that of the cow-pox. To this general rule, however, a few exceptions are said to have occurred. Certain it is, that a pustule has now and then been excited by the insertion of vaccine virus, in those who have had the small-pox, and that this pustule has been known to yield to the genuine virus; but it is not equally certain that the pustule has been perfect in all respects. Possibly, it may have been defective in point of size or duration, in respect to its areola, or the limpidity of its contents. such a pustule has, in some instances, yielded effectual virus, is admitted; but this is no more than what has often happened, in cases where persons who have had the small-pox are a second time submitted to that infection in the same form.

The artificial cow-pox in the human subject is much milder than the casual disease; and incomparably milder than the small-pox, even under the form of inoculation. It neither requires medicine nor regimen; it may be practised at any season of the year; and, not being infectious by cifluvia, one person may be inoculated without endangering the life of another.

This affection produces no pustulous eruptions. When such attend vaccine inoculation, they are owing to some adventitious cause, such as the small-pox, which it is well known may co-exist with the cowpox. The vaccine vesicle is confined to the parts where matter is inserted; it is, therefore, entirely a local and an inoculated disease. Nevertheless, it is certain, that eruptions of other kinds, in some instances, attend vaccine inoculation; such as a nettle-rash, or an eruption resembling a tooth-rash, but rather larger than what is commonly called by that name.

Among other singularities attending the cow-pox, the mildness of the disease, under the form of inoculation, has been urged as an argument against the practice, the cause appearing to ordinary comprehensions, in-adequate to the effect. This, it must be allowed, is the best apology that can be offered for skepticism on that point; but it will weigh but little when put into the scale against actual observation, and incontrovertible fact. The efficacy of the cow-pox as a safeguard against the small-pox, rests, perhaps, on more extensive evidence, and a more solid foundation, than any other axiom in the whole circle of medical science.

That the cow-pox is not infectious by effluvia, is naturally concluded from its never being communicated from one person to another in the dairies; where the disease is casual, and appears under its worst form. The same inference may be drawn from its never spreading in a family, when only one person is inoculated at a time. To confirm this proposition more fully, the vaccine pustules have been ruptured, and persons who have never had the disorder have been suffered to inhale the effluvia several times a day, but to no purpose. This is no more than might be expected, in an affection where the pustulous appearance on the surface of the body is nearly local.

As to the constitutional indisposition, it is seldom considerable, unless there is a complication of this with some other distemper; and whenever any unfavourable symptoms appear, they may in general be VAR VAR

neglect.

But notwithstanding the symptoms are so mild, they frequently occur at a very early period. A drowsiness, which is one of the most common attendants of the disease, is often remarked by the parents themselves, within forty-eight hours after the matter is inserted. In a majority of cases, a slight increase of heat is perceptible, together with an acceleration of the pulse, and other signs of pyrexia; but not in such a degree as to alarm the most timorous mother. Sometimes the pa-tient is restless at nights; and now and then a case is met with, in which vomiting occurs, but in many cases, no constitutional indisposition can be perceived. Even then, the cow-pox has never failed to prove an effectual preservative against the small-pox, provided the pustule has been perfect.

This being the grand criterion of the security of the patient, too minute an attention cannot be paid to its rise, progress, and decline. The best mode of inoculating is by making a very small oblique puncture in the arm, near the insertion of the deltoid muscle, with the point of a lancet charged with fluid matter. In order to render infection more certain, the instrument may be charged again, and wiped upon the puncture.

In places where the patient is likely to be exposed to variolous contagion, it is advisable to inoculate in more

places than one, but unless there is danger of catching the small-pox, it is better not to make more than one puncture in each arm, lest too much inflammation should ensue.

The vaccine fluid may be taken for inoculation as soon as a vesicle appears; but if the vesicle is punc-tured at a very early period, it is more apt to be injured. When virus is wanting for inoculating a considerable number, it is better to let the pustule remain untouched, till about the eighth day, by which time it has in general acquired a reasonable magnitude. After that day, if the pustule has made the usual progress, the matter begins to lose its virtue; but it may, in general, be used with safety, though with less certainty of producing infection, till the areola begins to be extensive.

The first sign of infection commonly appears on the A small red spot, rather elevated, may be third day. perceived at the place where the puncture was made. Sometimes, however, the mark of infection having succeeded is not visible till a much later period. It may be retarded, or even entirely prevented, by any other disorder, such as dentition, or any complaint attended with fever, or by extreme cold. Another frequent cause of a slow progress in the pustule, or a total failure of success, is debility. Sometimes it is impos-sible to discover any sign of infection for above a fortnight. In this respect the cow-pox is subject to the same laws, and liable to the same variation, as the small-pox.

When a considerable inflammation appears within two or three days after inoculation, there is reason to suspect that infection has not taken place; and if suppuration ensues, that suspicion ought, in general, to stand confirmed. Now and then, however, it happens, that after the spurious pustule, or more properly speaking, the phlegmon, has run its course, which is within a few days, a vesicle begins to appear, bearing every characteristic of the genuine vaccine disease, and yielding a limpid and efficient virus for future inocu-In this case the patient is as perfectly secured from all danger of the small-pox, as if no festering of the puncture had preceded. The occurrence of such a case, though rare, is worthy to be recorded; because some practitioners have concluded a spurious pustule to be a certain proof of failure.

The areola commonly begins to be extensive on the ninth day, and to decline about the eleventh or tweifth. At this period also the pustule begins to dry; the first sign of which is a brown spot in the centre. portion as this increases the surrounding efflorescence decreases, till at length nothing remains but a circular scab, of a dark-brown mahogany colour, approaching Sometimes it resembles the section of a to black. tamarind-stone; and it often retains the depression in the centre, which characterizes this disease before exsiccation takes place.

Instances have been known, where the vaccine pus-

traced to some other cause. We have indeed great reason to believe, that no ill consequence ever arises from the cow-pox itself, unless from ignorance or nor the attendants, have remarked any appearance of that symptom. In these cases, the patient has proved as insusceptible of variolous infection, as if the surrounding efflorescence had covered the whole arm. must, however, be confessed that we have no proof of the non-existence of an arcola in these cases. have been trivial; it might have been transient; yet it might have been effectual. There is, however, greater reason to believe, that the surrounding efflorescence, though usually a concomitant circumstance, is not an essential requisite to the vaccine disease.

If by any accident the vesicle is ruptured, suppuration often ensues. In this case, more attention than ordinary ought to be paid to the progress, and to all the phenomena of the local affection; both on account of the uncertainty of success in the pustule, as a pro-phylactic, and the greater probability of tedious ulcer-

If there is room for the least doubt of the sufficiency of the first inoculation, a second ought to be performed without delay. This, if unnecessary, is seldom attended with inconvenience, and never with danger. Either no effect is produced, or a slight festering, which terminates in a few days. An execution occurs but are nates in a few days. An exception occurs, but rarely, where a spurious, or perhaps, even a genuine pustule, takes place, in those persons who are known to have had the cow-pox or the small-pox already; but this cannot be the least cause of alarm to any one who knows the benign character of the distemper.

Various topical applications, both stimulant and sedative, have been recommended, in order to allay the violence of inflammation. If the operation for the insertion of matter is not unnecessarily severe, nor the pustule irritated by friction, or pressure, or other violence, no such applications are necessary. Nevertheless, if either the anxiety of the professional man, or the importunity of a tender parent, should demand a deviation from this general rule, any of the following remedies may be had recourse to. The pustule may be touched with very diluted sulphuric acid; which should be permitted to remain ou the part half a minute, and then be washed off with a sponge dipped in This has been ignorantly, or artfully, cold water. called an escharotic; but any one who tries the application will soon discover, that its operation is mild and

To avoid cavil and misrepresentation, it is better to apply a saturnine lotion; compresses, dipped in such a lotion, may be applied at any time when inflammation runs high, and renewed as occasion requires.

If the pustule should chance to be broken, a drop of the liquor plumbi acetatis, undiluted, may be applied as an exsiccant; but if ulceration threatens to become obstinate, or extensive, a mild cataplasm is the best resource. In case the ulceration is only superficial, and not attended with immoderate inflammation, a bit of any adhesive plaster, spread on linen, will prove the most convenient dressing, and seldom fail of success. It will, in general, be unnecessary to renew it oftener than every other day.

These minute observations no one will despise, unless there be any person so ignorant as not to know that the care of the arm is almost the whole duty of the medical practitioner in vaccine inoculation; and that nothing disgusts the public so much against the prac-tice, as a sore arm, and the ill consequences which, from a neglect of that symptom, too often ensue.

When fluid virus cannot be procured, it is necessary to be cautious how it is preserved in a dry state. most improper mode is that of keeping it on a lancet; for the metal quickly rusts, and the vaccine matter be-comes decomposed. This method, however, is as likely to succeed as any, when the matter is not to be kept above two or three days. If the virus be taken on glass, care must be taken not to dilute it much; otherwise it will probably fail.

Cotton thread is a very commodious vehicle. If it is intended to be sent to any considerable distance, it ought to be repeatedly dipped in the virus. No particular caution is necessary with regard to the exclusion of air; nevertheless, as it can be done with so little trouble, and is more satisfactory to those who receive the matter, it is better to comply with the practice. On this account, it may be enclosed in a glass tube, or in a

tobacco-pipe sealed at each end, or between two square | bits of glass, which may, if necessary, be also charged with the matter, and wrapped in gold-beater's skin.

Nothing is more destructive to the efficacy of cownothing is more destructive to the emcacy of cow-pock matter than heat: on this account it must not be dried near the fire, nor kept in a warm place. The advantage of inserting it in a fluid state is so great, that it is to be wished every practitioner would endea-vour to keep a constant supply for his own use, by in-oculating his patients in succession, at such periods as are most likely to answer that purpose.

The rapidity with which this practice now spreads in various parts of the globe, justifies our cherishing a hope, that it will ere long extinguish that most dreadful pestilence, and perpetual bane of human felicity, the

small-pox.

[Dr. Sylvanus Fansher, of Middletown, in Connecticut, has devoted much time and attention to vaccination; and, in the following letter to Dr. Mitchill, proposes a method to hasten the progress of the vaccine

" Middletown, (Conn.) March, 1828.

" DR. MITCHILL,

"Sir,-As you had the honour of announcing the happy tidings of the mild substitute for the small-pox in America, and as you once made honourable mention of my name relative to the art of preserving the vaccine virus, I therefore take the liberty to trouble you with the result of a series of experiments to hasten the progressive stages of the vaccine vesicle, which, I am induced to believe, promises to the world additional ad-

vantages from vaccination.

"During the earlier part of my vaccine practice, when persons came to me, with great concern, to know whether it would be too late to vaccinate a person, who had been exposed to the small-pox a week or more, and I have been under the painful necessity of expressing my fears that it would be too late; I have, from past experience, often felt their woes, and sighed for a power that seemed to be denied to vaccinators or inoculators, which was, to be able to force forward the vaccine process, so as to hasten the constitutional affection at an earlier period than the well-known time for symptoms in either inoculation or vaccination.

"Having been an eye-witness of the extreme anguish of two fine children in 1803 and 1804, who applied too late for vaccination, I commenced making experiments to expedite vaccination, by various methods of insert-ing the virus. At length I found, that by making broad punctures on the body and shoulders, with active vaccine virus. I was able to produce an early pustule, and bring on the symptoms from 30 to 40 hours sooner than And I am now able to produce above forty successful experiments to accelerate the vaccine process, substantiated by high medical authority. I write to you, Sir, because your sagacity and discernment will be the first to discover the usefulness of this improve-ment, and the first to detect error.

"I have the honour to be, &c.

"SYLVANUS FANSHER."

We may observe, from the above letter, that Dr. Fansher's method of hastening the vaccine process, by inserting the virus repeatedly by broad punctures on the body and shoulders, will probably prove efficacious. The ordinary mode of vaccination is, to introduce the smallest possible quantity of vaccine matter into the puncture; and hence it frequently happens, that the effect upon the constitution is so slight as to be hardly, or even not at all, perceptible. The consequence is, that cases of varioloid have sometimes occurred after vaccination, probably in cases in which it had not produced its proper influence on the system, or where that influence was insufficient. Dr. F.'s method will, doubtless, charge the system with the genuine disease, and prevent the after occurrence of varioloid, or variolus (small-pox). He thinks, however, that it will do more, and force the vaccine to outrun the small-pox, where exposure to infection has taken place. That it may do so, or at least that the effectual introduction of the vaccine may modify the small-pox, the following case, which a medical friend has reported to us, would seem to prove.

A child exposed to the influence of the natural smallpox was vaccinated, and four days after, the operation was repeated. On the eighth day from the first vaccination no appearance was observed of the progress of

sidered unnecessary and too late, and the parents were advised to have the child inoculated with the smallpox, which was preferable to having it in the natural Matter was taken from the brother, who had the small-pox very badly in the adjoining room, and inserted in the arm, near where the vaccine matter had been inserted. The pock rose on the arm, and to the surprise of the physician, the vaccine vesicle also rose, and they progressed together, modifying each other. The vaccine pock was smaller than usual, and went through its stages sooner than is common, though it had previously laid dormant, and appeared to have been put into activity by the small-pox. The smallpox was also modified, the pock were few, the sickness trifling, the confinement nothing; and the child recovered before his brother, who was first taken. A.]

VA'RIUS. (From varus, unequal: so called from the regularity of its shape.) The cuboid bone was forirregularity of its shape.) The cuboid bone warmerly called os varium, from its irregular shape.

VA'RIX. (From varus, i. e. obtortus.) A dilatation of a vein. A genus of disease in the Class Locales, and Order Tumores, of Cullen; known by a soft tumour on a vein which does not pulsate. Varicose veins mostly become serpentine, and often form a plexus of knots, especially in the groins and scrotum.

. VAROLI, Costanzo, was born at Bologna, in 1542, and became a professor of physic and surgery in his native city. At thirty, he was invited by Pope Gregory XIII. to settle at Rome as his first physician, and professor in the College of Sapienza. He was advancing in reputation by his anatomical discoveries, as well as the interaction of the control in his practice, when a premature death cut him off in 1573. He was particularly distinguished in the Anatomy of the Brain, which he described in his Work "De Nervis Opticis, &c.:" and among the parts discovered, or more accurately demonstrated by him, was that formed by the union of the crura cerebri, and cerebelli, which has been since called the Pons Varolii, and which gives origin to several nerves. After his death, was published "De Resolutione Corporis Humani," an anatomical compendium, chiefly according to the an cients, but with several new observations.

VA'RUS. See lonthus.

VAS. (Vas, vasis, n.; from vasum: hence in the plural, vasa, orum; a vescendo, because they convey drink.) A vessel: applied to arteries, veins, ey drink.) ducts, &c.

VAS DEFERENS. A duct which arises from the epi-didymis, and passes through the inguinal ring in the spermatic cord into the cavity of the pelvis, and terminates in the vesicula seminalis. Its use is to convey the semen secreted in the testicle, and brought to it by the epididymis into the vesicula seminalis.

Va'sa Brevia. The arteries which come from the

spleen, and run along the large arch of the stomach to

the diaphragm.

VASA VORTICOSA. The contorted vessels of the choroid membrane of the eye.

VA'STUS. (So called from its size.) A name given only to some muscles. VASTUS EXTERNUS. A large, thick, and fleshy muscle, situated on the outer side of the thigh: it arises by

a broad thick tendon, from the lower and anterior part of the great trochanter, and upper part of the linea aspera; it likewise adheres by fleshy fibres, to the whole outer edge of that rough line. Its fibres descend obliquely forwards, and after it has run four or five inches downwards, we find it adhering to the anterior surface and outer side of the cruraus, with which it continues to be connected to the lower part of the thigh, where we see it terminating in a broad tendon, which is inserted into the upper part of the patella laterally, and the tibia, and is continued down the leg.

Vastus internus. This muscle, which is less considerable than the vastus externus, is situated at the inner side of the thigh, being separated from the pre-

ceding by the rectus.

It arises tendinous and fleshy from between the fore part of the os femoris, and the root of the less trochanter, below the insertion of the psoas magnus, and the iliacus internus; and from all the inner side of the linea aspera. Like the vastus externus it is connected with the cruræus, but it continues longer fleshy than that muscle. A little above the knee we see its outer edge uniting with the inner edge of the rectus, after the kine-pock. Further vaccination was then con- which it is inserted tendinous into the upper part and

inner side of the patella, sending off an aponeurosis which adheres to the upper part of the tibia.

VEGETABLE. Vegetabilis. One of the three great divisions of nature. The most obvious difference between vegetables and animals is, that the latter are, in general, capable of conveying themselves from place to place; whereas vegetables, being fixed in the same place, absorb, by means of their roots and leaves, such

support as is within their reach.

The nutrition or support of plants appears to require water, earth, light, and air. There are various experiments which have been instituted to show, that water is the only aliment which the root draws from the earth. Van Helmont planted a willow, weighing fifty pounds, in a certain quantity of earth covered with sheet-lead he watered it for five years with distilled water; and at the end of that time the tree weighed one hundred and sixty-nine pounds three ounces, and the earth in which it had vegetated was found to have suffered a loss of no more than three ounces. Boyle repeated the same experiment upon a plant, which at the end of two years weighed fourteen pounds more, without the earth in which it had vegetated having lost any perceptible

portion of its weight.

Duhamel and Bonnet supported plants with moss, and fed them with mere water: they observed, that the vegetation was of the most vigorous kind; and the naturalist of Geneva observes, that the flowers were more odoriferous, and the fruit of a higher flavour. Care was taken to change the supports before they could suffer any alteration. Tillet has likewise raised plants, more especially of the gramineous kind, in a similar manner, with this difference only, that his supports were pounded glass, or quartz in powder. Hales has observed, that a plant, which weighed three pounds, gained three ounces after a heavy dew. Do we not every day observe hyacinths and other bulbous plants, as well as gramineous plants, raised in saucers or bot-tles containing mere water? And Braconnot has lately found mustard-seed to germinate, grow, and produce plants, that came to maturity, flowered, and ripened their seed, in litharge, flowers of sulphur, and very small unglazed shot. The last appeared least favourable to the growth of the plants, apparently because their roots could not penetrate between it so easily.

All plants do not demand the same quantity of water; and nature has varied the organs of the several individuals conformably to the necessity of their being supplied with this food. Plants which transpire little, such as the mosses and the lichens, have no need of a considerable quantity of this fluid; and accordingly they are fixed upon dry rocks, and have scarcely any roots; but plants which require a larger quantity, have

roots which extend to a great distance, and absorb humidity throughout their whole surface.

The leaves of plants have likewise the property of absorbing water, and of extracting from the atmosphere the same principle which the root draws from the earth. But plants which live in the water, and as it were swim in the element which serves them for food, have no need of roots; they receive the fluid at all their pores; and we accordingly find, that the fucus,

the ulva, &c. have no roots whatever.

The dung which is mixed with earths, and decomposed, not only affords the alimentary principles we have spoken of, but likewise favours the growth of the plant by that constant and steady heat which its ul-terior decomposition produces. Thus it is that Fa-broni affirms his having observed the developement of leaves and flowers in that part of the tree only, which was in the vicinity of a heap of dung.

From the preceding circumstances it appears, that the influence of the earth in vegetation is almost totally confined to the conveyance of water, and probably the elastic products from putrefying substances, to the

Vegetables cannot live without air. From the experiments of Priestley, Ingenhousz, and Sennebier, it is ascertained, that plants absorb the azotic part of the atmosphere; and this principle appears to be the cause of the fertility which arises from the use of putrefying matters in the form of manure. The carbonic acid is likewise absorbed by vegetables, when its quantity is small. If in large quantity, it is fatal to them.

Chaptal has observed, that carbonic acid predomi-

nates in the fungus, and other subterraneous plants. acid. Soluble in nitric acid, a But, by causing these vegetables, together with the principle and artificial tannin.

body upon which they were fixed, to pass, by imper-ceptible gradations, from an almost absolute darkness, into the light, the acid very nearly disappeared; the vegetable fibres being proportionally increased, at the same time that the resin and colouring principles were developed, which he ascribes to the oxygen of the same acid. Sennebier has observed, that the plants which he watered with water impregnated with carbonic acid, transpired an extraordinary quantity of oxygen, which likewise indicates a decomposition of

Light is almost absolutely necessary to plants. In the dark, they grow pale, languish, and die. The ten-dency of plants towards the light is remarkably seen in such vegetation as is effected in a chamber or place where the light is admitted on one side; for the plant never fails to grow in that direction. Whether the matter of light be condensed into the substance of plants, or whether it act merely as a stimulus or agent, without which the other requisite chemical processes

cannot be effected, is uncertain.

It is ascertained, that the processes in plants serve like those in animals, to produce a more equable temperature, which is for the most part above that of the atmosphere. Dr. Hunter, quoted by Chaptal, obthe atmosphere. Dr. Hunter, quoted by Chaptai, observed, by keeping a thermometer plunged in a hole made in a sound tree, that it constantly indicated a temperature several degrees above that of the atmosphere, when it was below the fifty-sixth division of Fahrenheit; whereas the vegetable heat, in hotter weather, was aiways several degrees below that of the atmosphere. The same philosopher has likewise observed, that the sap which, out of the tree, would freeze at 320, did not freeze in the tree unless the cold were augmented 150 more.

The vegetable heat may increase or diminish by several causes, of the nature of disease; and it may even become perceptible to the touch in very cold

weather, according to Buffon.

The principles of which vegetables are composed, if we pursue their analysis as far as our means have hitherto allowed, are chiefly carbon, hydrogen, and Nitrogen is a constituent principle of several, oxygen. for the most part in small quantity. soda, lime, magnesia, silex, alumina, sulphur, phos-phorus, iron, manganese, and muriatic acid, have likewise been reckoned in the number; but some of these occur only occasionally, and chiefly in very small quantities; and are scarcely more entitled to be considered as belonging to them than gold, or some other substances, that have been occasionally pro-cured from their decomposition.

The following are the principal products of vegeta-

tion :-

1. Sugar. Crystallizes. Soluble in water and alko-Taste sweet. Soluble in nitric acid, and yields oxalic acid.

2. Sarcocol. Does not crystallize. Soluble in water and alkohol. Taste bitter sweet. Soluble in nitric

acid, and yields oxalic acid.

3. Asparagin. Crystallizes. Taste cooling and nau-Soluble in nitric acid, and converted into bitter principle and artificial tannin.

4. Gum. Does not crystallize. Taste insipid. luble in water, and forms mucilage. Insoluble in alkohol. Precipitated by silicated potassa. Soluble in

alkonol. Precipitated by sincated polassa. Solution nitric acid, and forms mucous and oxalic acids.

5. Ulmin. Does not crystallize. Taste insipid. Soluble in water, and does not form mucilage. Precipitated by nitric and oxymuriatic acids in the state Insoluble in alkohol.

of resin. In 6. Inulin.

of resin. Insoluble in alkohol.

6. Inulin. A white powder. Insoluble in cold water. Soluble in boiling water; but precipitates unaltered after the solution cools. Insoluble in alkohol Soluble in nitric acid, and yields oxalic acid.

7. Starch. A white powder. Taste insipid. Insoluble in cold water. Soluble in hot water; opaque and glutinous. Precipitated by an infusion of nutgalls; precipitate redissolved by a heat of 120°. Insoluble in alkohol. Soluble in dilute nitric acid, and precipitated by alkohol. With nitric acid yields oxalic acid. tated by alkohol. With nitric acid yields oxalic acid and a waxy matter.

8. Indigo. A blue powder. Taste insipid. Insoluble in water, alkohol, ather. Soluble in sulphuric acid. Soluble in nitrle acid, and converted into bitter

Partially soluble in water; precipitated by infusion of nutgalls and oxygenized muriatic acid. Soluble in acetic acid and muriatic acid. Insoluble in alkohol. By fermentation becomes viscid and adhesive, and then assumes the properties of cheese. Soluble in nitric acid, and yields oxalic acid.

 Albumen. Soluble in cold water. Coagulated by heat, and becomes insoluble. Insoluble in alkohol. Precipitated by infusion of nutgalls. Soluble in nitric

acid. Soon putrefies. 11. Fibrin. Tastel Tasteless. Insoluble in water and alkohol. Soluble in diluted alkalies, and in nitric acid.

Soon putrefies.

12. Gelatin. Insipid. Soluble in water. Does not coagulate when heated. Precipitated by infusion of

Bitter principle. Colour yellow or brown.
 Taste bitter. Equally soluble in water and alkohol.
 Soluble in nitric acid. Precipitated by nitrate of silver.

Soluble in nitric acid. Precipitated by nitrate of survey.

14. Extractive. Soluble in water and alkohol. Insoluble in other. Precipitated by oxygenized muriatic auditate of alumina; but not by gelatin. Dyes fawn colour.

15. Tannin. Taste astringent. Soluble in water

and in alkohol of 0.810. Precipitated by gelatin, muriate of alumina, and muriate of tin.

16. Fixed oils. No smell. Insoluble in water and alkohol. Forms soaps with afkalies. Coagulated by earthy and metallic salts.

17. Waz. Insoluble in water. Soluble in alkohol, wither, and oils. Forms soap with alkalies. Fusible. 18. Volatile oil. Strong smell. Insoluble in water. Soluble in alkohol. Liquid. Volatile. Oily. By nitric acid inflamed, and converted into resinous substances.

19. Camphor. Strong odour. Crystallizes. Very little soluble in water. Soluble in alkohol, oils, acids. Insoluble in alkalies. Burns with a clear flame, and

volatilizes before melting.

20. Birdlime. Viscid. Taste insipid. Insoluble in

water. Partially soluble in alkohol. Very soluble in ather. Solution green.

21. Resins. Solid. Melt when heated. Insoluble in water. Soluble in alkohol, ather, and alkalies. Soluble in acetic acid. By nitric acid converted into artificial tannin.

Possesses the characters of resins : 22. Guaiacum. but dissolves in nitric acid, and yields oxalic acid and

no tannin.

23. Balsains. Possess the characters of the resins, but have a strong smell; when heated, benzoic acid sublimes. It sublimes also when they are dissolved in sulphuric acid. By nitric acid converted into artificial.

tannin.

24. Caoutchouc. Very elastic. Insoluble in water and alkohol. When steeped in wther, reduced to a pulp, which adheres to every thing. Fusible and

remains liquid. Very combustible.

25. Gum resins. Form milky solutions with water, transparent with alkohol. Soluble in alkalies. With With nitric acid converted into tannin. Strong smell. Brit-

tle, opaque, infusible.

26. Cotton. Composed of fibres. Tasteless. Very combustible. Insoluble in water, alkohol, and æther. Soluble in alkalies. Yields oxalic acid to nitric acid.

27. Suber. Burns bright, and swells. Converted by nitric acid into suberic acid and wax. Partially soluble in water and alkohol.

28. Wood. Composed of fibres. Tasteless. luble in water and alkohol. Soluble in weak alkaline lixivium. Precipitated by acids. Leaves much charcoal when distilled in a red heat. Soluble in nitric

acid, and yields oxalic acid.

To the preceding we may add, emetin, fungin, hematin, nicotin, pollenin; the new vegetable alkalies, aconita, atropia, brucia, cicuta, datura, delphia, hyos ciama, morphia, picrotoxia, strychnia, veratria; and the various vegetable acids.

Veil of mosses. See Calyptra.

VEIN. Vena. A long membranous canal, which continually becomes wider, does not pulsate, and returns the blood from the arteries to the heart. All veins originate from the extremities of arteries only, by anastomosis, and terminate in the auricles of the heart; e. g. the vene cave in the right, and the pul-monary veices in the left auricle. They are composed,

9. Gluten. Forms a ductile elastic mass with water. I like arteries, of three tunics, or coats, which are much more slender than in the arteries, and are supplied internally with semilunar membranes, or folds, called valves. Their use is to return the blood to the heart.

The blood is returned from every part of the body, except the lungs, into the right auricle, from three

1. The vena cava superior, which brings it from the

head, neck, thorax, and superior extremities.

2. The vena cava inferior, from the abdomen and inferior extremities.

3. The coronary vein receives it from the coronary arteries of the heart.

1. The vena cava superior. This vein terminates in the superior part of the right auricle, into which it evacuates the blood, from the right and left subclavian vein, and the vena azygos. The right and left subclavian veins receive the blood from the head and upper extremities, in the following manner. The veins of the fingers, called digitals, receive the blood from the digital arteries, and empty it into, The cephalic of the thumb, which runs on the back

of the hand along the thumb, and evacuates itself into

the external radial.

The salvatella, which runs along the little finger, unites with the former, and empties its blood into the internal and external cubital veins. At the bend of the forearm are three veins, called the great cephalic, the basilic, and the median.

The great cephalic runs along the superior part of the forearm, and receives the blood from the external radial.

The basilic ascends on the under side, and receives the blood from the external and internal cubital veins and some branches which accompany the brachial artery, called venæ satellites

The median is situated in the middle of the forearm, and arises from the union of several branches. These three veins all unite above the bend of the arm, and

The brachial vein, which receives all their blood, and is continued into the axilla, where it is called,

This receives also the blood The axillary vein. from the scapula, and superior and inferior parts of the chest, by the superior and inferior thoracic veix,

the vena muscularis, and the scapularis.

The axillary vein then passes under the clavicle, where it is called the subclavian, which unites with the external and internal jugular veins, and the verte bral vein which brings the blood from the vertebal sinuses; it receives also the blood from the mediastinal, pericardiae, diaphragmatic, thymic, internal mammary, and laryngeal veins, and then unites with its fellow, to form the vena cava superior, or, as it is sometimes called, vena cava descendens.

The blood from the external and internal parts of the head and face is returned in the following manner into the external and internal jugulars, which termi

nate in the subclavians.

the thorax.

The frontal, angular, temporal, auricular, sublingual, and occipital veins, receive the blood from the parts after which they are named; these all converge to each side of the neck, and form a trunk, called the

external jugular vein.

The blood from the brain, cerebellum, medulla oblon gata, and membranes of these parts, is received into the lateral sinuses, or vein of the dura mater, one of which empties its blood through the foramen lacerum in basi cranii on each side into the internal jugular, which descends in the neck by the carotid arteries, receives the blood from the thyroideal and internal maxillary veins, and empties itself into the subclavians within

The vena azygos receives the blood from the bron-

chial, superior asophageal, vertebral, and intercostal veins, and empties it into the superior cava.

2. Vena cava inferior. The vena cava inferior is the trunk of all the abdominal veins and those of the lower extremities, from which parts the blood is returned in the following manner. The veins of the toes, called the digital veins, receive the blood from the digital arteries, and form on the back of the foot three branches, one on the great toe, called the cephalic, another which runs along the little toe, called the vena saphena, and a third on the back of the foot, vene dorsalis pedis; and those on the sole of the foot evacuate themselves into the plantar veins,

The three veins on the upper part of the foot coming

together above the ankle, form the anterior tibial; and the plantar veins with a branch from the calf of the leg, called the sural vcin, from the posterior tibial; a branch also ascends in the direction of the fibula, called the peroncal vein. These three branches unite before the ham, into one branch, the subpopliteal vcin, which ascends through the ham, carrying all the blood from the foot: it then proceeds upon the anterior part of the thigh, where it is termed the crural or femoral vein, receives several muscular branches, and passes under Poupart's ligament into the cavity of the pelvis, where it is called the external iliac.

