A NEW MEDICAL DICTIONARY.

N Æ V

N. In prescription signifies number.

NA'BEA. See CENOPLIA.

NA'BIT. See SACCHARUM.

NA'CTA. See ABSOESSUS PECTORIS, and MAMMÆ.

NA'DUCEM. See MOLA.

NÆVUS, (from *gnævus*,—*à geno*, because it appears from the birth). *Nævus maternus*, A MOTHER'S MARK, *macula matricis*, *stigma*. (See MACULA.) The same term is applied to the WEN, *encystis*. Dr. Cullen gives the wen the general name *lupia*, places it in the class *locales* and order *tumores*, defining it an extubérance under the skin, moveable, soft, and without pain.

All preternatural tumours on the skin, in the form of a wart or tubercle, are called *excrecences*; by the Greeks *acrothymia*; and when observed at the birth, *nævi materni*, *metrocélides*, MARKS FROM THE MOTHER. Larger tumours depending from the skin are denominated *sarcoma*. The *nævi* appear on any part of the body, differing in their colour from the rest of the skin, sometimes resembling strawberries, grapes, &c. Heister advises their removal by means of a ligature, a cautery, or a knife, according to circumstances.

Dr. Aitkin, in his Elements of Surgery, divides the wen into the following species. 1. *Atheroma*. 2. *Meliceris*. 3. *Steatoma*, to which M. Litre adds the *lipome*, which contains fat. The *atheroma* is colourless, void of pain, containing in a cyst a matter like curds, intermixed sometimes with hard corpuscles, and sometimes with a hardish substance, like the macerated bones of chickens. It is of an irregular shape, not easily impressed with the finger, and very slightly elastic. If the contained matter resembles honey, it is named *meliceris*; if suet, *STEATOMA*, q. v. M. Litre describes the contents of the *lipome* to have all the qualities of common grease; and, though the fat of the *lipome* resembles in appearance that of the *steatoma*, yet the former melts and is inflammable. When the man who had the *lipome* was fatigued, or had drunk freely, it inflamed for some days after, and its contents increased the size of the tumour. See *Memoires de l'Academie Royale des Sciences*, l'Ann. 1709.

Mr. Bell, speaking of these tumours, observes, that they each have various degrees of consistence. In judging of their nature, some advantage may be derived

N A N

from attending to their situation. Thus, in some parts, fat is more apt to be secreted and deposited in the cellular substance than in others, and the steatomatous tumours are seldom, if ever, he thinks, met with in those parts of the body which are not usually in a state of health supplied with fat. The head, indeed, is more liable than any part of the body to encysted tumours, but they are very universally atheromata or meliceris. The meliceris, which is distinguished by the free fluctuation of its contents, must be treated as a common abscess, or as directed for the hydrocele of the tunica vaginalis. See HYDROCELE.

When a cyst containing matter adheres so firmly to the contiguous parts as to require much time to remove it by dissection, it should never be attempted, except the patient is firm and resolute. It will be sufficient to lay it freely open through its whole extent by an incision, and to remove any loose portion. The contents of the tumour will, in this manner, be completely removed by suppuration, and the cure may either be effected in the usual way, by preserving the wound open till it fills up with granulations from the bottom, or it may be attempted by drawing the divided edges of the skin together, and trusting to moderate pressure with the ordinary effects of inflammation. This plan, however, will often fail, and the whole degenerate into a malignant ulcer. If on a gland, it should never be attempted; and extirpation is, in general, the safest mode, if, from the distance of any large vessel, it is practicable.

See also the article STEATOMA for the method of dissecting the whole tumour out; which, when not very large, may be submitted to.

See Wiseman, Turner, White, Bell, and Heister's Surgery; Warner and Gooch's Cases and Remarks, p. 281, &c.

NA'I CORO'NA. See PHASEOLUS ZURATENSIS.

NA'KIR. A violent flatulence passing from one limb to another with pain. Schenkus.

NA'LUGN. A bacciferous shrub of an unknown genus in Malabar, which flowers twice a year. Its different parts are used by the natives in flatulent and spasmodic disorders. See Raii Historia.

NA'NDIA. See LYCIUM.

NANDI-E'RVATAM. A small East Indian shrub, the whole of which is lactescent; the juice destroys worms: but this plant also has not yet been noticed by the systematic botanist, or the indigenous name has not been preserved. See Raii Historia.

NANDI-ROBA, *fewillea scandens* Lin. Sp. Pl. 1457, used in St. Domingo, where it grows, as a remedy for the bites of serpents.

NAP, or **NAPE'CA**. See **ÆNOPLIA**.

NAPE'LLUS, (from its bulbous root resembling the turnip *napus*).

NA'PHÆ AQ. See **AURANTIUM HISPANICUM**.

NA'PHTHA, an Arabian word, applied by the Arabians to AMBER, (see AMBRA,) *nasa, terræ oleum*. It is the thinnest of the liquid bitumens, perfectly fluid, clear, colourless, of a strong smell, not highly fragrant, extremely subtile, so light as to swim on water, spreading to a large surface, exhibiting prismatic colours, and highly inflammable. It has the same appellation whether it is separated by nature or art from thick petroleum or grosser bituminous matter. There are three kinds as it arises naturally, the white, the reddish, and the grosser deep coloured, but each, by keeping, seeming from the addition of oxygen, becomes a dark resin.

Naphtha issues from the earth, at Baku, in Persia, on the borders of the Caspian; is collected from the surface of wells in the same regions, and sometimes found on the waters of Italy. Naphtha and petroleum are probably formed by the decomposition of bitumens by subterraneous fires; and the lighter fluid naphtha usually appears on the surface.

The true naphtha dissolves resins and balsams, but not gum resins or elastic gums: it is useful as an external application for removing old pains, chilblains, nervous disorders, cramps, contractions of the limbs, paralytic affections, &c. See **PETROLEUM**.

NA'PIUM, (from its resemblance to *napus, navew*). See **LAMPSANA**.

NA'PTA. (See **NAPHTHA**.) A name also for the tumour, called *nata* or *natta*.

NA'PUS, (a Rabbinical term). The seeds of this plant furnish a stimulating oil, called **RAPE OIL**, used in liniments. See **BUNIAS**.

NA'PY, (from *να, not*, and *παιω, to eat*; because it was thought not eatable from its pungent taste). See **SINAPI**.

NARCE, *ναρκη*, the **TORPEDO**, (from *ναρκω, to stupify*). A torpor, stupor, or dulness of sensation, either from disease or medicine.

NARCI'SSUS LUTÆUS SYLVE'STRIS, (from the youth, who, in poetical fable, is said to have been changed into this flower). *Bulbus sylvestris, narcissus pseudo-narcissus Anglicus* Lin. Sp. Pl. 414. **WILD DAFFODIL**. The roots are slightly purgative and emetic; the dose two drachms in infusion.

NARCO'SIS, (from *ναρκω, to stupify*). A **STUPEFACTION**.

NARCO'TICA, (from the same). See **ANODYNA**.

NA'RDUS CE'LTICA, (from the Syriac word *nard*). *Spica celtica, seliunca, CELTIC SPIKENARD, valeriana celtica* Lin. Sp. Pl. 46, is a small species of valerian, with uncut, oblong, obtuse, oval, leaves, a native of the Alps, from whence we have the dry roots, consisting of a number of blackish fibres, with the lower parts of the stalks adhering: the last are covered with thin yellow scales, the remains of the withered leaves. Its

virtues resemble those of valerian, which it possesses in a less degree.

The mountain nard is only the root of the large valerian. See Raii Historia.

NA'RDUS I'NDICA, NA'RDUS SYRI'ACA. *Spica, spica Indica, spica nardi*, **INDIAN SPIKENARD, NARD**, or **SYRIAN NARD, andropogon nardus Lin. Sp. Pl. 1482.**

Dioscorides thinks, without reason, the Indian and the Syrian nard to be different. They are the bushy top of the root, or the remains of the withered stalks and ribs of the leaves of an Indian grassy leaved plant. Linnæus, as just mentioned, has referred it to the genus *andropogon*; and Dr. Blane, in the Philosophical Transactions for 1790, considers it as another species of the same genus, of which the trivial name is the native appellation, viz. *jwarâncusa*. Sir W. Jones, however, in the second and fourth volumes of the Asiatic Researches, refers it, with much reason, to the genus *valeriana*, with the trivial name *jatamansi*. The error of supposing it a grass arose seemingly from the term *spica*; but this species of valerian rises from the ground in hairy spikes like ermines' tails. Dr. Roxborough, in the fourth volume of the Researches, has given a figure of this appearance, and indeed of the whole plant.

The nard, as brought to us, is a congeries of small, tough, reddish brown fibres, cohering close together, but not interwoven so as to form a bunch or spike, about the size of a finger. The spikenard of India and Syria alike resemble valerian in their virtues; but the Indian is warmer than the Syrian, and somewhat pungent and bitterish. It also agrees very nearly in its virtues with cypress.

The nard was highly valued in the east as a spice and perfume; and it was an ingredient in the theriaca and mithridate. Among the ancients the unguentum nardinum was used at the baths and feasts. All the ancient physicians recommended it in dropsy, gravel, and pains of the stomach, both internally given, and externally applied on wool. In the latter mode Galen relieved the emperor Marcus Aurelius in cholera. It is used in India as a febrifuge.

NA'RDUS ITA'LICA. See **LAVENDULA LATIFOLIA**.

NA'RDUS RUSTICA et MONTANA. See **ASARUM**.

NA'RES, (from the Hebrew, *naker*). The **NOSTRILS; nycteres**. The internal nares, or cavity of the nose, *hiator narium*, comprehend the whole space between the external nares and the posterior openings immediately above the arch of the palate, by which a probe may be passed from the nose to the fauces. From thence these cavities reach upwards to the lamina cribrosa of the os ethmoides, where they communicate forward with the frontal, and backward with the sphenoidal sinus. The two frontal sinuses, the two antra highmoriana, the cellulae of the os cuneiforme under the upper spongy bone of the nose, open into the nostrils, and from thence discharge their mucus. The spongy bones, two in each nostril, are covered with the mucous membrane also, and thus the secreting surface of the nostrils is enlarged. The olfactory nerves, without the dura mater, pierce through the holes in the os ethmoides, and spread themselves on the mucous membrane of the nostrils, with a branch from the fifth pair also. The membrana pituitaria, which lines the nose, is very vascular and papillous at those parts where it is most exposed to the stream of the air. The whole membrane is full of small glands which separate mucus; and from this membrane polypous excrescences

arise. The arteries of the nares are branches of the internal maxillary; the veins discharge their contents into the internal jugulars. The nerves are branches of the olfactory, ophthalmic, and superior maxillary.

The nostrils of infants are sometimes obstructed, and some unctuous substance is applied for relief; but three or four grains of white vitriol, dissolved in half an ounce of water, solicit more effectually a discharge of the too viscid mucus.

When the nostrils, after the small pox, are closed up, an opening may be made into them with a small knife, and kept distended until the wound is healed.

NARIFUSO'RIA, (from *nares*, the nostrils, and *fundo*, to pour). Medicines which are instilled into the nostrils.

NASA'LE, (from *nasus*, the nose). See ERRHINA.

NASA'LIS ARTE'RIA. See MAXILLARIE ARTERIE.

NASA'LIS, *musculus compressor naris, rinæus*, rises fleshy from the extremity of the os nasi, and adjacent parts of the os maxillare, and is inserted into all the cartilages of the ala. It dilates the nostrils.

NASA'LIS PROCE'SSUS. See MAXILLARIA SUPERIORA OSSA, and FRON'TIS OS.

NASCA'LE, (from *nasus*, the nose). A pessary made of wool or cotton to raise the nose when compressed.

NA'SI O'SSA. Two small bones which compose the upper part of the nose, and are supported by the septum nasi.

NA'SI A'LE. See PINNÆ.

NA'SITAS, (from *nasus*, the nose). A speaking through the nose.

NA'SO PALA'TINI DUC'TUS. See INCISORII DUCTUS.

NASTU'RTIUM. *Quasi nasi tormentum*, because the acrimony of the seed, while bruising, excites sneezing. It resembles the Mithridate mustard, distinguished by a less foliaceous margin, and multifid leaves. A name also for *barbarea*, *sophia*, and several other plants.

NASTU'RTIUM AQUA'TICUM, *laver odoratum, sisymbrium, cratevæ sium, cressio, cardamines*. WATER-CRESSES; *sisymbrium nasturtium* Lin. Sp. Pl. 916. A juicy plant with brownish, oblong, obtuse, leaves, set nearly in pairs, without pedicles, on a middle rib, terminated by an odd one larger and longer pointed than the rest. The stalks are hollow, pretty thick, channelled, and crooked; on the tops grow tufts of small tetrapetalous white flowers followed by oblong pods, which, bursting, throw out a number of roundish seeds. It grows in rivulets or the clearest standing waters, and flowers in June. The leaves remain green all the winter, but are in the greatest perfection in spring.

The leaves are to the taste moderately pungent: when rubbed between the fingers, their smell resembles mustard, though weaker. It is a mild, aperient antiscorbutic, supposed to purify the blood, and to open visceral obstructions. The expressed juice contains all the virtue of the plant; but whether eaten as a salad, or the juice drunk, its use should be long continued, since as a medicine it is inert. Water cresses form one of the ingredients for the *succus cochleariæ compositus*.

NASTU'RTIUM HORTE'NSE. *Lepidium sativum* Lin. Sp. Pl. 899. COMMON GARDEN CRESSES, a low plant, with variously cut winged leaves, bearing, on the top of the round stalk and branches, tufts of tetrapetalous white flowers, followed by roundish capsules, flattened on

one side, and full of reddish round seeds. It is annual, and raised in gardens, and an useful dietetic herb in scorbutic cases, and in debilities of the chylopoietic organs. It is milder than the water cresses: the seeds are more pungent than the leaves, and agree in their general qualities with those of mustard.

NASTU'RTIUM I'NDICUM. *Acriviola, nasturtium Peruvianum, cardamindum ampliori folio, and major flore, tropæolum majus* Lin. Sp. Pl. 490. GREATER INDIAN CRESS, or YELLOW LARK SPUR. The leaves are round, umbilicated, and placed alternately; the stalks trailing; the flowers consist of five petals, formed like violets; the seeds round and rough, three in each flower; a native of Peru. The young shoots are used as pickles; but the leaves and flowers resemble water cresses, emitting when bruised the smell of horse radish. Their medical virtues are similar to those of the sort common with us. See Raii Historia; Lewis's Materia Medica.

NA'SUS, (probably from the Hebrew *nasafih*, to blow). The NOSE; *mycter*. The external parts of the nose are the root, the arch, the back or spine, the sides, the tip, *acre*; the wings, *alæ*, or *pinne*, the external nares, and the part under the septum. The internal parts are, the internal nares, *septum narium*, the circumvolutions, the *conchæ superiores*, the *conchæ inferiores*, the posterior openings of the internal nares, the *sinus frontales*, *maxillares*, and *sphenodales*; *ductus lachrymalis* and *palatinus*. The nerves are the olfactory, and a branch from the fifth pair. The cartilaginous part of the nose is always open to admit of respiration; but grows gradually narrower. See NARES.

NA'TA, or NA'TTA; *nafhtha*, or *nafta*. A WEN, with a narrow basis. Linnæus speaks of it as rooted in a muscle.

NATA'TIO, (from *nato*, to swim). SWIMMING is a laborious exercise, and should not be continued to exhaust the strength. It is not natural to man as to quadrupeds, for the motions of the latter in swimming are the same as in walking. To man, however, it is by no means difficult, for the body is specifically lighter than water; so that to float it is only necessary to keep the head above the surface, for the body falls naturally forward with the head downward. A slight motion of the hands produces this effect, and the body is propelled by the impulse of the feet. Oribasius gives some directions on the subject, lib. vi. cap. 27. The dangers from swimming are spasms, which sometimes arise from the cold, sometimes from the great exertions, and the inconveniencies arising from the abuse of cold BATHING, q. v. It promotes perspiration, and attenuates the fluids if used in moderation.

NA'TES, (from *nato*, to flow; because the excrements are discharged from them). The BUTTOCKS; and a name of two prominences on the brain. See CEREBELLUM.

NA'TRIX TORQUA'TA, (from *nato*, to swim). See ANGUIS.

NA'TRON, (a lake in Judea, from whence it was produced). BARILLA, SODA, MINERAL and FOSSIL ALKALI. The mineral kingdom offers this alkali in large masses, though contaminated, usually, with sea salt, which shows its origin. It is also found in various plants, as the *salsola*, *kali*, *sativa*, *soda*, and *tragus*; *salicornia herbacea* and *arabica*; *mesembryanthemum nodiflorum*; *plantago squarrosa*; and *fucus vesiculosus*.

Lin. The *salsola kali* is the plant from which it is chiefly procured in the east; but the best is from the *s. sativa*; and the worst kind from the *s. tragus*. Where the natron forms a considerable article of commerce, the seeds of the *salsola* are regularly sown, the plants burnt, and the salt calcined. It always contains some common salt, Glauber's salt, sometimes a sulphurated kali, and occasionally a little iron. The pure crystals are of a rhomboidal figure, transparent, laminated. One hundred parts contain twenty of salt, sixteen of aerial acid, and sixty-four of water. An ounce of water, at 62° of Fahrenheit, dissolves about five drachms, fifteen grains of the crystals. See ALKALI.

NA'TRON MURIATUM. COMMON SALT. See MARI-NUS SAL.

NA'TRON PREPARATUM, i. e. SAL SODÆ. See ALKALI.

NA'TRON TARTARISATUM. See RUPELLENSIS SAL.

NA'TRON VITRIOLATUM. See GLAUBERI SAL.

NATSIA'TUM. See COCCULUS INDICUS.

NATU'RA, (from *nascor*, to proceed). NATURE. On this subject we find much unnecessary minuteness in various authors, which it would be useless to transcribe or examine. The term is sometimes used for the Author of nature, or the Supreme Being; sometimes for the whole of his works; occasionally for essential qualities of a body, or the usual series of causes and effects.

The atheists of the continent have exalted nature into a supreme power, forgetting that in this change of name they voluntarily admit the existence of a deity, and give the most unequivocal testimony of the necessity of an omnipotent superintending power. In this work, however, we must speak of nature in a more limited view; and it means, in medicine, the constitution which a man derives from his parents, or those powers, inherent in the whole system, by which deviations are corrected and losses repaired. We say a man is by nature weak; and that nature cures. In each case we express an effect only, without, by the reference to nature, assigning a cause. These changes may perhaps be the necessary consequences of structure; and in some cases, they appear to be so; but we know of no principle in the constitution by whose superintending power these salutary effects are produced, and we sometimes see such efforts really injurious. It is certainly more honourable to an all powerful author, that a system, like that of the human machine, shall be formed so as to correct accidental deviations, and to repair injuries, rather than to raise a subordinate agent, to interfere in every error or accident to which the functions of the body may be subject.

NATURA'LIA, (from *natura*, nature). See PUDENDA.

NAU'SEA, (from *navis*, a ship; because it is produced by the motion of a ship). CACOSITIA: its least degree means a loathing; or, according to Linnæus, a fixed aversion to food. This proceeds to nausea, retching, and vomiting.

Nausea is one of those irregular exertions, which we have described as arising from debility, and is accompanied by a slight degree of inversion of the natural peristaltic motion by which the food is swallowed.

A nausea always precedes a vomiting, and is attended with a tremulous motion of the lips; and a slight nausea is often followed with a discharge of a limpid mucus,

coming apparently from the œsophagus, which is certainly susceptible of the inverted peristaltic motion, without any affection of the stomach; as the upper part of the stomach is without the whole organ joining in the action. (See EMETICA.) Nausea may be excited by a variety of causes, and in particular habits by circumstances often scarcely, if at all, connected with the stomach. It accompanies also different affections of the brain, particularly every cause of irritation or oppression.

An emetic will often for a time relieve it; but when nausea continues, warm bitters with rhuarb or aloes are the best remedies. The effervescing draughts, sometimes warm opiates, and, when from bile, the juice of lemons, will often be successful. It is an almost constant attendant on fevers, and seldom is permanently relieved till the fever recedes. If it continues after the fever, an emetic is peculiarly necessary.

NAU'TICUS. A muscle chiefly used by sailors in climbing ropes. See TIBIALIS POSTICUS.

NAVICULA'RE, or NAVIFO'RME OS, (from *navicula*, a little vessel,) from its supposed resemblance to a boat; and from *navis* and *forma*. See SCAPHOIDES.

NAVIGA'TIO, (from *navigo*, to sail). SAILING is beneficial to weak persons. When the ship's motion is gentle, and steadily progressive, an uncommon alacrity, an increased perspiration, a keener appetite, and a quicker digestion, are the consequences; but when a patient is weak, violent agitation in a rough sea is dangerous. Sea voyages have been recommended in hypochondriac affections, visceral obstructions, scrofula, and particularly in consumptions; in the last, if properly conducted, it has been considered as a very valuable remedy. When speaking of exercise, we mentioned sailing as the most advantageous mode for those who could not bear bodily fatigue. The constant exertion to preserve the equilibrium keeps various muscles in action, and promotes, as we have seen, perspiration. This with the free open air will sufficiently account for all the advantages of a sea voyage. See ŒORA and GESTATIO. The Use of Sea Voyages in Medicine, by E. Gilchrist, M. D.

NEAPOLITANUM UNGUE'NTUM. NEAPOLITAN OINTMENT; an old preparation of mercury, for which the unguentum hydrargyri mite is usually substituted.

NEAPOLITA'NUS MO'RBUS, (because it is said to have been first observed among the French soldiers at the siege of Naples). See LUES VENEREA.

NE'BI POU'LI. See BILIMBI.

NE'BULA, (from *νεφελη*, a cloud). See ALBUGO.

NECRO'SIS, (from *νεκρωω*, to destroy). DRY GANGRENE, a slow mortification of a part, without any previous softness, and fetid dissolution, attended often with violent pain and stupor: induration and blackness of the parts succeed. It is slower in its progress than gangrene, becomes offensive, and soon terminates. (See MORTIFICATIO.) Sauvages enumerates six species.

1. NECRO'SIS USTILAGINEA, when it arises from eating corrupted grain. See RAPHANIA.

2. NECRO'SIS A VIRU, from virus generated in the habit, or poison thrown into it.

3. NECRO'SIS FEBRILIS, and

4. NECRO'SIS SCORBUTICA, when it succeeds the attack of a fever, or scurvy.

5. NECRO'SIS EPIDEMICA.

6. NECRO'SIS INFANTILIS. This complaint, according to Bell, never arises from inflammation; but

generally from some obstruction in the principal arteries, consequently from a defect of fluids. See Bell on Ulcers, edit. 3. p. 94. Edinburgh Medical Commentaries, vol. ix. p. 78. London Medical Journal, vol. iii. p. 369; vol. vii. p. 263.

NECTA'RIUM, (from *nectar, honey*), the melliferous part of the vegetable, peculiar to the flower. It commonly makes a part of the corolla, but is sometimes entirely distinct from it, and is then more strictly a nectary. It is frequently in the form of a horn, or spur, sometimes in that of a cup.

NE'DUM SCHE'TTI. The name of a bacciferous shrub which grows in the East Indies, of which an ointment is made by boiling in oil, used to relieve pruriginous disorders. It does not occur in the systematic authors.

NEDY'IA, NE'DYS, (from *νῆδυς, the belly*). See STOMACHUS and ABDOMEN.

NEDYU'SA, (from the same). See SITIS.

NEE'DLE. A surgical instrument of considerable importance, for securing arteries, for sewing wounds, and for sutures. The largest are used for the first, and the smallest for the last purpose. The instrument employed in depressing the cataract is styled a *needle*. For depressing the lens Mr. Ware advises the needle to be somewhat larger in its tongue than usually made.

NEFRE'NDES. SUCKING PIGS; but applied to young children, or old people, who have no teeth; quasi *nefrangentes*.

NE'GRO. See HOMO.

NEI'ÆRA, (from *νεῖσπος, farthermost*). See ABDOMEN.

NEIEM-EL-SALIB. See GRAMEN CRUCIS.

NELU'MBO. See FABA ÆGYPTIACA.

NEMORO'SA, (because it grows in woods). See ANEMONOIDES.

NE'NUFAR. See NYMPHÆA.

NE'PA. A CRAB, a SCORPION, and the name of the *genista spinosa major*.

NE'PA THEOPHRA'STI. See GENISTA SPARTIUM.

NEPE'NTES, (from *νῆ, a negative particle*, and *πενθος, morning*, from its exhilarating qualities). The nepenthes of the Egyptians is supposed to have been a preparation of opium and Datura, both the produce of Egypt. It was, according to Homer, the draught which Helen prepared to dissipate the uneasiness of her husband. Schultz's *Historia Medicinæ*. See also BANDURA.

NEPE'NTES DISTILLATORIA of Linnæus, Sp. Pl. 1354, is a singular plant of Ceylon, which has, at the extremities of its branches, a membranous cup, always in the morning covered with a lid, and full of water. The lid rises during the day, and the water is half evaporated; but restored before the next morning. See, says Linnæus, the true nepenthe for the exhausted botanist! The roots are said to be astringent, and the leaves are cooling. The water, in the urn, is used by the Indians in obstructions of urine.

NE'PETA, (from *nepete, German*). See MENTHA CATARIA.

NEPHRA'LGIA, (from *νεφρος, the kidney*, and *αλγος, pain*). Pain in the kidneys or ureters.

NEPHRA'LGIA CALCULO'SA. *Nephralgy*, from a STONE IN THE KIDNEYS. This differs from a nephritis

from the same cause, as it consists in a fixed pain in the region of the kidneys or ureters, without any acute febrile affection, and seems to depend on a large stone fixed in either part. It seldom happens in both sides, and the pain usually extends along the track of the ureter in the abdomen towards the bladder, attended with a painful drawing up of the testicle of the same side, or with a stupor, or numbness of the thigh. In the violence of the pain, a nausea and frequent vomiting come on: by lying on the pained side the uneasiness is mitigated, but on that which is opposite, increased. The urine, in the beginning, is watery, and small in quantity; afterwards turbid and copious, often extremely hot and bloody. The chief relief arises from bleeding, rest, diluting mucilaginous liquids, decoctions or infusions of lintseed, marshmallows, barley and gum arabic, anodynes, camphor, oily medicines, the warm bath, and a thin cooling diet. See CALCULUS and NEPHROTOMIA.

NEPHRA'LGIA RHEUMA'TICA. See RHEUMATISMUS.

NEPHRELMINTICA ISCHU'RIA, (from *νεφρος, the kidney*, and *ελμινξ, a worm*). A suppression of urine from worms. See ISCHURIA.

NEPHRI'TICA, (from *νεφρος, the kidney*). A suppression of urine from inflammation in the kidneys. See ISCHURIA.

NEPHRI'TICA A'QUA. See NUX MOSCHATA.

NEPHRI'TICUM LI'GNUM, (from *νεφρος, the kidney*), *peregrinum lignum*, NEPHRITIC WOOD, *guilandina moringa* Lin. Sp. Pl. 546; and probably the *nux behen* is a production of the same tree. (See BEN.) It is brought from America in large compact pieces, of a whitish or pale yellow colour without, and of a dark brownish or reddish colour within. If bruised, and macerated in water, it imparts a deep tincture, appearing, when placed betwixt the eye and the light, of a golden colour; but in other situations, of a fine blue; a property by which it differs from all other known woods. Other woods are often mixed with it, which only give a yellow tincture. With rectified spirit of wine the same blue tincture is procured, becoming yellow by adding an acid, but again blue by an alkali.

To the taste it is slightly bitter, and the raspings have a faint aromatic smell. A strong infusion in water is gently astringent, recommended in dysury, nephritic complaints, and all disorders of the kidneys and urinary passages. It does not, like the warmer diuretics, increase inflammation; but it is seldom employed. See Raii *Historia*; Lewis's *Materia Medica*.

NEPHRI'TICUS, (from *νεφρος, a kidney*). Belonging to the kidneys; and applied to the disorders of the kidneys or their remedies.

NEPHRI'TIS, (from *νεφρος, a kidney*). *Inflammatio renum*. AN INFLAMMATION IN THE KIDNEYS, placed by Dr. Cullen in the class *pyrexia*, and order *phlegmasia*. He defines it a febrile affection, attended with pain in the region of the kidney, often following the course of the ureter; frequent micturition, voiding water either thin and transparent, or very red; vomiting, numbness of the thigh, and retraction or pain of the testicle on the same side as the kidney affected. The pain is seldom very acute unless combined with rheumatism. The true species he calls *nephritis vera*: the symptomatic are; 1. *Nephritis calculosa*;

2. *Nephralgia calculosa*;—3. *Arenosa*;—4. *Purulenta*; and 5. *Arthritica*; from the various causes.

The general causes are, whatever obstructs the circulation in these vessels; as a wound, contusion, abscess, tumour, long continued defluxion, spasm, or a small stone; any impediment to the conveyance of the urine into the pelvis, ureters, and bladder; violent riding; excessive heat; a plethora; acrid diuretics, and poisons. When these vessels are inflamed, the constriction is so great that no urine can be discharged, or only in a small quantity. If this is pellucid, it is unfavourable. Pains and convulsions are often produced in the stomach, intestines, and uterus, from the irritation of the neighbouring nerves; and from hence arise eructation, nausea, vomiting, diarrhoea, iliac passion, retentions of urine, stupor, immobility of the legs, and preternatural heat in the loins.

A stone in the kidney usually excites inflammation in its internal membrane, and in the tubuli uriniferi.

Inflammation in the kidneys is distinguished from the gravel, or a stone obstructing the ureter, by the fever and the acute inflammatory pains; from an inflammation of psoas muscle, or other adjacent parts; by the pain which attends erecting the body, and the difficulty of putting either leg forward, which attend psoas inflammation, and the absence of the distinguishing signs of nephritis; from the colic, and other inflammatory and spasmodic pains in the intestines; by the seat of the pain.

If the disease is protracted beyond the seventh or eighth day, and there is a stupor or heaviness of the part, with frequent returns of chilliness and shivering, &c. there is reason to suspect that an abscess will ensue.

If the urine becomes higher coloured, is secreted in a larger quantity, and at last is copious, thick, and mixed with mucus, a gradual relief follows, and the cure is effected by affusion. It may also terminate in an abscess, a mortification, or pass off by a metastasis. Mortification is, however, uncommon, and more frequently the kidney gradually wastes. Inflammations in this part often suppurate on the fourth day, but an abscess may begin so late as the fourteenth. The pus may be discharged into the pelvis of the kidney, the abdomen, or externally through the integuments and the skin: in the first or last case a cure sometimes follows; the second is fatal.

When the inflammation is violent, bleeding in large quantities is absolutely necessary, though the pulse is seldom full or hard. Copious and repeated discharges from the bowels by means of the purging salts, or the oleum ricini, are indispensable. Relaxing, and occasionally anodyne clysters, are highly useful. With the same views a semicupium is often serviceable.

Decoctions of parsley roots, infusions of lintseed, or the Arabic emulsion, with a double quantity of the gum, are proper as common drink; and to prevent their palliating the appetite, a little lemon juice and sugar may be added.

In case of a suppuration, the treatment is nearly the same as in a suppuration of the liver. After the abscess is burst, the patient should drink freely of diluting and mucilaginous liquors, taking the bark freely.

If pains are excessive, opiates may be allowed; but care must be taken to prevent constipation. If the

vomiting is troublesome, saline draughts in a state of effervescence, with a few drops of laudanum, will relieve it. Small doses of nitre largely diluted are useful; and the camphor might, perhaps, be a serviceable remedy. The disease, however, is rare.

If a gangrene takes place, it is known by the violence of the cause and of the symptoms, the want of relief from medicine, and the sudden remission of the pain without apparent cause, cold sweats, a weak intermittent pulse, hiccoughs, urine black, fetid and foul, or retained, with a sudden and considerable loss of strength. In those cases, no cure can be expected.

See Boerhaave's Aphorisms, and Van Swieten's Commentary; Fordyce's Elements, part the second; Cullen's First Lines, edit. 4. vol. i. p. 387.

NEPHROLITICA ISCHURIA, (from *νεφρος*, the kidney, and *λίθος*, a stone). A suppression of urine from the stone in the kidneys. See ISCHURIA.

NEPHROME'TRÆ, (from *μήτρα*, womb). See Psoæ.

NEPHROPLETHORICA ISCHURIA. ISCHURIA, q. v. from a plethora.

NEPHROSPASTICA. ISCHURIA, q. v. from a spasm.

NEPHROTHROMBOIDES. ISCHURIA, q. v. from grumous blood.

NEPHROPYICA. ISCHURIA, q. v. from purulent matter in the kidneys.

NEPHROPHLEGMA'TICA. ISCHURIA, q. v. from pituitous or mucous matter.

NEPHROPLEGICA. ISCHURIA, q. v. from a paralytic state of the kidneys.

NEPHROS, (from *νεω*, to flow, and *φερω*, to bear, as conveying the urine). See REN.

NEPHROTOMIA, (from *νεφρος*, and *τεμνω*, to cut).

NEPHROTOMY, the extraction of a stone from the kidneys by an operation. Rousset first advised this operation, and in Mezeray's History of France there is an instance of its having succeeded on a convict; but from the course of the renal artery it does not appear to be possible without destroying the patient. (See RENES.) Heister has indeed told us that wounds in the kidneys are not mortal; and if a stone or an abscess can be felt externally, so as to be opened without exposing the cavity of the abdomen, there is no reason why the operation should not be attempted. See Avicenna, Serapion, Wedelius, Meckren, Heister; Medical Museum, vol. ii. p. 370; Bell's Surgery, vol. ii. p. 144; White's Surgery, p. 368.

NEPONES. See BARONES.

NERANTIA. See AURENTIA HYSPALENSIS.

NERIUM, (from *νερος*, humidus, because it grows in moist, generally maritime places). *Rhododaphne*, *rhododendron*, *oleander*, *laurus rosea*. The DWARF ROSE BAY, *nerium oleander* Lin. Sp. Pl. 305. Its flowers resemble a rose, and its leaves the bay; and it is rather a tree than a shrub. The branches are divided and subdivided by threes, and the leaves grow three together. The leaves and flowers are poisonous; the muscles of the pharynx become paralytic; and vomiting with purging soon comes on. Vinegar is said to be its antidote. See Raii Historia.

NERIUM ANTIDYSENTERICUM. Lin. Sp. Pl. 306. The plant which probably affords the cones or codagapala bark.

NEROLI O'LEUM. See AURANTIA HISPALENSIA.

NERONIA'NA. See PHLEBOTOMIA.

NERVALIA O'SSA, (from *nervus*, a nerve). See ARQUALIA OSSA.

NERVE'A SPONGIO'SA, (from the same). See CORPORA CAVERNOSA PENIS.

NERVI, *neuri*, (from *vivu*, to extend, because originally applied also to the tendons and sometimes even to the ligaments). Nerves are the prolongations of the medullary substance of the brain; and, though in their progress their whole bulk seems to be greater than the nervous cord, when it escapes from the cranium, this is apparently owing rather to the separation of the nervous by cellular substance, than any addition to their medullary portion. We shall find, however, some sources, from which additions may accrue.

To take a more distinct view of the nervous system than any anatomical author will afford, we must examine it comparatively, in the different animals of a lower order. In the human body we have described the brain, and found the spinal marrow a vast trunk, arising as from a root, from which the nervous filaments are the branches; and have seen another system, the sympathetic or great intercostal. This we shall term, for the sake of convenience in expression, the ganglionic system; for in this alone are the nerves united in ganglia, which are subsidiary masses of medulla with its attendant ciceritious substance, or communicate freely in a net work, styled a *plexus*. The ganglionic system is destined to the vital organs. The sensations it conveys are indistinct, and its activity, though subject to remissions, constant; while the cerebral system destined to the organs of sense, and to the voluntary muscles, conveys distinct sensations, requires repose, and is disposed in a regular order. As we descend in the scale of animated beings we find the cerebral system gradually lessen, till it disappears, and the ganglionic alone remains. As the former disappears, the functions of nutrition and generation are more active, while those of sensibility and intelligence diminish in the same proportion. There are consequently two nervous systems in vertebral animals, and one only, with some slight exceptions, in those without vertebræ, which are, at the same time, without voluntary loco-motion. If zoophytes have no visible nervous system, their sensibility shows that they contain nervous molecules, which may be compared to isolated ganglions.

Animals which have the ganglionic system only, possess no centre of vitality, but are often propagated like vegetables, by buds. Each ganglion is, to a certain extent, independent, and each can apparently supply the place of the other, in reproducing any part which has been lost.

In man, the ganglionic system begins in the neck by the superior cervical ganglion, the largest of the whole body. It is this which supplies the place of a brain in animals which have none. Below is the inferior cervical ganglion, which is often double. In the breast, the grand sympathetic nerve forms almost as many ganglia as it meets with nerves; and the nervous fibres scattered in every direction form two or three cords which descend to the abdomen, and there assume the appellation of the *splanic nerve*. This forms a considerable gan-

glion near the diaphragm. In the lower orders the ganglia are equally numerous in the abdomen.

The substance of the nerves appears, at first sight, a pulpy mass, but, if examined with a microscope, each nerve is found to consist of fibres in a parallel direction. Dr. Monro thought the fibres convoluted; a circumstance which no anatomist has since confirmed, owing apparently to optical illusion. When spread in the organs of sense, the fibres are no longer discerned, but the whole becomes a nervous membrane of peculiar delicacy. We have no reason, however, to suppose the structure changed, but the fibres discovered by the microscope are probably only fasciculi of more minute ones covered with a proper coat; and when this is deposited the fibrous structure eludes our sight. It is estimated, from the angle which the least visible object subtends, that the fibre which becomes sensible of a visible impression must be less than the thirty-two thousandth part of a hair. Every nerve is covered at its passage through the cranium by coats of the dura and pia mater, and tunica arachnoidea; the two latter are said to accompany the nervous fibrils in their course. This is, however, probably true only to a certain extent, for the nerves have also a fine coat from the cellular membrane, which may be expanded by inflation, so as totally to obscure the nervous fibres: these shrink also in drying, and almost disappear. The strong dura mater is absolutely necessary to enable them to bear the pressure of the bones, in passing through their foramina, and the shocks they are subject to in the extremities. Anatomists have, however, in general supposed, that the pia mater accompanies the nerves in their minuter ramifications; but, whatever the membrane may be, Reil thinks that he has discovered it by dissolving the medullary substance in an *alkaline* lixivium, and, on the contrary, has separated the nervous fibre by dissolving the coat in an *acid*. It is at least certain that we do not see the nervous substance distinct from its coverings, but in the retina, and the nerve dispersed on the cochlea, vestibulum, and semicircular canals of the ear. The nerves are probably in the same state when dispersed on the muscular fibres.

The arteries of the nervous chord are very numerous, and, as hinted in the article *MUSCULUS*, are necessary perhaps to give that tone or tension which is consistent with the due discharge of their functions; but it is sufficient in this place to remark, that the arteries are so numerous as with the usual fine injection to render the nerve of an apparently uniform colour. Though we have, however, employed the term tension, we mean not to insinuate that the nerves convey sensations as musical chords. They are incapable of *such* tension, and the term is rather used analogically, than strictly. The arteries are accompanied by veins, and probably also by lymphatics.

The ganglions have thicker coats, more numerous, and larger blood vessels than the nerves. They are larger than the nerves which form them; and, in general, when nerves unite, they are larger at their union than the cords of which they are composed. In the ganglion, the fibres are united, crossing each other in different directions, and the consequences have been already noticed.

We need not now stay to record the experiments which show that sense and motion depend exclusively

on the nerves, or rather on the nerves as accompanied by their arteries. It is not only certain, that to tie the artery will render a muscle paralytic, or destroy the sensation of an organ, but that a more active circulation will increase both tone and sensibility. Yet the latter has its bounds; and, in the organs of sense particularly, an increased fulness of the vessels will compress the nerve, and destroy its functions. May we not, however, distinguish between a more active circulation, and distention from fulness, in consequence of less irritable fibres? This is probable, and merits consideration, as it will influence the practice; but it is not our present object. Compressing, however, the nerve, will not immediately destroy the sensibility or irritability of a part, unless the pressure be near the organ. If at a distance, motion at least will remain some time, and be more quickly lost in proportion as the pressure advances nearer. The first *Monro* relates a similar experiment more pointedly. Grasp the phrenic nerve somewhat above the diaphragm, and draw the other hand along it, with some pressure towards the muscle. It will contract, and the experiment may be repeated; but the effect will soon cease, unless the pressure from the hand above be removed. If the pressure, however, at whatever distance, is long continued, the power of the muscle is not recovered. In the organs of sense, pressure has a more rapid effect; we allude particularly to the amaurosis from plethora, which may perhaps arise from its acting so near the extremity of the nerve, divested of its defences. Independent, however, of pressure, various vegetable and animal substances will destroy the functions of the nerves, by an action wholly distinct from any change in the organization, and, so far as we can perceive, from any chemical affinity: some gases will have a similar effect. Substances also which affect only the simple solid, as warm water astringents, or will give increased mobility or tone.

Affections of the medullary substance of the brain will, of consequence, affect the nerves. Irritation will increase their action, pressure destroy it, deleterious substances acting on any sensible organ, whose sympathy with the brain is strong and well established, be equally fatal to it. Disputes have arisen, whether any injury on the brain is felt in the nerves on the same or on the opposite side, for authors have imagined that the fibres of the brain cross each other within the cranium. This argument has been supported by some facts; and in the eye, by the fibres of the optic nerve evidently crossing each other in fish. In the human body, however, the rule is by no means without exception, even in the eye. Minute anatomists have, however, traced the fibrils of a nerve far beyond the spot, from whence it separates in a cord; and *Soëmering* has traced the roots of the nerves, particularly those of the organs of sense, to the eminences in the parietes of the ventricles. We shall, however, speak of them in the common language of anatomists, as arising from the spot where they first appear distinct from the cerebral mass. They, however, separate from the brain at very acute angles, and can, for a time, be easily traced within its substance, and indeed all their divarications are equally at acute angles.

Is sympathy between nerves of distant parts owing to this connexion within the brain? This has been the opinion of many authors; and, as it is wholly inexplicable

in any other view, there is less reason for rejecting it. We shall soon return to the subject.

Before we speak more particularly of the functions of the nerves, and the source of their energy, we shall enumerate the principal branches, and in this part we shall chiefly follow the first *Monro*, and *Viq. d'Azyr*, in the order of *Willis*.

From the encephalon ten pair of nerves proceed. The first pair are the OLFACTORY, arising from the corpora striata, but by the older anatomists said to arise from the processus mamillares; because in brutes these points projected, and from the extension of the lateral ventricles they were hollow; consequently, in their opinion these nerves were designed to convey the mucus from the cold, moist, brain. They become larger as they pass under the anterior lobes of the brain, and are joined, at the os ethmoides, by a branch of the fifth pair. They are very tender, and, suddenly expanding on a large surface, cannot be traced far. These tender nerves are defended from the weight of the anterior lobes of the brain, by being sunk in hollows, which give them a triangular shape, and, from the varied depth of either sulcus, one nerve seems occasionally larger than the other. Towards the fore part, these nerves expand into an oval lobe containing cineritious matter, which lies on the bone. They are apparently the organs of smelling. The branches of the fifth pair appear to supply the arteries and the mucous glands; the first pair only conveying the sensation.

The second pair, the OPTIC NERVES, arise from the thalami nervorum opticorum, or more directly, according to *Sabatier*, from the tubercula quadrigemina, and, after a long curve under the brain, unite at the fore part of the sella turcica, apparently blended. They then divide, and each running forward and outward, passes at its proper foramen into the orbit, to expand in the retina. It is, as we have said, sufficiently certain, on the whole, that the fibres do not decussate, though this certainly in some instances, takes place. We have ourselves seen from a blow on the head an affection of the opposite eye. With the optic nerve the ocular artery enters the orbit, and occasions an insensibility at that point, which may be ascertained by an easy experiment. It is, however, equally probable that the nerve is not fitted for sensation till it is expanded in the very delicate web, the retina. This membrane is, as usual, plentifully supplied with arteries, and the active circulation, through them, greatly increases its sensibility, while distention, for any time, destroys it.

The third pair MOTORES OCULORUM, first appear at the anterior part of the processus annularis, and, going out at the foramen lacerum, are dispersed on the muscles of the globe of the eye. In a more minute examination they seem to arise from the internal margin of the crura cerebri, and the perforated medullary matter, between them; and they pass between the posterior artery of the cerebrum, arising from the division of the basilar artery, and the anterior artery of the cerebellum. Each diverges, passing under the anterior part of the tentorium by the cavernous sinus. The situation of this nerve, near the artery, accounts, in the opinion of *Sabatier*, for the weight on the eyes at the approach of sleep; in fevers and states of inebriation.

The fourth pair, PATHETICI or TROCHLEARES, are the smallest of the encephalon, not exceeding in

size a common thread. They arise from the base of the testes, and running half round the root of the crura medullæ oblongatæ, adhere, by a membrane, to the anterior lateral part of the processus annularis, pass through the foramina lacera, and are spent on the muscoli trochleares, the superior oblique muscles of the eye. They are called *pathetici* from their rolling the eye with violence or fury. The origin of the trochleares is, however, various, and they seem to have a more intimate connection with the brain than any other nerves; yet no part of their office shows such a connection, or appears important.

The *fifth pair*, TRIGEMINI, arise from the annular process, where the medullary processes of the cerebellum are joined to the tuber. This nerve seems to arise in two portions: the anterior is small, and somewhat elevated above the other; the posterior originates a little lower. These portions are connected by a cellular membrane in which a little artery often creeps. In fact, though in a few individuals connected with the cerebrum, this is truly a nerve of the cerebellum. It enters the dura mater, near the point of the petrous process of the temporal bone, and sinking close by the receptacula at the sides of the sella turcica, each becomes thicker, forms a distinct ganglion, and passes from the skull in *three great branches*; one to the orbit of the eye and forehead, through the foramen lacerum; one to the upper jaw and face through the foramen rotundum; and another to the lower jaw and tongue, through the foramen ovale.

The *first*, the *ophthalmic*, before it passes through the foramen lacerum, sends off a branch to the intercostal, and forms the first connection between the two systems. It is then distributed to the glands, fat, membranes, and muscles of the eye, with a twig to the forehead, sending a considerable branch through the internal anterior orbital hole to the brain, in order to join the olfactory nerve. These very extensive connections explain various morbid phenomena, as the watering of the eyes, from a stimulus to the nerves of the nostrils, the effect of sneezing from a strong light, and stopping the same convulsion, by a pressure on the internal canthus, or indeed why sneezing itself, a convulsive action of the muscles of respiration, is occasioned by a stimulus to the nostrils.

The *second branch*, *maxillaris superior*, passes out at the foramen rotundum of the sphenoidal bone, and gives nerves to the palate, sphenoidal sinus, and nostrils, supplies the antrum maxillare, and the upper teeth. It comes out at the external orbital foramen, previously sending a branch through the substance of the os maxillare, which comes out at Stenos duct, to be distributed on the fore part of the palate. The remainder, which passes through, is lost on the orbicular muscle of the eyelids, the nose and upper lip, where it seems to unite with some branches of the seventh pair.

The *third*, *maxillaris inferior*, goes out at the foramen ovale of the sphenoidal bone, and supplies all the muscles of the lower jaw, and those between it and the os hyoides. It sends a branch to the tongue, where it meets the ninth pair, and from the root of this last branch the chorda tympani is reflected, or rather the chorda is added to the lingual nerve. It then supplies the salivary glands, the tonsils, the external ear, where it joins a branch of the portis dura of the seventh pair, the teeth of the lower jaw, and from thence the chin and under lip. From these connections, convulsions of the lower jaw are attended with salivation, angina, with

a pain of the ear and teeth, and the senses of smelling and tasting are probably related. If true, that compressing the nostrils will destroy the sensation of the palate, the reason will be sufficiently evident from this description, and we shall equally see why the toothach produces convulsions, as well as why cauteries to the external ear, or blisters behind it, sometimes relieve pains of the teeth.

The *sixth pair*, the ABDUCENTES, the smallest, except the fourth, arise from the fore part of the corpora pyramidalia; and, in their passage below the dura mater, where they are contiguous to the carotid, appear to send off a reflected branch, and when joined with some from the ophthalmic branch of the fifth pair, to form the original of the intercostal. The sixth pair, somewhat enlarged, now pass through the foramina lacera to be lost on the abductor muscle of the eye. A dispute has been maintained with obstinacy whether the sixth pair sends or receives this branch from the sympathetic; but anatomists have not decided the fact, and the knife probably cannot decide. The eye, of all the external organs, is, however, the only one whose motions are sometimes involuntary, and the intercostal system is exclusively destined to those muscles which are not under the influence of the will. It is singular that this circumstance, though so obvious, and useful in determining the controversy, should not have occurred; but the distinction is in a great measure new. We may add, at this place, that the third, fourth, fifth, and sixth pair of nerves, pass a considerable way under the dura mater, along the sides of the sella turcica, surrounded with a reticular plexus of vessels, and very near the large trunks of the internal carotid, before they pass through the foramina of the cranium.

The *seventh pair*, the AUDITORY, appear to come from the side of the root of the annular process, behind the conjunction of the medullary processes of the cerebellum with the tuber, accompanied by an artery of an unusual size, and entering the meatus auditorius, divides into two branches, the *portio mollis* and the *portio dura*. These two branches, however, on a minute examination, seem to have two distinct origins, the portio dura from the crus cerebelli, and the portio mollis from the striæ in the fourth ventricle. Prochaska indeed observes, that he has not been always able to trace their origin so far as these striæ; and, though many former anatomists of credit have supported this source, he thinks the striæ in the fourth ventricle by no means essential to the auditory nerve. The portio mollis soon loses its firm coats, and from this circumstance it is denominated. It enters the petrous bone, and in this softer state is disseminated on the internal ear. The other, supported by its harder coats, passes through Fallopius' aquæduct, in its passage by the side of the tympanum, where a nerve, sent to the lingual branch of the inferior maxillary nerve, along the outside of the Eustachian tube, and across the cavity of the tympanum (chorda tympani), is joined to it. The portio dura comes from the encephalon between the styloid and mastoid processes of the temporal bone, giving branches to the smaller muscles, and then passing through the parotid gland, supplies the muscles of the face, neck, and cranium, including the external ear. Its branches having thus a connection with the three branches of the fifth, and, as we shall see, of the second cervical, occasion numerous instances of sympathy, obvious to every one who reflects on their distribution.

The *eighth pair*, which, from its principal branch, is styled *PAR VAGUM*, rise from the superior and lateral part of the medulla oblongata, near the bases of the corpora olivaria, in distinct fibres. Strictly speaking, this pair of nerves consists of three distinct ones. The uppermost fibres, which may be traced separate from their origin, to their passage from the skull, is the *glossopharyngeal nerve*, which supplies the tongue and the pharynx. The chief medullary substance is the *par vagum*, and there is an additional portion, from the spinal marrow, the *nervous accessorius*. The *par vagum*, after its escape from the encephalon, gives nerves to the larynx, pharynx, and the ganglion of the intercostal nerve. Then separating from the ninth and intercostal, which seemed to accompany it, merely to receive additional branches for the superior cardiac plexus, it runs down the neck, at the outer side of the carotid, between it and the jugular vein. As it enters the thorax, by passing before the subclavian artery, it divides into two. The principal nerve accompanies the trachea to the root of the lungs, while the right branch turns round under the subclavian artery, on the left, under the arch of the aorta, and ascends behind the trachea to the larynx. This ascending branch is styled the *recurrent*, and on the right side is sometimes double. It ascends behind the carotid, and sometimes passes round the root of the thyroid artery. On the left, which is lower, in consequence of its running round the arch of the aorta, it gives off filaments, which go to the lower cardiac plexus, after having united with the branches of the sympathetic. Branches are also sent to this plexus from the recurrent, under the subclavian of the right side; and, on both, communicating branches are observable from the recurrent to or from the intercostal, for it will be recollected, that the functions of the lungs are not wholly voluntary. When the recurrent has turned round the artery, it ascends in a direction to pass between the trachea and œsophagus, giving branches to each, but its final distribution is to the larynx; though Sabatier describes a branch, which sometimes ascends and joins the sympathetic, high in the neck. Cutting the recurrent, and internal laryngeal nerves, it was supposed, would destroy the voice; but, in consequence of the numerous nervous communications, it is weakened only. When the latter is cut, the voice is weaker, but acute; when the former, which chiefly supplies the cartilages, it is graver and hoarse. The *par vagum*, in its progress downwards, forms the posterior pulmonic plexus, and, passing into the abdomen, with the œsophagus, supplies the stomach, particularly its upper part, and is at last lost in the numerous plexuses of the abdomen. In this extensive course it almost rivals the intercostal; but its functions are not so distinctly appropriated. We must regard it, however, as the great link between the cerebral and the ganglionic system, between the voluntary and involuntary functions of the body.

The last portion of the eighth pair is the *accessory nerve* of Willis. It arises from the cervical nerves, passes up through the foramen magnum, and comes out with the *par vagum*, like a nerve of the brain. When it has escaped from the encephalon it leaves the *par vagum*, and attaches itself to the ninth pair, sometimes by a filament, passes behind the jugular vein obliquely downward and backward, perforates the mastoid muscle, giving branches to it, and then, as if still wishing for support, entangles its branches with the third and

fourth cervical nerves, terminating in the posterior part of the trapezius muscle of the scapula. This peculiar distribution of the eighth pair will contribute to explain the reason, why tickling the fauces excites vomiting; the connection of vomiting and coughing, particularly in the hooping cough; the sensation of a ball in the throat, from distention of the stomach, perhaps the shrugging of the shoulders; and reply to the problem of Sabatier, why the more violent passions excite involuntary gesticulations.

The *ninth pair*, the *LINGUALES*, appear, first, at the inferior part of the corpora pyramidalia, between these and the corpora olivaria, rise in fasciculi, and in this disgregated state pass through the dura mater. They then unite and come out of the skull, by the condyloid foramen of the occipital bone, are connected with the eighth pair, and the ganglion of the sympathetic nerve. From its vicinity to the internal jugular vein, it is supposed to be compressed by it when full, as in paralytic, apoplectic, and even in drunken persons, occasioning a fulness and indistinctness of speech; for, as the name imports, it is at last dispersed on the tongue, united with the branch of the fifth pair, already mentioned as going to the tongue. When it comes out from under the occipital branch of the internal carotid, it gives off a branch called *descendens noni*, which passes over the trunk of the carotid, and under the thyroid vein. Two slender twigs, from the second and third cervical nerves, sometimes from the first origin of the phrenic nerve, uniting to this descending branch, together forming a ganglion, or plexus, from which many slender nerves go to the neighbouring muscles. Thus the ninth pair of nerves appears to have most extensive connections with the eighth pair, the spinal accessory, the sympathetic, the cervical, and the phrenic nerves. Shall we prove from this, that "out of the abundance of the heart the tongue speaketh?" At least we know, that the motions of the tongue are sometimes involuntary. This nerve seems to supply the motions of the tongue, while the sense of taste, which is by no means confined to the tongue, is derived from the branch of the fifth pair. It will be evident, however, that tremors of the tongue, and a loss of voice, often occasioned by hysteria, paralysis, and fevers, may, in a great degree, be accounted for, from these connections.

The *tenth pair*, or *SUBOCCIPITAL* nerves, which modern anatomists style the first of the cervical nerves, rise by two roots from the medulla spinalis, differing in many minute respects, which need not detain us in this place. The roots of this nerve are connected with the spinal accessory nerve, but seldom form a ganglion with it, and rather unite with the posterior roots of the second cervical nerve. The suboccipital nerve, passing transversely, and a little obliquely upward, goes out under the vertebral artery between it and the first vertebra of the neck. The trunk then rises a little way upward, swells into a kind of ganglion, and divides into two branches; the latter goes to the muscles of the head, the former chiefly adds to the ganglionic system. The following verses from an old anatomist, comprehend the principal uses of each pair of nerves in their order.

Olfaciens Cernens, oculosque Movens, Patiensque,
Gustans, Abducens, Audiensque, Vagansque, Loquensque.

We shall add a table of the synonyms of all these nerves, for which we are indebted to Mr. C. Bell.

- 1st pair—Olfactory nerves.
- 2d pair—Optic nerves.
- 3d pair—Motores oculorum.
- 4th pair—Trochleares.
- 5th pair—Trigemini.
- 6th pair—Abductores.
- 7th pair { Auditory nerves.
Nervus communicans faciei.
- 8th pair { Glosso pharyngeus.

1st spinal, or cervical nerve, of Haller.

The general course of the intercostal we have already described. To make, however, the view of the nerves more complete, we shall add a somewhat more particular account from the first Monro.

When the intercostal has escaped from the os petrosum it is joined by branches from the eighth, ninth, and tenth, and from the first and second cervical, to form the largest ganglion in the body, from which the nerve goes out to descend down the neck with the carotid artery. We have remarked, however, that this supposed origin is rather a branch sent upward, to it; but minuteness is here unnecessary. The intercostal, in its course down the neck, supplies the flexor muscles of the head and neck, and communicates with the cervical nerves; nor will it escape observation, that the motion of the head is often involuntary;

E'en mitred Rochester would nod his head.

As it is about to enter the thorax it again forms a ganglion, from which nerves are sent to the trachea arteria, and to the heart; those designed for the heart joining with the branches of the eighth pair, and passing between the two great arteries and the auricles to the substance of that muscle. The intercostal then runs down on the side of the *vertebræ* of the thorax, having additional nerves constantly sent to it from between these *vertebræ*. Where the addition is made to it from the fifth dorsal nerve, a branch goes off obliquely forward, which joined with others from the sixth, seventh, eighth, and ninth, forms the anterior trunk which passes through its own proper hole in the diaphragm, when it again forms a ganglion immediately above the *cæliac* artery, into which the eighth pair enters. From this, the nerves of the intestines, liver, spleen, pancreas, kidneys, and *glandulæ renales*, are derived. The posterior trunk continues in its straight course downward, communicating with the inferior dorsal and lumbar, and sending off branches to the kidneys and testicles. Some of its branches join with others, from the anterior trunk to form a ganglion, close to the inferior mesenteric artery, to supply part of the colon and rectum. The extremity of this nerve is even sent to the pelvis, to furnish the other parts there. In this progress the plexuses are numerous.

The SPINAL NERVES seldom rise in cords, but in separate fibres from the front and back part of the spine. They soon run into a ganglion, which is, however, chiefly formed by the posterior fibres, and they then acquire the firm coats peculiar to the other nerves. They are distinguished by the numbers of the *vertebræ* through which they pass, and the foramen is in the *vertebra* above. Seven come from the cervical *vertebræ*, twelve from the dorsal, five from the lumbar, and six from the false, *vertebræ*.

The first cervical pair come from between the first and second *vertebræ*, and its branches are immediately connected with the tenth pair of the head, the second cervical and intercostal. It supplies the flexors of the neck; but its larger branches are sent to the extensors, though not lost on them, as a few pass through them, and are spent in the teguments of the occiput. Some of its fibres are connected forward with the fifth pair of the head, and the *portio dura*. Thus a pain in the neck is sometimes felt in hysteria; and, in tetanus, the first

of the voluntary muscles affected are those of the neck.

The second *cervicals* unite, by branches, with the ninth of the head, the intercostal, and the first and third of the neck; and, by a large branch which comes out at the outer edge of the *sterno mastoideus*, with the accessory nerve. It is afterwards distributed to the muscles and glands of the head and neck, as well as the external ear, where it is connected to the *portio dura*, sometimes to the first cervical. The remainder passes to the levator *scapulæ*, and the extensors of the head and neck; but, at this place, another branch is usually sent off to join the accessory, near the superior angle of the *scapulæ*. These connections occasion the pain to extend to the clavicle in inflammations of the parotid, and the head to be drawn toward the shoulder of the affected side.

The third *cervical*, on its passing from between the *vertebræ*, unites with the second; and a branch passing down, uniting with the fourth cervical, forms the *phrenic nerve*, which enters the thorax, between the subclavian artery and vein. It passes by the pericardium, in a sulcus, and is lost on the diaphragm. The last *phrenic* goes outward, to pass over the apex of the heart. From this circumstance, palpitations of the heart are often attended with an acute pain, which is referred to the left orifice of the stomach. The other branches of this nerve are distributed to the muscles and teguments of the lower part of the neck, and top of the shoulder. The consequence is, that any disease of the diaphragm, or the parts immediately contiguous, if they irritate this muscle, are attended with pain on the top of the shoulder. This is particularly the case in inflammations of the liver.

The fourth *cervical* sends off a branch, as we have said, to join with one of the third, to form the *phrenic*, and sends filaments to the neighbouring parts. It then runs to the armpit, where it meets the fifth, sixth, and seventh *cervicals*, and the first dorsal. These unite and again separate in a complicated plexus, supply the teguments of the thorax, and then divide into different branches to the muscles of the upper extremity. These groups we shall describe.

The first of these, the *scapularis*, passes to the semi-lunar cavity of the upper costa of the scapula, a hole formed by a ligament passing between the angles of the scapula. It next supplies the *supra spinatus* and the muscles at the back of the scapula.

The *articularis* sinks in the axilla to avoid the head of the os humeri, to rise again at the back part of it, and is dispersed on the muscles which draw the arm back or elevate it. The name is derived from its surrounding the joint.

The *cutaneus* runs, superficially, down the fore part of the arm, giving branches to the skin, and divides on the inside of the fore arm to supply the teguments and the palm of the hand. The branches of this nerve are sometimes injured by opening the basilic vein.

The *musculo cutaneus* passes through the coracobrachialis muscle, supplies the biceps cubiti and brachialis internus; and passing behind the tendon of the biceps, and over the cephalic vein, is distributed on the teguments of the outside of the fore arm and hand. This is the nerve sometimes hurt in opening the cephalic vein.

The *muscularis* runs in a spiral direction from the axilla, under the os humeri, and backward to the external part of the bone supplying the extensors of the fore arm. A branch from the upper part of the fore arm, accompanying the supinator longus to the wrist, proceeds obliquely over the radius to supply the muscles on the back of the hand and fingers. The principal part, however, penetrates the supinator radii brevis to reach the extensors of the hand and fingers; and one part is sent to the ligament of the wrist.