The arteries which are distributed about the pelvis evacuate their blood into the external hamorrhoidal veins, the hypogastric veins, the internal pudendal, the vena magna ipsius penis, and obturatory veins, all of which unite in the pelvis, and form the internal iliac

The external iliac vein receives the blood from the external pudendal veins, and then unites with the internal iliac at the last vertebra of the loins; after which it forms with its fellow the vena cava inferior or ascendens, which ascends on the right side of the spine, receiving the blood from the sacral, lumbar, cmulgent, right spermatic veins, and the vena cava hepatica; and having arrived at the diaphragm, it passes through the right foramen, and enters the right auricle of the heart, into which it evacuates all the

blood from the abdominal viscera and lower extremities.

Vena caca hepatica. This vein ramifies in the substance of the liver, and brings the blood into the vena cava inferior from the branches of the vena porta, a great vein which carries the blood from the abdominal viscera into the substance of the liver. The trunk of this vein, about the fissure of the liver in which it is situated, is divided into the hepatic and abdominal portions. The abdominal portion is composed of the splenic, meseraic, and internal hamorrhoidal veins. These three venous branches carry all the blood from the stomach, spleen, pancreas, omentum, mesentery, gall-bladder, and the small and large intestines, into the sinus of the vena portse. The hepatic portion of the vena portse enters the substance of the liver, divides into innumerable ramifications, which secrete the bile, and the superfluous blood passes into corres-

ponding branches of the vena cava hepatica.

The action of the veins. Veins do not pulsate; the blood which they receive from the arteries flows through them very slowly, and is conveyed to the right auricle of the heart, by the contractility of their coats, the pressure of the blood from the arteries, called the vis a tergo, the contraction of the muscles, and respira-

vein by the valves, of which there are a great number.

Veinless leaf. See Avenius.

Veiny leaf. See Venosus.

Vejuca du guaco. A plant which has the power of curing and preventing the bite of venomous serpents. VELAME'NTUM BOMBYCINUM. The interior soft

membrane of the intestines.

VE'LUM. A veil.

VELUM PENDULUM PALATI. Velum; Velum palati-im. The soft palate. The soft part of the palate, which forms two arches, affixed laterally to the tongue and pharynx.

VELUM PUPILLE. See Membrana pupillaris.
VENA. (From venio, to come; because the blood

VENA. (From Sento, to come; because the blood comes through it.) A vein. See Vein.

Vena azygos. See Azygos vena.

Vena medinensis. See Medinensis vena.

Vena portæ. (Vena portæ, a portando; because through it things are carried.) Vena portarum. The great vein, situated at the entrance of the liver, which receives the blood from the abdominal viscera, and carries it into the substance of the liver. It is distinguished into the hepatic and abdominal portion; the former is ramified through the substance of the liver, and carries the blood destined for the formation of the bile, which is returned by branches to the trunk of the vena cava; the latter is composed of three branches; viz. the splenic, mesenteric, and internal hæmorrhoidal veins. See Vein.

The lacteal absorbents were so

VENE LACTEE. The lacteal absorbents were so called. See Lacteals.

VENEREAL. (Venereus; from Venus, because it belongs to acts of venery.) Of or belonging to the sexual intercourse.

Venereal disease. See Gonorrhaa and Syphilis. VENOSUS. Veiny. Applied by botanists to a leaf which has the vessels, by which it is nourished,

branched, subdivided, and more or less prominent, forming a network over either or both its surfaces; as in Crategus, Pyrolus terminalis, &c.
VE'NTER. A term formerly applied to the larger

circumscribed cavities of the body, as the abdomen and thorax.

VENTRICLE. (Ventriculus: from venter.) term given by anatomists to the cavities of the brain See Cerebrum, and Heart. and heart.

VENTRI'CULUS PULMONARIS. The right ventricle of

VENTRICULUS SUCCENTURIATUS. That portion of the duodenum, which is surrounded by the peritoneum, is sometimes so large as to resemble a second stomach,

and is so called by some writers.

VENTRILOQUISM. Gastriloquism. Engastrimythus. The formation of the voice within the mouth in such a way, as to imitate other voices than that which is natural to the person, and so as not to be seen to move the lips. Nothing is more easy to man than to imitate the different sounds he hears: this in fact he performs in many circumstances. Many persons imitate perfectly the voice and pronunciation of others; actors, for example. Hunters imitate the different cries of the game, and thus succeed in decoying it into their nets.

This faculty of imitating the different sounds, has given rise to the art called ventriloquism; but the persons who exercise this art, have no organization different from that of other men; they require only to have the organs of voice and speech very perfect, in order that they may readily produce the necessary

sounds.

The basis of this art is easily understood. We have found by experience, instinctively, that sounds are changed by many causes: for example, that they become feeble, less distinct, and that their expression changes, according as they are more distant from us: a man who is at the bottom of a well wishes to speak to persons who are at the top; but his voice will not reach their ears until it has received certain modifications, which depend upon the distance and the form of the tube through which it passes

If a person remark these modifications with care, and endeavour to imitate them, he will produce acoustic illusions, which would be equally deceiving to the ear as the observation of objects through a magnifying glass is to the eye. The error will be complete if he employ those deceptions which are necessary to dis-

tract the attention.

These illusions will be numerous in proportion to the talents of the performer: but we must not imagine that a ventriloquist produces vocal sounds, and articulates differently from other people. His voice is formed in the ordinary manner; only he is capable of modifying, according to his pleasure, the volume, the expression, &c. of it; and with regard to the words that he pronounces without moving his lips, he takes care to choose those into which no labial consonants enter, otherwise he would be obliged to move his lips. art is, in certain respects, for the ear what painting is for the eye. VE'NUS.

Copper was formerly so called by the

chemists.

VERATRIA. Veratrine. A new vegetable alkali, discovered lately by Pelletier and Caventou, in the veratrum sabatilla, or cevadilla, the veratrum album, or white hellebore, and the colchicum autumnale, or meadow saffron.

The seeds of cevadilla, after being freed from an unctuous and acrid matter by æther, were digested in boiling alkohol. As this infusion cooled, a little wax was deposited; and the liquid being evaporated to an extract, redissolved in water, and again concentrated by evaporation, parted with its colouring matter.

Acetate of lead was now poured into the solution, and an abundant yellow precipitate fell, leaving the fluid nearly colourless. The excess of lead was thrown down by sulphuretted hydrogen, and the filtered liquor being concentrated by evaporation, was treated with magnesia, and again filtered. The precipitate, boiled in alkohol, gave a solution, which, on evaporation, left a pulverulent matter, extremely bitter, and with decidedly alkaline characters. It was at first yellow, but

The precipitate by the acetate of lead, gave, on examination, gallic acid; and hence it is concluded, that the new alkali existed in the seed as a gallate.

Veratria was found in the other plants above men-tioned. It is white, pulverulent, has no odour, but excites violent sneezing. It is very acrid, but not bitter. It produced violent vomiting in very small doses, and, according to some experiments, a few grains may cause death. It is very little soluble in cold water. Boiling water dissolves about 1-1000th part, and becomes acrid

to the taste. It is very soluble in alkohol, and rather less soluble in ather.

VERATRINE. See Veratria.

VERATRUM. 1. The name of a genus of plants in the Linnwan system. Class, Polygamia; Order, Monacia.

The pharmacopæial name of white hellebore.

See Veratrum album. VERATRUM ALBUM. Helleborus albus; Elleborum album. White heliebore, or veratrum. Veratrumracemo supra-decomposito, corollis erectis, of Linnaus.
This plant is a native of Italy, Switzerland, Austria,
and Russia. Every part of the plant is extremely acrid
and poisonous. The dried root has no particular smell, but a durable, nauseous, and bitter taste, burning the mouth and fauces: when powdered, and applied to issues, or ulcers, it produces griping and purging; if snuffed up the nose, it proves a violent sternutatory. Gesner made an infusion of half an ounce of this root with two ounces of water; of this he took two drachms, which produced great heat about the scapulæ and in the face and head, as well as the tongue and throat, followed by singultus, which continued till vomiting was excited. Bergius also experienced very distressing symptoms, upon tasting this infusion. The root, taken in large doses, discovers such acrimony, and operates by the stomach and rectum with such violence, that blood is usually discharged; it likewise acts very powerfully upon the nervous system, producing great anxiety, tremors, vertigo, syncope, aphonia, interrupted respiration, sinking of the pulse, convulsions, spasms, and death. Upon opening those who have died of the effects of this poison, the stomach discovered marks of inflammation, with corrosions of its internal coat. The ancients exhibited this active medicine in maniacal cases, and it is said with success. The experience of Greding is somewhat similar: out of twenty-eight cases, in which he exhibited the bark of the root collected in the spring, five were cured. In almost every case that he relates, the medicine acted more or less upon all the excretions; vomiting and purging were very generally produced, and the matter thrown off the stomach was constantly mixed with bile; a florid redness frequently appeared on the face, and various cutaneous efflorescences upon the body; and, in some, pleuritic symptoms, with fever, supervened, so as to require bleeding; nor were the more alarming affections of spasms and convulsions unfre-Critical evacuations were also very evident; many sweating profusely, in some the urine was considerably increased, in others the saliva and mucous discharges: the uterine obstructions, of long duration, were often removed by its use. Veratrum has likewise been found useful in epilepsy, and other convulsive complaints: but the diseases in which its efficacy seems least equivocal, are those of the skin, as itch, and different prurient eruptions, herpes, morbus pediculosus, lepra, scrofula, &c.; and in many of these it has been successfully employed both internally and externally. As a powerful stimulant and irritating medicine, its use has been resorted to in desperate cases only, and even then it ought first to be exhibited in very small doses, as a grain, and in a diluted state, and to be gradually increased, according to the effects, which are generally of an alarming nature. The active ingredient of this plant is an alkali lately detected. See Veratria.

VERATRUM NIGRUM. See Helleborus niger.

by solution in alkohol, and precipitation by water, was obtained in a fine white powder.

The precipitate by the acetate of lead, gave, on exa-alkali has been detected in the seeds of this plant. See Veratria.

[VERATRUM VIRIDE. See American hellebore. VERBA'SCUM. (Quasi barbascum, from its hairy coat.) 1. The name of a genus of plants in the Linnaran system. Class, Pentandria; Order, Mono-

gynia.

2. The pharmacopæial name of the yellow and black

mullein.

Verbascum nigrum. The systematic name of the black mullein. Candela regia; Topsus barbatus; Candelaria; Lanaria. The Verbascum nigrum, and Verbaseum thapsus appear to be ordered indifferently by this name in the pharmacopeias. The flowers, leaves, and roots, are used occasionally as mild adstringents. The leaves possess a roughish taste, and promise to be of service in diarrheas and other debili-

romise to be of service in diarrheas and other debili-tated states of the intestines.

Verbascum thapses. The systematic name of the yellow mullein. See Verbascum nigrum.

VERBE'NA., (Quasi herbena; a name of distinc-tion for all herbs used in sacred rites.) Vervain. 1.

The name of a genus of plants in the Linnæan system. Class, Decandria; Order, Monogynia.

2. The pharmacopæial name of the vervain. See

Verbena officinalis.

Verbena rœmina. The hedge mustard is some-times so called. See Erysimum alliaria.

Verbenaca; Peristerium; Hierobotane; Herba sacra. Vervain. This plant is destitute of odour, and to the Vervain. taste manifests but a slight degree of bitterness and adstringency. In former times the verbena seems to have been held sacred, and was employed in celebrating the sacrificial rites; and with a view to this, more than the natural power of the plant, it was worn suspended about the neck as an amulet. This practice, thus founded on superstition, was, however, in process of time, adopted in medicine; and, therefore, to obtain its virtues more effectually, the vervain was directed to be bruised before it was appended to the neck; and of its good effects thus used for inveterate headaches, Forestus relates a remarkable instance. In still later times it has been employed in the way of cataplasm, by which we are told the most severe and obstinate cases of cephalalgia have been cured, for which we have the authorities of Etmuller, Hartman, and more have the authorities of Etmuller, Hartman, and more especially De Haën. Notwithstanding these testimonies in favour of the vervain, it has deservedly fallen into disuse in Britain; nor has the pamphlet of Mr. Morley, written professedly to recommend its use in scrofulous affections, had the effect of restoring its medical character. This gentleman directs the root of vervain to be tied with a yard of white satin riband round the neck, where it is to remain till the patient recovers. He also has recourse to infusions and ointments prepared from the leaves of the plant and ments prepared from the leaves of the plant, and occasionally calls in aid the most active medicines of the materia medica.

VERDIGRIS. Ærugo. An impure subacetate of copper. It is prepared by stratifying copper plates with the husks of grapes, after the expression of their juice, and when they have been kept for some time imperfectly exposed to the air, in an apartment warm. but not too dry, so as to pass to a state of fermentation, whence a quantity of vinegar is formed. The copper plates are placed in jars in strata, with the husks thus prepared, which are covered. At the end of twelve, fifteen, or twenty days, these are opened: the plates have an efflorescence on their surface of a green colour and silky lustre: they are repeatedly moistened with water; and at length a crust of verdigris is formed,

water; and at length a crust of verdigris is formed, which is scraped oif by a knife, is put into bags, and dried by exposure of these to the air and sun. It is of a green colour, with a slight tint of blue.

In this preparation the copper is oxidized, probably by the atmospheric air, aided by the affinity of the acetic acid; and a portion of this acid remains in combination with the oxide, not sufficient, however, to produce its saturation. When acted on by water, the acid with such a portion of oxide as it can retain in VERATRUM SIGRUM. See Hettleborus niger.

VERATRUM SABADILLA. Cevadilla hispanorum; bination with the oxide, not sufficient, however, to Seeadilla; Sabadilla; Hordeum causticum; Canis interfector. Indian caustic barley. The plant whose seeds are thus denominated, is a species of veratrum; they are powerfully caustic, and are administered with very great success as a vermifuge. They are also diurctic and emetic. The dose to a child, from two to th s water not being accidental, but existing in it in | state of the fluids prevails, indicated by prurient erup intimate combination.

Verdigris is used as a pigment in some of the processes of dying, and in surgery it is externally applied as a mild detergent in cleansing foul ulcers, or other open wounds. On account of its virulent properties, it ought not to be used as a medicine without professional advice; and in case any portion of this poison be accidentally swallowed, emetics should be first given, and afterward cold water, gently alkalized,

given, and afterward cold water, gently alkalized, ought to be drunk in abundance.

VERHEYEN, Philip, was born in 1648 at Vesbronck, in the county of Waes, and assumed the clerical profession; but an inflammation of his leg having rendered amputation necessary, he was determined afterward to study medicine. He accordingly graduated and settled at Louvain, where he was nominated professor of anatomy in 1689, and four years after of surgery also. His application was indefatigable, so that he attained distinguished eminence, and attached to his school a great number of nence, and attached to his school a great number of disciples. His celebrity was principally the result of a work, entitled, "Anatomia Corporis Humani," which passed through many editions and improvements, and superseded the compendium of Bartholine. He published also a Compendium of Medicine, a Treatise on Fevers, &c.

VERJUICE. An acid liquor prepared from grapes or apples, that are unfit to be converted into wine or cider. It is also made from crabs. It is principally used in sauces and ragouts, though it sometimes forms an ingredient in medicinal compounds.

VERMICULA'RIS. (From vermis, a worm.) Vermicular, shaped like or having the properties of a

worm, and forma, resemblance.) Worm-like.

VERMIFORM PROCESS. Protuberantia vermiformis. The substance which unites the two hemispheres of the cerebellum like a ring, forming a process. It is called vermiform, from its resemblance to the contor-

VERMIFUGE. (Vermifugus; from vermis, a worm, and fugo, to drive away.) See Anthelmintic. VERMILION. See Cinnabar. VE'RMIS. A worm. See Worm. VERMIS MORDICANS. Vermis repens. A species of herroric equations.

herpetic eruption on the skin.

VERNEY, GUICHARD-JOSEPH DU, was the son of a physician at Tours, and born in 1648. After studying at Avignon, he removed, at nineteen, to Paris, where he acquired high reputation as an anatomical lecturer. He was admitted, nine years after, into the Academy of Sciences, whose memoirs he enriched by his researches in natural history. In 1679 he was nominated professor of anatomy at the Royal Gardens. His work on the Organ of Hearing appeared about four years after, and was translated into various languages. He continued the pursuit of natural history with great ardour, and even to the detriment of his health, yet he was enabled, by a good constitution, to reach his eighty-second year. He bequeathed his valuable anatomical preparations to the academy. After his death, a treatise on the Diseases of the Bones was published from his manuscripts; and subsequently various other papers, under the title of "Œuvres Anatomique."

VERO'NICA. 1. The name of a genus of plants in the Linnæan system. Class, Diandria; Order, Mono-

gynia. Speedwell.

2. The pharmacopæial name of the male veronica.

See Veronica officinalis.

VERONICA BECCABUNGA. Beccabunga; Anagallis cquatica; Laver germanicum; Veronica aquatica; Cepaa. Water-pimpernel and brooklime. The plant Cepaa. Water-pimpernel and brooklime. The plant which bears these names, is the Veronica—racemis lateralibus, foliis ovatis planis, caule repente, of Linneus. It was formerly considered of much use in several diseases, and was applied externally to wounds and ulcers: but if it have any peculiar efficacy, it is to be derived from its antiscorbutic virtue. As a mild be derived from its antiscorbutic virtue. As a mild apophyses, a foramen, large enough to admit a finger. These foramina correspond with each other through all

tions upon the skin, or in what has been called the hot To derive much advantage from it, the juice ought to be taken in large quantities, or the fresh plant eaten as food.

VERONICA OFFICINALIS. The systematic name of Veronica officinalis. The systematic name of the plant which is called in the pharmacopæias Veronica mas; Thea germanica; Betonica pauli; Chamadrys spuria. Veronica—spicis lateralibus pedun culatis; foliis oppositis; caule procumbente, of Linnaus, is not unfrequent on dry barren grounds and heath, as that of Hampstead, flowering in June and July. This plant was formerly used as a pectoral against coughs and asthmatic affections, but it is now instly formatten. justly forgotten.

(Veronica virginica. This is a tall native plant, differing from the rest of its family in habit, and considered by Nuttall and some other botanists as a separate genus. Its root is very bitter, and somewhat nau-seous. It sometimes operates as a cathartic, in the dose of a scruple; but in several trials which I have made with it, I have found it uncertain in this respect.

Big. Mat. Med. A.]

VERRICULA'RIS TUNICA. The retina of the eye.

VERRUCA. 1. A wart, or thickening and indu ration of the cuticle which is raised up in different forms, mostly of the size of a lentil, or flat pea.

In botany, applied to a small round prominence on the inferior surface of the funguses.

VERRUCA'RIA. (From Vorruca, a wart: because it was supposed to destroy warts.) The Heliotropium

europæum, or turnsole.
VERRUCOSUS. Warty: applied to such appearances on vegetables, as on the stem of the Euonymus verrucesus; and to the appearance on the gourd-seed

vessel, as in the Gucurbita verrucosa. See Pepo.
VERTEBRA. (Vertebra, &, f.; from verto, to
turn.) The spine is a long bony column, which exturn.) The spine is a long bony column, which ex-tends from the head to the lower part of the trunk, and is composed of irregular bones, which are called vertebrae.

The spine may be considered as being composed of two irregular pyramids, which are united to each other in that part of the loins where the last of the

lumbar vertebræ is united to the os sacrum.

The vertebræ, which form the upper and longest pyramid, are called true vertebræ: and those which compose the lower pyramid, or the os sacrum and coccyx, are termed false vertebræ, because they do not in every thing resemble the others, and particularly because, in the adult state, they become perfectly immoveable, while the upper ones continue to be capable of motion. For it is upon the bones of the spine that the body turns, and their name has its derivation from the Latin verb verto, to turn, as observed above.

The true vertebræ, from their situations with respect

to the neck, back, and loins, are divided into three classes, of cervical, dorsal, and lumbar vertebræ. We will first consider the general structure of all these, and then separately describe their different classes.

In each of the vertebræ, as in other bones, we may remark the body of the bone, its process and cavities. The body may be compared to part of a cylinder cut off transversely; convex before, and concave behind, where it makes part of the cavity of the spine.

Each vertebra has commonly seven processes. first of these is the spinous process, which is placed at the back part of the vertebra, and gives the name of spine to the whole of this bony canal. Two others are called transverse processes, from their situation with respect to the spine, and are placed on each side of the spinous process. The four others, which are called oblique processes, are much smaller than the other three. There are two of these on the upper and two on the lower part of each vertebra, rising from near the basis of the transverse processes. They are sometimes called articular processes, because they are articulated with each other; that is, the two superior processes of one vertebra are articulated with the two inferior processes of the vertebra above it; and they are called oblique processes, from their situation with respect to the processes with which they are articulated. oblique processes are articulated to each other by a species of ginglymus, and each process is covered at its articulation with cartilage.

There is in every vertebra, between its body and

the vertebræ, and form a long bony conduit, for the lodgment of the spinal marrow.

Besides this great hole, there are four notches on each

side of every vertebra, between the oblique processes and the body of the vertebra. Two of these notches are at the upper, and two at the lower part of the bone. Each of the inferior notches, meeting with one of the superior notches of the vertebra below it, forms a foramen; while the superior notches do the same with the inferior notches of the vertebra above it. These four

foramina form passages for blood-vessels, and for the nerves that pass out of the spine.

The vertebræ are united together by means of a substance, compressible like cork, which forms a kind of partition between the several vertebræ. This intervertebral substance seems, in the fectus, to approach nearly to the nature of ligaments; in the adult it has a great resemblance to cartilage. When cut horizontally, it appears to consist of concentrical curved fibres: externally, it is firmest and hardest; internally, it becomes thinner and softer, till at length, in the centre, we find it in the form of a mucous substance, which facilitates the motion of the spine.

Genga, an Italian anatomist, long ago observed, that the change which takes place in these intervertebral cartilages, (as they are usually called,) in advanced life, occasions the decrease in stature, and the stooping forwards, which are usually to be observed in old people. The cartilages then become shrivelled, and consequently lose, in a great measure, their elasticity. besides this gradual effect of old age, these cartilages are subject to a temporary diminution, from the weight of the body in an erect posture, so that people who have been long standing, or who have carried a considerable weight, are found to be shorter than when they have been long in bed. Hence we are taller in the morning than at night. This fact, though seemingly obvious, was not ascertained till of late years. The difference in such cases depends on the age and size of the subject; in tall, young people, it will be nearly an inch; but in older, or shorter persons, it will be less considerable.

Besides the connexion of the several vertebræ, by means of these cartilages, there are likewise many strong ligaments, which unite the bones of the spine to each other. Some of these ligaments are external, and others internal. Among the external ligaments, we observe one which is common to all the vertebræ, extending, in a longitudinal direction, from the forepart of the body or the second vertebra of the neck, over all the other vertebræ, and becoming broader as it descends the other vertebræ, and becoming broader as it descends towards the os sacrum, where it becomes thinner, and gradually disappears. This external longitudinal ligament, if we may so call it, is strengthened by other shorter ligamentous fibres, which pass from one vertebra to another, throughout the whole spine. The internal ligament, the fibres of which, like the external one, are spread in a longitudinal direction, is extended over the back part of the bodies of the vertebræ, where they help to form the cavity of the spine, and reaches from the foramen of the occipital bone to the os

We may venture to remark, that all the vertebras diminish in density and firmness of texture, in proportion as they increase in size, so that the lower bræ, though larger, are not so heavy in proportion as those above them. In consequence of this mode-of structure, the size of the vertebræ is increased without adding to their weight; and this is an object of no little importance in a part of the body, which, besides flexibility and suppleness, seems to require lightness as one

of its essential properties.

In the fœtus, at the ordinary time of birth, each vertebra is found to be composed of three bony pieces, connected by cartilages which afterward ossify. One of these pieces is the body of the bone; the other two are the posterior and lateral portions, which form the foramen for the medulla spinalis. The oblique processes are at that time complete, and the transverse processes beginning to be formed, but the spinous processes are totally wanting. totally wanting.

The cervical vertebræ are seven in number; their bodies are smaller and of a firmer texture than the other bones of the spine. The transverse processes of these vertebræ are short, and forked for the lodgment of muscles; and, at the bottom of each of these processes, there is a foramen, for the passage of the cer-

vical artery and vein. The spinous process of each of these vertebræ is likewise shorter than the other verte-bræ, and forked at its extremity; by which means it allows a more convenient insertion to the muscles of the neck. Their oblique processes are more descrying of that name than either those of the dorsal or lumbar vertebræ. The uppermost of these processes are slightly concave, and the lowermost slightly convex. This may suffice for a general description of these ver-This may suffice for a general description of these vertebræ; but the first, second, and seventh deserve to be spoken of more particularly. The first, which is called Atlas, from its supporting the head, differs from all the other vertebræ of the spine. It forms a kind of bony ring, which may be divided into its anterior and posterior arches, and its lateral portions. Of these, the anterior arch is the smallest and flattest; at the middle of its convex forepart we observe a small tubercle which is here what the body is in the other vertebræ, is here what the body is in the other vertebræ. To this tubercle a ligament is attached, which helps to strengthen the articulation of the spine with the os occipitis. The back part of this anterior portion is concave, and covered with cartilage, where it receives the odontoid process of the second vertebra. The posterior portion of the vertebra, or, more properly speaking, the posterior arch, is larger than the anterior one. Instead of a spinous process, we observe a rising, or tubercle, larger than that which we have just now described, on the forepart of the bone. The lateral portions of the vertebra project, so as to form what are called the transverse processes, one on each side, which are transverse processes, one on each side, which are longer and larger than the transverse processes of the other vertebra. They terminate in a roundish tubercle, the end of which has a slight bend downwards. Like the other transverse processes, they are perforated at their basis, for the passage of the cervical artery. But, besides these transverse processes, we observe, both on the superior and inferior surface of these lateral portions of the first vertebra, an articulating surface. portions of the first vertebra, an articulating surface, covered with cartilage, answering to the oblique pro-cesses in the other vertebræ. The uppermost of these are oblong, and slightly concave, and their external edges rise somewhat higher than their internal brims. They receive the condyloid processes of the os occipitis, with which they are articulated by a species of gingly mus. The lowermost articulating surfaces, or the inferior oblique processes, as they are called, are large, concave, and circular, and are formed for receiving the superior oblique processes of the second vertebra; so that the atlas differs from the rest of the cervical verte bræ in receiving the bones, with which it is articulated both above and below. In the fætus we find this ver-tebra composed of five, instead of three pieces, as in the other vertebræ. One of these is the anterior arch; the other four are the posterior arch and the sides, each of

other four are the posterior arch and the sides, each of the latter being composed of two pieces. The transverse process, on each side, remains long in a state of epiphysis with respect to the rest of the bone.

The second vertebra is called dentatus, from the process on the upper part of its body, which has been, though perhaps improperly, compared to a tooth. This process, which is the most remarkable part of the vertebra, is of a cylindrical shape, slightly flattened, however, behind and before. Anteriorly, it has a convex, smooth, articulating surface, where it is received by the atlas, as we observed in our description of that yer. the atlas, as we observed in our description of that vertebra. It is by means of this articulation that the rotatory motion of the head is performed; the articulation of the os occipitis with the superior oblique processes of the first vertebra, allowing only a certain degree of motion backwards and forwards, so that when we turn the face either to the right or left, the atlas moves upon this odontoid process of the second vertebra. But as the face cannot turn a quarter of a circle, that is, to the shoulder, upon this vertebra alone, without being liable to injure the medulla spinalis, we find that all the cer-vical vertebra concur in this rotary motion, when it is in any considerable degree; and indeed we see many strong ligamentous fibres arising from the sides of the odontoid process, and passing over the first vertebra, to the os occipitis, which not only strengthen the articu-lation of these bones with each other, but serve to regulate and limit their motion. It is on this account that the name of moderators has sometimes been given to these ligaments. The transverse processes of the vertebra dentata are short, inclined downwards, and forked at their extremities. Its spinous process is short and thick. Its superior oblique processes are slightly con

VER VES

vex, and somewhat larger than the articulating surfaces of the first vertebra, by which mechanism the motion of that bone upon this second vertebra is performed with greater safety. Its inferior oblique processes have nothing singular in their structure.

The seventh vertebra of the neck differs from the rest chiefly in having its spino us process of a greater length, so that, upon this account, it has been sometimes

called vertebra prominens.

The dorsal vertebra, which are twelve in number, are of a middle size, between the cervical and lumbar vertebræ; the upper ones gradually losing their resemblance to those of the neck, and the lower ones coming nearer to those of the loms. The bodies of these vertebræ are more flattened at their sides, more convex before, and more concave behind, than the other bones of the spine. Their upper and lower surfaces are zontal. At their sides we observe two depressions, one at their upper, and the other at their lower edge, one at their upper, and the other at their lower edge, and the similar depressions in the vertebrase. above and below, form articulating surfaces, covered with cartilage, in which the heads of the ribs are received. These depressions, however, are not exactly ceived. These depressions, however, are not exactly alike in all the dorsal vertebre; for we find the head of the first rib articulated solely with the first of these vertebre, which has therefore the whole of the superior articulating surface within itself, independent of the vertebra above it. We may likewise observe a similarity in this respect in the eleventh and twelfth of the dorsal vertebre, with which the eleventh and twelfth ribs are articulated separately. Their spinous processes are long, flattened at the sides, divided at their upper and back part into two surfaces by a middle ridge. and back part into two surfaces by a middle ridge, which is received by a small groove in the inner part of the spinous process immediately above it, and connected to it by a ligament. These spinous processes are terminated by a kind of round tubercle, which slopes considerably downwards, except in the three lowermost vertebræ, where they are shorter and more erect. Their transverse processes are of considerable length and thickness, and are turned obliquely backwards. Anteriorly, they have an articulating surface, for receiving the tuberosity of the ribs, except in the eleventh and twelfth of the dorsal vertebræ to which the ribs are articulated by their heads only. In the last of these vertebræ the transverse processes are very short and thick, because otherwise they would be apt to strike against the lowermost ribs, when we bend the body to either side.

The lumbar vertebræ, the lowest of '\(\text{te} \) true vertebræ, are five in number. They are larger than the dorsal vertebræ. Their bodies are extremely prominent, and nearly of a circular form at their forepart; posteriorly they are concave. Their intermediate carrielly according to the concave. tilages are of considerable thickness, especially anteri-orly, by which means the curvature of the spine forwards, towards the abdomen, in this part, is greatly Their spinous processes are short and thick, of considerable breadth, erect, and terminated by a kind of tuberosity. Their oblique processes are of considerable thickness; the superior ones are concave, and turned inwards; the inferior ones convex, and turned outwards. Their transverse processes are thin and long, except in the first and last vertebra, where they are much shorter, that the lateral motions of the trunk might not be impeded. The inferior surface of all these vertebræ is slightly oblique, so that the fore-part of the body of each is somewhat thicker than its hind-part; but this is more particularly observable in the lowermost vertebra, which is connected with the os sacrum. Many anatomists describe the os sacrum and the os coccygis when considering the bones of the spine, while others regard them as belonging more properly to the pelvis. These bones the reader may con-It now remains to notice the uses of the spine. We find the spinal marrow lodged in this bony canal, secure from external injury. It defends the thoracic and abdominal viscera, and forms a pillar which supports the head, and gives a general firmness to the

whole trunk. To give it a firm basis, we find the bodies of the vertebræ gradually increasing in breadth as they descend; and to fit it for a variety of motion, it is composed of a great number of joints, with an intermediate elastic perfect flexibility.