The *ulnaris* extends along the inside of the arm to supply the extensors of the fore arm and the teguments of the elbow. At the lower part its course is somewhat oblique, that it may pass out at the groove behind the internal condyle of the os humeri, through which it runs to the ulna, supplying the neighbouring muscles and teguments till it reaches the wrist, when a branch is sent obliquely over the ulna to the back of the hand and the outside of the fingers. The largest portion of the nerve goes to the os pisiforme on the internal side of the wrist, where it sends off a branch which passes through the tendons to supply the interossei and lumbricales, terminating in the muscles of the thumb and fore finger. The remainder supplies the little finger, and divides into three branches, two of which pass with the sheath of the flexor tendons of the little finger to furnish its inside; while the other is disposed in the same way on the side of the ring finger. Some of the branches, however, from the last cervical and first dorsal run distinct to the ring and little finger, since these are sometimes affected independent of the other fingers, and a pain or a violent paralysis of these, when they are exclusively affected, has been removed by a caustic at the internal angle of the scapula. A numbness of the fingers often arises from leaning on the internal condyle, and a blow on it gives a tremulous sensation through the fore arm and hand.

The last bundle, the *radialis*, passes with the humeral artery to the elbow, supplying the flexors of the cubit in its way. It then pierces the pronator teres, supplies the muscles on the fore part of the fore arm, and continues its course to near the wrist, giving branches to the muscles in its way. Near the wrist it sometimes gives off a nerve to the back of the hand and fingers, instead of a branch of the *muscularis*. The larger part of the nerve, however, passes behind the annular ligament of the wrist, supplies the thumb, and sends a branch on each side of the sheath of the tendons of the flexors of the thumb, fore finger, and middle finger, and one to that side of the ring finger next the middle one. In each instance of these groups passing through muscles the action of these do not seem to affect the sensibility of the nerve, and we have already stated that the action of the muscles consists of contraction in length only.

The *twelve dorsal nerves* send each a branch to the intercostal, and others to the muscles behind. The principal trunk passes outward to the furrow in each rib, where they pass between the external and internal intercostals to supply the muscles and integuments of the thorax. The first dorsal having contributed its branch, forms with the two branches of the intercostal, as they come down the thorax, a considerable ganglion. The six lower dorsal nerves give branches to the diaphragm and abdominal muscles. The twelfth

joins with the first lumbar, and gives nerves to the quadratus lumborum and iliacus internus.

The *five lumbar nerves* on each side communicate with the intercostal and with each other, giving branches backward to the loins. The first joining with the last dorsal supplies the abdominal muscles, the psoas, iliacus, and the teguments of the fore part of the thigh, while its principal branch, with other nerves, forms the crural nerve. The second passes through the psoas, and is distributed like the former. The third has a similar distribution. Branches of the second, third, and fourth make up the *obturator or posterior crural nerve*, which passing through the pelvis, goes to the thigh at the notch of the foramen magnum, between the pubis and the ischium, and is lost on the adductores and the teguments on the inside. The *anterior crural* is formed by united branches from the first, second, third, and fourth lumbar nerves, runs along the psoas, and escaping with the iliac vessels under the tendon of the external oblique, supplies the muscles and teguments on the fore part of the thigh. One branch of this nerve runs down on the inside of the leg, near the vena saphæna to the upper part of the foot; and is sometimes wounded in opening this vein, near the ankle. The remainder of the fourth and fifth lumbar join in composing the sciatic nerve. From this distribution we see the reason why a stone passing through one of the ureters, which crosses the psoas obliquely, will occasion pain when the body is erected; a paralysis of the thigh; a swelling, and a convulsive retraction of the testicle.

The *six pair*, which come from the *false vertebræ*, are composed of small nerves sent posteriorly to the hips, and larger branches anteriorly. The three first joining with the fourth and fifth of the loins, form the sciatic nerve; which, after sending large nerves to different parts of the pelvis, organs of generation, and the thighs, passes behind the great tuber of the os ischium, and over the quadrigeminus muscles, down the back part of the thigh, close to the bone, supplying in its way the teguments and muscles. When it approaches the ham, it has the name of *popliteus*, and sends off a considerable branch, which passes over the fibula, and sinking among the muscles on the outside of the leg, goes to the foot, and is lost in the upper part of the larger toes, having supplied the muscles and teguments in its passage. The larger branch of the sciatic, after having been equally liberal to the muscles, &c. sends a large cutaneous nerve down the calf of the leg to supply the outside of the foot, and upper part of the lesser toes. It then sinks below the gemellus, and distributes nerves to the muscles of the back of the leg, continuing among them till it passes behind the inner ankle: in the internal hollow of the os calcis it divides into the external and internal plantar nerves, of which the first is divided among the sole of the foot and toes, nearly as the ulnar nerve is distributed on the concave side of the hand; and the second is distributed nearly as the radial nerve.

The fourth, fifth, and sixth nerves from the false vertebræ are much smaller than the others. The fourth is soon lost in the vesica urinaria and rectum; the fifth is chiefly distributed to the levatores ani. The sixth, which may be considered as the substance of the ligamentum, denticulatum, advances forward, and is

lost in the sphincter ani and the neighbouring teguments.

In general, the size of the nerves sent to the extremities are proportionally larger than those distributed to the different viscera; and the nerves of the inferior are larger than those of the superior extremities. We see, from the distribution of the nerves in the former, the cause of the numbness from sitting on one side, and why, in sciatica, the limb is not only weakened but wasted.

Such is the distribution of the nerves and the observations which they suggest. The nerves themselves, we have often hinted, do not differ from the simple solid, so far as chemical analysis has ascertained their nature; and the brain is apparently the same. When kept from the air it scarcely undergoes any spontaneous change; but in the air it soon becomes fetid, of a green colour, exhaling copiously ammonia. It contains phosphate of lime, of soda, and ammonia, though together in a very small proportion. The rest is apparently albuminous, though different in some of its affinities from albumen, and its real nature has hitherto eluded chemical investigation.

In our examination, therefore, of the NERVOUS INFLUENCE we must be guided by observation. We see cords extended from a common sensorium, consisting of pulpy matter, apparently fibrous, confined or defended by firm strong coats. These cords evidently convey impressions to the brain, and derive from it an active power, which a principle residing in the brain can direct to a determined end. Yet, for the purposes of mere animal life, a brain seems unnecessary, and what is a subordinate system in the human body, alone supplies the lower orders of animals: in them there is no common sensorium, apparently in the lowest, no volition. They seem to obey a principle which in the middle ranks of animated nature we call instinct, probably a necessary consequence of given stimuli in a system suitably organized. We must look then to the nerves themselves for the principles of sensation and of motion; for the brain is only a common centre, the residence of volition.

The phenomena of sensation and motion require a rapid communication from the extremities to the brain, or to that origin of nerves which supplies its place. The nerves are not elastic, and the idea that they convey impressions by tremors similar to those of a musical chord is consequently improbable. We acquire our ideas of solidity from resistance, and it may be said that this resistance which, variously modified, gives some information of the nature of the resisting body, may be the mean of conveying the impression to the mind. The numerous modifications, however, conveyed by the nerves, particularly by the nerves of the eye and the ear, are wholly incompatible with this system, and except, perhaps, the simple resistance, we obtain our knowledge of the nature of the resisting body by the medium of some fluid. It is at least generally agreed that the nervous power is a fluid. Dense fluids are incapable of rapid motion, so that it must be one of peculiar rarity; and as the effect continues for a short time after the object is removed, it is equally certain that this fluid is elastic. When we pursue the nerves to their extremities, where

their peculiar functions are exerted, we find them depositing all their coats, so that the peculiar properties of nerves cannot reside in these; on the contrary, as they do not appear in their course, it is highly probable that this fluid, whatever it may be, is confined by the coats. We may perhaps adduce as an argument for the opposite nature of the nerve, and the coat, the experiment just mentioned of Reil, who found the one soluble in an alkali and the other in an acid. Again, when we compare the appearance of the nervous cords in the best microscopes with the delicate pulpy membrane in their sentient extremities, we are led to suspect, as already hinted, that the fibres, which appear in the greatest magnifiers, are in reality fasciculi of more delicate ones; and that, therefore, it is highly improbable they should be hollow, or contain, within cavities, any fluid. Yet the fluid adheres to the nerves with some force. The language of the first Monro respecting the phrenic nerve is, that it must be "*gripped*" with one hand, and with the other "*stripped*" down in a direction below. Mr. Caverhill gives an equally strong representation of the necessary force; yet we must add, that these were applications to the nerves through their dense coats, the resistance of which it was necessary to overcome.

Every fact, every observation, as well as the most careful deductions from both, seem to show that the nerves are fibrous, that their power resides in a subtle, elastic fluid inherent in them, permeating freely through them, and confined by their coats, either from waste or an improper direction. This is no peculiar phenomenon in nature. The magnetic fluid is confined to iron in a peculiar state, and its direction is preserved by an armature of brass; the electric passes freely through metals, but is confined by glass or wax. Suppose, then, we now speak analogically, a metal divided into the minutest fibres, each coated with wax, and that coating deposited at one extremity: If the superior extremity is charged, the fluid will be conveyed with undiminished, possibly with increased, energy, to the lower. This analogy is realized in the torpedo. The galvanic shock, we have said, is of the nature of the electrical; it is peculiar to the nerves, which are disposed so as to confine it, and the principal nerves pass, in the electrical ray, commonly called the *torpedo*, under a muscle, which can check its influx. When the muscle is relaxed, apparently at the will of the animal, the whole force is directed to a given point. Like the nervous power, it is more active in proportion to the vigour of the animal; its activity is diminished by exertion, and is lost by death. We have said, that this is analogy only, but we may be allowed to add, it is analogy so close that it may assume a better name, and reason cannot revolt at its being styled a probable theory. Once more: electricity in activity excites the powers of a nerve following its fibres, equally confined by their coats. In a kindred fluid it will probably excite a similar activity, and the effect is the same with that of all inordinate stimuli, exhaustion, with a loss of irritability, which we commonly perceive from excessive excitement, or from deleterious miasmata; that it arises from excess of excitement is evinced by its causing pain and muscular contraction when not immediately fatal. See ELECTRICITAS and GALVANISMUS.

Whence then does this principle originate, how is it continued, how supported, and in what manner destroyed? These may be styled unfair questions, when we have professed to step, but a little way, beyond the confines of analogy. Yet we have no scruple to answer them. We consider then this fluid inherent in the nerves in their original germ, excited by the action which gives life, supported by the natural stimuli of food, warmth, &c. exhausted by too great excitement, or causes which at once destroy its activity, and ceasing finally to act when the solid which it accompanies loses its organization by the gradual diminution of its arteries. When we speak of the natural stimuli we may be accused of using the jargon of Brown. But, in his system, life itself is a forced state: we contend only that the *support* of life depends on causes of excitement, a fact rather than an opinion; and these stimuli appear to act exclusively by supporting the circulation, while the decay of old age arises from the obliteration of the arteries. The arteries, however, not only give activity to the nerves in their extremities, but seem to have a considerable influence on them in their origin. The brain, we have seen, is coated to a certain depth with cineritious substance, a colour derived from numerous minute vessels; but in various parts of the substance of the brain, in the ganglionic system, even in the nerves themselves, striæ of a similar colour are discoverable. This circumstance has led to the idea that the brain was a gland, and the nervous a secreted fluid. The glandular apparatus appeared to Dr. Cullen so striking, that while he would not admit a secreted fluid for the purposes of sensation and motion, he thought it assisted *NUTRITION*: vide in verbo.

There is, however, another view to be taken of this subject. We allowed the fibrin of the blood to be the most highly animalized of our fluids; we admitted its contraction by the Galvanic stimulus, and gave its full force to the argument, though we disclaimed the conclusion that contraction was the result of such organization. May it not then be said that the brain, a fibrous mass, is supplied with blood in vessels so exceedingly minute, that the circulation must be languid, and the fibrin strongly disposed to separate; that if animalization be connected with a fibrous structure, the cause will here be found adequate to the effect? It cannot, however, escape even a superficial inquirer that the animation of the fibre must be previous to the circulation; and every view which we have hitherto been able to take of the subject seems to show that the primordial germ is fibrous, and that it is animated in the moment of conception. If this be true, the separation of the fibrin is an effect only. But may it not supply nervous substance once lost? The question will arise, is nervous substance *ever* supplied with its original powers and functions? We think not. Nerves are united like any other simple solid; but from the experiments of Fontana, and his microscopical views of the united nerve, it seems to be only joined by a dense cellular substance. If the sensation below is not destroyed it is weaker, and we have every reason to believe that neighbouring nerves, when one is destroyed, acquire additional powers to supply its place. The fact recorded by Santorini is a very strong one, that the origin of the

portio mollis was particularly large in a blind man, whose hearing was peculiarly acute.

We have seen various communications between the nerves after escaping from the encephalon, and the influence of these communications in exciting what have been styled sympathetic motions. Many others (see *SYMPATHIA*.) cannot be explained by any known nervous connection, and physiologists have supposed with great reason that the nervous fibres communicate in the brain. We have seen that such communications are very extensive.

The sensibility and importance of a part must not be estimated by its proportion of nerves. Those of the heart are few and small, and some parts of the body, particularly the more compact ones, are acutely sensible when inflamed, though very inconsiderable fibres have been traced to them. This has appeared so striking to some physiologists, that they have been inclined to believe a nervous aura, from neighbouring organs, could give sensibility. Such is the opinion of Reil, but a highly improbable one. Many animals, as leeches, were said to be destitute of a nervous system, till they had been more accurately examined, and some parts of the body equally so, till the small nervous branches had been more minutely investigated. It is not at present asserted that the generation of mosses is equivocal, because the fructification of some kinds has not been indisputably demonstrated. We may be allowed in this place to sum up very shortly the whole doctrine which we have endeavoured to establish on this subject; though it will lead to some repetition, we are now by the additional steps enabled to give a complete view of the whole.

The primordial germ exists seemingly in the female. It is animated by the male, who certainly influences the form, the habits, the temperaments, and constitutional diseases. This germ contains in embryo the fibrous parts of the body only, convoluted into a form so minute as to escape for a time the assisted sight, and of this fibrous germ the principal part is the brain and nervous system, the *carina* of Malpighi. This animated nervous system gives vigour and activity to the other fibrous portions, the muscles, which soon impel a fluid, received from the maternal part of the uterus, and gradually evolve the rest of the body in succession. While the nervous power animates the arteries, it receives from them in turn a greater degree of vigour and activity. Inorganic matter is gradually added between the fibres, which is either loose in a cellular substance, or compacted with the fibres into membranes. Thus the body by degrees acquires a bulk. Its shape and form depend on that of the original fibrous, or more strictly the nervous, germ; for the body cannot expand beyond the point to which the convoluted nerves are able to extend, without death ensuing. That they will occasionally admit of a somewhat greater extent we see from painful tumours, which are supplied with arteries at times apparently of recent formation. If there is a power in the constitution to form new arteries, probably it is limited to the power of extension in the nerves. If it was unlimited, deformities and irregularity of figure would destroy the peculiar dignity of the human frame, and we should be justified in attributing all to chance.

Man thus slowly expands, and successive organs of peculiar structure, destined for their varied functions, are gradually evolved. The arteries, however, after a certain period begin to lose their energy; the blood is accumulated in the veins, the smaller vessels are obliterated, sensibility and irritability proportionally decrease, till the animation of the brain can be no longer supported, or some important vital function be discharged. The whole machine is then no longer in action, and the affinities of unanimated matter reduce it again to earth, to oil, to salts, and air!!

NERVI VA'GI, NERVI SYMPATHE'TICI MEDII, NERVI STOMA'CHICI. See PAR VAGUM.

NERVI'NA, (from *nervus*, a nerve). See NEURITICA.

NERVOSA FE'BRIS; *morbis cardiacus*. Nervous fever is the milder typhus of Cullen, and might perhaps with propriety have been referred to that head; but it is also so nearly connected with those slow fevers which sometimes arise from a sedentary life, from internal obstructions, and other causes, that it can, perhaps, be more advantageously considered in this place.

NERVOUS FEVER, the typhus mitior of Dr. Cullen, is defined, a contagious disease in which the heat is not much increased; the pulse small, weak, and generally frequent; the urine little changed; the functions of the sensorium much disturbed; and the strength greatly diminished. In the early stages there is no particular symptom to distinguish it from nervous diseases with fever, except the constitution of the patient, the existence of an epidemic, or occasionally a marked attack. In general, nervous fever comes on slowly, with occasional chilliness, so light as often to elude the attention and escape the recollection. It is, however, from the beginning attended with giddiness, or a mist before the eyes by day, and a want of sleep by night. A great lassitude, frequent yawnings, with flying pains, increased greatly towards the evening, want of appetite rising even to loathing and nausea, sighing, oppression at the region of the stomach, with dyspnoea, in succession come on. This gradual increase of symptoms, with the peculiar pale, sunk, countenance attending fever, will give the alarm, even when other nervous diseases with which the earlier symptoms have been confounded are present. The tongue continues for a time with little change, but is occasionally rough and dry, and after a few days white, at last assuming a browner hue. The pulse are usually quick and small from the beginning, and perhaps Dr. Cullen has been too cautious in stating it only, as "for the most part" frequent. The skin is generally dry, though profuse, clammy, debilitating sweats come on about the third day, and the heat is at no time considerable. After about the tenth day the weakness increases considerably; the tremors become convulsive; with despondency and alien-

ation of mind, at first observable only in the night, but soon continuing with little intermission. It is, however, only the mild delirium of pathologists; wandering rather than phrensy.

The disease is often protracted to the twenty-first day, and often to even a longer period. It seems seldom to have a regular crisis, but gradually proceeds to a fatal termination in debility and convulsions, or a gradual restoration to health, evinced by more natural sleep, a more favourable appearance of the look, the tongue more florid at the edges, the mind more collected, the nausea disappearing or changing to an appetite, often whimsical and unsteady, but still distant from the former loathing.

We have stated sufficiently the distinction of *nervous fever* from *nervous diseases with fever*. If the chilliness is not observable, the look and the evening exacerbation will generally decide, for purely nervous diseases are easier towards night. Another distinction is not less striking. Though in nervous diseases the appetite is capricious, yet food of a proper quality, and in moderate quantities, is borne with ease and even advantage. In fever it always overloads. In the former, wine cheers; in the latter, it heats and oppresses. Yet in the beginning of nervous fever, error is often unavoidable.

Nervous fever is seldom sporadic, and when epidemic usually proceeds from the common causes of epidemic fevers, viz. miasmata; nor is there any doubt of its being occasionally contagious. The form of this fever arises probably from the constitutions it affects, viz. the languid, the studious, and the sedentary. What in a crowded jail, in a camp, or in a besieged town, would be typhus petechialis, in a city where the air is free but the constitution debilitated, is probably typhus mitior or nervous fever. The disease is not, however, essentially different, and every cause of weakness predisposes to it.

The cause of fever we have endeavoured to show is debility, perhaps more strictly a debility of the sensorial power, attended with irregular action of the whole muscular system, and its consequences internal congestion, particularly, for the reasons stated, in the liver and the brain. We should not have repeated this opinion were it not to show how nearly it approaches to that of Dr. Clutterbuck, which in the moment of writing has reached us. He supposes fever a local disease, and to consist in inflammation of the brain, which, from its connection with the whole system, induces the various disorders in the vital, the animal, and the natural functions. We mean not to urge, in contradiction to his fair and well drawn inductions, that the intercostal system is distinct from the cerebral, and not likely to be affected by it, for this at present is untried ground, but to remark, that in his argument he seems not to have attended to the distinction between active inflammation and congestion. He distinctly proves the latter, but not the former. The best practitioners at this time will not admit of any practical distinction between membranous or parenchymatous inflammations, but no doubt can arise respecting the greater or less degree of inflammatory action. If this object had been in our view, we could not have pursued the distinction more closely than we have done in the article INFLAMMATION, q. v. and in the various parts of this

work where we have pointed out the effects of congestion as distinct from inflammation. The real difference arises first from age, where the congestion is chiefly venous; secondly, from the degree of the vis a tergo, excited by the obstruction. In the brain the limits in the first case, are the apoplexies in advanced life, and those cases which Hoffman calls *hemorrhagiæ cerebri*; in the second, the languid inflammation from Concussion. q. v. and the active ones which produce phrenitis. To come nearer the present point, the state of the brain in violent delirium from inflammatory fever, and in the mild delirium of the nervous, seems to be equally at the extremes of the beam; and though the former approaches phrenitis, the latter is far distant from it. With these distinctions we fully agree with Dr. Clutterbuck in his ideas of the state of the brain during fever; nor do we wish for more able supports of our opinion than the facts which he has so industriously collected, or so ingeniously applied.

There is, however, yet another view which we have taken of the subject, and which we think requires equal attention, viz. the state of the epigastric region, and particularly of the liver. This seems, in the treatment of every fever, to require a very particular attention, nor will the arguments which show the influence of the brain on the digestive organs, explain the fulness, the tension of the region of the liver, or explain the necessity or the good effects of laxatives. In the disease before us, the epigastric region is generally tense; and stools are easily borne. The affection of the head is the delirium mite only of pathologists. In fact, the debility is so great that the alteration in the balance of the circulation is less obvious, and the practice has been generally feeble and inefficacious; or mistaken and ill-directed.

We might refer, in general, to the observations on the remedies of fever (see FERRIS); but some modifications are necessary. Even when *bleeding* was considered as indispensable, the lancet was dreaded, or employed in this disease with a timid caution. Practitioners have since found it injurious, and even fatal; nor is there any period when it appears truly indicated. *Emetics* are useful in the beginning, but the active exertions of vomiting prevent their frequent repetition, as they seem to exhaust the strength and diminish the excitability: nauseating doses of antimonials exhaust it still more, and are highly injurious. *Purgatives* seem also to have been forbidden, as lowering the strength and lessening the vital powers; yet, at a time when in more active fevers clysters were chiefly trusted, and we were told, with the most frigid caution, that if stools were necessary, they must be procured by their means only, we shall not be surprised to find that in cases of such great debility the increase of the alvine discharge was dreaded. Nervous epidemics are, however, peculiarly rare, nor have we had an opportunity of bringing the use of purgatives to the test. In the last we saw they appeared injurious; but in the sporadic cases of this nature we have found them rather beneficial: but in such the practitioner must be "with caution bold."

The Peruvian bark would appear to be strongly indicated, and it has had powerful recommendations. Yet the period at which these recommendations appeared give us some room for doubt. It was when fevers of the continued kind were supposed to consist

of repeated paroxysms, and to be as easily checked by this remedy as intermittents. Practitioners too often see what they wish, and medicines always appear to answer a preconceived opinion.

The management, in which all seem to agree, is to check *colliquative sweats*, which often arise, by free cold air and cold drinks; to give wine with caution, according to the state of debility, and *opiates*, with or without stimulants, which alone seem to act as cordials. Yet to these we would add *blisters*, which are certainly necessary to lessen the accumulation in the brain, and *laxatives* at least to such an extent as will prevent or lessen the infarctions of the liver, which are inseparable from every fever which we have seen. The power of the laxative should be adapted to the patient's strength; but his feelings and his pulse, after every evacuation, should be carefully examined, for from thence we should draw our indications for their repetition. We strongly suspect that the bark would have been found a more useful medicine had laxatives been properly premised; but in the use of this remedy practitioners have been peculiarly timid.

Camphor is a medicine which has been spoken of differently, according, perhaps, to the nature of the epidemic, or the prejudice of the practitioner. In general, it promises to be effectual; and the ether, which seems never to have had a fair trial, is a remedy of equal, apparent, value. While the colliquative sweats have been often a troublesome symptom, practitioners have greatly feared the semicupium or warm fomentations; yet, in a low temperature, when the sweats do not come on, they may be useful. They should never be higher than 96° nor below 92°. The cold affusion has not been tried, though sponging the body with cold water, or water and vinegar, was no uncommon remedy among the ancients. The heat of the body is, however, so inconsiderable, that sponging only can be admitted, and this should be employed with caution.

When convulsions come on, either camphor, castor, or opium, are necessary; and these in combination are often highly useful. In this state also, mosch and the fetid gums have been employed with considerable advantage. Whatever be the inconveniences of the bark during the fever, it greatly assists the recovery of the strength during convalescence. The debility is often considerable, nor have we seen any fever where the mind is reduced to more infantine weakness.

NERVOSI MORBI, the *neurodes* of Dr. Cullen may seem to require some particular notice. These, however, occur under their respective heads; but a term so generally employed may be sought for in a dictionary, and we shall endeavour, on the foundation of our nervous pathology, to give some general and more distinct views than may be found in former authors, in the most concise, comprehensive, form.

The two great divisions of the morbid states of the nervous system are increased or diminished sensibility, connected with increased mobility and torpor in the moving fibres, with tenderness or firmness in the simple solid. The deranged state of the nervous system is chiefly considered in the article MANIA, q. v.

Nervous diseases, in the common meaning of the term, chiefly consist in the former state, in which, to

prevent prolixity, we shall constantly include its connections. This constitutes the hysteric constitution, and indeed, in imagination, "all the evils flesh is heir to." In hysteria, we considered that marked definite affection, distinguished by its appropriate symptoms; but there are many complaints depending on excess of excitement, sometimes within the limits of health, though occasionally stepping beyond the first boundaries of disease. As they are so numerous, we must pursue them in the different functions, distinguished as *vital*, *animal*, and *natural*.

The vital functions suffer numerous inconvenient deviations from their natural regularity. The circulation is usually rapid, but often greatly accelerated and irregular, not only in the synchronism of the action of the heart, but in the direction of the circulating fluids. We thus find, from the slightest excitement, the pulse unusually rapid; the heart fluttering with irregular beats; the face flushed, while the extremities are cold, or a sensation of cold water pouring down the back is felt. The respiration is equally irregular; the lungs are ineffectually expanded, and inspiration repeated, to relieve the anxiety thus occasioned. At times, the respiration and circulation cease, and a death like faintness, attended occasionally with convulsions, supervenes.

These symptoms recur at irregular intervals, and sometimes vanish spontaneously, leaving the usual delicacy of infirm health, but no particular inconvenience. They are induced and carried off by causes equally slight, and leave the patient subject to the charge of caprice, fancy, or dissimulation. Thus they are brought on by a sharp noise, a fetid odour, a disagreeable object, and carried off by similar means. To rouse the attention, to keep it suspended by anxiety and expectation, in fact, to take the patient from herself, since the morbid affection is almost peculiar to females, furnishes the best plan for relief. To bring on misfortunes is not the province of the physician, but accidental ones raise her above herself.

In the animal functions, the tendency to disease is no less conspicuous. The sensibility is extreme, and the "Miseries of Human Life," overcharged perhaps in the modern popular publication, are wholly the patient's own. The wind blows with too suffocating or too chilling a breeze; the birds chirp with too shrill a sound; the odour of new mown hay is offensive; and the glaring sun blinds the too tender eye. As the Indian is all face, the nervous patient feels in every organ as if that organ had no defence.

The affections of the *natural functions* are mixed with those of the vital and animal. The muscles, in general, are susceptible of sudden and violent contractions, no longer obedient to the will. These arise to hysteric, sometimes to epileptic, paroxysms. The appetite is capricious, irregular, and occasionally depraved; the stomach often distended with flatulence, and disturbed with borborygmi; the bowels unequal in their exertions; the kidneys occasionally yielding to the impulse of the blood, and secreting a serous fluid with little change, sometimes resisting the usual impulse, or obeying it, after some delay, when the urine is highly charged with its animal salts and oil.

Nervous patients, in this way, suffer acutely with little commiseration, and few attempts at relief. They are told that they must be their own physicians, and are

left to the pity, often to the ridicule, of the world. Yet, though not diseased, they nearly approach disease; and the only remedies are those which blunt too great sensibility, and those which restore the balance of the circulation.

To begin with the latter. An equable warmth is necessary, and every means by friction, by rubefacients, and by exercise, of keeping the lower extremities in a due temperature, are highly salutary. Exercise, however, should be employed with caution. If so violent as to fatigue, and a little *will* fatigue, it is injurious; nor can nervous patients often endure the requisite degree of bodily exercise without inconvenience. A carriage, or a horse, are therefore required, but, in each, the mind preys on itself, and it may be literally said, *post equitem sedet atra cura*. No general rules can be therefore laid down: the prudent physician will adapt his advice to the circumstances and the disposition of his patient; but, in general, a journey, cheerful company, a change of scene and of engagements, will best succeed. Thus do the fashionable watering places, the chalybeate springs, triumph.

Another mode of keeping up the due balance of the circulation is by the use of laxatives. The convulsive motions of the muscular organs take place in the stomach, and distention of this organ, followed by eructations, are often a most distressing symptom. It is necessary then to keep up the peristaltic motion of the bowels, which, while it contributes to carry down the flatulence, relieves the fulness of the vessels above. The medicines which succeed most effectually for this purpose are the stimulant cathartics, which increase the action, the peristaltic motion of the intestines, particularly the aloes and the rhubarb, and the effects of these are greatly increased by uniting them with the fetid gums.

Too great sensibility is blunted by various narcotics and carminatives. The complaints of the stomach are relieved by the fetid tinctures, by the warmer carminatives, and by every stimulus. It is painful to be obliged to add, that what was first resorted to as a medicine is often continued from habit, and the officinal tincture is exchanged for common spirits. Let therefore every nervous female be cautious in this respect, for thousands have been thus incautiously enticed to their ruin—the ruin of their constitutions and of their moral character. Let them recollect that aqua ammonia is less dangerous than brandy, and that infusions of pepper-mint, of rosemary, or the warmer aromatics of the east, though injurious in excess, are far less so than what are styled indirect stimulants, which lull rather than relieve pain, which intoxicate the senses, instead of removing the disease. In such cases, for this purpose, opium is often an useful remedy, but it should be confined to medical exhibition. In excess it acts only as a dram, and we fear, like spirit of lavender, is often used as such, under the name of medicine; many a patient "*pretextit nomine culham*."

Other narcotics are the henbane, the cicuta, perhaps the bayberries, and the narcotic bitters. The two former have been recommended as not producing costiveness, and the henbane seems particularly useful. The bayberries, though stimulant, unite the narcotic powers of the plant, and are often useful remedies. To restore the strength is rather to repress the mobility; and, in

this latter view, bitters appear chiefly useful. The narcotic ones are most effectual, and those which unite astringency often fail of producing the expected benefit. If the bark is ever useful, it is when combined with valerian. Acid in the stomach is corrected by lime water, by magnesia, often by the acid of vitriol, and sometimes even by columba root; occasional spasms by the fetids and carminatives. The metallic preparations, particularly iron, often recommended, are two powerfully astringent; and zinc, lately introduced in union with columba, often injurious. We have lately learnt from Dr. Bardsley that the oxide of bismuth is highly useful in these complaints, and that it calms the irritability of the stomach more effectually than any other medicine. This medicine was originally recommended by Dr. Odier, and communicated to the public by Dr. Marcel. (See *BISMUTHUM*.) It is particularly adapted, however, to the increased irritability in consequence of a scirrhus pylorus; and perhaps before we arrive at the article *SCIRRHUS*, we may be able to communicate the result of our own experience. Free air and large rooms are indispensable; and sea bathing often gives tone without increasing the inflammatory tendency. To discharge accumulations of phlegm, emetics are occasionally necessary, but should not be too often repeated.

What may be styled the moral treatment of such complaints requires a steady hand. While to ridicule fancies, not in the patient's power, is inhuman, to humour them is an indulgent cruelty. Every imagined feeling is to them a reality, every whim a want. Reason is often unavailing, authority is harshness, and a cold indifference cruel insensibility. Their own reason is inadequate to the task of correcting their wanderings, for they are truly such, nor will they hearken to that of others. In general, a kind indulgence in trifles, and a steady firmness in opposing the wilder eccentricities, is useful; and to point out with an affectionate mildness the errors, and their apparently certain consequences, will often succeed. Much, however, must be left to the prudence and judgment of the attendant, which must be regulated by the patient's temper and habits. The attendant should, however, have the confidence of the patient, which she should never forfeit by unnecessary harshness, or abuse by injurious indulgences.

Nervous diseases of the opposite kind are, we have said, those of torpor. Less varied in their forms and symptoms, we need not so studiously distinguish the functions affected, though we shall silently follow the same order. In these diseases, then, the circulation is slow, and sometimes sufficiently regular; but the equilibrium is by no means properly balanced. The liver and the brain, as usual, when the fluids are not properly distributed to the surface, have a large share; and as the muscular fibres are with difficulty excited to action, congestions, in each, take place. In the brain these appear by all the marks of compression, languor, inactivity, and insensibility: in the liver, by costiveness, indigestion, and a dark yellow hue on the skin. "Thick coming fancies" disturb the mind; the sleep is interrupted, or a torpor resembling sleep, in all but its refreshing power, succeeds. The appetite is inconsiderable, but sometimes voracious and indiscriminate, and the bowels generally torpid. It is the disease, as we have had occasion to remark, of the sedentary and the studious, who are found by the midnight lamp, and cheer or

instruct the world at the expense of their health and constitutions; for the mind is often vivid, when the body is depressed. The divine particula auræ will often appear then to burn with peculiar lustre; nor is this, when properly considered, an objection to our former opinions.

The remedies of this state are exercise, blended with some interesting occupation; an attention to the state of the bowels; and, above all, every method of keeping up the balance of the circulation, particularly directing it to the extremities. In general, the conduct in cases of *MELANCHOLIA*, q. v. of which this is a less degree, will be proper. The tepid bath, for reasons which will be readily understood, is a valuable remedy.

For nervous fever, see Huxham, Gilchrist in the *Edinburgh Medical Essays*, and Sydenham.

For nervous diseases, Whytt, and the authors referred to under the article *HYSTERIA*.

NERVO'SUS, (from *nervus*, a term in botany,) applied to a leaf whose vessels extend in lines from the base to the top without meeting. Nosologically, an epithet annexed to fever, and other diseases, where the nerves are supposed to be chiefly, and often primarily, affected. See *NERVOSA FEBRIS* and *NERVOSI MORBI*.

NERVO'RUM RESOLUTIO'NES, (from *resolvō*, to loosen). See *COMATA*.

NERVO'RUM TUM'ORES, are discovered by the pain being felt only in the direction of the nerve, particularly below. They may be extirpated without danger, but it is safer to divide the nerve than to run the risk of inflammation, unless it is large or highly important. See Home, in the *Transactions for the Improvement of Medicine and Surgery*.

NERVO'RUM VUL'ERA. Wounds of the nerves are often attended with very troublesome symptoms, and trismus or tetanus have been the consequence. The general opinion has decided, that if the nerve be wholly divided, the effect may be avoided or lessened, and with the remedies proper for these spasms, a division of the nerve is also necessary. In bleeding, the nerves, as we have shown, may be easily wounded; and when it is seen which vein has been cut, the injured nerve is immediately known, and it may be readily traced by dissection, so as to divide it above the wound. Mr. Pott supposes, that, as the wound must be at the upper or under angle of the orifice, it may be sufficient to enlarge it either above or below. In fact, however, the injury first produces inflammation, probably from the external air being admitted into the sheath of the nerves, and it will be therefore preferable to divide it above. Mr. Bell thinks a transverse incision above the original wound a sufficient security: but the dissection and division of the nerve above is the preferable plan. See *TRISMUS*.

NE'STIS, (from *est*, *non*, and *estēa*, to eat). See *JEJUNUM*.

NEU'RI. See *NERVI*.

NEUROCHONDRO'DES, (from *νευρον* and *χονδρος*, a cartilage). A hard round, cartilaginous ligament; sometimes a substance harder than a cartilage, and softer than a ligament. *CASTELLI*.

NEUROLO'GIA, (from *νευρον* and *λογος*). *NEUROLOGY*. A description of the nerves.

NEUROME'TORES, (from *νευρον* and *μετρα*, *metrix*). See *PSOE*.

NEURO'SES, (from *νευρον*, a nerve). **NERVOUS DISEASES** form the second class in Dr. Cullen's nosology, comprehending preternatural affections of sense or motion without fever, as a primary disease; and those which do not depend upon a topical affection of the organs, but upon a more general affection of the nervous system, and of the powers on which sense and motion more especially depend.

NEURO'TICA, vel **NERVI'NA**, (from *νευρον*, or *nervus*). By nervous medicines are meant those suited to relieve the diseases or correct disorders of the nervous system. The obscurity which still attends the mode of the operation of medicines upon the nervous system might excuse this term; but it is too general, and the whole subject will continue in obscurity until more precision is attained.

NEUROTO'MIA, (from *νευρον* and *τομω*, to cut). An anatomical dissection of the nerves.

NEUROTRO'TOS, from *νευρον* and *τιρωσχω*, to wound). A person who has received a wound of a nerve.

NEU'TRALIS, (from *neuter*, neither). **NEUTRAL**. Salts, formed of such proportions of acid and alkalies that neither predominates in the compound. They are in general *evacuants*; i. e. cathartics, diaphoretics, and diuretics; refrigerants or anti-emetics. Those which are formed of an acid and an earth, or an acid and a metal, are less strictly neutral, since they admit of very different portions of acid without materially altering their qualities.

NHA'MBI BRASILIE'NSIBUS, Lin. Sp. Pl. 1457? A plant in Brasil, whose leaves, when chewed, taste like mustard or nasturtium, and, if rubbed on a bubo, presently remove it. See Raii Historia.

NHA'MBU GUA'CU. See CATAPUTIA.

NHA'NDU, *piper caudatum*, a small shrub which grows in the woods in Brasil, and bears a species of katkins, full of round blackish seeds, as large as those of the poppy, and with a taste resembling that of pepper. The plant is little known, but it seems to be a cubeb, and by later authors has been referred to the genus *piper*, with the trivial name of CUBEBA, q. v. See Raii Historia.

NI'CKEL. See CHEMIA.

NI'CON. See HELLEBORUS.

NICOTIA'NA, (from Nicot, the name of the man who first brought it to France). *Petum; tabacum; hyoscyamus Peruvianus; picelt; nicotiana tabacum* Lin. Sp. Pl. 258; a plant with alternate leaves and monopetalous tubulous flowers, divided into five sections, followed by an oval capsule, which opening longitudinally, sheds numerous small seeds. It is an annual, sown in spring, and flowers in July.

NICOTIA'NA AMERICA'NA. **AMERICAN OR VIRGINIAN TOBACCO**, hath large sharp pointed, pale, green short leaves, about two feet in length, joined immediately to the stalk without pedicles. First brought from the island of Tobago, about the year 1560, and from thence called *tabacum*, now cultivated in many parts of Europe. Sir Francis Drake first brought it into England, and Sir Walter Raleigh rendered it fashionable. M. Thevet disputes with Nicot the honour of having introduced it into France.

The history of tobacco is singular. The production of a little island, or a little district in America, it has

fascinated the whole world. The Arab cultivates it in the burning desert; the Laplanders and Esquimaux risk their lives to procure this delicious refreshment; the seamen endures every privation while he can obtain this luxury: and the financier collects from it a copious revenue. Yet its fame has not been without occasional diminution. It has been opposed by physicians, proscribed by governments, and yet the fashion long prevailed; nor, until men were more humanized by female society, was the custom of smoking at least less prevalent.

The leaves have a strong disagreeable smell, and a burning acrid taste, yielding their active parts both to water and to spirit, but most perfectly to the latter; a very small proportion of its virtues, however, rise in distillation from either; but the watery extract is less pungent than the leaves, and the spirituous not greater. The American tobacco is stronger than that raised in England, and affords a more pungent extract, though in less quantity. This plant is evidently a narcotic, as is evinced by its botanical analogy, and effects. Small quantities snuffed up the nose have produced giddiness, stupor, and vomiting; and in a larger quantity there are instances of its being even a poison. But with these narcotic qualities it is said to stimulate, especially in the stomach and intestines, so as readily, in no great doses, to prove emetic and purgative, occasioning extreme anxiety, vertigo, stupor, and disorders of the senses: in proper quantities, it is, however, an effectual purgative in clysters. See HERNIA.

This stimulus is, however imaginary, for we have learnt that every narcotic will produce irregular action; and the vertigo and faintness, which always attends, when it produces vomiting, show it to be exclusively narcotic, except in the nostrils and mouth.

From its sedative power arises all the fascination of this plant. It gives that calm serenity always occasioned by the abstraction of stimuli, and, like tea, opium, and the betle nut, composes the mind under the greatest distress. It is necessary, however, to examine its effects in all the varieties of its use.

It certainly stimulates the nostrils, for it produces a pungent sensation and a discharge of mucus; but, as we have remarked, stupor and vertigo, and, in those accustomed to it, a tranquillity and a pleasing delirium.

Its stimulus to the salivary glands is more doubtful, for the action of chewing will alone excite their action. Yet it seems to produce the discharge more powerfully than the motion of the jaws will explain; and the tobacco, thus dissolved in the saliva, is always in some degree, and often copiously, swallowed. It then acts on the stomach, producing all the inconveniences of a narcotic poison, acidity, flatulence, indigestion, depraved appetite, &c. The same symptoms follow taking snuff, as a portion of the tobacco generally falls through the posterior fauces into the stomach. The advantages of each mode are nearly the same. The discharge of phlegm which they produce relieves accumulations in the head, and all the diseases depending on them. See ERRHINA and SIALAGOGA.

In *smoking*, the oil of the tobacco is separated, rendered empyreumatic by the heat, and of course applied to the fauces and lungs in its most active state. Musing over a pipe assists, it is said, reflection: its smoke accompanied Newton's "patient thinking," and added

to the wisdom of the politician; but it is now forbidden in the drawing room, as well as the dining parlour, and confined to the ale house. Like other forms of taking tobacco, smoking occasions a tranquillity, a freedom from care, a slight and harmless intoxication, increasing also the discharge of saliva.

Smoking generally produces a considerable discharge of this fluid, and from it, as well as the warmth, has been occasionally useful in pains of the teeth, in rheumatic affections of the head and jaws, and in asthmas both serous and spasmodic. It lessens, however, the appetite, blackens the teeth, and renders the whole person most offensive to those who possess the slightest delicacy of smell, or to whom a clean appearance is acceptable. The advantages of tobacco, in each mode, may be attained by errhines, sialagogues and expectorants of less equivocal nature, and of more certain operation.

If considered as a medicine it will be found a valuable one, though its emetic power often defeats the benefits we expect from it. In the form of infusion and of smoke it is introduced into the rectum, and is often effectual as an enema, when every thing else has failed. Its smoke probably penetrates farther than any liquid, and is more useful on this account, as well as from the oil acting in its separate state. Its operation is, however, generally attended with faintness, and therefore peculiarly useful in ileus and hernia, less so as a means of reviving those in asphyxy from drowning, or any other cause. Ascarides also, in the same form, it certainly kills. It is seldom employed as an emetic, as its sickness is peculiarly distressing; yet, in nauseating doses, we suspect, from its other qualities, that it may be equally effectual with, and less dangerous than, the digitalis, which stands very near it in the natural systems of the botanists. Its emetic power prevents it from acting as a laxative, except in clysters, and as a diuretic, except in the form of its alkali, after burning. The oil which remains adhering to the salts, adds to the diuretic power of the alkali, and it has been supposed useful in dropsies. In the days of its fashion we used it, but without such decided success as tempted us so continue it. Though boiling lessens this emetic property, it is not destroyed; and, though it is nearly lost in the extract, there is much doubt whether its virtues are not diminished in the same proportion. This extract and a syrup of tobacco appear in the foreign pharmacopœias, which are said to have cured epilepsy and mania. Twenty-five grains of powdered tobacco diluted with wine are said to have cured even quartans. The Edinburgh Pharmacopœia has preserved a vinous tincture.

The tobacco is in its purest state in the *segars*, which are only the leaf when in perfection, rolled up for the purpose of smoking. When in rolls, it has undergone a slight change from fermentation, and is probably rendered more acrid by some additions. In the manufacture of snuff numerous additions are probably made, which are kept secret. The varied acrimony of different snuffs are in part owing to the leaf being in greater or less perfection, in part to its having undergone some fermentation. The additions are common salt, for the purpose probably of increasing its weight, and it is said urine, to add to the pungency.

Tobacco is sometimes used in lotions and unguents for cleansing foul ulcers, and destroying cutaneous insects.

It is destructive to all insects, whether in the vegetable or animal world; on the skin, in the hair, or the intestines; beat into a poultice with vinegar, and applied to the hypochondria, it is said to have discussed tumours. Bergius recommends a fomentation of it in paraphymosis. Cullen's *Materia Medica*.

NICOTIA'NA MI'NOR, *hyoscyamus luteus*; *frisaheia*, YELLOW HENBANE, ENGLISH TOBACCO. *Nicotiana rustica* Lin. Sp. Pl. 258. Its leaves are short, sharp, and set on pedicles. It resembles the American tobacco, but is weaker. See Raii *Historia*; Lewis's *Materia Medica*; Neumann's *Chemical Works*; Edinburgh *Medical Essays*, vol. ii. art. 5.

NI'DI CYNI'PIDIS. See GALLÆ.

NI'DOR, (from *nideo*, to give a savour). The smell of burnt animal substances. Eructations, which resemble in smell and taste rotten eggs, are called *nidorous*.

NIGE'LLA, (from its black seed). *Nigella sativa* Lin. Sp. Pl. 753, is a plant whose root is annual, leaves capillaceous, and flowers rosaceous. It was formerly used as an expectorant and a deobstruent, a diuretic and a carminative. The species employed were *nigella damascena* Lin. Sp. Pl. 753.

NIGE'LLA ARVE'NSIS, *melanthium*; *nigella arvensis* Lin. Sp. Pl. 753. WILD FENNEL FLOWER.

NIGE'LLA ROMA'NA, *gith, git, melaspermum*, from its black seed. FENNEL FLOWER.

NIGELLA'STRUM, (from its resemblance). *Pseudomelanthium, lychnis segetum major, gethago, nigella officin lychnoides segetum*, COCKLE, or CORN CAMPION, *agrostemma calirosa* Lin. Sp. Pl. 624. The seeds are said to be useful in flatulent disorders, but are never given. The plant grows amongst corn, and flowers in June and July. See Raii *Historia*.

NIGRI'TIES OSSIUM, (from *niger*, black). See CARIÆ.

NI'GRUM PIGME'NTUM. See CHOROIDES.

NI'GUS. The worms which burrow under the toes of the Indians, and which are destroyed by the oil from the shells of cashew nuts.

NI'HIL A'LBUM, NI'HIL GRI'SEUM. See ALBUM GRÆCUM, and POMPHOLYX.

NI'IR-NO'TSJIL. A kind of shrub in Malabar, the leaves of which, when eaten with rue, are said to cure the lues venerea; but no such plant occurs in the systematic botanists. See Raii *Historia*.

NI'IR PONGE'LION. A tree of Malabar, resembling the pear tree. The seeds are used, with other ingredients, for making an antispasmodic liniment. See Raii *Historia*.

NI'L. See INDICUM, and COLINIL.

NI'NZIN. The *sium ninsi* of Linnæus, Sp. Pl. 361, inferior but similar to the GENSING, q. v.

NI'RLES. See MORBILLI.

NIRUA'LA. A large tree in Malabar, whose leaves externally applied are diuretic; probably a species of *phyllanthus*. See Raii *Historia*.

NI'TRAS. NITRAT, NITRIS, and NITRIT. Salts formed by nitrous and nitric acid with different bases.

NI'TRI PU'LVIS COMPO'SITUS. See DYSURIA.

NI'TRO DE PI'LULÆ. See DIACOLOCYNTHIDOS PILULÆ.

NI'TRUM, or NATHAR; Hebrew terms. NITRE. *Sal petræ, halinitrum*, and SALT PETRE; a neutral salt,

formed by the vegetable fixed alkali with the nitrous acid. It has a sharp though cooling taste, is soluble in seven times its weight of temperate, and an equal weight of boiling, water. The crystals are octagonal prisms, solid and not deliquescent, terminating in similar pyramids, sometimes dihedral. In a moderate heat it melts, and, when heated to ignition, deflagrates on the contact of any inflammable substance, with a bright flame, and a considerable hissing noise; leaving, after detonation, its fixed alkaline salt, the acid being decomposed in the process. Oxygen and nitrogen gas are produced, and the result is the *nitrum fixum* of the older chemists; in fact, the kali.

The origin of the acid of nitre has not been long known. When animal and vegetable substances, mixed with absorbent earths, have been exposed to the air till they are thoroughly decayed, they are found to contain a small portion of nitre, or to give out a little nitre to water, on being supplied with the proper alkaline basis. On this foundation nitre is prepared in several parts of Europe; where they expose earth, wet with urine, or animal dung, with every kind of animal and vegetable substance, open to the air, but covered from rain: on the surface of these heaps a nitrous crust is found. The greatest quantities are brought to us from Persia and the East Indies, crude and of different colours; but the best is blackish, as it requires only solution and crystallization. When mixed with sea salt it is purified as follows:

Filtre a solution of nitre, evaporate, and set it to crystallize in a cool place. The crystals will remain sufficiently pure, for the sea salt remains dissolved after the greatest part of the nitre hath crystallized.

Nitre, according to Mr. Kirwan, when dried at the temperature of 70°, consists of forty-four parts of nitric acid, fifty-one of kali, four and a half of water. It is decomposed by the sulphuric acid, by barytes, by the muriat and acetat of barytes, and the vitriolated salts. See CHEMIA, vol. i. p. 414.

Nitre is in part decomposed in the *sal prunellæ*, more completely in the *sal polycryst*; but in each it acquires different portions of the vitriolic acid, from the sulphur with which it is deflagrated. In the former preparation one half, and in the latter an equal part, of sulphur is employed, which makes the *sal polycryst* wholly a vitriolated kali.

The nitrous acid, formerly called *Glauber's spirit of nitre*, is made by adding to sixty ounces of nitre twenty-nine of a vitriolic acid. The mixture is then distilled. If two parts of nitre are added to one of oil of vitriol, the remaining alkaline basis of the nitre will be completely saturated with the acid, forming the vitriolated kali. If more nitre is used, part of it will remain blended with the vitriolated salt; if less, the residuum will not be neutral, but very acid. See CHEMIA.

The vitriolated nitre, *ducis holstatitiæ sal*, *sal de duobus*; *panacea duplicata*; *arcanum duplex*; *kali vitriolatum*, is usually made by decomposing the acid in the residuum, after the distillation of nitrous acid. It is the same with the *sal polycryst*.

The simple *aqua fortis* of the shops is made by mixing nitre and green vitriol, not calcined, of each three pounds, with a pound and a half of calcined green vitriol. This mixture is distilled with a strong fire, while any red

vapours arise. The product is a spirit of nitre, containing so much more water than Glauber's spirit, as the vitriol employed does more than an equivalent quantity of the oil of vitriol, and is liable to an admixture with the vitriolic acid, some of which generally passes over. For this the college order nitrous acid and distilled water, a pound of each, to be mixed together, and call it *acidum nitrosum dilutum*. Ph. Lond. 1788.

In the *aqua fortis duplex*, the green vitriol is calcined, and in equal quantity with the nitre, but is used only in the arts.

The *nitro muriatic acid*, called *aqua regia*, sometimes *aqua stygia*, and by Van Helmont *chrysulea*, is made by adding gradually to an ounce of crude sal ammoniac in powder four ounces of the spirit of nitre. They should be mixed in a large cucurbit, and stand in a sand heat until the salt is entirely dissolved. Or, the salt may be powdered and gradually added to spirit of a middle strength, between single *aqua fortis* and strong spirit of nitre.

The acid obtained from common nitre contains some of the marine and vitriolic acids: the first is discovered and separated by dropping in a little solution of silver; the latter by a solution of chalk, in the pure nitrous acid; the silver absorbing the marine acid, and the chalk the vitriolic, forming, with those acids, indissoluble compounds. The solutions may be slowly dropped in, until no more milkiness appears. If the spirit is required pure, it must be re-distilled.

The *cubic nitre* is a combination of the nitrous acid with soda, and is prepared according to the following process. Dissolve chalk or lime in purified *aqua fortis*, and add the solution, by degrees, to a solution of natron vitriolatum in water, while each fresh addition produces any milkiness. A white powder will be precipitated, which must be separated by a filtre, and the fluid set to crystallize.

The *nitrum flammans* of the elder chemists is the nitrated ammonia of the moderns. It is very pungent, and dissolves in rectified spirit of wine.

Solutions of calcareous earths in the nitrous acid are bitterish and pungent, crystallize with difficulty, and are deliquescent. The nitrous acid dissolves zinc, iron, copper, lead, bismuth, mercury, and silver, the most readily of all the acids, tin imperfectly, and it only corrodes the regulus of antimony, though the latter most readily. When diluted with spirit of wine, it produces a light fluid called *Æther*, q. v.

The nitrous acid agrees in its tonic power with the other mineral acids, but from its oxygen being more loosely connected with the other component parts, or from the acid being more easily borne on the stomach, it has lately been preferred to the vitriolic and marine, in cutaneous complaints, and other cases where a larger proportion of oxygen appears to be wanting (see MORBI FLUIDORUM) in the system. Its virtues in syphilis we have already noticed. See LUES.

Nitre is a very useful refrigerant, in the language of late pathologists as a powerful antiphlogistic. It restrains the too rapid current of the blood, reduces the pulse and heat of the body, and is not only a very valuable medicine in INFLAMMATORY FEVERS, and in INFLAMMATIONS, but also in HÆMORRHAGES, q. v.

In active inflammations of the throat and fauces, nitre, held in the mouth, will soon relieve. It is styled

diuretic, but it has this property only in a slight degree; and when the dose is increased, it often produces a difficulty and pain in making water. The inconveniences felt in the stomach from a large dose prevent it also from being used as a laxative. It seems to add to the virtues of camphor in removing pains in the head, and in the more violent fevers of the inflammatory kind; and, thus united, they have been celebrated, perhaps with little reason, for curing ulcers of the legs. In large doses it occasions violent pains in the stomach, bloody urine and stools, convulsions, and death. Pure nitre in solution is not affected by nitrates of silver and barytes. It should seldom be given in larger doses than fifteen grains; about ten grains is the most common and most effectual.

See Hoffman de Salium Medicorum, et de Præstantissima Nitri Virtute; Stahl de Usu Nitri Medico; Neumann's Chemical Works; Lewis's Materia Medica.

NI'TRUM ANTIQUO'RUM. See ANATRON.

NI'TRUM ARTIFICIA'LE HOFFMA'NI is made of the spirit of sal ammoniac and spirit of nitre. It perfectly dissolves in rectified spirit of wine.

NI'TRUM CALCA'REUM VE'RUM, a solution of calcareous earth in the nitrous acid. See also ACTON.

NI'TRUM FACTI'TIUM and NATI'VUM. See BORAX.

NI'TRUM STIBIA'TUM, *anodynum minerale* the salts collected by washing the residuum after making the calx of antimony. They contain but little of the antimony.

NIX. SNOW, a name given to substances which resemble snow in their colour and lightness.

NIX FU'MANS. See CALX.

NIX ANTIMONI'ALIS. See ANTIMONIUM.

NOCTAMBULA'TIO, (from *nox*, night, and *ambulo*, to walk). See SOMNAMBULO.

NOCTUI'NI O'CULI, (from *noctua*, the owl). GREY EYES, like those of the owl.

NOCTILUCA TERRE'STRIS, (*quia noctu luceat*). See CICINDELA.

NODOSA, (from *nodus*). KNOTTED. In surgery an epithet for a suture, for various bandages, and for gout, as attended with knots in the joints, in consequence of calcareous depositions. See ARTHRITIS.

NO'DULUS, (from *nodus*). A knot tied on a rag, including some medicinal ingredient with which an infusion or decoction is intended to be impregnated, as well as a bag, in which such ingredients are included.

NO'DUS, (from the Hebrew term *anad*, to tie). See GUMMA. A protuberant joint in the stem of some plants, particularly in corn and grapes, in order to strengthen their hollow culms.

NOE'LA TA'LI. The INDIAN BARBERRY TREE, with an orange leaf. It grows in Malabar; its fruit resembles barberries in their taste and virtues. See Raii Historia.

NO'LI ME TA'NGERE. *Formix*. TOUCH ME NOT. In botany, the *persicaria siliquosa*, or the *mimosa*. In surgery, a species of ulcer, and a kind of wart on the eyelid, which appears blackish, and, if touched, mortifies. Sometimes it means a cancerous sore, exasperated by medicines, or a species of *scirrhus* and *herpes*. See HERPES, POLYPUS NARIUM.

NO'MA, NO'ME, (from *nuw*, to eat away). A

phagedenic ulcer, sometimes a species of *herpes*. See HERPES.

NOMENCLA'TURA. It was the opinion of a poet of the middle ages, *Nomina si fiereunt, perit et cognitio rerum*; and the history of science shows, in the strongest light, that no impediment has so powerfully arrested its progress as a vague, imperfect, or a fanciful nomenclature. The list of synonyms has been thus unreasonably extended; and the student, misled by a name, has often found it difficult to recover the proper track. As this subject has lately engaged the particular attention of philosophers, a somewhat fuller account of their improvements, than would otherwise be necessary, may be required.

The nomenclature of a science implies its peculiar and technical terms. These have been generally kept distinct from the language of common life, perhaps at first from a wish to preserve an air of mystery, and give to the author a fancied pre-eminence above the world in general. There are, however, better reasons. In medicine we thus avoid the indelicacy of common appellations, and, in general, we escape the varying caprices of fashion; *quem penes arbitrium et jus et norma loquendi*. Some authors have adopted arbitrary appellations, particularly Van Helmont and Paracelsus, as we have seen in various articles; though it is not improbable that they had some fanciful allusion to the sources and action of the diseases and the remedies they designated. Later and more rational pharmacutists have sometimes also adopted these arbitrary terms. Modern botanists, in their appellations of new genera, have equally employed them in honour of different cultivators of their science, though probably without giving that perspicuous lustre to it which an opposite conduct might have afforded. How much superior, for instance, is the generic term *epilobium*, *επι λοβος* *ιον*, a violet on a silique, to Linnæa, Thunbergia, and Commersonia. Mineralogists have in general preferred announcing the quality and appearance by an euphonous appellation; and we hope to make some advances in the same way in the neglected doctrine of nosology. Such descriptive appellations have been preferred by anatomists, though not always formed with the most accurate precision, and more lately in the improved nomenclature of the chemists.

The object of a scientific nomenclature is to convey in one word a sufficiently distinct idea of the body or organs, to preclude a repetition of the description whenever it is mentioned. When, however, objects are numerous, and the discriminating points with difficulty seized, one word is not sufficient. This induces us, in botany, to adopt the first natural associations, styled genera, and the appellation of the genus must accompany that of the species. In nosology it is generally less necessary; in pharmacy it would be perhaps useless, as the form itself supplies the place of a genus, which in anatomy is understood from the part described.

As nomenclature has received the last polish from philology, in the chemical department, we shall first notice the improvements in its language lately introduced. We there find, among some absurdities, the descriptive language laboured with no common care, and the numerous synonyms of former systems are only retained as keys to the works of the elder chemists. The

genus is, in this case, preserved in the epithet. It is vitriolated kali, arsenical soda, sulphurated ammonia; and though we may dispute the propriety of some terms, as hydrogen or azot, they must be considered as constantly discriminating substances of distinct properties. One great difficulty arises from some of these being indeclinable. There is a want of euphony in oxygen gas, which disgusts the nicer ear; and these harshnesses pervade every branch of pneumatic chemistry. Another error in this part of the subject is a want of uniformity: thus the azot generally implies a substance in a gaseous form; but though we use the term azotic gas, oxygenated or nitrogenated gas are not allowable. Was chemistry more peculiarly our object, we might point out other anomalies which require correction. It is enough to notice those already adduced to lead chemists to a still farther reform. Dr. G. Pearson has laboured successfully in this field, and to his attention we would willingly leave it. The subject cannot be in better hands.

The improvements in the nomenclature of pharmacy have not kept pace with those of chemistry. The awkwardness arising from the indeclinable substances, kali and natron, might have been easily avoided by adopting the terms *lixivia* and *trona*; the former adopted in one of the older editions of the Edinburgh Dispensatory, and the other by Dr. Black. Many errors in nomenclature might be noticed, of which a prominent one is the *aquæ*, when applied to salts and earths in a liquid form. These are strictly solutions; and a distinction is necessary between these and the distilled waters, which are properly *aquæ*. The wines are also anomalies, which should have been avoided. They are properly infusions or solutions; but if a distinction was necessary, the old word *elixir* would have been applicable. Botanists employ single names as genera, and very generally a single epithet as a trivial distinction. These, as we have remarked, are sometimes descriptive, and the latter generally such. Single words strike the mind at once, and convey the idea unimpaired. When such single words, therefore, are sanctioned by custom, and readily understood, science is, we think, injured by a change. Thus *philonium*, *theriaca*, *cinnabar*, and some other appellations which had become denizens in the language of pharmacy, might have been, like alcohol, ether, and some others, properly retained, or at least, if changed, might have received euphonous titles *græco fonte parce detorta*; nor is it easy to say why we should deny to the pharmacists what has been so liberally granted to the botanists, the honour of giving an appellation from a name. We might consequently have retained the *confectio Fracastorii* and the *pillulæ Rufi*, when the nature of these compositions are generally understood, without any injury to science. The Edinburgh College, peculiarly eager and zealous in reform, have made their titles descriptions. We, in general, want only the vehicle and the proportions to supply the whole formula from them; and we have sometimes not only the nature of the formula, but often the means of preparing it. Another redundancy in their nomenclature is, the introduction of the trivial, as well as the generic names of plants. In pharmacy, the pharmaceutical term is only necessary. The botanical appellations are taught in other systems. The London College seems also to have refined too far, in adopting

the genitive case of the substantive instead of the adjective, according to the sound principles of the new chemical nomenclature, as *tinctura scillæ*, instead of *tinctura scillitica*. It is, in fact, a tincture possessing the nature and qualities of squills. Pharmacy is, however, a science in which method has not been introduced; but its objects are so few that arrangement is less necessary. We may, however, make some attempts to give it a more regular form in that article.

In anatomy the nomenclature is still very defective, and the synonyms, particularly of the muscles, consequently numerous. The terms superior and inferior, anterior and posterior, are fixed with little precision, and their meaning varies in different systems. Muscles are named from their shape, from their action, or the occupations in which they are used. Were the whole of the nomenclature reformed, much of minute and uninteresting description might be avoided. Vicq. d'Azyr made some unsuccessful attempts to attain greater accuracy. Chaussier's improvements were more judicious, and in osteology they merit great, though not unreserved, commendation. The same principle, however, viz. expressing by the terms the relations of proximity and connection, does not succeed so well in the myology; and the nomenclature of Chaussier, and his coadjutor Dumas, when applied to the muscles, exhibits an inelegant, unharmonious, combination of unpleasing sounds. The error is not in the principle, but in the authors' pursuing it with too great rigour. If they had aimed at less exactness they would have succeeded better.

Our countryman, Mr. Barclay, has attempted to reform the anatomical nomenclature with more success; and though the change cannot be rapidly made, we trust it will be gradually introduced. We at first intended to have employed it in the present work; but language so singular to the student would have perplexed, and might have misled him.

The terms superior and inferior are generally used with relation to the different parts of the human body in an erect position. Their force is, however, lost in a reclined one, and neither is peculiarly applicable to the relative organs in other animals. In the *TRUNK*, therefore, for these Mr. Barclay proposes the terms *atlantal* and *sacral*, from the two extremities of the spine; for anterior and posterior, which are subject to similar ambiguities, *sternal* and *dorsal*; for internal and external, *dermal* and *central*; or, with respect to an organ, *peripheral* or *central*. When external and internal signify the side and middle of a surface, suppose a plane, styled *mesion*, to pass along the middle of the neck, the *mediastinum* and *linea alba*, through the body parallel to the surface, then *lateral* and *mesial* may be the terms employed. Instead of right and left, Mr. Barclay employs *dextral* and *sinistral*, as less equivocal in some parts of comparative anatomy, or, when there is no occasion for distinction, *lateral* will be sufficient. In the *HEART*, what anatomists have styled the right and left ventricles are neither; and the terms anterior and posterior, though more correct, are not always applicable to comparative anatomy. Mr. Barclay's distinction in this case, perhaps less simple than the others, is to term the vessels which convey the blood *from* the lungs to the whole body, viz. the pulmonary veins, the left sinus, auricle, and ventricle, with the aorta and its branches,

systemic; those which carry it to the lungs, the *pulmonic*; and in marking their relative situation to the trunk, or to each other, the terms *atlantal*, *sacral*, &c. already mentioned, may be employed.

The *EXTREMITIES* are termed *atlantal* or *sacral*; the ends of the bones nearest or farthest from the trunk, *proximal* and *distal*. In the *atlantal* extremities the two lateral parts are, with Winslow, styled *radial* and *ulnar*, the two others *anconal* (from *ancon*, the Greek word for *olecranon*) and *thenal* (from *thenar*, the Greek appellation of the *palm*); but the peculiar term for the palm, in Mr. Barclay's system, is *vola*. The distinguishing aspects of the *sacral* extremities will, by similar reasoning, be *proximal* and *distal*; *dermal* and *central*; *tibial* and *fibular*; *popliteal* and *rotular*. *Planta* is the term for the sole on the popliteal side of the foot.

The usual terms of superior and posterior, &c. when applied to the *HEAD*, become very equivocal in those general discussions where the heads of animals, as well as men, are described. Mr. Barclay, therefore, proposes that the axis of the vertebral column should be, in imagination, prolonged till it meets some bone in the head or face. This bone he would call the *atlantal*; those opposite to them, at the basis of the skull, *sacral*. The terms *sternal* and *dorsal*, when applied to the *head*, are those parts in the same plane, or in planes parallel to the sternum and dorsum. Where these are parallel, the planes on the sternal side will always be *sternal*, and the contrary. In the human species the whole face and lateral sides of the head will be *sternal*; in sheep and oxen the maxillary curves will be so only; and in frogs and serpents the basis of the skull will be *sternal*, and the maxillary curves *dorsal*.

With respect to the particular bones of the *FACE*, *dermal*, *central*, *distal*, *sinistral*, and *mesial*, are applicable; but five new ones are required; for the base and crown, the hind fore part of the cranium, and for the face. The two first are to be styled the *basilar* and *coronal* aspects; the occiput, the *inial*, from *inior*, its Greek name. The opposite side to the inial, where the bones of the nose are united to the os frontis, he styles *glabellar*, from its Latin appellation *glabella*. The part of the face, at the greatest distance from the occiput (*inion*), in a straight line, is styled the *antinion*. If lines are drawn through these aspects, or from the right and left, they will form the *corono-basilar*; the *inio-glabellar*, the *inantilial*, and the *dextro-sinistral* diameters. The measure of these different diameters will show the varying proportions of the heads of different animals, of the same species, or of others in the lower scales. The facial angle and its variations we have already noticed. (See *CRANIOLOGIA*.) These terms, by altering the termination, may be used adverbially so as to signify a direction towards either aspect, and this termination is in *ad*, instead of *ab* and *ar*; and by changing it to *en*, it may express connexion. Thus a radial artery or muscle may be either with a radial aspect, while a radien artery enters the radius itself.

Such is the plan of Mr. Barclay, which, it may be observed, is in embryo only, neither co-extensive with what anatomy has demonstrated, nor with the great variety of animated nature in its different branches. Yet, in its present state, this nomenclature merits particular commendation; and, if divested of some refinement, par-

ticularly the mesion, which should perhaps be rendered more simple and familiar, might with great advantage be adopted. We know nothing less easily comprehended by the untutored mind than the doctrines of planes.

The nomenclature of muscles he has only slightly noticed in his introduction. We have already remarked, that the fixed point is named the origin, and the muscle is "*inserted*" into the bone to be moved. This, however, is at times with difficulty ascertained; nor is the motion usually performed by a single, or by a few, muscles. Many concur in fixing the origin; others in giving force and direction to the motion. Mr. Barclay proposes that the muscles should be classed from their origin and their insertion, and the name fixed from the most obvious distinction, neglecting the origin of the minuter bundles of fibres. Thus the *sterno-humeral* can mean nothing but the *pectoralis major*, which, in the nomenclature of Chaussier, is the *sterno-costoclavio-humeral*. In the blood vessels he points out the necessity of an uniformity of language; for the appellations of arteries often differ, as the names of the organs to which they are distributed vary. This, of course, requires an uniformity in the appellations of the organs themselves. The same name is at present often employed also to express two different relations, as the artery which runs along the humerus, and that which enters it is equally called *humeral*. Branches of arteries, and often minute branches, are sometimes honoured with a name, while the trunk from which they proceed is not distinguished by any. Such anomalies require a remedy; and we should be happy to find the language of anatomy freed from its great uncertainty and barbarous language.

Nosology, yet in its infancy, has had the advantages of the attention of Linnæus and Cullen, who have laboured to render its language euphonous, without greatly departing from the received appellations. They had, indeed, before them the Greek terms, which they could easily reduce to the Latin orthography, and they wanted no more. Selection was alone necessary, and we find no proofs of defective taste. In generalizing the inferior groups, it has been sometimes necessary to employ terms in a new signification, in the nosological sketch offered in the present volume. We trust that they have been selected with sufficient care.

See Barclay's *New Anatomical Nomenclature*; Chaussier's *Tabular View of the Skeleton*; Pearson's *Chemical Nomenclature*; Dickson's *Essay on Chemical Nomenclature*, with Kirwan's *Observations*; Linnæi *Critica Botanica*; Culleni *Nosologia*.

NONA'NA, (from *nonus*, the *ninth*). An erratic intermittent, returning every ninth day.

NON-NATURA'LIA. The *NON-NATURALS*. A fanciful term given to functions or accidents not strictly belonging to man: as, air; aliment; exercise and rest; passions and affections of the mind; wakefulness and sleep; repletion and evacuation.

See Dr. Fr. Clifton's *Translation of Hippocrates on Air, Water, and Situation*; Wainwright on the *Non-naturals*; Sanctorius's *Medical Statics*; Keil's *Animal Economy*; Mackenzie on *Health*.

NO'NUS HU'MERI MU'SCULUS PLACE'N-TINI. The ninth muscle of the shoulder. See *CO-RACO-BRACHÆUS*.

NORLANDICÆ BACCÆ. The cooling subacid fruits of the *rubus arcticus* Lin. Sp. Pl.

NORTHAW, or NORT HALL WATER, is of the purging kind, and similar to that of Epsom, but not so strong or so nauseous. It contains a little calcareous earth, selenite, with a small proportion of sea salt, and is slightly purgative.

NOSOCO'MIUM, NOSODO'CHIUM, (from νοσος, a disease, and κομω, to take care of, or δεχω, to receive). AN HOSPITAL.

The institution of hospitals, coeval probably with the era of Justinian, was the first effort of Christian charity, taught by its great master, who commanded us to love one another, and that HE was our neighbour who showed mercy. It is impossible to conceive a more pure philanthropy than the institution of a receptacle where the only claim to admission is the immediate necessity of relief; where to want is the only requisite to demand a supply. Ancient philosophy offers nothing so exalted; and even the benevolent host of Homer, who sat by the way side to assist travellers, *παῖς γὰρ φιλεῖσκε*, can scarcely exceed it. With regret, however, we learn, that the mortality of hospitals exceeds even the calculation that can be made from the state of the objects admitted. We allude not to the mortality of the Hotel Dieu, which may literally be said to contain the victims of the Almighty, but to modern institutions, where, perhaps ancient regulations are still too strictly followed. To consider the subject carefully, we shall first add some remarks on the construction of hospitals generally, and then apply them with those modifications which their particular object may seem to suggest; nor will this attempt be thought presumptuous in one who has been physician in a large hospital for thirty-three years.

Were a situation to be chosen for an hospital, it should be an elevated, dry spot, facing, as near as possible, east and west, for the sake of alternate changes of air and warmth. The building, at least the wards, should be single, so as to admit of transverse ventilation, and the windows should be from the top to the bottom, open at either extremity, carefully secured, however, at the bottom, to prevent air from crevices. The length of the ward should not exceed thirty feet, and it should be rather more than half that breadth. The beds should be placed at right angles to the wall, and there should be a window between every second bed. If the door is at one end, and the fire place at the other, one fire will be sufficient: if in the middle, there should be two. In this way the ventilation will be complete. The windows may be opened on either side, in different degrees, according to the state of the wind or weather, either above or below. The under windows should be opened for a short time every day, on either, or on both, sides, according to external circumstances; for carbonic acid gas is heavy. A ward, when opened, cannot always smell fresh and pure; but it should not be offensive or close. If the beds are parallel and close to the sides, the floor cannot be ventilated; if more numerous, the air cannot be admitted to each patient. We have not mentioned ventilators on the top; for if the temperature be moderate they will be useless, and they cannot be applied to a ground floor.

The privies should be at each extremity of the ward; but if that is impracticable there should be one in each,

and always separated from the ward by a short passage, in which there should be a ventilator or a window. If possible, each should be a water closet; but the dressings and the contents of the night boxes should be always immediately immersed under water.

The separate apartments for particular complaints should not be small, but should never contain more than two beds on the opposite sides of the room, while the door and the window on the two other sides will contribute to the ventilation. The chimney, if one is necessary, may be in the angle. If required for patients who may be occasionally in violent pain, in convulsive paroxysms, and delirium, they should be separated from the ward by a short passage. For the sake of attendance, they must be contiguous.

The offices containing the baths, the brew and bake houses, the elaboratory, &c. should be separated from the principal building, that they may not render it too warm; and the apartments for hectic and asthmatic patients should be also separated. These may be in pavillions, joined to the house by a colonade, which the architect may render ornamental, though this is of less importance. If any apartments are connected with the offices, it should be those adapted for chronic rheumatism, for syphilis, and for amenorrhæa. The colonade may furnish covered walks open to the north and south, and over these the apartments just mentioned may be situated. From this sketch it will be easy, we think, to construct an hospital, which will unite every advantage to be expected from such an institution.

In the arrangement of the house every impurity should be immediately removed, and every noxious matter immediately immersed in water; and, after the dressing of the sores, the upper and lower windows should in turn be for a short time opened, while the patients are secured from their effects by their bed clothes. The linen should be changed, not from the regulations of time, but of circumstances, under the directions of a judicious apothecary. Air and cleanliness will make all aspersions with vinegar and all fumigations useless.

Ointments afford an offensive smell; for the axunge cannot be long preserved free from rancidity. It is, therefore, highly proper that those plasters only which are employed in peculiar circumstances should be spread in the ward; and Dr. Percival's advice of using mucilage with neatsfoot oil, occasionally united with Gowland's extract, instead of the common plasters, is judicious. If lintseed meal be used, even the oil will be unnecessary.

The diet of hospitals is regulated by custom, which it is heresy to attack; nor is it indeed necessary to notice it particularly, since any occasional errors may be corrected by the physician. Perhaps, according to Dr. Percival's advice, salep may be occasionally substituted for rice, and malt infusion for beer; but his other observations in this respect rest too strongly on a disputable foundation, experiments out of the body.

Iron bedsteads will neither retain infection nor bugs; and their upper ends should be raised with a screw. It would be always proper to have supplementary wards; for nothing should hinder each ward from being white-washed, thoroughly cleaned, and the window frames painted, in distemper, every year. The beds also should be repeatedly ripped, and their contents aired.

See Percival's Thoughts on Hospitals, and the Memoires de la Societ  Royale de Medecine.

NOSOLOGY, (from *nosos*, a disease, and *logos*, a discourse). NOSOLOGY. When the numerous advantages of arrangement were so conspicuous in the advancement of botany, it was soon extended to many other branches of natural knowledge; and as the great end to be obtained from it was a ready and accurate distinction of species, it was soon suspected that it might be highly useful in sciences where discrimination was equally difficult and important. Yet, except in the arrangement of the vegetable kingdom, method has seldom been found singularly useful. In zoology it has connected animals of a nature very discordant, and living in elements essentially different: in mineralogy it has been obliged, till lately, to borrow assistance from the laboratory; and in medicine it has connected the most trifling with the most important diseases, and maladies of a nature very dissimilar. Even in botany, where its utility is acknowledged, the endless disputes which have arisen respecting the principles of arrangement, have at last subsided in the establishment of an artificial system, chiefly because it has been extended with the rapidly increasing bounds of our knowledge. Many of these difficulties, as well as their source, are easily understood. Systems are the work of our own minds; for nature advances by almost imperceptible shades; and where we can point out the termination of one family, and the commencement of another, it is only confessing that the intermediate link is unknown: thus, when our knowledge advances, the advantages of our systems lessen, for our limits are lost.

This disadvantage is felt even at the first step of our analysis of the objects of nature, namely, in our discrimination between the animal, vegetable, or mineral kingdom, and follows, with equal inconvenience, every subordinate distinction. It is felt less in artificial arrangements, and affords a strong argument in their favour; so as, in the opinion of many naturalists, even to counterbalance the advantages of a natural method. It is very inconvenient in mineralogy, where the component parts and the obvious qualities often differ very strikingly.

What, however, was so useful an assistant in botany, what was at least not injurious in zoology, and advantageous in the lower orders of animated nature, was tried with very unequal effect in mineralogy and diseases; but of mineralogy we have already spoken. The arrangement of diseases is still in a very imperfect state. To the inconveniences which attended the arrangement of minerals, some difficulties, apparently insurmountable, were added. If the forms, the hues, and other properties of the mineral forbade us to expect uniformity, the infinitely more fleeting, the more minutely varied forms of diseases seemingly mocked every attempt to bring them within the limits of a definition. If a foundation could be obtained, it was apparently by considering the disorder as connected with an internal change, which would then afford what might be styled an object, whose properties we might examine. This, however, increased the difficulty, for few would agree respecting this change; and the system must vary with the opinion, perhaps the fancy, of physicians respecting what we now call the immediate or proximate

cause. To this must be added, that, in a strict systematic view, the error would not be less than in classing minerals from their component parts, in other words, their chemical nature, as we have already observed. (See CAUSA and MORBUS.) It was necessary then to consider each disease as a concurrence of symptoms, in general fixed, leading to an injured function, and to some permanent change in the system, whatever it might be. In this way the disease is the unknown algebraical quantity designated by a letter; but this letter, in the hands of the mathematician, may be managed as readily as a determined object. It may have powers and proportions ultimately depending on the value to be discovered; but, at the same time, independent of it. Thus we can speak of a fever, its degree, its changes, and cure, without attempting to examine in what it consists. We can distinguish an unknown change by symptoms, and can arrange it from these alone. The importance of distinction will be at once obvious, when we recollect the extensive disquisitions in which every practical author engages under the head of diagnosis. Sydenham, certainly no friend to fanciful refinements, was seemingly the first author who suggested this method; and Gaubius, who had seen the systems of Sauvages, of Linn us, and probably of Vogel, hopes that an attempt so happily begun will soon be perfected. Since the time of Dr. Cullen, we have witnessed few attempts of this kind; and the neglect certainly has not arisen from the degree of perfection his arrangement has attained.

Nosology is seldom mentioned, but to be ridiculed or despised. Some late authors who have pretended to oppose it, have, in their arguments, shown not only their ignorance, but the necessity of the study; and those who have adopted systems of arrangement, have demonstrated that they have little attended to its principles. If nosology does not render the distinction of diseases easy and comparatively obvious; if, by bringing disorders of a similar nature together, it does not elucidate them as well as the method of treatment, it is useless, and will be deservedly neglected. We shall endeavour to show that each end may be readily obtained.

The reasons which have impeded the advancement of nosology are numerous; but it is needless to examine them minutely: even Linn us, by whom method had been so much improved, has wholly lost sight of his own rules, when applied to the arrangement of diseases; and Dr. Cullen, who has formed a system, imposing from its simplicity, elegance, and perspicuity, has erred in the threshold, by his first separation of general from local diseases. Yet no distinction appears more clear, more obvious, or on a more secure foundation: the difficulty is felt only in the application, and is soon perceived when we find the same disease sometimes general, sometimes local, and varying, with almost undistinguishable shades, from one to the other. To connect the feverish disorders into one class is equally judicious in appearance; but a similar objection recurs. The same disease is often attended with fever, and is occasionally without it, and this in almost every degree. Even in the genus *cynanche*, which he laboured with no common care, and in which he thought himself peculiarly successful, he has erred against his own principles; and formed, as we have

seen, *vide in verbo*, an association wholly discordant, merely from the vicinity of the parts affected.

It is singular that even in botany Linnæus began with establishing classes and orders; Ray and Jussieu in their more natural systems did the same, and perhaps it is unavoidable. The mind catches at the larger associations, and, captivated with their simplicity, or their theoretical connections, makes the subordinate parts bend to their powerful influence. The error is probably unavoidable: the fault consists in continuing to wear the fetters, when their weight and inconvenience is felt. Dr. Cullen, for instance, had an order of profluvia, which he placed in the class *pyrexia*, and thus limited the genera, omitting the catarrhus vesicæ, gonorrhœa, leucorrhœa, and many similar diseases. When this inconvenience was felt, he should perhaps have rejected the class. If he retained it in order to have an association strictly natural, his system was defective; for the nature of the other complaints was the same, the treatment in many respects similar.

The great difficulty which has, however, been felt by every systematic author, is to ascertain what individuals are species, and what varieties. Even in botany, where the species are now clearly distinguished, it was once so difficult, that in the system of the accurate Tournefort, one third of the species have been found varieties. In mineralogy the species are not yet clearly fixed; and, for obvious reasons, many fluctuations in the arrangement must take place before these can be ascertained. This difficulty is peculiarly felt in nosology, and it will be advantageous to consider the subject more fully.

Linnæus has justly observed, that the species are, in number, equal to the individuals created. Yet this remark affords little assistance to the systematic botanist. If he finds a plant differing in bulk and size only, with the more essential parts in some degree imperfect, he will readily suppose it to be a variety, changed in consequence of a less genial climate. In any greater difficulty he sows the seed, and finds, by degrees, the variations less. Though the botanist has many other resources in ascertaining the distinction between species and varieties, yet these are the more important methods, and peculiarly applicable to the present subject. Thus the erysipelas, which in the north assumes a phlegmonous appearance and nature, in a crowded metropolis must be treated with cordials and tonics. The remittent fever, which chiefly requires evacuations, with a moderate proportion of bark in temperate climates, soon proves fatal without a very different treatment within the tropics. The diseases are confessedly the same, and these are consequently varieties. The erysipelas and the remittent fever are therefore species.

Again: the small pox is a disorder propagated by infection. The seminum may be consequently considered as the seed of a plant. We know that the most distinct kind, in a bad constitution, and, by experiments probably not strictly justifiable, that the worst matter in a good one, will produce respectively a bad and good kind. Similar instances occur in the epidemic measles. These are cases analogous to the mode in which the botanist distinguishes species from varieties, and the variola and rubeola are consequently species,

If a botanist meets with a plant to him unknown, he at once supposes it a new species, or a variety of one formerly known. If it does not agree with any known group of species, for these constitute a GENUS, *q. v.* he supposes it a new one, or at least the fixed point to which others may be referred. It is a common error to say that a naturalist has discovered a new genus; for a genus is an association. If this be true, and we fear no contradiction, the real source of nosological error and difficulties is at once cut off, and we may proceed with the same steadiness and success which has crowned the labours of the botanist. The difference only is, that the sub-species or the varieties are of more importance than in other departments.

The great advantage of nosology is distinction, and the discussions connected with arrangement are so many points of discrimination, which the proper order has suggested. If the place of a disease cannot be ascertained, it is evident that the symptoms have been inaccurately described. One circumstance is, however, still wanting; the accurate discriminate language of description so useful in botanical arrangement. We still want a delineatio morbi in imitation of the delineatio plantæ in Linnæus.

The first attempt at classification of diseases was made by Sauvages. It was published in a more abridged form in octavo, before that vast mass of medical erudition, his two quarto volumes, were completed. It was first styled *pathologia*, and the name was changed to prevent its being confounded with a branch of the institutions of medicine. His first class was VITIA, slight cutaneous diseases, or such as require chirurgical assistance. The second, FEBRIS; the third, PHLEGMASIÆ; the fourth, SPASMI; the fifth, ANHELATIONES (difficult respiration); the sixth, DEBILITATES; the seventh, DOLORES; the eighth, VESANIÆ; the ninth, FLUXUS; and the tenth, CACHEXIÆ. Linnæus brought to this office all his comprehensive accuracy, with a quaintness of language which, when explained, is no longer displeasing. The EXANTHEMATICI are eruptive; the CRITICI, common fevers; and the PHLOGISTICI, fevers attended with inflammation. The DOLORESI are painful diseases; MENTALES consist in the abolition of judgment; the QUIETALES of motion; the MOTORII in involuntary motions; the SUPPRESSORII in obstructions of the natural passages; and the EVACUATORII in evacuations. The DEFORMES are changes in the solids, and the VITIA those of the surface. The classes of Vogel, whose work appeared in 1764, are, FEBRIS, PROFLUVIA, EPISCHESES (suppressions); DOLORES, SPASMI, ADYNAMIÆ (debilities); HYPERÆSTHESES (more acute or depraved sensations); CACHEXIÆ, PARANOIÆ (aberrations of mind); VITIA, superficial, and DEFORMITATES, more solid deformities.

Sagar, who published his nosology in 1776, has divided diseases into thirteen classes; VITIA; FLAGRÆ (wounds); CACHEXIÆ; DOLORES; FLUXUS; SUPPRESSIONES; SPASMI; ANHELATIONES; DEBILITATES; EXANTHEMATICA; PHLEGMASIÆ; FEBRES; and VESANIÆ. Dr. Cullen's classes are few: PYREXIÆ, NEUROSES, CACHEXIÆ, and LOCALES.

The last general work on this subject is the philosophical nosography of Pinel, differing little in its outlines

from the common systems, but with too great refinement, and, we think, useless minuteness in the subdivisions. The classes are FEVERS, INFLAMMATIONS, ACTIVE HÆMORRHAGES, NŒUROSES, LYMPHATIC DISEASES, with an indeterminate class. The existence of the last shows a want of those comprehensive views which every systematic author should possess; but as the work is not generally known, we shall pursue our account of it in the more subordinate divisions.

The first class of FEVERS contains six orders; the *angi-stenic* (inflammatory); the *meningo-gastric* (bilious); the *adeno-meningeal* (pituitous, containing the hectic and intermittents); the *adynamic* (putrid); the *ataxic* (malignant); and the *adeno-nervous* (the plague). We need scarcely observe, that in this arrangement fevers of the same type, of similar appearances, which are relieved by the same remedies, are scattered in different orders, from the occurrence of an accidental symptom: the genera are consequently, in many instances, varieties only. The plague is perhaps properly a fever; but it should have been arranged among the ataxic or adynamic diseases of our author.

The inflammations are divided into five orders; 1. the inflammation of *mucous membranes*; 2. of *diaphanous* ones; 3. of the cellular substance, the glands, or the parenchyma of the viscera; 4. of the muscles; 5. cutaneous inflammations, including the exanthemata.

The active hæmorrhages are those common to both sexes, and uterine hæmorrhages.

The nervous diseases contain four orders; 1. the *vesaniæ*, not febrile; 2. *spasms*; 3. *local anomalies of the nervous functions*; and 4. *comatous* affections.

The fifth class contains three orders; 1. *cutaneous diseases*; 2. *diseases of the lymphatic glands*, including phthisis, lues, and rachitis; 3. *dropsies*.

The undetermined class contains the jaundice of new born children: *diabetes*; *worms*; the bites of insects and serpents.

We need not add any remarks on this arrangement. Its imperfections will be at once obvious, nor is it one of the least, that often the general, frequently the subordinate, divisions, rest on the uncertain foundation of a theory; of theory, at least, not generally admitted in this country.

Were we to proceed to the genera we should find them badly arranged, imperfectly distinguished, with numerous omissions. Indeed, for many diseases, the author's system has no place.

A more limited system is that of Selle, whose *Rudimenta Pyretologiæ Methodicæ* was the subject of his thesis, and re-published at Halle in 1770, under the title of the *Methodi Febrium Naturalis Rudimenta*, and afterwards in a more extensive form, under the first title, at Berlin in 1786. As it is highly commended, and often quoted, we shall give a somewhat more extensive view of it than of the former systems.

The first order of fevers is styled *continentes*, divided into two genera, the *inflammatory continent*, and the putrid. The second order contains the *remittentes*, divided into the *gastric* or *bilious*, the *bilious inflammatory* fever, the *bilious putrid*, and the *pituitous* fever. The last is sub-divided, as it is combined with α , a wormy colluvies, ϵ , a metastasis of milk to the abdominal viscera, γ , internal ulcer, δ , obstruction of the viscera.

The third order is styled the *ataxiæ*, viz. the nervous and putrid fevers; and these are divided into the *sporadic*, *nervous* fever; the *epidemic from contagion*; and the *slow nervous* fever.

The fourth order is entitled *intermittentes*; and the genera are, the *inflammatory*, *bilious*, *pituitous*, *wormy*, and *nervous* intermittents.

The active inflammations are included under the inflammatory continent fever; and to these are added, in separate sub-divisions, *erysipelas* and *rheumatism*. Under the same genus we find the complications of *catarrh*, *dysentery*, and *exanthemata*. Many of these are repeated under the putrid continent fever, and under the different genera of remittents, with little accuracy of distinction.

Under the acute sporadic nervous fever we find as species, *phrenitis*, *hydrophobia*, and *febris soporosa*; and, under the contagious nervous fever, the *plague*, which in its mildest form is placed as a variety of putrid nervous fever.

To the last edition Selle has added natural classes of diseases. These are INFLAMMATORY, PUTRID, BILIOUS, PITUITOUS, WORMY, MILKY, NERVOUS, PERIODICAL, OBSTRUCTIONS, GOUTY, RICKETY, SCROFULOUS, CANCEROUS, VENEREAL, SCABIOUS, SCORBUTIC, POISONOUS, and ORGANIC. This is evidently only an outline, for the genera are not filled in, and it will be obvious that they depend almost exclusively on causes, and are consequently theoretical. They approach nearly in the manner of their formation the natural orders of plants by Jussieu.

These are the chief systems founded, or pretended to be founded, on symptoms; for the arrangement of Macbride into universal, local, sexual, and infantile diseases, scarcely merits our attention in this place. If we were to examine each system, it would appear that, except in those of Linnæus and Cullen, there is no arrangement of classes, no traces of what in the article botany we have styled a *methodus*. The *methodus* of Linnæus is somewhat fanciful, that of Dr. Cullen into universal and local diseases, as we have remarked, injurious. In all, the fundamental error appears of forming classes without having ascertained species; so that in reality the classes are orders, and the orders, in general, claim no higher rank than the first associations of species, *genera*. In general we may remark, that there are some associations so obvious, that they at once seize the attention of every nosologist, for no one thinks of separating fevers or inflammations, and, except Dr. Cullen, the passive hæmorrhages and profluvia from the active. Each slides into each other by such insensible shades, that we know not where the one begins and the other ends.

Another error, which seems to pervade every system, consists in the definitions. The symptoms are seldom scientifically arranged so as to facilitate investigation. In botany, either the character of the sections, or the first part of the character, at once informs the student whether the plant belongs to that species or to one far below. The nosologists have collected their symptoms with little care, and in their anxiety to distinguish diseases have rendered their definitions almost complete descriptions. This is particularly the error of Vogel and Sagar. To render their works also complete, they

have included the minutest deviations from the natural appearance, forgetting that it was an arrangement of diseases, the essence of which consists in injured functions.

Reflecting on these natural groups, and having established in our minds the distinctions between varieties, species, and genera, it occurred to us whether diseases might not be arranged in imitation of the natural orders of the botanists; and having succeeded at least to our own satisfaction in this attempt, we laid the foundation of it in what may have appeared the disproportioned or inapplicable inquiry into the foundation of natural methods in BOTANY, q. v. We shall therefore add

a new, and what appears to us an improved classification of diseases on the same principles.

The orders in this arrangement are twelve: PYREXIE, PHLEGMASIE, ERUPTIONES, PROFLUVIA, SUPPRESSORII, SPASMI, ADYNAMIE, PARANOIE, CACHEXIE, INTUMESCENTIE, ECTOPIE, PLAGE. In this arrangement there is a concealed methodus, which, as it is not an object of importance, we need not explain farther than by adding, that feverish complaints, increased and diminished evacuations, increased, diminished, and irregular nervous excitement, diseased fluids, appearing either in increased or diminished bulk, the displacements and solutions of continuity, follow in order.

Order I. PYREXIE.

Genus I. INTERMITTENS.

- Sp. 1. Quotidiana.
2. Tertian.
3. Quartana.
4. Erratica.
5. Complicata.

Genus II. EXACERBANS.

- Sp. 1. Mitis.
2. Maligna.
- α *Autumnalis.*
- β *Icterodes,*
- γ *Asthenica.*
3. Hectica.

Genus III. CONTINUA.

- Sp. 1. Synocha.
2. Typhus.
- α *Carceraum.*
- β *Neurodes.*
- γ *Gastrica.*
3. Synochus.

Order II. PHLEGMASIE.

Genus I. INFLAMMATIO.

- Sp. 1. Phlegmon.
2. Ophthalmia.
- α *Epidemica.*
- β *Sporadica.*
- γ *Tarsi.*
3. Phrenitis.
4. Cynanche.
- α *Faucium.*
- β *Tracheæ.*
- γ *Parotidea.*
5. Pneumonia.
- α *Pleuritica.*
- β *Peripneumonica.*
- γ *Diaphragmatica.*
- δ *Hepatica.*
- ε *Rheumatica.*
6. Hepatitis.
7. Carditis.
- α *Mediastina.*

β *Pericarditis.*

8. Gastritis.
9. Enteritis.
- α *Mesenterica.*
- β *Epiphloitis.*
- γ *Peritonitis.*
- δ *Rheumatica.*
10. Nephritis.
11. Cystitis.
12. Hysteritis.
13. Odontalgia.

Genus II. PHLOGOSIS.

- Sp. 1. Erythema.
2. Phrenitica.
3. Anginosa.
4. Pneumonica.
5. Puerperalis.

Genus III. CATARRHUS.

- Sp. 1. Coryza.
- α *Contagiosa.*
- β *Senilis.*
- γ *Arthritica.*
- δ *Trachealis.*
2. Dysenteria.
- α *Epidemica.*
- β *Sporadica.*
3. Phthisis.
4. Cœliaca.
5. Leucorrhœa.
6. Cystirrhœa.
7. Gonorrhœa.
8. Leucorrhœis.

Genus IV. ARTHRITIS.

- Sp. 1. Rheumatismus.
- α *Lumbago.*
- β *Ischias.*
- γ *Pleurodyne.*
2. Arthrodynia.
3. Podagra.
4. Hydrarthrus.
- α *Coxarius.*
- β *Genu.*

Genus V. EXOSTOSIS.

- Sp. 1. Perioste.

Order III. ERUPTIONES.

Genus I. EXANTHEMA.

§ I. Epidemicum.

- Sp. 1. Variola.
- α *Confluens.*
- β *Crystallina.*
2. Vaccina.
3. Rubeola.
- α *Maligna.*
- β *Variolodes.*
4. Varicella.
5. Milliaria.
- α *Purpura.*
- β *Alba.*
6. Scarlatina.
- α *Cynanchica.*
7. Erysipelas.
8. Pestis.
9. Pemphigus.
10. Aphtha.
- α *Maligna.*

§ II. Sporadicum.

11. Urticaria.
12. Strophulus--Infantum.
13. Achor.

Genus II. EFFLORESCENTIA.

- Sp. 1. Psora.
2. Prurigo.
- α *Pudendi.*
- β *Senilis.*
3. Lichen.
4. Petechia.
5. Vibex.
6. Phlyctena.
7. Herpes.
8. Tinea.
9. Eczema.

Order IV. PROFLUVIA.

Genus I. HÆMORRHAGIA.

- Sp. 1. Epistaxis.
 2. Stomacace.
 3. Hæmoptysis.
 α Febrilis.
 β Asthenica.
 4. Hæmatemesis.
 5. Melæna.
 6. Hæmorrhœis.
 7. Mænorrhagia.
 8. Hæmaturia.
 α Febrilis.
 β Senilis.
 9. Vicaria.
 α Narium.
 β Pulmonum.
 γ Ventriculi.
 δ Venarum Hæmorrhoidalium.
 ϵ Vesicæ.
 ξ Gingivarum.

Genus II. APOCENOSIS.

- Sp. 1. Vomitus.
 α Cholera.
 β Pyrosis.
 γ Atonica.
 2. Diarrhœa.
 α Lienteria.
 β Aquosa.
 3. Diabetes.
 α Mellitus.
 β Mucilaginosus.
 4. Diuresis.
 α Chronica.
 β Spasmodica.
 5. Ephidrosis.
 6. Plica.
 7. Epiphora.
 8. Ptyalismus.
 α Hydrargyratus.
 β Paralyticus.
 γ Mellitus.
 9. Exoneirosis.

Order V. SUPPRESSORII.

Genus I. CONSTRICTORIA.

- Sp. 1. Dysphagia.
 2. Obstipatio.
 α Pylori.
 β Intestinorum.
 γ Recti.
 3. Polypus.
 α Narium.
 β Cordis.
 γ Uteri.

Genus II. ANHELATIO.

- Sp. 1. Asthma.
 α Spontanæum.
 β Plethoricum.
 γ Senile.
 2. Dyspnœa.
 α Catarrhalis.

- β Terrea.
 γ Aquosa.
 δ Organica.
 ϵ Venenata.

Genus III. EPICHESES.

§ I. Sanguinis.

- Sp. 1. Amenorrhœa.
 2. Dyslochia.
 3. Dyshæmorrhœis.

§ II. Excretorum.

4. Icterus.
 α Calculosa.
 β Biliosa.
 γ Spasmodica.
 5. Ischuria.
 α Renalis.
 β Ureterica.
 γ Vesicalis.
 δ Urethralis.
 6. Dysuria.
 α Ardens.
 β Spasmodica.
 γ Compressionis.
 δ Irritata.
 7. Sitis.
 8. Dyspermatismus.
 α Organicus.
 β Spasmodicus.
 9. Agalaxis.

Order VI. SPASMI.

Genus I. TONOS.

- Sp. 1. Trismus.
 α Infantum.
 β Traumatica.
 2. Tetanus.
 α Opisthotonus.
 β Emprosthonus.
 γ Catochus.
 3. Contractura.
 α Colli.
 β Artuum.
 4. Priapismus.
 5. Strabismus.

Genus II. CLONOS.

- Sp. 1. Epilepsia.
 α Cerebralis.
 β Sympathica.
 γ Irritata.
 2. Convulsio.
 α Idiopathica.
 β Irritata.
 3. Hysteria.
 α Asthenica.
 β Irritata.
 4. Chorea.
 5. Raphania.

6. Palpitatio.
 α Hysterica.
 β Irritata.
 7. Pertussis.
 8. Colica.
 α Stercoraria.
 β Venenata.
 9. Hydrophobia.
 10. Pandiculatio.
 11. Beriberia.

Order VII. ADYNAMIÆ.

Genus I. COMA.

- Sp. 1. Carus.
 α Catalepsis.
 β Ecstasis.
 2. Apoplexia.
 α Sanguinea.
 β Serosa.
 γ Hydrocephalica.
 δ Asthenica.
 ϵ Suffocata.
 ξ Metastatica.
 3. Paralysis.
 α Hemiphlegia.
 β Paraplegia.
 γ Partialis.
 δ Venenata.
 4. Syncope.
 α Cardiaca.
 β Metastatica.
 γ Occasionalis.
 δ Angens.

Genus II. ANEPITHYMIA.

- Sp. 1. Anorexia.
 2. Dyspepsia.
 α Idiopathica.
 β Metastatica.
 3. Chlorosis.
 4. Amentia.
 5. Amaurosis.
 α Intermittens.
 β Nyctyalopia.
 6. Agenesia.
 7. Atrophia.

Order VIII. PARANOIÆ.

Genus I. MOROSITAS.

- Sp. 1. Bulimia.
 α Helluonum.
 β Syncopalis.
 γ Convalescentium.
 2. Pica.
 α Chlorotica.
 β Pregnantium.
 γ Afrorum.
 3. Hypochondriasis.
 α Nostalgia.

E

Genus II. HALLUCINATIO.

- Sp. 1. Satyriasis.
2. Nymphomania.
3. Erotomania.

Genus III. VESANIA.

- Sp. 1. Melancholia.
2. Mania.
 α *Mentalis*.
 β *Metastatica*.
 γ *Venenata*.
 Paraphrosyne. Auc-
 torum.
3. Oniroidynia.
 α *Activa*.
 β *Gravans*.

Order IX. CACHEXIÆ.

Genus I. IMPETIGO.

- Sp. 1. Scorbutus.
2. Syphilis.
3. Aurigo.
4. Phænigmus.
5. Melasma.
6. Rubigo.

Genus II. MACULA.

- Sp. 1. Echymosis.
2. Petechia.

Order X. INTUMESCENTIÆ.

Genus I. TUBER.

§ I. *Universi*.

- Sp. 1. Polysarcia.

§ II. *Partium*.

2. Rachitis.
3. Exostosis.
4. Physconia.
 α *Hepatica*.
 β *Splenica*.
 γ *Renalis*.
 δ *Uterina*.
 ϵ *Visceralis*.
 ζ *Mesenterica*.
 η *Externa*.

§ III. *Cutis*.

5. Elephantiasis.
6. Framboesia.
7. Pellagra.
8. Lepra.
9. Verruca.

10. Ganglion.

§ IV. *Glandium*.

11. Sarcoma.
 α *Pterygium*.
 β *Hordeolum*.
12. Scrophula.
13. Encystis.
 α *Atheroma*.
 β *Steatoma*.
 γ *Testudo*.
 δ *Meliceris*.
14. Scirrhus.
15. Cancer.
16. Parotis.

Genus II. PHLEGMATIA.

- Sp. 1. Anasarca.
 α *Opilata*.
 β *Exanthematica*.
 γ *Anæmia*.
 δ *Dolens*.
2. Hydrocephalus (ex-
 ternus).
3. Hydrorachitis (Spina
 Bifida).
4. Hydrothorax.
5. Ascites.
 α *Asthenica*.
 β *Metastatica*.
6. Hydrometra.
7. Hydrocele.
8. Exomphalos.

Genus III. CYSTIS.

- Sp. 1. Aneurisma.
2. Varix.
3. Mariscus.
4. Staphyloma.
5. Hydatid.
6. Abscessus.

Genus IV. EMPHYSEMA.

- Sp. 1. Pneumatosis.
 α *Traumatica*.
 β *Venenata*.
2. Tympanites.
 α *Intestinalis*.
 β *Abdominalis*.
3. Physometra.

Order XI. ECTOPIÆ.

Genus I. HERNIA.

- Sp. 1. Enterocoele. *Intestini*.
2. Epiplocele. *Omenti*.
3. Gastrocele. *Ventriculi*.
4. Hepatocoele. *Hepatis*.

5. Splenocoele. *Lienis*.
6. Hysterocele. *Uteri*.
7. Cystocoele. *Vesicæ*.
8. Encephalocoele. *Cere-
bri*.

Genus II. PROLAPSUS.

- Sp. 1. Exophthalmia. *Oculi*.
2. Blepharoptosis. *Pal-
pebræ*.
3. Hypostaphyle. *Uvulæ*.
4. Paraglossæ. *Lingua*.
5. Exania. *Recti*.
6. Exocyste. *Vesicæ*.
7. Hysteroptosis. *Uteri,
vel Vaginæ*.

Genus III. LUXATIO.

- Sp. 1. Calcis.
2. Capitis.
3. Carpi.
4. Claviculæ.

Order XII. PLAGÆ.

Genus I. DIALYSIS.

- Sp. 1. Vulnus.
2. Ulcus.
3. Punctura.
4. Excoriatio.
5. Ruptura.
6. Sinus.
7. Fistula.

Genus II. CLASIS.

- Sp. 1. Fractura.
2. Fissura.
3. Rhagas.
4. Arthrocace.

Genus III. DIASTASIS.

- Sp. 1. Symphysis Pubis.

Though from mature reflection we are convinced of the advantages of this plan, we have not ventured to disturb, through this work, the usual nomenclature, nor the received definitions. We have also, in general, avoided nosological disquisitions, as we wished to confine all our observations on these points to a single article; and, consequently, if our ideas are rejected, we shall occasion no difficulty to the student, either by innovations of language or arrangements. We shall, therefore, now proceed to the definitions, and shall close this article with some remarks in defence of the present system; and the definitions now introduced.

Order I. PYREXIÆ. Heat, after coldness and shivering; debility; mind unsteady; tendons of the wrist tense; pulse either preternaturally quick or weak.

Genus I. INTERMITTENS. "Fever," returning after various and generally regular intervals, having each paroxysm apparently terminated by sweating.

- Sp. 1. *Quotidiana*. Intermittent fever, returning after an interval of twenty-four hours.
 2. *Tertian*. Returning after an interval of forty-eight hours.
 3. *Quartana*. After an interval of seventy-two hours.
 4. *Erratica*. After intervals generally uncertain, but always longer than seventy-two hours.
 5. *Complicata*. Irregularly returning paroxysms, from a complication of a tertian and a quartan, two tertians, or two quartans.

Genus II. EXACERBANS. "Fever," exacerbating and remitting, without ever disappearing; remissions distinguished by sweating, or a cloud in the urine; one paroxysm only occurring in twenty-four hours.

- Sp. 1. *Mitis*. "Exacerbating fever," without remarkable debility or putridity.
 2. *Maligna*. With great debility, often with putrefactive symptoms, rapid and usually fatal.
 3. *Hectica*. Exacerbations distinctly returning every evening, terminated very commonly by sweating.

Genus III. CONTINUA. "Fever," with remissions less evident, and seldom marked by critical discharges; having usually two exacerbations in twenty-four hours.

- Sp. 1. *Synocha*. "Continued fever," with great heat, frequent, strong and hard pulse, urine red; mind but slightly affected.
 2. *Typhus*. "Continued fever," with pulse and heat, in the beginning moderate, and remissions unusually distinct; mind very unsteady; debility considerable; urine clear; in the advanced stages, putridity, tremors, and convulsions.
 3. *Synochus*. "Continued fever," commencing like synocha; in its progress resembling typhus, though more mild, and often attended with bilious discharges.

Order II. PHLEGMASIE. Local fixed pains, with a læsion of the functions of the diseased organ, an increased discharge from its vessels, usually attended with "fever." When external, the parts affected are floridly red, generally swollen; the tumour often circumscribed, ending in effusion, suppuration, or gangrene.

Genus I. INFLAMMATIO. Local "phlegmasia" with fever, usually inflammatory.

Sp. 1. *Phlegmon*. "Local inflammation" on the surface, pain generally throbbing.

2. *Ophthalmia*. Inflammation in the eye, or its lids; light painful, and the pain peculiarly acute.

Var. α *Epidemica*, Egyptian ophthalmia.

β *Sporadica*, accidental inflammation of the eye.

γ *Tarsi*, inflammation of the eye lids.

3. *Phrenitis*. Pain of the head; the pain from light and sound highly acute; face flushed; eyes red; synocha, with watchfulness and delirium.

4. *Cynanche*. Redness and pain of the fauces and throat; swallowing painful and difficult, often impossible; swelling in the tonsils, and sometimes in the neck; breathing occasionally difficult, and stridulous.

Var. α *Faucium*. Redness at the back part of the throat, conspicuous and considerable.

β *Tracheæ*. Redness less conspicuous, breathing difficult and stridulous.

δ *Parotidæa*. Tumours external, difficulty of swallowing slight, often alternating, with tumours of the testes; in females of the mammæ.

5. *Pneumonia*. Pain in some parts of the chest; cough, at first day, afterwards attended with expectoration, often bloody.

Var. α *Pleuræ*. Pulse full and hard; pain violent; synocha severe; often without expectoration.

β *Pulmonum*. Pulse less hard, and pain less pungent; dyspnœa acute; suffocation on lying down; face purple; sputum glutinous, green, and yellow; towards the solution white and equable.

γ *Diaphragmatis*. Pain at the lower ribs, extending to the back; breathing interrupted and painful; hic-cough, without expectoration.

ϵ *Hepatica*. Pain extending downward toward the right side; pulse less full and hard; sputum yellow.

ζ *Rheumatica*. Pulse hard and strong, without cough; side affected, externally sore.

6. *Hepatitis*. Tension and often soreness in the right hypochondrium, extending occasionally to the right shoulder; expectoration generally yellow.

7. *Carditis*. Pain under the sternum, sometimes

pungent; violent palpitation, with great anxiety; pulse small, and generally unequal.

Var. α *Mediastina*. Pain more strictly confined to the middle of the sternum, with less palpitation and anxiety; without expectoration.

β *Pericarditis*. Pain more acute; palpitation violent.

8. *Gastritis*. Pain with frequently a circumscribed tumour, and soreness at the pit of the stomach; vomiting, even of the mildest fluids, incessant; pulse soft, weak, and sometimes fluttering.

9. *Enteritis*. Violent colic, with soreness of the abdomen; costiveness obstinate, often with vomiting, frequently with ischuria.

Var. α *Mesenterica*. Pain deeply seated, without soreness of the abdomen; costiveness and ischuria less violent.

β *Epiploitis*. Tumour more sensible; seldom with ischuria.

γ *Peritonitis*. External soreness, and pain extreme, increased on raising the body; without constipation or relief from stools.

δ *Rheumatica*. Great external soreness and acute pain, chiefly felt at the lowest ribs, and the spine of the ileum.

10. *Nephritis*. Pain shooting from the loins into the thighs; micturition painful and frequent, with a retraction of either testicle, and a numbness of the thigh on the same side; often with vomiting.

11. *Cystitis*. Inflammation, pain, and swelling of the hypogastrium; micturition painful or obstructed; frequently with tenesmus.

12. *Hysteritis*. Swelling and pain of the hypogastrium; micturition slightly affected; the os tincæ sore and painful.

13. *Odontalgia*. Pain of the teeth and jaws, extending to the ear, and often to every part of the head on the side affected; at first increased, afterwards relieved, by heat.

Genus II. PHLOGOSIS. Inflammation; pain less violent; tumour inconsiderable; redness less florid, irregular, extending; with debility, often with typhus; terminating generally and rapidly in gangrene.

Sp. 1. *Erythema*. External "Phlogosis" of a pink colour, disappearing on pressure; pain burning; terminating generally in branny scales, often in phlyctenæ or vesicles, at last in gangrene.

Var. α *Mitis*.

Pernio. From cold, generally in the fingers, toes, or heel.

Combustio. From violent heat.

β *Maligna*.

Anthrax. A hard deep seated tumour with a burning heat, of a dark colour, rapidly hastening to gangrene.

2. *Phrenitica*. Pain of the head inconsiderable;

face pale; restlessness, low delirium, with occasional fits of violence.

3. *Anginosa*. "Phlogosis" of the throat and fauces, frequently with ulcerations, deep and ragged at the edges; severe typhus; delirium; often with erythema on the skin.

4. *Pneumonica*. Symptoms of pneumonia, but with the face pale, the features sunk, and a pulse, though apparently strong, stopped by a slight pressure; delirium, particularly after discharges.

5. *Puerperalis*. Typhus, usually attacking on the third day after delivery; pain and soreness of the abdomen; face pale; eyes sunk; a tensive pain in the forehead, with a retrocession of the milk.

Genus III. CATARRHUS. Inflammation of the glands of the mucous membrane, with an increased discharge of mucus, at first thin, acrid and discoloured, afterwards whiter and of a greater consistence.

Sp. 1. *Cozyra*. Catarrhal inflammation of the membrane of the nose, fauces, and bronchiæ, with sneezing and coughing; occasionally epidemic and infectious.

Var. α *Contagiosa*, with typhus, and considerable depression of strength.

β *Senilis*, with fever slight and inconsiderable, but with great discharge of mucus.

γ *Arthritica*. From gout repelled or irregular, with a copious discharge of an acrid, greenish, mucus.

δ *Trachealis*. Great difficulty of breathing, with a stridulous sound, terminating in suffocation from a concreted effusion.

2. *Dysenteria*. Violent colic, with tenesmus; very frequent stools, mucous and often bloody, rarely, except in the decline of the disease, feculent; often epidemic; generally infectious.

Var. α *Epidemica*. With typhoid fever, great dejection of spirits, and loss of strength.

β *Sporadica*. With milder fever, and less debility; not epidemic.

3. *Caliaca*. Colic generally without fever, except after some continuance; without tenesmus; the discharges mucous without infection.

4. *Phthisis*. Cough, at first short and dry, afterwards more violent, with a mucous, and at last a purulent, expectoration; great debility and emaciation; fever exacerbating in the evening, pulse unusually quick.

5. *Cystirrhæa*. A light, white, flocculent discharge accompanying the urine, not fetid; micturition painful without tenesmus.

6. *Leucorrhæa*. A mucous discharge from the vagina, of a yellowish white colour, verging to green; without infection, or pain in

making water; disappearing during menstruation.

7. *Gonorrhœa*. A discharge resembling that of leucorrhœa, from the penis or vagina, generally with inflammation at the orifice of the urethra, and pain in making water; not disappearing during menstruation.

Var. α *Veneræa*. From venereal infection; contagious.

β *Benigna*. With little pain in making water; not contagious.

8. *Leucorrhœis*. A whitish discharge from the anus, often with hæmorrhoidal tumours, sometimes periodical.

Genus IV. *ARTHRITIS*. Inflammation usually confined to the joints, occasionally extending to the adjoining muscles; generally with fever; often with hectic.

- Sp. 1. *Rheumatismus*. "Articular inflammation," chiefly of the large joints, with pain; synocha; generally increased heat of the part; not terminating in suppuration.

Var. α *Lumbago*. Rheumatic pain in the loins, not shooting down the thigh; chiefly felt on motion.

β *Ischias*. Pain in the hip joint; without peculiar debility, emaciation of the nates on the affected side, or elongation of the limb.

γ *Pleurodyne*. Pneumonia rheumatica, q. v.

2. *Arthrodynia*. "Articular inflammation," with little or no fever; limb cold and rigid, without swelling.

3. *Podagra*. Inflammation and pain, chiefly of the smaller joints, preceded by anorexia, dyspepsia, a dejection of spirits, or want of sleep; returning after intervals, sometimes regular, and alternating with atonic, occasionally with inflammatory, affections of the head, stomach, or bowels.

4. *Hydrarthrus*. Deep-seated pain in the joints; swelling slight, without discoloration, often ending in suppuration, sometimes within the capsular ligament; attended with hectic.

Var. α *Psoadicus*. Pain beginning in the back, increased by stooping, or extending either leg; the suppuration pointing in the groin, the thigh, or the back; with hectic.

β *Coxarius*. Pain in the coxendix, at first slight and obtuse, afterwards acute; nates of the side affected extenuated, leg elongated, attended at last with hectic.

γ *Genu*. Hydrarthrus affecting the knee, attended in the latter stages with acute pain and hectic fever; in favourable circumstances terminated by ankylosis.

Genus V. *EXOSTOSIS*. A swelling apparently of the bone, generally near the middle, painful,

in the heat of the bed, and sore to the touch, generally from lues.

- Sp. 1. *Periosteæa*. Chiefly confined to the periosteum.

Order III. *ERUPTIONES*. Erythematous or phlegmonous eruptions on the surface, or the fauces, generally distinct; the latter rising above the skin, circumscribed, roundish; generally containing a fluid, sometimes in the decline purulent.

Genus I. *EXANTHEMA*. Eruptions generally depending on specific contagion, often epidemic, usually with fever.

- Sp. 1. *Variola*. Synocha, followed on the third day by the eruption of small phlegmons, completed on the fifth, suppurating, and forming crusts on the eighth, frequently leaving cuticular cicatrices or depressions.

Var. α *Confluens*. Phlegmons numerous and crowded, not rising in separate heads.

β *Crystallina*. Phlegmons filled with a clear watery fluid, seldom or imperfectly suppurating.

2. *Vaccina*. Phlegmon only on the part affected, from inoculation or infection in consequence of milking diseased cows; the phlegmon nearly round, with a dark brown depression in the middle; fever usually inconsiderable.

3. *Rubeola*. Catarrhus, with synocha; cough harsh; eyes inflamed and watery; followed by red papulæ, running together, scarcely rising above the skin; terminating in branny scales.

Var. α *Maligna*. Catarrhus with typhus; the papulæ dark, interspersed with dark coloured petechiæ; great oppression at the breast, without expectoration.

β *Variolodes*. Papulæ resembling phlegmons, catarrhal symptoms absent or inconsiderable.

4. *Varicella*. Pustulæ resembling the variolous, following a slight fever, after no definite period; seldom suppurating, but disappearing in branny scales.

5. *Miliaria*. Fever typhoid, with sighing, anxiety, and sweat of a sour smell; followed by numerous distinct papulæ, terminating in points.

Var. α *Purpura*. Apices of the papulæ purple; with typhus.

β *Alba*. Apices of the papulæ white, with slight synocha.

6. *Scarlatina*. Fever, often at night with delirium; on the fourth day a swelling, and a scarlet effusion on the face, with a similar effusion soon afterward on the breast, and in succession on the body and legs; the effusion often in large spots, frequently coalescing and terminating in branny scales.

Var. α *Cynanchica*. Scarlatina, "with phlogosis anginosa."

7. *Erysipelas*. After a fever of three or four days, phlogosis in the face, occasionally in other parts, accompanied, more often succeeded, by delirium; terminating in branny scales.

Var. α *Intermittens*. Erysipelas irregularly returning at distant intervals, chronic, with little fever.

8. *Pestis*. Asthenic fever, with great internal heat, terminating in bubos of the groin or axilla, sometimes in anthrax.
9. *Pemphigus*. Fever generally typhoid, terminating in vesicles filled with thin ichor; sometimes with a lighter coloured serum.
10. *Aphtha*. Fever followed after a few days by a swelling in the tongue, and a purplish colour on the fauces, terminating in white, frequently distinct, sloughs on the fauces and palate; frequently with diarrhoea and cœliaca, sometimes with hæmorrhage.

Var. α *Maligna*. The sloughs of a darker colour, leaving, when abraded, a dark ragged ulcer.

β *Sporadica*. Seldom attacking numbers at the same time; the eruption more slightly connected with fever.

11. *Urticaria*. Exacerbating fever; eruptions after each attack, sometimes resembling the stinging of nettles, sometimes rising in small papulæ; seldom suppurating, but terminating in dry scabs.
12. *Strophulus*. After sickness and uneasiness in new born children, an eruption of red papulæ, rising above the skin, frequently coalescing, though sometimes distinct, and filled with a serous fluid.
13. *Achor*. Swellings in different parts of the body, resembling phlegmons, discharging sebaceous, sometimes puriform, matter, from minute foramina; fever slight, often indistinct.

Genus II. *EFFLORESCENTIA*. Eruptions not rising, or rising slightly above the skin, without fever; not epidemic.

- Sp. 1. *Psora*. Pustules, at first white, afterwards filling with serum, degenerating into little red inflamed papulæ, chiefly between the fingers; itching, particularly when warm in bed; contagious.

2. *Prurigo*. Itching in different parts, often without pustules, or with pustules not filling with serum; terminating in branny scales.

3. *Lichen*. An extensive eruption of papulæ, generally connected with internal disease, usually terminating in scurf; recurrent; not contagious.

Var. α *Purpura chronica scorbutica Hoffmani*.

4. *Herpes*. Efflorescence, consisting of clusters of small red pustules, itching with a burning heat, and terminating in a branny crust.

5. *Phlyctena*. Vesicles pellucid, filled with a serous fluid, inflamed at the base; painful when burst.

6. *Petechia*. Spots not rising above the skin, re-

sembling the bites of fleas, at first red, afterwards of a cinnamon colour, in succession brown and black, often with spontaneous hæmorrhage.

7. *Vibex*. Marks on the skin in stripes, of a dark brown colour, often mixed with petechiæ.

8. *Tinea*. Ulcers in the hairy scalp, pouring out a fluid concreting into a white friable crust; generally rounded in its figure.

9. *Eczema*. Small vesicles with considerable itching; vesicles scarcely distinguishable from papulæ, with often an erysipelatous swelling; from the use of mercury.

Order IV. *PROFLUVIA*. A flow of blood, or of secreted fluids, from their respective vessels or ducts; often with fever.

Genus I. *HÆMORRHAGIA*. A discharge of blood.

- Sp. 1. *Epistaxis*. "Hæmorrhage" from the nose, preceded by headach, and often a burning heat in the nose.

2. *Stomacace*. Blood oozing from the gums, without fever.

3. *Hæmoptysis*. Blood thrown up by coughing, preceded by flushed cheeks, dyspnœa, a sense of weight in the head and breast.

4. *Hæmatemesis*. Blood thrown up by vomiting, preceded by sickness and faintness; seldom coagulated, generally in considerable quantity.

Var. α *Febrilis*, preceded or attended by fever.

β *Asthenica*, in weak or scorbutic habits.

5. *Melæna*. A discharge of a blackish substance from the stomach or intestines often foliated or filamentous, sometimes verging to a yellowish brown colour.

6. *Hæmorrhoids*. Blood flowing from the anus, often preceded by pain and load in the head; frequently accompanied by painful, livid tumours near the verge of the anus, or a painful weight within the rectum.

7. *Ménorrhagia*. An unusual flow of blood from the vagina, often with a sense of weight in the loins, and occasionally with a sensation of weight forcing down on the os externum.

8. *Hæmaturia*. A considerable discharge of blood with the urine, often with violent forcing pains, felt at the extremity of the penis; tenesmus, without sickness.

9. *Vicaria*. Discharges of blood from different organs, in consequence of suppressed evacuations, or the natural ones not taking place.

Var. α *Narium*, from the nose.

β *Pulmonum*, from the lungs.

γ *Ventriculi*, from the stomach.

δ *Venarum hæmorrhoidalium*, from the hæmorrhoidal veins.

ϵ *Vesicæ*, from the urinary bladder.

ξ *Gingivarum*, from the gums.

Genus II. *APOCENOSIS*. Increased discharges from

glands, or the cavities into which their contents are usually poured; in general without fever.

Sp. 1. *Vomitus*. A discharge from the stomach, either bilious, mucous, or watery.

Var. α . *Cholera*. A discharge of bile, often with colic; when violent and incessant, attended with spasms of the legs.

β . *Pyrosis*. A discharge of cold water, generally preceded by acute pain.

γ . *Atonica*. Constant vomiting of whatever is taken in, with a large proportion of heavy mucus; often after repelled gout and eruptions, generally in old age; the consequence often of high living, and the abuse of spirituous liquors.

2. *Diarrhœa*. Frequent discharges by stool; often with colic; generally without fever.

Var. α . *Lienteria*. The discharge apparently chylous.

β . *Aquosa*. Without fœces or scybala.

3. *Diabetes*. An immoderate discharge of urine, with thirst, anorexia, and emaciation; without pain or fever.

Var. α . *Mellitus*. Urine sweet, without any portion of the urea or animal matter.

β . *Aquosus*. Urine differing little from water; discharged often involuntarily.

γ . *Mucilaginosus*. Containing a large proportion of mucilage or gluten.

4. *Diuresis*. A discharge of limpid urine, returning at intervals, without emaciation.

5. *Ephidrosis*. An immoderate discharge of sweat without fever.

6. *Plica*. The hair twisted in cirrhi, in consequence of a discharge of blood or serum from the bulbs into the cavities of each hair; with fever; contagious; and in Poland endemical.

7. *Epiphora*. An increased discharge from the lachrymal glands.

8. *Ptyalismus*. An increased discharge of saliva.

Var. α . *Hydrargyratus*. In consequence of large doses of mercury, often continuing after the medicine has ceased to act.

β . *Asthenicus*. The drivelling of idiots, or those affected with palsy.

γ . *Mellitus*. With a sweetness or mucilaginous taste in the mouth.

9. *Exoneirosis*. An involuntary discharge of semen during sleep, independent of lascivious dreams.

Order V. SUPPRESSORII. Obstructions of natural passages, and of natural or morbidly critical discharges.