We have already observed, that the lowermost and

largest vertebræ are not so heavy in proportion as those above them; their bodies being more spongy, excepting at their circumference, where they are more immediately exposed to pressure; so that nature seems every where endeavouring to relieve us of an unnecessary weight of bone. But behind, where the spinal marrow is more exposed to injury, we find the processes com-posed of very hard bone; and the spinous processes are in general placed over each other in a slanting direction, so that a pointed instrument cannot easily get between them, excepting in the neck, where they are almost perpendicular, and leave a greater space between them. Hence, in some countries, it is usual to kill cattle by thrusting a pointed instrument between the occiput and the atlas, or between the atlas and the second vertebra. Besides these uses of the vertebræ in defending the spinal marrow, and in articulating the several vertebra, as is the case with the oblique pro-cesses, we shall find that they all serve to form a greater surface for the lodgment of muscles, and to enable the latter to act more powerfully on the trunk, by affording them a lever of considerable length.

In the neck, we see the spine projecting somewhat forward, to support the head, which, without this assistance, would require a greater number of muscles. Through the whole length of the thorax it is carried in a curved direction backwards, and thus adds considerably to the cavity of the chest, and consequently affords more room to the lungs, heart, and large blood-vessels. In the loins, the spine again projects forwards, in a direction with the centre of gravity, by which means the body is easily kept in an erect posture; for otherwise we should be liable to fall forwards. But, at its inferior part, it again recedes backwards, and helps to form a cavity called the pelvis, in which the urinary bladder, intestinum rectum, and other viscera, are placed.

In a part of the body that is composed of so great a number of bones, and constructed for such a variety of motion, as the spine is, luxation is more to be expected than fracture; and this is very wisely guarded against in every direction, by the many processes that are to be found in each vertebra, and by the cartilages, liga-ments, and other means of comexion, which we have described as uniting them together.

VERTEBRAL. Vertebralis. Appertaining to the vertebræ, or bones of the spine.

VERTEBRAL ARTERY. Arteria vertebralis. A branch of the subclavian, proceeding through the vertebræ to within the cranium, where, with its fellow, it forms the basilary artery, the internal auditory, and the posterior artery of the dura mater.

VE'RTEX. (Vertex, 1cis, m.; from verto.) The crown of the head. The os verticis is the parietal

bone.

VERTICALIA OSSA. See Parietal bones. VERTICALIS. Vertical. Perpendicular. Applied to leaves which have both sides at right angles with the orizon; as in Lactuca scariola.

VERTICELLUS. A whorl. The name of a spe

cies of inflorescence, in which the flowers surround the stem in a sort of ring.

From the insertion of the flowers, the vesture, and

distance of the verticellus, it is called,
1. Pedunculatus; as in Milissa officinalis.
2. Sessilis, in Mentha arvensis.

3. Dimidiatus, going half round; as in Ballota disticha.

- 4. Nudus, without floral or other leaf; as in Salvia verticellata.
 - 5. Bracteatus, in Ballota nigra. 6. Distans, in Salvia indica.
 - Confertus, when crowded together.

7. Confertus, when crowded together.
VE'RTICIS OS. See Parietal bones.
VERTIGO. Giddiness.
VERVAIN. See Verbena officinalis.
Vervain, female. See Erysimum alliaria.
VESA LIUS, ANDREW, was born at Brussels about the year 1514. After pursuing his studies at different universities, and serving for two years professionally with the imperial army, he settled at Padua, and taught anatomy with great applause, which he subsequently anatomy with great applause, which he subsequently continued at some other schools in Italy. In 1544, he became physician to Charles V., and resided chiefly at the imperial court. About twenty years after, in the midst of his professional career, an extraordinary circumstance occurred, which was the cause of his ruin Being summoned to examine the body of a Spanish

gentleman, and having begun the operation too precipitately, the heart was observed to palpitate; in consequence of which, he was accused before the Inquisition: but the interposition of Philip II. procured him to be merely enjoined to make a pilgrimage to the Holy Land. While at Jerusalem, he was invited to the ana-tomical chair at Padua; but on his return, the ship was wrecked on the coast of Zante, where he soon after wrecked on the coast of Zante, where he soon after died. Vesalius has been represented as the first person who rescued anatomy from the slavery imposed upon it by deference to ancient opinions, and led the way to modern improvements. His first publication of note was a set of Anatomical Tables, which was soon followed by his great work "De Corporis Humani Fabrica," printed at Basil in 1543, and often since in several countries. The earliest impressions of the plates are most valued, but the explanations were made subsequently more correct. In a treatise "De Radicis Chinae Usu," he severely criticised the errors of Galen, which engaged him in a controversy with Fallopius. which engaged him in a controversy with Fallopius. His medical and surgical writings are not held in much estimation.

VESA'NIÆ. (The plural of vesania; from vesanas, a madman.) The fourth order in the Class Neuroses, of Cullen's nosological arrangement; comprehending diseases in which the judgment is impaired,

without either coma or pyrexia.

VESI'CA. (Diminutive of vas, a vessel.) VESI'CA.

bladder.

VESICA FELLIS. The gall-bladder. See Gall-bladder. VESICA URINARIA. The urinary bladder. See VESICA URINARIA.
Urinary bladder.
VESICATORY. (

Urinary bladder.

VESICATORY. (Vesicatorius; from vesica, a bladder: because it raises a bladder.) See Epispastic.

VESICLE. (Vesicula; a diminutive of vesica, a bladder.) An elevation of the cuticle, containing a transparent watery fluid.

VESICULA. See Vesicle.

VESICULA FELLIS. The gall-bladder.

VESICULA FRANCE. The confluent small-

VESICULE DIVE BARBARE. The confluent small-

Vesiculæ gingivarum. The thrush.
Vesiculæ pulmonales. The air-cells which compose the greatest part of the lungs, and are situated at the termination of the bronchia.

the termination of the bronchia.

Vesiculæ seminalæs. Two membranous receptacles, situated on the back part of the bladder, above its neck. The excretory ducts are called ejaculatory ducts. They proceed to the urethra, into which they open by a peculiar orifice at the top of the verumontanum. They have vessels and nerves from the neighbouring parts, and are well a pplied with absorbent vessels, which proceed to the lymphatic glands about the loins. The use of the vesiculæ seminales is to receive the semen brought into them by the vasa defeceive the semen brought into them by the vasa deferentia, to retain, somewhat inspissate, and to excern it sub coitu into the urethra, from whence it is pro-

pelled into the vagina uteri.

Vesicular fever. See Pemphigus.

VESTIBULUM. A round cavity of the internal ear, between the cochlea and semicircular canals, in which are an oval opening communicating with the cavity of the tympanum, and the orifices of the semi-circular canals. It is within this cavity and the semicircular canals, that the new apparatus discovered by the celebrated neurologist Scarpa, lies. He has demonstrated membranous tubes, collected loosely by cellular texture, within the bony semicircular canals, each of which is dilated in the cavity of the vestibule into an ampulla; it is upon these ampulæ, which communicate by means of an alreus communis, that branches of the portion mollis are expanded. the portio mollis are expanded.

VESUVIAN. Idocrase of Hauy. A subspecies of pyramidal garnet of a green or brown colour, found in great abundance in unaltered ejected rocks in the vi-

vexillum. (Vexillum, i, n.; a banner or standard.) The standard, or large uppermost petal at the back of a papilionaceous flower.

VIA. A way or passage. Used in anatomy. See

Primæ viæ. VI'BEX.

VIBEX. (Viber, icis, plu. Vibices.) The large purple spot which appears under the skin in certain malignant fevers.

VIBRI'SSÆ. (Vibrissa; from vibro, to quaver.)
Hairs growing in the nostrils. See Capillus.

VIBURNUM LANTANA. Liburnum. The pliant menty

VIN

The berries are considered as adstringent.

HY. The name of a town in France, in the VICHY. vichy. The name of a town in real spring. neighbourhood of which is a tepid mineral spring. account of its chalybeate and alkaline ingredients, it is taken internally, being reputed to be of great service in bilious colics, diarrheas, and in disorders of the stomach, especially such as arise from a relaxed or debilitated state of that organ.

These waters are likewise very useful when employed as a tepid-bath, particularly in rheumatism, sciatica, gout, &c. By combining the internal use with the external application, they have often effected a cure where other remedies had failed to afford relief.

VICIA. (Viscia, an old Latin name, derived by some etymologists from Vincio, to bind together, as the various species of this genus twine, with their tendrils, round other plants.) The name of a genus of plants in the Linnæan system. Class, Diadelphia; Order, Decandria.

Decandria. VICIA FABA. Vicia Faba. The systematic name of the common bean-plant. It is a native of Egypt. There are many varieties. Beans are very wholesome and nutritious to those whose stomachs are strong, and accustomed to the coarser modes of living. In delicate stomachs they produce flatulency, dyspepsia, cardialgia, &c. especially when old. See Legumina.

Victorial is Longa. See Allium victorialis.

VIEUSSENS RAYMOND, was born at a village in

VIEUSSENS, RAYMOND, was born at a village in Rovergne, graduated at Montpellier, and in 1671 was chosen physician to the hospital of St. Eloy. The result of his anatomical researches in this situation was published under the title of Neurolegy, and gained him great reputation. His name became known at court, and Mad. de Montpensier made him her physician. After her death he returned to Montpellier, and directed his attention to chemistry; and having found an acid in the caput mortuum of the blood, he made this

the groundwork of a new medical theory. In advanced life, his writings were multiplied without augmenting his reputation. He died in 1726.

VIGILANCE. Pervigilium. Vigilance, when attended by anxiety, pain in the head, loss of appetite, and diminution of strength, is by Sauvages and Sagar considered as a genus of discase, and is called Agrypnia.

VILLOSUS. Villous, shaggy: applied in anatomy to a velvet-like arrangement of fibres or vessels, as the villous coat of the intestines: and in botany to the stem of the Cineraria integrifolia, and to other parts of plants; as the receptacle of the Artemisia absynthium.

VILLUS. A species of hairy pubescens of plants, consisting of soft, slender, upright, short, and scarcely conspicuous, and for the most part white hair-like fila-

VI'NCA. (From vincio, to bind: because of its usefulness in making bands.) The name of a genus of plants in the Linnwan system. Class, Pentandria;

Order, Monogynia.

Vinca minor. The systematic name of the less periwinkle. Vinca pervinca; Clematis daphnoides major. It possesses bitter and adstringent virtues, and is said to be efficacious in stopping nasal harmorrhages when bruised and put into the nose. Boiled, it forms a useful adstringent gargle in common sore throat, and it is given by some in phthisical complaints.

VINCA PERVINCA. See Vinca minor.
VINCETO'XICUM. (From vinco, to overcome, and toxicum, poison: so named from its supposed virtue of resisting and expelling poison.) See Asclepias vince-

VINE. See Vitis. Vine, white. See Bryonia alba. Vine, wild. See Bryonia alba. VINEGAR. See Acctum.

VINEGAR. See Acctum.

Vinegar, aromatic. See Acctum aromaticum.

Vinegar, distilled See Acctum.

Vinegar, spirits of. See Acctum.

Vinegar of squills. See Acctum scilla.

Vinegar, thienes'. See Acctum aromaticum.

VI'NUM. See Wine.

VINUM ALOES. Wine of aloes. Formerly known by the names of Tinctura hiera, and Tinctura sacra.

Take of extract of spiked aloe, eight ounces; canellabark, two ounces; wine, six pints; proof spirits, two pints. Rub the aloes into powder with white sand, previously cleansed from any impurities; rub the capreviously cleansed from any impurities; rub the canella-bark also into powder; and after having mixed

these powders together, pour on the wine and spirit. | remedy for the crusta lactea. Macerate for fourteen days occasionally shaking the mixture, and afterward strain. A stomachic purga-tive, calculated for the aged and phlegmatic, who are not troubled with the piles. The dose is from a half to a whole fluid ounce.

VINUM ANTIMONII. In small doses this proves alterative and diaphoretic, and a large dose emetic; in which last intention it is the common emetic for chil-

dren.

VINUM ANTIMONII TARTARIZATI. See Antimonium

tartarizatum.

VINUM FERRI-Wine of iron, formerly called Vinum chalybeatum. Take of iron filings, two ounces; wine, two pints. Mix, and set the mixture by for a month, occasionally shaking it; then filter it through paper. For its virtues, see Ferrum tartarizatum.

VINUM IPECACUANHA. Wine of ipecacuanha. Take of ipecacuanha-root, bruised, two ounces; wine, two pints. Macerate for fourteen days, and strain. The dose, when used as an emetic, is from two fluid drachms

to half a fluid ounce.

VINUM OPII. Wine of opium, formerly known by the names of Laudanum tiquidum sydenhami, and Tinctura thebaica. Take of extract of opium, an ounce; cinnamon-bark, bruised, cloves, bruised, of each a drachm; wine, a pint. Macerate for eight days, and strain. See Opium.

VINUM VERATRI. Wine of white hellebore. Take of white hellebore-root, sliced, eight ounces; wine, two pints and a half; macerate for fourteen days, and

strain. See Veratrum.

VI'OLA. (From low; because it was first found in Ionia.) 1. The name of a genus of plants in the Linnwan system. Class, Syngenesia; Order, Monogynia. The violet.

2. The pharmacopæial name of the sweet violet.

See Viola odorata. VIOLA CANINA. The dog-violet. The root of this plant possesses the power of vomiting and purging the bowels; with which intention a scruple of the dried root must be exhibited. It appears, though neglected in this country, worthy the attention of physicians.

VIOLA IPECACUANHA. The plant which was sup-

posed to afford the ipecacuanha root.

VIOLA LUTEA. See Cheiranthus cheiri.
VIOLA ODORATA. The systematic name of the sweet violet. Viola—acaulis, foliis cordatis, stolonibus repentibus, of Linnæus. The recent flowers of his plant are received into the catalogues of the materia medica. They have an agreeable sweet smell, and a mucilaginous bitterish taste. Their virtues are purgative or laxative, and by some they are said to possess an anodyne and pectoral quality. The officinal preparation of this flower is a syrup, which, to young children, answers the purpose of a purgative; it is also of considerable utility in many chemical inquiries, to detect an acid or an alkali; the former changing the blue colour to a red, and the latter to a green.

VIOLA PALUSTRIS. See Pinguicula. VIOLA PEDATA. The violets are generally mucila-VIOLA PEDATA. ginous plants, and employed as demulcents in catarrhand strangury. Some of them are allied to ipecacuanha, and contain emetin in their substance. The
viola pedata, a native species retained in the pharmacoppeia, is considered a useful expectorant and lubri-

copeda, is considered a useful expectorant and hibricating medicine in pulmonary complaints, and is given in syrup or decoction. Big. Mat. Med. A.]
VIOLA TRICOLOR. Harts-ease. Pansies. This well-known beautiful little plant grows in corn-fields, waste and cultivated grounds, flowering all the summer months. It varies much by cultivation; and by the vivid colouring of its flowers often becomes extremely beautiful in gardens, where it is distinguished by various names. To the taste, this plant in its recent state is extremely glutinous, or mucilaginous, accompanied with the common herbaceous flavour and roughness. By distillation with water, according to Haase, it affords a small quantity of odorous essential oil, of a somewhat acrid taste. The dried herb yields about half its weight of watery extract, the fresh plant about one-eighth. Though many of the old writers on the materia medica represent this plant as a powerful medicine in epilepsy, asthma, ulcers, scabies, and cutaneous complaints, yet the viola tricolor owes its present character as a medicine to the modern authorities of Starck, Metzger, Haase, and others, especially as a

remedy for the crusta lactea. For this purpose, a handful of the fresh herb, or half a drachm of it dried, boiled two hours in milk, is to be strained and taken night and morning. Bread, with this decoction, is also to be formed into a poultice, and applied to the part. By this treatment, it has been observed, that the eruption during the first eight days, increases, and that the urine, when the medicine succeeds, has an odour similar to that of cats; but on continuing the use of the plant a sufficient time, this smell goes off, the scabs disappear, and the skin recovers its natural purity. Instances of the successful exhibition of this medicine, as cited by these authors, are very numerous; indeed this remedy, under their management, seems rarely, if ever, to have failed. It appears, however, that Mursinna, Akermann, and Henning were less fortunate in the employment of this plant: the last of whom declares, that in the different cutaneous disorders in which he used it, no benefit was derived. Haase, who administered this species of violet in various forms and large doses, extended its use to many chronic disorders; and from the great number of cases in which it proved successful, we are desirous of re-

It is remarkable that Bergius speaks of this plant as a useful mucilaginous purgative, and takes no notice. of its efficacy in the crustea lactea, or in any other

disease.

VIS. Power. In physiology, applied to vital power and its effects: hence we vita, vis insita, vis irritabilis, vis nervia, &c.

VIS CONSERVATRIX. See Vis medicatrix natura.

VIS ELASTICA. Elasticity.
VIS INERTIÆ. The propensity to rest inherent in nature.

Vis Insita. This property is defined by Haller to be that power by which a muscle, when wounded, touched, or irritated, contracts, independent of the will of the animal that is the object of the experiment, and without its feeling pain. See Irritability.

VIS MEDICATRIX NATURA. Vis conservatriz. term employed by physicians to express that healing power in an animated body, by which, when diseased, the body is enabled to regain its healthy actions.

Vis Mortua. That property by which a muscle, after the death of the animal, or a muscle, immediately after having been cut out from a living body, contracts.

Vis Plastica. That facility of formation which

spontaneously operates in animals.

VIS A TERGO. Any impulsive power.
VIS VITE. The natural power of the animal machine in preserving life.

From the most remote antiquity, philosophers were persuaded that a great part of the phenomena peculiar to living bodies, did not follow the same course, nor obey the same laws, as the phenomena proper to brute matter.

To these phenomena of living bodies, a particular cause has been assigned, which has received different denominations. Hippocrates bestows on it the appellation of physis, or nature; Aristotle calls it the mosting or generating principle; Kaw Boerhaave, the impetum faciens; Van Helmont, archæa; Stahl, the soul; others, the vis insita, vis vita, vital force, &c.
VISCIDITY. (Viciditas; from viscus.) Viscosity: glutinous, sticky, like the bird-lime.
VISCIDUS. Viscid. 1. Of the nature of ropy pulp of the viscum, or missletoe. In general use to imply viscidity in fluids, &c.

viscidity in fluids, &c.

See Leator.
 VI SCUM. (Viscum, i, n.; and Viscus, i, m. Derived from the Greek, ιξος, altered by the Æolians into βισκος.)
 The fruit of the misletoe. See Viscum

album.

2. The name of a genus of parasitical plants in the Linnæan system. Class Diacia; Order, Tetran-

Viscum album. Viscus guercinus. Misletoe. This singular parasitical plant most commonly grows on apple-trees, also on the pear, hawthorn, service, and the pear, hawthorn, service, willow elm. hornoak, hazel, maple, ash, lime-tree, willow, elm, horn-bean, &c. It is supposed to be propagated by birds, especially by the field-fare and thrush, which feed upon its berries, the seeds of which pass through the bowels unchanged; and along with the excrement adhere to the branches of trees where they vegetate.

The misletoe of the oak has, from the times of the ancient Druids, been always preferred to that produced on other trees; but it is now well known that the viscus

guercus differs in no respect from others.

This plant is the εξ of the Greeks, and was in former times thought to possess many medicinal virtues; however, we learn but little concerning its efficacy from the ancient writers on the Materia Medica, nor will it be deemed necessary to state-the extraordinary powers ascribed to the misletoe by the crafty designs of Druidical knavery. Both the leaves and branches of the dical knavery. Both the leaves and branenes of the plant have very little smell, and a very weak taste of the nauseous kind. In distillation they impregnate water with their faint unpleasant smell, but yield no essential oil. Extracts made from them by water, are bitterish, roughish, and subsaline. The spirituous extract of the wood has the greatest austerity, and that of the leaves the greatest bitterness. The berries abound with an extremely tenacious and most unabound with an extremely tenacious and most ungrateful sweet mucilage.

The viscus quercus obtained great reputation for the The viscus quercus obtained great reputation for the cure of epilepsy; and a case of this disease, of a woman of quality, in which it proved remarkably successful, is mentioned by Boyle. Some years afterward its use was strongly recommended in various convulsive disorders by Colbach, who has related several instances of its good effects. He administered it in substance in doses of half a drachm, or a descent of the wood or leaves or an infusion of an drachm, of the wood or leaves, or an infusion of an ounce. This author was followed by others, who have not only given testimony of the efficacy of the misletoe in different convulsive affections, but also in those complaints denominated nervous, in which it was supposed to act in the character of a tonic. But all that has been written in favour of this remedy, which is certainly well deserving of notice, has not prevented to the college of t it from falling into general neglect; and the colleges of London and Edinburgh have, perhaps not without reason, expunged it from their catalogues of the Materia Medica.

VI'SCUS. (Viscus, eris, n.; plural, viscera.) 1. Any organ or part which has an appropriate use, as the viscera of the abdomen, &c.

2. (Viscus, i, m.) The name of the misletoe. Sec

Viscum album.

VISION. (Visus, us, m.) The function which enables us to perceive the magnitude, figure, colour, distance, &c. of bodies. The organs which compose the apparatus of vision enter into action under the influence of a particular excitant, or stimulus, called

We perceive bodies, we take cognizance of many of their properties, though they are often at a great distance;—there must then be between them and our eye some intermediate agent; this intermediate substance we denominate light. Light is an excessively subtle fluid, which emanates from those bodies called luminous, as the sun, the fixed stars, bodies in a state of ignition, phosphorescence, &c. Light is composed of atoms which move with a prodigious rapidity, since they pass through about eighty thousand leagues of space in a second.

A series of atoms, or particles, which succeed each other in a right line without interruption are denominated a ray of light. The atoms which compose every ray of light are separated by intervals, that are considerable in proportion to their mass; which circumstances permit a considerable number of rays to cross each other in the same point, without their par-

ticles coming in contact.

The light that proceeds from luminous bodies forms diverging cones, which would prolong themselves in-definitely, did they meet with no obstacles. Philoso-phers have from thence concluded, that the intensity of light in any place, is always in an inverse ratio to the square of the distance of the luminous bodies from which it proceeds. The cones that are formed by the light in passing from luminous bodies, are, in general, called pencils of light, or pencils of rays, and the bodies through which the light moves are designated

by the name of media.

When light happens to come in contact with certain bodies that are called opaque, it is repulsed, and its direction is modified according to the disposition of those bodies.—The change that light suffers in its course is, in this case, called reflection. The study of reflection constitutes that part of physics, which is

named catoptrics.

named catoptrics.

Certain bodies allow the light to pass through them; for instance glass: they are said to be transparent. In passing through these bodies, light suffers a certain change which is called refraction. As the mechanism of vision rests entirely upon the principle of refraction, the examination of these becomes, therefore, a matter of importance.

The point where a ray of light enters into a medium is called the point of immersion; and that where it

goes out is called the point of emergence.

If the ray comes in contact with a medium in a line perpendicular to its surface, the ray then continues its direction without any change; but if its direction is oblique to the surface of the medium, the ray is then turned out of its course, and appears broken at the point of immersion

point of immersion.

The angle of incidence is that which the incidentray makes with a perpendicular line drawn over the
point of immersion upon the surface of the medium,
and the angle of refraction is that which the broken
ray makes with the perpendicular.

If the ray of light pass from a rare medium into one
more dense, it inclines towards the perpendicular at
the point of contact; but it declines from it if it pass
from a dense medium into one that is rarer. The same phenomenon takes place, but in a contrary direction, when the ray enters into the first medium; this takes place in such a manner, that if the two surfaces of the medium traversed by the ray are parallel to each other, the ray in passing into the surrounding medium, will take a direction parallel to that of the incident ray. incident ray.

Bodies refract the light in proportion to their den-ty and combustibility. Thus, of two bodies of equal sity and combustibility. Thus, of two bodies of equal density, one of which being composed of more combustible elements than the other, the refractive bustible elements than the other, the refractive power of the first will be greater than that of the

All transparent bodies refract at the same time that they reflect the light. On account of this property these bodies are capable of being used as a sort of mirror. When their density is very inconsiderable, they are not wishle upless that such as that of the air, they are not visible unless their mass be considerable.

The form of a refractive body has no influence upon its refractive power; but it modifies the disposition of the refracted rays in respect to each other. In fact, the perpendiculars to the surfaces of the body, approaching or receding according to the form of the body, the refracting rays should at the same time approach or receding.

When, by the effort of a refractive body, the rays tend towards each other, the point where they unite is called the focus of the refractive body. Bodies of a lenticular form are those which present principally this

phenomenon.

A refractive body, with parallel surfaces, does not change the direction of the rays, but it inclines them towards its axis by a sort of transportation. A refractive body of two convex sides does not possess a greater refractive power than a body convex on one side, and

plane on the other; but the point behind it in which |

the rays are united is much nearer.

The discovery of the action of refractive bodies upon light has not been an object of simple curiosity; it has led to the construction of ingenious instruments, by means of which the sphere of human vision has been extended to an extraordinary degree.

Apparatus of vision.—The apparatus of vision is composed of three distinct parts.

The first modifies the light.

The second receives the impression of that fluid. The third transmits this impression to the brain.

The apparatus of vision is of an extremely delicate texture, capable of being deranged by the least accident. Nature has also placed before this apparatus a series of organs, the use of which is to protect and maintain it in those conditions necessary to the perfect exercise of its functions. Those protecting parts are the eyebrows, the eyelids, and the secreting and exercing apparatus of the tears.

eyebrows, which are peculiar to man, are

formed,

By hair, of a variable colour.
 By the skin.

3. By sebaceous follicles placed at the root of every hair.

4. By muscles destined for their various motions, viz. the frontal portion of the occipito-frontalis, the superior edge of the orbicularis palpebrarum, the supercilium.

5. Numerous vessels.

Nerves.

The eye is composed of parts which have very dif-ferent uses in the production of vision. They may be distinguished into refractive, and non-refractive.

The refractive parts are:

A. The transparent cornea, a refractive body, convex and concave, which, in its transparency, its form, and its insertion, pretty much resembles the glass that is placed before the face of a watch.

B. The aqueous humour which fills the chambers of the eye; a liquid which is not purely aqueous, as its name indicates, but is essentially composed of water, and of a little albumen.

C. The crystalline humour, which is improperly compared to a lens. The comparison would be exact, were it merely for the form; but it is defective in regard to structure. The crystalline is composed of concentric layers, the hardness of which increases from the surface to the centre, and which probably possesses different refractive powers. The crystalline is, besides, surrounded by a membrane, which has a great effect upon vision, as experience teaches us. A lens is homogeneous in all its parts; at its surface, as in every point of its substance; it possesses every where the same refractive power. However, it is necessary to remark that the curve of the anterior surface of the crystalline is very far from being similar to that of the posterior aspect. This last belongs to a sphere, of which the diameter is much less than that of the sphere to which the curve of the anterior surface belongs. Until now it has been understood that the crystalline was composed mostly of albumen; but according to a new analysis of Berzelius, it does not contain any: it is formed almost entirely of water, and of a peculiar matter that has a great analogy, in its chemical properties, to the colouring matter of the blood.

D. Behind the crystalline is the vitreous humour, so called because of its resemblance to melted glass.

Each of the parts which we have noticed is enveloped by a very thin membrane, which is transparent like the part that it covers: thus, before the cornea is the conjunctiva; behind it is the membrane of the aqueous humour, which lines all the anterior chamber of the gray, that is, the application surface of the iris. of the eye; that is, the anterior surface of the iris, and the posterior surface of the cornea.

The crystalline is surrounded by the crystalline capsule, which adheres by its circumference to the mem-brane that covers the vitreous humour. This, in passing from the circumference of the crystalline upon the anterior and posterior surfaces of this part, leaves between an interval which has been called the canal

goudronne. The vitreous humour is also surrounded by a membrane called hyaloid. This membrane does not alone brane called hyaloid. This membrane does not alone converge from the perpendicular towards the point of

separating, forms it into cells. The details of anatomy, with regard to the disposition of the cells, have not hitherto added any thing to what is known of the use of the vitreous humour.

The eye is not only composed of parts that are re-fractive, but it is composed also of membranes which

have each a particular use; these are:

A. The sclerotic, the exterior envelope of the eye, which is a membrane of a fibrous nature; it is thick and resisting, and its use is evidently to protect the interior parts of the organ; it serves besides as a point of insection for many muscles that move the eye.

B. The choroid, a vascular and nervous membrane, formed by two distinct plates; it is impregnated with a dark matter which is very important to vision.

C. The iris, which is seen behind the transparent cornea, is differently coloured in different individuals; it is pierced in the centre by an opening called the pupil, which dilates or contracts according to certain circumstances which we shall notice. The iris adheres outwardly, and by its circumference, to the sclerotic, by a cellular tissue of a particular nature, which is called the ciliary, or iridian ligament. There are, behind the iris, if they were sufficiently prolonged: these are

the ciliary processes.

Neither the use nor the structure of these bodies has been properly determined: they are believed by some to be nervous, by others to be muscular, while others think them glandular, or vascular. The truth is, their real

structure is not understood.

The colour of the iris depends on its structure, which is variable, and on that of the dark layer of its posterior surface, the colour of which shines through the iris. For instance, the tissue of the iris is nearly white in blue eyes; in this case the dark colour behind appears almost alone, and determines the colour of the

eyes Anatomists differ about the nature of the tissue of the iris: some think it entirely like that of the choroid, essentially composed of vessels and of nerves; others have imagined they saw a great many muscular fibres in it; others consider this membrane a tissue sui generis; and others confound it with the erectile structure. Estwards has shown that the iris is formed by four layers very easy to be distinguished, two of which are a continuation of the laminæ of the choroid; a third belongs to the membrane of the aqueous humour;

and a fourth forms the proper tissue of the iris.

Between the choroid and the hyaloid there exists a membrane essentially nervous. This membrane, known by the name of the retina, is almost transparent; it presents a slight opacity, and a tint feebly inclining to lilac; it is composed of the expansion of the threads which compose the optic nerve.

The eye receives a great number of vessels, the ciliary arteries and veins, and many nerves, the greater part of which come from the ophthalmic gan-

glion.
The optic nerve preserves the communication be-

tween the brain and the eye.

Mechanism of vision.—In order the better to explain
the action of light in the eye, let us suppose a luminous cone commencing in a point placed in the prolongation of the anterior-posterior axis of the eye. We see that only the light which falls upon the cornea can be useful for vision; that which falls on the white of the eye, the eyelids and eyelashes, contributes nothing; it is reflected by those parts differently according to their colour. The cornea itself does not receive the light on its whole extent; for it is generally covered in part by the border of the eyelids.

The cornea having a fine polish on its surface, as soon as the light reaches it, part of it is reflected, which contributes to form the brilliancy of the eye. The same reflected light forms the images which one sees behind the cornea. In this case the cornea acts as a convex mirror. The form of the cornea indicates the influence it should have upon the light which enters the cye: on account of its thickness, it only causes the rays to converge a little towards the axis of the pencil; in other words it increases the intensity of the light which penetrates into the anterior chamber.

The rays, in traversing the cornea, pass from a more rare to a denser medium; consequently they ought to

VIS VIS

contact. If, on entering into the anterior chamber, they passed out again, they would diverge as much from the perpendicular as they had converged before; and would, therefore, assume their former divergence; but as they enter into the aqueous humour, which is a medium more refractive than air—they incline less from the percenticular and the percenti from the perpendicular, and consequently diverge less than if they had passed back into the air.

Of all the light transmitted to the anterior chamber, only that which passes the pupil can be of use to vision; all that which falls upon the iris is reflected, returns through the cornea, and exhibits the colour of the iris. In traversing the posterior chamber the light undergoes no new modification, as it proceeds always in the same medium (the aqueous humour).