Genus I. CONSTRICTORIA. "Obstruction" from organic disease.

Sp. 1. *Dysphagia*. Difficulty of swallowing from a sensible obstruction of the œsophagus.

2. *Obstipatio*. Obstruction in the track of the stomach and intestines below the œsophagus.

Var. α . *Pylori*. Food taken into the stomach, often returned by vomiting, eructations, loss of strength and flesh; with costiveness; frequently unconquerable, always obstinate.

β . *Intestinorum*. Bowels obstinately costive, without vomiting; fulness often in some part of the abdomen, to be felt through the integuments.

γ . *Recti*. A retention of solid feculent matter, with tenesmus, and a slight watery diarrhœa; a contraction often within the reach of the finger.

3. *Polyphus*. Obstructions in the heart or other natural passages.

Var. α . *Narium*. Breathing through the nose difficult or impossible; sometimes with load in the head, or symptoms of hydrocephalus.

β . *Cordis*. Palpitation of the heart, with anxiety and dyspnœa.

γ . *Uteri*. Weight and bearing down of the uterus, generally with amenorrhœa, often with a serous discharge resembling leucorrhœa; generally without pain.

Genus II. ANHELATIO. An obstruction to the passage of air into the lungs.

Sp. 1. *Asthma*. A difficulty of breathing, with a sense of constriction in the breast; hissing sound in respiration; cough, terminated by expectoration; temporary; recurrent.

Var. α . *Spontanæum*. Suddenly, often unexpectedly, recurring without any other disease; seldom terminated by expectoration, or at least expectoration in any considerable quantity.

β . *Plethoricum*. From suppressed sanguineous discharges, or from plethora.

γ . *Senile*. Frequently recurring, with copious expectoration.

2. *Dyspnœa*. Difficulty of breathing constant, with a sensation of weight, rather than constriction on the breast; cough constant, with little or insufficient expectoration.

Var. α . *Catarrhalis*. Chronic catarrh of old people.

β . *Terrea*. Dyspnœa from calculous concretions, frequently discharged.

γ . *Aquosa*. With a scanty discharge of urine, in leucophlegmatic habits.

Genus III. EPISCHEISIS.

§ I. *Sanguinea*.

Sp. 1. *Amenorrhœa*. A deficiency or obstruction of the menstrual discharge, at the time of life, or the periods, when it should naturally take place.

Var. *a. Dolorifica*. A deficient discharge, attended with violent pain.

2. *Dyslochia*. A want or suppression of the lochial discharge.

3. *Dyshæmorrhœia*. A suppression of the hæmorrhoidal discharge, attended with head-ach, dyspepsia, and fever.

§ II. *Excretorium*.

4. *Icterus*. An obstruction of the bile, known from unfrequent, white stools, and a yellowness of the skin; urine of a yellow red colour, tinging linen immersed in it of a yellow colour.

Var. *a. Calculosa*. With acute pain at the pit of the stomach.

β Biliosa. In persons of a studious, sedentary life, often attended with hypochondriasis.

γ Spasmodica. Following violent fits of anger.

3. *Ischuria*. An obstinate, and often a complete, suppression of urine.

a Renalis. With a pain and weight in the loins, without tumour in the hypogastric region.

β Ureterica. With a sense of weight in the lower part of the pelvis, without hypogastric tumour.

γ Vesicalis. With a tumour in the hypogastrium, a frequent desire to make water; a pain felt at the extremity of the penis.

δ Uræthralis. With a tumour in the hypogastrium, a frequent desire to make water, and a sense of obstruction in the urethra, not admitting the introduction of a catheter.

ε Paralytica. Without symptoms of accumulation in any part of the urinary track.

6. *Dysuria*. A painful, and in some degree an obstructed, discharge of urine.

Var. *a. Ardens*. With pain, and often inflammation of the bladder and urethra.

β Spasmodica. From spasm in other parts, communicated to the neck of the bladder.

γ Compressa. From tumours in the neighbouring parts, compressing the neck of the bladder.

δ Irritata. From calculus.

ε Arthritica. In gouty habits, with a discharge of greenish mucus.

7. *Sitis*. An unconquerable desire for liquids, sometimes accompanying diabetes or fever.

8. *Dyspermatusmus*. An obstruction to the excretion of semen, or a slow, painful, and insufficient discharge of it.

Var. *a. Organicus*. From strictures of the urethra, or neighbouring tumours.

β Spasmodicus. From terror, apprehension, or sudden surprise.

9. *Agalaxis*. A suppression of milk, either when first expected, or after the secretion has come on.

Order VI. SPASMI. Violently continued or irregular action of the muscular fibres of different parts.

Genus I. TONOS. Muscular contractions, sometimes remitting, but not succeeded by complete relaxation.

Sp. 1. *Trismus*. A violent and continued action of the muscles which close the lower jaw.

Var. *a Infantum*. Trismus of newly born infants, with usually a retention of the meconium.

β Traumatica. From wounds, particularly lacerated ones in hot climates; sometimes from ulcers.

2. *Tetanus*. Tonic spasm of the voluntary muscles, beginning with pain and tension on the back of the neck, occasionally confined to one side, or, at least, a considerable portion of the body.

Var. *a Emprosthotonus*. Tetanus of the flexor muscles.

β Opisthotonus. Tetanus of the extensors.

γ Catochus. Tetanus gradually approaching without dyspnœa.

3. *Contractura*. Tonic spasm of particular muscles.

Var. *a Colli*. Of the sterno mastoid, producing the wry neck.

β Artuum. Of different limbs, chiefly from confinement or the irritation of abscesses.

4. *Priapismus*. Tonic spasm of the erectores penis, with violent pain.

5. *Strabismus*. Tonic spasm of the abductores, the adductores, occasionally of the other muscles of the eye, usually at first attended with double vision.

Genus II. CLONOS. Muscular contractions rapidly and repeatedly succeeded by relaxation.

Sp. 1. *Epilepsia*. Clonic spasm of all the muscles, generally with carus, returning after intervals, often regular.

Var. *a Cerebralis*. Without evident cause, or preceding symptoms, except sometimes a slight giddiness.

β Sympathica. Preceded by an obscure feeling in a distant part, and a sensation of cold air, rising from that part to the head.

γ Irritata. From irritation in different parts, particularly the stomach and the head, without the sensation of cold air.

2. *Convulsio*. Clonic spasm of all the muscles, without carus, seldom recurrent.

Var. *a Irritata*. From the stomach, injuries of the brain, teething, &c.

3. *Hysteria*. Clonic spasm, preceded frequently by a rumbling sound of the stomach, with a sensation of a ball in the throat, impeding deglutition; urine copious and limpid; temper variable.

Var. α *Asthenica*. In weak mobile habits, often without any evident cause.

β *Irritata*. From any sudden affection of the mind, or irritations in the stomach and bowels.

4. *Chorea*. Clonic spasm, particularly in the fingers, legs, and lips, producing strange gesticulations and grimaces; with a weakness of either leg; often insensibility.

5. *Raphania*. Clonic spasm, with often a contraction of the joints; pain very violent; intermitting.

6. *Palpitatio*. Violent and irregular action of the heart.

Var. α *Cardiaca*. From diseases of the heart, or larger arteries.

β *Hysterica*. Occurring in the mobile habits, subject to hysteria.

γ *Irritata*. From irritations chiefly in the stomach and bowels.

7. *Pertussis*. Cough violently convulsive; inspiration sonorous; recurring in paroxysms; contagious; at the end with expectoration.

8. *Colica*. Violent pain in the bowels, remitting and exacerbating, chiefly felt about the navel, with vomiting and costiveness.

Var. α *Stercoraria*. From accumulated contents of the intestines, preceded by costiveness or slight watery stools.

β *Venenata*. From poisons, often of lead.

9. *Hydrophobia*. Convulsions of the pharynx, excited by an attempt to drink water or any fluid, preceded by melancholy, and increased sensibility; in consequence of the bite of a mad animal.

10. *Pandiculatio*. The extension of almost all the limbs; involuntary, generally with gaping.

11. *Beriberia*. A convulsive retraction of the knees in walking, with tremor, a sense of creeping, and a hoarseness of voice.

Order VII. ADYNAMIÆ. A defect or a diminution of sensation, motion, or the natural functions; often with stupor.

Genus I. COMA. A deep and continued stupor, with a diminution or loss of muscular power; often with stertor.

Sp. 1. *Carus*. A continued stupor, and insensibility without stertor.

Var. α *Cataleptis*. Limbs flexible, continuing in the posture in which they were placed.

β *Ecstasis*. Limbs rigid, retaining the position in which the person was seized.

2. *Apoplexia*. Coma with stertor.

Var. α *Sanguinea*. After heat, violent exercise, or blows on the head; in the young and plethoric.

β *Serosa*. Coma gradually approaching in advanced life.

γ *Hydrocephalica*. Coma, with scanty

urine, obstinate costiveness, and strabismus.

δ *Asthenica*. Coma, rapidly, often suddenly approaching in impaired constitutions; frequently with convulsions.

ϵ *Suffocata*. From noxious gases, hanging or drowning.

ζ *Metastatica*. From serous, excretory, or sanguineous obstruction, gout or repelled eruptions.

3. *Paralysis*. A loss of motion in some of the limbs, and impaired natural functions; without stertor; sometimes, without stupor.

Var. α *Hemiplegia*. With loss of motion on one side.

β *Paraplegia*. With loss of motion in the lower extremities without stupor.

γ *Partialis*. With loss of motion in particular limbs, without stupor or stertor.

δ *Venenata*. From poison of lead, tobacco, or deleterious gases.

4. *Syncope*. A diminished motion of the heart and arteries, often with stupor; occasionally recurring.

Var. α *Cardiaca*. From some defect in the heart or larger vessels.

β *Metastatica*. From retrocession or repulsion of exanthemata, or gout; sometimes from fever or scurvy.

γ *Angens*. With violent pain in the breast, shooting down to the arms, often with a sense of stricture, on the breast.

Genus II. ANEPITHYMIA. A diminution of power in the different functions.

Sp. 1. *Anorexia*. Loss of appetite, with languor, flatulence, and a sense of sinking in the stomach.

2. *Dyspepsia*. Flatulence with sour eructations; often with sickness, and a putrid taste at the back part of the fauces.

Var. α *Idiopathica*. Without any previous disease.

β *Metastatica*. From repelled eruptions, obstructed discharges, depressing passions, atonic gout, &c.

3. *Chlorosis*. Languor and debility, with pale complexion, often dyspepsia; without fever; generally attendant on amenorrhœa.

4. *Amentia*. Impaired mental functions from excessive evacuations, irregular living, or old age; generally with debility.

5. *Amaurosis*. Impaired sight, with an enlarged pupil, not contracting on the approach of a strong light.

Var. α *Intermittens*. Blindness sometimes recurring at night; at others only on the return of daylight, nyctylopiæ auctorum.

6. *Agnesia*. The power of generation impaired.

7. *Atrophia*. Emaciation of the whole body,

F

often with hectica, frequently with a swelling of the abdomen.

Order VIII. PARANOLÆ. Violent or irregular exertion of the different corporeal or mental functions, often alternating with languor and depression of body or mind.

Genus I. MOROSITAS. Violent or irregular derangements of the appetite, occasionally of digestion.

Sp. 1. *Bulimia*. A craving appetite for a larger proportion of food than the stomach can digest, or oftener than the system requires.

Var. α *Helluonum*. From indulgence of gluttony.

β *Syncopalis*. From a sense of inanition.

γ *Convalescentium*. After fevers, or excessive discharges.

2. *Pica*. An aversion to common food, and an eager desire for substances not esculent or alimentary.

Var. α *Chlorotica*. Attending amenorrhœa, often about the age of puberty.

β *Pregnantium*. The pica of pregnancy.

γ *Afrorum*. Cachexia, Africana, dirt eating; a disease of negroes in Jamaica.

3. *Hypochondriasis*. Dyspepsia with costiveness, fancies irregular, mind desponding.

Var. α *Nostalgia*. Hypochondriasis, with a longing for home, when in a foreign country.

Genus II. HALLUCINATIO. Violent or irregular sexual passions.

Sp. 1. *Satyriasis*. Violent and excessive lust, with priapism.

2. *Nymphomania*. Satyriasis of females, with inflammation of the nymphæ.

3. *Erotomania*. Chaste love in excess, when the object is unattainable; with melancholy, sleeplessness, and often hectic.

Genus III. VESANIA. Irregular exertion of the mental functions, occasionally with excess of excitement, sometimes of depression; without coma or fever.

Sp. 1. *Melancholia*. Depression of the mental powers with erroneous judgment, though in general with correct perceptions, without dyspepsia.

2. *Mania*. Erroneous perceptions or judgment, often of both; with great violence.

Var. α *Mentalis*. Apparently from passions of the mind only.

β *Metastatica*. From repelled eruptions, gout, or obstructed discharges.

γ *Venenata*. From narcotic poisons, paraphrosyne auctorum. Van Helmont.

3. *Oneirodynia*. Disturbed sleep, sometimes with an imagination peculiarly active, at others, with a sense of oppression.

Var. α *Activa*. Sonambulism.

β *Gravans*. Ephialtes, night mare.

Order IX. CACHEXIÆ. A change in the colour of

the skin, generally from a chemical change in the nature of the fluids.

Genus I. IMPETIGO. A change of colour in the whole body.

Sp. 1. *Scorbutus*. Livid spots over the whole body, particularly at the roots of the hair, with great loss of strength, and bleeding from the gums; generally from food not alimentary.

Var. α *Nautarum*. The scurvy of sailors on long voyages, without a supply of vegetables.

β *Asthenica*. Occurring in besieged towns, or from poor living in confined apartments without exercise.

2. *Syphilis*. Spots sometimes level with the skin, but occasionally rising in small tubercles, particularly at the roots of the hair, degenerating into crusty ulcers; pains in the middle of the bones, particularly when warm in bed, with exostosis; generally after some local complaint of the genitals.

3. *Aurigo*. A dark yellowness of the skin, with dyspepsia, generally terminating in dropsy; stools natural; urine not tinging linen yellow.

4. *Phenigmus*. Redness of the skin, either diffused or in spots; without fever.

5. *Melasma*. A dark blue or purple colour of the skin, generally with dyspnoea and palpitation, from the blood not flowing freely through the lungs.

6. *Rubigo*. A general redness of the skin: often with coma.

Genus II. MACULA. A partial change of colour.

Sp. 1. *Ecchymosis*. A blue colour in particular parts, sometimes black, changing to a brown and yellow; from fluids effused in consequence of a bruise.

2. *Nevus*. Irregular marks on the skin, sometimes of a bright red, at other times yellow or brown, absurdly attributed to the mother's longing.

Order X. INTUMESCENTIÆ. Enlargement of the whole body, or of particular parts.

§ I. Total.

Sp. 1. *Polysarcia*. General enlargement, usually from accumulated fat.

§ II. Partial.

2. *Rachitis*. Bones of the joints enlarged, head swollen, particularly in front; with physconia.

3. *Exostosis*. See PERIOSTEÆ.

4. *Physconia*. Enlargement of the abdomen, without fluctuation.

Var. α *Hepatica*. A hard tumour in the right hypochondrium, verging towards, and sometimes appearing at, the pit of the stomach.

β *Splenica*. A little below the false ribs, on the left side, and towards the spine of that side.

- γ *Renalis*. Oblong; in the loins on either side, near the spine.
- δ *Uterina*. In the hypogastrium on either side; hard, with unequal edges.
- ε *Visceralis*. Filling more generally the abdomen.
- ζ *Mesenterica*. In irregular masses, yielding to pressure.
- η *Externa*. Distinct tumours, not referrible to any other species, of very different degrees of hardness and size.

§ III. Cuticular.

5. *Elephantiasis*. Skin thick and rough; hair falling off; face deformed by hard tuberosities; insensibility in the limbs; voice harsh and nasal; contagious.
6. *Frambesia*. Small tubercles resembling mulberries, chronic; often contagious.
7. *Pellagra*. Inflation of the skin, with tubercles, in parts exposed to the air except the face; at first remitting; preceded by melancholy and debility; at last constant, with increased irritability and an alienation of mind.
8. *Lepros*. Skin covered with hard, branny, white crusts; hair thin, or falling off; voice harsh and weak; contagious.
 Var. α *L. Ichthyosis*. Crusts imbricated like the scales of a fish.
 β *L. Furfuracea*. Crusts branny, deciduous, leaving an inflamed, often an ulcerated, surface.
9. *Verruca*. Hard cuticular swellings, circumscribed and distinct; red at the base; painful when bruised.
10. *Ganglion*. Soft round swellings on the tendons, elastic.

§ IV. Glandular.

11. *Sarcoma*. Soft swellings of the consistence of flesh, frequently in the sebaceous glands.
 Var. α *Pterygium*. In the canthus of the eye.
 β *Hordeolum*. At the edge of the eyelids.
12. *Scrofula*. Swellings of the conglobate glands, chiefly in the neck; with a florid complexion, fair smooth skin; upper lip usually enlarged; tumours seldom suppurating, or the wounds with difficulty healed.
13. *Encystis*. A moveable soft swelling without pain or inflammation.
 The varieties are not easily distinguished; or synonymous.
14. *Bronchocoele*. A swelling of the glands in the fore part of the neck without inflammation or scrofula, never suppurating, sometimes occasioning dyspnoea.
15. *Scirrhus*. A tumour of any gland, hard, and unequal to the touch.
16. *Cancer*. An ulcer in any glandular organ, sometimes in other parts, frequently following scirrhus; swelling large and livid, veins full and dark, pains acutely lancinating.
17. *Parotis*. A large, hard, irregular swelling below the ear; suppurating with difficulty, forming a malignant ulcer, without much pain, generally with hectic.

Genus II. PHLEGMATIA. Increased bulk from accumulated fluids, generally with a dry parched tongue, and a diminished secretion of urine.

Sp. 1. *Anasarca*. A pale inelastic swelling at first in the legs, afterward extending over the whole body, generally serous.

Var. α *Opilata*. From compression of the veins, in consequence of tumours either natural, as in gravidity, or morbid, which prevent the return of venous blood.

β *Exanthematica*. After erysipelas or scarlatina, occasionally after other eruptions if suppressed.

γ *Anæmia*. In constitutions exhausted after long fevers.

δ *Dolens*. Tumour of one leg painful, inelastic; after parturition.

2. *Hydrocephalus*. A soft inelastic swelling of the head, with the sutures of the skull preternaturally open.

3. *Hydrorachitis*. A soft inelastic tumour on the loins; vertebræ deficient; lower extremities paralytic.

4. *Hydrothorax*. A sense of fulness and tension in the chest; dyspnoea on lying down; sleep disturbed by epialtic symptoms.

5. *Ascites*. A swelling of the belly, tense, imperfectly elastic; with a sense of fluctuation if the hand be placed on one side of the belly, and a slight stroke given to the other.

Var. α *Asthenica* in exhausted constitutions.

β *Metastatica*. From repelled gout or eruptions.

γ *Opilata*. From diseased viscera.

δ *Imperfecta*. Fluctuation partial, with irregular hardness in the other parts of the abdomen.

6. *Hydrometra*. A circumscribed tumour in the hypogastrium; urine in small quantities, without ischuria or pregnancy.

7. *Hydrocele*. Soft pellucid pyriform tumour of the scrotum, gradually increasing without pain.

8. *Exomphalos*. A soft inelastic tumour at the navel, yielding to the touch with a sense of fluctuation.

Genus III. CYSTIS. Increased bulk, without the affection of any large portion of the body; generally from a fluid.

Sp. 1. *Aneurisma*. A soft tumour in the course of a large artery, with pulsations, synchronous with those of the heart; not steatomatous nor glandular.

2. *Varix*. A soft tumour on and connected with a vein; veins above indistinct.

3. *Mariscus*. Small, soft, and often livid tumours round the anus.

4. *Staphyloma*. A watery tumour on the eye.

5. *Hydatis*. A cuticular vesicle full of a clear fluid in the viscera, often the causes of ascites. Vide in verbo.

6. *Abcessus*. A circumscribed phlegmonous

tumour, at first hard, afterward with a feeling of fluctuation, generally with a peculiarly soft point at one particular part.

Genus IV. EMPHYSEMA. Increased bulk; tumour elastic; with a crackling sound when pressed.

Sp. 1. *Pneumatosia*. Emphysema of the whole body.
Var. α *Traumatica*. From a wound of the thorax.

β *Venenata*. From fish poison, or other narcotics.

2. *Tympanites*. Emphysema of the abdomen, sometimes with costiveness and atrophy.

α *Intestinalis*. From wind confined in the intestinal canal, relieved by discharges of flatus, or by stools.

β *Abdominalis*. From wind in the cavity of the abdomen, without costiveness.

3. *Physometra*. A smooth elastic tumour in the hypogastrium, with occasional discharge of flatus through the os tincæ.

Order XI. ECTOPIÆ. Parts removed from their proper place, with tumour in the region usually below, and disordered functions of the displaced organ; with superficial, sometimes with deep-seated inflammation; generally painful.

Genus I. HERNIA. Displaced viscera covered with the integuments.

For the species, see general classification.

II. PROLAPSUS. Organic displacements without integuments.

See general classification.

III. LUXATIO. Displacement of any joint from its socket, or articulation. See LUXATIO.

Order XII. PLAGÆ. A separation of parts naturally united.

Genus I. DIALYSIS. A disunion of soft parts.

Sp. 1. *Ulcus*. Dialysis, with purulent or ichorous discharge, and generally loss of substance.

2. *Vulnus*. Dialysis by mechanical force, generally bloody.

3. *Punctura*. A division of the skin extending inwards.

4. *Excoriatio*. A separation of the cuticle or skin not extending inwards.

5. *Ruptura*. A separation of tendon or ligament, without displacement of the joint.

6. *Sinus*. An ulcerated cavity, extensively sinus, terminating in a narrow orifice.

7. *Fistula*. A sinus with callous sides often reaching an ulcerated or carious bone.

Genus II. CLASIS. A disunion of hard parts.

Sp. 1. *Fractura*. A violent and mechanical disunion of bone.

α *Complicata*, combined with "Vulnus."

2. *Fissura*. Bone not wholly divided, but partially split.

3. *Rhagas*. A hardened crustaceous wound.

4. *Arthrocace*. An ulcer in the marrow, or in the epiphyses, with caries, exostosis, pain and hectic.

Genus III. DIASTASIS. Separated cartilages.

Sp. 1. *Symphysis pubis*.

Having thus offered those definitions which, in the generality of diseases, are sufficiently descriptive for the purpose of discrimination, we shall add a few remarks in defence of our arrangement and nomenclature, limiting their extent chiefly to necessary explanations.

We have observed, that the natural groups of diseases, like the natural orders of the botanists, were too obvious not to be caught at by every nosologist. Fevers, inflammations, and hæmorrhages, are as evidently connected as the tetradynamizæ, siliquosæ, or umbellatæ; and it is only necessary either to escape from confines purposely narrowed, or from wanderings too extensive.

Fevers form certainly one of these natural groups, and we have separated them from inflammation, since, in many diseases which decidedly merit the latter appellation, the fever is occasionally slight or inconsiderable; so that complaints sometimes attended with considerable fever, if we wear the strict fetters of Dr. Cullen, must be placed at an immeasurable distance. The definition of fever has been supposed a task of peculiar difficulty, but this has been enhanced by refinements, perhaps quibbles. The previous shivering is sometimes not observed, but, in such cases, it ushers in the paroxysms, which are at first distinct: the pulse is not always quickened, but this exception is peculiarly rare, and, if not quickened, they are extremely weak. In every case of fever, the powers of the mind are, in some degree, impaired, the tendons, at the wrist, tense. Headach, which occurs in many definitions, is here omitted, as unnecessary to the distinction, and as connecting fevers with inflammation. According to Dr. Clutterbuck's idea (see *NERVOSA FEBRIS*) it would be indispensable, but it certainly is owing to congestion in the brain, and, consistently with the ideas offered, is more connected with active inflammation than with pure fever.

The first genus is *intermittens*, and, from the view formerly given, it must be strictly a genus, since it is composed of individual diseases, which are varied only by accidental circumstances. A question has arisen, whether a febrile attack, terminated by one paroxysm, is truly a fever. We have not included an ephemera, as it is often an accidental circumstance, and admits of no practical directions, which will not apply to intermittents, consisting of repeated paroxysms. Were an ephemera to be admitted, the sudor anglicus, terminating either in returning health or in death, within twenty-four hours, should be a species; but the disease is no longer known, and the circumstances relating to it are not ascertained with such precision as to ensure our confidence.

It was necessary to introduce the terms "generally regular," since the quintana, sextana, &c. of authors are confessedly irregular, and these are included under the "erratica." The last species, *complicata*, includes the tertianæ and quartanæ duplices or duplicatæ of authors. Each occasions an apparent irregularity, and the succession of the double intermittents may give some

ambiguity to the character, as it precludes, in a few instances, the termination by sweating.

If a specific distinction can be established in any branch of natural history, it must be so in the separation of *remittents* from *intermittents*. The fever, in no period wholly disappears, and one paroxysm only occurs in twenty-four hours. It is chiefly necessary to remark, that by *icterodes* is meant the yellow fever of America, and by *asthenica*, highly debilitating remittents, which De Hahn observed at Breslaw, and sir John Chardin experienced at Gombron. These are generally epidemics, and we have introduced the *hectica*, to discriminate that kind of exacerbating fever which arises from causes *within* the system. It is indeed generally symptomatic, but when the original disease is not obvious it is itself original. Indeed this fever merits particular attention, since it so frequently attends weak and irritable habits as to give to chlorosis often the appearance of phthisis, and it admits of accurate discrimination.

The genus *continua*, continued fevers of authors, is sufficiently established, and the species are those of Dr. Cullen. The existence of *synocha*, independent of topical affection, has been doubted, but the subject has been already considered. See *INFLAMMATORIA FEBRIS*. The varieties of typhus are sufficiently obvious, but we may add, that the *neurodes* is the *NERVOSA FEBRIS*, q. v. and the *gastrica*, the common bilious epidemic. The only doubt which will arise is, whether this is not a species of *synochus*. Perhaps it ought to be so; and, in general, the greater number of typhi are truly *synochi*.

We reserved, when treating of fever, for this place, a very obvious subject of discussion, viz. how far the numerous varieties described by authors really merit particular distinction. To examine it fully, however, would require a reference to each, and an examination of the peculiar symptoms of the fever, which every author has described; an inquiry that might fill a volume. In general, however, it would be found, that these numerous fevers are chiefly distinguished by some leading symptom; that the epidemic is, in other respects, the same; nor can any be discovered, which is not either intermittent, exacerbating, or more continued, which has not one or two remissions in twenty-four hours. (See *PITUITA*.) Dr. Cullen, with almost every practitioner of discernment, rejects the *continent* fever of authors, viz. fever which continues without variation.

Phlegmasiæ constitute an order so strictly natural, that it could not escape the attention of any nosologist. Yet there are such obvious anomalies in the order, as established by each author, that if comprehensive, it must be in the same proportion less natural. If active inflammations are arranged in this order, many of the erythemata must be included: if inflammations of the mucous membrane form a subordinate group, we cannot separate *leucorrhœa* and *gonorrhœa*, because general fever is occasionally wanting. It was necessary to guard the definition with peculiar care, and the diseases of this kind are distinguished by fixed pain, læsion of the functions of the part affected, with increased discharge from its vessels. When this increased discharge is not immediately obvious, it is discovered from the consequences, as adhesions, &c. The diseases of this order are the true inflammations; the erysipelatous; inflammations of the mucous membranes; of the joints,

of the muscles chiefly felt in the joints; and in the bones, often the periosteum. These are distributed in five genera; *inflammatio*; *phlogosis*, a term derived from the burning heat; *catarrhus*, a title taken in its more general sense; *arthritis*, rescued also from its more confined meaning; and *exostosis*, a word commonly employed. *Inflammatio* is chiefly distinguished by the character of the order, and the species are the usual genera. I shall add only some remarks, which may be less obvious.

The chances of war have obtruded on our notice an epidemic and contagious *ophthalmia*, the Egyptian; the sporadic is the common disease from cold; and the *o. tarsi*, the inflammation of the lids, usually a symptom of scrofula, though sometimes a truly epidemic disease. The *cynanche* has only two varieties in the strictest sense, yet, as a febrile disease, sometimes obstructing swallowing from local inflammation, the *parotidæa* (the mumps) could not be excluded; though, from what we have observed, we should be inclined to include it under *exanthema*. There are certainly doubts respecting the second, the *trachæalis*, for it generally accompanies the erythematous *cynanche*: it would, however, be rash to assert, that it never is seen from active inflammation of the upper part of the larynx. The difficulty of breathing generally arises from the tumour. The *crophi* is more properly referred to *catarrhus*.

The species arranged as varieties of *pneumonia* are, in almost every author, raised to the rank of *genera*; but the cause is the same, the part affected contiguous, the symptoms very nearly alike, and they often pass into each other. We have seen the same fever successively attended with each. These varieties cannot, indeed, be always discriminated; nor, in a practical view, is distinction necessary.

The *mediastina* of authors cannot, we think, be separated from *carditis*; and the *pericarditis* is equally undistinguishable. The varieties of *enteritis* cannot probably be always distinguished, though we have endeavoured to discriminate, with care, the one which more particularly requires distinction, the *c. peritonitis*, as its practical treatment differs. We are by no means confident that the other varieties can be distinguished, except the *rheumatica*, in which the pain is felt at the origin and insertion of the muscles. We have often distinctly observed this pathognomonic symptom.

The character of *nephritis* is certainly confined to one species, the *n. calculosa*, from a stone either in the pelvis of the kidney, or escaping through the ureters into the bladder. It is difficult, if not impossible, to distinguish real inflammation of the kidney, as the organ is, in general, insensible; and when inflamed, from its deep seat, the disease is generally confounded with *enteritis*: perhaps minute distinction is unnecessary. *Odontalgia* is generally considered as *rheumatic*, and it seems more properly to belong to articular inflammations. If disputed, however, there will be little inconvenience in removing it.

To include the erysipelatous inflammations, which we have connected under the genus *phlogosis* in this order, may appear improper, as the topical affection and the fever are so essentially different. Yet, in different climates, the same disease approaches to either genus. *Phlogosis* also is attended with topical redness, a læsion of the functions of the part, and a discharge from the neighbouring vessels. An additional advantage

arises from this arrangement, as it brings together diseases nearly resembling each other, which require distinction, as the inflammatory and putrid sore throat, the more active and putrid pneumonia. We see the distinction externally, in phlegmon and erythema, which are equally accounted inflammations; and authors have so generally acknowledged the connexion, that they have divided inflammations into membranous and parenchymatous. Dissection does not, however, countenance this arrangement; and if we examine minutely their definitions of the latter, they often seem to point out the diseases we have united in the present genus, which is a perfectly natural association, nor do the species require a comment. The number might perhaps be increased, since every active inflammation may be occasionally erysipelatous.

It has been remarked, that we have extended the meaning of *catarrhus*; and for this we have the authority of Schneider and Hoffman; indeed the etymology of the complaint. It was necessary to distinguish what is usually called *catarrhus*, therefore, by a new term, and we have adopted one of its synonyms, *coryza*. The varieties require some particular remarks. Of these, the first is, that, in nosological arrangements, the fever cannot always form a discriminating mark, since it even differs in the varieties of one species which cannot be excluded from it. Thus the *c. senilis* and *c. arthritica* are seldom attended with fever, while the common and contagious coryzae are accompanied with violent febrile symptoms, though of opposite kinds. 2. Even in diseases most apparently similar, the practice must be often different and even opposite, for the contagious and common coryzae require medicines very dissimilar, the *senilis* and *arthritica* still different ones. It does not, however, follow from hence, that methodical arrangement is of no utility, since it is not one of the least of its advantages to prevent prescribing to a name, and to obviate a general, indiscriminating, practice. The addition of the *croup* to this species is a step which requires some apology. It is, however, certainly an inflammation of a mucous membrane, attended with a discharge from the vessels of the part: the organs affected are the same as in coryza; this complaint very generally precedes, and the disease differs only in the nature of the discharge, which is gluten. The peculiar symptoms arise wholly from its inspissation.

The definition of *dysentery* is laboured with peculiar care, to distinguish it from diarrhoea, cœliaca, and leucorrhœis, with which it is very often confounded. *Phthisis*, if diseases are to be distinguished by symptoms, must belong to the genus *catarrhus*, for, though we know from dissection, that it sometimes arises from suppurating vomicæ, yet the symptoms are through its whole course truly catarrhal, as limited in the definition of the genus; and there certainly are cases which prove occasionally fatal, in which purulent matter is never discharged. (See *PHTHISIS*.) The definitions of the other species scarcely require a remark.

Arthritis is rescued from its limited sense, and extended to a generic association from its etymology. It is a genus strictly natural, for each species is attended with fever occasionally exacerbating. The *arthrodynia* is too intimately connected with rheumatism to be separated, though it approaches very near to palsy; and indeed we have remarked, that in the most violent pains

of gout, there is a weight and numbness of the limb, which distinguish it from other inflammatory affections. The *hydrarthrus* consists in that chronic inflammation of the muscles or joints which insidiously hastens on to suppuration, and destroys by its peculiar fever. If odontalgia be admitted in this genus, where few perhaps would look for it, as the union of the teeth with a jaw, though a pure articulation, would scarcely occur without some reflection, it should follow rheumatismus, or perhaps be included among its varieties.

Exostosis scarcely deserves the rank of a genus, yet it could not with great propriety be arranged under phlegmon, and its peculiar appearance as well as its cause required a particular distinction.

The greatest difficulty in constructing the third order, which is certainly a natural one, consisted in finding a title. *ERUPTIONES* is, in no respect, scientific or euphonous, but a better could not be discovered, except at the risk of occasioning confusion. The definition is sufficiently discriminating, and includes all the diseases, except the eighth species of exanthema. *Pestis*, included in this order from the authority of Dr. Cullen, should perhaps have been arranged under asthenic fever. In connecting diseases of the skin, nosologists have erred by contracting their limits too rigorously, or extending them too liberally. While Dr. Cullen confined himself to febrile exanthemata, and from specific infection, his inferior associations would be necessarily few, and those not strictly limited by the definition of his order. If every cutaneous disease, on the contrary, be included under the title, the list will be too miscellaneous to deserve the appellation of natural, and many appearances within the limits of health will find a place, as in the systems of Sauvages, Linnæus, and Vogel. In limiting this order, it was necessary at first to select the febrile exanthemata, without confining our views to specific infection, or, in reality, without contracting them within the common idea of eruptions. This was the real reason for our originally including *pestis*, which, on reflection, appears improper. *Aphtha* is more strictly related to cynanche, but we have seen a mild kind, more than once, epidemic, without any affection of the throat. This seems to justify its insertion.

The diseases which can be traced to specific infection consequently are first introduced, and others, usually epidemic, are added, though no peculiar virus is suspected. These are included in the first section. In the second are the sporadic eruptions, attended with fever, though less distinctly depending on it. The genus *exanthema* includes both. Of the *variola* two varieties are marked, the *confluent* from the difference of the appearance, and the *crystalline* for the same reason, and as there appears some probability that the second attacks of small pox have been pustules of this kind. Were the fact well ascertained, it would justify the formation of a new species, and we thus perceive one of the numerous advantages of nosology in suggesting circumstances of inquiry. *Vaccina* will now be acknowledged a distinct species, since doubts have arisen whether it be really a security from small pox. We have formed the definition with some hesitation, uncertain if it will in all cases clearly distinguish the vaccine pustule; yet its peculiarly rounded figure, and the brown depression (the Latin word *coccineus* would probably discriminate it more distinctly) appear to be sufficient for

his purpose. The *malignant* rubeola, in Dr. Willan's opinion, is a scarlatina; yet, as authors have pointed out a disease of this kind, and as, from the analogy of other fevers with topical affection, such may occur, we have inserted it. The other variety has not been very clearly distinguished, and the absence, or the very slight appearance, of catarrhal symptoms, render us somewhat sceptical on the subject. It seems more probably the *essere* included under urticaria. It has been supposed owing to an union of small pox and measles, but this is not true; for, when these diseases are present in the system, at the same time, they are never mixed. We have seen two epidemics of this kind, and have found, that, if small pox was the first disease, measles would stop its progress; and on their recession the small pox has resumed its course. If small pox preceded, both would go on together, but the pustules of each would preserve their own character.

Miliaria we have mentioned at some length, and have considered it as sometimes an idiopathic disease. The definition is collected from authors who have seen it more frequently than ourselves. But we can add, from our own observation, that the sour smell is often owing to an overflow of milk. The *scarlatina* sometimes occurs without an affection of the throat; and, on the other hand, during the prevalence of *scarlatina*, the throat is sometimes diseased with very inconsiderable, general fever, and no eruption. It will scarcely be credited, that in such circumstances children have experienced very little inconvenience, though the throat has been full of ragged deep ulcers. The distinction of the variety of *cynanchica* is thus obvious, but the disease, without eruption, belongs to another species, the *phlogosis anginosa*. If the definition be compared with that of rubeola, no difficulty of distinction can be felt.

As erythema, externally, is opposed to phlegmon, so is erysipelas to variola. We have no doubt of its being an idiopathic disease, as we have twice seen it epidemic. The delirium, which sometimes follows the complaint, occasionally attends it, and there is no reason for thinking it owing to metastasis, as the inflammation of the head and face continue at the same time. There may be doubt, whether the chronic, intermitting erysipelas should not be rather referred to erythema; but some fever we think generally attends, and this is the most proper place for its insertion. The only other species, which requires a remark, is *urticaria*. The definition is left somewhat too open, to include numerous papular eruptions, which require notice. We need not, however, add to what we have said, under the article *ESSERE*, q. v.

The genus *efflorescentia* is designed to include those cuticular diseases in which fever is not a constant attendant, or with which it is not indispensably connected: these, however, so nearly resemble the exanthemata, as to render a distinction necessary. As we have thus extended the limits of eruptions in a general view, it will be reasonably asked why we do not include lepra, pellagra, and similar complaints in the same rank. The reason was that the species included in the genus *efflorescentia* were diseases of the extreme vessels, not depending on a general state of the fluids, while the lepra appears in the constitution, before the defecation of the surface comes on. The voice is previously observed to be shrill and tremulous; the complaint can

be traced to an hereditary disposition; the faculties of the mind decay with the impaired health. The same general disease appears more strongly in the pellagra, as described by Strambio, in his collections on this disease (Mediolani 1786-89, 3 vols. 4to.) We have observed the same previous changes in elephantiasis; and the Cretins are equally distinguished by imbecile minds, and weak bodies.

To enumerate all the species of *efflorescentia*, however strictly limited, would be a difficult task. They appear in every form and every variety; and we have left one species open, as already remarked, to include the anomalies. In general, they are chronic diseases, and connected with effusions on, or under, the skin. In prurigo, indeed, there is no evidence of this effusion; but the itching seems to show that it probably exists. The only ambiguity arises from syphilitic eruptions, which ought, perhaps, strictly, to be included in this order, from the appearances; but, as connected with depraved fluids, is grouped with other associations. The eruption, however, is only symptomatic, and the difficulty may be removed by a comparison of the additional symptoms.

The definitions of the species will sufficiently distinguish them. The only circumstance of doubt respects the *lichen*, which, perhaps, is only the chronic, intermitting, erysipelas. The purple colour of the more violent species, and its general appearance, seem to indicate a disease in some measure distinct; but it is sufficient to suggest the question for further examination. *Petechiæ* are often symptomatic, yet they sometimes appear independent of fever and of any considerable debility. The *morbus petechialis sine febre* is noticed by the French and German authors, of which we have seen several instances.

The title of the fourth order, *profluvia*, is limited to its simple obvious sense, morbid discharges; and the association requires no comment. *Profluvia* differ either as the discharge is bloody, or excrementitious; a fever, though occasionally a leading symptom of hæmorrhages, is but slightly connected with this order, as they most commonly happen independent of it, or at least, its degrees are so various, and its appearance so fleeting, as often to evade the possibility of distinguishing it in any given profluvium, and prevent us from availing ourselves, except in the marked instances of active hæmorrhage, of such distinction in practice.

The species require no comment; but the insertion of *vicaria* is scarcely regular in a systematic view, for all vicarious hæmorrhages must be symptomatic. Yet so numerous are these discharges, and so important are they in a practical view, that we trust the physician will commend, what the nosologist must disapprove. The definitions of *hæmoptysis* and *hæmatemesis* are peculiarly contrasted, as distinction is sometimes difficult. We mean not to defend what in each may appear doubtful, but only to observe, that such are the respective symptoms as they have occurred to us; such at least we have thought the distinguishing circumstances of hæmorrhage from either organ. It is difficult sometimes to distinguish the hæmorrhage from the bladder, from the blood discharged in consequence of the irritation of a calculus; but the quantity of the discharge, and the absence of the more striking symptoms of calculus, will prevent any error. The two varieties will be easily

distinguished. It will be obvious from the character of *melænu*, that we rather consider it as a bilious than a bloody discharge; but we need not add to what we have observed in that article, *vide in verbo*. In compliance with the language and opinions of practitioners, its insertion in this place was indispensable.

The title of the next genus is borrowed from Dr. Cullen, but used in a more limited sense. The definition requires neither apology nor defence, and the species are sufficiently connected. *Vomit* may appear a simple object, but it involves some contradictions, at least some subjects of disquisition. It may be said, that the aliment, not the excrementitious fluids are discharged, and sometimes no fluid which is naturally carried to it. The first objection is, however, guarded against, in the definition of the genus; and it may be fairly observed, that no vomiting takes place without some evacuation of the mucus of the stomach. The *pyrosis*, however, consists in a discharge not naturally contained in that organ, viz. a cold fluid; but however difficult the explanation may be found, the variety is obviously connected with the species, and the latter with the genus. The atonic vomiting, the consequence of retrocedent gout, repelled eruptions, &c. is equally a subordinate affection inseparable from the rest.

Diarrhæa is usually divided into different species from its causes, but it seems, in practice, or in its symptoms, to require only two subdivisions, viz. where the discharge is chylous, or where it is watery, in which the truly feculent matter is retained. The mucous discharges from the intestines would appear to be properly inserted in this place, but these are more generally attended with fever, and mucus is scarcely a natural evacuation from the bowels.

Of the *diabetes* we have mentioned two varieties, for, in every instance, the chief form of the complaint is understood by the species; at least it should be, and the varieties are marked, when they are exceptions to the usual form, or when they require a variety in practice. The first of these is the *mellitus*, for, if the discharge is merely the increased watery secretion, it is understood from the definition of the species. The *diabetes mellitus* has lately claimed much attention, but the pathology and the cure are still imperfect. We have added another species, chiefly to notice a singular fact, that, when dropsical swellings are observable in almost all the cavities, if the urine is in considerable quantities, a large proportion of mucilage or gluten is found in it.

The species *diuresis* may require an apology, for it is often a symptom, but sometimes it appears rather as an idiopathic disease, arising from terror, surprise, or any peculiar sound, in some constitutions; as when "a bagpipe sings in the nose." Its distinction is obvious from the definition. The species *ephidrosis* may appear superfluous, for it is often a symptom of fever or debility; but its partial occurrence, particularly in the feet, is sometimes the object of the practitioner's attention.

For *plica* we could find no more suitable place, though it is less proper in this order, as connected with fever. Did we know the nature of the fever better, we might place it with more accurate discrimination, but at present we must look on it as an increased excrementitious discharge; and does not Shakspeare call Autolycus' beard, "the pedlar's excrement?" If this

be not authority, we have no better. The *Ptyalismus mellitus* is introduced on the authority of one striking case, though we have observed, in several, an approach towards it.

Obstructions are generally connected in every nosological system, except where the local are separated from universal diseases; but in the species enumerated are many of these local diseases, which are the objects of general practice. *Dysphagia* may arise from tumour, accretion, inverted motion, flatus, spasm, or debility. The two first are the only objects of the genus, which is limited to organic affections. The third is a symptom of palsy. The fourth and fifth of hysteria, and the last of vomiting. The existence of tumour, or accretion, cannot be ascertained in many instances, even by the probang, for spasm, as we have seen, will give the sensation of resistance, like a tumour, both in the œsophagus and urethra; but a repetition of the trial will show the nature of the cause, for spasm is seldom constant.

Obstipatio is generally passed over in nosological systems, as a local disease, but it is an object of considerable importance. A scirrhus pylorus, tumours of the omentum, or of some of the chylipoietic viscera, intusceptio, and a scirrhus contracting the rectum, are diseases which require distinction, and which can be discovered only by the symptoms. These we have endeavoured to distinguish in the different definitions, so far as the variety of symptoms would permit. *Polyphus* requires no particular remark, except the fact of its sometimes preventing the return of blood from the head. A case of this kind occurred some years since, while transcribing the definition, and the fact was confirmed by dissection.

It was necessary to form a separate genus for *asthma*, and *dyspnœa*, since they certainly belong to this order, and are not always organic, nor constantly depending on suppression of excrementitious discharges. The term *anhelatio* is familiar to nosologists, and neither the species nor the definitions require a comment.

The genus *epischesis* can require neither comment nor defence. The definition of *dys hæmorrhœis* is guarded in a manner, which would not be accepted in the school of Stahl, since it implies that the discharge is not required, except when established from habit. See *Hæmorrhœis*.

Obstructions of the secreted fluids are regularly associated, though, as there is a group of diseases depending on discoloration of the skin, perhaps *icterus* might have been more properly referred to it. The white stools are, however, a symptom equally obvious, and it is a disease much more general than the greater number which occur in that association. By the definition of the calculus icterus we do not mean to say that every instance of calculus is attended with pain, or that every painful jaundice is owing to calculus. Such, however, are the more common cases; and the spasmodic icterus is generally pointed out by authors. We find no subject of remark, or explanation, in the other genera, except to add, that *sitis* we have seen in two instances as idiopathic disease; at least, we have not been able to trace it to any morbid state of the body, except the vague idea of acrimony, apparently shown by slight eruptions on the skin. It was proper, however, with these cases in our view, to mark it especially, as we had the sanction of former nosologists.

The order *spasmi* is an association so constant, that it requires little observation; nor are the species so uncommon, the definition so peculiar, as to demand any commentary. It will be obvious that we have kept in view the distinction formerly made of convulsions being irregular rather than increased action, and the species chorea, raphania, and beriberia, are evidently proofs that this irregular action is closely connected with extreme debility, as each verges on, and is sometimes terminated by, palsy. *Pandiculatio* is equally connected with imperfect or irregular excitement. In the varieties, where it was necessary, we have equally kept in view the principle of convulsion arising from sensible irritation, or, in weak mobile habits, from irritation, often unperceived. The history of hysteria fully illustrates this principle, which pervades, without the author being conscious of it, the whole of Dr. Whytt's works on nervous diseases.

The *adynamia* form equally a natural association. We have scarcely stepped from the common systems, except in the varieties of apoplexy. The distinctions of the second and fourth may appear to be made without a difference. We meant, however, to distinguish the last moments of a constitution gradually sinking from that progressive stupor, which arises from effusion: each case we have distinctly observed. The *a. hydrocephalica* we have introduced in compliance with the authority of Dr. Quin, of Dublin; and we think that we have been able to distinguish this species, though we know not that any words will discriminate it, from hydrocephalus. It chiefly occurs in females of a fair complexion, blue eyes, and light hair. Perhaps, however, this is the strictly proper place for internal hydrocephalus, since there is no increased bulk.

The *paranoia*, a term derived from preceding nosologists, comprehends all the irregular or excessive appetites, and all the irregular exertions of the nervous powers. We begin with the diseases of the stomach, followed by those of the sexual organs, in which the mind is particularly affected, and ascend to those in which the mind chiefly suffers. Hypochondriasis is the connecting link; but the arrangement would have been more perfect; if the sexual passions had preceded, as the hypochondriasis and melancholia are so nearly connected. The introduction of *erotomania* may excite a smile; but it is often truly a disease, and, as an unsuspected one, is frequently troublesome. The species and their definitions require no farther remark than the pages of this work will afford. Under the *mania venenata*, Van Helmont is quoted, who relates with singular eloquence his own feelings in these circumstances.

The *cachexia* also require no remark, except that the *rubigo* is inserted from the authority of Coutanceau, in the Memoirs of the Medical Society of Emulation, who calls it cutaneous apoplexy.

The *intumescencia* scarcely form a natural order, and even the genera are not always natural associations; but it was impossible to avoid these anomalies. We have endeavoured to remedy the inconvenience, by passing from the more to the less solid, from thence, in succession, to the watery and aerial tumours; and on a comparison of the species of the first genus, it will be obvious that these could not be associated with the eruptions. We have again introduced *exostosis*; and it may remain if the inflammation is not thought a

sufficient reason for its retaining the former position.

The genus *phyaconia*, is, like some others, left open for anomalous tumours, of which the more important are distinguished, and may be ascertained by the organ affected. The *p. hepatica* and *uterina* (including in a more enlarged sense the whole uterine system, and particularly the parts most commonly affected, the ovaria) are the most common. The *externa* can be confined by no definition. We have thus included scirrhouidea, the sarcomatica, the graviditates falsæ, the megala, and polypsplachnina, the steatomatosa and strumosa of authors; but have not noticed the hydatidosa, because we could find no symptoms by which they may be distinguished, as we have confessed under the species *hydatidis*, which authority, rather than conviction, induced us to insert. The dropsies, *phlegmatia*, require no comment; and if some of these are partial tumours, the general relation will excuse the anomaly.

The *hernia* we have not again enumerated. Lest the list might be unnecessarily prolonged, we have also omitted the varieties, arising from the situation of a prolapsed intestine, which may be seen in the present work, and the impaired functions will at all times furnish the symptoms. See *HERNIA*; *LUXATIO*; and the different terms inserted in the general classification under *prolapsus*.

The species of *diastasis* have not been noticed by authors, though several may be observed; and the only one which has particularly challenged the attention of practitioners is that mentioned supposed to occur in labour, and facilitate delivery. Having concluded a new arrangement of diseases, we must leave it to the candour of the public. Had we not thought it meriting their attention, we should not have offered it in this place. While its reception is uncertain, it would have been improper to disturb the general system by even these few novelties of appellations or arrangement. If received with approbation, it may at a future period be incorporated with the whole, when its utility and application will be more striking, and when its foundations may be more fully developed. At present it has been with great care abridged, that those who disapprove, may not complain that much time and space have been mis-spent or misapplied. See Sauvagesii Nosologia, 2 vols. 4to.; Culleni Nosologia; Macbride's System of Medicine; Pinel Nosographie Methodique, 2 vols. 8vo.; Selle Pyretologia Methodica; De Haen Theses, Sistentes Febrium Divisiones.

NO'SOS, (from the Hebrew term *nosis*, *infirm*). See MORBUS.

NOSTALGIA, (from *nostras*, *our own country*, and *algia*, *maror*). NATIONAL INSANITY, in which strangers have such an unconquerable desire to return to their own country, that they become restless, with loss of appetite and strength, succeeded by dejection of spirits, insanity, or death. Dr. Cullen distinguishes two species, *nostalgia simplex*, and *complicata*. It is, in fact, a species of insanity from hope delayed, to which the Swiss, from a strong attachment to their native country, are generally subject; and the familiar tune, called *Ranz de vaches*, played at milking the cows, is forbidden in foreign armies, as it excites the tender recollection of what they have left.

NO'STOCH. See CÆLI FLOS.

G

NO'THÆ CO'STÆ, (from *volæ*, *spurious*). See COSTÆ.

NO'THUS, (from the same). A variety often of a disease, not attended with the acute symptoms of the more active kind. Thus peripneumonia notha is a catarrh without violent inflammatory symptoms.

NOTI'ÆUS, (from *notos*, *the back*). See MEDULLA SPINALIS.

NUBE'CULA and NU'BES. See URINA ENCAUMA, and ALBUGO.

NUBE'CULA SUSPE'NSA. See ENÆOREMA.

NUCAME'NTA, (quasi *nucis amentum*). See AMENTACEI FLORES.

NU'CES OLEO'SÆ. See FARINACEA.

NU'CES PURGA'NTES. See CATAPUTIA MINOR.

NU'CHA, (from the Arabic terms *nucha*, *the spinal marrow*, or *nekra*, *the cavity between the shoulders*). The BACK of the NECK.

NU'CIPRUNI'FERA, and NUCI'FERA. See NUX VIRGINIANA.

NUCIO'SITAS. See MYOPIA.

NUSIPE'RSICA, (quasi *nux Persica*). The NECTARINE.

NUCI'STA. See NUX MOSCHATA.

NU'CLEUS, (ð *nuce*). A KERNEL, that part of the fruit which is inclosed in a hard shell.

NU'CULA TERRE'STRIS, (a dim. of *nux*). See BULBOCASTANUM.

NU'CULÆ SAPONA'RIÆ, *baccæ Bermudenses*, the fruit of the *sapindus saponaria* Lin. Sp. Pl. 526. These fruits resemble in size a cherry, and are transparent, showing the nut within. The part employed in medicine is the cortical, and it has been used in chlorosis, but is now neglected. It is a bitter of the narcotic kind.

NUMMU'LARIA, (from *nummus*, *money*, because its round leaves are of the size of a silver penny). *Lysimachia nummularia* Lin. Sp. Pl. 211; from its supposed utility, *centi-morbia*; in English HERB TWO PENCE, and MONEY WORT, is a low creeping plant, with square stalks, and smooth, little, roundish, or heart shaped leaves, set in pairs at the joints, upon short pedicles; in their bosoms appear yellow solitary monopetalous flowers, each divided into five oval segments, and followed by small round capsules, full of minute seeds; perennial, grows wild in moist pasture grounds, and flowers from May to the end of summer. It is said to be astringent, antiscorbutic, and vulnerary; resembling a mixture of cochlearia with acetosa. See Raii Historia; Lewis's Materia Medica.

NUSCITIO'SUS. See NYCTYALOPS.

NUTRICA'TIO, (from *nutrico*, *to nourish*). *Accretio*, *alitura*. NUTRITION, ACCRETION, or GROWTH.

The progressive increase of the body and the successive development of different organs we have explained in a variety of articles, and have traced the aliment from the stomach through its various stages to the blood vessels. The question then returns. How is the nourishment applied to the increase of the body, to the development of these different organs? Two opinions have prevailed, one that it is applied by the extremities of the arteries; the other that it is a fluid secreted from the vessels of the brain, and conveyed by the nerves. Dr. Cullen was so much struck with the glandular appearance of the brain, that he seemed to want an object for the application of its secreted fluid;

and the fact, that when the nerve leading to any part was divided, the latter was emaciated, seemed to assist the conjecture. It was no more, for he never rested on it, nor did it form any part of his system. We shall now, therefore, bring together, in a few words, the doctrines often inculcated, to give a view of the whole subject, without concealing its weaker parts.

The germ, we have said, contains in miniature the whole body, convoluted and contracted within a bulk so small, that we thought some illustration of comparative magnitude and littleness necessary to render the idea less shocking. The organs are gradually expanded by the successive filling of the arteries, and the extent to which the parts will admit of expansion is the "internal mould," which forms the shape, and limits the bulk. The food taken in differs from the fluids in the proportion of many of its ingredients; but the great change is in the very great diminution of carbon, and increase, often the formation, of azot. The process of digestion consists partly of separation, in part of solution, but most essentially in the assimilation of the aliment to the nature of the animal fluids. The latter is apparently effected by the remains of the former meal, acting as a kind of leaven; for the gastric fluid appears to be nearly a common mucus, and to possess no qualities but what it derives from the relics of former aliment. We cannot explain the gradual change of carbon to azot; the only part of the problem unexplained till chemistry lends us farther aid, which we are on the point perhaps of receiving; when we shall probably also see the connection between the muriatic and the phosphoric acids, since the latter also is apparently of animal formation.

The azot is not, however, exclusively the creature of the animal process. It has been found that some portion of this principle is occasionally absorbed from the atmosphere, and, even in the most strictly vegetable diet, some portion of azot is contained. This will not, however, account for the whole change, and there is some probability that the hydrogen, by some play of affinity, is changed to azot; but, as we have just remarked, chemistry has not yet afforded us sufficient light to enable us to perceive the source of the change.

The animal fluids then, distending the vessels, expand the convoluted fibres, and deposit in their interstices, dilated perhaps into a cellular substance the peculiar matter of which they consist. Every appearance of the animal economy seems to show that the state of the exhalent arteries forms or changes the nature of the fluid which they pour out, and the whole mystery of secretion consists probably in the various states of these vessels. Physiologists have supposed that fibres are not enlarged, but only elongated. They seem to be neither; but we believe that what we style fibres are only the larger fasciculi; and this we gather from finding in the extremities of nerves which are evidently fibrous, a structure which eludes even the assisted sight. When we speak then of the interstices of fibres, and the cellular substance, we do not mean that grosser kind which we see and handle, but that interposed between fibres, which escapes our glasses: animal matters of different natures are thus deposited in different organs, favouring or assisting their separate functions; and this matter is progressively absorbed, and again deposited. It is absorbed, say physiologists, when it becomes

effete, a term without a meaning: in fact, the change from carbon to azot is continually going on, and the oxygen gradually disappearing. When the proportion of the azot is too great, threatening dissolution to the system by the putrefaction which it favours, it is absorbed, and again supplied by the arteries. The nourishment is deposited in a fluid form, and this fluid seems to have a greater affinity to the azotic animal matter than to the recent substance. The former then becomes fluid, and is taken up by the lymphatics; for we know that nothing is adapted to their orifices but a fluid, or what approaches in consistence to it. This is not fanciful or hypothetical. Putrid matter of every kind shows its attraction for watery fluids, and assumes this soft consistence. When madder is mixed with the food of animals, it gives a red colour to the bones, for an obvious reason, it has been said, because its affinity to the calcareous phosphat occasions it to be deposited with this salt. It occasioned, indeed, some surprise that so hard a substance as bone should be so soon deposited and absorbed, till the difficulty was explained by a French chemist, who confirmed the former affinity; but found that the colouring part of madder had a greater attraction to the serum of the blood than even to the earthy neutral. This observation confirms also, in a striking manner, the successive deposition and absorption of the fresh and azotic animal matter; while it explains what has been thought a difficult problem, how the matter to be absorbed attains fluidity.

The parts of the body are thus successively renewed, and it has been conjectured that in seven years the whole was changed. This suspicion, for it is no more, must, of course, vary in infancy, more in advanced life, and in old age; but, if our conjectures respecting the primordial germ are right, the added matter is only changed; the original fibrous structure remains the same, and with it the metaphysician will say *personal identity*. It will be obvious, that, to supply nourishment, the power of the exhalents must be unimpaired; and this will sufficiently explain the reason why, on destroying a nerve, or impeding its influence by a ligature, the limb which it supplies is emaciated. In general, nutrition appears wholly conveyed by the arteries.

Every nutritious substance must be capable of some change in the stomach, must be susceptible, not of fermentation in the strict chemical sense of the term, but of assimilation from the influence of the remaining leaven. When reduced to its principles, and these are again combined, they form a simple fluid called chyle, which is conveyed to the arterial system, and, by its access to the air in successive circulations, forms blood. From hence the nutritious matter is secreted. Its nature is uncertain; and various have been the opinions on this subject. Lorry thinks it a mucous substance; Cullen a saccharine one; Halle an hydrocarbonated oxide, differing from the oxalic acid by having a smaller proportion of oxygen. He explains, with some propriety and force, the disappearance of the carbon and oxygen by their forming carbonic acid gas, which is carried off in respiration. In the same process, the azot is, he thinks, separated from the venous blood, to combine with the newly assimilated chylous matter. The remaining carbon, mixing with the oxygen of the air, at the surface, is still farther separated, leaving the blood, *sit venia verbo*, azotized. This explanation is,

however, more ingenious than true. The azot is an excrementitious fluid: instead of wanting it to animalize the chyle, the latter is necessary to correct the azot. The nutritious fluid, whatever it may be, is apparently simple; and we could, were this a place to build systems, give some striking reasons for supposing it pure albumen.

See HOMO, HÆMORRHOIDS, MENSES, FÆTUS; For-dyce's Elements, Part I.; Halleri Elementa Physiologiæ; Whytt's Physiological Essays; Monro's Observations on the Nervous System; Richerand's Elements of Physiology.

NUTRITUM UNGUENTUM was formerly made by mixing certain proportions of vinegar, oil, and litharge; but the London College substituted, as a neater application, the *unguentum cerussæ acetatæ*, made in the following manner: Take of acetated ceruse two drachms, and white wax two ounces by weight; olive oil half a pint: rub the acetated ceruse, previously powdered, with some part of the olive oil; then add it to the wax, melted with the remaining oil. Stir the mixture till cold. Ph. Lond. 1788.

The unguentum nutritum was formerly made by mixing three ounces of litharge with seven of olive oil and four of strong vinegar, and the term "sine corpore" was added, because the vinegar was united to the oil without the medium of mucilage or albumen. The process was, however, tedious, since the trituration was incessantly continued many days. Baumé shortened it, by using olive oil coagulated by cold, which kept the litharge suspended, while the vinegar dissolved it, or hastening the union by means of heat.

M. Dubuc, an apothecary at Rouen, has attempted to improve this formula by means of the new lights of chemistry, and we shall add a short abstract of his remarks. When we wish to *nourish* the vinegar, with the litharge, and the oil, for that was the origin of Lemery's fanciful term *nutritum*, since they were rubbed together till they formed a *body*, which neither ingredient had separately, we must dissolve a little of the litharge in the acetous acid, and introduce a sufficient quantity of carbonic acid to change the greatest part of the litharge into a white carbonate, which remains mixed with the oil, and to thicken the oily mixture; an effect analogous to thickening soap by the same acid. If so much vinegar is employed as to form a saline, *saturated*, compound, the consistence will not be proper. If too great heat is employed, according to Baumé's plan, a portion of the carbonic acid is separated, and a yellow oxide of lead remains uncombined.