It is in traversing the crystalline that light undergoes the most important modification. Philosophers comthe most important modification. Finisoppiers compare the action of this body to that of a lens, the use of which would be to assemble all the rays of any cone of light upon a certain point of the retina. But as the crystalline is very far from being like a lens, we merely mention this opinion, which is generally received, to remark that it merits a fresh investigation. Every thing positive which can be said on the subject is, that the crystalline ought to increase the intensity of the light which is directed towards the bottom of the eye, with an energy proportionate to the convexity of its posterior surface. It may be added, that the light which passes near the circumference of the crystalline is probably reflected in a different manner from that which passes through the centre; and that therefore the contraction and dilatation of the pupil ought to possess an influence upon the mechanism of vision, which deserves the attention of philosophers.

The whole of the light which arrives at the anterior

surface of the crystalline, does not penetrate into the vitreous body; it is partly reflected. One part of this reflected light traverses the aqueous humour and the cornea, and contributes to form the brilliancy of the eye; another falls upon the posterior surface of the iris, and is absorbed by the dark matter found there.

It is probable that something of this sort happens at

every one of the strata or layers which forms the crys-

The vitreous body possesses a less refractive power than the crystalline, consequently the rays of light which, after having passed the crystalline, penetrate into the vitreous body, diverge from the perpendicular at the point of contact. Its use then, with regard to the direction of the rays in the eye, is to increase their con-vergence. It might be said, that in order to produce the same result, nature had only to render the crystalline a little more refractive; but the vitreous humour has another most essential use, which is, to give a larger extent to the retina, and thus to increase the field

of vision.

What we said about a cone of light, commencing in a point placed in the prolongation of the anterio-posterior axis of the eye, must be repeated for every luminous cone commencing in other points, and directed towards the eye; with this difference, that, in the first case, the light tends to unite at the centre of the retina; while the light of the other cones tends to unite in different points, according to that form which they commence. Thus the luminous cones commencing from the commence of the retina while these below, unite at the upper part of the retina, while those that come from above, unite at the lower part of this membrane. The other rays follow a direction analogous; so that there will be formed at the bottom of the eye an exact representation of every body placed before it, with this difference, that the images will be inverted, or in a position contrary to that of the objects they represent.

This result is ascertained by different means.

this purpose, eyes, constructed artificially of glass, which represent the transparent cornea, and the crys-

which represent the transparent cornea, and the crystalline; and of water, which represents the aqueous and vitreous humours, have long been employed.

Motions of the iris.—Some say that the pupil varies its dimensions according to the distance of the object. This fact has not been sufficiently demonstrated; hitherto the influence of the intensity of light is the only thing that has been correctly observed.

The choroid is of use to vision, principally by the dark matter with which it is impregnated, and which absorbs the light immediately after it has traversed the retina. One may consider, as a confirmation of this

opinion, what happens to some individuals in whork some parts of this membrane become varicose: the dilated vessels throw off the darker matter which covered them, and every time that the image of the object falls upon the point of the retina corresponding to these vessels, the object appears spotted with red.

The state of vision in Albino men and animals, in which the choroid and the iris are not coloured black, approach will make this control of the retinal control of the retinal

supports still more this assertion; vision is extremely imperfect in them: during the day, they can scarcely see sufficiently to go about. Mariotte, Lecat, and others, have allowed to the choroid the faculty of perceiving light. This idea is completely without proof.

We know very little, that is certain, of the ciliary processes. They are generally supposed contractile; but some think that they are destined to the motions of the iris, while others imagine they are intended to bring

the iris, while others imagine they are intended to bring forward the crystalline.

The rays of light have now reached the refina, which receives the impression of light when it is within certain limits of intensity. A very feeble light is not felt by the retina; too strong a light hurts it, and renders it unfit for action.

When the retina receives too strong a light, the impression is called dazzling; the retina is then incapable for some time of feeling the presence of the light. This happens when one looks at the sun. After having been long in the dark, even a very feeble light produces dazzling.—When the light is exceedingly weak, and the eye made to observe objects narrowly, the retina becomes fatigued, there follows a painful feeling in the orbit, and also in the head.

A light, of which the intensity is not very strong, but which acts for a certain time upon a determined point of the retina, renders it at last insensible in this point. When we look for some time at a white spot upon a black ground, and afterward carry the eye to a white ground, we seem to perceive a black spot; this happens because the retinal has become insensible in the point which was formerly fatiered by the white light. which was formerly fatigued by the white light. In the same manner, after the retina has been some time without acting in one of its points while the others have acted, the point which has been in repose becomes of an extreme sensibility, and on this account objects seem as if they were spotted. In this manner it is explained, why, after having looked a long time at a red spot, white bodies appear as if spotted with green: in this case, the retina has been mentioned in the other red rays; and we know that a ray of white light from rays, and we know that a ray of white light, from which the red is subtracted, produces the sensation of

The same sort of phenomena happens when we have The same sort of phenomena happens when we have looked long at a red body, or one of any other colour, and afterward look at, white, or differently coloured bodies.—We perceive with facility the direction of the light received by the retina. We believe instinctively that light proceeds in a right line, and that this line is the prolongation of that according to which the light penetrated into the cornea. Therefore, whenever the hight has been modified in its direction, before reaching the eye, the rating gives us nothing certain. Optical the eye, the retina gives us nothing certain. Optical illusions proceed principally from this cause

The retina can receive at the same time impressions in every point of its extent, but the sensations which result from them are then incorrect. It may be affected by the image of one or two objects only, though a much greater number be impressed on it; the vision is then much more defined.

The central part of the membrane appears to possess much more sensibility than the rest of its extent; we therefore make the image fall on this part when we wish to examine an object with attention.

Does the light act upon the retina by simple contact only, or must it traverse this membrane? The pre-sence of the choroid in the eye, or rather the dark matter which covers it, renders this second opinion the most probable.

That part of the retina which corresponds with the centre of the optic nerve, has been said to be insensible to the impression of light. I know nothing which can

directly prove this assertion.

There is no doubt that the optic nerve transmits to the brain, in an instant, the impression that the light makes on the retina; but by what mechanism we are entirely ignorant. The manner in which the two optic nerves are confounded upon the sphenoid bone, ought, doubtless, to have a considerable influence upon the

any probable conjecture.

Notwithstanding what has been said at different periods, as well as the late efforts of Gall, to prove that we see with only one eye at a time, there seems sufficient proof not only that the two eyes concur at the same time in the production of vision, but that it is absolutely necessary this should be so, for certain most important operations of this function. There are however certain cases in which it is more convenient to employ only one eye; for instance, when it is necessary to understand perfectly the direction of the light, or the situation of any body relative to us. Thus we shut one eye to take aim with a gun, or to place a number of bodies upon a level in a right line.

Another case in which it is advantageous to employ only one eye is, when the two organs are unequal, either in refractive power or insensibility. For the same reason we shut one eye when we employ a telescope. But, except in these particular cases, it is of the ntmost importance to employ both eyes at once. The following experiment proves that both eyes see the

same object at the same time.

Receive the image of the sun upon a plane in a dark chamber; put before your eyes too thick glasses, each of which presents one of the prismatic colours. If your eyes are good and both equally strong, the image of the sun will appear of a dirty white, whatever be the colour of the glasses employed. If one of your eyes is much stronger than the other, the image of the sun will be seen of the same colour as the glass which is before the strongest eye.

One object produces then really two impressions while the brain perceives only one. To produce this the motions of the two eyes must be in unison. If, after a disease, the movement of the eyes are no longer regular, we receive two impressions from the same object, which constitutes strabismus, or squinting. We may also, at pleasure, receive two impressions from one body; for that purpose, it is only necessary to derange the harmony of the two eyes.

Estimation of the distance of objects.—Vision is produced essentially by the action of light upon the retina,

and yet we always consider the bodies from which light proceeds as being the cause of it, though they are often placed at a considerable distance. This result can be

produced only by an intellectual operation.

We judge differently of the distance of bodies according to the degree of that distance; we judge correctly when they are near us, but it is not the same when they are at a short distance; our judgment is then often incorrect: but when they are at a great distance, we are constantly deceived. The united action of the two eyes is absolutely necessary to determine exactly

the distance, as the following experiment proves.

Suspend a ring by a thread, and fix a hook to the end of a long rod, of a size that will easily pass the ring; stand at a convenient distance, and try to introduce the hook: in using both eyes, you may succeed with ease in every attempt you make; but if you shut one eye, and then endeavour to pass the hook through, you will not succeed any longer; the hook will go either too far or else not far enough, and it will only be after trying repeatedly that it will be got through. Those persons whose eyes are very unequal in their power, are sure to fail in this experiment, even when they use them

When a person loses an eye by accident, it is sometimes a whole year before he can judge correctly of the distance of a body placed near him. Those who have only one eye, determine distance, for the most part, very incorrectly. The size of the object, the intensity of the light that proceeds from it, the presence of intermediate bodies, &c. have a great influence upon our

just estimation of distance.

We judge most correctly of objects that are placed upon a level with our bodies. Thus, when we look from the top of a tower at the objects below, they appear much less than they would if they were placed at the same distance, on the same plane with ourselves. Hence the necessity of giving a considerable volume to objects that are intended to be placed on the tops of buildings, and which are to be seen from a distance. The smaller the dimensions of an object are, the nearer it ought to be to the eye, in order to be distinctly seen. What is called the distinct point of view, is also very

variable. A horse is seen very distinctly at six yards, but a bird could not be distinctly seen at the same distance. If we wish to examine the hair or the feathers of those animals, the eye requires to be much nearer. However, the same object may be seen distinctly at different distances; for example, it is quite the same to many persons whether they place the book that they are reading at one or two feet of distance from the eye. The intensity of the light which illuminates an object, has a considerable effect upon the distance at which it can be distinctly seen.

Estimation of the size of bodies.—The manner in which we arrive at a just determination of the size of bodies, depends more upon knowledge and habit tnan upon the action of the apparatus of vision. We form our judgment relative to the dimensions of bodies, from the size of the image which is formed in the eye, from the intensity of the light which proceeds from the ob-ject, from the distance at which we think it is placed, and, above all, from the habit of seeing such objects.
We therefore judge with difficulty of the size of a body that we see for the first time, when we cannot appre-ciate the distance. A mountain which we see at a dis-tance for the first time, appears generally much less than it really is; we think it is near us when it is very far away.

Beyond a distance somewhat considerable, we are so completely deceived, that judgment is unable to correct us. Objects appear to us infinitely less than they really are: as happens with the celestial bodies.

Estimation of the motion of bodies.—We judge of the motion of a body by that of its image upon the retina, by the variations of the size of this image, or, which is the same thing, by the change of the direction of the

light which arrives at the eye.

In order that we may be able to follow the motion of a body, it ought not to be displaced too rapidly, for we could not then perceive it; this happens with bodies projected by the force of gunpowder, particularly when they pass near us. When they move at a distance from us, the light comes from them to the eye for a much longer space of time, because the field of view is much greater, and we can see them with more facility. ought to be ourselves at rest, in order to judge correctly of the motions of bodies.

When bodies are at a considerable distance from us, we cannot easily perceive their motions to or from us. In this case, we judge of the motion of the body, only by the variation of the size of its image. Now this variation being infinitely small, because the body is at a great distance, it is very difficult, and frequently impossible, for us to estimate its motion. Generally we perceive with great difficulty, sometimes we cannot perceive at all, the motion of a body which moves extremely slow; this may be on account of the slowness of its own motion, as in the case of the hand of a watch, or it may be the result of the slow motion of the image, which happens with the stars, and objects very far from us.

Of optical illusions .- After what we have just said, of the manner in which we estimate the distance, the size, and the motion of bodies, we may easily see that we are often deceived by sight. These deceptions are known in Physics, and in Physiology, by the name of optical illusions. Generally we judge pretty well of bodies placed near us; but we are most commonly deceived with regard to those that are distant. Those illusions which happen to us with regard to objects that are near us, are the result, sometimes of the reflection, sometimes of the refraction, of light before it reaches the eye; and sometimes of the law that we establish instinctively; namely, that light proceeds always in right lines

We must refer to this cause those illusions occasioned by mirrors: objects are seen in plane mirrors at the same distance behind them, as the mirrors are distant from the eye. To this cause may be attributed also the apparent increase, or diminution of bodies seen through a glass. If the glass make the rays converge, the body will appear greater; if it cause them to diverge, the body will appear less. These glasses produce still another illusion; objects appear surrounded by the colours of the solar spectrum, because their surfaces not being parallel, they decompose light in the manner of the prism.

We are constantly deceived by objects at a distance, in a manner that we cannot prevent, because thos

deceptions result from certain laws which govern the animal economy. An object seems near us in propor-tion as its image occupies a greater space upon the retina; or in proportion to the intensity of the light which proceeds from it.

Of two objects of a different volume, equally illuminated and placed at the same distance, the greatest will appear the nearest, should circumstances be such as to admit of the distance being justly estimated. Of two objects of equal volume, placed at an equal distance from the eye, but unequally illuminated, the brightest will appear the nearest; it would be the same, if the objects were at unequal distances, as can be easily seen in looking at a string of lawns; if there easily seen in looking at a string of lamps: if there happen to be one of them brighter than the rest, it will appear the nearest, while that which is really the nearest will appear the farthest, if it is the least bright. An object seen without any intermedium, always ap-pears nearer than when there happens to be between it and the eye, some body that may have an influence upon the estimation that we make of its distance.

When a bright object strikes the eye, while all the objects around it are obscured, it appears much nearer than it really is; a light in the night produces this

Objects appear always small in proportion as they are distant; thus, the trees in a long alley, appear so much smaller, and so much nearer together, in proportion as they are farther from us. It is by observing these illusions, and the laws of the animal economy, upon which they are founded, that art has been en-abled to imitate them. The art of painting, in certain cases, merely transfers to the canvass those optical errors into which we most habitually fall.

The construction of optical instruments is also founded upon these principles: some of them augment the intensity of the light, which proceeds from the objects observed; others cause it to diverge, or converge, in order to increase or diminish their apparent vo-

By the constant exercise of the sense of sight, we are enabled to get over many optical illusions, as will be proved by the curious history of the blind youth, spoken of by Cheselden. This celebrated surgeon, by a surgical operation, generally said to be that for cataract, but, more probably, it was a division of the membrana pupillaris, procured sight to a very intelligent person which this sense was developed in this young ner in which this sense was developed in this young man. "When he saw the light for the first time, he man. "When he saw the light for the first time, he knew so little how to judge of distances, that he believed the objects which he saw touched his eyes (and this was his expression) as the things which he felt touched his skin. The objects which were most pleasant to him were those whose form was regular and smooth, though he had no idea of their form, nor could he tell why they pleased him better than the others. During the time of his blindness he had such an imperfect idea of colours, that he was then able to disfect idea of colours, that he was then able to distinguish, by a very strong light, that they had not left an impression sufficient by which he could again recognise them. Indeed, when he saw them, he said the colours he then saw were not the same as those he had seen formerly; he did not know the form of any object; nor could he distinguish one object from another, however different their figure or size might be: when objects were shown to him which he had known formerly by the touch, he looked at them with attention, and observed them carefully in order to know them again; but as he had too many objects to retain at once, he forgot the greater part of them, and when he first learned, as he said, to see and to know objects, he forgot a thousand for one that he recollected. It was two months before he discovered that pictures represent solid bodies; until that time he had considered them as planes and surfaces differently coloured, and diversified by a variety of shades; but when he began to conceive that these pictures represented solid bodies, in touching the canvass of a picture with his hand he expected to find in reality something solid upon it, and he was much astonished when, upon touching those parts which seemed round and unequal, he found them flat and smooth like the state has a deal which them flat, and smooth like the rest; he asked, which was the sense that deceived him,—the sight or the touch? There was shown to him a little portrait of his father, which was in the case of his mother's watch he said, that he knew very well it was the resemblance !

of his father; but he asked, with great astonishment, he wit was possible for so large a visage to be kept in so small a space, as that appeared to him as impossible as that 2 bushel should be contained in a pint. He could not support much light at first, and every object seemed very large to him; but after he had seen larger things he considered the first smaller; he thought there was nothing beyond the limits of his sight. The same operation was performed on the other eye about a year after the first, and it succeeded equally well. At first he saw objects with his second eye much larger than with the other, but not so large, however, as he had seen them with the first eye; and when he looked at the same object with both eyes at once, he said that it appeared twice as large as with the first eye; but he did not see double, at least it could not be ascertained that he saw objects double, after he had got the sight

This observation is not singular; there exists a number of others, and they have all given results nearly alike. The conclusion that may be drawn from it is, that the exact manner in which we determine the distance, size, and form of objects, is the result of habit, or, which is the same thing, of the education of the

sense of sight.

VITELLUS. (Vitellus, i, m.; from vita, life; because the life of the chick is in it.)

1. The velk of an ess.

1. The yelk of an egg.
2. In botany applied by Gærtner to that part of a seed which is very firmly and inseparably connected with the embryo, yet never rising out of the integuments of the seed in germination, but absorbed, like the albumen, for the nourishment of the embryo. If the albumen be present, the vitellus is always situated between it and the embryo, and yet is constantly distinct from the former. It is esteemed by Gærtner to com-pose the bulk of the seed in the fusci, mosses, and ferns. In the natural order of grasses, the vitellus forms a scale betwen the embryo and the albumen. Sir J. Smith thinks the vitellus is nothing else than a

subterraneous cotyledon. See Albumen.

VITEX. (From vico, to bind.) The name of a genus of plants in the Linnman system. Class, Didynamia; Order, Angiospermia.

VITEX AGNUS CASTUS. The systematic name of the Agnus castus; Elwagnon. The chaste tree. Vitez
-foliis digitatis, serratis, spicis verticillatis, of Linnwus. The seeds are the medicinal part, which have, when fresh, a fragrant smell, and an acrid aromatic taste. Formerly they were celebrated as anaphro-disiacs; but experience does not discover in them any degree of such virtue, and some have described to them

an opposite one. They are now fallen into disuse.

VI'TI SALTUS. See Chorea.

VITILI'GO. (Vitiligo, inis, f.; from vitio, to infect.) See Alphus.

VITIS. 1. The name of a genus of plants in the Linnæan system. Class, Pentandria; Order, Monogynia.

2. The pharmacopæial name of the grape. See Vitis vinifera.

VITIS ALBA. See Bryonia alba.
VITIS CORINTHICA. The dried fruit of this tree is the Uva passa minor; Passa corinthiaca. The virtues of the currant are similar to those of the raisin. See Vitis vinifera.

VITIS IDEA. See Vaccinium.

VITIS SYLVESTRIS. White bryony.
VITIS VINIPERA. The systematic name of the grapeee. Vitis—foliis lobatis sinuatis nudis, of Linnæus. Vine leaves and the tendrils have an adstringent taste, and were formerly used in diarrhœas, hæmorrhages, and other disorders requiring refrigerant and styptic medicines. The juice or sap of the vine called lachry-ma, has been recommended in calculous disorders: and it is said to be an excellent application to weak eyes

and specks of the cornea. The unripe fruit has a harsh, rough, sour taste; its expressed juice, called ver-juice, was formerly much esteemed, but is now superseded by the juice of lemons; for external use, however, particularly in bruises and pains, verjuice is still employed, and considered to be a very useful applica-tion. The dried fruit is termed *Uva passa major*. Passula major, the raisin. Raisins are prepared by immersing the fresh fruit into a solution of alkaline salt and soap-ley, made boiling hot, to which is added some olive oil, and a small quantity of common salt, and afterward drying them in the shao. They are used as agreeable, lubricating, acescent sweets in pectoral decoctions, and for obtunding the acrimony in other medicines, and rendering them grateful to the palate and stomach. They are directed in the decocvitra'ria. The pellitory of the wall.

Vitra'ria. The pellitory of the wall.

Vitra'ria. (Vitreus; from vitrum, glass: so named from its transparency.) Glassy: applied to parts of the body.

VITREOUS HUMOUR. Humor vitreus. The pellucid body which fills the whole bulb of the eye behind the crystalline lens. The vitreous substance is composed of small cells which communicate with each other, and are distended with a transparent fluid.

VITRIOL. See Vitriolum.
Vitriol, acid of. See Sulphuric acid.
Vitriol, blue. See Cupri sulphas.
Vitriol, green. See Ferri sulphas.
Vitriol, Roman. See Cupri sulphas.
Vitriol, sweet, spirit of. See Spiritus atheris sul-

Sce Zinci sulphas.

Vitriolated kali. See Potassæ sulphas.
VITRI'OLUM. (From vitrum, glass: so called om its likeness to glass. Hollandus says this word from its likeness to glass. is fictitious, and composed from the initials of the following sentence: Vade in terram rimando, invenies, optimum lapidem veram medicinam.) Calcadinum; Calcatar; Calcotar; Calcanthos; Calcanthum; Cal-citea. Vitriol, or sulphate of iron. See Ferri sul-

VITRIOLUM ALBUM. See Zinci sulphas. VITRIOLUM CERULEUM. See Cupri sulphas.
VITRIOLUM ROMANUM. See Cupri sulphas.
VITRIOLUM VIRIDE. See Ferri sulphas.
VI'TRUM. (Vitrum, i, n.) Glass.
VITRUM ANTIMONII. Glass of antimony.

VITRUM ANTIMONII. mony first calcined, then fused in a crucible.

VITRUM ANTIMONII CERATUM. A diaphoretic compound exhibited in the cure of dysenteries arising from checked perspiration.

VITRUM HYPOCLEPTICUM. A funnel to separate oil

from water.

VIVERRA. The name of a genus of animals in the Order Feræ, of the Linnman classification.

VIVERRA CIVETTA. The systematic name of the ash-coloured weazel, which, with the following specific of the perfume called civet. cies, affords the perfume called civet.

VIVERRA ZIBETHA. The systematic name of the

VIVERRA ZIBETHA.

civet-cat. See Civetta. VIVUM. A name variously applied: to mercury, because it moves about as if it were alive; hence argentum vivum: to lime, because when moisture is added it cracks and swells, as if alive.

VOICE. Voz. By voice we understand the sound which is produced in the larynx, at the instant when the air traverses this organ, either to enter or go out of

the trachea.

In order to understand the mechanism by which the voice is produced and modified, we must say something of the manner in which sound is produced, in which it is propagated and modified in wind instruments, particularly those that have most analogy with the organ of voice.

A wind instrument is generally formed of a tube, either straight or bent, in which, by various processes,

the air is made to vibrate.

Wind instruments are of two sorts: the one sort are called mouth instruments, the other sort reed instru-

In the mouth instruments (the horn, trumpet, trombone, flageolet, flute, organ,) the column of air contained in the tube is the sonorous body. The air must be caused to vibrate in it in order to produce sounds.

For this purpose, the means employed are variable, according to the sort of instrument. The length, the width, the form of the tube, the openings in its sides, or its extremities, the power of the vibrations, and the manner in which they are excited, are the causes of the various sounds of this sort of instruments. The nature of the matter which forms the sounds has no influence but upon the tone.

The reed instruments are the most necessary to be known, for the organ of the voice is of this kind. Their theory is, unfortunately, much more imperfect than that of the other sort. In this sort of instruments, (the clarionet, hautboy, bassoon, voice organ, &c.) we ought to distinguish between the reed, or anche, and the body of the tube. Their mechanism is essentially dif-

A reed is always formed of one, and sometimes of two, thin plates, susceptible of a rapid motion, the alternate vibrations of which are intended to intercept and permit, by turns, the passage of a current of air. For this reason, the sounds which they produce do not follow the same laws as the sounds formed by elastic plates, with one end fixed, and the other free, which produce sonorous undulations in the open air. In the reed instruments, the reed alone produces and modifies the sound. If the plate is long, the motions are long, slow, and consequently the sounds are grave. On the sounds are grave. contrary, a short plate produces acute sounds, because the alternations of transmission and interception of the current of air are more rapid.

When a number of different sounds are intended to be produced by a reed, it is necessary to vary the length of the plate. The bassoon and clarionet players do this when they wish to produce different sounds on the same instrument. We add, as an important circumstance, that the greater or less elevation of sound produced by the instrument, partly depends on the elasti-city, the weight, and the form of the little tongue, or plate, and on the force of the current of air. these elements are not the same, the length being inva-

riable, the tone will be different.

A reed is never employed alone; it is always fitted to a tube through which the wind passes that has been blown into the reed, and which ought, on this account, to be open at the two extremities. The tube has no influence upon the tone of the music; it acts only upon the intensity, the timbre, and upon the power of making the reed speak.

Apparatus of voice.—The larynx ought properly to be considered as the organ of voice.

The size of the larynx varies according to age and sex. It is placed at the anterior part of the neck where a small projection is seen, between the tongue and the trachea. It is small in children and women, greater in young men, and still larger in adult age.

The larynx not only produces the voice, but it is also the agent of its principal modifications; on which ac-count, a perfect knowledge of the anatomy of this organis indispensably necessary to a perfect knowledge of the mechanism of voice. As we cannot enter here into all the details of the structure of the larynx, we will only touch upon such as are most necessary to be known, many of which are not yet well understood. Four cartilages and three fibro-cartilages enter into

the composition of the larynx, and form the skeleton of it. The cartilages are the cricoid, the thyroid, and the two arytanoid. The thyroid joins with the cricoid by the extremity of its two inferior horns. In the living state, the thyroid is fixed with respect to the cricoid, which is contrary to what is generally supposed. Every arytanoid cartilage is articulated with the cricoid by means of a surface, which is oblong, and concave in a transverse direction. The cricoid presents a surface which is similarly disposed to that of the arytanoid, which is similarly disposed to that of the arytanoid, with this difference, that it is convex in the same direction in which the other is concave. Round the articulation there is a synovial capsule, firm before and behind, and moveable without and within. Before the articulation is the thyro-arytanoid ligament; behind is a strong ligamentous band that might be called crico-arytanoid, on account of the manner in which it is fixed.

Thus disposed, the articulation admits only of lateral movements of the arytanoid upon the cricoid cartilage. No movement forward or backward can take place, nor a certain movement up and down, mentioned in anatomical books, which none of the muscles is so dis-

posed as to produce. This articulation ought to be con-Sidered as a simple lateral ginglymus. The fibro-cartilages of the larynx are the epiglottis, and two small podies that are found above the top of the arytanoid cartilages, and that have been called by Santorini,

capitula cartilaginum arytenoidearum.

There are a great many muscles attached to the rynx. These muscles are called external: they are intended to move the whole organ, either in carrying it up or down, backward or forward, &c. The larynx has also other muscles, whose use is to give a movement to the different parts in respect of each other. These muscles have been called internal. They are,

Ist, The crico-thyroid, the use of which is not, as has hitherto been believed, to lower the thyroid upon the cricoid cartilage, but, on the contrary, to raise the cricoid towards the thyroid cartilage, or in making it pass

a little below its inferior edge.

2d, The muscles crico-arytanoideus posterior, and the crico-arytanoideus lateralis, the use of which is to draw outwards the arytanoid cartilages, in separating them from one another.

3d, The arytanoid muscle, which draws the aryta-

noid cartilages together.

4th, The thyro-arytanoideus, a knowledge of which is more important than that of all the muscles of the larynx, because its vibrations produce the vocal sound. This muscle forms the lips of the glottis, and the inforior, superior, and lateral sides of the ventricles of the

5th, Lastly, the muscles of the epiglottis, which are the thyro-epiglottideus, the arytano-epiglottideus, and some fibres that may be considered as the vestige of the glosso-epiglottideus muscle that exists in some animals, whose contraction has an influence upon the position

of the epiglottis.

The larynx is covered within by a mucous membrane.
This membrane, in passing from the epiglottis to the arytænoid and thyroid cartilages, forms two folds, called ateral ligaments of the epiglottis. They concur in the ormation of the superior and inferior ligaments of the

In the substance of the epiglottis, and behind it, are found a great number of mucous follicles, and some mucous glands. Within the mass of the ligaments of the epiglottis, there exists a collection of those bodies that have been very improperly called arytanoid

glands.

Between the epiglottis behind, and the os hyoides and thyroid cartilage before, there is seen a considerable quantity of the adipose cellular tissue, which is very elastic, and similar to that which exists near certain articulations. There has been no use assigned to this body. Dr. Magendie believes it serves to facilitate the frequent movements of the thyroid cartilage upon the posterior face of the os hyoides, and to keep the epiglottis separated from the upper part of this bone, while, at the same time, it provides it with a very elastic support, favourable to the action of the fibrocartilages in the production of the voice, or in deglu-

The vessels of the larynx present nothing remarka-It is not so with the nerves of this organ. Their distribution merits a careful examination. four of these nerves, the superior laryngeal and the

The recurrent nerve is distributed to the posterior crico-arytænoid, to the lateral crico-arytænoid, and thyro-arytænoid. None of the ramifications of this nerve go to the arytænoid, or to the crico-thyroid, mus-cles. On the contrary, the superior nerve of the larynx goes to the arytænoid muscle, which it provides with a considerable branch; and to the crico-thyroid, to which it gives a small filament, more remarkable for the distance it proceeds than for its size. In certain cases this filament does not exist. The external branch of the nerve of the larynx is then of a larger size. mainder of the filaments of the laryngeal nerves are distributed to the epiglottis, and to the mucous membrane which covers the entrance of the larynx. part possesses an extraordinary sensibility.

The interval which separates the thyro-arytenoid muscles, and the arytenoid cartilages, is called glottis. In the dead body, the glottis presents the appearance of a longitudinal slit of about eight or ten lines long, and two or three wide; it is wider behind than before

into the thyroid cartilage. The posterior extremity of the glottis is formed by the arytanoid muscles.

If the arytænoid cartilages are brought together so as to touch on their internal faces, the glottis is diminished to touch on their internal faces, the glottis is diminished nearly a third of its length. It then presents a slit which is from five to six lines long, and from half a line to a line long. The sides of this slit are called the *lips* of the glottis. They present a sharp edge turned upward and inward. They are essentially formed by the arytænoid muscle, and by the ligament of the same name, which, as an aponeurosis, covers the muscle to which it adheres strongly, and which, being itself covered by the mucous membrane, forms the thinnest parts or edge of the *lip*. These lips of the glottis vibrate parts or edge of the lip. These lips of the glottis vibrate in the production of the voice; they might be called the human reed. Above the inferoir ligaments of the glottis are the ventricles of the larynz, the cavity of which is larger than it seems at first sight. The superior, inferior, and external sides of it are formed by the thyro-arytenoid muscle, turned upon itself. The extremity, or anterior side, is formed by the thyroid cartilage. By means of these ventricles, the lips of the glottis are completely isolated upon their upper side.

Above the opening of the ventricles we see two bodies, which, in their manner of being disposed, have a great deal of analogy with the vocal chords, and which form a sort of second glottis above the first. These bodies are called the superior ligaments of the glottis. They are formed by the superior edge of the thyro ary tænoid muscle, a little adipose cellular tissue, and the mucous membrane of the larynx, which covers them before penetrating into the ventricles. These observa-The glottis of a living person has never been examined, at least there has been nothing written on this subject; but when those of animals, as of dogs, are examined, they contract and enlarge alternately. The arytænoid cartilages are directed outwards when the air pene-

cartilages are directed outwards when the air penetrates into the lungs; and in the instant when the air
passes out, they come close together.

Mechanism of the Production of Voice.—If we take
the trachea and the larynx of an animal or of a man,
and blow air strongly into the trachea, directing it to
wards the larynx, there is no sound produced, but only
a slight noise, resulting from the pressure of the air
against the sides of the larynx. If, in blowing, we
bring together the arytamoid cartilages, so that they
may touch upon their internal face, a sound will be
produced, something like the voice of the animal to
which the larynx used in the experiment belongs.

The sound will be dull or sharp, according as the cartilages are pressed more or less forcibly together: its
intensity will be more or less, according to the intensity
of the air. It is easily seen, in this experiment, that
the sound is produced by the vibrations of the inferior
ligament of the glottis.

ligament of the glottis.

Both man and the animals are deprived of voice by making an opening below the larynx. The voice reproduced if the opening is closed mechanically. Magendie knows a person who has been in this situa-tion for four years. He cannot speak without pressing a cravat strongly against a fistulous opening in the la-rynx. The same thing takes place when the larynx is opened below the inferior ligaments of the glottis.

But if a wound exists above the glottis, if the epi-glottis and its muscles are affected, if the superior ligament of the glottis, even if the superior aspect of the arytanoid cartilages are injured, the voice continues.

Lastly, the glottis of an animal being laid bare in the instant that it cries, shows very well that voice is produced by the vibrations of the vocal chords, or lips of the glottis. This is enough to prove, beyond all doubt, that the voice is formed in the glottis by the motion of its inferior ligaments.

This fact being established, is it possible, on physical principles, to account for the formation of the voice? The following explanation appears the most probable.

The air being pressed from the lungs, proceeds in a pipe of considerable size. This pipe very soon becomes contracted, and the air is forced to pass through a narrow slit, the two sides of which are vibrating plates, which permit and intercept the air, like the plates of reeds, and which ought, in the same manner, by these alternations, to produce sonorous undulations in the transmitted current of air.

But, in blowing into the trachea of a dead body, why Here the two sides meet at the point of their insertion | does it not produce a sound like that of the human voice? Why is the palsied state of the internal muscles of this organ followed by the loss of the voice? Why, in a word, is an act of the will necessary to produce the vocal sound? The answer to this is not difficult. The ligaments of the glottis have not the faculty of vibrating like plates of reeds, except the thyro-aryof vibrating like plates of reeds, except the thyro-ary-tænoid muscles are contracted; and, therefore, in every case in which the muscles are not contracted, the voice will not be produced.

Experiments performed on animals are perfectly in unison with this doctrine. Divide the two recurrent nerves, and the voice will cease. If only one is cut,

the voice will be only half lost.

Dr. Magendie, however, has seen a number of animals, in which the two recurrent nerves had been cut, cry very loud when they suffered severe pain. sounds were very similar to the sounds that would be produced mechanically with the larynx of the animal when dead, by blowing into the trachea, and bringing together the arytenoid cartilages. This phenomenon is easily understood by the distribution of the nerves of the larynx. The recurrents being cut, the thyroarytænoid muscles do not contract, and thence results the loss of voice; but the arytenoid muscle, that receives its nerves from the superior laryngeal, contracts, and brings together, in the instant of a strong expira-tion, the arytenoid cartilages, and the slit of the glottis becomes sufficiently narrow for the air to throw the thyro-arytenoid muscles, though they are not contract-

ed, into vibration.

Intensity or volume of the voice. The intensity of the voice, like that of all other sounds, depends upon the extent of the vibrations.

The vibrations of the vocal chords will be in proportion to the force with which the air is expelled from the breast; and the longer the chords are, that is, the more voluminous the larynx is, the more considerable will be the extent of the vibrations. A strong person, with a large chest, and a larynx of large dimensions, A strong person, presents the most advantageous condition for the intensity of the voice. If such a person becomes sick, his voice, on account of his weakness, loses much of its intensity, because it is no longer expelled with the same force from the chest.

Children, women, and eunuchs, whose larynx is pro-portionably less than that of a man in adult age, have

In the ordinary production of the voice, it results from the simultaneous motions of the two sides of the glottis. Were one of these sides to lose the faculty of causing the air to vibrate, the voice would lose, necessarily, half its intensity, the force of expiration being the same. This may be proved in cutting one of the recurrent nerves of a dog, or in paying attention to the voice of a person who has had a complete attack of heministric.

Tone of the voice.—Every individual has a particular tone of voice by which he is known: there is also a particular tone which belongs to the different sexes and age. The tone of the voice presents an infinite num-ber of modifications. Upon what circumstances do these depend? This is unknown. The feminine tone, however, which is found in children and eunuchs, generally agrees with the state of the cartilages of the On the contrary, the masculine tone which women sometimes possess, appears to be connected with the state of these cartilages, and particularly with that of the thyroids. Tone is a modification of sound, of which philosophers have by no means given an exact explanation.

Of the extent of the voice.-The sounds which the human larynx is capable of producing are very nume-Many celebrated authors have endeavoured to explain the manner of their formation; but they have rather given us comparisons than explanations

We have examined the reed of the organ of voice we shall now consider the tube that the vocal sound traverses after having been produced. In proceeding from below upwards, the tube is composed, 1st, of the interval between the epiglottis before, its lateral liga-ments upon the sides, and of the posterior side of the pharynx; 2dly, of the pharynx behind, and laterally, and of the most posterior part of the base of the tongue before; 3dly, sometimes of the mouth, and sometimes of the nasal cavities; at other times, of these two cavities together.

This tube, capable of being prolonged or shortened,

susceptible; of increasing the intensity of the vocal sound, by taking a conical form, with the base outwards; of giving a roundness and agreeableness to the sound, by suitably exposing its exterior opening, or by almost entirely shutting it, &c.
Until the influence of the tube of reed instruments

has been determined with precision, it is evident that we can form only probable conjectures respecting the influence of the tube of the organ of voice. In this respect we can make only a small number of observations, which relate particularly to the most apparent

A. The larynx is raised in the production of acute sounds; it is lowered, on the contrary, in the formation of those that are grave; consequently, the vocal tube is shortened in the first case, and lengthened in the

We suppose that a short tube is more favourable to the transmission of acute sounds, while a long one is more so for those that are grave. The tube changes its length at the same time that it changes its breadth; and this is remarkable, as we have seen above that the breadth of the tube has a great influence upon its

facility of transmitting sounds.

When the larynx descends, that is, when the vocal tube is prolonged, the thyroid cartilage descends, and removes from the os hyoides the whole height of the thyro-hyoid membrane. By this separation the gland of the epiglottis is carried forward, and places itself in the cavity of the posterior aspect of the os hyoides; this gland draws after it the epiglottis: from this results a considerable enlargement of the inferior part of the vocal tube.

The contrary phenomenon happens when the larynx is raised. The thyroid cartilage then rises, and becomes engaged behind the os hyoides, by displacing and pushing back ward the epiglottid gland; this pushes the epiglottis, and the vocal tube is much contracted. By imitating the motion upon the dead body, we may By imitating the motion upon the dead body, we may easily ascertain that the narrowing may proceed to five-sixths of the breadth of the tube. Now, we adapt a large tube to a reed for the purpose of producing grave sounds; on the contrary, it is a narrow tube which is generally employed for the purpose of transmitting acute sounds. We can then, to a certain degree, account for the utility of the changes of breadth which take place in the inferior part of the vocal tube. tube.

B. The presence of the ventricles of the larynx immediately above the inferior ligaments of the glottis, appears intended to isolate those ligaments, so that they may vibrate freely in the air. When foreign bodies enter the ventricles, or when a false membrane, or mucosities are formed, the voice is generally extinguished, or much weakened.

C. From its form, its position, its elasticity; from the motions which its muscles impress upon it, the epiglottis appears to belong essentially to the apparatus of the voice; but what are its uses? We have already seen that it contributes powerfully to the narrowing of the vocal tube; it may be supposed that it has a more important function.

D. The vocal tube has visibly an influence upon the intensity of the voice. The most intense sounds which the voice can produce, cause the mouth to be opened very wide, the tongue to be drawn a little back, and the velum of the palate raised into a borizontal position, and to become elastic, closing all com-

munication with the nostrils.

In this case the pharynx and the mouth evidently perform the office of a speaking trumpet, that is to say they represent very exactly a tube with a reed, which increases in wideness outwards, the effect of which is increases in wideness outwards, the effect of which is to augment the intensity of the sound produced by the reed. If the mouth is in part closed, the lips carried forward and turned towards each other, the sound will acquire rotundity, and an agreeable expression; but it will lose part of its intensity: this result is easily explained after what we have said of the influence of the form of tubes in reed instruments.

For the same reasons, whenever the vocal souns

passes into the nose, it will become dull, for the form | produce the same sort of sounds with his larynx, and of the cavities of the nose is well fitted for diminishing the intensity of sounds. If the mouth and nose are

shut at the same time, no sound can be produced.

E. We have seen, in considering the production of voice, that a great number of modifications relative to expression arise from changes of the thickness, and of the elasticity of the lips of the glottis. The tube may produce a number of others, according to its different degrees of length or breadth; according to its form, the contraction of the pharynx, the position of the tongue, or of the velum of the palate; according as the sound passes wholly or in part through the mouth, or the nose, or both together; according to the individual disposition of the mouth or nose; the existence or non-existence of teeth; the size of the tongue, &c.; the expression of the voice is continually modified according to all these circumstances. For example, whenever the sound traverses the nasal cavities, it becomes disagreeably nasal.

Those persons are mistaken, who think that the in-tensity of vocal sound may be augmented by repercus-sion, in passing through the nasal cavities; these cavi-ties produce quite a contrary effect. Whenever the voice is introduced into them, from whatever cause, it

becomes dull.

F. Besides the numerous modifications which the tube of the vocal organ causes in the intensity and the tube of the vocal organ causes in the intensity and the expression of the voice, in alternately permitting or intercepting its productions: there is another very important kind of modification produced by it. By means of this the vocal sound is divided into very small portions, each possessing a distinct character, because each of them is produced by a distinct motion of the tube. This sort of influence of the vocal tube is called the faculty of articulating, which presents, besides, an infinite variety of individual differences suitable to the peculiar organization of the vocal suitable to the peculiar organization of the vocal tube

We have hitherto treated of the human voice in a general manner; we now proceed to speak of its principal modifications; namely, the cry or native voice; the voice properly so called, or acquired voice; speech, or articulate voice; singing, or appreciable

The cry, or native voice.—The cry is a sound which cannot be appreciated; it is, like all those sounds produced by the larynx, susceptible of variation in tone, intensity, and expression. The cry is easily distinguished from all other vocal sounds; but as its character depends upon the expression, it is impossible to account physically for the difference between it and the latter. Whatever is the condition of man, or whetever his are the is capable of crying. The new conditions are the conditions. the latter. Whatever is the condition of man, or whatever his age, he is capable of crying. The newborn child, the idiot, the person deaf from birth, the savage, the civilized, the decrepit old man, all are capable of producing cries. We ought, then, to consider the cry as particularly attached to organization; indeed, we may be convinced of this in examining its

By the cry we express vivid sensations, whether they proceed from without or within; whether they are agreeable or painful:—there are cries of pleasure and of pain. By the cry we express our most simple instinctive wants, the natural passions. There is a cry of fury, another of fear, &c.

The social wants and passions, not being an indispensable consequence of committation, and the state of

pensable consequence of organization, and the state of civilization being necessary for their developement, they have no peculiar cry. Theory comprehends, generally, the most intense sounds that the organ of voice can produce; its expression has often something in it which offends the ear, and it has a strong action upon those who are near it.

By means of the cry, important relations are established among mankind. The cry of joy inclines to joy; the cry of pain excites pity; the cry produced by terror causes fear, even in those at a distance, &c. This sort of language is found in most animals; it is almost the only language which here here given them. almost the only language which has been given them; the song of birds ought to be considered as a modification of their cry.

Acquired voice, or voice properly so called.—In the usual state of man, that is, when he lives in society, and when he is possessed of the faculty of hearing, he knows, from earliest youth, that mankind utter sounds

immediately, what is called acquired voice, is developed in him, by the effect of imitation, and the advantages he derives from it. A deaf child cannot make any remark with regard to sound, and, therefore, he never acquires it. There seems to be no difference between the voice and the cry, except in intensity and expression, for it is likewise formed of inappreciable sounds or of sounds whose intervals are not exactly. sounds, or of sounds whose intervals are not exactly distinguished by the ear.

Since the voice is the consequence of hearing, and of an intellectual process, it cannot be developed if those circumstances, by which it is produced, do not exist. In fact, children born deaf, who have never had any idea of sound; idiots, that establish no relation between the sounds which they hear, and those which their larynx can produce, have no voice, though the vocal apparatus of both may be fit to form and modify sounds as well as that of individuals perfectly formed.

For the same reason those whom we improperly term savages, because they have been found wandering in forests since their infancy, can have no voice; the understanding not being developed in a solitary state,

but only in social life.

The expression, the intensity, the tone of the voice, are susceptible of numerous modifications on the part of the larynx; the vocal tube also exerts a powerful influence upon the voice: speech and singing are only modifications of the social voice.

Modifications of the voice by age.—The larynx is in proportion very small in the fectus, and the new-born infant; its small volume forms a contrast with that of the os hyoides, with the tongue and other organs of deglutition, which are already much developed. Besides, it is round, and the thyroid cartilage forms no projection in the neck.

The lips of the glottis, the ventricles, the superior ligaments, are very short in proportion to what they become afterward; for the thyroid cartilage not being much developed, they consequently occupy a small space. The cartilages are flexible, and have not nearly

space. The cartilages are flexible, and have not nearly the solidity which they possess afterward.

The larynx preserves these characters almost till puberty; at this period a general revolution takes place in the economy. The development of the genital organs determines a sudden increase in the nutricular of many of the except of the which that of the contract of tion of many of the organs, of which that of the voice

is one.

The greatest activity of nutrition is first remarked in the muscles; afterward, but more slowly, it is seen in the cartilages: the general form of the larynx is then modified; the thyroid cartilage becomes developed in its anterior part, it forms a projection in the neck, but greater in the male than in the female. From this circumstance results a considerable prolongation of the

lips of the glottis, or thyro-arytænoid muscles; and this phenomenon is much more worthy of remark than the general increase of the glottis which happens at the same time.

Though these changes in the larynx are rapid, they do not happen all at once; sometimes it is six or eight

months before they terminate.

After puberty the larynx does not suffer any other remarkable changes; its volume and the projection of the thyroid cartilage continue to increase, and become more strongly marked. The cartilages become par-tially ossified in manhood.

In old age the ossification of the cartilages continues and becomes almost complete; the epiglottid gland diminishes considerably, and the internal muscles, but those particularly that form the lips of the glottis, diminish in volume, assume a colour less deep, and lose their elasticity; in a word, they take the same modifications as the muscular system in general.

The production of voice, as it supposes the passage of air to and from the lungs to take place, cannot exist in the fœtus, plunged as it is in the liquor amnii; but the child is capable of producing very acute sounds at the instant of birth.

Vagitus is the name that is given to this voice, or cry of children, by which they express their wants and We must recollect that this is the object of feelings. the cry.

Towards the end of the first year, the child begins to form sounds that are easily distinguished from the vagitus. These sounds, at first vague and irregular, very which are not cries he very soon finds that he can I soon become more distinct and connected; nurses then begin to make them pronounce the most simple words, I the sun, as with Convolvulus sapium, the French and afterward, those that are more complicated.

The pronunciation of children has very little resemblance to that of adults; but there is also a great dif-ference between them. In children, the teeth have not yet quitted their alveoli; the tongue is comparatively very large; when the lips are closed they are larger than is necessary for covering anteriorly the gums; the nasal cavities are not much developed, &c.

Children advance only by degrees, and in proportion as their organs of pronunciation approach those of the adult, to articulate exactly the different combinations addit, to arithmate exactly the different combinations of letters. They are not capable of forming appreciable sounds, or of singing, until long after they have acquired the faculty of speech. This sort of sounds is the voice properly so called, or acquired: they could not exist in the child were it deaf. They ought not to be considered as a modification of the vagitus.

Until the period of puberty, the larynx remains pro-portionably very small, as well as the lips of the glottis: the voice is also composed entirely of acute sounds. It is physically impossible that the larynx should pro-

duce grave ones.

At puberty, particularly in males, the voice under-goes a remarkable modification: it acquires in a few

days, often all at once, a gravity, and a dull or deaf ex-pression, that it was far from having before. It sinks in general about an octave. The voice of a It sinks in general about an octave. The voice of a young man is said to moult, according to the common expression. In certain cases the voice is almost en-tirely lost for some weeks; it frequently contracts a marked hoarseness. Sometimes it happens that the young man produces involuntarily a very acute sound when he wishes to produce a grave one; it is then scarcely possible for him to produce appreciable sounds,

or to sing true.

This state of things continues sometimes nearly a year, after which the voice becomes more clear, and remains so during life: but some individuals lose entirely, during the moulting of the voice, the faculty of singing; others, who having a fine extensive voice before the moulting, have afterward only a very ordinary one.

The gravity that the voice acquires depends evidently upon the developement of the larynx, and particularly on the prolongation of the lips of the glottis. As these parts cannot stretch backward, they come forward: it is also at this time that the larynx projects in the neck, and the pomum adami appears. In the female, the lips of the glottis do not present at puberty this increase in breadth; the voice also generally remains acute.

The voice generally preserves the same characters until after adult age; at least the modifications that it undergoes in the interval are but inconsiderable, and undergoes in the interval are but inconsiderable, and affect principally the expression, and the volume. wards the beginning of old age, the voice changes anew, its expression alters, and its extent diminishes: singing is more difficult, the sounds become noisy, and their production painful and fatiguing. The organs of pronunciation being changed by the effect of age, the teeth become shorter, and frequently being lost, the pronunciation is sensibly changed. All these phenomena are more noted in confirmed old age. The voice is weak, shaking, and broken; singing has the same characters which depend on impaired muscular contraction. Speech also undergoes remarkable modifications of the medians of the modifications; the slowness of the motions of the tongue, the want of the teeth, the lips proportionably longer, &c. necessarily influence the pronunciation."—Magendie's

Physiology.
VOLATICUS. (Folaticus; from vole, to fly.) Volatile; that goeth or flieth, as it were, away suddenly.

VOLATILE. See Volaticus. Volatile alkali. See Ammonia.

Volatile caustic, alkali. See Ammonia. VOLATILITY. The properties of bodies by which they are disposed to assume the vaporous or elastic volcanite. See Augite.

Volse LLA. A probang, or instrument to remove bodies sticking in the throat.

VOLUBILIS. Twining. Botanists apply it to stems which twine round other plants by their own spiral form, either from left to right, supposing the observer in the centre (or, in other words, according to the apparent motions of the sun); as in Tamus communis, and the honeysuckle: or from right to left contrary to

VOLVA. (Folva, &, f.; from valva.) The wrap-per or covering of the fungous tribe, of a membranous texture, concealing their parts of fructification, and in due time bursting all round, forming a ring upon the stalk, as in Agaricus campestris. Such is the original meaning of this term, as explained by Linnæus; but it meaning of this term, as explained by Linnieus; but it has become more generally used by Linnieus himself for the fleshy external covering of some other fungi, which is scarcely raised out of the ground, and enfolds the whole plant when young. It is simple, double, or stellated, very much cut; as in Lycopodium stellatum. VO'LVULUS. (From volvo, to roll up.) The iliac passion, or inflammation in the bowels, called twisting of the guts. See Hine passion.

of the guts. See Iliac passion.
Volvulus Terrestris. Small bind-weed.

Convolvulus minor.

VO'MER. Named from its great resemblance to a oughshare. It is a slender thin bone, separating the ploughshare. nostrils from each other, consisting of two plates much compressed together, very dense and strong, yet so thin as to be transparent; these two plates seem at every as to be transparent; these two plates seem at every edge to separate from each other, and thus a groove is formed at every side.—1. This groove on the upper edge, or, as it may be called, its base, is wide, and receives into it the projecting points of the ethmoid and sphenoid bones, and thus it stands very firmly and securely on the skull, and capable of resisting blows of considerable violence.—2. The groove, upon the lower cart is preserved and receives the visits like his the part, is narrower, and receives the rising line in the middle of the palate plate, where the bones join to form the palate suture. At the forepart it is united by a ragged surface, and by something like a groove, to the middle cartilage of the nose, and as the vomer receives the other bones into its grooves, it is, as it were, locked in on all sides, receiving support and strength from each, but more particularly from the thick and strong membrane which covers the whole, and which is so continuous as to resemble a periosteum, or rather a continued ligament, from its strength; thus the slender vomer possesses sufficient strength to avert from it all those evils which must inevitably have occurred, had it been less wisely or less strongly constructed.

VO'MICA. (From vomo, to spit up; because it discharges a sanies.) An abscess of the lungs.

VOMITING. Vomitio. A forcible ejection of food, or any other substance from the stomach, through the

esophagus and mouth.
"That internal sensation which announces the necessity of vomiting is called nausea; it consists of a general uneasiness, with a feeling of dizziness in the head, or in the epigastric region: the lower lip trembles, and the saliva flows in abundance. Instantly, and involuntarily, convulsive contractions of the abdominal muscles, and at the same time, of the dia-phragm, succeed to this state; the first are not very intense, but those that follow are more so; they at last become such, that the matters contained in the stomach surmount the resistance of the cardia, and are thus darted, as it were, into the asophagus and mouth; the same effect is produced many times in succession; it ceases for a time, and begins again after some in-

At the instant that the matters driven from the stomach traverse the pharynx and the mouth, the glottis shuts, the velum of the palate rises, and becomes horizontal, as in deglutition; nevertheless, every time that one vomits, a certain quantity of liquid is intro-

that one vomits, a certain quantity of fiquid is intro-duced either into the larynx, or the nasal canals. Vomiting was long believed to depend upon the rapid convulsive contraction of the stomach; but it has been shown, by a series of experiments, that, in the process, this viscus is nearly passive; and that the true agents of vomiting are, on the one hand, the dia-phragm, and, on the other, the large abdominal muscles. In the ordinary state, the diaphragm and the muscles.

In the ordinary state, the diaphragm and the muscles of the abdomen co-operate in vomiting; but each of the godoner co-operate in voluting, but each of them can, nevertheless, produce it separately. Thus, an animal still vomits, though the diaphragm has been rendered immoveable by cutting the diaphragmatic nerves; it vomits the same, though the whole abda-minal muscles have been taken away by the knife, with the precaution of leaving the linea alba and the peritonæum untouched."

Vomiting of blood. See Hamatemesis. Vo'mitus cruentus. See Hamatemesis.

Voracious appetite. See Bulimia. Vox abscissa. Hoarseness, and also a loss of voice. Vulga'go. The asarabacca was so called. See

Asarum.
VULNERA'RIA. (From vulnus, a wound.) Medicines which heal wounds. An herb named from its

VULNERARIA AQUA. Arquebusade. VU'LNUS. A wound. VULNUS SCLOPETICUM. A gun-shot wound.

VULPENITE. A mineral of a grayish-white co-lour, found along with granular foliated limestone, at

Vulpino, in Italy.

VU'LVA. (Quasivalva, the aperture to the womb; or quasi volva, because the fætus is wrapped up in it.)

The pudendum muliebre, or parts of generation proper to women; also a foramen in the brain.

VULVA'RIA. (From vulva, the womb; so named from its smell, or use in disorders of the womb.) Stinking orach. See Chenopodium vulvaria.

WALTHER, AUGUSTINE FREDERIC, a physician, was appointed, in 1723, professor of anatomy and surgery at Leyden. Several of his dissertations on anatomical subjects are commended, and have been reprinted by Haller. The best of his larger pieces is "De Lingua Humana Libellus," in quarto. As a botanist he published a Catalogue of the Plants in his own garden, and a work on the Structure of Plants. He died about the year 1746.

WALTON. A town, near Tewkesbury in Gloucestershire, where there is a mineral spring, containing a small portion of iron dissolved in fixed air; of absorbent earth combined with hepatic air; of vitriolated magnesia, and muriated mineral alkali; but the proportions of these constituent parts have not been accu-

portions of these constituent parts have not been accu-

rately ascertained. Walton water is chiefly effica-cious in obstructions and other affections of the glands. [WARREN, Dr. Joseph, was born in Roxbury, near Boston, in 1741. He was a distinguished physician and patriot of the American Revolution, and was killed early in the contest, at the battle of Bunker's Hill, June The following is from Thacher's Life of

"The calmness and indifference of the veteran 'in clouds of dust and seas of blood,' can only be acquired by long acquaintance with the trade of death; but the heights of Charlestown will bear eternal testimony, how suddenly in the cause of freedom the peaceful citizen can become the invincible warrior; stung by oppression, he springs forward from his tranquil pur-suits, undaunted by opposition and undismayed by danger, to fight even to death for the defence of his rights. Parents, wives, children, and country, all the hallowed properties of existence, are to him the talisman that takes fear from his heart and nerves his arm to victory. In the requiem over those who have fallen in the cause of their country, which 'Time, with his own eternal lips shall sing,' the praises of Warren shall be

The blood of those patriots who have fallen in defence of republics has often 'cried from the ground,' against the ingratitude of the country for which it was shed. No monument was reared to their fame; no record of their virtues written; no fostering hand extended to their offspring; but they and their deeds were neglected and forgotten. Towards Warren there was no ingratitude,—our country is free from this stain.

Congress were the guardians of his honours, and remembered that his children were unprotected orphans. Within a year after his death, Congress passed the fol-

lowing resolution:

That a monument be erected to the memory of General Warren, in the town of Boston, with the fol-

lowing inscription:-In Honour of JOSEPH WARREN, Major-General of Massachusetts Bay. He devoted his life to the liberties of his country; and in bravely defending them, fell an early victim in the BATTLE OF BUNKER HILL,

an acknowledgment of his services and distinguished merit, have erected this monument to his memory."

It was resolved, likewise, 'That the eldest son of General Warren should be educated from that time at the expense of the United States.' On the first of July, 1780, Congress, recognising these former resolutions, further resolved, 'That it should be recommended to the executive of Massachusetts Ray, to make to the executive of Massachusetts Bay, to make provi-sion for the maintenance and education of his three younger children; and that Congress would defray the expense to the amount of the half-pay of a major-general; to commence at the time of his death, and continue till the youngest of the children should be of age.' tinue till the youngest of the children should be of age.' The part of the resolutions relating to the educating of the children, was carried into effect accordingly. The monument is not yet erected, but it is not too late. The shade of Warren will not repine at this neglect, while the ashes of Washington repose without gravestone or epitaph." Thach. Med. Biog. A.]

WATER. Aqua. This fluid is so well known, as scarcely to require any definition.

It is transparent, without colour, smell, or taste; in a very slight degree compressible; when pure, not liable to spontaneous change; liquid in the common temperature of our atmosphere, assuming the solid form at 32° Fahrenheit, and the gaseous at 212°, but returning unaltered to its liquid state on resuming any

returning unaltered to its liquid state on resuming any degree of heat between these points; capable of dis-solving a greater number of natural bodies than any other fluid whatever, and especially those known by the name of the saline; performing the most impor-tant functions in the vegetable and animal kingdoms, and entering largely into their composition as a constituent part.

"Native water is seldom, if ever, found perfectly pure. The waters that flow within or upon the sur-face of the earth, contain various earthy, saline, metallic, vegetable, or animal particles, according to the substances over or through which they pass. Rain and snow waters are much purer than these, although they also contain whatever floats in the air, or has been exhaled along with the watery vapours.

The purity of water may be known by the following

marks or properties of pure water:—

1. Pure water is lighter than water that is not pure.

2. Pure water is more fluid than water that is not pure.

 It has no colour, smell, or taste.
 It wets more easily than the waters containing metallic and earthy salts, called hard waters, and feels softer when touched.

5. Soap, or a solution of soap in alkohol, mixes easily

and perfectly with it.

6. It is not rendered turbid by adding to it a solution of gold in aqua regia, or a solution of silver, or of lead, or of mercury, in nitric acid, or a solution of acetate of lead in water.

Water was, till modern times, considered as an ele-

mentary or simple substance.

Previous to the month of October, 1776, the cele-Previous to the month of October, 1776, the cele-brated Macquer, assisted by Sigaud de la Fond, made an experiment by burning hydrogen gas in a bottle, without explosion, and holding a white china saucer over the flame. His intention appears to have been that of ascertaining whether any fuliginous smoke was produced, and he observes, that the saucer remained perfectly clean and white, but was moistened with pertest was applied to ascertain this purity, neither does

he make any remark on the fact.

In the month of September, 1777, Bucquet and Lavoisier, not being acquainted with the fact which is incidentally and concisely mentioned by Macquer, made an experiment to discover what is produced by the combustion of hydrogen. They fired five or six pints of hydrogen in an open and wide-mouthed bottle. and instantly poured two ounces of lime-water through the flame, agitating the bottle during the time the combustion lasted. The result of this experiment showed,

that carbonic acid was not produced.

Before the month of April, 1781, Mr. John Warltire, encouraged by Dr. Priestley, fired a mixture of common air and hydrogen gas in a close copper vessel, and found its weight diminished. Dr. Priestley, like-wise, before the same period, fired a like mixture of hydrogen and oxygen gas in a closed glass vessel, Mr. Warltire being present. The inside of the vessel, though clean and dry before, became dewy, and was lined with a sooty substance. These experiments were afterward repeated by Mr. Cavendish and Dr. Priestley; and it was found, that the diminution of weight did not take place, neither was the sooty matter perceived. These circumstances, therefore, must have arisen from some imperfection in the apparatus or materials with which the former experiments were

It was the summer of the year 1781, that Mr. Henry Cavendish was busied in examining what becomes of the air lost by combustion, and made those valuable experiments which were read before the Royal Society on the 15th of January, 1784. He burned 500,000 grain measures of hydrogen gas, with about two and a half times the quantity of common air, and by causing the burned air to pass through a glass tube eight feet in length, 135 grains of pure water were condensed. He also exploded a finiture of 19,500 grain measures of oxygen gas, and 37,000 of hydrogen, in a close vessel. The condensed liquor was found to contain a small portion of nitric acid, when the mixture of the air was such, that the burned air still contained a considerable portion of oxygen. In this case it may be presumed, that some of the oxygen combines with a portion of nitrogen present.

In the mean time, Lavoisier continued his researches, and during the winter of 1781-1782, together with Gingembre, he filled a bottle of six pints with hydrogen, which being fired, and two ounces of lime-water poured in, was instantly stopped with a cork, through which a flexible tube communicating with a vessel of oxygen was passed. The inflammation ceased, except oxygen was passed. The innamental at the orifice of the tube, through which the oxygen at the orifice of the tube, through which the oxygen was pressed, where a beautiful flame appeared. combustion continued a considerable time, during which the lime-water was agitated in the bottle. Neither this, nor the same experiment repeated with pure water, and with a weak solution of alkali instead of lime-water, afforded the information sought after, for these substances were not at all altered.

The inference of Mr. Warltire, respecting the moisture on the inside of the glass in which Dr. Priestley

first fired hydrogen and common air, was, that these airs, by combustion, deposited the moisture they con-Mr. Wart, however, inferred from experiments, that water is a compound of the burned airs, which have given out their latent heat by combustion; and communicated his sentiments to Dr. Priestley in a letter dated April 26, 1783

It does not appear, that the composition of water was known or admitted in France, till the summer of 1783, when Lavoisier and De la Place, on the 24th of June, repeated the experiment of burning hydrogen and oxygen in a glass vessel over mercury, in a still greater quantity than had been burned by Mr. Cavendish. The result was nearly five gross of pure water. Monge made a similar experiment at Paris nearly at the same time, or perhaps before.

This assidance and accurate philosopher then pro-

This assiduous and accurate philosopher then pro-ceeded, in conjunction with Meusnier, to pass the steam of water through a red-hot iron tube, and found

ceptible drops of a clear fluid, resembling water; and similar results, the water disappearing and hydrogen which, in fact, appeared to him and his assistant to be nothing but pure water. He does not say whether any accounted for by Lavoisier, by supposing the water

accounted for by Lavoisier, by supposing the water to be decomposed into its component parts, oxygen and hydrogen, the former of which unites with the ignited substance, while the latter is disengaged.