It has been proposed to accelerate the preparation by adding hogs' lard; but this addition diminishes the bulk and lightness. In Germany, one half part of oil of roses is added to the vinegar of lead, which produces an ointment as white as wax, and of the consistence of a liniment; sometimes one half as much oil of olives, which produces a whitish ointment of a moderate consistence; sometimes with one part of oil of olives, as much vinegar of litharge, and half as much wax, which produces an ointment of a waxy whiteness and a firm consistence; but these are all mixtures, and by no means such intimate combinations as the true nutritum. We have engaged in this detail, not only from its curiosity, but to suggest a suspicion that we have probably sacrificed, in this preparation, too much to the ease of

the pharmacist. The utility of the old nutritum arose in a great measure from its levity, in consequence of a proportion of air, probably of carbonic acid gas, mixed with it; above all, from its being so imperfect a conductor of caloric.

In the Pharmacopœia Chirurgica the litharge plaster is employed, lowered in consistence by olive oil, adding vinegar to dissolve the litharge. This appears to be following the first plan of Baumé, as the plaster supplies the place of the congealed oil: but this application wants the lightness and the cooling quality of the real nutritum; and the unguentum cerussæ acetatæ, unless extemporaneously prepared, soon becomes rancid. See UNGUENTUM LITHARGYRI ACETATI, under LITHARGYRUS.

NUX, (from the Hebrew term *luz*). A NUT, a term belonging to many vegetable productions, viz.

NUX BARBADENSIS. See RICINUS, and CATAPUTIA MAJOR.

NUX BEN. Vide BEN.

NUX BENGALENSIS. Vide MYROBALLANI CITRINI.

NUX CATHARTICA AMERICANA. See RICINUS.

NUX DE BECUBA. A resinous Indian fruit from an unknown tree, whose oil is said to be a specific against cancers and colics.

NUX INDICA. See CACAO.

NUX METHEL. The fruit of the STRAMONIUM METHEL.

NUX NARCOTICA. An Indian fruit which occasions vertigo and delirium. It is used in anodyne plasters; but the plant has not been described.

NUX SERPENTINA. The fruit of the AHOVAI, q. v.

NUX MOSCHA'TA, *myristica nux*, *nucista*, *hala*, *chrysobalanus* Galeni, *unguentaria*, *assala*, *nux aromatica*, the NUTMEG, *myristica officinalis* Lin. Supplement, Pl. m. *moschita* of the Fragments, and the later editions of Schreber. In reality, however, the jealousy of the Dutch concealed the real plant, nor was it ever accurately described till the description of La Marck appeared in the Memoirs of the Academy of Sciences for 1788. He found it to be a dioecious plant, of the natural family of the Laurineæ, containing exotic trees or shrubs, evergreen, whose leaves are entire and alternate, and whose little axillary flowers are united in numbers on peduncles, divided, and longer than the leaves. He styles it the *myristica aromatica*. The fruit is a rounded or oval drupa, containing a large solid, oily, often aromatic, seed, through the internal parts of which veins branch, of different colours, but chiefly brown. The seed is defended by different coats. The first is fleshy, though sometimes dry and coriaceous; the second is the mace, a coloured membrane, deeply divided; the third the shell, which is thin, hard, and brittle, externally impressed with the ramifications of the mace.

The nutmeg is said to have been known to the ancients, and to have been the *comacum* of Theophrastus; but this author speaks vaguely only of the comacum as a spice brought from India; while the nutmeg is not from India: it is a production of the Molucca Islands and the Isle of Banda, and it is highly probable, as C. Bauhine and L'Ecluse have thought, that it was not known to the ancients. The Arabians first introduced it under the name of *jiansiban* (Avicenna II. c. 503), the nut of Banda. It is the *jenzave*, or *jus-*

bage, of Serapion, the *moschocarion* of the modern Greeks.

More modern naturalists were equally divided respecting the real plant which produced the nutmeg. Piso thought it resembled a pear or a cherry tree; others mistook the mace for the flower; Valentini and Rumphius saw only the female flowers, and their description was, of course, erroneous. They indeed gave the name of male and female to different species; but in the spirit of a grammarian, who tells us, "that the masculine is more worthy than the feminine." So the long nutmeg was the male, and the inferior round one the female: the different plants were distinguished on the same principle. Linnæus in his later works, Adanson and Sonnerat approached nearer the real plant in their descriptions; but the account of each was imperfect. Thunberg, in the Stockholm Transactions of 1782, gave a more faithful description of the plant, but it was still erroneous; nor, until the nutmeg tree was conveyed to the Isle of France, and branches, with perfect fructifications, sent to La Marck, did we properly know its form or habit. The general account already given is sufficient for our present purpose.

The *myristica aromatica* is continually in bloom, while the plant bears, at the same time, fruit of all ages, and its leaves fall in so small a proportion, that their loss is almost insensible. It is impossible to distinguish the male from the female tree by its leaves or habit. Some nutmeg trees produce both oblong and round seeds; others only round ones. The embryo of the future plant is at the large end of the nutmeg, where it is contiguous to the peduncle. In the plants sown, the males have been found more numerous than the females; a considerable inconvenience, as the sex could only be distinguished by the flowers. It was corrected by one planter, who preserved, in each tree, two branches, on one of which he grafted a female twig. The trunk, branches, and even the leaves of the nutmeg tree, when wounded, pour out, in sufficient abundance, a viscid juice of a pale red colour, which gives a durable mark to linen: the wood is light and porous, without any smell. The leaves slightly smell of the nutmeg, when fresh only. The fruit is ripe nine months after the flower has withered, and its pulp is sharply astringent. It is preserved, and a kind of marmalade made of it. The virola of Aublet and Jussieu, the tallow tree, appears to be a species of *myristica*. The other species of *myristica* are distinguished from their country, viz. the Philippine Islands, the coast of Malabar, and the Island of Madagascar, or from the shape of their leaves or their fruit. We learn nothing from La Marck of the comparative merit of their several seeds. The tree, we know, is propagated by birds, who break the shell; but in whose intestines the nutmeg is not digested. The hint has been taken apparently from this fact, and the nutmeg is planted without its shell. In this way, it vegetates sooner, and the worms have no time to eat it.

Nutmegs, preserved entire, are introduced in India with tea, but the mace and pulp are only eaten: the nut is thrown away. In cold climates, and voyages in the higher latitudes, the nut is chewed every morning.

The nutmeg is moderately warm, grateful to the taste, and unctuous. It is cordial, carminative, and astringent,

in doses of from three to fifteen grains; but to increase its astringency it is roasted, and used in diarrhoeas and dysenteries. In large quantities it is said to affect the head, and to be dangerous. Bontius says, this is a frequent occurrence in India; and Dr. Cullen saw a remarkable instance of its anodyne power in a person, who took two drachms of nutmeg in powder. See Cullen's *Materia Medica*, vol. ii. p. 204. An ordinary kind of nutmeg is called *areca*, *avellana Indica*, &c. From 1920 parts of nutmeg Neumann procured 480 of spirituous, and 280 of watery extract, with 320 of oil or tallow. The two last were insipid.

By an inverse operation he procured 600 parts of watery extract, fifty of sebaceous matter, and ten of volatile oil, afterwards 120 of an unctuous spirituous extract, and 300 more of fixed oil. The same quantity by expression gave 540 parts of oil, and afterwards 480 of watery extract; a strong distilled water, eighty grains of spirituous extract, and sixty of insipid oil.

The London College directs a gallon of proof spirit to be drawn by distillation from two ounces of nutmegs, called *spiritus nucis moschatæ*; but when a few hawthorn flowers are added, it is called *aqua nephritica*. A tincture made from the nutmeg, in proof spirit, is a valuable medicine.

By a distillation with water nutmegs yield nearly one-tenth of their weight of a limpid essential oil, *oleum nucis moschatæ essentielle*, very grateful, possessing the flavour of the spice in perfection; it is recommended as antispasmodic and anodyne, similar to the oil of mace, but is not so grateful.

On the surface of the remaining liquor an unctuous concrete, like tallow, swims, of a white colour, nearly insipid, not corruptible, commended as a basis for odoriferous balsams. The decoction, strained and inspissated, leaves a weakly bitter sub-astringent extract. We have already remarked that the tallow tree is a species of *myristica*.

Rectified spirit takes up the whole smell and taste of the nutmegs, and receives from them a deep bright yellow colour. The spirit drawn off from the filtered tincture is very slightly impregnated with their flavour; the greatest part of the specific smell, as well as the aromatic warmth, bitterness, and sub-astringency of the spice, remaining concentrated in the extract. Both the oil, the spirituous tincture, and extracts, agree better with weak stomachs than the nutmeg itself.

When nutmegs are heated, and strongly pressed, they give out a fluid yellow oil, which concretes on growing cold, into a sebaceous consistence. We are informed, that in the spice islands the imperfect and damaged nuts are separated for this purpose. In the shops we find three sorts, under the name of *oil of mace*. The best, brought from the East Indies in stone jars, is softish, of a yellowish colour, an agreeable fragrance, greatly resembling that of the nutmeg itself, but of the colour of mace. The next, from Holland, in solid masses, generally flat, and of a square figure, is paler coloured, weaker in its smell, and inferior in its quality to that of India. The last seems to be a composition of suet or palm-oil, flavoured with a little of the genuine oil of nutmeg. The chief use of these is for liniments, to be applied to the stomach, or as an ingredient in anodyne and nervous ointments. See Tournefort,

Lewis, and Cullen's *Materia Medica*; Neumann's *Chémistry*.

NU'X vel GLANS UNGUENTU'ARIA. See MYROBALANI.

NUX METE'LLA. See NUX VOMICA.

NUX VIRGINIA'NA; *prunus prunifera*, *nucifera*, *nucifera*, *nucifera*, *mastichen odoratum fundens*, a variety apparently of the *sapindus saponaria* Lin. Sp. Pl. 526, MASTICH of LIGON, and VIRGINIA NUT. Its leaves shine like those of the bay tree, and it differs from other pruniferous trees in its fruit, which is small, turbinate, containing but a little pulp.

The fruit is of the shape and size of a filbert, smooth, of a brown colour, with an eye near one end, containing a hard stone; and the kernel is white and globular, of a bitterish taste, and an aromatic smell. It is said to be antiscorbutic, deobstruent, and cordial. See Raii *Dendrologia*.

NUX VO'MICA, *nux metella*, *caniram*; *faba febrifuga*, *igasur*, is a flat roundish seed or kernel, about an inch broad, and a quarter of an inch thick, with a prominence in the middle, on both sides of a grey colour, covered with wool, internally hard and tough like horn, the produce of a large tree in the East Indies; *Strychnos nux vomica* Lin. Sp. Pl. 271.

It is bitter to the taste, and this quality chiefly resides in its resin; for the gum is but slightly so. Fallopius observes, that in doses to 3 ss. it procures sweat; but Hoffman informs us, that two doses of seven or eight grains each were fatal to a girl of ten years old. These nuts poison dogs, crows, &c. When imprudently swallowed by men, they produce great anxiety, convulsions, paralytic symptoms, retching, an increased action of the heart and of the lungs. The bitter is evidently in a high degree narcotic; but in Germany it has been given as an antidote against the plague, in mania, and hysteria; in hydrophobia, hypochondriasis, rheumatism, and gout. They have been employed with various, but not considerable, success in dysentery (London Medical Journal, vol. iii. p. 189,) as an anthelmintic in cases of tænia; and lately by Loureiro, after roasting, in fluor albus. This operation seems to mitigate their virulence. In this country, however, they have been seldom given. See Raii *Historia*; Lewis's *Materia Medica*; Neumann's *Chemical Works*.

NUX VO'MICA SERAPIO'NIS; *faba sancti Ignatii*, *pepita nux*, *faba Indica*, *catalongay*; ST. IGNATIUS'S BEAN, the produce of a tree called *mananaog*, or *cantara*, found in the East Indies and the Philippine Islands. It was supposed to be the production of a species of *strychnos*, with the trivial name of *volubilis*; but the younger Linnæus, and succeeding naturalists, have referred it to a distinct genus, *ignatia amara*. Each appellation Willdenow has preserved, vol. i. 1053. The fruit resembles a gourd, in each of which are from twenty to thirty seeds, improperly called beans. They are of a roundish figure, irregular, and uneven, of the size of a middling nutmeg, semi-transparent, of a horny texture, and of a white colour, slightly tinged with blue. These seeds have a bitter taste, but only a musty scent while fresh. The inhabitants of the Philippine Islands use them as a medicine; but their effects are violent, and they are never employed in any other country. They are chiefly used in the Philippines, in intermit-

tents, amenorrhœa, asthma, epilepsy, and as anthelmintics. See Philosophical Transactions, N° 249, p. 44; Medical Museum, vol. iii.

The other vegetable productions to which the term *nux* is applied are,

NUX BASILICA, EUBOICA, PERSICA, et REGIA. See JUGLANS.

NUX MALABARICA. See CUMBULU.

NUX VOMICA MINOR MOLUCCANA, ALTERA. See COLUBRINUM.

NYCTALOPIA. See AMELYOPIA.

NYCTALOPS, (from *νύξ*, night, and *ὤψ*, an eye).

NIGHT BLINDNESS. *Imbecillitas oculorum*. Sometimes such patients are called *luscitiosi*, but improperly; for this term is applied to those who, from some defect of the eye, see better in the evening than at noon. In the Greek and Latin writers the word *nyctalops* has opposite meanings; sometimes signifying those who see by night; at others, those who cannot see during the night. It is now understood to signify that disorder, in which, as the night approaches, the patient loses his sight, and remains blind until the morning. The sight thus continues to return in the day, and to depart at night.

The word *hemeralopia*, in Vogel's system, stands for blindness in the night, and sight in the day; and *nyctalopia*, in Linnæus's and Vogel's Genera, stands for blindness in the day, and sight in the night.

It appears to be an intermittent, arising in one instance from too great sensibility of the retina, and in the other from torpor. In the former, the light of the day is too great for the organ to bear; in the latter, the impression is too weak to excite vision.

An endemic species occurs among some of the more irritable inhabitants of the burning regions of the torrid zone, and a possible case has been suggested where, on the contraction of the pupil in a strong light, the rays converge on a spot of the retina previously paralytic, which is avoided by a slight motion of the head when the pupil is dilated. The proper disease is of the intermitting nature just described, and its best remedy is the bark. It is peculiarly rare, however, in its occurrence.

See London Medical Transactions, vol. i.; and London Medical Observations and Inquiries, vol. i. p. 111. &c.

NYMPHÆ, (from *νυμφα*, a water nymph). *Alæ internæ minores clitoridis, colliculum, collicula, myrtocheilides*, are foldings of the skin within the labia, rising from above the clitoris, and passing obliquely downward and outward, till they are lost about the entrance of the vagina. Between them is the orifice of the meatus urinarius. The substance of the nymphæ is spongy, and the orifices of numerous glands are visible on its surface.

NYMPHÆA, (from the same). *Nenuphar leuco-nymphæa, micro-leuco-nymphæa*. The GREAT WHITE WATER LILY. *Ny mphæa alba et lutea* Lin. Sp. Pl. 729. Each is an aquatic plant, said to be anodyne and demulcent, but too insignificant to demand any further notice. See Râii Historia. The name also of a preternatural excrescence on the nymphæ.

NYMPHÆA GLANDIFERA, INDI'CA, and MADRASPA'STANA. See FABA ÆGYPTIA.

NYMPHÆA LOTUS. Lin. Sp. Pl. 729. an Egyptian plant, whose fruit is employed in making bread, and whose root is sweetish, resembling in colour the yolk of an egg when boiled. It seems to be referred improperly to this genus. See Alpinus de Plantis Exoticis, vol. iii. p. 227, &c. Willdenow has, however, retained it.

NYMPHOMA'NIA, (from *νυμφια*, nymphæ, and *μανια*, furor). See FUROR UTERINUS.

NYMPHOTO'MIA, (from *νυμφα*, and *τεμνω*, secō). In warm countries, the nymphæ or clitoris are sometimes inconveniently or morbidly large; and a portion is cut off by an operation, which has this appellation, for the ancients called the clitoris by the name of nymphæ. It is commonly styled circumcision of the clitoris.

NYSTA'GMOS, (from *νυσταζειν*, to be drowsy). A WINKING or TWINKLING with the eyes, such as happens when a person is very sleepy. When a disease, it is an instance of the chronic kind of convulsion, and arises from any cause of irritation in the eye, and is observable in all nervous irritable constitutions.

O.

O B L

OB according to Selden was usually translated Python, or magician. The *ob* of the ancients was a spirit, or dæmon, that gave answers which seemed to come from some part of the body, but with a voice so low, as not to be distinctly heard. The *obi* of the Africans is a filthy malignant spirit. See Mosely on Sugar, second edition.

OBCO'NICUS, (from *ob*, and *conus*, a cone,) somewhat conical.

OBELE'A, (from *ὀέλος*, a dart, because it is straight,) **SAGITTALIS SUTURA**, q. v.

OBE'SITAS, (from *obesus*, fat). **FATNESS**. This state is peculiarly common in England and Holland, supposed to arise from the use of new malt liquors, or from a less active life; but more generally referrible to the phlegmatic temperament, or to idiosyncrasy. Vinegar never prevents fatness, but by destroying the vigour of the stomach; and the best means of avoiding the accumulation of fat, is active life, with a diet rather of vegetable than animal substances. It often predisposes to disease, though it cannot alone be styled morbid. A remarkable instance is described in the London Medical Observations and Inquiries, p. 69—84. See **POLYSARCIA**.

OBFUSCA'TIO. See **OFFUSCATIO**.

OBLA'TES PURGA'NTES. Cakes, made of flour, sugar, and purging ingredients; not an uncommon form of quack medicines for worms. Ching's lozenges are of this kind; but, in the greater number of such formulæ, calomel, not often in the best state, is a frequent ingredient.

OBLI'QUUS, (from *ob*, and *liquo*, to flow aside). An appellation of muscles whose fibres are oblique; a name also of the *pronator teres*.

OBLI'QUUS, ASCE'NDENS vel INTE'RNUS. ACCLIVIS. These muscles arise fleshy from the spine of the os ilium and ligamentum pubis, and the upper edge of the os sacrum, according to Dr. Hunter; but other anatomists describe them as passing forward and upward from the ossa pubis and ilii, forming a broad membranous thin tendon, implanted into the whole length of the linea alba, and the cartilages of the eighth, ninth, tenth, eleventh, and twelfth ribs. Their tendons divide into two lamellæ, one of which joins the rectus on each side, and the other the transversalis. These muscles are not perforated by the spermatic cord. Besides their use in compressing the belly, that part which arises fleshy towards the back part of the edge

O B L

of the os ilium, and goes to the cartilaginous endings of the ribs, not only depresses them, and straightens the thorax in expiration, but from the order of its fibres counteracts the descending obliques in turning the trunk of the body, on the axis of the vertebræ. On its contrary side, as the series of its fleshy fibres is parallel to those of the descending oblique muscle, they may concur with them in discharging their office.

OBLI'QUUS DESCE'NDENS, vel EXTE'RNUS. DECLIVIS. They are the external muscles of the belly, denominated from the progress of their fibres, which run obliquely downwards. They arise by productions partly fleshy, and partly tendinous, from the lower edge of the fifth, sixth, seventh, and the greater number of the inferior ribs, which indent themselves into the fleshy dentiform processes of the serratus anticus major. Their fibres run forward and downward, terminating in the spine of the ilium, os pubis, and linea alba. Part of these fibres, which run toward the ilium, are lost in the fascia of the thigh, and those which run toward the os pubis are reverted, and consequently double, forming what is called the *ligament of Poupart*, and through it the spermatic vessels of men, and the round ligaments of the womb in women pass, for which purpose the tendinous fibres separate, and form a ring. From their origins, which are mostly fleshy, their oblique descending fleshy parts expand themselves into a broad membranous tendon, before they go over the rectus to their insertion in the linea alba and os pubis, from whence, still descending, they end partly tendinous in the ligamentum pubis, but chiefly fleshy on the superior and fore part of the circular edge of the os ilium. They do not adhere to the transverse processes of the vertebræ lumbares, but the largest, last, and most fleshy digitations, leaving the lowest bastard rib at its extreme point, in their oblique descent going forward, still recede gradually from the vertebræ, forming a triangular interstice, filled by the sacrolumbus and os ilium, on its lower side; in this area the fibres of the subjacent muscles plainly appear. These muscles give strength to the parietes of the belly, sustain and compress the viscera, propel the fæces, urine, and the fœtus: that part between the linea alba, os pubis, and the spine of the os ilium, bearing an analogy in its position to the mastoideus of the head, serves for the circumrotation of the trunk, upon the axis of the vertebræ, when we turn the body to the contrary side, and the feet remain unmoved.

OBLI'QUUS INFERIOR and **MAJOR**, *capitis obliquus inferior*. One of these muscles rises on each side, from the lateral part of the spinal process of the vertebra dentata, goes upward and outward, and is inserted into the transverse process of the atlas. Together they act by giving a rotatory motion to the head, and run in a contrary direction to the *obliquus superior*.

OBLI'QUUS MAJOR O'culi, *superior; trochlearis; amatorius; longissimus oculi*. It is called *trochlearis* from its tendon passing through a cartilaginous pulley, situated in the orbit of the eye, to the inside of the internal angular process of the os frontis, near the inner angle. This muscle rises tendinous from the bottom of the socket near the entrance of the optic nerve, and passing towards the upper part of the socket, near the great angle of the eye, its round tendon runs through a cartilaginous pulley, fixed to a cavity in the os frontis; from thence it is reflected, runs obliquely backward, enclosed in a ligamentous sheath, and is inserted tendinous into the sclerotica, upon the upper part of the globe of the eye, a little behind the insertion of the rectus superior. When it acts singly, it rolls the eye round its axis. When it acts in conjunction with the *obliquus minor*, the eye is drawn outward or forward.

OBLI'QUUS MINOR. See **RECTUS MINOR**.

OBLI'QUUS MINOR vel INFERIOR O'culi, *Amatorius*, rises chiefly fleshy, just within the edge of the lower and anterior part of the socket, near the caruncula lachrymalis, and, passing obliquely backwards under the globe, is inserted into the sclerotica, on the external side of the eye, near the optic nerve.

OBLI'QUUS NASI, *laterales musculi*, thin muscles running along the sides of the pyramidales nasi, fixed to the apophysis nasalis of the ossa maxillaria, and inserted into the ala narium.

OBLI'QUUS PALPEBRARUM, consists of all that extent of fleshy fibres which, by a thin stratum, surrounds the edge of each orbit, and from thence wholly covers the two eyelids. They are transversely oval, adhere to the skin of the eyelids, and wrinkle them.

OBLI'QUUS SUPERIOR. *Capitis obliquus superior*. These muscles are on each side covered by the head of the trachelo mastoideus; each rises from the transverse process of the atlas, and is inserted into the os petrosus and os occipitale, near the processus mastoideus. They bend the head backward.

OBLI'QUUS SUPERIOR O'culi. See **OBLI'QUUS MAJOR O'culi**.

OBLI'VIO, (from *obliviscor*, to forget). See **AMEN-TIA**.

OBLONGUS; applied to the leaf of a plant, whose longitudinal diameter exceeds that of its transverse.

O'BOLUS. A weight of about nine grains.

OBOVA'TUM. **OVAL**.

OBSIDIA'NUM, (from *Obsidianus*, its inventor). See **ANTIMONIUM VITRIFICATUM**.

OBSIDIA'NUS LA'PIS. See **AMPELITIS**.

OBSONIO'RUM RHUS. See **RHUS**.

OBSTETRICA'TIO, (from *obstetrix*, quod *dolori obsistat*). **MIDWIFERY**. By midwifery is strictly meant the actual operation of delivery, but in a more extensive view it includes the management of female diseases in the unimpregnated or pregnant state. The word is not, however, always employed in such an extensive sense, and it usually includes the conduct in the preg-

nant or parturient state only, to which is usually added the management of the complaints of newly born children.

Midwifery, like medicine, was in its earlier periods the result of sagacity assisted by more mature, or more extensive observation; nor is it surprising, in the ruder states of society, when science had not dawned, that it should be confined to women, who alone would probably attend in such circumstances. These were the practitioners among the Jews, very generally among the Grecians and Romans. The names of Cleopatra, the voluptuous queen of Egypt, of the courtesan Aspasia, of Sotira, Salpe, and many others, who distinguished themselves in this department, have reached us; but whether the conduct of a labour was, in those periods, ever intrusted to a male practitioner, is a question not yet determined. Women and slaves, at Athens, were forbid to study medicine, but this prohibition would not apply to the more domestic treatment of parturient women; and Hippocrates, Galen, and Aëtius, speak of female practitioners. Among the Romans, though the generality of midwives were females, accoucheurs of the other sex were not uncommon. The works of the supposed freed man of Julia were those of a female slave, and probably neither the productions of Erotis nor Trotula, to whom they have been attributed. Trotula is quoted in them.

When we speak of more regular practitioners, Hippocrates must, as usual, be in the foremost rank; yet it does not appear that he was himself a practitioner, and his directions are equally harsh and injudicious. Little was known, by the accoucheurs, or at least little taught, respecting the manual operation, previous to the restoration of learning. The only writers of an earlier period treated, in general of the diseases of women, and in more indefinite terms of the manual assistance to be given in labours. One of the first of these was Paulus of Aegina, in the seventh century. The delivery by the feet was usually condemned, unless the child could not be brought forth by other means: even the crotchet was preferred to it by Hippocrates. The best of Galen's works on this subject is the *Tract de Formatione Fœtus*, in the fifth volume of Chartier's elegant but inaccurate edition. Some other tracts, on subjects connected with midwifery, are left us by Galen.

The works attributed to *Cleopatra* are probably spurious, and are full of the most trifling and superstitious receipts; nor, as we have just observed, are those of *Erotis* free from suspicion. The first author, among the Romans, who speaks of deliveries and female complaints, is *Celsus*: he broke the shackles imposed by Hippocrates, and taught us that the child might be delivered by the feet. He was followed at some distance by Moschion, a late author of the methodic sect, about the time of Galen, without adding any remarks on the operation itself. Yet probably the means of assisting delivery had been studied, and some mechanical contrivances suggested; for, in *Albucasis*, we find the coarse rudiments of the forceps, the crotchet, and other instruments, which the delicacy and improvement of modern practice have rejected; for no instrument is found so powerful, in the greater number of cases, as the unassisted efforts of nature. In the darker ages, we find the name of *Albertus Magnus* prefixed to an indecent, and probably a spurious, work, *De Secretis Mulierum*;

and, about the end of the fourth century, similar tracts appeared under the names of *Henricus de Saxonia*, and *Michaelis Scotius*, in the latter case appended to his *Treatise de Physiognomia*. It will be obvious that science could gain little by such works.

In the beginning of the sixteenth century we find midwifery cultivated with greater skill, under better auspices. This was nearly the era of *Eucherius Rosslin*, known better by the name of *Rhodion*, of Frankfort; and soon afterwards *Rueff*, of Zurich, and *Ruff* (*Rivius*), of Strasburg, followed in the same line, though not strictly in the manual departments of midwifery. This nearly was the era of the dawn of midwifery in this kingdom; for in the year 1540 was published, in English, the *Byrthe of Mankind*, or the *Woman's Booke*, by *Thomas Raynold*, physician. It was held in high estimation, and continued a standard work for more than ninety years. In this interval, however, *Harvey* had published his *Exercitatio de Partu*, *Sydenham* his *Observations on the Diseases of Child-bed Women*; and different tracts relative to midwifery had appeared by *Charleton*, *Wharton*, and others in this kingdom. The increasing character, however, of *Ambrose Paré's* Surgery, first published in 1573, the works of *Roussel* and *Guillemeau*, which rapidly succeeded, before the close of the century, soon eclipsed these feeble lights, and gave a new era to the art. *Paré* was the first modern author who recommended turning the child and delivering by the feet, a practice which *Guillemeau* supported and extended.

About the beginning of the seventeenth century, we find the first undisputed work of a female midwife *Louise Boursier* (*Bourgeois*), who is styled by authors *obstetrix regia*. She was a pupil of *Ambrose Paré*, and published observations on sterility, abortions, fertility, lyings-in, the diseases of women, and newly-born infants. About the middle of this century *Chamberlen*, catching perhaps a hint from the Arabians, boasted of a new invention to facilitate delivery. This was the forceps, or more probably the vectis. He was a man of abilities and experience, though not, as *Mauriceau* in his fifth edition boasts, physician to the king. It was not himself, but one of his sons, who went to Paris for the purpose of selling his secret; but returned unsuccessful, from having miscarried in his first attempt. He had before translated the third or fourth edition of *Mauriceau's* midwifery, which was published in 1672. The invention of the vectis has been claimed for *Roonhuyzen*, whose works were published at Amsterdam from 1663 to 1672, though more properly belonging to his son *Roger*, if really an invention; but he seems to have purchased the secret of *Chamberlen*, and to have afterwards used only a single blade. In this period, the works of another female, *Justina Siegmund*, who was born in Silesia, but who practised at Brandenburg, appeared in 4to. at Berlin; and *Dr. Willoughby's* manuscript treatise, quoted with considerable extracts by *Dr. Denman*, belongs also to the present era. *Deventer's* midwifery, published at Leyden at the end of this century, must be now chiefly noted for his aversion to instruments, for it scarcely merits any particular commendation. His works are chiefly distinguished for an opinion that delivery is often retarded by an obliquity of the womb, a circumstance denied by many

subsequent accoucheurs. It is certain that the womb, in the pregnant state, occasionally inclines to either side, and sometimes presses forwards, but never, except when retroverted, in a degree to retard or impede delivery.

The fame of *Chamberlen* equally excited emulation and opposition. *Dr. Bambar* supported the credit of instruments, while *Dr. Maubray*, the first English public teacher of midwifery, in 1723, with greater zeal decried them. The foreign authors, in the early part of this century, were *De la Motte*, a Frenchman, and *Dengs*, of Leyden. The *Traité des Accouchemens* of the former is an excellent work, and may be perused, at this time, with advantage: that of the latter is more concise, and of inferior value. *Dion's* midwifery was published in 1718, translated into English in the following year; and in 1727 appeared *Dr. Simson's* "System of the Womb," a work rather ingenious than of practical utility. *Chapman's* "Treatise on the Improvement of Midwifery" was published in 1733, and, in the following year, *Dr. Hody* published *Gifford's* "Collection of Cases," which occurred in his own practice, and which he describes with great simplicity and fidelity. He used the forceps, then called the extractors, but seems not to have trusted them beyond the reach of his hand. In 1736, *Dawke's* "Midwife Rightly Instructed," and, in 1737, *Brachen's* "Midwife's Companion" appeared.

In 1739 *sir Richard Manningham* published his *Compendium Artis Obstetriciæ*, having previously taught at a lying-in hospital of his own institution. He succeeded *Chapman*, who was the second teacher of the art in this kingdom; and he was followed by *sir Fielding Oulde*, of Dublin, who published in 1741 his "Treatise on Midwifery." In 1752 we received "Elementa Artis Obstetriciæ," from *Roderer*, and, in 1759, his "Icones Uteri Humani," both published at Gottingen. *Smellie's* Anatomical Tables followed in 1754, and *Dr. Hunter's* very accurate ones in 1774. *Smellie's* "Treatise on the Theory and Practice of Midwifery" appeared in 1752, and a very elaborate, but not a very important, work, by *Mr. Wallace Johnson* in 1769. *M. Puzot* of Paris published his *Traité des Accouchemens* in 1759; *Levret* in 1761; *Plenck's* his *Treatise* at Vienna in 1768; *Fried* in 1769, and *Stein* in 1770; works in the German, and little known in England. Within a few years we received *Dr. Denman's* very valuable work on this subject, the improved edition of his former volumes; and successive editions of *Dr. Alexander Hamilton's* Elements, or Outlines, have been published by himself, and his very able, respectable successor, *Dr. James Hamilton*. Though short, as a syllabus, they are comprehensive and satisfactory.

We have thus brought the sketch of the history of midwifery somewhat lower than our former histories, since, as, from the nature of the subject, it must be rather a catalogue of works than a descriptive account of their contents, we trod more safely over the ashes, with less apprehension of the fire underneath. For the same reason, we shall only, in general, refer for the conduct and qualifications of the accoucheur to what we have said on that subject at the end of the article CHIRURGIA.

Midwifery, at present, is taught and practised as a distinct branch of art; and the practitioner is supposed to possess a competent knowledge of the parts of the pelvis, its dimensions, the depth of its cavity, its various distortions, &c.; the parts of women subservient to generation; the state of the womb and its neck, in the different periods of gestation; extra-uterine fœtuses; moles; the progress of a child's head through the different parts of the pelvis in a natural labour; the secundines; the various complaints which usually attend pregnancy; the manner and utility of touching; the difference betwixt false and true labour pains; the different kinds of labour; the various modes of the child's presenting, with the methods of delivery; the disorders of childbed women; the management of the child and its mother during the time of lying-in, &c. See PELVIS, PARTURITIO, GESTATIO, INVOLUCRA, PRÆSENTATIO, &c.

OBSTIPA'TIO, (from *obstipō*, to stop up). **COSTIVENESS**, a disease placed by Dr. Cullen in the class *locales*, and order *epischeses*, which he defines no discharge of fæces, or less frequent than usual. Its species are, 1. *Obstipatio debiliū*; in lax and weak habits. 2. *Obstipatio rigidiorum*; in those of rigid fibres, and hypochondriacs. 3. *Obstipatio obstructorum*, with symptoms of colic, or from stony concretions in the bowels. See CONSTIPATIO.

OBSTI'PITAS, (from the same). See CONTRACTURA.

OBSTRU'CTIO, (from *obstruo*, to shut). Obstruction in the vessels of any part; is a term applied when any obstacle opposes the circulation of their proper fluids. Vide MORBI FLUIDORUM. The word *ophilitatio* is used by ancient authors as a more complete or fixed obstruction. Rhodius.

OBTUNDE'NTIA, (from *obtundo*, to make blunt). Medicines suited to cover the acrimony of the fluids. See DEMULCENTIA.

OBTURA'TOR EXTE'RNUS, (from *obturo*, to shut up). *Marsupialis, bursalis musculus*. This muscle covers the foramen magnum ischii, and, rising from the bone before the foramen, runs backward under the head of the os femoris; covered by the quadratus femoris, and is inserted into the trochanter major, contiguous to the internus. Like it, this muscle is a rotator.

OBTURA'TOR INTE'RNUS, more frequently than the preceding called *marsupialis et bursalis musculus*, arises from the inner circumference of the foramen magnum ischii, passes round the ischium as on a pulley, and is inserted into the trochanter major, contiguous to the pyriformis. It is a rotator of the thigh; and its tendon plainly forms a groove on the bone in its passage.

OBTURA'TOR NE'RVUS, a branch of the crural; it passes through the foramen ovale, and is lost in the inner muscles of the thigh.

OBTURA'TRIX ARTE'RIA, (from *obturator*,) a branch of the hypogastric, which perforates the obturator muscle, and goes out of the pelvis, at the upper part of the ligament of the foramen ovale, having first sent a branch over the symphysis of the os ilium, and os pubis, to the inguinal glands and integuments. It sends out a branch which communicates with a branch of the sciatica arteria; gives out branches to the adja-

cent muscles, and sends many small ones by the neck of the thigh bone.

OBTURA'TRIX VE'NA, is a branch from the hypogastric vein, and receives this name where it enters the internal obturator muscle.

OBVOLU'TUS, (from *obvolvo*, to roll up). Folded or rolled up.

O'CCA. See CETE ADMIRABILE.

OCCIPITA' LIS ARTE'RIA, (from *occiput*,) is the first external, or posterior branch of the external carotid. It passes obliquely before the internal jugular vein; and having sent out branches to the adjacent muscles, it runs between the styloid and mastoid apophyses, along the mastoid groove, and goes to the muscles and integuments which cover the occipital bone. It communicates with the temporal, vertebral, and cervical arteries.

OCCIPITA' LIS MU'SCULUS is one of the quadrati, mentioned by Columbus, and accurately described by Fallopius. These muscles are short, broad, thin, and fleshy, situated on the occiput, where the mastoideus and splenius are inserted. They soon become tendinous, join with the pericranium, which firmly adheres to the hairy scalp on the sinciput. When they act, they pull the hairy scalp backwards.

OCCIPITA' LIS NE'RVUS. A branch from the tenth pair of nerves which proceed from within the skull: it spreads and runs on the upper and lateral parts of the head.

OCCIPITA' LIS POSTE'RIOR ARTE'RIA is a branch from the vertebral, spreading on the occiput.

OCCIPITA' LIS VE'NA. A branch from the posterior, or upper external jugular; but sometimes proceeding from the vertebralis, or axillaris. It branches on the occiput.

OCCI'PITIS OS, is of a rhomboidal figure; a transverse ridge running from the mastoid process of one side to that of the other, divides it into two parts. Its external surface is convex, except at the cuneiform process, at the base of which, on each side of the foramen magnum, are the condyles which connect the head to the spine. On the outside of these condyles the bone projects, and there is a notch where the internal jugular vein passes. It is divided into four cavities in its inside, by a crucial spine, in which there are canals for the superior, the longitudinal, and the inferior, frequently for the occipital sinus; those canals on each side, for the lateral sinuses, are continuations of the longitudinal. There are five foramina proper to this bone; the foramen magnum, a hole on each side just above the condyle for the ninth pair of nerves, and generally two which penetrate from behind the condyles to the fossæ of the lateral sinuses. Besides these, there are two common foramina, one on each side, between the processus cuneiformis and os petrosum.

The os occipitis is peculiarly thick, apparently to defend the cerebellum, and it is stronger than any other bone of the head, except the os petrosum. Below, and at its sides, the large muscles have apparently rendered it thinner, but they also defend it from injury. This bone is joined, by its cuneiform process, to the sphenoidal, and, in old age, unites with it. The lambdoidal suture unites it to the parietal bones, and the additional part of the temporal suture to the temporal bones. The

condyles of this bone connect it with the first vertebra; but these admit only of a slight lateral motion, for the rotatory motion of the head is owing to that of the atlas on the second vertebra.

In the fœtus this bone is divided by cartilage into four parts. The largest forms all the bone which is above the great foramen. Two other parts form the sides of the foramen. The cuneiform process, which is the last, appears often distinct at the age of six or seven.

OCCI'PITO-FRONTA'LIS MUSCULUS; *epicranium*, rises from the posterior part of the occiput, goes over the upper part of the os parietale and os frontis, and is lost in the eyebrows. It is a very thin muscle, raises the eyebrows, and wrinkles the forehead; an antagonist to the corrugator Coiterii.

O'CCIPUT, (from *ob* and *caput*, the hinder part of the head,) *prona, inion*. Inion is confined by Blanchard to the beginning of the spinal marrow; by others, to the back part of the neck.

OCHEU'S, (from *οχηω*, to carry). See **SCROTUM**.

OCHLAGO'GI, (from *οχλος*, *populus*, and *αγωγος*, *ductor*). See **AGYRTÆ**.

O'CHRA, (from *οχρος*, *pale*, *earth of a pale yellowish colour*). **YELLOW OCHRE**, sometimes brown, occasionally red: the latter is called **RED OCHRE**, *rubrica fabrilis*, *Creta rubra*, *arcanne*, **MARKING STONE**, **RUDD**, and **RUDDLE**, oxydated iron of Haüy, iv. 105. See Lewis's *Materia Medica*. Neumann's Chemistry.

O'CHRA NI'GRA. See **PLUMBUM NIGRUM**.

O'CHRUS, (from *οχρος*, *pale*, from the pale muddy colour of its flowers,) *lathyrus*, *ervilia*, *pisum ocrus* Lin. Sp. Pl. 1027. It bears cylindrical pods with round seeds as large as peas, which, though eatable, are indigestible.

OCHTHO'DES, (from *οχθος*, *callous*, *tumid*, *lips of ulcers*). See **ULCERS**.

OCIMA'STRUM, **OCYMA'STRUM**, (a dim. of *ocimum*, *basil*), *lychnis sylvestris alba simplex*; **WILD WHITE CAMPION**; *lychnis dioica* Lin. Sp. Pl. 626. β. Found in hedges and borders of fields; flowers in May. The flower is said to check the fluor albus and inward bleedings; the herb to cure convulsions in children: but its virtues have not obtained it a place in practice. See Raii *Historia*. It is a name for the *circæa lutetiana*, and several species of *lychnis*.

O'C-KOW. A Chinese remedy for diseases of the breast, said to be the flesh of the common ass, boiled down to the consistence of a thick glue. It succeeded in relieving the author of this account, in the eleventh number of the Edinburgh Medical Journal, Dr. Baildon, of a consumptive complaint; but the digitalis was taken at the same time, so that the effects of the remedy are equivocal.

OCRE'A. See **TIBIA**.

OCTA'NA, (from *octo*, *eight*). An erratic intermitting fever, which returns every eighth day.

OCTA'VUS HU'MERI MU'SCULUS, **OCTA'VUS HU'MERI PLACENTI'NI MU'SCULUS MINOR**. See **TERES**.

OCTANDRI'A (from *octo*, *eight*, and *ανδρ*, *a man*). A class of plants having eight stamina.

OCULA'RES COMMU'NES, (from *oculus*, *an eye*). See **MOTORES OCULORUM**.

OCULA'RES EXTERNI. See **MOTORES OCULORUM EXTERNI**.

OCULA'RIA, (from its use in complaints of the eye). See **EUPHRAGIA**.

O'CULI CANCRO'RUM, **CRABS' EYES**, *cancro-rum lapides*, *et lapilli*, are stony concretions, found in the head of the *astacus fluviatilis*, or river craw fish, lodged in a bag on each side. These stones are roundish, flattened on one side, white, having sometimes a reddish, and at others a bluish cast, of which the blue are preferred, as the white are taken out after the fish hath been boiled: they are internally foliated. The largest quantities are the produce of Muscovy, particularly of the river Don.

They were formerly used as absorbents of acid humours in the primæ viæ, and supposed, when combined with the acid, to be more aperient than the other absorbent earths. The earth of crabs' eyes differs much from that of crabs' claws, for the first is not convertible into quick lime; and in its chemical relations is said to resemble the earth of hartshorn. It is therefore, like the bones, a calcareous phosphat.

These stones are counterfeited with pipe clay, chalk, or the shells of fishes; but these compositions are easily distinguished from true crabs' eyes, which are of an uniform texture, stick to the tongue, soften with water, and dissolve in acids. See Tournefort's and Lewis's *Materia Medica*.

O'CULO-MUSCULA'RES. See **MOTORES OCULORUM**.

O'CULO-MUSCULA'RES EXTERNI. See **MOTORES OCULORUM EXTERNI**.

O'CLUSUS, (from *οπλομαι*, *to see*). **THE EYE**; *illos*. The external parts are the eyebrows, the eyelids, the extremities of which, where the eyelashes grow, are called *orchos*, the cilia, the fore part of the globe, the *membrana conjunctiva*, the *cornea lucida*, the iris, the pupilla, the *carunculæ lachrymales*, and angles of the eyelids, &c. The external eyes are named *paropia*; the internal *pegæ*. The internal parts are the globe of the eye, the *adnata* or *albuginea*, the extremity of which is called *premnon*; the *sclerotica*, the *choroides*, the *retina*, the aqueous humour (*hydatodes*, *hydatoides*; *ooides*; *ovatus oviformis vel albuginosus humor*); the vitreous humour, *hyaloides*; crystalline humour, *phacoides*; the muscles that move the eye, and the optic nerve, &c. For the particular descriptions, see the different articles in *verbis*. To explain, however, the theory of vision, it will be necessary to add a short account of the different parts of the organ in a connected view.

The eye is an irregular spheroid, projecting a little at its fore part, where it is seen between the lids. In this projecting portion we find a fluid, in which a fine membrane, perforated in the centre, floats. Beyond this fluid is a more solid transparent body, in the shape of a lens, and still farther back, a gelatinous fluid which covers a very fine semi-opaque membrane. All these fluids are confined by a dense substance which supports and protects them, called the coats of the eye.

Having given this very general idea of the organ, we shall proceed to notice the containing coats. From the eyelids to the ball of the eye a very thin vascular membrane is extended, in some degree to support the eye, and to prevent substances passing between it and

the edges of the orbit. This is the *adnata* or *conjunctiva*, in which, even when not diseased, red vessels may be distinctly seen, and which is the most common seat of ophthalmia. A hard, white, firm, tendinous substance forms the outer coat, viz. the *sclerotica*, which in the projecting part of the eye is transparent, and called the *cornea*. The *sclerotica* is peculiarly strong in the fœtus; the cornea comparatively weaker than in the adult; each may be divided into laminæ, but these are more distinct in the cornea, and separated by a cellular substance, containing a watery fluid, distinct from the aqueous humour already mentioned. In fact, if the compacted laminæ of the *sclerotica* are supposed to be separated, with a very pellucid fluid interposed between each, it will at once give a correct idea of the projection of the cornea, and of its transparency. When the optic nerve, which is inserted behind, reaches the globe, the external coat of its sheath covers the *sclerotica* externally, and the internal, internally: the external membrane of the eye is thus inserted between the coats. Le Cat and others have described the eye as a bottle blown from the optic nerve, preserving its coats in the coats of the organ; but this is a refinement, if true, of no practical advantage either in the theory of vision or the pathology of the organ.

The projecting part, or *cornea*, is described as the segment of a smaller circle; but it is by no means a portion of a circle, as its margin is flat towards the nose. The fluid between the laminæ gives it transparency; for in fevers this fluid becomes more opaque, and the eye acquires that dulness so constantly observed: when coagulated at the approach of death, the light is even reflected from it, and the eyes are said to be glassy. Over the cornea there is a very thin glassy membrane, probably derived from the *adnata*, and by maceration it is said that the cornea separates from the *sclerotica*. The cornea is sometimes the seat of abscesses, and seems to be supplied with vessels; but in a sound state these do not carry red blood.

Within the *sclerotica* is the *choroid coat*, covered with a black, or at least with a dark coloured pigment, which, in very fair persons, is of a lighter colour, and in the albinos, almost white. The choroid is minutely vascular, and not in every part connected with the retina. It consists of two laminæ; the outermost is that which supports the numerous vessels, and the innermost, the *tunica ruyschiana*, has the structure of a secreting membrane, for the appearance is villous, and these villi have been styled *tapetum*. The black pigment is a mucous substance, sometimes wanting in old persons, and in animals who seek their prey by night. It seems, however, more conformable to the analogy of nature, that in these, as in the albinos, it is of a grey or white colour.

When the choroid coat reaches the margin of the *sclerotica*, to accommodate it to the smaller circle of the cornea, it is folded in plaits, called the *ciliary processes*, still covered with the dark pigment, resembling, when this is washed away, the valvular doublings of the villous coat of the intestines. Previous to its inflection it is firmly fixed to the *sclerotica*, and is closely united with the root of the iris. At their internal extremities they are attached to neither, but are loose and floating. These processes leave an impression both on the

vitreous humour and the retina at the edges, where they are in conjunction, which have been styled *sulci ciliares*, the ciliary processes of the retina, &c. which only confound a simple idea, and multiply terms without reason. The ciliary processes collectively are called *corona* or *circulus ciliaris*, *ligamentum* or *corpus ciliare*, and are of great importance in vision: it is of consequence to remark, that their connection with the retina is the only means by which it is kept expanded, and the only mode of connection between the humours of the eye and their coats.

The *iris* or *uvea* is the coloured circle which we see in the eye, perforated by the black spot, styled the *pupil*. When put in water and examined with a microscope, the anterior surface appears to be covered by minute villi, whose colour fades when putrefaction begins. The fibres of the iris are transparent, and the colour chiefly depends on the pigment at the posterior surface.

The iris consists, it is said, of two sets of fibres, both irritable and muscular; the one surrounding the pupil, the other radiating from or to the circular, and, as it is called, muscular margin. The muscularity, however, has been denied, and its contraction and relaxation supposed to depend wholly on a stimulus on the retina. It is copiously supplied with nerves from the ciliary. Two large ciliary arteries, and two lesser anterior arteries, which pierce the *ligamentum ciliare*, freely anastomose round its root, and send serpentine branches to the margin of the pupil, where they again anastomose, and send off branches towards the edge of the iris. The corresponding veins pass into the *vasa vorticiosa* of the choroid coat; some between the choroid and *sclerotic*, and some piercing the latter, pass out, and spread on the surface of the eye. In fact, these vessels seem to constitute the whole of the iris, which is probably vascular rather than muscular.

The *retina* is the most important part of the eye, since it is the nervous expansion on which visible objects are painted; and by this means the image, we mean not to say the material image, is conveyed to the sensorium. The optic nerve enters, we have said, not immediately at the back part of the eye, but a little on the inward side towards the nose. At some distance, before it passes through the *sclerotic* coat, an artery penetrates its vagina, the *arteria centralis retinae*, so that if the optic nerve be cut after its entrance, the artery retracting, leaves a little foramen, called by ancient anatomists the *forus opticus*. The extremity of the optic nerve, before it expands in the retina, forms a little conical point, which we suspect to be a ganglion.

The retina itself is spread over the choroid coat, resting on a reticulated membrane which supports its vessels, probably derived from the pia mater, the *lamina cribrosa*: from its texture the name was apparently given. In this membrane the branches of the *arteria centralis*, derived from the optic and ophthalmic artery, and soon after entering the *sclerotica*, divided into many large branches, from which numerous anastomosing subdivisions proceed, are most profusely scattered. The retina seems to terminate at the ciliary processes, but the *lamina cribrosa* probably passes over the posterior part of the lens. This idea will reconcile many disputes, and some, seemingly discordant, observations.

The *membrana pupillaris* is a small vascular membrane

which extends over the pupil in the fœtus. At about the seventh month it begins to disappear, and is scarcely, if at all, discernible at the ninth. Its larger arteries come from the iris; smaller and more numerous branches from those of the lens. Its use is not known, nor does it merit any minute disquisition. It certainly prevents the iris from contracting in utero; but there is no cause for its contraction, and apparently no inconvenience would arise if no impediment existed. It is not impossible that some imperceptible remains of this membrane may prevent too violent effects from the first access of light.

The fluid, in which the iris floats, is called the aqueous humour, and its floating fibres are supposed to divide the projecting part of the eye into two chambers, the anterior before, and the posterior behind, the iris. The error, however, is considerable, for there is no space behind the iris which merits the name of a chamber, since the iris moves almost in contact with the lens. In the fœtus, this fluid is red and turbid, in the adult, perfectly transparent, but seldom exceeding in weight five grains. Mr. Chevenix found it to be an albuminous fluid, containing also gelatine and muriat of soda, but in such small proportions that the specific gravity of this fluid is not more than 10,053. We might perhaps remark, that the common salt assists the transparency, since salt water is peculiarly so, but that it is in so small a proportion that the aqueous humour has little, if any, taste. (Philosophical Transactions for 1803, p. 96.) It seems to be secreted from the vessels of the iris, and is regenerated, after being discharged, within a few hours.

The crystalline is almost immediately behind the iris. It resembles a flatted sphere. The anterior surface is the segment of a sphere about eight lines, the posterior of about five lines. The anterior is consequently the flatter surface. The crystalline increases in density from the surface to the centre. On the average its specific gravity is about 10,790, without any traces of muriatic acid. It contains, therefore, much larger proportions of albumen and gelatine, with less water. It putrefies rapidly, splits when dry, into lamellæ, so that at first it exhibits a star-like fissure, and is at last divided into shreds. When its density, its rapid putrefaction, and its fibrous structure are considered, we must conclude, that it contains a large proportion of fibrin, and we shall more readily admit the modern doctrine of its muscularity. The lens, it is now acknowledged, has a distinct capsule, and a canal surrounds it, called from its discoverer, Petit.

The vitreous humour fills the larger proportion of the cavity of the eye. It does not float loosely, but is contained in cells, so as not to flow freely without pressure. When removed from these it appeared of the same specific gravity as the aqueous humour, and similar in its chemical relations. Fourcroy found in these humours some phosphat of lime, which Mr. Chevenix could not discover. The canal of Petit is formed, it is supposed, by a double layer of the vitreous humour, which forms also the capsule of the lens; but the capsule and the canal are distinct. Mr. Bell supposes that the Petition canal is formed by the vascular membrane of the retina, which also forms the membrana pupillaris of the fœtus; and his arguments render the opinion highly probable.

The eye is surrounded by numerous muscles, whose

irregular action occasion that motion of objects which we perceive in vertigo. These muscles arise round the foramen, and are inserted into different parts of the orbit, giving, by their tendinous expansions, the brilliant whiteness of the fore part of the organ. Four of these muscles are called *recti* from the direction of their fibres, and it is these which have been supposed to compress and change the figure of the eye.

The *rectus superior* rises the eye upwards, the *attolens* and *levator oculi*, and as it expresses pride, is called also *superbus*.

The *rectus inferior* lowers the eye, styled, for similar reasons, *deprimens* and *humilis*.

The *rectus internus* moves the eye towards the nose *adducens oculi*; and as it is directed to the glass while drinking, *bibitorius*.

The *rectus externus* turns the eye outward; *abductor oculi*, *indigabundus*. The origin and insertion of these muscles will be obvious from their action.

There are two *oblique muscles*. The first is the *obliquus inferior, longissimus*, which rises from the bottom of the orbit by a slender tendon, passes the upper part of the eye ball fleshy; then forming a smooth round tendon, it passes through a cartilaginous pulley, in the margin of the orbit, and is inserted in the middle of the eye ball. It gives an oblique motion to the eye, and contributes with the other muscles to roll it. From its passing over the pulley, it is styled *trochlearis*.

The last is the *obliquus superior brevissimus*. It rises from the nasal process of the superior maxillary bone in the edge of the orbit, passing obliquely backwards and outwards under the ball of the eye, is inserted opposite to the obliquus superior. This muscle is in every respect the antagonist of the *inferior*.

The eye is an organ of peculiar delicacy and importance; but without the other senses it would afford generally imperfect, and often erroneous, ideas of external objects. This subject has been examined at some length, with great ingenuity, by Dr. Reid, (Inquiry into the Human Mind,) in what he styles the geometry of visibles; to which we must refer the reader, as it scarcely forms a part of our present subject. To explain the theory of vision, we premise a few remarks on some of the first principles of optics.

When light passes through a flat plate of glass it proceeds in a direct line, or at least nearly so; but when the glass is convex on either side it is bent from its direction towards the axis, or the line which passes through the centre. Numerous rays passing, therefore, from a point, and necessarily converging through a convex glass, are turned towards the axis, which must of course occasion them to meet at some point on the opposite side. This is styled the refraction of the rays; but rays impinging on the glass with a considerable obliquity do not pass through it, but are thrown back; and this is called the reflection of light. The degree of refraction differs with the density and the nature of the medium through which it passes.

To apply this popular view of the subject to vision we must remark, that the pupil of the eye, the aperture at which the light enters, projects, that it consists of transparent laminae, with a very bright fluid interposed. By passing through this fluid the light is a little diverted from a rectilineal course, but it is more so in passing through the lens and the vitreous humour. By

their united effects the rays meet in a point, at the bottom of the eye or on the retina. Its image is there accurately painted, and this image conveys to the mind an idea of an object, corrected by the touch and by experience. The touch corrects the idea respecting the form of the object; experience respecting its distance. We have observed that the refraction is greater in proportion to the density of the body, through which light passes, and it is greater in proportion to the obliquity of the impinging rays; if that is not in so great a degree as to occasion reflexion. To bring all the rays from a given point accurately to a focus, the density of the refracting body must therefore not be uniform, but must increase at its centre, where the obliquity of the rays is less. This is the case with the lens; and when, from causes to be hereafter explained, the image is not distinct, the eye lids are partly closed, to prevent the more oblique rays from entering.

It may appear singular, that while refraction is so simple an operation, such a number of refracting media are connected in the organ. In general, however, refraction is not regular. Some rays are broken in the operation, and resolved into their colours, giving the image, or spectrum as it is called, with coloured (iridescent) fringes. This irregularity is different in different bodies, and sometimes the irregularity is on opposite sides. The opticians, therefore, who felt its bad effects in telescopes, employed glass of such kinds as to correct this defect by their opposed powers; and it is singular that the structure of the eye had not suggested this mode of correction, rather than that the correction should elucidate the accuracy of the image in vision. It appears probable that the fluid interposed between the laminae of the cornea has some effect in this way, and that the irregularities of refraction from passing through the cornea are thus corrected, previous to the rays reaching the lens. The only inconvenience is the loss of light; for rays passing through different media are lost, or rather give an indistinct glare. The object of nature, however, in the structure of the eye, is to moderate the light; and we not only find many rays thus suffocated, but the vitreous humour is enclosed in cells, so that the refracted rays must be every moment passing through media of different densities before they form the image. When it is at last formed, it is comparatively very minute; and as each part conveys a correct idea to the mind, it is evident that every portion must, at least, impinge on a nervous fibre, and that each fibre must be of the minuteness of the image which the least visible object affords. Thus De la Hire calculates, that the image of the sail of a windmill, at the distance of 4000 toises, is but $\frac{1}{4000}$ of an inch, but very minute portions of this sail may be distinguished; and such reflections induced us to remark, when speaking of the nervous fibres, that what appeared in the microscope the smallest fibre was more probably only a fasciculus, and perhaps not the ultimate one.

When it was observed that the image was pictured on the retina, it was at once supposed that it was thus conveyed to the brain, and contemplated by the immaterial principle at its leisure. This, however, is highly improbable for the reasons stated, that, without the corrections of touching and experience, our ideas of visible objects are often erroneous. It is improbable, also, from another circumstance; the image in the eye is inverted,

and numerous have been the speculations to explain how this inverted image is again restored to its proper position. It was once supposed that the fibres in the optic nerves decussate in crossing; and again, that they are mixed in a ganglion near the sella turcica. The former is not true, nor would either explain the difficulty. Others have supposed that the soul looks at the image by reflection; an idle fancy, unworthy of a philosopher. The fact is, that experience corrects this and other errors: our knowledge of relations and relative positions are not conveyed by the eye.

With two eyes we see only a single object. This too has been explained on the principle of decussation which does not take place, and of the ganglion which can have no such effect. It chiefly arises from the axes of the eye being directed to the same point, which gives individuality to the idea excited in the mind. Experience teaches us that two objects cannot be in the same place, and we thus conclude the image to be single. This may be evinced by an easy experiment. A slight distortion of either eye, in every one's power, will give the appearance of a double object. If the uniform direction of the axes be gradually restored, the two objects will be seen to coalesce and become one. By diseases which affect the very minute motions of the eye, as a foul stomach, narcotic poisons, or spirituous liquors, which produce irregular action, no longer under the command of the will, objects seem also double.

Why then, it may be asked, have we two eyes? With two we see objects brighter; we see them more completely, for we take in a larger circle; nor are we left in the miserable state of blindness should an accident happen to one. It has been said, that when one is destroyed the other expands, and the loss is after a short period no longer felt; but this is not true. The person from habit is not sensible, indeed, of his loss, unless particularly required to examine the whole of an object, as of a column, and a minute motion of the head may assist him in this examination; but no expansion of the remaining eye can take place, for there is no apparatus for such a purpose.

Our ideas of the distance of objects is, we have said, the effect of experience; but the power of accommodating our vision, so as to survey objects at very different distances, has been the subject of much controversy. It has been supposed that the ciliary ligament is muscular, and draws back the lens; that the lens itself is muscular, and can change its own shape; or that the recti muscles, whose tendons may be supposed to reach, perhaps to spread over, the cornea, may contribute to flatten it. Each opinion has had its advocates. Yet this accommodation of the eye to distance is very limited. A near-sighted person, with all his efforts, cannot easily extend his sphere of distinct vision, though he can considerably reduce it; but to reduce it he must render the eye more convex, which neither of the means suggested will effect. Much of this supposed change in the form of the eye, however, apparently results from a greater exertion of attention, as images within the sphere of distinct vision, when from some accidental circumstance confused, are readily perceived by an exertion of attention, without any change in the external circumstances. If either of the powers above mentioned have any effect in this respect, it is the action of the recti muscles; and in trying experiments of this kind with attention,

we think we have been sensible of compression on the ball of the eye.

Habit has, however, a very considerable effect on the appearances of objects. Distortion of either eye, the effect of accident, is at first attended with double vision; but the object is soon seen single, though the cause remains. This circumstance, however, does not invalidate the former reasoning, since it arises from the power we possess of examining objects with one eye only. This is often done, particularly when the eyes are not equally acute.

Distinctness of vision depends much on the state of the organ, and this on the state of health. In disease we see imperfectly, because the eye rolls with an involuntary motion; and the person who sees dark spots in the bed clothes, in a fever, constantly finds them moving, and his hands rove to catch them. It is not enough for peculiarly distinct vision that the object should be at the proper distance. All adventitious light should be removed; for this, as opticians know, gives a fringe, an indistinctness, to the outline. If objects are carried to the remotest limits of distinct vision, by an exertion of attention, they will be seen more perfectly. Objects reflected from a convex mirror, or looked at through a glass somewhat more concave than the eye requires, will appear at a distance indeed, but peculiarly distinct.

In the article *AMBYLOPIA*, we anticipated some of the most common irregularities of distinct vision; viz. the myopia and presbytia. We are now in a capacity to consider them more accurately. The *myopia*, it was observed, arises from too great refraction of the rays, so that they are brought to a focus before the image reaches the retina. The defect has been attributed to a greater convexity of the cornea, which, as we shall find, flattens by age, so that the disease is by time diminished. This, however, is but one cause, for many near sighted persons are not relieved by advancing years. From what we have said, it will appear that it may arise from an increased density, and consequently the increased refractive power of the fluid between the laminae of the cornea, the increased density of the lens in general, its less uniform increase towards the centre, or the increased refractive power of the vitreous humour. That these causes often take place is certain, since, in many families, short sight is constitutional and hereditary. There is no doubt, however, but that both the myopia and presbytia may be acquired. The former is often the disease of those accustomed to survey minute objects at short distances, as the student, the watch maker, &c.; the latter of persons used to strain their sight to distant views, as the sailor. How this is acquired we are not prepared to say. When we spoke of distinct vision, we admitted, in some degree, the power of the recti muscles to flatten the eye; and in the sailor this power may produce the effect. The opposite change is more difficult of explanation. But is it a change? May not the eye naturally admit of distention; and may not this distention be particularly directed forward, as the coats of the eye are there less dense, unless counteracted by the recti muscles? When not exerted we may readily suppose that, as usual, their tone is weakened. In this supposition there is some probability, since it is the

acquired myopia which is chiefly relieved by age. It may be some confirmation of this opinion to add, that if a short sighted person uses a glass of too great concavity, he feels his eyes peculiarly weak; and he finds it difficult to adapt them even to the usual distance of distinct vision.