The grand experiment of the composition of water by Fourcroy, Vauquelin, and Seguin, was begun on Wednesday, May 13, 1790, and was finished on Friday, the 22d of the same month. The combustion was kept up 185 hours with little interruption, during which time the machine was not quitted for a moment. The experimenters alternately refreshed themselves when fatigued, by lying for a few hours on mattresses in the

laboratory

To obtain the hydrogen, 1. Zinc was melted and rubbed into a powder in a very hot mortar. 2. This metal was dissolved in concentrated sulphuric acid diluted with seven parts of water. The air procured was made to pass through caustic alkali. To obtain the oxygen, two pounds and a half of crystallized hyperoxymuriate of potassa were distilled, and the air

was transferred through caustic alkali.

The volume of hydrogen employed was 25063.568 cubic inches, and the weight was 1039.358 grains.

The volume of oxygen was 12570.942, and the weight was 6200.860 are inches.

was 6209.869 grains,

The total weight of both elastic fluids was 7249.227. The weight of water obtained was 7244 grains, or 12 ounces 4 gros.45 grains.

The weight of water which should have been ob-

tained was 12 ounces 4 gros 49.227 grains.
The deficit was 4.227 grains.

The quantity of azotic air before the experiment was 415.256 cubic inches, and at the close of it 467. The excess after the experiment was consequently 51.744 cubic inches. This augmentation is to be attributed, the academicians think, to the small quantity of atmospheric air in the cylinders of the gasometers at the time the other airs were introduced. These additional 51 cubic inches could not arise from the hydrogen, for experiment showed, that it contained no azotic air. Some addition of this last fluid, the experimenters think, cannot be avoided, on account of the construction of the machine.

The water being examined, was found to be as pure as distilled water. Its specific gravity to distilled water was as 18671: 18670.

The decomposition of water is most elegantly ef-

The decomposition of water is most degandy effected by electricity.

The composition of water is best demonstrated by exploding 2 volumes of hydrogen and 1 of oxygen, in the eudiometer. They disappear totally, and pure water results. A cubic inch of this liquid, at 60°, weighs 252.52 grains, consisting of 28.06 grains hydrogen, and

224.46 oxygen. The bulk of the former gas is 1325 cubic inches. That of the latter is 662

1987

Hence there is a condensation of nearly two thousand rence there is a condensation of nearly two thousand volumes into one; and one volume of water contains 662 volumes of oxygen. The prime equivalent of water is 1.125; composed of a prime of oxygen = 1.0+ a prime of hydrogen = 0.125; or 9 parts by weight of water, consisting of 8 oxygen + 1 hydrogen."

The simple waters are the following:

1. Distilled water. This is the lightest of all others, containing neither solid nor vascous substances in solu

The simple waters are the lightest of all others, 1. Distilled water. This is the lightest of all others, containing neither solid nor gaseous substances in solution, is perfectly void of taste and smell, colourless and beautifully transparent, has a soft feel, and wets a solution of the second the fingers more readily than any other. It mixes uniformly with soap into a smooth opaline mixture, but may be added to a solution of soap in spirit of wine without injuring its transparency. The clearness of distilled water is not impaired by the proof delications. of distilled water is not impaired by the most delicate chemical reagents, such as lime-water, a solution of barytes in any acid, nitrated silver, or acid of sugar. When evaporated in a silver vessel it leaves no residuum; if preserved from access of foreign matter floating in the air, it may be kept for ages unaltered in steam of water through a red-hot iron tube, and found that the iron was oxydized, and hydrogen disengaged; and the steam of water being passed over a variety of other combustible or oxidable substances, produced vessels upon which it has no action, as it does not possess within itself the power of decomposition. As it freezes exactly at 32° of Fahrenbeit, and boils at 212° under the atmospherical pressure of 29.8 inches

WAT WAT

these points are made use of as the standard ones for thermometrical division; and its specific weight being always the same under the mean pressure and tempe rature, it is employed for the comparative standard of

specific gravity

Pure distilled water can only be procured from water which contains no volatile matters that will rise in distillation, and continue still in union with the vapour when condensed. Many substances are volatile during distillation, but most of the gases, such as common air, carbonic acid, and the like, are incapable of uniting with water at a high temperature: other bodies, however, such as vegetable essential oil, and, in general, much of that which gives the peculiar odour to vegetable and animal matter, will remain in water after distillation. So the steam of many animal and vegetable decoctions has a certain flavour which distinguishes it from pure water; and the aqueous exhalation from living bodies, which is a kind of distillation, has a similar impregnation.

To obtain distilled water perfectly pure, much stress was laid by former chemists on repeating the process a great number of times; but it was found by Lavoi-

a great number of times; but it was found by Lavoisier, that rain water once distilled, rejecting the first
and last products, was as pure a water as could be
procured by any subsequent distillations.

Distilled water appears to possess a higher power
than any other as a resolvent of all animal and vegetable matter, and these it holds in solution as little as
possible altered from the state in which they existed possible altered from the state in which they existed in the body that yielded them. Hence the great practical utility of that kind of chemical analysis which presents the proximate constituent parts of these bodies, and which is effected particularly by the assistance of pure water. On the other hand, a saline, earthy, or otherwise impure water, will alter the texture of some of the parts, impair their solubility, produce material changes on the colouring matter, and become a less accurate analyzer on account of the

admixture of foreign contents.

Distilled water is seldom employed to any extent in the preparation of food, or in manufactures, on account the preparation of food, or in manufactures, on account of the trouble of procuring it in large quantities; but for preparing a great number of medicines, and in almost every one of the nicer chemical processes that are carried on in the liquid way, this water is an essential requisite. The only cases in which it has been used largely as an article of drink, have been in those important trials made of the practicability of procuring it by condensing the steam of sea water by means of a simple apparatus adapted to a ship's boiler; and these have fully shown the ease with which a large quantity of fresh water, of the purest kind, may be had at sea, at a moderate expense, whereby one of the most distressing of all wants may be relieved. the most distressing of all wants may be relieved. There are one or two circumstances which seem to show that water, when not already loaded with foreign matter, may become a solvent for concretions in urinary passages. At least, we know that very material advantage has been derived in these cases from very pure natural springs, and hence a course of distilled water has been recommended as a fair subject

of experiment.

2. Rain water, the next in purity to distilled water, is that which has undergone a natural distillation from the earth, and is condensed in the form of rain. This is a water so nearly approaching to absolute purity as probably to be equal to distilled water for every purposes in the nicer chemical experiments. The pose except in the nicer chemical experiments. foreign contents of rain water appear to vary according to the state of the air through which it falls. The heterogeneous atmosphere of a smoky town will give some impregnation to rain as it passes through, and this, though it may not be at once perceptible on chemical examination, will yet render it liable to spontaneous change; and hence, rain water, if long kept, especially in hot climates, acquires a strong smell, becomes full of animalcula, and in some degree putrid. According to Margraaff, the constant foreign contents of rain water appear to be some traces of the muriatic and nitric acids; but as this water is always very soft, it is admirably adapted for dissolving soap, or for the solution of alimentary or colouring matter, and it is ing to the state of the air through which it falls. solution of alimentary or colouring matter, and it is accordingly used largely for these purposes. The specific gravity of rain water is so nearly the same as that of distilled water, that it requires the most delicate instruments to ascertain the difference. Rain, that Rain, that

falls in towns, acquires a small quantity of lime and calcareous matter from the mortar and plaster of the

3. Ice and snow water. This equals rain water in purity, and, when fresh melted, contains no air, which is expelled during freezing. In cold climates and in high latitudes, thawed snow forms the constant drink of the inhabitants during winter; and the vast masses of ice which float on the polar saes afford an abundant supply to the mariner. It is well known, that in a weak brine, exposed to a moderate freezing cold, it is only the watery part that congeals, leaving the unfrozen liquor proportionably stronger of the salt. The same happens with a dilute solution of vegetable acids, with fermented liquors, and the like; and advantage is taken of this property to reduce the saline part to a more concentrated form. Snow water has long lain under the imputation of occasioning those strumous swellings in the neck which deform the inhabitants of many of the Alpine valleys; but this opinion is not supported by any well-authenticated, indisputable facts, and is rendered still more improbable, if not entirely overturned, by the frequency of the disease in Sumatra, where ice and snow are never seen, and its being quite unknown in Chili and in Thibet, though the rivers of these coun-tries are chiefly supplied by the melting of the snow,

with which the mountains are covered.

4. Spring water. Under this comprehensive class are included all waters that spring from some depth beneath the soil, and are used at the fountain head, or at least before they have run any considerable distance exposed to the air. It is obvious that spring water will be as various in its contents as the substances that com-pose the soil through which it flows. When the ingredients are not such as to give any peculiar medical or sensible properties, and the water is used for common purposes, it is distinguished as a hard or soft spring, sweet or brackish, clear or turbid, and the like. Ordinary springs insensibly pass into mineral springs, as their foreign contents become more notable and un common; though sometimes waters have acquired great

medical reputation from mere purity.

By far the greater number of springs are cold; but as they take their origin at some depth from the surface, and below the influence of the external atmosphere, their temperature is, in general, pretty uniform during every vicissitude of season, and always several degrees higher than the freezing point. Others, again, arise constantly hot, or with a temperature always exceeding the summer heat; and the warmth possessed by the water is entirely independent of that of the atmosphere,

and varies little, winter or summer.

One of the principal inconveniences in almost every spring water, is its hardness, owing to the presence of earthy salts, which, in by far the greater number of cases, are only the insipid substances, chalk, and sele-nite, which do not impair the taste of the water; while nite, which do not impair the taste of the water; while the air which it contains, and its grateful coolness, render it a most agreeable, and generally a perfectly innocent drink; though sometimes, in weak stomachs, it is apt to occasion an uneasy sense of weight in that organ, followed by a degree of dyspepsia. The quantity of earthy salts varies considerably; but, in general, it appears that the proportion of five grains of these in the prior will constitute a hard water, unfit for washing with pint will constitute a hard water, unfit for washing with soap, and for many other purposes of household use or manufactures. The water of deep wells is always, ceteris paribus, much harder than that of springs which overflow their channel; for much agitation and exposure to air produce a gradual deposition of the calcareous earth; and hence spring water often incrusts to a considerable thickness the inside of any kind of tube through which it flows, as it arises from the earth. The specific gravity of these waters is also, in general, greater than that of any other kind of water, that of the sea excepted. Springs that overflow their channel, and form to themselves a limited bed, pass insensibly into

form to themselves a fimited led, pass insensibly into the state of stream or river water, and become thereby altered in some of their chemical properties.

5. River water.—This is in general much softer and more free from earthy salts than the last, but contains less air of any kind: for, by the agitation of a long current and in most cases, a great increase of terrors. rent, and in most cases a great increase of temperature, it loses common air and carbonic acid, and, with this last, much of the lime which it held in solution. The specific gravity thereby becomes less, the taste not so harsh, but less fresh and agreeable, and out of a hard

cious rock, and flow in a sandy or stony bed, are from the outset remarkably pure. Such are the mountain lakes and rivulets in the rocky districts of Wales, the source of the beautiful waters of the Dee, and numberless other rivers that flow through the hollow of every valley. Switzerland has long been celebrated for the purity and excellence of its waters, which pour in copious streams from the mountains, and give rise to some of the finest rivers in Europe. An excellent observer and naturalist, the illustrious Haller, thus speaks of the Swiss waters:-"Vulgaribus aquis Helvetia super omnes fere Europæ regiones excellit. Nusquam liquidas illas aquas et crystalli simillimas se mihi obtulisse memini postquam ex Helvetia excessi. scopulis enim nostræ per puros silices percolatæ nulla terra vitiantur." Some of them never freeze in the severest winter, the cause of which is probably, as Haller conjectures, that they spring at once out of a subterraneous reservoir so deep as to be out of the reach of frost; and during their short course, when exposed to day, they have not time to be cooled down from 53°,

their original temperature, to below the freezing point.

Some river waters, however, that do not take their rise from a rocky soil, and are indeed at first considerably charged with foreign matter, during a long course, even over a rich cultivated plain, become remarkably pure as to saline contents, but often fouled with mud, and vegetable or animal exuviæ, which are rather sus pended than held in true solution. Such is that of the Thames, which, taken up at London at low water, is a very soft and good water, and, after rest and filtration, it holds but a very small portion of any thing that could prove noxious or impede any manufacture. It is also excellently fitted for sea-store; but it here undergoes a remarkable spontaneous change. No water carried to sea becomes putrid sooner than that of the Thames. When a cask is opened after being kept a month or two, a quantity of inflammable air escapes, and the water is so black and offensive as scarcely to be borne. Upon racking it off, however, into large earthen vessels (oil jars are commonly used for the purpose), and ex-posing it to the air, it gradually deposites a quantity of black slimy mud, becomes clear as crystal, and remarkably sweet and palatable. The Seine has as high a reputation in France, and appears from accurate experiments to be a river of great purity. It might be expected that a river which has passed by a large town, and received all its impurities, and been used by numerous dyers, tanners, hatters, and the like, that crowd to its hanks for the convenience of plenty of water, should thereby acquire such a foulness as to be very percep-tible to chemical examination for a considerable distance below the town; but it appears, from the most accurate examination, that where the stream is at all considerable, these kinds of impurity have but little influence in permanently altering the quality of the water, especially as they are for the most part only sus-pended, and not truly dissolved; and, therefore, mere rest, and especially filtration, will restore the water to its original purity. Probably, therefore, the most accu-rate chemist would find it difficult to distinguish water taken up at London from that procured at Hampton Court, after each has been purified by simple filtration. 6. Stagnated waters.—The waters that present the

greatest impurities to the senses, are those of stagnant pools, and low marshy countries. They are filled with the remains of animal and vegetable matter undergoing decomposition, and, during that process, becoming in part soluble in water, thereby affording a rich nutri-ment to the succession of living plants and insects which is supplying the place of those that perish. From the want of sufficient agitation in these waters, vegetation goes on undisturbed, and the surface be-comes covered with conferva and other aquatic plants and as these standing waters are in general shallow, they receive the full influence of the sun, which further promotes all the changes that are going on within them. The taste is generally vapid, and destitute of that freshness and agrecable coolness which distinguish spring water. However, it should be remarked, that stagnant waters are generally soft, and many of the impurities are only suspended, and therefore separable by filtration; and perhaps the unpalatableness of this drink has caused it to be in worse credit than it de-

spring is often made a stream of sufficient purity for serves, on the score of salubrity. The decidedly nox-most of the purposes where a soft water is required. Some streams, however, that arise from a clean silinant pools, have been often supposed to extend to the clear rock, and flow in a sendy or stream a clean silinant pools, have been often supposed to extend to the nant pools, have been often supposed to extend to the internal use of these waters; and often, especially in hot climates, a residence near these places has been as much condemned on the one account as on the other; and, in like manner, an improvement in health has been as much attributed to a change of water as of air. WEDEL, GEORGE WOLFFGANG, Was born in 1645, at Golzan in Lusatia, and graduated at Jena in 1667 where, after a temporary exercise of his profession at Gotha, he became medical professor; in which station he continued with reputation for almost half a century. He combined with his skill in medicine a considerable acquaintance with mathematics and philology, as well as with the oriental and classical languages. He was an associate to the Academy Natura Curiosorum, and to the Royal Society of Berlin, physician to several German sovereigns, a count palatine, and an imperial counsellor. Notwithstanding these high offices and numerous engagements, he was attentive to the poor, and assiduous in his literary labours. He is celebrated for his pharmaceutical knowledge, and his elegance of prescription, so that many of his compositions have been adopted in dispensatories. Of his works, besides his academical dissertations, the principal are "Opiologia;" "Pharmacia in Artis formam redacta;" "De Medicamentorum Facultatibus;" "De Morbis Infanand "Exercitationes Medico-Philologicae."

WELD. Woald. The Reseda Inteola of Linnaus,

which is used as a yellow dye.

WEPFER, JOHN JAMES, was born in 1620, at Schaff-hausen, and after visiting several universities in Italy, graduated at Basil, and settled in his native place. His reputation was extensive there and in Germany, and he attained, by his dissections and experiments, a high rank among those who have contributed to improve medical science. In 1658, he published a celebrated work, entitled "Observationes Anatomica," &c., since often reprinted with the title of "Historia Apoplecti-In an epistle " De Dubiis Anatomicis," he asserted the entire glandular structure of the liver, prior to Malpighi. Another valuable work is called "Cicutæ Aquaticæ Historia et Noxæ." His constitution was injured by attendance, at an advanced age, on the duke of Wurtemburg, and the imperial army under his command; and he was carried off by a dropsy in 1695. His papers were published by two of his grand-sons, in a work entitled "Observationes Medico-Prac-ticæ," &c. To the Ephemerides Naturæ Curicsorum he made several valuable communications, being a member of that society

WERNERITE. Foliated scapolite.
WHARTON, THOMAS, was born in Yorkshire in
1610, and educated at Cambridge. He afterward be-1610, and educated at Cambridge. He alterward became a private tutor at Oxford: but on the commencement of the civil wars, he removed to London, and engaged in the practice of physic. On the surrender of Oxford to the parliament in 1646, he obtained a doctor's degree there, became a member of the College of Physicians in London, and got into considerable tractice. In 1659, he read became a member of the considerable tractice. practice. In 1652, he read lectures on the glands before the College; and he afterward published a work on that subject, entitled "Adenographia." The descriptions cannot be relied upon, being chiefly taken from brutes; yet there are some useful observations on the diseases of those organs. His name has been affixed WHEAT Triticum The coads of the 70

WHE WHI

is to these plants, therefore, we are indebted for our bread, and the various kinds of pastry. Wheat is first ground between mill-stones, and then sifted to obtain its faring or flour. The flour of wheat may be separated into its three constituent parts, in the following manner. The flour is to be kneaded into a paste with water in an earthen vessel, and the water continue pouring upon it from a cock; this liquid, as it falls upon the paste, takes up from it a very fine white powder, by means of which it acquires the colour and consistency of milk. This process is to be continued till the water run off clear, when the flour will be separated into three distinct parts: 1. A gray elastic matter that sticks to the hand, and on account of its properties has gained the name of the glutinous, or vegeto-animal part.

2. A white powder which falls to the bottom of the water, and is the forced water or starch. the water, and is the faculum or starch. 3. A matter which remains dissolved in the water, and seems to be

a sort of mucilaginous extract.

Flour, from whatever species of corn obtained, is likewise disposed to vinous fermentation, on account of its saccharine contents. The aptitude for fermentation of these mealy seeds increases if they be first converted into malt; insomuch as by this process, the gluten which forms the germ is separated, and the starchy part appears to be converted into saccharine matter. The making of malt, for which purpose barley and wheat are generally chosen, is as follows: The grains are put in the malting tub, and immersed in cold water, in a temperate and warm season, changin cold water, in a temperate and warm season, changing this fluid several times, especially in hot weather, and they are thus kept soaking till they be sufficiently soft to the touch. Upon this they are piled up in heaps on a roomy, clean, airy floor, where, by the heat spontaneously taking place, the vegetation begins, and the grains germinate. To cause the germination to go on uniformly, the heaps are frequently turned. In this state the vegetation is suffered to continue till the germs have about two-thirds or three-fourths of the length of the corn. It is carried too far when the leafy length of the corn. It is carried too far when the leafy germs have begun to sprout.

For this reason, limits are set to the germination by drying the mait, which is effected by transferring it to the kiln, or by spreading it about in spacious airy lofts. Dried in the last way, it is called air-dried malt; in the first, kiln-malt. In drying this latter, care must be taken that it does not receive a burned smell, or be in

part converted into coal.

From this malt, beer is made by extraction with

water and fermentation.

With this view, a quantity of malt freed from its germs, and sufficient for one intended brewing, is coarsely bruised by grinding, and in the mash-tub first well mixed with some cold, then scalded with hot water, drawn upon it from the boiler. It is afterward strongly and uniformly stirred. When the whole mass has stood quietly for a certain time, the extract, (mash,) or sweetwort, is brought into the boiler, and the malt remaining in the tub is once more extracted by infusion with hot water.

This second extract, treated in like manner, is added

to the first, and both are boiled together.

This clear decoction is now drawn off, and called boiled wort. To make the beer more fit for digestion, and at the same time to deprive it of its too great and unpleasant sweetness, the wort is mixed with a decoction of hops, or else these are boiled with it. After which it ought to be quickly cooled, to prevent its transition into acetous fermentation, which would ensue if it were kept too long in a high temperature.

On this account the wort is transferred into the cooler, where it is exposed with a large surface to cold air, and from this to the fermenting tub, that by addition of a sufficient portion of recent yest it may begin to ferment. When this fermentation has proceeded to a due degree, and the yest ceases to rise, the beer is When this fermentation has proceeded conveyed into casks placed in cool cellars, where it finishes its fermentation, and where it is well kept and preserved, under the name of barrelled beer, with the precaution of filling up occasionally the vacancy caused in the vessels by evaporation; or the beer is bottled before it has done fermenting, and the bottles are stopped a little before the fermentation is completely over. By so doing the bottled beer is rendered spark-ling. In this state it frequently bursts the bottles, by the disengagement of the carbonic acid gas which it

hibernum, and estirum, of Linnæus, are so termed. It contains, and it strongly froths, like champaign, when brought into contact with air on being poured into another vessel.

Beer well prepared should be limpid and clear, possess a due quantity of spirit, and excite no disagreeable sweet taste, and contain no disengaged acid. By these properties it is a species of vinous beverage, and is distinguished from wine in the strict sense, and other liquors of that kind, by the much greater quantity of mucilaginous matter which it has received by extrac-tion from the malted grains, but which also makes it more nourishing. Brown beer derives its colour from malt strongly roasted in the kiln, and its bitterish taste from the hops. Pale beer is brewed from malt dried in the air, or our sug-hops at all. See Beer. Wheat, buck. See Polygonum fagopyrum. Wheat, buck. See Polygonum divaricain the air, or but slightly roasted, with but little or no

Wheat, Indian. See Zea mays: WHEAT, TURKEY. The Turkey wheat is a native Wheat, Turkey. The Turkey wheat is a native of America, where it is much cultivated, as it is also in some parts of Europe, especially in Italy and Germany. There are many varieties, which differ in the colour of the grain, and are frequently raised in our gardens by way of curiosity, whereby the plant is well known. It is the chief bread-corn in some of the southern parts of America, but since the introduction of rice into Carolina, it is but little used in the northern colonies. It makes a main part too of the food of the poor peo-ple in Italy and Germany. This is the sort of wheat mentioned in the book of Ruth, where it is said that mentioned in the book of Ruth, where it is said that Boaz treated Ruth with parched ears of corn dipped in vinegar. This method of eating the roasted ears of Turkey wheat is still practised in the East; they gather in the cars when about half ripe, and having scorched them to their minds, eat them with as much satisfaction as we do the best flour-bread.

In several parts of South America they parch the ripe corn, never making it into bread, but grinding it be tween two stones, mix it with water in a calabash, and so eat it. The Indians make a sort of drink from this grain, which they call bici. This liquor is very windy and intoxicating, and has nearly the taste of sour small beer: but they do not use it in common, being too lazy to make it often, and therefore it is chiefly kept for the celebration of feasts and weddings, at which times they mostly get intolerably drunk with it. The manthey mostly get intolerably drunk with it. The manner of making this precious beverage, is to steep a parcel of corn in a vessel of water, till it grows sour, then the old women being provided with calabashes for the purpose, chew some grains of the corn in their mouths, and spitting it into the calabashes, empty them, spittle and all, into the sour liquor, having previously drawn off the latter into another vessel.

The chewed grain soon raises a fermentation, and when this ceases, the liquor is let off from the dregs, and set by till wanted. In some of the islands in the South Sea, where each individual is his own lawgiver, it is no uncommon thing for a near relation to excuse

a murderer for a good drunken bout of ciri

[Turkey wheat is the Indian corn of America. It makes a rich, wholesome, and nutritious bread-corn, and may be cooked in a greater variety of ways than any other grain. Dr. Hooper is mistaken in supposing it is but little used in the northern parts of the United States (formerly colonies). There is not a farm or plantation in any part of the country without a portion planted in Indian corn. A portion of Indian meal mixed with wheat or rye flour, improves the bread wheel with wheel of years, improves the stead made in that way. A.]
WHET-SLATE. A greenish gray-coloured mineral, used to sharpen steel instruments.
WHEY. The fluid part of milk which remains after

the curd has been separated. It contains a saccharine matter, some butter, and a small portion of cheese. WHISKEY. A dilute alkohol obtained by distifling

(Whiskey is obtained in this country from rye, Indian corn, potatoes, &c. It is a spirit which, when concentrated by repeated distillation, produces alkohol, and may be obtained from various fruits, roots, seeds, &c.

See Fruits, affording spirit. A.]
WHISPERING. A lowness of speech, caused by uttering the words so feebly, as not to produce any

vibration of the larynx.

White-swelling. See Arthropuosis, and Hydarthrus,

WHITES. See Leucorrhaa. WHITING. See Gadus.

Whortleberry, bears'. See Arbutus uva ursi. Whortleberry, red. See Vaccinium vitis idwa.

WHYTT, Robert, was born in 1714, at Edinburgh, where he studied physic, and after visiting the medical schools at London, Paris, and Leyden, settled in the exercise of his profession, became a fellow, then president of the college, and chairman of the Institutions of Medicine in that university. As a medical practitioner and teacher, and also as a writer, he acquired deserved celebrity. The first of his publications was an "Essay on the Vital and other involuntary Motions of Animals," 1751, in which he opposed the Stahlian Theory, and ascribed them to the operation of stimuli. Four years after, his "Physiological Essays" appeared, in which he supposes the circulation assisted by an oscillatory motion of the minute vessels, and treats of sensibility dent of the college, and chairman of the Institutions of motion of the minute vessels, and treats of sensibility and irritability. He also wrote on the Use of Lime-water in Calculous Complaints; and on Nervous Diseases; and contributed likewise some papers to the Edinburgh Essays. The Observations on Hydrocephalus, were published after his death, which occurred in 1766, after labouring long under a complication of chronic complaints.

WILLIS, THOMAS, was born in Wiltshire, about the year 1621, and entered at Oxford, with a view to the clerical profession; but he afterward changed to physic, took his bachelor's degree in 1646, and commenced practice at the university. He distinguished himself by his steady attachment to the church of England, and also by his love of science, so that he became one of the first members of that philosophical society at Oxford, which laid the foundation of the Royal Society of London. He was ambitious of excelling as a chemist, and published, in 1659, a treatise on Fermentation, and another on Fever, with a Dissertation on the Urine. After the Restoration he was appointed to the Sedleian prothe Restoration he was appointed to the Sedleian pro-fessorship of Natural Philosophy, and received his doc-tor's degree. In 1664, he published his celebrated work "Cerebri Anatome," with a description of the nerves; which was followed, after three years, by his "Patho-logia Cerebri et Nervosi Generis," in which he treats of Convulsive Diseases, and the Scurvy. In the mean time he had settled in London, and being nominated a physician in ordinary to the king, was advancing to the first rank in practice. His next publication was on Hysteria, and Hypochondriasis. In 1672, he produced Hysteria and Hypochondriasis. In 1672, he produced another work, "De Anima Brutorum;" which he supposed like the vital principle in man of a corporeal nature. The year following he began to print his "Pharmaceutice Rationalis," which he did not live to complete being accepted. plete, being carried off by a pleurisy in his fifty-fourth His works engaged great attention at first, and are still admired, though modern improvements have diminished their value. They are written in an ele-

gant Latin style. WILLOW. See Salix.

Willow-leaved oak. See Quercus phellos. WINE. Vinum. "Chemists give the name of wine in general to all liquors that have become spirituous by fermentation. Thus cider, beer, hydromel or mead, and other similar liquors, are wines.

The principles and theory of the fermentation which produces these liquors are essentially the same.

All those nutritive, vegetable, and animal matters which contain sugar ready formed, are susceptible of the spirituous fermentation. Thus wine may be made of all the juices of plants, the sap of trees, the infusions and decoctions of farinaceous vegetables, the milk of frugiverous animals; and, lastly, it may be made of all ripe succulent fruits; but all these substances are not equally proper to be changed into a good and generous

As the production of alkohol is the result of the spi- tion is t

rituous fermentation, that wine may be considered as essentially the best, which contains most alkohol. But of all substances susceptible of the spirituous fermenta-tion, none is capable of being converted into so good wine, as the juice of the grapes of France, or of other countries that are nearly in the same latitude, or in the same temperature. The grapes of hotter countries, and even those of the southern provinces of France, do indeed furnish wines that have a more agreeable, that is, more of a saccharine taste; but these wines, though they are sufficiently strong, are not so spirituous as those of the provinces near the middle of France: at least from these latter wines the best vinegar and brandy are made. As an example, therefore, of spiritnous fermentation in general, we shall describe the method of making wine from the juice of the grapes of

This juice, when newly expressed, and before it has begun to ferment, is called must, and in common language sweet wine. It is turbid, has an agreeable and very saccharine taste. It is very laxative; and when drunk too freely, or by persons disposed to diarrheas, it is apt to occasion these disorders. Its consistence is somewhat less fluid than that of water, and it becomes

almost of a phehy thickness when dried.

When the must is pressed from the grapes, and but into a proper vessel and place, with a temperature between fifty-five and sixty degrees, very sensible effects are produced in it, in a shorter or longer time accordring to the nature of the liquor, and the exposure of the place. It then swells, and is so rarefied, that it frequently overflows the vessel containing it, if this be nearly full. An intestine motion is excited among its parts, accompanied with a small hissing noise and evident ebullition. The bubbles rise to the surface, and at the same time is disengaged a quantity of carbonic acid of such purity, and so subtle and dangerous, that it is capable of killing instantly men and animals exposed to it in a place where the air is not renewed. The skins, stones, and other grosser matters of the grapes, are buoyed up by the particles of disengaged air that adhere to their surface, are variously agitated, and are raised in form of a scum, or soft and spongy crust, that covers the whole liquor. During the fermenta-tion, this crust is frequently raised, and broken by the air disengaged from the liquor which forces its way through it; afterward the crust subsides, and becomes entire as before.

These effects continue while the fermentation is brisk, and at last gradually cease: then the crust, being no longer supported, falls in pieces to the bottom of the liquor. At this time, if we would have a strong and generous wine, all sensible fermentation must be stopped. This is done by putting the wine into close vessels, and carrying these into a cellar or other cool

After this first operation, an interval of repose takes place, as is indicated by the cessation of the sensible effects of the spirituous fermentation; and thus enables us to preserve a liquor no less agreeable in its taste, than useful for its reviving and nutritive qualities, when

drunk moderately.

If we examine the wine produced by this first fermentation, we shall find, that it differs entirely and essentially from the juice of grapes before fermentation. Its sweet and saccharine taste is changed into one that is very different, though still agreeable, and somewhat spirituous and piquant. It has not the laxative quality of must, but affects the head, and occastons, as is well known, drunkenness. Lasuy, in distilled, it yields, instead of the insipid water obtained from must by distillation with the heat of boiling water, and inflammable liquor, called a volatile, spirituous, and inflammable liquor, called spirit of wine, or alkohol. This spirit is consequently a new being, produced by the kind of fermentation, called the vinous or spirituous.