The remedy of myopia is obvious. As it is impossible to lessen by any art the convexity of the cornea, or the too great density of the humours, it is necessary to lessen the obliquity of the rays. This is effected in part by wrinkling the brow and closing the eyelids. The latter alone is not sufficient, for the arch of either lid is the segment of so large a circle, that to close the lid only, would scarcely impede any oblique rays. By wrinkling the brow we depress the inner corner of each lid, and cut off the oblique rays which pass by the inner canthus, and in some, though in a less degree, those at the outer. As a concave glass, by a power opposite to that of a convex, disperses the rays, so a glass slightly concave lessens their obliquity, and prevents their union by refraction so early. To choose then the degree of concavity which will produce the requisite obliquity only, will be an object of importance. It is advised, in general, to ascertain such a degree of it (marked usually by numbers from one to fourteen,) as will bring the eye to the common state of perfect vision, and to select the number immediately below, because it is supposed that the use of the glass will by degrees correct the defect. This indeed would be the case had the eye the considerable power of accommodating itself to different distances, which physiologists have been so anxious to explain. We believe, however, that no change takes place by such a glass which would not otherwise be observed; and, indeed, we know that after many years using an inferior number, that above it has been found in the same degree of superior utility as at first. If, therefore, a glass must be employed during a whole life, there is no reason for abandoning the peculiar advantage of the most perfect vision which art can supply. In the constitutional myopia there is seldom any change; and even the habits of the sailor will not conquer it. We have not, however, seen any such instance, except where the cornea has been distinctly prominent; so little foundation is there in the remark, that age will flatten it.

The *presbytia* is in every respect the opposite disease. It arises from the gradual change in old age, when the vessels, no longer distended, are in part obliterated. The eye sinks, the cornea is flatter, and but that the humours apparently increase in density and refractive power, sight would decay faster. This corresponding, or rather antagonising change, seems to preserve the sight of some old persons to a very advanced period. When from the diminished refraction, the picture thus falls beyond the retina, it is remedied by a convex glass, which more strongly refracts the rays, and brings the image more correctly on the retina. These glasses are neither so accurately ground nor so regularly numbered as the concave, and should be bought of an optician of character, rather than an itinerant, who purchases the glasses refused by the former. It was thought at one time advantageous to have the glasses tinged of a green or blue colour; but this defect is accompanied with some insensibility of the retina, and

to read, a strong light must be often thrown on the paper, either from the sun or a large candle.

Each complaint varies in its degree, according to the state of health; but disease seems chiefly to weaken the attention, and to affect the mind rather than the organ. If any part of the change in the shape of the eye depends, however, on muscular action, we may readily suppose, that diminished or increased irritability, or diminished tone, may have a considerable effect on distant vision.

We have spoken, through the whole of this discussion, of the retina as the seat of vision, though fully aware of the controversies which have arisen on this subject. The difficulty first arose from the insensibility of the spot where the optic nerve enters the globe of the eye; and as the choroid coat was discontinued on that part while the nerve was there, it was supposed that the coat rather than the nerve was the proper seat. We need not enlarge, however, on this point, for we know that any disease of the nerve between the eye and the brain will prevent our being sensible of visible objects; and there is no communication between the choroid coat and the brain. This would be decisive, independent of the numerous facts which prove that the state of the visual organ corresponds with that of the brain. The fact is, that in no instance do the nerves in their course show their peculiar properties or powers. They must be divested of their armature, and their evolved fibres exposed to the impressions. Much of the difficulty has arisen from the idea that the picture was essential to vision; but the impression alone is so, and the picture is an accidental, rather than a necessary effect.

The dilatation and contraction of the iris on the diminution or increase of light is, with difficulty, explained. The contraction is not owing to the stimulus of light on the iris, for it seems to have no muscular power. The ends do not recede when divided; it is not contracted when wounded, or light thrown on it, without entering the pupil. It has been thought sufficient to remark, that its motions correspond with the stimulus on the retina. This is, however, in many respects unsatisfactory; and it has been with more reason concluded, that the dilated is the active, the contracted the passive state of the iris. The author of this opinion thinks the action of light stimulates the arteries of the reticulated coat of the retina, and the increased action of its vessels fills also those of the iris, which communicate with them. But vessels when filled are tortuous, and of course shorter in straight lines (see Exeter Essays, p. 202); the breadth of the iris is consequently less, and the pupil enlarged. We more readily acquiesce in this idea, since we think that it explains one remarkable fact, that in some cases of amaurosis the pupil contracts and dilates. This we can easily suppose may depend on the state of the vessels. If the palsy, as usually happens, is communicated to them, contraction and dilatation will not on this system occur. In contrary circumstances these alternations may be observed.

The crystalline lens, as we have hinted, grows denser, and somewhat coloured by age; and in general its transparency is preserved by warmth, and, after death, may be restored by it. Cold seems chiefly to act by coagulating the fluids. In new born children its density

is inconsiderable, and the cornea is not stretched to its due degree of convexity; so that they see imperfectly. The aqueous humour in this early period also is sometimes not transparent, and it is by no means certain that some portion of the membrana pupillaris may not remain. All these circumstances will increase the imperfection, and occasion the phenomena already noticed.

A new born child never keeps its eyes fixed on any one object, and it will not wink if any object approaches it. It does not, however, follow that he does not see, but that his vision is imperfect, the reason of which has been explained.

See a Description of the Eye, and its Adjacent Parts, by J. Warner; Winslow's Anatomy; Cheselden; Bell; Zinn; and the very elegant plates of Soemmering.

Artificial eyes are made of concave plates of gold, silver, or glass, stained so as to resemble the natural organ. They must be taken out to clean every night, and replaced in the morning. If no more of a diseased eye is removed than what preternaturally projects, or if the muscles are unhurt, the artificial eye will have a little motion. If it does not fit well, it irritates and inflames the other eye.

On disorders of the eyes, see St. Yves; Benedict Duddell; Remarks on the Ophthalmia, by J. Ware, and J. Warner; Bell's Surgery, vol. iii. p. 232—519; Scarpa on the Diseases of the Eye.

In botany *oculus* means the bud of a plant, and also a name affixed to many herbs supposed to resemble the eye of some animal.

O'CULUS. See COLIQUAMENTUM.

O'CULUS BOVINUS and ELEPHANTINUS. See PROPTOSIS.

O'CULUS BOVIS. See BELLIS MAJOR.

O'CULUS BU'BULUS. See PROPTOSIS.

O'CULUS CHRISTI. See HORMINUM SYLVESTRE.

O'CULUS GENU. See PATELLA.

O'CULUS LACHRYMANS. See EPIPHORA.

OCYMASTRUM. See OCIMASTRUM.

OCYMASTRUM VERRUCCARIUM. See CIRCEA.

OCYMOIDES, (from *οκυμος*, basil, and *ειδος*, likeness,) *lychnis sylvestris*, sive *aquatica purpurea simplex*. RED WILD CAMPION, *silene armeria* Lin. Sp. Pl. 601, grows in hedges, and flowers in summer. The seeds are cathartic, but it is not at present employed. See Raii Historia.

O'CYMUM, *οκυς*, swift, (from its sudden growth.) *Basilicum*. OCYUM BASILICUM Lin. Sp. Pl. 833. *Ocyum* is chiefly used for improving the flavour of sp. volatilis aromaticus.

O'CYMUM CARYOPHILLATUM, *minimum*, *vulgarius*, *medium*, *citratum*. See BASILICUM.

ODAXISMOS, (from *οδης*, a tooth, and *δακνω*, to bite). A biting sensation, pain or itching in the gums. See DENTITIO.

ODONTAGO'GOS, (from *οδους*, and *αγω* to draw). See DENTAGRA.

ODONTA'GRA, (from *οδης*, and *αγειν*, to seize).

ODONTA'LGIA, (from *οδης*, and *αλγος*, pain). The TOOTHACH, a disease arranged by Cullen in the class *pyrexia*, and order *phlegmasia*, which he defines a rheumatism or pain of the jaws from carious teeth. The causes are those of caries in the body of the tooth, which frequently arises in the little cavities between the

fangs; often from tartar at the collum of the tooth, depressing the gum, and admitting the air; sometimes from a little erosion of the enamel where it is thinnest, near the collum.

In these pains the nerve may be sometimes destroyed by a hot iron, rendered torpid by essential oils, or by camphor and opium united.

The lady bird, *coccinella septem punctata*, and indeed all the species of *coccinellæ*, are said to relieve tooth-ach, if bruised between the finger and thumb, and applied to the tooth or rubbed on the gum.

If the external aperture is smaller than the carious cavity, after clearing away the carious matter the access of air may be impeded by stuffing of gold or silver leaf, or tin foil.

The more general remedies are, blisters behind the ear, on the affected side; burning the edge of the helix of the ear, as a branch of the fifth pair of nerves, which supplies the teeth, are lost on the external ear; constantly holding lukewarm water, or milk and water in the mouth, with or without opium; or large doses of opium internally. It is generally recommended to extract the tooth if carious, but no advice can be more injudicious. A carious tooth is certainly pained by accidental colds, but in such cases every sound tooth would have equally suffered; and those who adopt such rash, indiscriminate practice, have been known to draw each tooth in succession, and then to suffer equally in the gums. On the contrary, when the nerve is accustomed to the access of the air, it will continue carious for many years without pain, and be truly useful.

When odontalgia is connected with rheumatism, or gout, which sometimes happens, the remedies of either should be employed.

In extracting a tooth the force may be directed on either side, except in drawing the dentes sapientiæ of the lower jaw, and then the direction of the force should be on the outside, for the jaw within is so thin that it may be easily splintered. An instrument which would raise the tooth without any lateral force, is a great desideratum; and the second Monro, for many years, exhibited one in his class, but it has probably failed, since it is not employed. On pulling the tooth, the force exerted should be firm and steady, not violently rapid; and if the instrument slips, it should be applied on the opposite side. When fairly loosened, it may be raised by the fingers or forceps. The common precautions and the usual management are sufficiently known. See Bell's Surgery, vol. iv. p. 248; Dr. Cullen's First Lines, edit. 4. vol. ii. p. 38; also DENS.

ODONTIA'SIS, (from *odontia*, to put forth the teeth). See DENTITIO.

ODO'NTICA, (from *odontos*). Remedies for pains in the teeth.

ODONTIRRHE'A, (from *odontos* and *rhē*, to flow). Bleeding from the socket of the jaw after tooth drawing.

ODO'NTIS and ODONTI'TIS, (from *odontos*; because the decoction was supposed to relieve toothach). *Lychnis, flos cuculi* Lin. Sp. Pl. 625, β.

ODONTOGLY'PHON, (from *odontos*, and *γλυφω*, to scrape). See DENTISCALPIUM.

ODONTOI'DES, (from *odontos*, and *ειδος*, form). The tooth-like process of the second vertebra of the neck.

VOL. II.

ODONTOPHY'IA, (from *odontos*, and *φυω*, to grow). See DENTITIO.

ODONTOTRI'MMA, (from *odontos*, and *τριβω*, to wear away). See DENTIFRICIUM.

ODORA'TUS, (from *odoro*, *ὀζω*, to smell). See OLFACTUS.

ODORI'FERÆ GLA'NDULÆ. Sebaceous glands under the prepuce, behind the labia and in the axilla, denominated from their odour resembling musk. Dr. Hunter says he never could discover the orifices of these in the axilla, therefore he supposes the discharge to be from innumerable, small, imperceptible pores.

OE'A, (from *οἶω*, to bear, from its fertility). See SORBUS.

OECONO'MIA, (from *οἶκος*, a house, and *νομος*, a law, or rule). Hippocrates uses this word to express the management of a sick person; and it is the title of an Hippocratic lexicon added by Fæsius to his edition of the works of the Coan sage. The animal economy is the conduct of nature in conducting the animal process, and preserving animal bodies.

OEDE'MA, (from *οἰδω*, *tumeco*). See TUMOR; any inelastic tumour resembling anasarcaous swellings. See ANASARCA.

OEDE'MA ERYSIPELATOI'DES, *erysipelas bullatum*, inflammation. An œdematous tumour, white, pellucid, and accompanied by heat.

Dr. Kirkland, in the first volume of his Inquiry, describes an inflammatory œdema which attacks suddenly, sometimes accompanied with an erysipelas, or more commonly a simple inflammation of the skin. He considers œdema as always local.

As soon as the swelling begins to subside, a bandage, or a laced stocking, may be applied, and its tightness gradually increased. Small doses of calomel may be given at night, and the following morning a saline purgative. The bark will be ultimately useful, but the diuretic salt should be at first added. Kirkland's Medical Surgery, vol. i. p. 468.

OEDE'MA LACTEUM. See LYMPHÆDUCTUS.

OEDEMATO'DES, (from *οἰδημα*). See OEDEMA.

OEDEMOSA'RCA, (from *οἰδημα*, and *σαρξ*, flesh,) *uteriformis abscessus*, of a more solid consistence than œdema. Severinus.

ELSNI'CHIUM and ELSNI'TIUM. *Tysselium* Plinii, *apium sylvestre*, *selinum sylvestre* Lin. Sp. Pl. 350. MILKY PARSLEY. The root is perennial, large, and the whole plant full of milky juice. The leaves resemble those of the ferula; the seed is oval, flat, large, striated, and marginated. Another species of selinum, the s. palustre, agrees with this plant in its pungency and acrimony: the roots of both are aperient and detergent; their milky juice, it is said, resembles scammony. See Raii Historia.

ENANTHA'RIA, (from *οἶνος*, wine, and *ανθος*, a flower). SWEET SCENTED OINTMENTS. Their appellation is not derived from having *enanthe* as one of their ingredients, but from their fragrance, or on account of the wine and lilies which are ingredients in them.

ENAN'THE CHÆROPHY'LLI FO'LIIS, (from *οἶνη*, *vitis*, and *ανθος*, *flos*, because its flowers smell like the vine,) *ananthe petroselinii folio venenosa*, *ananthe*

cicutæ facie lobelii, filipendula cicutæ facie. HEMLOCK DROP WORT. DEAD TONGUE, *ananthe crocata* Lin. Sp. Pl. 365.

The root is long, thick, tuberous, extremely succulent; and, on exposure to the external air, the juice becomes yellow; the stalk striated, round, branched, of a yellowish red colour, about three feet high; the leaves of a pale green, winged or doubly winged; the folioles wedge shaped, smooth, streaked, and jagged at the edges; the flowers very small and white, disposed in umbels, placed among the principal stalks, with short ones at the subdivisions; each flower composed of five petals; some of them are bent inward, and heart shaped; tips, purple or brown; fruit stalks angular, scored; the general fence not always present; the seeds striated on one side, and dented on the other. It is found on the banks of rivers; is perennial; flowers in June or July.

The whole of this plant is poisonous, and the root is said to be the most virulent of all our indigenous vegetable poisons, producing epileptic symptoms, &c. See VENENUM. The general effects of this poison are convulsions, locked jaw, giddiness, madness, loss of hair and nails, violent heat in the throat and stomach, vertigo, sickness, and purging.

This herb hath been mistaken for wild celery, water parsnep, smallage, and for Macedonian parsley. The root hath no ill taste; and is therefore seldom suspected.

In Pembrokeshire it is called five fingered root, and is used in cataplasms for whitlows, &c.; in Cumberland, dead tongue, and applied in cataplasms to some diseases of horses. An infusion of the leaves, or three tea spoonfuls of the juice of the root taken every morning, is said to have been effectual in curing obstinate cutaneous diseases, but not without violent effects. It is injurious to dogs, but goats eat it with impunity.

For the treatment of the effects of this root, see VENENUM.

Withering's Botanical Arrangements. Wilmer's Observations on Poisonous Vegetables. London Medical Journal, vol. ii. p. 40, &c. It is the appellation also of water hemlock, and a species of thalictrum.

ÆNAREIA, (from *αιναρη*, the cuttings of vines). The ashes prepared of the twigs of vines.

ÆNELÆUM, (from *αινος*, wine, and *ελαιον*, oil). A mixture of oil and wine.

ÆNOGALA, (from *αινος*, and *γαλα*, milk). A mixture of wine and milk; or, wine as warm as new milk.

ÆNOPLIA, (from *αινος*, wine,) *nabea*, *phaliurus*, *naf*, *nafeca*, GREAT JUJUBE, is produced in Egypt and Crete; and is astringent before it is ripe. The fruit is eaten as a delicacy in Egypt and Turkey; and its juice resembles that of the grape.

ÆNUS, (from *αινος*, vinum). WINE.

ÆNUS A'NDRIUS. GENEROUS WINE, or wine of the island of Andros.

ÆNUS A'NTINOS. FLOWERY WINE; wine impregnated with flowers, in which sense it is an epithet for the cyceon. Galen.

ÆNUS ANTHO'SMIAS, (from *ανθος*, and *σμη*, a smell). SWEET SCENTED WINES.

ÆNUS APODÆ'DUS. Wine in which the dias or tæda hath been boiled.

ÆNUS APEZE'SMENUS. A wine heated to a great degree, and prescribed among other things, as garlic, salt, milk, and vinegar.

ÆNUS DEU'TERUS. Wines of the second pressing.

ÆNUS DIACHEO'MENUS. Wine diffused in large vessels cooled, and strained from the lees, to render it thinner and weaker. Such wines are called *saccati*, from the bag through which they are strained.

ÆNUS GALACTO'DES. Wine with milk, or wine made as warm as new milk.

ÆNUS MA'LACUS, sive MALTHACUS. Soft, or weak and thin wine, opposed to strong; or mild, in opposition to austere.

ÆNUS ME'LICHROUS. Wine in which honey is mixed.

ÆNUS OENO'DES. Strong wine.

ÆNUS SIRÆ'OS. See SAPA.

ÆNUS STRAPHI'DIOS LEU'COS. White wine made from raisins.

ÆNUS TETHALA'SMENOS. Wine mixed with sea water.

ÆNOSTA'GMA, (from *αινος*, and *σταζω*, to distil). See VINUM ADUSTUM.

ÆNO'THERA, (from its dried root smelling like wine). See LYSIMACHIA.

ÆPATA. See ANACARDIUM.

ÆSOPHAGÆ'Æ ARTE'RIÆ, (from *æso*, *phagus*), rise anteriorly from the aorta descendens, and are distributed to the *æso*phagus. Sometimes the uppermost *æso*phagæa produces a bronchial artery. Occasionally there is one only.

ÆSOPHAGÆ'US. See ÆSOPHAGUS.

ÆSOPHAGISMUS, (from *αισοφαγος*; the gullet). IMPEDED DEGLUTITION, or spasm of the *æso*phagus.

ÆSO'PHAGUS, (from *αισω*, the future tense of *φειω*, to carry, and *φαγω*, to eat, because it carries the meat into the stomach,) *gula*, *læmos*, *laucania*; the GULLET is the contracted continuation of the pharynx, the last part of the fauces, called by the Latins *infundibulum*. Its anterior part is connected with the root of the tongue, the os hyoides, and the larynx; it closely adheres behind to the vertebræ of the neck, and is moved by various muscles, which elevate or dilate the pharynx, and by others which shut it. One pair of these muscles, arising by three origins from the os hyoides, the cartilago cricoides, and the cartilago thyroïdes, totally surrounds the pharynx, called *æso*phagæus, the sphincter of the *æso*phagus. The others are called *cephalo-pharyngæus*, *spheno-pharyngæus*, and *stylo-pharyngæus*. The *æso*phagus first runs straight between the *aspera arteria* and the vertebræ of the neck and back, but turns to the right about the fifth vertebra, and to the left about the ninth; then proceeding through the middle of the thorax and the muscular part of the diaphragm, behind the little lobe of the liver, it terminates in the superior orifice of the stomach. The *æso*phagus consists of four coats, the outermost coat is a thin, vascular, cellular membrane originating from the pleura, uniting the gullet to the adjacent parts. The next coat is muscular, furnished with orbicular fibres, and above these with longitudinal ones. The third is

nervous, common to the mouth and fauces, and extending a little way within the stomach; it is glandular, and the glands secrete a mucus. The innermost coat is covered with mucus, is villous, and the orifices of the glands are numerous. The cuticle lines the *œsophagus*, but is too thin to be demonstrated. Besides the glands mentioned, the dorsal about the fifth vertebra of the back, adhering to the gullet, and the thyroid gland, situated between the thyro-cricoid cartilage and the *œsophagus*, are enumerated as belonging to this organ. Its upper part receives arteries from the internal carotids, its middle from the aorta and intercostal, and its inferior part from the gastric arteries. Veins from the jugulars, from the vena sine pari, and from the coronary veins of the stomach, return the blood in the respective portions. The nerves proceed from the par vagum. See Incapability of Swallowing, under DEGLUTITIO, INFLAMMATIO *ÆSOPHAGI*.

Spasms of the *œsophagus* are symptoms of hysteria only, and accompanied by all the peculiar appearances of that proteiform disease.

Spasms of the pharynx are distinguished from a paralysis or relaxation of the canal, by the difficulty of swallowing, being in the latter continual, in the former intermitting: in paralysis solids are more easily swallowed than liquids; in spasms the difficulty of swallowing solids and liquids is equal. The latter are distinguished from inflammation by the absence of swelling, redness, heat in the fauces, thirst, and fever; from tumours and excrescences, by cold liquids exciting greater difficulty than warm, and by pains in the scapulæ.

Spasms of the pharynx, from acrid substances, threaten an inflammation; from hysteric passions, an apoplexy. Etmuller observes, that a difficulty of swallowing from a convulsion, in wounds, is dangerous; and Hippocrates, that a sudden contortion of the neck, obstructing deglutition, without any swelling in fevers, is mortal. Spasms are removed by antispasmodics and anodynes, mixed with discutients, both given internally, and applied externally. The more violent the constriction, the more necessary are external remedies. But the most active anodynes internally must not be omitted; and should swelling, with a livid colour of the face, come on, and there be no time for the operation of a blister, leeches opening the temporal artery or jugular vein are necessary. The bowels must in every instance be kept open, and acrid poisons, if such be the cause, must be diluted and sheathed by mucilages, oil, milk, &c. Blisters, or antispasmodics applied to the spine of the neck, are often serviceable; but, except as a symptom of hysteria or apoplexy, the disease is peculiarly rare.

In spasms of the lower gullet externals are best applied to the spine, with which the *œsophagus* is immediately connected. If the spasms are so violent that the patient cannot swallow, he must be supported by nourishing clysters.

See Hoffman's Practice of Physic, translated by Lewis, vol. ii. p. 147, &c.; Percival's Essays, Medical and Experimental, vol. ii. p. 141, &c.; London Medical Transactions, vol. i. p. 165. vol. ii. p. 90.

ÆSTRUM. See BOVINA AFFECTIO.

ÆSTRUM VENERIS. See CLITORIS.

ÆSTROMANIA, (from *αἰσχος*, the pudenda of a woman, and *μαίνομαι*, to rage). See FUROR UTERINUS.

ÆSYPE, (from *αἶς*, a sheep, and *ῥυτίς*, sordes). The greasy sordes of wool.

O'FFA ALBA HELMO'NTII. If rectified spirit of wine be poured gently into a fully saturated volatile alkaline solution, down the side of a glass, an opaque dense coagulum is formed, which, on gently shaking, becomes a consistent mass, separating, by warmth, into a solid and fluid part: the solid part is called *offa alba*, and is supposed to be a volatile soap, but is only the excess of the salt, which the united spirit and water cannot dissolve.

OFFICINA'LIA. OFFICINALS; an appellation given to such medicines, whether simple or compound, as are required to be constantly kept; or to such vegetables as are selected for medicinal purposes.

OFFUSCA'TIO, (from *obfusceo*, to darken). See AMAUROSIS.

OLA'MPI. The name of a gum which resembles copal, brought from America. It is sweet to the taste, and somewhat astringent, but not used in this country.

OLCACA'TZAN. See CHINA OCCIDENTALIS.

O'LEA, seu OLIVA, (from *ελαια*), the OLIVE TREE, *cotinus*, *olea Europæa* Lin. Sp. Pl. 11, is an evergreen, with oblong, narrow, willow-like leaves, and monopetalous whitish flowers, cut into four sections, followed by clusters of oval black fruit, containing, under a fleshy pulp, a hard rough stone. It is a native of the southern parts of Europe, and bears the ordinary winters of our climate. The olives are called *drupas*, *dryfa*.

The fruit hath a bitter, austere, disagreeable taste; but when pickled proves less ungrateful, and is supposed to promote an appetite, assist digestion, and attenuate viscid phlegm. The Lucca olives are the smallest, and mildest; the Spanish, the largest, and most acrid. Those of a middling size, brought from Provence, are generally most esteemed; but the principal consumption of this fruit is for their oil, which, when taken from the unripe fruit, is called *omotribes omphacinum*. The oil for use is procured when the fruit is ripe. The purer and finer oil is procured by gentle pressure; and inferior sorts, on heating the residuum, and pressing it more strongly. The best olive oil is of a bright pale amber colour, bland to the taste, and without smell, becoming rancid by age, particularly in a warm situation; by cold, at the 38th degree of Fahrenheit's thermometer, it congeals, and does not become rancid at the freezing point of water. All the mild expressed vegetable oils are nearly of the same nature; but the most fluid, particularly the oil of olives, and of almonds, are most commonly directed for internal use. See AMYGDALÆ; and GROSS and EXPRESSED OILS, under OLEUM.

OLEA'MEN, (from *oleum*, oil). A thin liniment composed of oils.

OLEA'NDER, (from its resemblance to the olive tree). See NERION.

OLEA'STER, (from the same). The WILD OLIVE, *elæagnus*, *agrielæa*, differs from the garden olive only from the want of cultivation.

OLE'CRANON, (from *ωλενη*, cubitus, and *κρανον*, the head). The ELBOW; *ανκον*, *pechys*, is the largest of the two apophyses at the upper end of the ulna, ending in a rough tuberosity and an obtuse point. The tuberosity makes the corner of the elbow, called *acrotenion*; and the point is lodged in the posterior cavity of

the lower extremity of the os humeri, when the fore arm is extended.

O'LENE, (from *ωλενη*, the cubit). See CUBITUS.

OLEOSA'CCHARUM, (from *oleum*, and *saccharum*). Essential oils, ground with eight or ten times their weight of sugar, become soluble in water, and may be diluted to any assigned degree. These oleosacchara may be kept in well stopped bottles for making extemporaneous distilled waters. Mucilages render oils miscible with water into a milky liquor; and they dissolve in a little more than their weight of rectified spirit of wine. The extemporaneous waters made in this way are not so grateful as those that are distilled, as the more volatile finer portion escapes.

O'LEUM, (from *olea*, a name first confined to the oil expressed from the olive, but now applied to many other substances). OIL. Oils are animal, vegetable, and mineral. Animal oil is the fluid fat of animals, and all animal substances yield it by distillation. Vegetable oils are procured by expression, distillation, or boiling; the mineral spontaneously, and by distillation.

1. *Fixed oils* are usually liquid, or become so in a moderate temperature. They are combustible, insoluble in water and alcohol, mild to the taste, unctuous to the touch, without smell, and their boiling point is usually above 600°. Oils, or what are styled fat, expressed oils, are procured from the seeds of plants; in the animal kingdom, from the adipose membrane, the cells and cavities of bones, and the livers: it is contained in a small proportion in the egg. Olive oil, taken as a standard, was found by Lavoisier (*Journal de Physique*, Juillet, 1787) to contain, in 100 parts, 79 of carbon, and 21 of hydrogen. It is usually yellowish or greenish, and of the specific gravity of about 0.9278; does not unite with water, unless assisted by some mucilaginous substance, and then it is a mixture only, which, on standing, separates. When distilled it seems in part decomposed; water and sebatic acid, if the oil be from an animal, are formed; and the oil in the receiver no longer possesses its former qualities. It was once called *oleum philosophorum*.

Since the time of Lavoisier, however, the Dutch chemists, Deiman, Troostwyk, &c. have made some further advances in the analysis of oil. When alcohol is decomposed by the sulphuric acid at high temperatures, or when alcohol or ether are passed through a red hot earthen tube, a gas is obtained, styled the *heavy carbonated hydrogen*. This gas is nearly as heavy as common air, unaffected by water, of a foetid odour, burning with a strong compact flame, like resin. Its most singular property, however, is, that when combined with oxygenated muriatic acid gas, oil is obtained. They, therefore, called it *olefiant gas*. The carbon, in this gas, is in excess, and the oxygen seems to precipitate the superabundant portion; for, on igniting them, carbon is always separated. When the olefiant gas is passed through an ignited tube the hydrogen seems to be separated, and it will no longer produce oil, though it is usually said that the change is produced by the loss of the carbon. With pure alkali oils unite, and produce that useful concrete, soap.

If exposed to cold they lose much of their fluidity, sometimes at a very moderate temperature. In warm air, they become thin, rancid, and acrimonious: in this state, instead of allaying irritation they occasion it. When this acrimony appears in the kernels, it is covered

by the remaining mucilage, and the emulsion becomes sour, for the rancidity depends on the evolution of the sebatic acid. In a degree of heat which will occasion a small evaporation from these oils, a pungent acid vapour arises; and when cool they are found to have acquired a greater degree of consistence than before, with an acrid taste. In a heat approaching to ignition, in close vessels, the oil rises in an empyreumatic state, leaving a black coal behind.

In order to obtain these oils, the seeds which contain them must be ground or powdered small, included in proper bags, wrapped in hair cloths, and committed to the press, by which the oil is forced out. To facilitate the expression, it is usual to warm either the press or the plates, or to heat the substance to be pressed. But heat occasions rancidity, and should only be admitted when intended for immediate use. Olives, almonds, linseed, rape, and mustard seed, now chiefly employed, yield an oil not essentially different as a medicine, and each is an emollient and demulcent. For this purpose oil is prescribed in some coughs, catarrhal affections, and erosions, successfully used in worm cases, in nephritic pains, spasms, colics, constipation of the bowels, &c. and has been recommended in cases of canine madness. (See HYDROPHOBIA.) Externally, it is used in bites and stings of various poisonous animals, burns, and tumours, or mixed in liniments, injections, clysters, and poultices. Rubbed over the body, it has been thought beneficial in dropsies, particularly in ascites. The oily clyster consists of two ounces of oil to a pint of barley water; and if intended as a laxative, two ounces of Glauber's salts are added.

Four ounces of oil, with two drachms of tincture of opium are thrown up as a clyster, in spasmodic affections of the bladder and the neighbouring parts; sometimes the opiate instead of the oil, is united to a dilute solution of starch. The compound oily liniment is composed of two ounces and a half of olive oil, an ounce of oil of turpentine, with forty-five drops of oil of vitriol. The acid must be gradually added to the other ingredients in an open vessel. In chronic affections of the joints, in debility from sprains and bruises, this is said to be an efficacious, but it is not an elegant application.

Though expressed oils may be combined with water, by the intervention of gum or mucilage, yet they do not unite with the gummy mucilaginous parts of vegetables. Expressed oils, are, therefore, as we have said, similar, whatever may be their source. They may, however, be tinged by vegetable matters of almost all colours; and, in making the officinal oils by decoction, in order to have the colour clear and strong, the oil should be strained as soon as it hath acquired a sufficiently deep hue, and then boiled until no aqueous vapours exhale. If the water is not wholly evaporated the oil will have a dark colour, and be soon mouldy; and if the leaves are boiled after they become crisp, they occasion a disagreeable blackness. What are styled *fat oils*, differ only from the common expressed oils, by containing a larger proportion of mucilage.

2. *A gross sebaceous matter*. From the kernel of some fruits, as of the cocoa nut, a substance of a butyraceous consistence is obtained. It is best extracted by boiling the nut in water, when it separates, rising to the surface, and resuming its proper consistence as the liquor cools. These substances have the same general properties with expressed oils, but are less disposed to

become rancid than most of the common fluid oils. It is supposed that their thicker consistence is owing to a larger admixture of an acid principle, most probably of oxygen; for by fire they yield a vapour more sensibly acid than the fluid oils; and these by the admixture of concentrated acids are reduced to a thick and a solid mass.

Oils of this kind are styled drying oils, because they dry without losing their transparency. Lintseed oil possesses this quality in the greatest degree; but it is usually increased by adding litharge, which, when boiled with it, is in part reduced to its metallic state. From hence, and from the effect of acids, we conclude that the change consists in the addition of oxygen. The highly oxygenated metallic salts, as the hydrargyrus muriatus, will have a similar effect. The thick opaque whiteness produced by the access of air, in what are styled fat oils, as those of olives, almonds, rape seed, and ben, depends on a similar addition; for it is immediately produced on the addition of oxygen gas: (Senebier.)

Oils in different disguises constitute a great part of our nourishment; but it is not easily digested in a separate state, nor when intimately combined with mucilage in the kernels of nuts. Oil is used internally as a DEMULCENT, and its operation is explained under that head. Many difficulties attend the explanation of its effects when carried into the system. Yet the German physicians, particularly De Haen, give it freely in inflammations of the lungs; and we have thought soap, which must be considered as a form of oil, useful in peripneumony. In Switzerland it is used to destroy tania; and as a gentle laxative it is employed in preference to others in nephritis, in colics, and constipation of the bowels.

The external use of oil as a medicine is of very high antiquity. It was a part of the complicated system of bathing, as employed by the ancients, either as a remedy, or for the preservation of health. Bathing was of peculiar importance, since they were unacquainted with linen; and their woollen garments were not very regularly or very nicely cleaned. The peculiar advantages of oily applications, independent of the friction employed, except in giving softness and flexibility to the limbs, are not easily ascertained. After exercise they were undoubtedly refreshing, and prevented stiffness; but as preservatives they seem to have been chiefly useful in preventing the too copious perspiration. When we compare all the directions for anointing, we can see no other point in which they meet; and this, in a climate so warm, after violent exercise, and the relaxation of the warm bath, must have been an object of importance. The use of oil as an external remedy was introduced by Prodicus, more probably Herodicus, the inventor of gymnastics; and in fevers it seems to be directed to the purposes mentioned. We have not the works of this ancient author, but find copious directions for its use in Pliny. It still seemed an appendage to the bath; for, in slow fever, the oil was used in cold water; in the cold fits, united with warm substances. In general, it was supposed to strengthen and to fortify the body against the access of cold. So strong was the ancient opinion of its utility in this respect, that to defend the body *intus vino, foris oleo* was the frequently repeated maxim for prolonging life.

Independent of its subsidiary aid to the balneum, it

was used by the ancients, in many diseases, applied externally, and often rubbed along the spine; in palsies, in lethargy, in tetanus, in dropsy, and in ephidrosis. In hydrophobia the patients were thrown into the cold bath, and then into oil; in melancholia, into a bath of water and oil. It was supposed to allay irritation, and we still retain its use in burns, in bites of insects, in prurigo, &c.; but the ancients employed it to allay pain after severe operations, to soften the exuberant callus of bones, to remove the pain attending luxations or wounds. St. Luke, whom we now quote as a physician, describes the good Samaritan as pouring oil and wine into the wounds of him who fell among thieves, x. 34.

When luxury increased, this salutary custom was, as usual, abused, and the oil was combined with the most costly perfumes. The simplicity of ancient manners consigned, without a blush, the fatigued body of the traveller to the hands of a female; but this custom was afterwards extended, and the bath became the scene of wantonness and lust. In the progress of empire, of science, and the arts, eastward, the use of oil might have been carried, unless the same necessity which suggested it in Greece introduced it also in Indostan; though the cotton dress would, in a great degree, render the use of the bath less necessary.

In the east the use of oil, however, seems of considerable antiquity; and, besides the more obvious effects of giving sleekness to the skin, and flexibility to the limbs, it is supposed to assist the strength, increase the secretion of fat and of the semen, as well as to prolong life. The Hindoos use oil to cure fevers, epilepsy, mania, dropsy, worms, and cutaneous diseases; to relieve pains from bruises, and the colic; to prevent bad effects from the bites of mad animals, and of serpents.

Modern practice continues the application of oil to allay irritation, particularly the pains felt in old fractures, or wounds, on the change of weather, as advised by Rosenstein; and in irritations of the genital organs, as recommended by Hufeland.

Oil, we have said, was used externally by the ancients in low fevers, and the practice continued in Egypt to the time of Prosper Alpinus. On this foundation it may have been recommended in the plague, in which it has been said to be of essential use. Its advantages, however, arise not from the oil, but from the friction; for, unless continued so as to excite perspiration, it is of little utility. In dropsies also the oil seems only to assist the friction, by preventing the excoriation, which might otherwise soon occur. In tetanus, if ever useful, it is also perhaps in consequence of the friction and the perspiration excited, by means of the friction.

In the bites of insects it seems to relieve pain, but in those of serpents Fontana found it inefficacious; nor are the experiments of Mr. Baldwin on its effects in the bites of scorpions, or rats, unexceptionable. In hydrophobia it has been recommended on the authority of an ancient Greek manuscript; and, though we have received accounts of cases in which it seemed to relieve the spasms, it has not been found to cure the disease.

That oil may be useful in securing a person from contagion appears from evidence apparently more decisive. From very different sources we find that oil porters, oil sellers, tallow chandlers, and tanners, are unusually exempt from the plague, and the worst epidemics.

It has been supposed that frictions with oil are nutritive, as they are said to increase obesity: butchers and cooks are proverbially fat. This effect has, however, been doubted, sometimes denied.

3. *Essential oils* are obtained only from the odiferous parts of vegetables, since on these the odour, often the pungency, and other active powers of the subject depend. They are consequently called essences and essential oils. These oils are very combustible, boil nearly at the same point as water, evaporate without leaving a stain on paper, unite with different proportions of rectified spirit of wine, and even water will imbibe some more subtle portion, and be impregnated with their flavour. By the mixture of sugar, gum, &c. they unite with water in a transparent fluid. Digested with volatile alkalies the colour often varies, and some of the less odorous acquire a considerable degree of fragrance, while fixed alkalies universally impair their odour. Their medium specific gravity is 0.9553, and they seem to contain a larger proportion of hydrogen than expressed oils. In the heat of boiling water these oils totally exhale, and on this principle they are readily extracted; for an aqueous fluid is only volatile in this temperature, from which part of the oil is easily separated. In their resolution by a burning heat they differ little from expressed oils. From continued exposure to a warm air, instead of growing thin, rancid, and acrimonious, they gradually become thick, hardening at last into a solid, brittle, concrete, sometimes into a saline substance, with a remarkable diminution of their volatility, fragrance, and pungency. (See GAUBII ADVERSARIA.) The mixture of a concentrated acid instantly produces a similar change.

The oils expressed from aromatic substances differ from those obtained from olives, almonds, &c. They retain a portion of the aromatic matter of the subject; and a nutmeg yields, upon expression, an oil impregnated with the flavour of the spice, and a purgative oil is expressed from the seeds of the ricinus. The rinds of oranges, lemons, and citrons, yield, by expression, essential oils nearly similar to those obtained from them by distillation. They are most conveniently obtained by rubbing a piece of lump sugar on the surface of the fresh peels: the vesicles in which the oil is contained are thus burst, and the sugar imbibes it.

Moist essential oils are drawn by distillation, adding a sufficient quantity of water, to prevent burning, in which the subject is macerated a little before the distillation: the oil comes over with the water, and either floats on its surface, or falls to the bottom. The water employed in distilling essential oils imbibes some portion of them; so that the saturated water of former distillations may be advantageously employed instead of common water in future operations, since this portion of the oil cannot be separated.

Essential oils are very often adulterated. If with an expressed oil, the fraud is discovered by adding a little rectified spirit of wine, which dissolves the essential oil, and leaves the expressed untouched. If a heavier essential oil be dropped into water, after a brisk agitation, it falls to the bottom, and the expressed oil swims at the top; or if evaporated in a silver spoon, the essential oil will leave the expressed behind. If adulterated with rectified spirit of wine, when dropped into water, or into spirit of turpentine, a milkiness will appear on the mixture being shaken. If an essential

oil is mixed with a cheaper one, a drop rubbed on the hand, and held to the fire, will leave the odour of the added oil sufficiently distinct behind. The added oils are usually those of turpentine, which are also discovered by a milkiness when dropped into spirit of wine.

Essential oils, medically considered, agree in the general qualities of pungency and heat, but differ according to the subjects from which they are obtained. Some of these are used to correct the irritating griping quality of resinous purgatives, in which respect they are useful, as general stimulants, as carminatives, and sometimes light astringents. These oils may be administered with powders, pills, boluses, or electuaries.

4. *Concrete essential oil.* Some vegetables, as the roots of elecampane, yield a substance possessing the general properties of essential oils, but of a thicker and sebaceous consistence. It is equally volatile and subtle with the fluid oils; exhales equally in the heat of boiling water, and concretes upon the surface of the collected fluid. The exhalation of this matter and its concreting again, without any separation, into a fluid and a solid part, distinguishes it from essential oils that have been thickened or indurated by age or by acids. See Hoffmann's *Observationes Physico-chemicæ*, lib. i.; Neumann's *Chemical Works*.

OLE'UM AMYGDALA'RUM. See AMYGDALÆ.

OLE'UM ANIMALE is an empyreumatic oil from animal substances, usually prepared from bones or harts-horn, refined by repeated distillations till it is nearly colourless. It always retains some smell, which is pungent, but not unpleasant; and is used chiefly as an antispasmodic, sometimes as a diaphoretic. It was first introduced by Dippel, and the preparation has been greatly improved by Model, a Russian chemist. The dose is from fifteen to thirty drops, and it is given in convulsions, the whooping-cough, and similar complaints. Externally it has been employed in bruises; and the *British oil*, a quack remedy, is of this kind. By keeping it acquires its former unpleasant qualities, probably by attracting azot from the air.

OLE'UM CAMPHORATUM is the camphor in a liquid form, exuding from the trees which produce it. (See CAMPHORA.) It may be used for all the purposes of camphor; but was first introduced as an external application to cure gout. It seemed to relieve the pain, which, however, returned to another part; and had it not done so, all the inconveniences of repelled gout would probably have followed.

OLE'UM JECORIS ASELLI. THE OIL OF THE LIVER OF THE COD FISH, is procured by the process of putrefaction, when it spontaneously separates. It is imported in barrels from Newfoundland, and was first, we believe, prescribed by Dr. Percival in the Manchester infirmary, in doses from one to three table spoonfuls. It was given for chronic rheumatism; and, though highly nauseous, was found so successful, that patients petitioned to be allowed the same remedy. Dr. Bardsley has lately added his testimony to its salutary virtues in this complaint; and we have, we think, seen chronic rheumatisms yield to a steady constant use of this oil which had resisted every other remedy. By habit the palate is less offended by its taste.

OLE'UM MACIS. See NUX MYRISTICA. As an external application it is said to be anodyne.

OLE'UM MALABATHII. An oil said to be procured

from the leaves of the *laurus cinnamomum*; but what is brought to us from India seems to be flavoured by cloves, if not drawn from them.

OLE'UM NEROLI. An oil procured from the flowers of the Seville orange tree, used only as a perfume.

OLE'UM OLIVARUM. See *OLEA*, or *OLIVA*.

OLE'UM ORIGANI and *SASSAFRÆ*. Two acrid essential oils, often serviceable in relieving toothach. They appear to act as narcotics.

OLE'UM PALMÆ. See *PALMÆ OLEUM*.

OLE'UM PAPYRI. A fetid empyreumatic oil, used for relieving the toothach. A sheet of paper is rolled up in a small cylinder, and set on fire at one end, while the other is enclosed in a cavity formed by two tea cups. When the paper is consumed, and the apparatus cold, a dense oil is found in the lower cup.

OLE'UM PETRÆ. See *PETROLEUM*.

OLE'UM RICINI. See *CATAPUTIA*.

OLE'UM SINAPEOS. The oil of mustard is perfectly mild. What is usually styled the *essence of mustard* is only the oil of turpentine combined with spirit of wine, with the addition of camphor, opium, and a small proportion of the flour of mustard.

OLE'UM SULPHURATUM. The modern appellation of *BALSAM OF SULPHUR*, q. v.

OLE'UM SYRIÆ. A fragrant essential oil obtained from the *pinus balsamea* Lin. Sp. Pl. 1421.

OLE'UM TEMPLINUM. See *ABIES*.

OLE'UM VINI. An oily fluid which arises in the distillation of ether, after the finer fluid has come over. A proportion of this oil gives Mr. Tickell's ether its distinguishing qualities.

Oleum is a term for the product of several substances, viz.

O'LEUM BALSAMI. See *BALSAMUM*.

O'LEUM SA'LIS. See *CIRCULATUM*.

O'LEUM MY'RRHÆ per DELIQ. See *MYRRHA*.

O'LEUM ANTIMO'NI. See *ANTIMONIUM*.

OLFA'CTORII NERVI, (from *olfactus*), the OLFACTORY NERVES, were formerly called *processus mammillares*. They are the first pair of nerves from the brain, and seem to approach as they pass towards the crista galli, where they divide into many small filaments, which pass through the foramina of the os ethmoides. On these nerves no covering from the dura mater can be traced. See *OLFACTUS*.

OLFA'CTUS, (from *olfacio*), the SENSE OF SMELLING; *odoratus*. The mucous membrane which lines the nostrils is expanded in the two frontal sinuses, the antra of Highmore, the cells in the sphenoid bone, and the spongy bones of the nostrils. The olfactory nerves pierce the holes in the ethmoid bone, and spread themselves in this membrane. No where are the nerves so soft, naked, and consequently so easily affected and injured, though defended by an insipid mucus. A branch from the fifth pair is also sent to this membrane, by the irritation of which sneezing is excited on the irritation of acrid mucus, or any other stimulant. The objects of smell are those substances which float in the atmosphere; but from experiments it is plain that the spirit chiefly excites the sense of smelling, for as it is separated from the oil the latter is inodorous. The sense of smell is only excited when the odorous effluvia contained in the air are impressed on the olfactory nerves.

The longer the nostrils, and the more extensive the surface, the more acute is the sense of smelling.

OLIBANUM, (from the Chaldee word *lebana*), *condensatus*, *thus masculinum*, and *corticolum*. **LYCIAN JUNIPER** or CEDAR. (See *THUS*.) It is a gummy resin brought from Turkey and the East Indies; but Dale found in a species of cedar, in Carolina, a gum so nearly resembling it that he could not perceive any difference. The tree which usually affords it is the *juniperus lycia* Lin. Sp. Pl. 1470. We usually receive the olibanum in drops or tears like those of mastich, but larger, of a pale yellowish colour, by age becoming reddish. The single tears are called simply *olibanum* or *thus*; when two are joined together, *thus masculinum*; if very large, *thus femininum*. When four or five large tears have adhered together, found probably on the bark of the tree, they have been named *thus corticosum*; the finer powder *mica thuris*; the coarser, *manna thuris*. The appellation of *thus* is now, however, disused.

Olibanum has a moderately strong, not very agreeable smell, and a bitterish taste. In chewing, it sticks to the teeth, and renders the saliva milky. Laid on a red hot iron it readily burns with a strong, not unpleasant smell. On trituration with water, the greatest part of it dissolves into a milky liquor, which, on standing, deposits a portion of resinous matter, which, on inspissation, leaves a yellow extract, retaining much of the smell and taste of the olibanum. Rectified spirit of wine dissolves less than water, but takes up nearly all the medicinal virtue. It has been recommended in disorders of the head and breast, in hæmoptoes, and in alvine and uterine fluxes, in a dose of about ʒss. Dr. Cullen thinks it has no medicinal virtues, and takes no notice of it; but it is sometimes prescribed in gleets, leucorrhœa, and other discharges, where stimulants in the urinary passages or parts contiguous are necessary. It seems useful as a carminative; and we have sometimes thought it advantageous in the catarrhus suffocativus of old people. In hysteric complaints it is frequently ordered; and applied externally in a plaster as a corroborant. See Lewis's *Materia Medica*. Neumann's *Chemical Works*.

OLISTHE'MA, (from *ολισθαίνω*, to fall out). See *LUXATIO*.

OLIVA'RIA CORPO'RA, (from *oliva*, the olive,) resembling an olive. Two eminences on the lower part of the medulla oblongata, at the commencement of the medulla spinalis. See *CEREBRUM*.

O'LLI. See *CAOUTCHOUC*.

OLOPHLY'CTIDES, (from *ὅλος*, whole, and *φλυκτῖς*, a pustule, because they cover the whole body). See *PHLYCTENÆ*.

OLSEN'CHIUM. See *CELSNITIUM*.

O'LUS A'TRUM, (*olus*, herb, *ab alendo*, and *atrum*, black, from its leaves). See *HIPPOSELINUM*.

O'LUS AU'REUM. See *ATRIPLEX*.

O'LUS HISPANICUM. See *SPINACHIA*.

OMA'GRA, (from *ὤμος*, shoulder, and *αγρία*, seizure), See *ARTHRITIS*.

O'MASUM, or **O'MASUS**, (quasi *comasum*, or *comesium*, from *comedo*, to eat). See *ABOMASUM*.

OMELY'SIS, (from *ωμος*, crude,) the meal of barley not parched; or any sort of meal.

OME'NTA. See *DURA MATER*.

OMENTA'LIS, and OMENTI'TIS, (from *omentum*). See PERITONITIS.

OME'NTUM, (from *omen*, because the soothsayers prophesied from the inspection of this part,) *epifloon*; *reticulum*, *dertron*, *gangamon*, from its structure resembling that of a net; the caul which extends sometimes to the hypogastrium, sometimes scarcely below the navel. It is bordered with fat; the lines by which it is divided are fatty, and between the bands of fat it is sometimes plaited, resembling in shape a net or an empty pouch, floating over the intestines. Its superior portion is divided into two borders, one of which is fixed along the great arch of the colon, and the other along the great curvature of the stomach. The union of these two borders on the right side is fixed to the ligament, or adhesion of the duodenum and colon, and to their contiguous parts; that on the left side to the longitudinal scissure of the spleen, to the extremity of the pancreas, and to the convex side of the great extremity of the stomach. It connects also the membranous ligament which sustains the ductus choledochus to the ventral vena portæ.

The inferior portion is the *saculus epifloicus*; the anterior and posterior styled the *laminæ*; but Dr. Monro prefers the term *ale*.

The omentum is composed of two laminæ joined by cellular substance which is looser near the blood vessels, forming broad bands, in which the latter ramify, and which Dr. Monro calls *bands* or *portions of fat*.

The little omentum (see MESOGASTRION) is a small bag fixed, by its whole circumference, to the small curvature of the stomach, and to the concave side of the liver before the sinus of the vena portæ, so that it surrounds the prominent portion of the lobulus. It is thinner than the greater omentum, and ends in a narrower cavity, often in different pointed sacculi. Its laminæ seem, in part, to be continuations of the external membranes of the stomach, the liver and the contiguous portion of the diaphragm. Those of the great omentum are equally continuations of the contiguous membranes of the stomach, colon, and in part of the spleen; at least, it is intimately connected with these organs. The fatty appendices of the colon and rectum have been called *appendices epifloicæ*, and are elongations of their external coat, resembling in structure the omentum. Each rests on a broad thin basis next the intestine, terminating by irregular papillæ. The bases are at first longitudinal, then, in their progress, oblique, and near the rectum transverse. The longitudinal appendices sometimes communicate with each other.

The blood vessels of the omentum are from the gastricæ, and consequently called *gastro epifloicæ*. The arteries on the right side answer to the hepatic; on the left to the splenic: both communicate with the arteria ventriculi coronaria, and with the mesenteric arteries respectively. The veins answer equally to the vena portæ. The vessels of the lesser omentum come chiefly from the coronaries of the stomach; those of the appendices from the vessels of their respective intestines.

The omentum is generally larger on the left side than the right, often forms a part of a hernial tumour, and suffers with the peritonæum in child-bed fever. Its use is unknown. It is said, without reason, to lubricate

with its fat the intestines; but these are kept distinct by an halitus. From its communication with those viscera, which are subject to considerable distention, there is little doubt but that it is subservient to their functions, though in a manner not easily explained.

OMOCO'TYLE, (from *ὤμος*, the shoulder, and *κοῦλη*, a cavity). See SCAPULA.

OMOHYOIDE'US MU'SCULUS, (from *ὤμος*, and *ὕοις*, the hyoid bone). See CORACO HYOIDÆUS MUSCULUS.

OMOLI'NON, (from *ἄμμος*, crude, and *λίαν*, linum). RAW FLAX; which Hippocrates used for burning or cauterizing, or in the cure of the fistula in ano, a mode which Paulus calls *apolinosis*; in a tubercle of the side after cutting and cauterizing; or in dropsy.

OMOPLA'TA, (from *ὤμος*, the shoulder, and *πλαῖς*, broad). See SCAPULA.

OMOPLA'TO HYOIDÆ'US. Synonymous with *omohyoidæus*. See CORACO HYOIDÆUS MUSCULUS.

O'MOS, (from *οἶω*, to bear). See HUMERUS and UTERUS.

OMPHA'CIUM, (from *ομφακον*, an uterine grape). See VITIS.

OMPHACI'TIS, (from the same). A small kind of gall.

OMPHACOME'LI, (from *ομφακον*, and *μέλι*, honey,) oxymel made of the juice of unripe grapes and honey.

OMPHALOCA'RPOS, (*ομφαλος*, a navel, and *καρπος*, fructus, from its resembling the navel). See APARINE.

OMPHALOC'E'LE, (from *ομφαλος*, the navel, and *κλή*, a rupture). See HERNIA UMBILICALIS.

O'MPHALOS, (from *ομφαλίσκω*, to roll up). See UMBILICUS, and HERNIA UMBILICALIS.

O'MPHAX, (quasi *ὡμῃ εἰς τὸ φαγεῖν*, from its crude state). See AGRESTA.

ONA'GRA. See ARTHRITIS.

ONEIRODY'NIA, (from *ονειρον*, somnium, and *ὀδυνή*, cruciatus). DISTURBED OR TROUBLED SLEEP. Dr. Cullen places this disease in the class *neuroses*, and orders *vesania*, and defines it, violent or disturbed action of the imagination during sleep. The species are,

1. ONEIRODY'NIA ACTIVA. See SOMNAMBULISMUS.

2. ONEIRODY'NIA GRAVANS. See INCUBUS.

ONEIRO'GMOS, (from *ονειρωτῶ*, semen in somno profundure). Cælius Aurelianus gives this appellation to the complaint in which the patient is disturbed with delusive dreams, frequently emitting his semen during sleep. He considers it as the result of impressions on the fancy, arising from extraordinary desire of, or great abstinence from, venery. Cælius Aurelianus de Morbis Chronicis, lib. v. c. 7. See GONORRHEA.

ONEIRO'GHONOS, (from *ονειρος*, a dream, and *σπέρμα*, seed). The oneiroghmos, occurring rarely.

ONI'SCUS, (ab *ovos*, multipeda). See ASELLI.

ONI'TIS, (from *ovos*, an ass, because asses are fond of it). See ORIGANUM CRETICUM, and ANGLICUM.

NOBRY'CHIS, (from *ovos*, and *βρυχω*, to bray, because its smell makes asses bray). *Polygalon Gesneri*, *caput gallinaceum*, *hedysarum onobrychis* Lin. Sp. Pl. 1059, HOLYHAY, COCK'S HEAD VETCH, SAINTFOIN. It grows on hills, in high ways, and corn fields; but

always in a chalky soil, exposed to the sun. It is cultivated for feeding of cattle, and is said to increase the flow of milk in cows.

ONOCHE' LIS, ONOCLE' A (from *ovos*, and *χειλος*, a lip; from its supposed resemblance). See ANCHUSA.

ONO'NIS (from *ovos*, because it interrupts asses when at plough). See ANONIS.

ONO'PTERIS MAS, (from *ovos*, and *πτερις*, fern; because eaten by asses). *Onosma echinoides* Lin. Sp. Pl. 196. It is the plant which produces the *anchusa lutea* of some foreign dispensaries, commended as an emmenagogue. See ADRIANTHUM NIGRUM.

ONY'CHIA, (from *ονυξ*, a nail). See PARONYCHIA.

O'NYX, (from *ονυξ*). The Greeks gave this name to a disease of the eye; a spot resembling in shape the finger nail. See ABSCESSUS OCULI, and ALBUGO.

OOI'DES (from *ovon*, an egg, and *ειδος*, likeness). See OCULUS.

OPERCULA'RES, (from *operio*, to close). See COCHLEÆ.

OPERCULA'TUS, (from *operculum*, a cover). A kind of moss whose anthera is furnished with a lid.

OPE'RCULUM CO'CHLEÆ CÆLA'TÆ. See UMBILICUS MARINUS.

OPHIA'SIS, (from *ophis*, a serpent; because the serpent casts his skin). See ALOPECIA.

OPHIOGLO'SSUM, (from *ophis*, and *γλωσσα*, a tongue). ADDER'S TONGUE; *brassatella*; *lingua serpentis*, *ephioglossum vulgatum* Lin. Sp. Pl. 1518. This plant hath only one leaf, with a slender stalk arising from its bottom, the edges dented, and supposed to resemble the tongue of a serpent; it grows in meadows, the leaf is thick, of a fresh green colour, and juicy; the seed is in a green spike. It has not been lately used in medicine.

OPHIOSCO'RDON, or OPHIOSCO'RODON, (from *ophis*, and *σκορδον*, garlic; spotted like a serpent,) *victorialis*; *allium agninum*, and *alpinum*; *allium montanum latifolium maculatum*; *idæa*; *moly alpinum*; SPOTTED RAMSONS; BROAD LEAVED MOUNTAIN GARLIC, similar in virtue to the common garlic. See Raii Historia.

OPHIOSTA'PHYLLON, (from *ophis*, and *σταφυλη*, a berry; because serpents feed upon its berry). See BRYONIA ALBA.

O'PHRIS, and O'PHRIS MA'JOR. See BIFOLIUM.

O'PHRYS, (*οφρυς*). See FRONTS, OS.

O'PHRYS UNIFO'LIA. See MONOPHYLLON.

OPHTHA'LMIA, (from *οφθαλμος*, an eye). *Inflammatio oculi*; *ophthalmitis*; *blephoritis*; *chemosis*. An inflammation of the membranes which invest the eyes; particularly the adnata.

Dr. Cullen places this disease in the class *pyrexia*, and order *phlegmasia*, defining it redness, and pain of the eye, with incapacity of bearing the light, and most commonly with tears. He distinguishes two species: 1. The *ophthalmia membranarum*; 2. *ophthalmia tarsi*, when attended with tumour, erosion, and glutinous exudation of the edges of the eye lids. The first he considers as varying according to its degree. The second includes but two varieties. He distinguishes also between the idiopathic and the symptomatic oph-

thalmia, including in the first the species mentioned, and distinguishing the last from the primary disease. There is, however, no disease in which the practical views are so much confounded by nosological strictness as in ophthalmia, which is often an acute fever with highly active inflammation; but from this point it frequently diminishes in activity, so as to become merely a redness from over distended vessels; though from the great sensibility of the organ, pain, impatience of light, and effusion of tears, remain. In this gradual progress the remedies must differ, and be often of a very opposite nature. In our description of the disease we shall keep, therefore, this change in view.

Ophthalmia is seldom ushered in by a marked paroxysm of fever. The first sensation is that of a pricking, often of a stabbing pain; and, where these sensations have been felt most pungent, a little fasciculus of peculiarly distended vessels may often be discovered. A sense of heat is felt in the eyes, with heaviness of the head, often with itching, and an effusion of tears. The eye lids are stiff, and closed to guard against the impression of light, which is peculiarly painful and distressing. If the habit is irritable, the pulse is quickened, especially towards the evening; slight shiverings, with nausea, and an inclination to vomit, sometimes come on.

By proper treatment the violence of the pain and the increased sensibility are mitigated, and the patient sleeps with ease, and can bear some degree of light. But the eyes continue red, and the former applications fail to relieve. They must then be changed, in the manner to be afterwards described.

This is the form of the common acute ophthalmia. The more severe differs rather in degree than in symptoms. In this form of the disease, the heat in the eyes is a sensation of violent burning; the organ itself feels spasmodically contracted; the weakest light is intolerable; the tears are continual, copious, highly acrid, and mixed with mucus; or the eye is dry and scorched; the pupil is contracted, and, instead of a redness of the adnata, the whole is sometimes a projecting excrescence of unvaried redness. Sometimes the vessels burst, and the whole adnata swells beyond the eye lids; sometimes the vessels yield internally, and the organization of the eye is destroyed. This is occasionally known by a sudden sensation of bursting, with usually a flash of light. Sometimes the ophthalmia commences internally and the adnata appears only inflamed from the communication. In this case the deep seated heat, the intolerance of light, and the spasmodic contraction, are first felt. The consequences are often the same, viz. the destruction of the organ.

The external causes of this inflammation are cold air; dust; irritation of every kind, sometimes even of a swollen tarsus, or a tumour in the calix; too great light; vivid colours; blows, wounds, &c. The internal causes are those of fever in general, the measles and small pox, scrofula, repelled eruptions, and suppressed discharges.

Dr. Cullen considers all the varieties of ophthalmia membranarum as the same disease, differing only in situation or degree. Should we, from the views just mentioned, and in subservience to practice, attempt to divide the varieties of ophthalmia, they would be the following:

- Ophthalmia, 1. Acuta.
 2. Epidemica.
 3. Intermittens.
 4. Metastatica.
 5. Symptomata.
 6. A tarso.

The first of these is the common disease, differing in violence, according to the circumstances; the second, the Egyptian ophthalmia; the third, the common intermitting kind; the fourth, that which arises from repelled discharges; the fifth, the disease which arises from fullness of the vessels of the brain; and the last, the ophthalmia from tumours of the tarsus. The two first are constantly acute; the third only during the access of fever; the last inflammation has only a very slight degree of activity.

The ophthalmia subsequent to blows on the head, by which the meninges are injured, shows considerable danger. When it appears in the beginning of the small pox, the consequence is often fatal. When attended with long and violent headaches, blindness frequently follows. The humid species, the erysipelatous and venereal kinds, that of the choroides, and the chemosis, all greatly endanger the sight.

The cure must be regulated by the violence of the disease. In the active kinds, the general bleeding must be very copious; for in a disease in a great degree local, small bleedings will have little effect. Besides general bleedings, for a similar reason, topical ones are necessary. When the pain and the inflammation are so acute as to threaten destruction to the organ, the temporal artery must be opened; or it will be preferable, according to the plan of Mr. Ware, to cut it through. Opening the jugular vein is less useful, for the purpose of a topical evacuation, and not always convenient as a general one. Mr. Ware recommends opening the vein at the inner canthus of the eye; but from this little blood can be obtained. Other modes of topical bleeding are leeches and cupping glasses. Authors have been apprehensive of leeches, because they are supposed to add to the irritation. They sometimes certainly produce erysipelatous inflammation; but we have never known this increase the prior disease. Cupping glasses, well managed, are undoubtedly a less equivocal remedy; but unless the surgeon is peculiarly dexterous, little blood can be obtained, while, from leeches, any assigned quantity may be procured.

Blisters and laxatives should immediately follow the bleeding, and the former should not be applied nearer to the part affected than the nape of the neck, or behind either ear. The laxatives should be chiefly saline, unless the quantity required should be so great as to nauseate the stomach, and then some more active cathartic may be added; but they should be given so as to procure very profuse discharges. Emetics have been indeed given, from an idea that sordes in the stomach might produce or aggravate the disease. They undoubtedly determine to the head; but we have already observed, that by the determination to the surface in general, they are more serviceable than injurious by the former effect.

The applications at this period must be of the mildest and most soothing kind: moderately warm milk and water, or combined with a little mucilage, will be suffi-

cient; and it will be useful to insert either the white of a fresh egg, a little mucilage or mild ointment, between the lids, if it can be done without irritating. The most perfect repose in a dark room is necessary.

By these means the general fever, as well as the more active inflammation, is checked. The acrid tears no longer flow, and a mild mucus is discharged from the tarsi; but the pain and the inflammation, in a less active form, continue. At this period, the saturnine applications are chiefly admissible, and blisters may then be applied to the temples; for, in the acute form of the disease, these appear too irritating, so near the inflammation. The mildest collyrium consists of equal parts of the aqua ammoniæ acetatæ and rose water, or with a less proportion of water. If a more cooling application is wanted, five drops of the aqua lythargyri acetati may be added to four ounces of distilled water, or to as much camphorated julep. By degrees the proportion of the saturnine preparation may be increased. Repose is still necessary, and light must be still as much as possible avoided. If the collyria, when cold, produce pain, they should be at first slightly warmed.

This is the period, we think, best adapted to the division of the vessels of the cornea by the point of a lancet, or to cutting off any projecting fasciculi of vessels with crooked scissors. It is often recommended earlier; but we have found that it is then impracticable to admit sufficient light to direct the operator.

The more active astringents, viz. the vitriolated zinc, the hydrargyrus muriatus, or the opium, are not admissible till the inflammation or the sensibility are still further lessened. From five to ten grains of vitriolated zinc may be dissolved in four ounces of water, or, by degrees, a scruple of the zinc with six grains of camphor may be allowed to this quantity of water. The muriated mercury is sometimes employed for this purpose, in the proportion of a grain to four ounces of distilled water. Opium is occasionally added to either of the former collyria, usually in the form of tincture; and two grains of camphor with one of opium have been rubbed together, with four ounces of boiling water, and then strained. Mr. Ware has recommended a drop or two of the vinous tincture of opium to be dropped into the eye, night and morning; other practitioners have employed the spirituous; but, as the vinous tincture cannot easily be procured, we have usually added a proportion of water to the spirituous, till the inflammation was so much abated as to admit the latter undiluted. At almost every period of the disease, except the most acute, a proportion of brandy in water is useful. About one-eighth may be at first added, and the proportion increased, so as to produce a slight pungency, without any considerable pain: powders are in general less convenient or useful than fluids; but the latter should be applied immediately to the inflamed parts, and if soft muslin gives pain, as will be often the case, the eye cup must be employed. The only admissible powder is the natron vitriolatum, which Dr. Kirkland advises to be blown into the eye. The pain, as with the tincture of opium, is at first increased; but a flow of tears soon comes on, and relieves the inflammation.

If the eye remains very weak after the inflammation abates, the best applications are the alum curd, which may be spread thin on a rag, and applied over the eyes

every night; and a solution of alum, in the proportion of a drachm to half a pint of water; to which may be added the white of one egg. The patient may afterwards bathe in the sea, or cold water may be poured upon his head every morning for some time.

When the transparency of the cornea is diminished by films, borax is an useful remedy, and half a drachm may be dissolved, and may be used in two ounces of water; of which a little may be frequently dropped into the affected eye. Other collyria for this purpose are æruginis pp. gr. iv. ammoniæ muriatæ 3 ss. aq. calcis recentis 3 viii. m. and liquoris hydrargyri muriati, gutt. i. aq. distillat. 3 iv. Pellier's ointment is thus prepared. R hydrargyri nitrati rubri, lapidis calamin. pp. aa. 3 i. ss. lythargyri levigati 3 i. tutiæ pp. 3 ss. hydrargyri sulphurati 3 i. bene commisceantur, deinde adjiciantur adipis suillæ 3 ij. balsam Peruviani. gutt. xv. m. f. unguentum. When pimples on the eye attend an inflammation, the solution of vitriolated zinc usually succeeds; when these pimples suppurate, they should be opened with the point of a lancet, and washed with the solution of vitriolated zinc.

It will be necessary to notice the varieties of the ophthalmia membranarum, which we have pointed out as admitting of many modifications in practice.

1. *Acuta*. This is nearly the disease which we have described, but which authors have chosen to call *chemosis*. We now mention it to remark, that the whole of the curative plans, in all their activity, will be necessary in this complaint. The room should be completely darkened, the applications be perfectly cold, if such can be borne, and they should be the most imperfect conductors of caloric.

2. *Epidemica*. The Egyptian ophthalmia was for a long time supposed to be owing to the sands and dust of that arid country; but later observations have shown that it is acquired by sleeping in damp situations, with imperfect covering; that it is contagious, and epidemic from contagion chiefly, if not exclusively. The contagious nature of this complaint, if by contagion is not meant sympathy, though this scarcely alters the question, is evinced by Dr. Edmondson, not only from his own observation, but from the concurring testimony of ancient authors, establishing the position of Ovid more strictly than he ever intended it,

Dum spectant oculis læsos, læduntur et ipsi.

In support of this doctrine, he remarks, that even looking on a diseased person was enough to induce the ophthalmia in those who returned in the late expedition to Egypt; and it was conveyed, like other fevers, not only by immediate contact, but even by clothes, by ships, and barracks. The fever was also obviously remittent: the evening exacerbation and the morning remission were too clearly marked to be mistaken. Yet Egypt was not in former ages ravaged with this destructive enemy to our dearest enjoyments. Historians are eloquent in their praises of its fertility and beauty; without a hint of the sting which would sully the charms; and it was probably only at a later era, when many of the mouths of the Nile no longer carried its fertilizing waters to the sea, that the remaining marshes left their destructive miasmata; or when, under the iron hand of despotism, the land was no longer drained and cultivated with the former care.

The disease in this form does not greatly differ from the severe kind already described. The fever, however, is more strongly marked, and its remittent nature more obvious. The irritability of the muscles of the eye is increased in a greater degree, and we thus trace the peculiar action of the marsh miasmata. The uniform redness comes on rapidly, and in a day, or at most two, a puriform matter, which is, however, a sebaceous mucus, is discharged from the eye; small yellow spots rise on the conjunctiva, which soon render the whole membrane spongy; and the headach, at first slight, becomes so violent and incessant as generally to threaten delirium, sometimes induce it. The morning remission of the third day concludes the first stage. The acute pain is succeeded by a sense of weight, and a peculiar sensation of weakness on exposure to light. The vessels of the conjunctiva, still distended, become of a purple colour, and the matter discharged is thicker and milder. The spongy appearance of the cornea gradually disappears, and a kind of depression follows. All the symptoms gradually diminish, leaving a cloudiness and weakness of sight only.

When at the termination of the first stage the disease does not remit, the pain is pungent and deep seated, extending to the temples and forehead, occasioning an obstinate and distressing headach. The effusions of blood increase, and successive preternatural membranes are formed on the cornea. Collections of purulent matter gradually destroy the organ, and the cornea bursting, the protrusion of the different parts produce staphyloma. Ulcerations take place in the eye lids, and the adhesive inflammation connects these with the ball of the eye. Relapses are frequent on slight irregularity; but the disease is each time milder, and the blindness which often follows depends on the gradual thickening of the cornea. The inflammation is usually confined to one eye; but, if it ceases in that, the other is soon affected, which strongly proves that the fever is the principal disease.

The treatment of the epidemic ophthalmia does not greatly differ from that of the acute. General bleeding, by almost any author, is scarcely mentioned; and of the topical bleeding, the scarification of the vessels of the eye seems to be preferred. Dr. Edmondson remarks, with great apparent propriety, that in this variety the scarification should be performed while the vessels are distinct, florid, and round. If delayed till the redness is more diffused, and the hue purple, it is evident that the active period of the inflammation is passed; and Savaresi distinguishes the same period of asthenic inflammation, by a diminution of the swelling of the eyes, and a swelling coming on in the lids, by which they are turned up. Dr. Edmondson depends little on the opening of the temporal artery, as the eye is not supplied from thence; and we may add, that cutting it through will more probably determine a fuller current to the anastomosing branches. The purgatives he recommends are the neutral salts; but dissuades, with the generality of practitioners, violent purging. With this remedy, though the discharges are considerable, the system is not greatly debilitated. Mild lotions are also highly commended, at first milk warm, afterwards cold, and in the end artificially cooled. In the second stage the acetite of alumine is said to be an advantageous application. Half a drachm of alum is dissolved in four ounces

of water, and a scruple of acetite of lead in the same quantity. When these solutions are mixed, a double decomposition takes place, and the sulphat of lead falls to the bottom. Opium is commended also by Dr. Edmondson, who confines its use to the second stage. Where there is great sensibility and irritability, he employs the watery tincture, and, if not effectual, two parts of water are added to one part of the tincture of opium, lessening gradually the proportion of water. One part of brandy, with two parts of water, form a still more stimulant application.

3. *Intermittens*. The intermittent ophthalmia is nearly allied to the epidemic. Each is violent in its attack, and each recedes, though in different degrees, while both perhaps depend on a similar cause. Yet we think we have seen an intermitting ophthalmia connected with a venereal lues, or at least relieved by a course of mercury. In this case we generally lose sight of the local affection to attend to the original complaint, the intermitting; nor are the remedies of ophthalmia employed unless the inflammation during the paroxysm is violent. The bark, or Grant's electuary for the hæmicrania will generally relieve. As the disease is rare, we have had no opportunity of trying the arsenic, which, from its utility in similar complaints, we should suspect to be highly useful.

4. *Metastatica*. The most striking instance of metastatic ophthalmia, adduced by authors, is that from gonorrhœa. It is spoken of with confidence, derived apparently from one author to another without much reflection: We remember, about thirty years since, that a similar metastatical gonorrhœa was supposed to occur in the nose, till it became evident that there was in two or three cases which happened about the same time, actual infection from the pocket handkerchiefs. Yet, if consent of parts, as Scarpa insinuates, be the cause of the translation of a disease from one mucous membrane to another, it is more probable that this metastasis would be to the nose than to an organ whose secretions are from different glands, viz. the sebaceous. As we write, however, to instruct, not to establish systems, we shall describe the disease as it occurs in authors.

Two kinds of this inflammation are described; one when the whole system is affected with syphilitic virus, the other where gonorrhœa has been imprudently suppressed. Each is distinguished, by a sense of itching, which increases towards night, and goes off in the morning: the hairs drop from the cilia, the colour of the iris is changed, the pupil acquires a rugged appearance, the cornea becomes opaque and milky, sometimes so protuberant as to destroy the sight, and disfigure the organ. Mr. Bell describes it as occasionally attacking suddenly, with all the appearances of amaurosis. There are, however, strong doubts of these complaints being syphilitic. They have very decidedly the appearance of lepra; and we were not disappointed on finding that the chief reliance of the original authors was on their being cured by mercury. In this case, at least, there is no metastasis.

The second kind is more properly our present object. The symptoms are as rapid and violent as in the Egyptian ophthalmia. The swelling, the pain, the headach, the tumefaction of the eye lids, are almost in an equal degree; but we do not observe the exacerbating nature of the fever, and the discharge from the cilia is

said to be greenish, like the matter of gonorrhœa. Swediaur describes three cases which occurred in an extreme cold winter, and the observations of different authors are so vague, some describing it as coming on after the suppression of gonorrhœa, some as continuing with it; one class speaking of it as accompanying, or immediately following, the acute stage; another as following this period at a greater distance; and all confessing it to be rare, that we should have been justified in considering its existence as ideal, or as accidental, had not Mr. Pearson given his very extensive experience on the same side. This very respectable practitioner could never trace such a connection between the eye and urethra as authors, and particularly Scarpa, had pointed out. It is possible, indeed, that the fingers or the handkerchief might convey the virus; but when this metastasis takes place, we have the express opinion of Scarpa that the gonorrhœa is mild in its appearance, and not rapid in its progress. Dr. Edmondson examines the question with great precision and propriety, and his conclusions are very correctly drawn; but, unable to escape from positive assertions, he admits the consent of the urethra and the eye lids from the consent of functions; both being, in the opinion of Bichat, mucous membranes. If the question, however, be determined by the identity of functions, both from structure and disease, it may safely be denied that the membrane of the eye lids is a mucous membrane, or that the discharge of this translated gonorrhœa arises from inflammation of these membranes. If any dependence can be placed on the description of authors, the discharge is from the sebaceous glands of the cilia. While, then, the supposed metastasis to a neighbouring organ, the testicle, is now found to be a communication of inflammation, not a translation of morbid matter; while membranes decidedly mucous do not suffer, and glands of a different nature are in this case affected; we are, we think, justified in considering this supposed metastatic ophthalmia as an accidental occurrence only. We have engaged at greater length in this discussion to guard young practitioners, in such instances, from depending, as they might do, on mercury for the relief of this ophthalmia, and neglecting the remedies for the real inflammation. Ophthalmia certainly does occur more remotely from lues; but this variety rests on a very different foundation, and will be afterwards noticed.

Other cases of this variety rest on a more certain basis. On the suppression of the menstrual discharge, of that from fistula in ano, or from piles, the eyes are sometimes affected. These are scarcely, however, in strictness, cases of metastasis, nor is the ophthalmia acute. Gout repelled has been sometimes followed by ophthalmia; ulcers in the legs imprudently cured, or erysipelas suddenly dried by astringents, have had the same consequences; but such diseases are easily understood from the nature of the original ones.

5. *A tarso*. We mean in this case to notice a distinct inflammation from the ophthalmia tarsi, and to point out the existence of real membranous inflammation from previous disease of the tarsus. We might, perhaps, have been contented with referring to it as symptomatic; but that if ever lues really produces ophthalmia, it is when the tarsus is diseased with the little tubercles which sometimes affect it.

6. *Symptomatica*. Ophthalmia is often a symptom of

affections in the head from blows, shocks, &c.; of apoplexy, when violent and sanguineous; palsy, and of scrofula. It was necessary to point out this variety; but the disease is not very acute, and the treatment is that connected with the original complaint.

CONSEQUENCES OF OPHTHALMIA. Repeated inflammations in the eyes produce various diseases of this organ, among which the most frequent and distressing is that laxity and debility of the vessels which admits most commonly red blood in a larger proportion than usual, and which occasions increased accumulations in them on the slightest cold or irregularity. This forms the **CHRONIC OPHTHALMIA**, which we shall first consider, and at greater length, as the directions will be applicable to the disease in its less active state.

When *chronic ophthalmia* is increased from colds, &c. it approaches more nearly the acute disease, and must be treated like the acute kind, in its second or third stage. In the interval the more active astringents may be employed; the first of which is cold. Cold bathing in general is sometimes useful; but bathing the face and eyes in the coldest water every morning is highly useful. Solutions of vitriolated zinc may be occasionally, though not constantly, used; but the purer and more active astringents, alum excepted, have not been employed. The tincture of galls, at first diluted, we should think an useful application, as combining a portion of spirit with a powerful astringent; and sometimes those narcotics which lessen irritability will be equally useful, as the tincture of opium, and probably a cold infusion of green tea, with a proportion of brandy. The discharge of a perpetual blister, or an issue, will take off the inflammatory disposition, and prevent the effects of cold. Both the blisters and the issues should, however, be as near to the head as possible. Blisters and setons on the temples have been advised, and are undoubtedly very powerful, as well as successful, remedies, should the disease be so violent and dangerous as to counterbalance the inconveniences and the unsightly scars. The narcotic bitters have been taken with some success, and the cicuta has had its advocates; but in general the constitution loses more by their deleterious power than the eyes gain by their sedative effects. This disease is, however, often idiopathic, and arises from the unsuspected intrusion of any minute hard body between the ball and the lids of the eye; the inversion of some of the hairs of the cilia, a disease of the *caruncula lachrymalis*, a small ulcer of the cornea, and, as we have said, any enlargement or inflammation of the tarsus.

Encanthis is the consequence most commonly of scrofulous ophthalmia, and the tumour feels hard and granular. Vide in verbo.

Pterygium, according to Scarpa, is a separation of the thin external lamina of the conjunctiva, which changes into a varicose membrane, from long obstinate ophthalmia, or from a shorter attack, if very severe. It differs both from the *ALBUGO* and *UNGUIS*, q. v. and often succeeds either the chronic or epidemic kinds. It is always triangular, and its point is towards the cornea, where the membranes are most closely united.

Ulceration of the Cornea. Though we must now speak of this complaint chiefly as a consequence of ophthalmia, yet, as we shall not have occasion to resume the subject, we may add, that it is occasionally an

idiopathic disease. As a consequence of ophthalmia, the ulcer is often already formed; but, in the latter case, it rises sometimes on, sometimes between, the laminae of the cornea, and is attended with marks of acute ophthalmia: but though highly painful, and the tumour visible, yet opening it will not relieve the sufferings; for the matter is very tenacious, and will not flow out. The opacity of the cornea is increased by the operation, and another small abscess is often formed in the neighbourhood. When it bursts spontaneously, the symptoms of ophthalmia are greatly increased, and a little excavation is obvious. On its first appearance it is of a livid cineritious colour, with an inflamed base, and an irregularly tumid margin. When matured, however, it often remains inactive, and when it bursts naturally, the discharge is serous and acrid, the tumour, like that of all secreting surfaces, liable to spread; and in violent ophthalmia the ulcer penetrates to the humours, occasioning their discharge, and a protrusion of the iris, or some portion of the vitreous humour. This is said to have been the consequence of the Egyptian ophthalmia, and occasionally of what is styled the gonorrhœal, which we must consider only as the violent epidemic disease. The inflamed eyes of children, however, often terminate in slight ulcers, which have no such formidable consequences. They heal with little difficulty, leaving sometimes a slight depression, which gradually fills up without even deformity.

The ulcer is healed only by those means which destroy the irritability of the nerves. The most effectual is caustic. The *argentum nitratum*, cut to a point, must touch the ulcer long enough to form an eschar; and, should any part of it be dissolved by the tears, it must be washed off by dropping a little milk into the eye. The pain of the application is acute, but momentary, and the relief is soon almost complete; but, on the separation of the eschar the burning heat, &c. return, only removed by successive applications of the caustic. The permanent effect is perceived by degrees, and at last the ashy coloured appearance of the ulcer is changed to a brighter red, and the symptoms of ophthalmia disappear. When this change is obvious the caustic should no longer be applied, but the collyrium of vitriolated zinc substituted. In the slighter cases this collyrium is alone sufficient: indeed, they are often little more than abrasions, sometimes the ulcer appears fungous, and to derive its nourishment from a small fasciculus of vessels. If then neglected, or treated only with slight astringents, the whole organ is destroyed. In this case the fungus and the bundle of vessels must be cut off with the crooked scissors; and when the blood has been allowed to flow, the caustic freely applied. If, on the exfoliation of the eschar, the morbid part should not be wholly separated, the application of the caustic must be repeated. Each lid must be most carefully kept open during the application; the upper with a small spatula, which the operator must hold in his left hand, and the lower by an assistant.

Opacity of the Cornea. This also, though a frequent effect of inflammation, sometimes appears independent of it; and is in that case rapid in its access, but temporary in duration. It seems, from an experiment of Dr. Barclay, recorded by Dr. Edmondson, to arise merely from fulness, chiefly from an excess in the proportion of the aqueous humour. It is then successfully removed

by general and topical evacuations only. When it succeeds ophthalmia, and is connected with varicose veins, giving a cloudiness only, without elevation to the eye, and impeding rather than obstructing vision, it is styled *nebula*. It seems to arise from a dilatation of the veins, and from Scarpa's experiment, of these exclusively. This complaint differs from albugo in being a recent, slight, superficial opacity of the cornea, preceded and accompanied by chronic inflammation, through which the pupil and iris may be seen. When opacity of the cornea is the effect of more violent and active inflammation, it is styled *ALBUGO*, and its worst kind *LEUCOMA*, q. v. A very effectual mode of cure is to divide the vessels, leading to the cornea; for the opacity is the effect of effusion, in consequence of increased action.

Hypophyon, vide in verbo. *Staphyloma* is the consequence often of very severe ophthalmia, and consists in an opacity of the cornea, with irregular projections. In the earlier periods the cornea is thick and compact, in the latter its thickness diminishes, apparently from the compression from within, and the pressure of the eye lids without. It seems to consist in an effusion from the vessels of the conjunctiva; but in many cases we suspect that the serous fluid between the laminae of the cornea coagulates in consequence of an alteration in its nature. From this cause the form seems to continue permanent. When, from distention or wound, any part of the iris, or, as we have seen, of the vitreous humour, protrudes, it is called *staphyloma*, though with less propriety.

OPHTHALMIA TARSI, *psorophthalmia* of Plenck, and some modern authors; mucous or puriform ophthalmia. Dr. Cullen has carefully included the *psorophthalmia* in his definition, by adding "the glutinous exudation of the tarsus," which is peculiarly conspicuous; and were even a cavit to arise, it may be removed, by subjoining, "and occasionally of the internal surface of the palpebrae." The disease is sufficiently obvious, and is often first felt by an obstruction of the lachrymal sac, giving the appearance of fistula lachrymalis. In fact, when this more glutinous fluid is mixed with the tears it obstructs the ducts; and, when the tumour is pressed, this puriform matter is pressed through the puncta lachrymalia. If, in this case, the tarsus be examined, and either eye lid turned back, particularly the lower, the internal surface will sometimes have a villous appearance, Merbomius' glands will be obviously swollen, and an ulcer on the tarsus, or at its union with the internal membrane, will be obvious. We were aware of this morbid appearance when we opposed the opinion of Bichat, that the internal membrane was not a mucous one. In fact, when it puts on that appearance the discharge is very different from mucus.

The scrofulous swelling of the tarsus differs, only in degree, from the *psorophthalmia* described, in which the displeasing eversion of the eye lids most frequently occurs. The purulent eye, as it is styled, is not uncommon in new born children; and the conjunctiva is spongy, the cornea dull, and, if the complaint be not carefully attended to, an opacity of the latter comes on. This disease in children is not connected either with scrofula or luës, but there is constantly a griping, and a discharge of dark fetid matter by stool, with which it seems intimately connected.

When it is a disease of the adult it is often at first at-

tended with a little inflammation, and the more cooling, slightly astringent, applications of the second stage of ophthalmia are necessary, with occasional scarifications, or the application of leeches. This stage is, however, soon at an end, and more active astringents are now necessary. The oxide of zinc, combined with axunge, in the proportion of one to six, is sometimes alone successful; but, when the disease is more violent, some mercurial is required to give a more active stimulus. Janin's ointment is composed of four parts of axunge, two of prepared tutty, as much Armenian bole, and one part of the white calx of mercury. The unguentum nitratis hydrargyri of the Edinburgh dispensatory, lowered with three times its weight of axunge, or the red oxide, by means of nitrous acid, combined with twelve times its weight of axunge, has been recommended. We have found, for the greater number of cases, equal parts of the strong mercurial ointment and the unguentum cerusæ acetatæ sufficient; occasionally adding, in more obstinate diseases, a small proportion of the unguentum citrinum.

If the ulcers are not cicatrized by these means, the solution of blue vitriol, in the proportion of fifteen grains to an ounce of water, will be useful. Each application must be made by means of a camel hair brush, and the ointments softened by a gentle heat. When the ointments are used, they must be applied in the evening, and continue on the part all night; the solution must be used two or three times a day, and the redundant fluid washed away with a syringe and a little cold water. Tincture of opium may be occasionally employed. When the disease is violent, an adhesion of the eye to the upper lid sometimes takes place, which should be carefully separated, by raising the lid, and dissecting cautiously with a round edged scalpel. Instead of the mercurial or the cupreous solution, the argentum nitratum, according to St. Yves, may be drawn along the edge of the palpebrae, washing the eye, immediately afterwards, with milk and water. The puncta lachrymalia should be kept open by injections of warm water, with a slight proportion of brandy.

In the general conduct of all these remedies, they should excite on their application, a slight irritation, by which the puriform secretion is at first increased; but by degrees the edges of the eye lids become soft, the glands lessen, the internal surface of the palpebrae become smooth, and of its usual paleness.

In conducting the puriform ophthalmia of new born children, we must recollect the intimate connexion between this disease and the state of the bowels, nor is it one of the least important parts of the treatment to keep up a steady discharge by stool. The eye lids should be scarified by a lancet, and a leech or two applied in the neighbourhood.

The eye while in a tender inflamed state must be washed with a collyrium of equal parts of the common emulsion and julep of camphor, or warm barley water; and until the swelling of the eye lids subside, cooling ointments and emollient cataplasms may be applied. When the turgescence of the eye lids abates, and the inflammation of the conjunctiva disappears, the decoctum corticis Peruviani is given internally, and astringent collyriums employed. Though blisters are generally applied, and commonly useful, they have not been considered as essentially necessary. Mr. Ware proposes on the first attack to resist the discharge of mucus, by strengthening

the external coat of the eye. He consequently directs the eye to be cleared of the morbid mucus, by injecting into it, by a syringe, a gentle astringent collyrium; in particular he prefers the aq. cupri vitriolati camphorata, diluted with common water, in the proportion of about a drachm, to two ounces. This practice he uses in all the stages of the disease. As the matter increases, the collyrium may be employed more frequently, and gradually increased in its strength: in a slight case it may be used two or three times a day, but in the more violent ones it may be repeated every hour, and the astringency of the collyrium may be increased in proportion; as the disorder gives way, the strength of the medicine, and the frequency of using it, may both be decreased. Some authors recommend a solution of sulphats of copper and alumina. Of each a scruple may be dissolved in ten ounces of water, with a few drops of sulphuric acid, to keep the alumina suspended. But this we have found too stimulating, unless diluted with a third or fourth part of water. To abate the swelling of the eye lids Mr. Ware prefers a cataplasm of the coagulum aluminosum et unguentum florum sambucian. p. æq. applied cold. When the eye lids adhere strongly, they will be best separated by washing their edges with fresh butter dissolved in warm milk; but this may be prevented by interposing between the eye lids at night the unguentum oxydis zinci, or the combination of the mercurial and saturnine ointments. If the inside of the eye lids turns outward only when the child cries, and returns as soon as it ceases, nothing is particularly necessary; but if this symptom is constant, it will require a more frequent repetition of the injection, and immediately after the use of it, the lids must be returned, and a compress, dipped in the diluted aqua camphorata, constantly kept on it with the finger. When the inside of the eye lid is much inflamed, the diluted tinctura opii may be dropped on it with advantage every day; and when the quantity of mucus is so diminished as that the tincture may come in contact with the eye, it may be applied once a day to it. If there is reason to suspect any particular disease in the habit, the proper alteratives will be necessary.

Mr. Ware gives an instance of a case in which blood instead of mucus was discharged, and which gave way to the treatment here recommended.

OPHTHALMIA SI'CCA, et TA'RSI. See XEROPHTHALMIA.

OPHTHALMIC OR LENTICULAR GANGLION, is formed in the orbit by the union of a branch of the third or fourth pair of nerves with the first branch of the fifth pair. From this union the eye is sometimes affected in the TIC DOLOREUX, q. v.

OPHTHALMICI EXTE'RNI, (from οφθαλμος). See MOTORES OCULORUM EXTERNI.

OPHTHALMICUS WILLISII. The ophthalmic is the first branch of the fifth pair of nerves, which runs through the foramen lacerum to the orbit, con-

nected in its passage with the sixth pair, and distributed to the ball of the eye, with the third; to the nose along with the olfactory, which the branch of the fifth that passes through the foramen orbitarium internum joins. This branch likewise supplies the parts at the internal canthus of the orbit; the glandula lachrymalis, fat, membranes, muscles, and teguments of the eye lids; its farthest extended branch passing through the foramen superciliare of the os frontis, to be distributed to the forehead. See TRIGEMINI.

OPHTHALMITIS, (from the same). See OPHTHALMIA.

OPHTHALMODY'NIA, (from οφθαλμος, and οδυνη, pain.) An itching burning pain in the eye without redness, and without greatly increased sensibility. It is seldom distinct from ophthalmoponia, and has been ascribed to a rheumatic affection, or a spasm of the muscles. A deep seated pain is sometimes felt from an accumulation of the aqueous humour (hydrophthalmia), sometimes from a cancer, or from a caries of a portion of the orbit.

OPHTHALMOPO'NIA, (from οφθαλμος, and πονω, to labour). An intense pain in the eye, rendering light intolerable, usually arising from inflammation in the internal parts of the orbit.

OPHTHALMOPTO'SIS, (οφθαλμος, and πτοσις, a fall). A falling down of the eye, or its displacement in any direction. The eye falls down almost exclusively from relaxation, but it may be displaced by blows, by tumours of any kind within the orbit. When staphyloma depresses the lower eye lid, the disease is referrible to a different head.

OPHTHALMORRHA'GIA, (from οφθαλμος, and ρεω, to flow). Bleeding from the eye or eye lid.

OPHTHALMO'XYSIS, (from οφθαλμος, and ξωω, to scrape off.) A brushing of the eye.

OPHTHALMOXY'STRUM, (from οφθαλμος, and ξυστρον, a brush). A BRUSH FOR THE EYE, blepharoxystis, formerly made of the beards from barley or rye. It was drawn across the inside of the eye lids, to draw blood.

OPIA'TA, (from opium). Medicines in which are opium; but an appellation also of ELECTARIUM, q. v.

O'PII. TINCTU'RA CAMPHORA'TA. See PAREGORICUM ELIXIR.

OPISTHO'TONOS, (from οπισθεν, backward, and τενος, from τενω, to stretch). See TETANUS.

O'PIUM, (from οπος, juice; μικανος οπος; and, from hence, κατ' εζοχην, οπιον). Affion, afiun, anfiun, manus Dei. Opium is the milky juice of the papaver somniferum Lin. Sp. Pl. 726, α, when incisions are made in their heads; and it is gradually dried in the sun to the consistence in which we receive it. Opium is brought from Turkey, Egypt, and the East Indies, obtained, according to Neumann, by pressing the juice from the heads of the poppies; but the best kind is that obtained from the incisions.

In many provinces of Asia they sow the white poppy (for this is the variety from which the true opium is procured) as we sow wheat. As soon as the heads appear, a slight incision is made in them, and some drops of a milky fluid exude, which are suffered to dry, and then collected. Tournefort tells us, that the greatest quantity of opium is made by bruising and pressing the heads; but Kämpfer and Belon, though they speak

of three kinds of opium, describe each as produced by incision and exudation only. In Persia, the opium is collected in summer, when the heads are nearly ripe; and these are wounded on one side by a knife, which makes five incisions at once. The next morning, the inspissated juice is collected with a spatula. The operation is then repeated on the other side of the heads, but the first tears, styled *gobaar*, are preferred: these are whitish, or of a light yellow, but become brown in the sun, or when too much dried. The second tears are darker, and less efficacious; those of the third operation, black and inefficacious.

When the opium is collected, it is beat up with a little water or honey, till it has the brilliancy of pitch. It is then rolled into cylinders, and, in this state, offered to sale. If small quantities are wanted, they are cut off with scissors. Sometimes the honey is in so large a proportion as to prevent its drying, and to soften its bitterness. This is the state of the East India opium. The most remarkable preparation of opium, in the East, is uniting it with nutmeg, cardamoms, canella, and mace. It is called *philonia*, and is the philonum of the Persians, supposed to strengthen the heart and the brain. Others add only saffron and ambergris, and almost every one varies the additions, according to his fancy. A celebrated liquor, called *Cocomar*, is mentioned by Kämpfer, which is an infusion or a decoction of the leaves, sometimes of the heads, adding various ingredients to please the palate. Another preparation to produce a temporary intoxication is called an electuary, and often employed.

Olivier in his travels into Asia saw the plantations of poppies on a large scale, chiefly in the vicinity of a village, called Affiom Kara-Hissar (the black castle of opium). The poppy is sown in autumn, transplanted in spring, and the harvest is collected about July.

Various attempts have been made to cultivate the poppy in England for the purpose of making opium, and Mr. Ball received a premium for this purpose from the Society for the Encouragement of Arts; but the quantity used is too inconsiderable to render it a national object, and the uncertainty of our climate will render it a very precarious speculation. The inspissated juice of the decoction of our white poppies is sometimes used, and the heads are boiled down to make the poppy syrup; but the former is of inferior virtue, though apparently less virulently narcotic, and white. We think the syrup, when properly made, an highly useful preparation, for reasons to be assigned hereafter; we fear, it is seldom the true watery extract of the poppy head. The seeds of the poppy are oily, and the flowers are cultivated in France for that purpose.

Opium is brought into Europe in flat cakes, or irregular masses, from four to sixteen ounces in weight, covered with leaves. It is a gummy resinous substance, softish, and tenacious, especially when warm, or much handled; of a dark reddish brown colour in the mass, and yellowish when reduced to powder, with a faint disagreeable smell, and a bitter taste. If chewed a little, it affects the tongue with a very slight sense of heat, which spreads to the palate, and then in a less degree to the lips, provoking a discharge of saliva, and sometimes sneezing.

That in which no visible impurities are lodged; which, when broken, appears of a dark red blackish colour;

dry, not unctuous, but moderately ponderous and compact; that which is inflammable, of an acrid bitter taste, a faint smell resembling the odour of unripe poppy heads, without any empyreumatic flavour, communicating to water a reddish tincture, is the best.

Belon observes, that sometimes a pound contains only about four ounces of pure genuine opium; but such adulterated kinds rarely reach us. Sand is added to increase its weight, and many foreign bodies are found mixed with it. It is ordered to be purified by dissolving it in twelve times its quantity of proof spirit, and distilling the tincture to dryness, after filtering.

Opium is softened by the heat of the fingers, but is not fusible, though highly inflammable. Water and alcohol dissolve it in different proportions, and no separation of the opium in the watery solution takes place on the addition of alcohol. When water is added to the tincture, some resin is deposited. Alcohol or water carry over, into a receiver, the narcotic powers of opium, which, by long boiling, or drying, are lost. A portion remains, which neither alcohol nor water will dissolve, supposed, by Gren, to be albuminous; by Bucholtz, caoutchouc; by Josse, a virulent glutinous substance; by Proust, wax, or combined with wax; by Duncan, gluten, approaching in its nature to the fibrin of the blood. Neumann procured from 1920 parts of opium 1520 of alcoholic, and 80 of watery extract; and, inversely, 1280 of watery, and 200 of alcoholic extract. In the first case, the residuum was 320, in the last 440 parts. The solutions of opium, especially the watery, give copious precipitations by infusions of galls. The resin is separated either in a soft or hard state, and the former is sometimes called its essential oil: in this the narcotic power has been supposed to reside. The gummy part seems to contain a small proportion of an earthy salt.

It would be useless to enlarge on the numerous disquisitions to which the chemical analysis of opium have given a temporary importance, but we shall add a few remarks, applicable to practice, that may be drawn from them. This celebrated drug contains, like all other matters, a resin and gum. The extractive matter contains the mucilaginous portion with resin, and it appears, that, while this union is least interrupted, we attain the sedative power with the smallest portion of the virulently narcotic. By the long tedious processes of the French chemists, we obtain a large portion of resin; but this is the product of the operator in consequence of the union of oxygen. The black drop, prepared at Lancaster, is not, we have said, the solution of opium in a vegetable acid; nor does it appear to be a strong spirituous tincture, and is certainly more active than any tincture not virulent after its immediate action. It is equal, in efficacy, in the dose of four drops to seven of the common tincture of opium, and, in the mildness of its effects, though not in their degree, we have come near to it by a tincture made with a weak spirit; for we have uniformly found, that, with a diminished portion of the uncombined resin, the anodyne effects were best secured, without the subsequent inconveniences of head-ach, nausea, &c. We should, therefore, suspect that it is a weak, spirituous tincture, with a proportion of watery extract. At least, we know, that in this way, a medicine of very similar powers may be procured. With this exception, we think Dr. Duncan has very

justly observed, that the attempts of some pharmacologists to obtain a preparation of opium, which should possess its sedative without its narcotic effects, only succeeded in so far as they diminished its activity.

The effects of opium on the living body have been represented in very opposite, contradictory, terms. It has been keenly disputed whether it is stimulant or sedative, as if it was necessary that it should be either. If by stimulant is meant a medicine, which, by its action on the stomach, will increase the heat of the body and the quickness of the pulse, it by no means deserves the title. If given to a healthy person, the pulse and the heat are both lowered; every pain, every care, is soothed; cheerfulness and hilarity are the consequence. If the dose is increased, the face is somewhat flushed, the hilarity rises to intoxication, the mind is unsteady, and the hands tremble. Nausea, faintness, and headach follow, when the influence of the medicine is at an end. This brings the medicine within our class of indirect stimuli, which are generally narcotics; and the error seems to have arisen from what we have often stated as a fundamental one in medical reasoning, viz. not distinguishing between increased and irregular action. If we speak of its effects more generally, to the serenity and calmness which it induces, we should add respiration, slow and deep, a suppression of all the excretions, except that of the skin, pulse slower and fuller, with sleep in circumstances often the most unfavourable to it. With some persons, however, instead of sleep, a mild pleasing delirium comes on, the mind wanders in the delightful regions of fancy, and the duration of time is to the imagination greatly extended. It is a striking instance of a material cause influencing an intellectual idea. With others, this delirium is attended with horror. Suspended rocks are ready to fall; the torrent hastens to overwhelm them, or the edge of a precipice yields under their feet. After considerable doses, vertigo, convulsions, and apoplexy come on, the blood is confined to the large vessels, usually the veins, and a rupture has sometimes ensued.

To explain these symptoms has appeared difficult. It was supposed, from dissections where venous plethora was so conspicuous, that the blood was rarefied, and that sleep was produced from its pressure; but this opinion is no longer supported, for opium produces its effects in very small quantities, and more rapidly than will admit of its reaching the circulating system. In general, it has been concluded that it possesses both stimulating and sedative powers, the first of which is conspicuous soon after its exhibition, and at last conquered by the second. It is not easy, however, to conceive two such opposite powers in a substance, except where the excitement is so violent as to exhaust the irritability, and then the medicine would be strictly a stimulant.

In conformity with the principle which we have just stated, we think it will appear to be a sedative, or rather a narcotic only; and we shall endeavour to explain all its effects from this power. A sedative or narcotic remedy will necessarily first lessen irritability, and this power is immediately obvious in the calm serenity it induces, in consequence of lessening the effect of irritation. The pulse becomes slower and fuller, because the heart, less irritable, is more completely filled before it is stimulated to contraction; the mind is unsteady

from diminished, and of course unequal, excitement; the secretions checked from the confinement of the blood in the larger vessels; and those of the skin more full, as the relaxation of the cutis, by which they are confined, diminishes the resistance. A similar effect we have seen from warm bathing. (See *BALNEUM*.) In the other secretions there is no obstacle to the fullness of the vessels from a constricting membrane.

Marks of a stimulus are however occasionally striking. If given in inflammatory complaints, it will sometimes increase the action of the pulse; and if it does not produce sleep, it renders the patient unusually restless. Yet these effects may be readily explained without contradicting the general principle. If, as in cases of pneumonia, the solution of the disease depends on the yielding of the excretories, to oppose this effect must aggravate all the symptoms, particularly the fever. Yet it aggravates also acute rheumatism, though said to open the cuticular excretories. But, in this case, it opposes a disease which consists, as we shall find, in a constriction of the cuticular vessels, from a different cause. If this constriction is not relaxed by very different medicines, we must expect injurious effects from opium. This reasoning will be confirmed by the advantages derived from peculiar modes of administering it, which coincide with the principle laid down, of its being purely sedative. See *RHEUMATISMUS*.

Nor is it surprising, that, when it excites unpleasant images, and renders the patient restless and uneasy, it should increase fever. The constant agitation is alone sufficient for this purpose; and, when the excitement is unequal, it depends on idiosyncrasy whether the delirium shall be pleasant or distressing.

When the idea of its changing the circulating fluids was abandoned, it was doubted whether it acted on the stomach or the heart; and the second Monro has published some experiments, which seem to show that its chief effects are on the latter. These, however, only prove that, when opium is injected into the sanguiferous system, it produces no effect till it reaches the heart. The small quantity which in the stomach will produce the peculiar effects; the little diminution which is found in a pill of opium, when it has proved fatal; and the rapidity of its action, sufficiently show that, in diseases, it acts exclusively on the stomach. All the subsequent symptoms, those which follow its continued use, and those which arise from the increased dose, contribute to show a sedative power.

The test of this reasoning must, however, be sought for in practice; and, for this purpose, we shall consider its utility in the various diseases for which it has, at any time, been recommended.

We know of no question either in theory or practice more difficult than the use of opium in *FEVERS*, q. v. We have in that article given the outline of its advantages, but we must consider the subject more carefully, at this time, when we possess the necessary information respecting its action. If fevers consist in debility and in irregular action, and opium is a sedative, producing also irregular action, it will appear that no medicine is so unsuitable to the disease. We might rest on this, and at once, with many respectable practitioners, condemn it; but experience forbids; and we must examine whether any unsuspected circumstance of the disease, or any new property of the medicine, either alone or in

combination, will explain the apparent inconsistency. When we spoke, with Dr. Darwin, of the quiescent state of the capillaries during fever, we did not exclude spasm, or irregular action, in consequence of debility; and in considering the state of the brain, we saw numerous proofs of unequal excitement. If, then, the irritation from the latter cause could be prevented; if, by any means, we could determine to the surface without increasing the heat, we might expect to relieve the febrile state. These ends may, we think, be obtained by moderate doses of camphor, joined with the opium, and occasionally with an antimonial. Each is assisted by the warmer ammoniacal neutral, and, as we have remarked, should opium not disagree, we preserve the strength by a few hours rest. When the unequal excitement, in consequence of increasing debility, is so great as to produce subsultus and convulsions, there can be little doubt of checking the inequality by removing all irritation; and this we are often compelled to attempt by opium, though aware of its sedative power, since the excitability would be soon destroyed by the violent excitement. Camphor, in this case, acts not only by its antispasmodic power, but also by its stimulus; for, in considering the effects of this peculiar medicine, we remarked, that we were more frequently obliged to add nitre than aromatics to it.

INTERMITTENTS. The use of opium in intermittents supports, we think, the former reasoning. It is employed with the warmer stimulants, sometimes with relaxants, to keep up the discharge from the surface, and prevent the formation of the cold fit. Boerhaave's *sudorificum antipyreticon raro fallens* contained two grains of opium; and the compound powder of ipecacuanha, assisted with the ammonia, will often succeed. In the hot fit it produces, according to Lind, that relaxation of the skin which hastens and facilitates the sweating stage, relieving by this means the headache and delirium, rendering the solution more complete, and the fever less liable to return.

IN CONTINUED FEVERS, according to the same principles, it will contribute to determine the fluids to the surface, as we have already explained, and to diminish irritation; but we must be particularly cautious that it do not stop the other secretions, particularly the alvine, on which the success of our practice so much depends.

IN INFLAMMATIONS, opium, for the reasons assigned, viz. its tendency to check secretions that would be salutary, is not very frequently employed. Yet with calomel it has been given in every form of active inflammation, with success; for reasons which will be readily understood, since to a medicine which determines so steadily to the skin, opium must be an useful auxiliary. In *phrenitis*, opium is inapplicable, except as a diaphoretic; and in *cynanche*, as it occasions thirst and dryness of the mouth, it can seldom be used with advantage. In *pneumonia*, except where a diarrhoea is found to exhaust the strength, and check expectoration, opium is seldom admissible, since it will have a similar effect; and is only employed to prevent exhaustion, since it is scarcely more than a temporary impediment to the salutary discharge. Yet De Haen gave two grains of opium with two ounces of olive oil, a practice which has not been imitated; and we have left it in doubt (see *OLEUM*), whether oil may really assist expectora-

tion. In *enteritis* opium is highly useful; and we have already spoken of the propriety of checking the spasm previous to the exhibition of laxatives. But, independent of this power, it is often necessary to quiet that irritation of the stomach which prevents food or medicine from being retained. In *nephritis* it is often necessary, with oily laxatives, to relieve pain; but, as it powerfully checks the discharge of urine, diluting liquors should be freely drank with it. In *rheumatism*, with relaxing remedies, often with calomel, it is highly useful (see *RHEUMATISMUS*). In *gout* it is frequently indispensable to relieve the pain, nor is it found, if the action of the bowels be supported, really injurious.

In the *EXANTHEMATA*, opium is often a valuable medicine; and in *variola*, it is an exception to the injuries feared from it in inflammations, for when these tend to suppuration, no inconvenience results from its use. In the convulsions, previous to the eruptions, it is highly advantageous; and on the sixth and seventh days, it allays the pain of suppuration, without checking the ptyalism. In *morbilli* it is less useful, as will be obvious, if what we have alleged of the utility of a free discharge from the bowels be considered. In every view, the dry cough and the pneumonic symptoms forbid its use, unless considerable irritation prevail. In the *scarlatina*, as in *cynanche*, it is still less proper.

In the *HÆMORRHAGIE* it is not often employed, from the apprehension of its stimulus; but, as it soothes and calms, rendering the pulse slower, and determining to the surface, it will be often of service. We have found it so, and particularly in those hæmorrhages attended with considerable irritation, as the uterine, and those which precede or threaten abortion.

When hæmoptysis is aggravated by cough, it is equally so, and when discharges of blood from the anus are produced by diarrhoea, opium is the most salutary remedy, particularly if joined with demulcents.

In the *PROFLUVIA* of Dr. Cullen, it is chiefly useful in *dysentery*, and with the mild laxatives, occasionally with the relaxing antimonials, or with ipecacuanha, very effectually relieves. In *catarrh*, unless joined with peripneumony, it is a most useful medicine.

If there were in nosological systems a class of *DOLORES*, opium would be the chief remedy. It is useful in pains of the stomach, the violent pains from the passage of a biliary or urinary calculus; in *pyrosis*, in *dysmenorrhœa*, *odontalgia*, in those cases of *sphacelus* attended with great pain. In general, also, in painful diseases, as in spasms, the dose of opium, however large, acts only on the constitution, in that portion which is in excess beyond what is necessary to relieve the pain. Thus, if ten grains are given, and nine are required, to procure ease, the constitution only experiences the inconvenience which would arise from one grain.

In *SPASMS* of every kind it is an almost indispensable remedy, particularly in *tetanus*, *trismus*, *convulsio*, &c. In *puerperal convulsions*, after bleeding, it is almost the only effectual remedy. In all flatulent diseases, it acts as the most effectual carminative.

Opium, some years since, was recommended as an infallible remedy in *venereal complaints*, and constantly used, for a time, in the military hospitals. It indeed seemed to *suspend* the disease, without making any progress in the cure. It may be used, therefore, like the nitric acid, to prevent the symptoms from increasing,

while the constitution recovers some degree of strength from former mercurial courses, but cannot be depended on for a complete victory over the disease.

With many, opium disagrees, and numerous have been the correctors proposed. Ammonia sometimes succeeds; more often camphor; or camphor with castor. The vegetable acids, so highly extolled, have been in our hands useless in this respect. Five grains of camphor, with as much castor, made into three pills, with conserve, may be combined with a grain, or a grain and half, of opium; and, in this form, will frequently produce no inconvenience. While a blister is rising, opium will be often borne with ease; and, in almost every case of fever, camphor should be combined.

The nausea, the drowsiness, and vertigo, after taking opium, are relieved most effectually by a cup of strong coffee; but seldom disappear till after a night of sound sleep. Opium should not be given with astringents, alkalis, or metallic salts, as by these it is precipitated when in solution. It is not, however, certain that any real chemical change in the essential part of the remedy takes place; but should it be suspected, the combinations may be made in pills, where there is little room for the play of affinities.

The chief official preparations of opium are, the pulvis ipecacuanhæ compositus; pulvis opiat; tinctura opii confectio opiata; pulv. è creta C. cum opio. In the *pilula ex opio*, it is mixed with liquorice in the proportion of one grain to ten. In the *camphorated pills of opium*, each grain of the latter is united to two of the former. In the *compound opium pills*, a grain of opium and of camphor are united with a quarter of a grain of tartarized antimony. The *emplastrum opiatum* contains a very small proportion of opium, with the litharge plaster, stiffened with dry pitch and some wax. As an anodyne it is wholly useless. For opiate clysters and injections, see ENEMA and INJECTIO.

One grain of pure opium is generally a sufficient dose; three grains can scarcely be taken with impunity by a person not accustomed to it; though, by habit, even an ounce in a day may be administered. Garcias knew a person who took ten drachms a day; and in Turkey, five or six drachms are often taken when violent pains, or other symptoms, require it. Frequent experience manifests the propriety of large doses in spasmodic complaints; twenty-two grains of pure opium, besides three hundred drops of laudanum, have been given in the space of thirty-six hours, without any remarkable inconvenience. Different constitutions require different doses to produce the desired effect; so that practitioners should be careful in ascertaining the proper dose for each constitution, by beginning with small portions, and gradually increasing them till the end is obtained.

Where, however, opium disagrees, both small and large doses are equally inconvenient. In general, the doses should seldom be less than a grain, unless often repeated. The effects of opium seldom continue above eight hours, and if the action is to be continued, it should be repeated in six. In large doses it does not check the secretions, but, on the contrary, sometimes seems to promote them. When it conquers obstructions, it often appears to do so; and in taking off the spasm which prevented the passage of a stone or obstructed the bile,

or, in similar effects in the urinary passages, it seems to be laxative or diuretic.

When imprudent doses have been taken from mistake, or design, stupidity, giddiness, a redness of the face, swelling of the lips, troublesome dreams, starting, convulsions, cold sweats, a considerable dilatation of the pupil, imperfect speech, slow full pulse, quick breathing, nausea, itching in the skin, vomiting, madness, hiccough, fainting, &c. follow. A vomit of vitriolated zinc is then necessary, and after it a spoonful of sharp vinegar is recommended; sinapisms must be applied to the feet, blisters to the arms, and frictions freely employed. Vinegar is the supposed antidote, but cordials and ammonia will be more successful.

Alkaline salts diminish, it is said, the soporific effect of opium; and the fixed alkaline salts are supposed to render it diuretic. The volatile carries it through the skin; and acids, in the opinion of many authors, destroy its powers.

See Kœmpfer's *Amœnitates Exoticæ*; Wedelius's *Opiologia*; Cullen's and Lewis's *Materia Medica*; Neumann's *Chemistry*; Alston's *Dissertation on Opium* in the *Edinburgh Medical Essays*, vol. v.; *Medical Museum*, vol. i. page 473, &c.; Jones's *Mystery of Opium*; Tralles' *Usus Opii*.

OPOBA'LSAMUM, (from *οπος*, juice, and *βαλσαμον*).

BALSAM OF GILEAD. See BALSAMUM.

OPOCA'LPASON, (from *οπος*, and *καλπασον*, a tree of that name). *Ophocarpason*, or *ophocarpithaton*. See CARPASUS.

OPODE'LDON. The name of a liniment said to be invented by Mindererus; but often mentioned by Paracelsus. (See LINIMENTUM SAPONACEUM.) A composition is sold under the name of *Steer's Ophodeldon*, considered as a powerful remedy for strains, bruises, and similar complaints. It is made in the following manner: \mathcal{R} . Solution. saponis cum camphora aq. ammoniæ acetatæ āā \mathfrak{z} i. aquæ ammoniæ puræ \mathfrak{z} ss. m.

OPODEOCE'LE. A hernia through the foramen ischii, and into the labia pudenda.

OPO'PONAX, (from *οπος*, juice, and *παναξ*, the *panacea*). The plant from whence the gum *thus* is produced is known by the names of *ophoponacum*, *panax heracleum*, *costinum*, and *pastinacea*. HERCULES' ALL-HEAL, *pastinaca ophoponax* Lin. Sp. Pl. 376, nat. order *umbellatæ*. See PASTINACA OLUSATRA.

This gum is brought from Turkey and the East Indies, sometimes in little round drops, but generally in irregular lumps, of a reddish yellow colour on the outside, with specks of white, internally of a paler colour, and often variegated with large white pieces. It has a disagreeable smell, and a bitter, acrid, nauseous taste, dissolving in water and in spirit, and yielding a little essential oil in distillation. As a medicine, it is used as an attenuant and deobstruent; and, in large doses is said to be laxative: its dose is from \mathfrak{z} i. to \mathfrak{z} i. *Ophoponax* resembles, and is the least disagreeable of the fetid gums, probably also of the least virtue. See Raii *Historia*; Cullen's and Lewis's *Materia Medica*; Neumann's *Chemistry*.

OPPILA'TIO. See OBSTRUCTIO.

OPPO'NENS POLLICIS. The flexor of the metacarpal bone of the thumb.

OPPOSITIFOLIUS PEDUNCULUS, (from *opposito-*

situs and *folium*). Growing opposite to a leaf of a plant.

OPPRESSIO. See CATALEPSIS.

O'PTICI NE'RVĪ, (from *ὀπτομαι*, to see). The OPTIC NERVES are the second pair united in the brain, but soon becoming two distinct cords, each passing through the foramen opticum of the sphenoid bone, to their respective orbits. They unite on the anterior part of the glandula pituitaria, before they escape from the skull; but soon separate again, without mixing their fibres, and are inserted obliquely towards the nose. The optic nerves are surrounded by the four recti muscles of the eye.

OPU'NTIA. *Cactus opuntia* Lin. Sp. Pl. 669, a shrub which nourishes the cochineal insect, whose flowers expand like a case, having each a great number of stamina in the centre, growing upon the tops of the ovary. The ovary becomes a fleshy umbilicated fruit, with a soft pulp, inclosing many seeds of an angular shape. The leaves are used as emollients in inflammation. See COCCINILLA.

OPUNTIOI'DES, (from *opuntia*, and *ειδος*, likeness,) a marine plant, shaped like the opuntia, but brittle and hard, reckoned among the vermifuges.

O'RANGIA. See AURANTIA HISPALIENSIA.

ORBI'CULARIS LABIO'RUM, (from *orbiculus*, a little ring). See LABIA.

ORBICULA'RE OS, (from the same). *Lenticulare os*. See AURIS.

ORBICULARIS PALPEBRA'RUM MUSCULUS, (from the same). *Constrictor palpebrarum*. The orbicular muscles of the eye lids rise fleshy from the outer edge of the orbital process of the superior maxillary bone, and from a tendon near the inner angle of the eye. The fibres run a little downward and outward over the upper part of the cheek below the orbit, covering the under eye lid, and surround the external angle. Then passing over the superciliary ridge of the os frontis, they mix near the inner canthus with the fibres of the occipito frontalis and corrugator supercillii. After covering the upper eye lid, they descend to the inner angle, and adhere to the inner angular process of the os frontis, and to the short round tendon which serves to fix the palpebræ. It is inserted into the nasal process of the superior maxillary by a tendon which covers the anterior and upper part of the lachrymal sac. The fibres which run on the eye lids are elliptical. These muscles shut the eye lids, compress the lachrymal gland, and convey the tears to the puncta lachrymalia.

ORBICULA'RIS, (from the same). See SPHINCTER ANI, and LYCOPERDON VULGARE.

ORBICULA'RIS CLAUSOR. The orbicular muscle of the eye lid.

ORBICULA'RIS LABIO'RUM. See SPHINCTER LABIORUM.

O'RBITA, (a dim. of *orbis*, a globe). *Cyclos*. The ORBIT of the EYE, or the spheroidal cavity in which the eye is placed; its angles are called *canthi*.

ORBITA'LES ARTE'RIÆ, (from *orbita*), are branches of the inferior maxillary arteries. See MAXILLARIS ARTERIA.

ORBITA'RE EXTE'RNUM FORA'MEN, is in the os maxillare, below the orbit. Through it the nerves and vessels, which come from the teeth, pass to the cheek.

ORBITA'RE INTE'RNUM FORA'MEN, is a little above the os planum; through it goes a branch of the fifth pair of nerves to the nose.

ORBITA'RII NE'RVĪ. See MOTORES OCULORUM EXTERNI.

ORBITA'RIVS PROCESSUS. See MAXILLARIA SUPERIORA OSSA, FRONTIS OS, and SPHENOIDES OS.

ORCHE'A, (from *ὄρχις*, a testicle). See SCROTUM.

O'RBHIS, (from *ὀρεσμαι*, to desire,) the name of a plant with a testiculated root; *satyrion*; *cynosorchis*; *testiculus caninus*; *scrapias*; *orchis morio* Lin. Sp. Pl. 1333. MALE ORCHIES; SATYRION.

This plant hath six or seven long, narrow, smooth leaves, variegated with dark coloured spots, issuing from the root, and one or two embracing a single, roundish, and striated stalk. On its top appears a long loose spike of irregular, naked, purplish red flowers, consisting each of six petals, one of which is large, cut into three sections, hanging downward; the other smaller, forming a kind of hood above it, with a tail behind. The root consists of two roundish, whitish tubercles, about the size of nutmegs; one plump and juicy, the other fungous and somewhat shrivelled, with a few large fibres at the top. It is perennial, grows wild in shady grounds and moist meadows, and flowers in May.

The plump roots, which are alone used in medicine, have a faint smell, and sweetish viscid taste. When the seed is formed, and the stalk ready to fall, the new bulb, of which the salep is made, has arrived at maturity, and may be distinguished from the old one by a white bud, rising from the top, the germ of the orchis of the succeeding year. It is mucilaginous, and similar to the althæa. The dried roots are brought from Turkey, under the name of *salep*; but those of our own growth are equally good. The salep brought from Turkey is in yellowish white oval pieces, hard, clear, and pellucid, without smell, tasting like gum tragacanth. Our orchis roots, decorticated and dried in the air, are similar in appearance. Reduced to powder, and boiled in water, they form a very nourishing mucilage. Half an ounce of the powder will produce a gallon of thick mucilage, if first sprinkled with a little boiling water, then mixed well with it, and afterwards with the water in which it is to be boiled. If kept dry, it never spoils, so that it might form an excellent part of seamen's diet; and as a drachm and a half of salt in a pint of portable salep, is not disagreeable, it may be made with a portion of salt water when fresh is scarce. As a diet, it excels rice; and for children, particularly, it is peculiarly proper, as it seems to retard the acetous fermentation of milk. This powder, and the dried gelatinous part of flesh, or portable soup, dissolved in boiling water, form a rich thick jelly, capable of supporting life for a considerable time. One ounce of each of these articles, with two quarts of boiling water, will be sufficient subsistence for a man one day. Dr. Percival thinks, that a small proportion of it would be an useful addition to flour in making bread; but we perceive that it must be small and less than one eighth. As a medicine, the salep is mucilaginous, demulcent, and sheaths, it is said, the acrimony of the sea scurvy. In diarrhœas and dysenteries, it is useful by lubricating the bowels and correcting putrefaction. In symptomatic fevers, from the absorption of pus, a

plentiful use of salep acts as a demulcent. In the stranguery and dysury it is of service by its mucilage; and it is a useful aliment for calculous patients. See Cullen's and Lewis's *Materia Medica*; Percival's *Essays*; *Georgical Essays*, vol. iv.

O'RHIS BIFO'LIA, Lin. Sp. Pl. 1331. See BIFOLIUM. Dr. Cullen has seen salep prepared from this species as perfect as that from Turkey.

O'RHOS, (from ὄρεος, a plantation, or orchard). The extremities of the eye lids where the eyelashes grow; from the regularity of their insertion. See OCLUS.

ORCHOTO'MIA, (from ὄρχις, testicle, and τέμνω, to cut). See CASTRATIO.

O'RDO, (method, or disposition). ORDER. The second division under which naturalists arrange the objects of nature. See NOSOLOGIA, and Cullen's *Synopsis Nosologiæ Methodicæ*.

ORE'LLONS. See CYNANCHE PAROTIDÆA.

ORELLA'NA. See ORLEANA.

OREOSELI'NUM, (from ὄρος, a mountain, and σελινον, parsley). MOUNTAIN PARSLEY. *Athamanta oreoselinum* Lin. Sp. Pl. 352. *Apium montanum nigrum*; *oreoselinum apii folio minus*. The roots are slenderer than those of the daucus, and not lactescent; the leaves like those of the parsley; the seeds oval, flat, large, striated, margined, and sometimes cast off their husks. It grows on the mountainous parts of Germany and other countries, is pungent and diuretic.

OREOSELI'NUM PRATE'NSE CICU'TE FO'LIO; *heucedanum Alsaticum* Lin. Sp. Pl. 354. *Daucus Alsaticus*; *angelica pratensis apii folio*.

OREOSELI'NUM A'PHI FO'LIO MA'JUS; *athamanta libanotis* Lin. Sp. Pl. 351. *Libanotis nigra*; *gentiana nigra*; *daucus montanus*; *cervaria nigra*; *daucus selinoides major*; MOUNTAIN DAUKE, or BLACK HERO FRANKINCENSE. The seeds of these plants resemble those of the mountain parsley, and are styled diuretic and emmenagogue, but are seldom employed.