When any liquor undergoes the spirituous fermentation, all its parts seem not to ferment at the same time, otherwise the fermentation would probably be very quickly completed, and the appearances would be much more striking: hence, in a liquor much disposed to fer-mentation, this motion is more quick and simultaneous than in another liquor less disposed. Experience has shown, that a wine, the fermentation of which is very slow and tedious, is never good or very spirituous; and therefore, when the weather is too cold, the fermenta-

WIN WIN

the wine is made. A proposal has been made by a person very intelligent in economical affairs, to apply a greater than the usual heat to accelerate the fermentation of the wine, in those years in which grapes have not been sufficiently ripened, and when the juice is not suffi-

ciently disposed to fermentation.

A too hasty and violent fermentation is perhaps also hurtful, from the dissipation and loss of some of the spirit; but of this we are not certain. However, we may distinguish, in the ordinary method of making wines of grapes, two periods in the fermentation, the first of which lasts during the appearance of the sensible effecis above mentioned in which the greatest number of fermentable particles ferment. After this first effort of fermentation, these effects sensibly diminish, and ought to be stopped, for reasons hereafter to be mentioned. The fermentative motion of the liquors then ceases. The heterogeneous parts that were suspended in the wines by this motion, and render it muddy, are separated and form a sediment, called the lees; after which the wine becomes clear; but though the operation is then considered as finished, and the fermentation apparently ceases, it does not really cease; and it ought to be continued in some degree, if we would have good wine.

In this new wine a part of the liquor probably re-mains that has not fermented, and which afterward ferments, but so very slowly, that none of the sensible effects produced in the first fermentation are here per-The fermentation, therefore, still continues in the wine, during a longer or shorter time, although in an imperceptible manner; and this is the second period of the spirituous fermentation, which may be called the imperceptible fermentation. We may easily perceive that the effect of this imperceptible fermentation is the gradual increase of the quantity of alkohol. It has also another effect no less advantageous, namely, the separation of the acid salt called tartar from the This matter is, therefore, a second sediment, that is formed in the wine, and adheres to the sides of the containing vessels. As the taste of tartar is harsh and disagreeable, it is evident that the wine, which by means of the insensible fermentation has acquired more alkohol, and has disengaged itself of the greater part of its tartar, ought to be much better and more agreeable; and for this reason chiefly old wine is universally preferable to new wine.

But insensible fermentation can only ripen and meliorate the wine, if the sensible fermentation have regularly proceeded, and been stopped in due time. We know certainly that if a sufficient time have not been allowed for the first period of the fermentation, the unfermented matter that remains, being in too large a quantity, will then ferment in the bottles, or close vessels, in which the wine is put, and will occasion effects so much more sensible, as the first fermenta-tion shall have been sooner interrupted: hence these wines are always turbid, emit bubbles, and sometimes break the bottles from the large quantity of air disen-

gaged during the fermentation.

We have an instance of these effects in the wine of Champaign, and in others of the same kind. The sensible termentation of these wines is interrupted, or rather suppressed, that they may have this sparkling quality. It is well known that these wines make the corks fly out of the bottles; that they sparkle and froth when they are poured into glasses; and lastly, that they have a taste much more lively and more piquant than wines that do not sparkle; but this sparkling quality, and all the effects depending on it, are only caused by a considerable quantity of carbonic acid gas, which is disengaged during the confined fermentation that the wine has undergone in close vessels. This air, not having an opportunity of escaping, and of being dissipated as fast as it is disengaged, and being interposed between all the parts of the wine, combines in some measure with them, and adheres in the same manner as it does to certain mineral waters, in which it produces nearly the same effects. When this air is entirely disengaged from these wines, they no longer sparkle, they lose their piquancy of taste, become mild, and even almost insipid.

Such are the qualities that wine acquires in time, when its first fermentation has not continued sufficiently long. These qualities are given processely to

ciently long. These qualities are given purposely to certain kinds of wine, to indulge taste or caprice; but such wines are supposed to be unfit for daily use.

Wines for daily use ought to have undergone so completely the sensible fermentation, that the succeeding fermentation shall be insensible, or at least exceedingly little perceived. Wine, in which the first fermenta-tion has been too far advanced, is liable to worse in-conveniences than that in which the first fermentation has been too quickly suppressed; for every fermentable liquor is, from its nature, in a continual intestine motion, more or less strong according to circumstances, from the first instant of the spirituous fermentation, till it is completely purified: hence, from the time of the completion of the spirituous fermentation, or even before, the wine begins to undergo the acid or acetous fermentation. This acid fermentation is very slow and insensible, when the wine is included in very close vessels, and in a cool place; but it gradually advances, so that in a certain time the wine, instead of being improved, becomes at last sour. This evil cannot be remedied; because the fermentation may advance, but cannot be reverted.

Wine-merchants, therefore, when their wines become sour, can only conceal or absorb this acidity by certain substances, as by alkalies and absorbent earths. But these substances give to wine a dark-greenish colour, and a taste which, though not acid, is somewhat dis-agreeable. Besides, calcareous earths accelerate con-siderably the total destruction and putrefaction of the wine. Oxides of lead, having the property of forming with the acid of vinegar a salt of an agreeable saccharine taste, which does not alter the colour of the wine, and which besides has the advantage of stopping ferand which besides has the advantage of stopping fermentation and putrefaction, might be very well employed to remedy the acidity of wine, if lead and all its preparations were not pernicious to health, as they occasion most terrible colics, and even death, when taken internally. We cannot believe that any winemerchant, knowing the evil consequences of lead, should, for the sake of gain, employ it for the purpose mentioned; but if there be any such persons, they must be considered as the poisoners and murderers of the public. At Alicant, where very sweet wines are made, it is the practice to mix a little lime with the grapes before they are pressed. This, however, can only neutralize the acid already existing in the grape.

If wine contain litharge, or any other oxide of lead,

If wine contain litharge, or any other oxide of lead, it may be discovered by evaporating some pints of it to dryness, and melting the residuum in a crucible, at the bottom of which a small button of lead may be found after the fusion: but an easier and more expeditious proof is by pouring into the wine some liquid sulphuret. If the precipitate occasioned by this addition of the sulphuret be white, or only coloured by the wine, we may know that no lead is contained in it; but if the precipitate be dark coloured, brown, or blackish, we may conclude, that it contains lead or iron.

The only substances that cannot absorb or destroy, but cover and render supportable the sharpness of wine, without any inconvenience, are, sugar, honey, and other saccharine alimentary matters; but they can succeed only when the wine is very little acid, and when an exceeding small quantity only of these substances is sufficient to produce the desired effect; otherwise the wine would have a sweetish, tart, and not agreeable taste.

From what is here said concerning the acescency of wine, we may conclude that when this accident happens, it cannot by any good method be remedied, and that nothing remains to be done with sour wine but to self it to vinegar-makers, as all honest wine-mer-

chants do.

As the must of the grape contains a greater proportion of tartar than our currant or gooseberry julces do, Dr. Ure has been accustomed, for many years, to recommend, in his lectures, the addition of a small portion of that salt to our must, to make it ferment into a more genuine wine. Dr. M'Culloch has lately prescribed the same addition in his popular treatise on the art of making wine.

The wines principally used in medicine are, the vinum album hispanicum, or sherry, vinum canarium, canary or sack wine, the vinum rhenanum, or Rhenish wine, and the vinum rubrum, or port wine. These differ from each other in the proportion of their constituent principles, and particularly in that of alkohol, which they contain. The qualities of wines depend not only upon the difference of the grapes, as containing more or less of saccharine juice and the acid matter which accompanies it, but also upon circumstances. ter which accompanies it, but also upon circumstances attending the process of fermentation. New wines are liable to a strong degree of acescency when taken into the stomach, and thereby occasion much flatulency and cructations of acid matter; heartburn and violent and criticitions of acid matter, heater and pains in the stomach from spasms are also often produced; and the acid matter, by passing into the intestines and mixing with the bile, is apt to occasion colics or excite diarrheas. Sweet wines are likewise more disposed to become acescent in the stomach than others; but as the quantity of alkohol which they contain is more considerable than appears sensibly to the taste, their acescency is thereby in a great measure counteracted. Red port, and most of the red wines, have an adstringent quality, by which they strengthen the stomach, and prove useful in restraining immoderate evacuations; on the contrary, those which are of an acid nature, as Rhenish, pass freely by the kidneys, and gently loosen the belly. But this, and perhaps all the thin or weak wines, though of an agreeable flavour, yet as containing little alkohol, are readily disposed to become acid in the stomach, and thereby to aggravate all arthritic and calculous complaints, as well as to produce the effects of new wine. The general effects of wine are, to stimulate the stomach, exhilarate the spirits, warm the habit, quicken the circulation, promote perspiration, and, in large quantities, to prove intoxicating, and powerfully sedative. In many disorders, wine is universally admitted to be of important service, and especially in fevers of the typhus kind, or of a putrid tendency; in which it is found to raise the pulse, support the strength, promote a diaphoresis, and to resist putrefaction; and in many cases it proves of more immediate advantage than the Peruvian bark. Delirium, which is the consequence of excessive irritability, and a defective state of nervous energy, is often entirely removed by the free use of wine. also a well-founded observation, that those who indulge in the use of wine are less subject to fevers of the ma-lignant and intermittent kind. In the putrid sore throat, in the small-pox, when attended with great debility and symptoms of putridity, in gangrenes, and in the plague, wine is to be considered as a principal remedy; and in almost all cases of languor, and of great prostration of strength, wine is experienced to be a more grateful and efficacious cordial than can be furnished from the whole class of aromatics.

WING. See Ala.

WINSLOW, JAMES BENIGNUS, was born in 1669, in the isle of Funen, and having studied a year under Borrichius, was, sent with a pension from the king of Denmark, to seek improvement in the principal universities of Europe. In 1698, he became a pupil of the celebrated Duverney, at Paris, where he was induced to abjure the Protestant religion; and the patronage of Bossuet, who converted him, procured for him the degree of doctor in 1705. He afterward read lectures of anatomy and surgery at the Royal Gardens; and in 1743 was promoted to the professorship in that institution. In the mean time, he communicated several papers on anatomical and physiological subjects to the Academy of Sciences, by whom, as well as by the Royal Society of Berlin, he was admitted an associate. His great work, mentioned by Haller as superseding all former compositions of anatomy, and entitled "Exposition Anatomique de la Structure du Corps Humain,"

first appeared at Paris in 1732, 4to. It was frequently reprinted, and translated into various languages; and is still regarded as of standard authority. It was intended as a plan of a larger work, which, however, he did not finish. He reached the advanced age of ninety-one.

Winter-bark. See Winteranus cortez.

Winter-cherry. See Physalis alkekengi. WINTE'RA. (Named after Captain Winter, who brought the bark from the straits of Magellan in 1579, and introduced it to the knowledge of physicians as

useful in scurvy, &c.)

WINTERA AROMATICA. The systematic name of the winter-bark tree. The bark is called Cortex winteranus; Cortex magellanicus; Cortex canella alba; and the tree, Winteranus spurius; Canella cubana; Win-terania canella, and Winteria aromatica-pedunculis aggregatis terminalibus, pistalis quatuor, of Linnaeus. It is a native of the West Indics. The bark is brought into Europe in long quills, somewhat thicker than cinnamon. Their taste is moderately warm, aromatic, and bitterish, and of an agreeable smell somewhat resembling that of cloves. alba has been supposed to possess considerable me-dicinal powers in the cure of scurvy and some other complaints. It is now merely considered as a useful and cheap aromatic, and is chiefly employed for the purpose of correcting and rendering less disagreeable the more powerful and nauseous drugs; with which view it is used in the tinctura amara, vinum amarum, vinum rhai, &c. of the Edinburgh Pharmacopæia.

WINTERANUS CORTEX. See Wintera aromatica.

WINTERA'NUS SPURIUS. See Canella alba.
[WINTER GREEN See Pyrola umbellata. A.]
WISEMAN, RICHARD, was first known as a surgeou in the civil wars of Charles I., and accompanied geon in the civil wars of Charles I., and accompanied Prince Charles, when a fugitive, in France, Holland, and Flanders. He served for three years in the Spanish navy, and, returning with the prince to Scotland, was made prisoner in the battle of Worcester. After his liberation in 1652, he settled in London. When Charles II. was restored, he became eminent in his profession, and was made one of the sergeant-surgeons to the king. In 1676, he appears, from the preface to his works, to have been a sufferer by ill health for twenty years: but the time of his death is not known. The result of his experience was given in "Several Surgical Treatises on Tumours, Ulcers, Diseases of the Apus, Scrofula, Wounds, Gunshot Wounds, Fractures and Luxations, and Syphilis." He seems to have given a faithful account of more than six hundred cases, recording his failures as well as his cures. He advocated the efficacy of the royal touch in scrofula, though the fallacy is evident even from his own narration. His writings have long been regarded as standard authority

WITHERING, WILLIAM, was born in 1741, and finished his medical education at Edinburgh, where he took his degree at twenty-five. From Stafford, where he first settled and married, he removed to Birmingham, and speedily obtained a very extensive practice by his skill and assiduity, without neglecting his scientific pursuits, which were chiefly in botany and chemistry. He was author of several valuable publications: "A Botanical Arrangement of British Plants," which appeared at first in 1776, in two volumes, 8vo., but propeared at first in 1776, in two volumes, 8vo., but progressively increased to four; a translation of Bergman's "Sciagraphia Regni Mineralis;" and some chemical and mineralogical papers contributed to the Royal Society, of which he was a fellow. "Account of the Scarlet Fever, &c.;" "Account of the Foxglove," with Practical Remarks on the Dropsy and other Diseases, published in 1785. His lungs being weak, he found it necessary, in the winter of 1793, to go to Lisbon, and afterward to relax from his professional exertions. His death occurred in 1799. sional exertions. His death occurred in 1799. WITHERITE. See *Heavy-spar*.

Womb, inflammation of. See Hysteritis.

Then passing some time on the Continent, he settled near his native place, and practised there for five or six years. He next came to London, and was soon appointed a physician to the Middlesex Dispensary. In 1790, he published the first part, which was after-ward completed in four quarto volumes, of a highly valuable work, entitled "Medical Botany." The fol-Hospital; and in executing the duties of that office he displayed the highest zeal. He gave a manifest proof of his attention to the subject, by publishing in 1796 the first part of a "Highest zear". first part of a "History of the Small-pox in Great Britain, &c.;" but the discovery of vaccination superseded the necessity of completing that work. Dr. Woodville was duly impressed with the importance of what had been announced by Dr. Jenner; but feeling a proper degree of skepticism at first, he was anxious to inves-tigate the practice fully, before he gave it his sanction. Unfortunately he was led into an error at the outset, by not keeping in recollection, that the atmosphere of the hospital was loaded with variolous contagion, whence some unpleasant results appeared; but this being suggested to him, he was induced, on more mature consideration, strenuously to advocate the practice of vaccination; and by the excellent opportunities he enjoyed, he contributed very materially to its rapid ccess. He died in 1805. WOODWARD, Jons, was born in Derbyshire in

1664, and put apprentice to some trade in London; but evincing an ardour for science, Dr. Barwick took him into his family, and for four years instructed him in medicine and anatomy; after which he procured him the medical professorship at Gresham College. He published about this time an essay towards a Natural History of the Earth, which, though executed without sufficient preparation, procured his election into the Royal Society. In 1695, he was created M.D. by Archbishop Tenison, and the year after obtained the same degree from Cambridge; whence he was admitted into the College of Physicians as a fellow in 1700. into the College of Physicians as a fellow, in 1702. He however pursued his inquiries into natural history and antiquities for some time with great zeal. In 1718, he published a work entitled "The State of Physic and of Diseases," containing some fanciful theories, which were ably confuted by Dr. Freind, both ludicrorsly and seriously. He died at Gresham College in 1727, bequeathing his personal property to the University of Cambridge, for the endowment of an annual lectureship, on some subject taken from his own writings. Soon after his death, a catalogue of his fossils was published in 1737, his "Select Cases and Consultations in Physic," containing some valuable observations. in Physic," containing some valuable observations. He supposed the vital principle to reside not in the nerves, but in the blood, and other parts of the body; and he made many experiments to establish the vis insita of muscles.

Woody nightshade. See Solanum dulcamara.

WORL.

See Verticillus.

Vermis. There are several kinds of ani-WORM. mals which infest the human body. Their usual di-vision is into those which inhabit only the intestinal canal, as the ascarides, &c.; and those which are found in other parts, as hydatids, &c. Such is the nature and office of the human stomach and intestines, that insects and worms, or their ovula, may not unfrequently be conveyed into that canal with those things that are continually taken as food; but such insects, or worms, do not live long, and seldom, if ever, generate in a situation so different from their natural one. Besides these, there are worms that are never found in any other situation than the human stomach or interior. other situation than the human stomach or intestines, and which there generate and produce their species. Thus it appears that the human stomach and intestines are the scat for animalcula, which are translated from their natural situation, and also for worms proper to them, which live in no other situation.

First Class. This contains those which are gene-

First Class. This contains those which are generated and nourished in the human intestinal canal, and which there propagate their species.

Second Class, comprehends those insects or worms that accidentally enter the human primæ viæ ab extra, Wood-louse. See Oniscus asellus.

WOODVILLE, WILLIAM, was born at Cockermouth in 1752. After serving a short apprenticeship to an apothecary he graduated at Edinburgh in 1775.

the physician, which, from the variety it affords, may be divided into different orders, genera, and species.

Order I. Round worms. Genus I. Intestinal ascarides.

Character. Body round, head obtuse, and furnished with three vesicles.

Species 1. Ascaris lumbricoides. The long round worm, or lumbricoid ascaris.

When full grown, a foot in length. Character. Mouth triangular.

2. Ascaris vermicularis. The thread or mawworm.

Character. When full grown, half an inch in length. Tail terminates in a fine point.

Genus II. Intestinal trichurides.

Character. Body round, tail three times the length of the body, head without vesicles.

Species. Trichuris vulgaris. The trichuris, or long

Species. thread-worm.

Character. The head furn Order II. The flat worms. The head furnished with a proboscis.

Genus I. Intestinal tape-worm. Body flat and jointed. Character.

Species 1. Tania osculis marginalibus. The long tape-worm.

Character. The oscula are situated upon the margin of the joints.

2. Tania osculis superficialibus. The broad tape-

worm. Character. The oscula are placed upon the flattened surface.

These worms were all known to the ancients, the trichuris only excepted, and are mentioned in the works of Hippocrates, Galen, Celsus, Paulus Ægineta,

and Pliny. When worms are generated in the intestines, they often produce the following symptoms, viz. variable appetite, fætid breath, acrid eructations and pains in the stomach, grinding of the teeth during sleep, picking of the nose, paleness of the countenance; sometimes dizziness, hardness and fulness of the belly; slimy stools, with occasional griping pains, more particularly about the navel, heat and itching about the anus; short dry cough; emaciation of the body; slow fever, with evening exacerbations and irregular pulse, and sometimes convulsive fits.

WORT. An infusion of malt. This has been found useful in the cure of the scurvy. Dr. Macbride, in his very ingenious experimental essays, having laid down as a principle, "that the cure of the scurvy depends on the forms that it is the removal to the forms. the fermentative quality in the remedies made use of," was led to inquire after a substance capable of being preserved during a long sea-voyage, and yet containing materials by which a fermentation might occasionally be excited in the bowels. Such a one appeared to him to be found in malt, which is well known to be the grain of bades, brought and book and the property of bades. grain of barley, brought suddenly to a germinating state by heat and moisture, and then dried, whereby its saccharine principle is developed, and rendered easy of extraction by watery liquors. The sweet infusion of this he proposed to give as a dietic article to scorbutic persons, expecting that it would ferment in their bowels, and give out its fixed air, by the antiseptic powers of which the strong tendency to putrefaction in this disease might be corrected.

It was some time before a fair trial of this purposed remedy could be obtained; and different reports were made concerning it. By some cases, however, published in a postscript of the second edition of the doctor's work in 1767, it appears that scorbutic complaints of the most dangerous kind have actually been cured at sea by the use of wort. Its general effects were to keep the patient's bowels open, and to prove highly nutritious and strengthening. It sometimes purged too much, but this effect was easily obviated by the tinctura thebaica. Other unquestionable cases of its success in this disease are to be seen in the London Medical Es-

says and Inquiries.

The use of wort has hence been adopted in other cases where a strong and putrid disposition in the fluids appeared to prevail, as in cancerous and phagedenic ulcers; and instances are published, in the fourth volume of the work above mentioned, of its remarkable good

effects in these case

As the cificacy of the malt infusion depends upon its producing changes in the whole mass of fluids, it is obvious that it must be taken in large quantities for a considerable length of time, and rather as an article of diet than medicine. From one to four pints daily have generally been directed. The proportion recommended in preparing it, is one measure of ground malt to three equal measures of boiling water. The mixture must be well stirred, and left to stand, covered, three or four

hours. It should be made fresh every day.

WOUNDWORT. See Laserpitium chironium.

WRAPPER. See Valva

WRIST. See Carpus:

XALA'PPA. (From the province of Xalappa, in New Spain, whence it comes.) Jalap.

XA'NTHIUM. (From ξανθος, yellow: so named because it is said to make the hair yellow.) The name of a genus of plants in the Linnman system. Class, Monæcia; Order, Pentandria. The less burdeck

XANTHIUM STRUMARIUM. The systematic name of the less burdock. This herb of Linnæus was once esteemed in the cure of scrofula, but, like most other remedies against this disease, proves ineffectual. seeds are administered internally in some countries against erysipelas.

[Xanthoxylum frazincum. See Prickly-ash. A.] XERA'SIA. (From ξηρος, dry.) An excessive te-nuity, or softness of the hairs, similar to down.

XEROCOLLY'RIUM. (From ξηρος, dry, and κολλυριον, a collyrium.) A dry collyrium.

XEROMY'RUM. (From ξηρος, dry, and ρυρον, an ointment.) A dry ointment.

XEROPHTHA'LMIA. (Ξηρος, dry, and οφθαλμια, an inflammation of the eye.) A dry inflammation of the eye without discharge. the eye without discharge.

Xi'PHIUM. (From ξιφος, a sword: so named from the sword-like shape of its leaves.) Spurgewort.

XIPHOID. (Xiphoides; from ξιφος, a sword, and ειδος, likeness.) A term given by anatomists to parts which had some resemblance to an ancient sword, as the xiphoid cartilage. the xiphoid cartilage.

YPSILOGLO'SSUS. (From υψιλοιιδες, the ypsiloid bone, and γλωσσα, the tongue.) A muscle originating in the os hyoides, and terminating in the tongue.
YPSILOI'DES. (From υ, the Greek letter, called ypsilon, and αιδος, a likeness.) The os hyoides: so named from its likeness to the Greek letter ypsilon.
YTTRIA. This is a new earth discovered in 1794, by Professor, Gadolin, in a stone from Ytterby, in

by Professor Gadolin, in a stone from Ytterby, in Sweden.

It may be obtained most readily by fusing the gadoin may be obtained most readily by fusing the gado-linite with two parts of caustic potassa, washing the mass with boiling water, and filtering the liquor, which is of a fine green. This liquor is to be evaporated, till no more oxide of manganese falls down from it in a black powder; after which the liquid is to be saturated with nitric acid. At the same time digest the sediment that was not dissolved, in very dilute nitric acid, which will dissolve the earth with much heat, leaving the siley and the highly oxided iron, undissolved. Mix the silex, and the highly oxided iron, undissolved. Mix the silex, and the highly oxided fron, undissolved. Mix the two liquors, evaporate them to dryness, redissolve and filter, which will separate any silex or oxide of tron that may have been left. A few drops of a solution of carbonate of potassa will separate any lime that may be present, and a cautious addition of hydrosulphuret of potassa will throw down the oxide of manganese that may have been left; but if too much be employed, it will throw down the yttria likewise. Lastly, the yttria is to be precipitated by pure ammoria, well washed and dried.

Yttria is perfectly white, when not contaminated.

Yttria is perfectly white, when not contaminated

with oxide of manganese, from which it is not easily freed. Its specific gravity is 4.842. It has neither taste nor smell. It is infusible alone; but with borax melts into a transparent glass, or opaque white, if the borax were in excess. It is insoluble in water, and in caustic fixed alkalies; but it dissolves in carbonate of ammonia, though it requires five or six times as much as glucine. It is soluble in most of the acids. The oxalic acid, or oxalate of ammonia, forms precipitates in its solutions perfectly resembling the muriate of silver. Prussiate of potassa, crystallized and redissolved in water, throws it down in white grains; phosphate of soda, in white gelatinous flakes; infusion of galls, in brown flocks.

Some chemists are inclined to consider yttria rather as a metallic than as an earthy substance: their reasons are, its specific gravity, its forming coloured salts, and its property of oxygenizing muriatic acid after it has undergone a long calcination.

When yttria is treated with potassium in the same when yetra is treated with potassium in the same manner as the other earths, similar results are obtained; the potassium becomes potassa, and the earth gains appearances of metallization; so that it is scarcely to be doubted, says Sir H. Davy, that yttria consists of inflammable matter, metallic in its nature, combined with oxygen. The salts of yttria have the following general descriptions: following general characters

Many of them are insoluble in water.
 Precipitates are occasioned in those which dissolve, by phosphate of soda, carbonate of soda, oxalate of ammonia, tartrate of potassa, and ferroprussiate of

If we except the sweet-tasted soluble sulphate of yuria, the other salts of this earth resemble those with

the base of lime in their solubility.
YTTRO-CERITE. A mineral of a reddish, grayish white, and a violet-blue colour, consisting of oxide of cerium, yttria, lime, and fluoric acid, found hitherto only at Finbo, in Sweden.
YTTRO-TANTALITE. An ore of tantalum, from which the columbic acid is procured.

YUCCA. (Yucca, Yuca, or Iucca, of the original inhabitants of America.) The name of a genus of plants in the Linnwan system. Class, Hexandria: Order, Monogynia.
YUCCA GLORIOSA. See Adam's needle.

ZEA

ZA'CCHARUM. See Saccharum.
ZACCHIA, PAOLO, an eminent physician, was born at Rome in 1585, and became distinguished by his learning and accomplishments, as well as by his prolearning and accomplishments, as well as by his professional skill. He was physician to Pope Innocent X., and celebrated among his contemporaries by various publications, of which the principal is entitled, "Quæstiones Medico-legales," and has been often reprinted. He was also the author, in Italian, of two esteemed works, on the Lent diet, and on hypochondriacal affections. He died in 1659.

ZAYERAN. (Arabian.) Saffron.

ZA'FFRAN. (Arabian.) Saffron. ZAFFRE. Saffre. The residuum of cobalt after the sulphur, arsenic, and other volatile matters of this mineral have been expelled by calcination.

Zai'Bac. (Arabian.) Quicksilver.

Za'Rza. An ancient and provincial name of the

sarsaparilla.

ZE'A. (Zea, a, f.; a name borrowed from the ancient Greeks, whose ζεια appears to have been some kind of Triticum or Hordeum, agreeing with this genus only as being a grain cultivated for the use of man.) The maize.

ZEO

ZEA MAYS. The systematic name of the Indian wheat-plant, the common maize, or Indian corn, a native of America and cultivated in Italy and several parts of Europe, for its grain, which is ground for the same purposes as our wheat, to which it is very little

ZEDOA'RIA. 1. The name of a genus of plants in the Linnean system. Class, Monandria; Order, Monogynia. Zedoary.

ZEDOARY. See Zedoaria. The round root of the ze-

ZEINE. A yellow substance, having the appearance of wax, obtained from maize or Indian corn.

ZEOLITE. The name of a very extensive mineral

genus, containing the following species:
1. Dodecahedral zeolite, or leucite.

Hexahedral zeolite, or analcime. Rhomboidal zeolite, chabasite, or chabasie

4. Pyramidal zeolite, or cross stone.

5. Diprismatic zeolite, or laumonite.

 Prismatic zeolite, or mesotype, divided into three subspecies: natrolite; mealy zeolite, of a white colour, of various shades; and fibrous zeolite, of which there are two kinds.

a. The acicular, or needle zeolite, the mesotype of Hauy. This is of a grayish, yellowish, or reddishwhite colour. It is found in Scotland.

Common fibrous zeolite, of a white colour.
 Prismatoidal zeolite, or stilbite, comprehending,

a. Foliated zeolite, stilbite of Hauy of a white and red colour, beautiful specimens of which are found in

b. Radiated zeolite, of a yellowish-white, or grayish-

white colour.

8. Axifrangible zeolite, or apophyllite.

ZE'RNA. An ulcerated impetigo.
ZERO. The commencement of a scale marked 0 thus we say, the zero of Fahrenheit, which is 320 below the melting point of ice; the zero of the centigrade scale, which coincides with the freezing of water. The absolute zero is the imaginary point in the scale of temperature, when the whole heat is exhausted: the term of absolute cold or privation of

ZI'BETHUM. (From Zobeth, Arabian.) Civetta. Civet. A soft, unctuous, odoriferous substance, about the consistence of honey or butter, of a whitish, yellowish, or brownish colour, sometimes blackish, con-

tained in some excretory follicles near the anus of the Viverra zibetha, of Linnæus. It has a grateful smell when diluted, and an unctuous subacrid taste, and possesses stimulating, nervine, and antispasmodic

ZIMMERMAN, JOHN GEORGE, was born in 1728, at Brug, in the canton of Bern, and studied medicine under Haller at Gottingen, where he took his degree at 23. Having married a relation of Haller, at he settled as a physician in his native town; the retirement of which gave him an opportunity of composing many pieces in prose and verse, and particularly a sketch of his popular work "On Solitude." His treatise "On the Experience of Medicine," appeared in 1763, and three years after, that on dysentery. 1768, he accepted the post of physician to the king of England for Hanover, whither he removed. Here the accumulation of business tended in some measure to allay the irritability of his temper; and being obliged about three years after, to put himself under the care of a surgeon at Berlin for some local complaint, the notice that was taken of him, even by the king, contributed much to improve his health and spirits, and of course his happiness. Having lost his first wife, he formed a second matrimonial connexion in 1782; which helped much to alleviate the afflictions to which he was afterward exposed. In 1786 he was sent for to attend the great Frederick in his last illness: and he published an account of the conversations which he had with that celebrated prince. He was led, too, to defend the character of Frederick against the censures of Count de Mirabeau, which suffered him to severe criticisms. His political and religious principles in-duced him also to attack those societies which paved the way to the French revolution; and he advised the Emperor Leopold to suppress them by force; and having laid an unavowed publication to the charge of a particular person, he subjected himself to a prosecution for a libel. His mind had arrived to such a state of irritation, that the approach of the French towards Hanover almost subverted his reason; he abstained from food, and died absolutely worn out in 1795. ZIMOME. See Gluten, vegetable.

ZINC. (Zincum, a German word.) A metal found in nature combined with oxygen, carbonic acid, and A metal found sulphuric acid; and mineralized by sulphur. Native oxide of zinc is commonly called calamine. It occurs in a loose, and in a compact form, amorphous, of a white, gray, yellow, or brown colour, without lustre, or transparency. Combined with carbonic acid, it is called vitreous zinc ore, or natine carbonate of zinc. It is found in solid masses, sometimes in six-sided compressed prisms, both ends being covered with pentagons. Its colour is generally grayish inclining to black. It is often transparent. Sulphate of zinc is found efflorescent in the form of stalactites, or in rhombs. Sulpharet of zinc, or blende, is the most abundant ore. It is found of various colours; brown, yellow, hyacinth, black, &c., and with various degrees of lustre and transparency. This zinc ore is contaminated with iron, lead, argillaceous and silicious earths, &c. It occurs both in amorphous masses and crystallized in a diversity of polygonal figures.

It is of a bluish-white colour, somewhat brighter than lead; of considerable hardness, and so malleable as not to be broken with the hammer, though it cannot be much extended in this way. It is very easily extended by the rollers of the flatting mill. Its sp. gr. is from 6.9 to 7.2. In a temperature between 210° and 300° of F., it has so much ductility that it can be drawn into wire, as well as laminated.

When broken by bending, its texture appears as if omposed of cubical grains. On account of its imper-fect malleability, it is difficult to reduce it into small parts by filing or hammering; but it may be granu-lated, like the malleable metals, by pouring it, when fused, into cold water; or, if it be heated nearly to melting, it is then sufficiently brittle to be pulverized.

It melts long before ignition, at about the 700th degree of Fahrenheit's thermometer; and, soon after it becomes red-hot, it burns with a dazzling white flame, of a bluish or yellowish tinge, and is oxidized with such rapidity, that it flies up in the form of white flowers, called the flowers of zinc, or philosophical wool. These are generated so plentifully, that the access of air is soon intercepted; and the combustion ceases, unless the matter be stirred, and a considerable heat kent up. The white oxide of since is considerable. heat kept up. The white oxide of zinc is not volatile, heat kept up. The white oxide of zinc is not volatile, but is driven up merely by the force of the combustion. When it is again urged by a strong heat, it becomes converted into a clear yellow glass. If zinc be heated in closed vessels, it rises without decomposition.

When zinc is burned in chlorine, a solid substance

is formed of a whitish-gray colour, and semitrans-parent. This is the only chloride of zinc, as there is only one oxide of the metal. It may likewise be made by heating together zinc filings and corrosive sublimate. is as soft as wax, fuses at a temperature a little above 2120, and rises in the gaseous form at a heat much below ignition. Its taste is intensely acrid, and it corrodes the skin. It acts upon water, and dissolves in it, producing much heat; and its solution decomposed, by an alkali, affords the white hydrated oxide of zinc. This chloride has been called butter of zinc, and muriate of zinc.

Blende is the native sulphuret of zinc. The two bodies are difficult to combine artificially. The salts of zinc possess the following general characters:

1. They generally yield colourless solutions with

2. Ferroprussiate of potassa, hydrosulphuret of potassa, hydriodate of potassa, sulphuretted hydrogen, and alkalies, occasion white precipitates.

Infusion of gall produces no precipitate.

The diluted sulphuric acid dissolves zinc: at the same time that the temperature of the solvent is increased, and much hydrogen escapes, an undissolved residue is left, which has been supposed to consist of plumbago. Proust, however, says, that it is a mixture of arsenic, lead, and copper. As the combination of the sulphuric acid and the oxide proceeds, the temperature diminishes, and the sulphate of zinc, which is ture diminishes, and the sulphate of zinc, which is more soluble in hot than cold water, begins to separate, and disturb the transparency of the fluid. If more water be added, the salt may be obtained in fine prismatic four-sided crystals. The white vitriol, or copperas, usually sold, is crystallized hastily, in the same manner as loaf-sugar, which on this account it resembles in appearance; it is slightly efflorescent. The white oxide of zinc is soluble in the sulphuric acid, and forms the same salt as is afforded by zinc itself. itself.

The hydrogen gas that is extricated from water by the action of sulphuric acid, carries up with it a por-tion of zinc, which is apparently dissolved in it; but this is deposited spontaneously, at least in part, if not wholly, by standing. It burns with a brighter flame than common hydrogen.

Sulphate of zinc is prepared in the large way from some varieties of the native sulphuret. The ore is roasted, wetted with water, and exposed to the air. The sulphur attracts oxygen, and is converted into sulphuric acid; and the metal, being at the same time oxidized, combines with the acid. After some time, the

ZIN ZIN

sulphate is extracted by solution in water; and the solution being evaporated to dryness, the mass is run into moulds. Thus the white vitriol of the shops generally contains a small portion of iron, and sometimes of lead.

Sulphurous acid dissolves zinc, and sulphuretted hydrogen is evolved. The solution, by exposure to the air, deposites needly crystals, which, according to Fourcroy and Vauquelin, are sulphuretted sulphite of zinc. By dissolving oxide of zinc in sulphurous acid, the pure sulphite is obtained. This is soluble, and crystallizable

crystallizable.

Diluted nitric acid combines rapidly with zinc, and produces much heat, at the same time that a large quantity of nitrous air flies off. The solution is very caustic, and affords crystals by evaporation and cooling, which slightly detonate upon hot coals, and leave oxide of zinc behind. This salt is deliquescent.

oxide of zinc behind. This salt is deliquescent.

Muriatic acid acts very strongly upon zinc, and disengages much hydrogen; the solution, when evaporated, does not afford crystals, but becomes gelatinous. By a strong heat it is partly decomposed, a portion of the acid being expelled, and part of the muriate sublimes and condenses in a congeries of prisms.

Phosphoric acid dissolves zinc. The phosphate does not crystallize, but becomes gelatinous, and may be fused by a strong heat. The concrete phosphoric acid

fused by a strong heat. The concrete phosphoric acid heated with zinc filings is decomposed.

Fluoric acid likewise dissolves zinc.

The boracic acid digested with zinc becomes milky; and if a solution of borax be added to a solution of muriate or nitrate of zinc, an insoluble borate of zinc is thrown down.

A solution of carbonic acid in water dissolves a small quantity of zinc, and more readily its oxide. If the solution be exposed to the air, a thin iridescent pellicle forms on its surface.

The acetic acid readily dissolves zinc, and yields by evaporation crystals of acetate of zinc, forming rhomboidal or hexagonal plates. These are not altered by exposure to the air, are soluble in water, and burn with a blue flame.

The succinic acid dissolves zinc with effervescence, and the solution yields long, slender, foliated

crystals.

Zinc is readily dissolved in benzoic acid, and the solution yields needle-shaped crystals, which are soluble both in water and in alkohol. Heat decomposes them

by volatilizing their acid.

The oxalic acid attacks zinc with a violent effervescence, and a white powder soon subsides, which is oxalate of zinc. If oxalic acid be dropped into a solution of sulphate, nitrate, or muriate of zinc, the same salt is precipitated; it being scarcely soluble in water unless an excess of acid be present. It contains seventyfive per cent. of metal.

The tartaric acid likewise dissolves zinc with effer-vescence, and forms a salt difficult of solution in water.

The citric acid attacks zinc with effervescence, and small brilliant crystals of citrate of zinc are gradually deposited, which are insoluble in water. Their taste is styptic and metallic, and they are composed of equal parts of the acid and of oxide of zinc.

The malic acid dissolves zinc, and affords beautiful

Lactic acid acts upon zinc with effervescence, and produces a crystallizable salt.

The metallic acids likewise combine with zinc. If arsenic acid be poured on it, an effervescence takes place, arsenical hydrogen gas is emitted, and a black powder falls down, which is arsenic in the metallic state, the zinc having deprived a portion of the arsenic, as well as the water, of its oxygen. If one part of zinc filings, and two parts of dry arsenic acid be distilled in a retort, a violent detonation takes place when the retort becomes red, occasioned by the sudden absorption of the oxygen of the acid by the zinc. The arseniate of zinc may be precipitated by pouring arsenic acid into the solution of acetate of zinc, or by mixing a solution of an alkaline arseniate with that of sulphate of zinc.

It is a white powder, insoluble in water.

By a similar process zinc may be combined with the molybdic acid, and with the oxide of tungsten, the tungstic acid of some, with both of which it forms a white insoluble compound; and with the chromic acid, the result of which compound is equally insoluble, but

of an orange-red colour.

Zinc likewise forms some triple salts. Thus, if the white oxide of zinc be boiled in a solution of muriate of ammonia, a considerable portion is dissolved; and though part of the oxide is again deposited as the solution cools, some of it remains combined with the acid and alkali in the solution, and is not precipitable either by pure alkalies or their carbonates. This triple salt does not crystallize.

If the acidulous tartrate of potassa be boiled in water with zinc filings, a triple compound will be formed, which is very soluble in water, but not easily crystal-This, like the preceding, cannot be precipitated from its solution either by pure or carbonated alkalies.

A triple sulphate of zinc and iron may be formed by mixing together the sulphates of iron and of zinc dissolved in water, or by dissolving iron and zinc in dilute sulphuric acid. This salt crystallizes in rhomboids, which nearly resemble the sulphate of zinc in figure, but are of a pale green-colour. In taste, and in degree of solubility, it differs little from the sulphate of zinc. It contains a much larger proportion of zinc than of iron.

A triple sulphate of zinc and cobalt, as first noticed by Link, may be obtained by digesting zaffre in a solu-tion of sulphate of zinc. On evaporation, large quad-rilateral prisms are obtained, which effloresce on exposure to the air.

Zinc is precipitated from acids by the soluble earths and the alkalies: the latter redissolve the precipitate, if

they be added in excess.

Zinc decomposes, or alters, the neutral sulphates in the dry way. When fused with sulphate of potassa, it converts that salt into a sulphuret: the zinc at the same time being oxidized, and partly dissolved in the sulphuret. When pulverized zinc is added to fused nitre, or projected together with that salt into a red-hot crucible, a very violent detonation takes place; insomuch that it is necessary for the operator to be careful in using only small quantities, lest the burning matter should be thrown about. The zinc is oxidized, and part of the oxide combines with the alkali, with which it forms a compound soluble in water.

Zinc decomposes common salt, and also sal ammo-niac, by combining with the muriatic acid. The filings of zinc likewise decompose alum, when boiled in a solution of that salt, probably by combining with its

excess of acid.

Zinc may be combined with phosphorus, by projecting small pieces of phosphorus on the zinc melted in a crucible, the zinc being covered with a little resin, to prevent its oxidation. Phosphuret of zinc is white, with a shade of bluish-gray, has a metallic lustre, and is a intle mallcable. When zinc and phosphorus are exposed to heat in a retort, a red sublimate rises, and likewise a bluish sublimate in needly crystals with a metallic lustre. If zinc and phosphoric acid be heated together, with or without a little charcoal, needly crystals are sublimed, of a silvery-white colour. All these, according to Pelletier, are phosphuretted oxides of zinc.

Most of the metallic combinations of zinc have been already treated of. It forms a brittle compound with antimony; and its effects on manganese, tungsten, and

antimony; and its enects on manganese, tangsten, and molybdena, have not yet been ascertained.

Zinc, vitriolated. See Zinci sulphas.
Zi'nci acetas. See Acetas zinci.

Zinci oxidum. Zincum calcinatum. Oxide of zinc.
Flowers of zinc. Nihil album; Lana philosophorum.
"Throw gradually little pieces of zinc into a large deep crucible placed obliquely and made of a white heat, another crucible being placed over it, so that the zinc may be exposed to the air, and that it may be frequently stirred with an iron spatula; take out directly the oxide, which is formed from time to time; then pass the white and lighter part of it through a sieve. Lastly, pour water upon this, that a very fine powder may be formed, in the same manner as chalk is directed to be prepared." The properties of this oxide are analogous to those of the sulphate, (except that it is hardly active enough to excite vomiting,) if given in larger doses: but it is more precarious in its effects; and chiefly used at present as an external astringent.

ZINCI SULPHAS. Zincum vitriolatum. Vitriolum album. Sulphate of zinc. White vitriol. This occurs native, but not sufficiently pure for medical use: It is thus prepared in the pharmacopæia. "Take of zinc, broken to little pieces, three ounces; sulphuric acid, by weight, five ounces; water, four pints. Mix

them in a glass vessel, and when the effervescence is silex, potassa, and oxide of iron. Dissolve it in muthem in a glass vessel, and when the enervescence is over, filter the solution through paper; then boil it down, till a pellicle appears, and set it by to crystalize." This preparation is given internally in the dose of from 9j to 3 ss, as a vomit. In small doses it cures dropsies, intermitting headaches, and some nervous diseases; and is a powerful antispasmodic and tonic. A solution of white vitriol is also used to remove gleets, gonorrheas, and for cleaning foul ulcers, having an astringent or stimulant effect, according to its strength.

ZI'NCUM. See Zinc.

ZINCUM CALCINATUM. See Zinci oxidum. ZINCUM VITRIOLATUM. See Zinci sulphas.

ZINCUM VITRIOLATUM PURIFICATUM. See Zinci zulphas. Zingi.

An ancient name of the stellated aniseed.

See Illicium anisatum.

Zi NGIBER. (Zingiberis, is, f. Zingiber, eris, n. Zingiberi; indec. Ζιγγιβερις, of Dioscorides, a name which the Greeks seem to have taken from the Arabians, when they got the plant.) The name of a genus of plants, according to Roscoe. Class, Monandria; Order, Monogynia.

ZINGIBER ALBUM. Ginger-root when deprived of its

radicles and sordes.

ZINGIBER COMMUNE. See Zingiber officinale.
ZINGIBER NIGRUM. The root of the zingiber officinale is so called when suffered to dry with its radicles

and the sordes which usually hang to it.

ZINGIBER OFFICINALE. The systematic name of the ginger-plant. Zingiber album; Zingiber nigrum; Zingiber commune; Zinziber; Amonum zingiber, of Linnæus. The white and black ginger are both the produce of the same plant, the difference depending upon the mode of preparing them. Ginger is generally considered as an aromatic, and less pungent and heating to the system than might be expected from its effects upon the organ of taste. It is used as an antispasmodic and carminative. The cases in which it is more immediately serviceable are flatulent colics, de-bility, and laxity of the stomach and intestines; and in torpid and phlegmatic constitutions to excite brisker vascular action. It is seldom given but in combination with other medicines. In the pharmacopæias it is directed in the form of a syrup and condiment, and in

many compositions ordered as a subsidiary ingredient. ZINN, JOHN GODFREY, was born in 1726, studied under Haller at Gottingen, and became botanical pro-fessor in that university. His first experiments were undertaken to ascertain the sensibility of different parts of the brain; he then proceeded to the examinaparts of the brain; he then proceeded to the examina-tion of the eye, on which he published a work in much estimation. The result of his botanical labours ap-peared in several papers, and in a catalogue of the plants about Gottingen, arranged according to the plan of his preceptor. He died prematurely in 1758. He was a member of several learned societies.

ZI'NZIBER. See Zingiber.

ZIRCONIA. Zircon. An earth discovered in the year 1793, by Klaproth of Berlin, in the Zircon or Jargon, a gem first brought from the island of Ceylon, but also found in France, Spain, and other parts of Europe. Its colour is either gray, greenish, yellowish, reddish-brown, or purple. It has little lustre, and is nearly opaque. Zircon is likewise found in another gem called the hyacinth. This stone is of a yellowishred colour, mixed with brown. It possesses lustre and transparency. To obtain it, the stone should be calcined and thrown into cold water, to render it friable, Mix the and then powdered in an agate mortar. powder with nine parts of pure potassa, and project the mixture by spoonfuls into a red-hot crucible, taking care that each portion is fused before another is added. Keep the whole in fusion, with an increased heat, for an hour and a half. When cold, break the crucible, separate its contents, powder and boil in water, to dissolve the alkali. Wash the insoluble part; dissolve in muriatic acid; heat the solution, that the silex may fall down; and precipitate the zircon by caustic fixed alkali. Or the zircon may be precipitated by carbonate of soda, and the carbonic acid expelled by heat.

New process for preparing pure zirconia.—Powder the zircons very fine, mix them with two parts of pure potassa, and heat them red-hot in a silver crucible, for an hour. Treat the substance obtained with distilled water, pour it on a filter, and wash the inso-luble part well; it will be a compound of zirconia,

riatic acid, and evaporate to dryness, to separate the silex. Redissolve the muriates of zirconia and iron in water; and to separate the zirconia which adheres to the silex, wash it with weak muriatic acid, and add this to the solution. Filter the fluid, and precipitate the zirconia and iron by pure ammonia; wash the precipitates well, and then treat the hydrates with oxalic acid, boiling them well together, that the acid may act on the iron, retaining it in solution, while an insoluble oxalate of zirconia is formed. It is then to be filtered, and the oxalate washed, until no iron can be detected in the water that passes. The earthy oxalate is, when dry, of an opaline colour. After being well washed, it is to be decomposed by heat in a platinum crucible.

Thus obtained, the zirconia is perfectly pure, but is not affected by acids. It must be reacted on by po-tassa as before, and then washed until the alkali is removed. Afterward dissolve it in muriatic acid, and precipitate by ammonia. The hydrate thrown down, when well washed, is perfectly pure, and easily soluble

Zircon is a fine white powder, without taste or smell, but somewhat harsh to the touch. It is insosmell, but somewhat narsh to the touch. It is insoluble in water; yet if slowly dried, it coalesces into a semitransparent yellowish mass, like gum-arabic, which retains one-third its weight of water. It unites with all the acids. It is insoluble in pure alkalies; but the alkaline carbonates dissolve it. Heated with the blowpipe, it does not melt, but emits a yellowish phospharia light. Heated in a crucible of charcoal, hedded phoric light. Heated in a crucible of charcoal, bedded in charcoal powder, placed in a stone crucible, and exposed to a good forge fire for some hours, it undergoes a pasty fusion, which unites its particles into a gray opaque mass, not truly vitreous, but more resembling porcelain. In this state it is sufficiently hard to strike fire with steel, and scratch glass; and is of the specific gravity of 4.3.

There is the same evidence for believing that zirco-nia is a compound of a metal and oxygen, as that afforded by the action of potassium on the other earths. afforded by the action of potassium on the other earths. The alkaline metal, when brought into contact with zirconia ignited to whiteness, is, for the most part, converted into potassa, and dark particles, which, when examined by a magnifying glass, appear metallic in some parts, of a chocolate-brown in others, are found diffused through the potassa and the decomposition of the potassa and the potassa and the decomposition of the potassa and the potassa and the decomposition of the potassa and the potassa and the potassa and the potassa and the decomposition of the potassa and the potassa and

pounded earth.

According to Sir H. Davy, 4.66 is the prime equiva-lent of zirconium on the oxygen scale, and 5.66 that of zirconia.

ZIZA'NIA. (An ancient rame, ζιζανιον, of the Greeks, synonymous with infelix lolium, of the Latins.) The name of a genus of plants in the Linnæan system. Class, Monæcia; Order, Hexandria.

ZIZANIA AQUATICA. The systematic name of a reed, the grain of which is much esteemed in Jamaica and Virginia. The Indians are exceedingly fond of it, and account it more delicious than rice.

account it more delicious than rice.

[The zizania aquatica is a native of most of the northern parts of the United States, but it has disap-peared in the settled and cultivated parts of the counpeared in the settled and cultivated parts of the country. It is now principally found on the streams and shoal waters of the north-western lakes and rivers, where it grows spontaneously in the water, like rice in the southern states. During seed-time, the aborigines of the country collect it for food; which they use by parching with fire, and then pounding with a stone. The meal thus produced tastes much like parched Indian corn. The plant is the Fausse avoine, or false oats of the French Canadians. The grain is black, and from half an inch to an inch in length, with much of the appearance, when growing, of oats or rice. A.] ZIZYPHUS. The jujubes were formerly so called. See Rhamnus zizyphus.

ZOISITE. A subspecies of prismatic augite, which is divided into two kinds:

1. Common zoisite, of a yellowish-gray colour, found

1. Common zoisite, of a yellowish-gray colour, found in Corinthia.

2. Friable zoisite, of a reddish colour, which comes also from Corinthia.

ZO'NA. (From ζωννυμι, to surround.) The shingles. See Erysipelas.
ZOOLOGY. (Zoologia; from ζωον, an animal, and λογος, a discourse.) That part of natural history which treats of animals.

ZOONIC ACID. In the liquid procured by distilla-tion from animal substances, which had been supposed to contain only carbonate of ammonia and an oil, Berthollet imagined he had discovered a peculiar acid, to which he gave the name of zoonic. Thenard, howwhich he gave the name of zoonic. Thenard, how-ever, has demonstrated that it is merely acetic acid

combined with animal matter.

ZOONO'MIA. (From ζωον, an animal, and νομος, a law.) The laws of organic life.

ZOOPHYTE. (Zoophyte, i, n.; from ζωον, an animal, and φυτον, a plant.) A kind of intermediate body, supposed to partake both of the nature of an animal and a vegetable. In the Linnæan system, zoophytes constitute an order of the Class Vermes.

ZOOTOMY. (Zootomia; from ζωον, an animal, and τεμνω, to cut.) The dissection of animals.

ZO'STER. (From ζωννυμι, to gird.) A kind of erysipelas which goes round the body like a girdle.

ZU'CHAR. (Arabian.) Sugar.

ZUMATE. A compound of the zumic acid, with a salifiable basis

salifiable basis.

ZUMIC ACID. ZUMIC ACID. (Acidum zumicum, from ζυμη, lea-ven.) An acid produced from vegetable substances which have undergone the acetous fermentation. Its claim to be considered as a distinct compound is doubt-

ful. See Manceic acid.

ZUNDERERZ. Tinder ore. An ore of silver.

ZYGO'MA. (From ζυγος, a yoke: because it transmits the tendon of the temporal muscle like a yoke.) The cavity under the zygomatic process of the temporal bone, and os maia.

ZYGOMATIC. (Zygomaticus; from zygoma.) Belonging to the zygoma.

ZYGONATIC PROCESS. An apophysis of the os jugale, and another of the temporal bone, are so called.

ZYGOMATIC SUTURE. Sutura zygomatica. The union of the zygomatic process of the temporal bone to the cheek bone.

ZYGOMATICUS MAJOR. This muscle arises from the cheek bone near the zygomatic suture, taking a direc-tion downwards and inwards to the angle of the mouth. It is a long stender muscle, which ends by mixing its fibres with the orbicularis oris, and the depressor of

the lip.

Zygomaticus minor. This muscle arises a little higher up than the zygomaticus major, upon the cheek bone; but nearer the nose; it is much more slender than that muscle, and is often wanting. It is the zygo-matic muscle that marks the face with that line which extends from the cheek bone to the corner of the mouth, which is particularly distinguishable in some persons. The zygomatic muscles pull the angles of the mouth up as in laughter, and from, in this way, rendering the face distorted, it has obtained the name of distortor oris. The strong action of this muscle is more parti-

oris. The strong action of this muscle is more particularly seen in laughter, rage, or grinning.

Zytho'Galla. Zυθογαλα. Beer and milk, which make together what we commonly call posset-drink; a term often to be met with in Sydenham.

ZZ. The ancients signify Myrrk by these two letters, from ζανονη, a name for it common among them. They have also been used for Zingiber.

APPENDIX.

[THE following obsolete terms have been omitted in the body of the work, but to preserve Dr. Hooper's Dictionary perfect, they are inserted in the present place and form.

An obsolete term used by some ancient ! alchemists for lead.

A'BANET. (Hebrew. The girdle worn by the Jew-ish priests.) A girdle-like bandage.

ABA'RTAMEN. Lead. A'BAS. An Arabian term for the scald-head, and also for epilepsy.

ABO'IT. An Arabic term for white lead.
A'BRIC. An Arabic term for sulphur.

ABSTRACTI'TIUS. (From abstraho, to draw away.)
An obsolete term formerly applied to any native spirit,
not produced by fermentation.

Aca ca. (Ακακος; from α, neg., and κακος, bad.) Formerly applied to those diseases, which are rather troublesome than dangerous.

Aca'lai. (Arabian.) Common salt.
Aca'lcum. Tin.
Aca'nor. (Hebrew.) A furnace.
Aca'zdir. Tin.

A'CCIB. An obsolete term for lead. A'CESIS. (From ακισμαι, to cure (From aκεομαι, to cure.) 1. A remedy

2. The herb water-sage; so called from its supposed healing qualities.

Ace storis. (From aκεομαι, to cure.) It strictly Eignifies a female physician, and is used for a midwife. ACHMA'DIUM. Antimony. A'CHNE. An obsolete term applied to

1. Chaff.

2. Scum or froth of the sea.

3. A white mucus in the fauces, thrown up from the lungs, like froth.

4. A whitish mucilage in the eyes of those who have

fevers, according to Hippocrates.
5. It signifies also lint.

ACONITUM. (Aconitum, i, m. Of this name various derivations are given by etymologists; as, ακονη, a whetstone or rock, because it is usually found in barren and rocky places: akovitos, a, neg., and kovis, dust; because it grows without earth, or on barren situations; agreeable to Ovid's description, "Quæ quia nascuntur dura vivacia caute, Agrestes aconita vocant:" ακοναω, to sharpen; because it was used in medicine intended to quicken the sight: ακων, ακη, a dart; because they poison darts therewith: or, aκοντζομαι, to accelerate; for it hastens death.) Aconite. 1. A genus of plants in the Linnæan system, all the species of which have powerful effects on the human body. Class, Polyandria; Order, Trigynia.
2. The pharmacopæial name of the common, or blue

wolf's-bane. See Aconitum napellies.

Aco'num. A little mortar.

ACORITES. (From acopor, galangal.) Acorites vinum. A wine mentioned by Dioscorides, made with galangal, liquorice, &c. infused with wine.

ACORTINUS. A lupin.

A'CRA. (An Arabian word.) Acrai.

Excessive venereal appetite.
 The time of menstruation.

A village four miles from London, where is a well that affords a purging water. This is one of the strongest purging waters near London; and has been drank in the quantity of from one to three pints in a morning, against scorbutic and cutaneous affections.

This medical spring is no longer resorted to by the

Adalces. Sal-ammoniac.

ADARI'GES. An ammoniacal salt.

A'DEC. Sour milk, or buttermilk.

ADIATHOROSUS. A spirit distilled from tartar Obsolete.

ADIBAT. Mercury.

A'DICE. Αδικη. A nettle.
ADI'RIGE. Ammoniacal salt.
A'DOC. Milk.

A'DRAM. Fossil salt.

AET GLUCES. (From αει, always, and γλυκυς, sweet.)
A sweetish wine, or must.
Æ'ON. The spinal marrow.

ÆONE'SIS. A washing or sprinkling the whole body. ÆSCHROMYTHE'SIS. The obscene language of the

delirious.

ÆSECA'VUM. Brass. ÆSTA'TES. Freckles in the face; sunburnings.

ÆTAS CREPITA. See Age. ÆTAS VIRILIS. See Age. ÆTHNA. A chemical furnace.

A. THOCES. Ætholices. Superficial pustules in the skin, raised by heat, as boils, fiery pustules.

ÆTHYA. A mortar.

Æ'TTIOI PHLEBES. Eagle veins. The veins which pass through the temples to the head, were so called formerly by Rufus Ephesius.

ÆTOLIUM. See Ætocion.
A'FFION. An Arabic name for opium.
A'FFIUM. An Arabic name for opium.

AGERA'TUS LAPIS. (Ageratus, common.) A stone used by cobblers

A'GES. (From ayn5, wicked: so called because it is generally the instrument of wicked acts.) The palm of the hand,

of the hand.

A'GIS. The thigh or femur.

A'GMA. Agme. A fracture.

Ago'ce. 1 The deduction or reasoning upon diseases from their symptoms and appearances.

2. The order, state, or tenour of a disease or body.

Ago's ros. (From ayω, to bring, or lead.) That part of the arm from the elbow to the fingers; also the palm or hollow of the hand.

AGRESTA. (Aypios, wild.) 1. The immature

fruit of the vine.

2. Verjuice, which is made from the wild apple.

AGRE'STEN. Common tartar.

AGUIA. (From a, priv., and yetov, a member.)

Paralytic weakness of a limb. Where the use of the members is defective or lost.

A'gut. Alhagi. An Arabian name for the Syrian thorn. The leaves are purgative

AGYION. See Aguia.

AGY'RTÆ. (From αγυρις, a crowd of people, or a mob; or from αγυρις, to gather together.) It formerly expressed certain strollers, who pretended to strange things from supernatural assistances; it was afterward applied to all illiterate dabblers in medicine. Now obsolete.

The Hebrew name of Lignum aloes, AHALOTH.

See Lignum aloes.

AHAME'LLA. See Achmella.

AHO'VAI THEVETICLUSH. A chesnut-like fruit of Brazil, of a poisonous nature.

AHU'SAL. Orpiment.

AI'LMAD. Antimony.

Antimony.

Al'TMAD. Antimony.
AJURA'RAT. Lead.
ALA'BARI. Lead.
A'LACAR. Sal ammoniac.

A'LACAR. Sai annionnae.
A'LAFI. Alafor. Alafort. Alcaline.
A'LAMAD. Alamed. Antimony.
ALA'MBIC. Mercury.
ALAPOU'LI. See Bilimbi.
ALASALET. Alaset. Ammoniacum. Alcaline.

ALASI. Alafor. An alcaline sait.
ALASTROB. Lead.
A'LATAN. Litharge.
ALAU'RAT. Nitre.

APPENDIX.

ALBADAL. An Arabic name for the sesamoid bone of the first joint of the great toe. of lead. ALBAGE'NZI. Albagiazi. Arabic names for the os ALBA'RA. (Chaldean.) The white leprosy. ALBARAS. 1. Arsenic. 2. A white pustule. A'LBERAS. (Arabian.) White pustules on the face: also, staphisagria, because its juice was said to remove these pustules. ALBE STON. Quicklime. A'LBETAD. Galbanum. A'LBI SUBLIMATI. Muriated mercury. A'LEIMEC. Orpiment. See Arsenic. A'LBOR. Urine. ALBO'REA. Quicksilver.
A'LBOT. A crucible.
ALBO'TAL Turpentine.
A'LBOTAR. Turpentine. A'LBOTAT. White lead. Turpentine. A'LBOTIM. A'LBOTIS. A cutaneous phlegmon or boil.

ALBUHAR. White lead.

A'LCEBAR. See Lignum aloes.

A'LCEBRIS VIVUM. This signifies, according to Rulandus, Sulphur vivum. A'LCHABRIC. Sulphur vivum. A'LCHACHIL. Rosemary. A'LCHARITH. Quicksilver. A'LCHIBRIC. Sulphur. A'LCHIBRIC. Sulphur.
A'LCHIEN. This word occurs in the Theatrum Chemicum, and seems to signify that power in nature by which all corruption and generation are effected
ALCHIMELEC. (Hebrew.) The Egyptian melilot.
A'LCHLYS. A speck on the pupil of the eye, somewhat obscuring vision. A'LCHUTE. The mulberry. A'LCIMAD. Antimony. A'LCOB. Sal ammonisc. ALCO'CALUM. Most probably the Indian name of the artichoke.

A'LCOFOL. Antimony.
A'LCOLA. (Hebrew.) 1. The thrush.
2. Paracelsus gives this name to tartar, or excrement of urine, whether it appears as sand, mucilage, &c.

ALCOLITA. Urine.

ALCO'NE. Brass.
A'LCOR. Æs ustum.
A'LCTE. The name of a plant mentioned by Hippocrates, supposed to be the elder.

ALCU'BRITH. Sulphur.

ALEARA. A cucurbit.

ALEBRIA. (From alo, to nourish.) An obsolete term for that which is nourishing.

A'LEC. Alech. Vitriol.

ALE'CHARITH. Mercury,

ALEI'MMA. (From αλειφω, to anoint.) An ointment. the artichoke. D G H R ΑLΕΙ' ΜΜΑ. (From αλειφω, to anoint.) An ointment. ALE'MZADAR. Sal ammoniac. ALE'MZADAT. Sal ammoniac. ALEMZADAT. Sal ammoniac.

ALFA'CTA. Distillation.

A'LFADAS. Alfides. Cerusse.

ALFA'SRA. Alphesara. Arabic terms for the vine. Z ALFA'TIDE. Sal ammoniac. Sal ammoniac. Z A'LFUSA. Tutty. A'LGALI. A catheter. A'LGALI. A catheter. Also nitre.
A'LGARAH. See Anchilops.
ALGE'RIE. Algirie. Lime.
A'LGEROTH. See Algaroth.