ORE'STION, (from ὄρος, a mountain,) *helenium Dioscoridis*, *inula helenium* Lin. Sp. Pl. 1236. See ENULA.

ORGA'NUM. Any part of the animal body, which from its structure is adapted to particular offices. This structure is from thence called *organizatio*.

ORGA'SMUS, (from ὀργασμός, turgeo). SUDDEN VEHEMENCE, generally applied to the venereal impulse. Hippocrates transferred this term to the agitation excited by superfluous excrementitious fluids, to produce the necessary discharges. Linnæus calls it a subsultus of the arteries. Quincy considers it as an impetus of the blood or spirits, distending the muscles with unusual force. It is in fact a violent determination of the blood to any organ.

ORI'CIA. A species of fir, called from Oricus, a city of Epirus, where it grows.

ORIENTA'LIA FO'LIA, (from oriens, the east). See SENNA ALEXANDRINA.

ORIENTA'LE GU'MMI. See GUM SENEGAL.

ORI'GANUM, (from ὄρος, a mountain, and γανω, to rejoice; because it grows most luxuriantly on mountains). WILD MARJORAM; *marjorana sylvestris*, *oleacea*, et *mancarana*; *origanum anglicum*, et *spontanæum*; *onitis major*; *origanum vulgare* Lin. Sp. Pl. 824. *Heracleoticum*, from Heraclea. COMMON WILD MARJORAM is a plant with firm round stalks; oval, acuminate, uncut, and somewhat hairy leaves, set in

pairs on short pedicles. On the tops grow scaly heads of pale-red labiated flowers, whose upper lips are entire, the lower cut into three segments, set in a convex umbel, intermixed with roundish, purplish leaves; each flower is followed by four minute seeds inclosed in the cup. It is perennial, grows wild on dry chalky hills and gravelly grounds in several parts of England, and flowers in June.

The leaves and flowery tops have an agreeable aromatic swell, and a pungent taste, warmer than the garden marjoram, and much resembling thyme, with which they agree in medicinal virtue, as well as with marjoram. Infusions of the leaves are drunk as tea in weakness of the stomach, and disorders of the breast, to promote perspiration, the fluid secretions in general, and the catamenia. They are sometimes used in anti-rheumatic baths; and the dry leaves powdered are a good errhine. For internal use, half an ounce of the leaves is infused in a pint of water. In distillation with water they yield a moderate quantity of a very acrid, penetrating, essential oil, smelling strongly of the origanum, but less agreeable than the herb, called oil of thyme, often put into a hollow tooth to allay pain. See Lewis's *Materia Medica*, and Neumann's *Chemistry*.

ORI'GANUM CRE'TICUM. See DICTAMNUS CRE-TICUS.

ORI'GANUM MAJORA'NA, seu FOLII OVATIS. See MAJORANA MAJORI FOLIO.

ORLEA'NA, (from the place where it grows,) *arbor Mexicana*; *orellana*; the ROUCOU or ARNOTTO TREE, *bixa orellana* Lin. Sp. Pl. 730.

This curious shrub rises commonly to the height of eight or nine feet, thrives best in a cool rich soil, and shoots most luxuriantly near springs and rivulets. The seeds are covered with a kind of wax called *terra orellana*, *roucou*, and *arnotto*. When the seed vessels are mature, the seeds are put into convenient jars, to which is added as much hot water as will suspend the wax. When this is washed off, the seeds are taken out, and the fluid left at rest till the wax thoroughly subsides. The clear liquor is then decanted, and the sediment dried gradually in the shade. This mass is afterwards made into balls or cakes, and dried in an airy place, until fit for use, or the market. The wax is a cool, agreeable, rich cordial, and hath been long in use amongst the Indians and Spaniards in America, who still mix it with their chocolate, both to heighten the flavour and raise the colour. It is said to be a successful remedy in dysentery, is used as a pigment, and often mixed with other ingredients both by painters and dyers. The roots resemble in virtue the wax, but are more diuretic. The Indians prepare an arnotto of a bright shining red colour, almost equal to carmine.

The arnotto dissolves with difficulty in water, tinged it of a pale brownish yellow; more readily in rectified spirit of wine, to which it gives an orange-red colour; and it is used in varnishes, to give an orange hue to the pale yellows. Alkaline salt renders it soluble in boiling water, without altering its colour. See ACHOTE.

ORNITHO'GALUM, (from ὄρνις, of a bird, and γαλα, milk; because the colour of its flower resembles the milky fluid found in eggs). *Ornithogalum umbellatum medium angustifolium*; *ornithogalare*, *ornithogalum umbellatum* Lin. Sp. Pl. 441, the STAR OF BETHLEHEM, flowers in May. The root is bulbous or tuberous, and

is a wholesome nutrient: indeed the roots of all the species possess the same properties. (See Raii Historia.) It is also a name for squills. See SCILLA.

ORNITHOGLOSSUM, (from *ornis*, a bird, and *γλωσσα*, a tongue, from their shape). BIRD'S TONGUE. The seeds of the common ash tree.

ORNITHOPODIUM, (from *ornis*, and *πῦς*, a foot, from the likeness of its pods to a bird's claw). BIRD'S FOOT; telephium; chironium; scorpioides; SCORPION WORT; *ornithopous scorpioides* Lin. Sp. Pl. 1049, grows on sandy and gravelly places, and flowers in summer. The seeds are said to destroy the stone in the kidneys; but are very rarely used. See Raii Historia.

O'RNUS, (from the Hebrew term *orn*). See FRAXINUS ORNUS. It is also an appellation of the *sorbus aucuparia*. See SORBUS SYLVESTRIS.

OROBANCHE, (from *οροβος*, a wild pea, and *αρχω*, to suffocate; because it twines round and suffocates the orobus). See HYPOCISTIS.

O'ROBUS, (from *ἰσπελω*, to eat). *Karemyle astragalus*; *astragaloides*; *orobus tuberosus* Lin. Sp. Pl. 1028. WOOD PEASE, HEATH PEASE; grows in woody places, flowers in April, ripens its seed in May. The tubera of the root are highly nutritious, taste like liquorice, and in Scotland are used for the same purposes, and chewed like tobacco. See Raii Historia.

O'ROBUS, and OROBRYCHIS PEREGRINA, (from *οροβος*, and *βρυχω*, to eat). See ERVUM.

OR'PIMENT. See AURIPIGMENTUM.

O'RRIS. See IRIS VULGARIS.

ORTHOCOLON, (from *ορθος*, straight, and *κωλον*, a limb). See ANCHYLOSIS.

ORTHOPONCEA, (from *ορθος*, erect, and *πνεω*, to breathe). This disease, when neither connected with asthma nor dyspnoea, is only a symptomatic. It consists in a sighing suffocating respiration, and the patient must be erect to breathe. It is a symptom often of hysteria, sometimes of hydrothorax, occasionally of polypi and diseases of the heart or larger vessels. In some cases it arises from fat, from poisons, deleterious vapours, or any cause of compression on the lungs.

ORVALA, (from *orvale*, French). See HORMINUM.

ORVIETANUM. A celebrated antidote, called from Orvieto, a city of Italy, where first used, or from Orvietanus, its inventor.

ORYZA, (from the Arabic term *orez*). RICE; the seeds of the *oryza sativa* Lin. Sp. Pl. 475; ARAC. Its grains are disposed in an oval panicle, covered with a thick husk, like barley. It is less viscous than wheat, but less nourishing, and used as a diet in diarrhoeas; but the salep is preferred by Dr. Percival. It ferments slowly, and corrects putrefaction imperfectly; but is preferred by Dr. Cullen as a grain highly productive and nutritious. The idea of its being hurtful to the eyes is without foundation. Rice flourishes in a moist soil, and even in water. In China the liquor called *arrack* is distilled from it. See ARAC.

ORYZA GERMANICA. A species of barley.

Os, *ossis*, (from the Hebrew term *ozam*, strength). A BONE. Bones consist of a mucilage and an earthy matter. Acids dissolve this earthy matter, leaving the bone of its original shape, but soft. See BONES.

Os, ORIS, (from *ορρα*, the voice). The MOUTH.

Its external parts are the lips, the angles of the mouth, the border or edge of each lip, the fossula which runs from the septum narium to the edge of the upper lip, and the transverse fold which separates the under lip from the chin. The internal parts are the palate, the septum palati, the uvula, the amygdalæ, the gums, the fræna of the lips, and the tongue, with its apex, root, sides, and frænum.

Os EXTERNUM, and INTERNUM. The first is the entrance into the vagina; the second the mouth of the womb.

Os LEO'NIS. See ANTIRRHINUM.

Os TINCE, *amphideon* and *oscheon*. If the os internum is long and hard, when pains, like labour, come on, a clyster and an anodyne may be given, for labour has not commenced. The os tinæ is sometimes open, a month or two before the period of labour; but its thickness and softness remain the same, until labour comes on. Nor does it always point in one direction during pregnancy, or in the beginning of labour. When opened by the membranes, it is soft, and if contracted again from the discharge of the waters, it is easily dilated. It sometimes is hardened and thickened by age, or by frequent labours; and the birth, though natural, is in that case somewhat retarded. To dilate these parts, the fingers must be gradually introduced, and when the hand is in the vagina, the os internum must be slowly and cautiously dilated; and the more carefully in proportion to the rigidity of the parts. When the hand can be introduced into the uterus, the back should be contiguous to it, and the palm to the membranes.

OSCE'DO, (from *os*). See OSCITATIO.

OSCHEOCE'LE, or OSCHEOPHY'MA, (from *οσχιον*, the scrotum, and *κηλη*, or *φυμα*, a tumour). See HYDROCELE and HERNIA.

O'SCHEON, (*οσχιων*). See SCROTUM, and Os INTERNUM.

OSCILATORIUS MOTUS, (from *os*, a mouth, and *cilleo*, moveo). VIBRATION; as of a *pendulum*. Borelli thinks that such a motion takes place in the blood by means of the inspired air mixed with it in equal proportions, regulating and governing the motion of the spirits by its elasticity; and physiologists, without any distinct ideas, have spoken of a similar motion in the extreme blood vessels. They certainly act often irregularly, and perhaps independent of the heart, as in blushing; but such action is very different from oscillatory motion, and the introduction of the term only produces confusion.

O'SCITANS, (from *oscito*, to gape). The YAWNING FEVER.

Yawning is undoubtedly an early symptom of fever; but there is no peculiar kind distinguished by this symptom.

OSCITA'TIO, (from the same,) *chasma*, *oscedo*. YAWNING. The effect of yawning in the healthy, according to Boerhaave, is to move, accelerate, and equally distribute the fluids through all the vessels of the body, consequently to fit the muscles and organs of sensation for their various functions. It is an irregular, partly a convulsive, action of the muscles of the lower jaw, and, like stretching, takes place when the muscular power is not completely restored. A French physiologist has told us that it is designed to

restore the due power to the extensor muscles, which they lost by the superior action of the flexors during sleep. See MUSCULI.

When yawning is troublesome, a long deep respiration, or drawing in the air at long intervals, cures it. Hippocrates.

OSCOLATO'RIUS MU'SCULUS, (from *osculo*, to kiss). See SPHINCTER LABIORUM.

OSCOLUM, (a diminutive of *os*), a small orifice.

OSMA'ZOME, (from *οσμη*, smell, and *ζωμος*, broth). We should not have introduced this singular term, but that the experiments of M. Thenard, who suggested it, were not within our reach when the former part of this work was written. It is the animal substance peculiar to muscles, or muscular flesh, which gives odour and flavour to the decoction or soup; and by these qualities, as well as its colour, is distinguished from gelatine. Its proportion to the latter, in flesh, is as about one to five. Four pounds of muscular flesh, bruised and washed with cold water, produced nearly six drachms of this substance. The decoction of bones is gelatinous only. This is the animal matter not yet sufficiently examined, which gives the zoonic acid its peculiar properties, for it is originally the acetous.

OSMU'NDA VULGARIS, PALU'STRIS, and REGA'LIS. See FILIX FLORIDA.

O'SSA BA'TUS. See BORZAIL.

O'SSA SPONGIOSA, sometimes distinguished by the epithet *inferiora*, as two turbinated portions of the ethmoid bone, by some anatomists described as parts of the ossa palati, are frequently called *superiora*. They are certainly distinct in the early periods of life, and consist of a spongy lamella in each nostril, the convex surface of which is towards the septum, and the concave towards the maxillary bone, covering the opening of the lachrymal duct. Two processes rise from its upper edge. The posterior (the broadest) hangs on the edge of the antrum highmorianum; and the anterior forms the os unguis, and a part of the lachrymal duct. These bones are complete in the fetus, and lined with the mucous membrane. The sides of the maxillary sinus, apparently turned downwards, seem to form two other bones, and some smaller bones, irregular in their size and uncertain in their number, occasionally project into the nostrils to extend the surface of the olfactory organ.

O'SSA E CO'RDE CE'RVII. THE BONE OF A STAG'S HEART, formed by the ossification of the arteries, was formerly used in asthma.

OSSI'cula AUDI'TUS. See AURIS.

OSSI'culum, (a dim. of *os*, a bone). In botany it is the shell or hard covering of seeds, like bony lamellæ.

OSSIFICA'TIO, (from *os*, a bone, and *fo*, to become). OSSIFICATION. The calcareous phosphat of which bone consists is deposited from arteries; but previous to the deposition, the arteries are distended; and those which did not before carry red blood are now visible from their containing this fluid. In this blood the knife discovers hard particles, which gradually unite; for these bony fibres are flat, and radiate as from a centre; no membranous parts are formed, and their shape is generally irregular. In the blood vessels the membranes supply the place of those usually connecting the

osseous particles in cartilages, forming the body of the cartilage from which the bone by maceration slips perfectly distinct. While the bones are increasing within cartilages, the cartilages are extended; and from the pressure which they suffer from the bone within and the integuments externally, they decrease continually, and are at last entirely destroyed.

Dr. Hunter, in his Lectures, supports this opinion, by curious anatomical preparations, in opposition to Kerkringius and others, who contend that bones are originally cartilaginous.

Dr. Hunter had a preparation of the patella, in which he demonstrated that the ossification of that bone began by the arteries ossifying in the centre of the cartilage, which, in young subjects, supplies the place of the bony patella. Mr. Cruikshank prosecuted the subject, from the first appearance of an ossifying artery, to the perfect formation of the patella. He supposed that the same thing took place in all other bones, and demonstrated that ossification is not only begun but carried on by the ossifying of the arteries.

Morbid ossifications frequently happen in the aorta, lungs, pericardium, and even in the corpora cavernosa penis. The natural process advances in infants in proportion to their strength. In flat bones it begins in the centre, and shoots towards the circumference; in long ones, in the middle, shooting towards the extremities.

See Kerkringius, Ruysch, Nesbit, Albinus, and Monro.

OSSIFRA'GA, (from *os*, a bone, and *frango*, to break). See OSTEOCOLLA.

OSTA'GRA, (from *οστιον*, a bone, and *αγρα*, a laying hold of). A forceps to take out bones; and also a pain in the bones.

OSTI'TES, OSTEOCO'LLA, (from *οστιον*, a bone, and *κωλλω*, to glue), *ossifraga*, *osteolithos*, *holosteus*, *amosteus*, *ostracites*, *stelochites*, GLUE BONE, STONE OR BONE BINDER, is the petrified root of a poplar, or pine; found in sandy places in several parts of Germany. This sand hath a large mixture of fine, white, calcareous earth, which sticks to the fingers, resembles meal, and when washed by the rains into any cavity hath the appearance of an emulsion. Of this sand, and calcareous earth insinuated into the roots of the trees, is the osteocola formed, long famed for its virtues of promoting a coalition of fractured bones. See Lewis's *Materia Medica*; Neumann's *Chemistry*; and the *Philosophical Transactions*.

OSTEO'COPAS, (from *οστιον*, a bone, and *κοπος*, uneasiness). A constant and remarkable pain of the bones from an affection of the internal periosteum, not increased by pressure, arising chiefly from acrimony of the humours in the spina ventosa. These pains resemble those of great weariness.

OSTEOGENEI'A, (from *οστιον*, and *γενεια*, generation). OSTEOGENY, treats of the production of a bone in its progressive states. See OSSIFICATION.

OSTEOGE'NICA, (from *οστιον*, and *γενναω*, to beget), medicines ridiculously supposed to promote the generation of a callus.

OSTEOGRA'PHIA. OSTEOGRAPHY (from *οστιον*, and *γραφω*, to describe), describes a skeleton, and all the bones which compose its different parts.

OSTEOLITHOS, (from *ὀστρεον*, and *λίθος*, a stone). See OSTEODOLLA.

OSTEOLOGIA, (from *ὀστέον*, and *λόγος*). A DESCRIPTION OF THE BONES. The doctrine relative to the bones includes osteogeny, osteography, and synosteography. See MONRO'S Osteology.

OSTEOSARCO'SIS, (from *ὀστρεον*, *ος*, and *σάρξ*, flesh). Softness and flexibility of the bones.

OSTIA'RUS, (from *ostium*, a door). See PYLORUS.

OSTIO'LA, (a dim. of *ostium*). The valves in the vessels of the heart. Mundinus.

OSTRACITES, (from *ὀστρακον*, a shell). *Ostrea labris non crenatis*. HOBGOBLIN'S CLAW, a stony substance, of the shape of an oyster shell, used instead of the pumice stone, to take off hairs. A name of the *osteocolla*; see also CADMIA.

O'STREA, (from the same). The OYSTER. A light, easy, nutritious diet, which is said not to pass off freely by perspiration. In the reign of Galen it was supposed to be cold; and Dr. Moffat tells us, that to eat oysters and drink cold water is certain death. It has been since recommended, so mutable is fashion, as an aphrodisiac. If roasted or scalloped, it is hard of digestion; and vinegar seems to add to its insolubility. The shells are excellent absorbents, and generally used to correct acidity in the primæ viæ. When burnt in the fire they are supposed to form a lime peculiarly adapted to calculous complaints; and after being repeatedly used for making lime water, they may be employed, were it necessary, as absorbents. The hollow shells contain most of the fine white earth; the rougher matter of the shell much sea salt. See NEUMANN'S Chemistry; Lewis's Materia Medica.

OSTRI'TIUM. See IMPERATORIA.

OSY'RIS; *cassia poetica* Lobellii, *cassia Latinorum*, *lignea Montsfeliensis*. *Osyris alba* Lin. Sp. Pl. 1450. POET'S ROSEMARY: the whole shrub is astringent; it grows in the southern parts of Europe, and is sometimes corruptly called *auxyris*.

OSY'RIS, (from *ουρον*, urine; because it promotes a discharge of urine). See LINARIA.

OTALGIA, (from *οὖς*, an ear, and *αλγος*, pain). A PAIN IN THE EAR. This disorder affects the concha, and the whole meatus auditorius; and is attended with inflammation, tumour, pulsation, and a sense of weight. Dr. Cullen considers it to be a variety of phlogosis phlegmone, from its situation.

It is, in general, an inflammatory complaint, often from its usual cause, cold, directed from a crevice to the part, and sometimes followed by suppuration; but any cause of irritation may produce pain in this very sensible organ; and hardened wax, or any extraneous body, in the meatus auditorius, are frequent causes. Numerous are the causes and distinctions in authors, and in our predecessor's work; but acrimony, the fermentation of the wax, or turgid glands, are at least unfrequent sources of the complaint. Indeed they are incompatible with the nature of the organ or its secretions. We must therefore confine our ideas to inflammation and irritation. In the former case, blisters behind the ear, cooling laxatives, and the frequent injection of warm fluids are necessary, and alone often complete a cure, especially if joined with the relaxing diaphoretics and anodynes.

Warm olive oil seems to have no particular claim to

our notice, above any other warm fluid; but it has probably been preferred, from apprehension of the pain being occasioned by some insect, which it often destroys. If this be the case, however, he may be enveloped in the cerumen; and tobacco smoke has a better chance of relieving the complaint. Other warm applications are, warm sea water, a roasted onion, and similar modes of conveying heat. If these fail of giving relief, they at least hasten suppuration when the pain ceases. Suppuration seldom takes place within the tympanum; but when it does so, the matter finds a way through it.

Inflammation in the part itself is not the only cause of this disease. It may be secondary from the throat, the teeth, and occasionally from rheumatism on the side of the head. It is only necessary to be aware of these causes to ascertain their existence, and obviate them by appropriate remedies.

There are, however, pains in the ear, whose sources are less obvious. If it be hardened wax, it may be seen by throwing a strong light into the meatus auditorius; and, in that case, syringing the ear with soap and water is often effectual. Salt water is a better menstruum for the wax, and may be employed. There is reason, however, for apprehending one bad effect from this remedy, viz. giving such a susceptibility to the organ, that it is more liable in future to be affected by cold, and therefore this remedy must be employed with caution.

When the wax is not in fault, and the pain is deeply seated, we cannot ascertain the cause, and our conduct must be more empirical. In these cases a warm infusion of poppy heads, the warm essential oils, the balm of Gilead, a solution of camphor, joined with opium and similar medicines, may be dropped into the meatus with good effect.

OTENCHY'TES, (from *ωτος*, the genitive of *οὖς*, an ear, and *εγγχεω*, to flour in). A SYRINGE for the EARS.

OTHONNA (from *θεον*, lint). See CHELIDONIUM MINUS.

OTITIS, (from *οὖς*, the ear). Inflammation in the internal ear, inducing fever, restlessness, and even, in some cases, delirium. Independent of the remedies of OTALGIA, q. v. from inflammation, the general remedies for fever are required.

OTOPLA'TOS, a fetid discharge from behind the ears. It is generally critical, and consequently must not be imprudently checked. The utmost cleanliness is, however, indispensable.

OTOPUO'SIS, (from *οὖς*, and *πυον*, pus). A purulent discharge from the ear.

OTORRHŒ'A, (from *οὖς*, and *ῥεω*, fluo). A discharge of blood or of bloody matter from the ear.

OUY'COU. See CASSADA.

OU'RLES. See CYNANCHE PAROTIDÆA.

OVA ZEPHYRIA. Eggs not impregnated by the cock; WIND EGGS, said to be conceived in a westerly wind.

OVA'LE FORA'MEN, (from its shape). See COR.

OVA'RIA, (from *ovum*, an egg). The OVARIES; formerly called the female testicles; but now supposed to be the receptacles of ova or the female seed, taken up and conveyed in the form of an ovum by the Fallopian tube to the uterus. (See GENERATIO.) The ovaries are two small bodies situated behind each

Fallopian tube, near the fundus uteri, to which they are fixed by a short round ligament, and inclosed with it, between the folds of the ligamenta lata. The substance of the ovaria, like that of the testicles, is spongy; but each ovarium seems to contain numerous little vesicles, styled *ova*, each of which seems surrounded by a spongy covering. The outer coat of the ovary is from the peritonæum; and when a woman has conceived, a fissure is observable on this coat of a different size and figure, even in the same body. At the age of puberty they are of the proper size, and continue plump and full until the menses begin to disappear. They receive vessels from the spermatics, which run on to the uterus, and anastomose with the hypogastrics. The nerves are from the intercostals, lumbal and sacral. Besides the liquor which resembles the white of egg, they contain two or three vascular bodies called *corpora lutea*, and which, by some, are called the eggs, but in reality are apparently the part of the ovarium from which the egg has dropped, since it is not found before a woman has conceived. It is not again wholly filled for three or four months, but is very vascular, as is the case when any lost substance is to be supplied.

The ovaries are subject to great distention from water. See HYDROPS OVARII, and also a singular case in Gooch's Observations and Remarks.

OVA'TUS, or OVIFORMIS HU'MOR. OVAL, EGG-SHAPED. See OCULUS.

O'VI CA'NDIDUM, (from *candeo*, to shine). See ALBUMEN OVI.

O'VI DUC'TUS, the Fallopian tube.

OVIPAROUS, animals which exclude their young under the covering of an ovum.

OVO'RUM TE'STÆ; *anatum*, and, when calcined, *anora*, EGG SHELLS, are prepared by boiling them in water, separating the membrane, which lines the inner surface, and powdering them by levigation. They are similar to the other absorbents, but said to be less astringent.

O'VUM, (from *ovum*). AN EGG. Eggs are nutritious, but if boiled hard, are with difficulty digested. They seem to be less alkalescent than almost any other animal substance, and during digestion to be less stimulant; but they should be eaten when quite fresh, for as they approach to a putrescent state they become offensive to the stomach; nor is it material from what birds they are taken, except those which feed almost exclusively on putrid animal substances. The yolk is used as a medium for uniting balsams with water. There is great analogy between the serum of the blood and the white of an egg. See Neumann's Chemistry. Cullen's Materia Medica.

O'VUM PHILOSOPHO'RUM. A glass whose body is of an oval figure, by which a liquor may be distilled by circulation.

O'VUM SUBLIMATO'RUM. See CUCURBITA.

O'XALAS, (from *oxalis*, wood sorrel). OXALATS. Salts formed by the combination of the oxalic acid (acid of wood sorrel; see ACETOSILLA) with different bases. These salts are decomposed by lime water, and the precipitate is soluble in the acetous acid. Most of the alkaline oxalats are capable of combining with an excess of acid. The earthy oxalats are generally insoluble, but may be decomposed by a red heat.

OXA'LIC ACID. See CHEMIA.

VOL. II.

OXA'LIS (from *οξύς*, sharp). See ACETOSA.

OXA'LME, (from *οξύς*, and *αλς*, salt). A mixture of vinegar and salt.

OXELÆ'UM, (from *οξύς*, and *ελαιον*, oleum). A mixture of vinegar and oil.

O'XYA, (from *οξύς*). See FAGUS.

OXYACA'NTHA, (from *οξύς*, and *ακανθα*, a thorn; from the acidity of its fruit). The BARBERRY. See BERBERIS and SPINA ALBA.

OXYCE'DRUS, (from *οξύς*, and *κεδρος*, a cedar; from the sharp termination of its leaves). See CEDRUS FOLIO CYPRI.

OXYCO'CCUS, (from *οξύς*, and *κοκκος*, a berry,) *vaccinia palustris*, *vitis Idea palustris*. *Vaccinium oxycoccus* Lin. Sp. Pl. 500. MOOR or CRANE BERRIES. This plant grows in marshy and rich soils, and flowers in June. The fruit is cooling and astringent; and in Sweden they are used as refrigerants. See Dale, and Raii Historia.

OXYCRA'TUM, (from *οξύς*, and *κραννυμι*, to mix). OXYCRATE; vinegar mixed with a portion of water, and rendered milder by the addition of a little honey.

OXYCRO'CEUM EMPLA'STRUM, (from *οξύς*, and *κροκος*, saffron,) a plaster containing saffron and vinegar.

O'XYDS, (from *οξύς*, acid). Substances formed by the union of oxygen with any basis; as a metal or an acid.

O'XYGEN, (from *οξύς*, and *γίνομαι*, gignor). The atmospheric air is composed of two æriform fluids (see AER); one of which, oxygen, is capable, by respiration, of contributing to animal life, in which metals are calcinable, and combustible bodies may burn;—the other azot, on the contrary, is distinguished by opposite qualities. The properties of this base is to form acids by combining with many different substances: and this process is termed *oxygenation*. The union of oxygen with caloric is called *oxygen gas*, the same as was formerly called *empyreal*, *vital*, *dephlogisticated*, or *pure air*. When oxygen is united with a combustible substance, it is said the conversion of that substance into an acid is to oxygenate it. See CHEMIA.

OXYGENATED MURIATIC ACID. Muriatic with an excess of oxygen, by distilling it from any metallic oxide, particularly that of manganese. It is yellow, transparent, with a peculiar suffocating smell; apparently less acid than the common muriatic, and its oxygen is soon separated by light.

OXYDE'RCES, and OXYDE'RCICA, (from *οξύς*, and *δεικω*, to see). Medicines which relieve those affections of the eyes which occasion imperfect vision.

OXYDO'RCIA. See DACNERON.

OXYGA'LA, (from *οξύς*, sour, and *γαλα*, milk). SOUR MILK.

OXYGA'RUM, (from *οξύς*, acid, and *γαρον*, garum). See GARON or GARUM.

OXYGENA'TIO, and OXYGE'NIUM. See OXYGEN.

OXYGLI'CUM, (from *οξύς*, and *γλυκος*, sweet). See APOMELI.

OXYLA'PATHUM, (from *οξύς*, and *λαπαθον*). See ACETOSA, and LAPATHUM ACUTUM.

O'XYMEL, (from *οξύς*, vinegar, and *μελι*, honey). Honey and vinegar, boiled together so as to form a

M

syrup, is called *simple oxymel* and *apomeli*. To this Hippocrates applies the term *adipsion*, a preventer or allayer of thirst. (See MEL.) Oxymels of different denominations are made by macerating medicinal ingredients in vinegar, and then boiling them with honey.

O'XYMEL ÆRU'GINIS. See ÆGYPTIACUM UNGUENTUM.

O'XYMEL CO'LOCHICI. See COLCHICUM.

O'XYMEL SCI'LLÆ. See SCILLA.

OXYMYRRHI'NE, or OXYMERSI'NE, (from οξύς, and μυρρίνη, the myrtle, from its resembling myrtle). See RUSCUS.

OXY'OPIA, (from οξύς, and οφίς, vision,) a peculiar acuteness of sight usually found in fair persons, the pigment of whose choroid coats is of a light colour.

OXYPHLEGMA'SIA, (from οξύς, and φλεγω, to burn). See INFLAMMATIO.

OXYPHCE'NICA, (from οξύς, and φοινίξ, the tamarind). See TAMARINDUS.

OXYPHY'LLON, (from οξύς, and φύλλον, a leaf,) *cnicus* of Oribasius; but he seems to intend by it a

different plant from that which we call by that name; probably a species of *carthamus*.

OXYPHO'NIA, (from οξύς, and φωνή, voice). See PARAPHONIA.

OXYRE'GMIA, (from οξύς, and ερεγγω). An ACID ERUCTION.

OXYRRHO'DINON, (from οξύς, and ῥοδινον, oil of roses). A composition of vinegar and oil of roses.

O'XYS. See ACETOSELLA.

OXYSA'CCHARUM, (from οξύς, and σακχαρον, sugar). A composition of vinegar and sugar.

O'XYSAL DIAPHORE'TICUM, (from οξύς, acid, sal, salt, and διαφωρίω, to perspire). Salts with an excess of acid, prepared by Angelus Sala; but nature offers us many such in the tartar, salt of wood sorrel, &c.

OXY'TOCA, (from οξύς quick, and τίκτω, to bring forth). Medicines which promote delivery.

OXYTRIPHY'LLUM, (from οξύς, and τριφύλλον, trefoil). See ACETOSELLA.

OZÆ'NA, (from οἴζος, a fetid smell). See ABSCESSUS NARIUM.

P.

PAD

P, in prescription, sometimes signifies *pugillum*, *pugil*, or the eighth part of a handful; sometimes *parts*.

P. Æ. PARTES ÆQUALES. EQUAL PARTS.

PA'CAL. A tree in Peru, the ashes of which, mixed with soap, in the form of an ointment, are used for the cure of leprous disorders. It is not noticed in the botanical systems. See Raii Historia.

PACHIONIA'NÆ GLANDU'LÆ. See CEREBRUM.

PA'CHYS, (from *παχυνω*, to *incrassate*). THICK. The name of a disorder unknown to us, but which has been described only by Hippocrates, more probably by the Cnidian school. Hippocrates condemns them for multiplying the species of diseases without necessity; and of this they make four species, with symptoms very incompatible. The description of this disease, which is called *παχυ νόσημα*, occurs indeed in the treatise De Internis Affectionibus, which is generally accounted spurious; and the different species are certainly different diseases; for the first is an asthenic typhus, with considerable accumulations of bile, &c. in the epigastric region; and the last, the dropsy, which follows fevers of peculiar severity. See James' Medical Dictionary, and Le Clerc's Histoire de Medecine, lib. iii. c. 11. page 181.

PACO CA'ATINGA. A coniferous species of Brazilian canna, the *costus arabicus* Lin. Sp. Pl. 2. Its stalk, if chewed, occasions a spitting: if the saliva is swallowed, it is said to cure gonorrhœa in a few days; and to be occasionally lithontriptic. See Raii Historia Plantarum.

PACOEI'RA. See BANANA.

PA'DRI. A siliqueous tree in Malabar, not yet accurately described: the juice of the leaves is a cure for mania; that of the bark, mixed with the fruit of the pera, is supposed to restrain the menses. See Raii Historia.

PA'DUS; *prunus padus* Lin. Sp. Pl. 677; *cerasus avium nigra*, *cerasus racemosa*; the WILD CLUSTER CHERRY, the BIRD'S CHERRY, grows on mountains, and the berries are used to hang about the necks of children as a cure for the epilepsy; and internally to cure dysentery. The bark, a narcotic bitter, and slightly astringent, has been said to cure intermittents and syphilis. (See Dale, and Raii Historia.) A name, as is said, also for the lauro cerasus, but in reality a species of *prunus*, resembling the lauro cersus, so called by

PÆO

Clusius. See Lin. Sp. Pl. 678, where it is arranged with this trivial name.

PÆDA'NCHONE, (from *παις*, a child, and *αγχω*, to strangle). See ANGINA.

PÆDARTHROCA'CE, (from *παις*, *αρθρον*, a joint, and *κακον*, an evil). The JOINT EVIL; as it frequently appears about the joints of children, and oftener than in adults. Severinus calls the spina ventosa by this name; and adds that its tumours are frequently attended with pain, redness, and all the appearances of inflammation, while the pædarthroca has little or no pain in the beginning. But these names are used very promiscuously; and the term is sometimes applied to anasarca. Dr. Cullen places it as a variety of the first species of phlogosis, under phlogosis phlegmone. See M. A. Severinus's Treatise De Reconditâ Abscessuum Naturâ; also SPINA VENTOSA, and CARIES.

PÆDOPHLEBOTO'MIA, (from *παις*, and *φλεβοτομία*, opening a vein). The bleeding of children.

PÆNO'E, *vateria Indica* Lin. Sp. Pl. 734. A large tree in Malabar; the root, bark, and fruit of which yield a resin, which is burnt instead of incense in their sacrifices. The kernels of the fruit, made into an emulsion with warm water, is supposed to strengthen the stomach, relieve nausea, colics, and cholera. See Raii Historia.

PÆO'NIA, (from *Pæon*, who is supposed to have first used it). PIONY; *ephialtia*, *idæus dactylus*, *pentorobus*, *pæonia officinalis* Lin. Sp. Pl. 747, α and β, viz. MALE and FEMALE PIONY.

The male piony hath dark green leaves, pale red single flowers, long thick roots, with red streaks in the stalks and pedicles; the female, longer, pale, and narrower leaves, deep red, double flowers, and irregular roots, composed of several tuberous pieces, hanging by rough filaments from one head. The male is preferred; but the difference is inconsiderable, and the female is most frequently used. The fresh roots and seeds have a faint narcotic smell, with a slight acrimonious bitter and astringent taste; but, when dried, lose wholly, or in a great degree, both. Watery extracts are insipid, spirituous ones bitter, and slightly astringent.

Every part of this plant has been considered as antispasmodic and tonic. The roots were at first directed to be hung round the neck; and if relief did not follow, a drachm of the dried root was to be taken two or

three times a day. On the continent the expressed juice is preferred. The piony is chiefly used in epilepsy; but in this country it has not succeeded, and is now neglected. The roots, flowers, and seeds, are anodyne, but their efficacy is very inconsiderable. The flowers impart their colour, smell, and taste, to water and to spirit. See Lewis's *Materia Medica*.

PAGA'NICA. A ball used by the Romans in their exercises; confined to the villages.

PAG'NA, (from *πηγνῶ*, to compose). The superior and inferior superficies of the leaf of a plant.

PAGU'RUS, (from *παγος*, a rock, and *εμειν*, to keep; because found in rocky places). See **CANCER MARINUS**.

PAHUATLA'NICA. See **CHINA OCCIDENTALIS**.

PAIA'NELI; *bignonia Indica* Lin. Sp. Pl. 871. A tall pod bearing tree in Malabar, used by the natives in several disorders. See Raii *Historia*.

PAIDATRO'PHIA, (from *παίς*, and *ατροφία*, *atrophy*). See **ATROPHIA**.

PAIDI'ON, (from *παίς*, a perfect child in the womb). Hippocrates. See **CONCEPTIO**.

PAIN DE MADAGA'SCAR. See **CASSADA**.

PAI PARCEA, *couradi*; *grewia orientalis* Lin. Sp. Pl. 1367. A bacciferous shrub in Malabar. An apozem prepared of the leaves, fruit, and roots in water, is said to be useful in gout. See Raii *Historia*.

PA'LA. See **NUX MOSCHATA**. Also a tall pod bearing tree in Malabar, *tabernaemontana citrifolia* Lin. Sp. Pl. 308; used in various disorders. See Raii *Hist.*

PALE'TYRUS, (from *παλαιος*, old, and *τυρος*, cheese). See **CASEUS**.

PALA'TI O'SSA, (from *palatum*, *palate*). The BONES of the PALATE are two, irregular, and continued up the back part of the nostrils to the orbit. These additional parts, viz. the pterygoid process, the nasal lamella, and orbital process, we shall soon notice. The square bones situated in the roof of the mouth join each other backwards, and the maxillary bones forward; on the posterior part there is a lunated edge, whence the velum pendulum palati is suspended. The upper part of its internal edge rises in a spine, to be joined with the vomer: its anterior edge is ragged, to connect it more firmly with the process of the maxillary bone. The internal edges, by which they join, are thick and smooth. The internal point projects, for the origin of the palato staphylinus. On the side towards the maxillary bone there is a fossa, which, applied to a similar one in the maxillary bone, forms a passage for the palatine branch of the fifth pair of nerves, and a small twig passes through a hole behind. The pterygoid process of this bone passes between the os maxillare superius, and the pterygoid process of the os sphenoides: it is of a triangular shape, broad at its basis, and small above. The nasal process is very thin and brittle, rising upwards, covering a large part of the aperture of the maxillary sinus, and closing the cavity between the sphenoid and the projecting part of the maxillary bone. From the middle internal side of this plate, a cross ridge, resting on a similar one of the maxillary bone, extends, and on it the back part of the os spongiosum inferius rests. A perpendicular fossa, made by the palate nerve, is observable on its outside. At its superior part the os palati divides into two processes, called the orbital, of which the anterior is the larger, and its fore part

is contiguous to the back of the maxillary sinus: its posterior surface is cellular, contiguous to the ethmoid cells, and placed on the opening of the sphenoidal sinus, so as to leave a small hole above. Sometimes this hole is wholly in the palate bone, and through it a nerve artery and vein belonging to the nostrils pass.

The palate bones are very complete in the infant, and the nasal plates are thicker and stronger than in the adult, but the orbital processes have no cells. In old persons, all these bones are firmly united. From the connexions described, we see why the eyes are so often affected in ulcers of the palate; or why, on the other hand, the palate suffers from EGYLOPS, q. v.

PALATI'NÆ GLA'NDULÆ, (from *palatum*, the *palate*), are conglomerated glands, situated in the septum and arch of the palate, near the tonsils.

PALATI'NUS, (from *palatum*, the *palate*), is a branch of the upper maxillary branch of the fifth pair of nerves, running before the pterygoid apophyses of the os sphenoides in the canal formed by the os maxillare and os palati, and through the foramen palatinum posterius: it spreads in the glandular coat of the palate, and parts adjacent.

PALATI'NUS DUCTUS. The Eustachian tube.

PALATI'NUS PROCE'SSUS, (from *palatum*). See **MAXILLARIA SUPERIORA OSSA**.

PALA'TO PHARYNGÆ'US, (from *palatum* φάρυγξ). See **CONSTRUCTOR ISTHMI FAUCIUM**; **PERISTAPHILO PHARYNGÆI**; and **PHARYNX**.

PALA'TO SALPINGÆ'US, (from *palatum*, and *σαλπιγξ*, a trumpet, from its origin and shape). See **CIRCUMFLEXUS PALATI**.

PALA'TUM, (from *palos*, to hedge in, as it apparently is by the teeth). The PALATE, *cerebri basis*, *hyperoæ*, is that arch of the mouth which is surrounded before by the teeth and gums, and extending backward the whole breadth of the upper part of the mouth, as far as the great opening of the pharynx. This arch is partly hard and immoveable, and partly soft and moveable. The solid part is formed by the two ossa maxillaria, and the two ossa palati. The soft part lies behind the other, and it is lined by a membrane full of small glands. When a child is born with the hare lip, the fleshy and the long parts of the palate are sometimes defective, from a fissure, or a division through it into the nostrils; the uvula also is occasionally divided into two. In this case the child must be fed by a spoon, for it cannot suck.

PALA'TUM MO'LLE; *septum*, and *valvula palati*. Behind the bony palate lies the soft palate, from the middle of which the uvula hangs down: the two arches on each side are called *columnæ septi palati*.

PALEA, (from *παλλω*, to agitate, because easily driven by wind). **CHAFF**, **POLLEN**. In botany it is applied to the thin membrane which separates the floscules.

PALEA DE ME'CHA. See **JUNCTUS ODORATUS**.

PALIMPISSA, (from *παλιν*, iterum, and *πίσσα*, pitch). See **PIX NIGRA**.

PALIURUS, (from *παλλω*, to move, and *ουρον*, urine). **CHRIST'S THORN**, or **WILD JUJUBE**; *ænochia*, *ramnus*, *zyzyphus* Lin. Sp. Pl. 282, is a species of thorn in the southern parts of Europe. The leaves and roots are moderately astringent and diuretic; but from the length of its spines it is more valuable for making hedges.

PALLIUM PURPUREUM, (from *pallium*, a cloak). A PURPLE CLOAK. A powder, prepared of an amalgama of gold and mercury put into a retort, where the mercury being separated, what remains is calcined with sulphur, and turned a purple colour. Basil Valentine.

PALMA, (from *παλλω*, to move). The PALM of the HAND; *thenar*, *ages*, *agostus*.

PALMA, (so called because its leaves are extended from the top like the fingers upon the hand,) the PALM TREE. The palms are a family of plants, which generally grow between the tropics, and furnish, with little trouble, food, clothing, and habitations.

They are remarkable from their height, from the perpetual verdure of their tops, and the abundance of their fruit. The stalk is simple and shrubby, composed of the leaves of the former growth. The green foliage of the top is ranged circularly by stages, each leaf covering the other, at its base. These leaves rise from a large bud, which terminates the stalk.

The stalk of the palm tree does not enlarge by successive annual strata. Each leaf of a palm is formed by an elongation of the woody fibres, and the cellular substance of the trunk; and the latter is formed by the remains of leaves, which annually rise out of it. As the woody and the cellular substance, however, of the new leaves arise from the centre, they throw back the old ones. On this account, the density of the trunk is greater, the nearer it is to the circumference; and when this density has arrived to a certain degree, the expansive power of the centre will have no effect in enlarging it. Such, at least, is M. Daubenton's explanation. Desfontaines, in an excellent memoir on the organization of the monocotyledones, in the first volume of the Memoirs of the Institute, observes, that the size of the trunk is not always the same, but depends on the degree of nourishment. Thus, if a young palm is transplanted from a barren to a rich soil, the later shoots will be larger than the old ones, which will retain their former size, and the contrary.

Palm trees bear two sorts of leaves; the one resembling in shape a fan, others compounded of many leaflets on a common foot stalk. Their number is usually the same in each individual. The leaflets are folded lengthwise double, resting against the foot stalk, which is turned back. The disposition of the leaves, rising out of the trunk, resembles that of the ferns, to which the palms are related. Strictly speaking, the palms have no trunk, though rising often to the height of one hundred feet; but what has been styled so is a prolongation of the root, and the leaves are truly radical ones. The flowers are usually small, yellowish, or greenish, without any splendour. They are not provided with separate peduncles, but are collected in great numbers on common simple peduncles, naked at their base, more or less ramified or paniculated at the upper parts, to which the name of *spadix* has been assigned, and this spadix arises from the axillæ of the flowers. They are concealed, before the bloom, in very thick coriaceous spathæ, which, though monophyllous, are subject to be torn in two, or more pieces. Independent of this general spatha, which is not found in many of the genera, there are smaller ones enveloping each division. Few palms bear hermaphrodite flowers: they are, in general, monoicous or dioicous. In the former case,

each sex is sometimes inclosed by the same spadix, sometimes by distinct ones. In each sex we find the rudiments of the other, so that palms appear monoicous or dioicous only in consequence of abortive blossoms.

Fourcroy, in the sixth number of the Annals of the Museum of Natural History at Paris, gives an analysis of the pollen of the date tree, by which it appears to contain a large proportion of malic acid already formed, which may be separated by cold water; phosphats of lime and magnesia, separated by the washing, as the acid contributes to their solution; an animal matter dissolved also in the water by means of the acid, found to be a kind of gelatine; a powdery substance, apparently covered by the former bodies, insoluble in water, and, by putrefaction, producing ammonia. Thus this pollen has a considerable resemblance to animal substances, and still more to the seminal fluid of animals, which some of the species show by the smell of the flowers. Bory St. Vincent has also shown, by an ingenious experiment, that at the moment of blooming, the anthers of the palm trees had a temperature superior to that of the atmosphere.

The fruit of the palm is commonly a dry berry, whose shell is formed of numerous fibres, closely compacted, concealing a woody kernel, varying in its form, and sometimes equalling in size a man's head, with two or three seeds, which are very hard, and inserted at the base of the kernel. The embryo is very small, situated in a cavity on the back sides, or base, of the perisperm; at first soft, often liquid, eatable, and gradually hardening to the consistence of horn.

The genera of palms are twenty-three in number, arranged in four divisions, determined by the sex of the flowers, and which may be sub-divided according to the shape of the leaves; but many are imperfectly known.

1. The palms with hermaphrodite flowers, include the Rotang, licanis, and the corypha Lin.
2. Those with polygamous flowers, the chæmærops Lin. and the raphis.
3. With monoicous flowers, the areca, the elate, and the cocos Lin. caryota, nipa, sagus, bactris, arenga, hyphæna, and euterpe.
4. With dioicous flowers, phœnix, and borassus Lin. elais, laodicea, and cleophorus.

The palms, whose sex is scarcely, if at all, known, are the mauritia, caranda, maniquana, and hyophorhis.

The palms are of the most general utility to the inhabitants of the tropics, for every part is of use. The external parts of the trunks of some species furnish a wood, hard and durable as iron, and, indeed, substituted for it by many savage tribes of India and America. In others, the spatha is so compact as to contain the thinnest fluids; and, in some places, vessels are made from them which will bear the fire. The trunks of the larger palms may be formed into planks, by which houses, unaltered by the air, may be built and covered with the leaves: the latter, transformed into mats, blinds, &c. serve to adorn them within.

The fibrous pericarpium in many species, the filamentous membrane which covers the trunk in others, the leaves, and the foot stalk in almost all, furnish

threads, which may be wove into garments, twisted into cords, &c. Many subordinate advantages may be derived from these trees; fans, hats, paper for writing, a substance for artificial flowers, canes, dishes, &c. are furnished by them. Let it not be supposed that we are relating a fairy tale. They are the giants of regions where nothing is minute, where nature exerts her most active powers with the utmost energy, in the greatest and least of her productions; where all is grand or beautiful; often salutary and generally useful.

We must not, however, in these more extensive views, overlook our more immediate object. As administering to the necessities of mankind, in the most important points of nourishment and medicine, the palms are of the greatest importance. Not one species possesses injurious properties; almost every one is salutary or useful. We find in the soft pulp of some the perisperm of the seeds of many, and the terminal bud of almost all, a wholesome and savoury food, which may be dressed in a variety of ways. The fluid found in the green spathæ, or the vast cavity of the perisperm, affords a copious and a salutary draught, from which, by evaporation, good sugar may be procured; and by the common processes, wine, spirit, or vinegar. From the pericarp, or seeds, sweet oil, or a butter scarcely inferior to that from milk, may be expressed. If the trunk of other species are split, a very wholesome fæcula, the sago, is obtained. The medicinal palms we shall notice under their proper titles.

PA'LMA A'DY. See ADY.

PA'LMA CHRISTI, and OLEUM. See CATAPUTIA.

PA'LMA COCCIFERA; *cocos*, *nucifera*, Lin. Sp. Pl. 1658, *palma Indica coccigera angulosa*, *cocceira Indica*, *coccys*, *palma Indica nucifera*, *nux Indica*. The COCONUT TREE.

From this tree the Indians extract a species of sugar called *jagra*, the liquor *suri*, from which they distil the arrac. The milk in the shell of the nut is grateful and cooling. The exterior covering of the nuts, in their early state edible, are gratefully acid and gently restraining. By boiling, an oil like that from almonds is obtained from the kernel of the nut.

PA'LMA DACTYLIFERA. See DACTYLUS PALMULA.

PA'LMA HU'MILIS. See MUSA.

PA'LMA JAPONICA; *sagou*, *palma Indica*, *arbor farnifera*, *todda*, *monta fanna*; the LIBBY TREE, INDIAN BREAD, or SAGO TREE. *Cycas circinalis* Lin. Sp. Pl. 1658. The medulla of this tree, well beat in a mortar with water, forms a fæcula, which, when dried, is sago. The fruit is somewhat astringent; but this quality is moderated when eaten with sugar.

Sago is very nourishing, and used by the Indians when rice is scarce. Boiled in water it becomes an insipid, almost transparent, jelly, readily soluble, and an useful aliment in weak constitutions and consumptive complaints. It is demulcent, never ferments in the stomach, and is, therefore, preferable to wheat flour for the food of infants.

PA'LMA MA'JOR. See DACTYLUS, and DACTYLUS PALMULA.

PA'LMA MI'NOR, *palma humilis dactylifera et Hispanica spinosa*, et non spinosa, *palmites*, *chamæriphe*, *chamærophi humilis* Lin. Sp. Pl. 1657. The DWARF PALM. Its fruit is astringent.

PA'LMA NO'BILIS, *regulis Jamaicensis et Barbadosensis*,

palmitis, *palmeto royal*, a species of *areca*, Lin. Sp. Pl. 1659, styled *oleracea*. The CABBAGE TREE; the cabbage of which are called *chou de palmitis*. It is a tall straight tree, often more than two hundred feet high. The terminal bud is a white, tender, savoury, medullary substance, which, if eaten raw, resembles a walnut, but boiled and pickled with the white leaves, which surround it, is one of the greatest delicacies in the Leeward Islands. In the Isle of France, where it is chiefly found, there is another species which is poisonous. See Raii Historia.

PA'LMÆ O'LEUM is produced from the *PALMA foliorum pediculis spinosis, fructu pruniformi luteo oleoso*. *PALMA SPINOSA minor fructu pruniformi*, &c. of Brown, called in Jamaica the MACKAW TREE. He observes, that the rind of the fruit is thick, and yields a fattish substance, not unlike or inferior to the real palm oil. The fruit of the great mackaw tree differs but little from that of the little mackaw tree, and the husks of the fruit are also full of oil. He adds, that the negroes say it is the tree which yields the true palm oil. In the Pharmacopœia of the Edinburgh college this species is described as being the *palma foliorum pediculis spinosis, fructu pruniformi luteo oleoso*. Sloane's Jamaica and Adanson's Senegal. Mr. Curtis, in his Catalogue of Medicinal, &c. Plants in the London Botanical Garden, calls the tree *palma oleosa* Lin.; but it has been more lately referred to the genus *cocos*, with the trivial name of *butyracea*. The tree is tall and unbranched, with long winged leaves, furnished with two ranks of simple leaflets. Several species of it are met with in the warmer countries. The fruit is pressed, or first bruised, and then boiled in water; by either of these methods an oil of the consistence of butter is obtained, and eaten by the inhabitants of Guinea, and the Cape Verd Islands. It is of a strong, but not disagreeable, smell, and hath but very little taste. The colour, whilst good, is of a deep yellow inclined to red; but by long keeping it becomes pale, and is then to be rejected. There is, indeed, some little inconsistency in the different accounts, which may be reconciled, by supposing that a sweeter butter, which will not soon become rancid, may be prepared without pressure. This oil is used, when mixed with some warm penetrating ingredients, to rub on parts affected with old pains, and in some nervous disorders.

PALMA'RIS BRE'VIS, and CUTA'NEUS, (from *palma*). *Caro musculosa quadrata* of Brown. Cananus pointed out this muscle to Fallopius, and it was first published by Valverde, in his Anatomy. It rises from the fascia of the annular ligament, runs across the ball of the little finger, and is inserted into the os pisiforme, and lost in the skin and fat that cover the abductor minimi digiti.

PALMA'RIS LO'NGUS, (from the same,) *ulnaris gracilis*. This muscle lies on the inside of the extensor carpi radialis, and, rising tendinous from the inner condyle of the os humeri, soon becomes fleshy, and then again unites in a long slender tendon, which, near the wrist, separates into two portions, one of which is inserted into the internal annular ligament, and the other loses itself in the aponeurosis palmaris. Some of the fibres of this muscle adhere to the metacarpal bones, and the first joint of the fingers. It bends the hand, and stretches the aponeurosis palmaris.

PALME'TO RO'YAL, and PALMI'STE. See PALMA NOBILIS.

PALMITES. See PALMA MINOR.

PA'LMOS, (from *παλλω*, to beat). A PALPITATION OF THE HEART. See PALPITATIO.

PA'LMULA, (a dim. of *palma*, the hand). A DATE. The name also of the broad and flat end of a rib; from *palma*.

PA'LPESBRÆ, à *palpitando*, from their frequent motion). The EYE LIDS; *blephara*; are connected to the circumference of the socket by the tunica conjunctiva (see ADNATA); and composed of the common teguments, a cartilage called *tarsus*, and an external membrane. They have two angles or corners styled *canthi*, one small and external, the other large and internal. The form of each eye lid is that of a segment of a large circle, and when both eye lids are shut they make an uniform arch, adapted to the convexity of the eye, and in contact with it; but when shut, their edges leave a very minute opening, narrow toward the outward, and wider toward the inner, angle, serving to conduct the tears and the sebaceous matter to the lachrymal points. The margin, or basis of each eye lid, is a cartilage of a considerable thickness, divided into the outer and inner edges; but the outward edge only of each lid is supposed to join when they are shut, the inner edge forming by its obliquity the channel first mentioned. This margin is called the tarsus, of which that in the upper eye lids is the broadest; and the edges furnished with hairs are called *cilia*. The cutis is very thin, and almost transparent on them. On the internal edge of each lid in the tarsus is a row of small holes, which are the excretory ducts of the ciliary glands. From the upper edge of the upper tarsus, and the inferior of the lower, is contained a membranous expansion to the neighbouring edges of the orbit; each of those membranes, together with its respective tarsus, has the form of the eye lid to which it belongs, and is called *ligamentum tarsi*. The ligaments of the eye lids are reckoned to be three: from the inner angle to the nasal process of the os maxillare superius, we see one which is the tendon of the orbicularis; at the external angle we see another ligament more diffused on the bony brim, blended with the cellular membrane; a third goes all round, proceeding out of the brim of the orbit from the periosteum. The broad ligaments of each tarsus are membranous elongations, formed by the union of the periosteum of the orbits and pericranium, along both edges of each orbit. The superior is broader than the inferior, and each is fixed to the edge of its cartilage.

In man the superior palpebra has much more motion than the inferior. *Twinkling* is the effect of the alternate contraction of the levator palpebræ and orbicularis. The inside of the eye lids are lined by the ADNATA, q. v. The muscles subservient to the motions of the eye lids are the orbicularis, and levator palpebræ superioris; and these, as well as the lids, are furnished with branches from the angular, temporal, and frontal arteries, which communicate with those sent to the internal membrane of the eye lids. The levator palpebræ receives a branch from the internal maxillary artery. The veins correspond very nearly with the arteries, and carry their blood into the external jugulars, by means of the veins in

the temples and face. The nerves proceed from the ophthalmic branch of the fifth pair, from the superior maxillary branch of the fifth pair, and from the portio dura of the seventh pair; the levator palpebræ superioris receives a branch from the third pair. The eye lids defend the eyes from the light during sleep; and preserve the eye from becoming dry by their frequent motion, which spreads the tears over the external surface of the globe. See LACHRYMALES GLANDULÆ, LACHRYMALIA PUNCTA.

PALPE'RIA. See APOPLEXIA.

PALPITA'TIO, (from *palpito*, to vibrate). *Palmos* of the Greeks. Dr. Cullen places it among the *spasmi*, defining it a violent, irregular motion of the heart. The only species is the palpitation cardiaca; a palpitation almost constant, at least often returning, without any other evident disease. The arthritic, chlorotic, hysterical, melancholic, and febrile palpitation, with some others, are species; but rather symptomatic.

There is a morbid chronical palpitation of the heart, when violent, called *diognus*: and in persons otherwise healthy, the disease may be occasioned by strong passions, surprise, violent exercise, &c. Actuarius distinguishes palpitation owing to plenitude or heat in the blood, from the disease in consequence of vapours. In the first, he says, the pulse is unequal; in the latter unaffected.

Those most subject to palpitation are of a sanguine temperament, very mobile and irritable, of delicate minds, and in whom natural or artificial evacuations have been suppressed.

Palpitation may be owing to general mobility, when the heart shares in the irritability of the whole system, or from any disease of this organ or the larger vessels in its vicinity. A common, though often an unsuspected, cause is, accumulations in the stomach and bowels; and in our experience it has brought on the disease in sixteen of twenty. Plethora will alone often produce it; for this is a very frequent cause of increased irritability. See PLETHORA; and MORBI FLUIDORUM.

The more remote causes are organic diseases of the heart, or the distant parts. Of the first kind, the most frequent and considerable are polypous concretions in the ventricles or auricles of the heart, sometimes extending to the veins, or the arteries, according to their situation; ossifications in the heart, which sometimes are found in its substance, frequently in the valves shooting out in little processes resembling crystallizations; aneurisms of the heart or larger vessels; dropsy of the pericardium, sometimes of the chest.

The more distant causes are, costiveness; obstructions in the circulation through the abdominal viscera; repelled gout or eruptions; disturbances of mind; intense thought; particular odours; flatulent aliment, or indigestion. It is not easy to see how these causes operate, except by increasing general irritability; and, indeed, those which immediately affect the heart would appear rather to produce a tardy circulation than spasm, but, in a muscle regularly acting, every cause of irritation, every thing which disturbs that regularity, produces in a certain degree spasm or convulsions, as we perceive in the stomach and bowels, in the eye, and occasionally in the urethra. See POLYPUS.

The disease frequently intermits, especially while at

rest; but from any cause of agitation or increased circulation it returns: the pulsations are sometimes so great that the motions of the heart may be perceived on the outside of the clothes. Sometimes it attacks during sleep, and awakens the patient suddenly; often only during the day, and is worse after eating; occasionally preceded by anxiety or uneasiness in the precordia. In the paroxysm of palpitation, the breathing is difficult; and though the pulse intermits, it does not correspond with the motion of the heart, but is languid and diminished. In a violent paroxysm, a great uneasiness is perceived in the region of the precordia; and a considerable languor of the body, with a tremor of the joints, remains after the paroxysm is over. When from polypous concretions in the heart, the palpitation is immediately increased after violent exercise, or the slightest increase of the circulation; and, indeed, this is the case when any enlargement of the vessels of the heart, or any contraction of the cavities around, takes place; and in such circumstances a flushed, or even a livid countenance, with sense of suffocation, and fainting, also occur. When a redundancy of blood is the cause, the countenance is florid, the vessels turgid, and the pulse full. In a very violent paroxysm the pulse is peculiarly slow, and the longer the intervals, the more strong are the attacks.

A palpitation of the heart should be distinguished from that which is perceived in women about the last months of pregnancy in the epigastric region, and which is only a pulsation of the cœliac arteries, in consequence of too much blood being conveyed through them. One remarkable symptom attending a violent palpitation of the heart, is an acute pain immediately above the right orifice of the stomach, which is easily accounted for when the course of the right phrenic nerve, round the apex of the heart, already described, is considered.

When palpitation frequently returns, continues long, or is violent, it often ends in a fatal syncope, or a suffocation. An unequal pulse, or difficulty of breathing attending the paroxysms, are dangerous circumstances. When the disorder is idiopathic, there is very little dependence on any remedy; when symptomatic, as is most frequently the case, the cure is often easily effected by the removal of the original complaint. When it proceeds from terror, and returns often, it produces polypi, which again may increase the disease, and at last produce a fatal termination. Palpitations attend various diseases, and always increase their danger.

The complaint is best relieved by keeping the mind and body at rest, avoiding every cause of irritation, mental or bodily, and keeping up a proper equilibrium of the circulation. All ligatures should be avoided, and the clothes made easy. The patient should never continue long in the cold; and, when the fit approaches, a clyster should be instantly administered, and the extremities rubbed.

During the paroxysm, bleeding is often necessary, except the cause be debility or relaxation. In these circumstances warm cordials are more salutary. An emetic, with repeated cathartics, should be early employed, for the reasons assigned; but, in full plethoric habits, bleeding should be premised, unless the fulness be accompanied with peculiar irritability. In full and irritable

habits the diet should be carefully regulated. It should not be of vegetables, because of their flatulence, nor of strong animal foods. The meat of milder, young, animals will be the best, and, in such cases, fish may be also allowed. When, by this means, and gentle laxatives, there is less danger from emetics, these should be also given.

With a view of keeping the circulation in its due equilibrium, besides gentle laxatives, nitre, with small doses of camphor, may be given, and Hoffman's anodyne liquor is often serviceable. Opium, where it does not produce restlessness, is highly useful, and may be joined at night with the camphor. The feet should be kept dry and warm, frequently rubbed, and if not otherwise warm, with powdered mustard seed. When it does not yield to the evacuations, and has followed suppressed gout and evacuations, a perpetual blister, or a seton, with warm cordials and tonics, are often necessary, and essentially useful.

In the intervals, the bark, with valerian, perhaps the arsenic, will be useful, especially if any considerable irritability of the system accompanies the disease; and could it be certainly ascertained that no fixed obstruction occurs in the heart, or larger vessels, the cold bath also in the intervals would greatly contribute to prevent the return. Steel, as a tonic, has been advised; but its stimulus is too inflammatory, and our utmost exertions should be employed to keep the circulation tranquil. All violent emotions should be avoided, and the external heat regulated with the utmost caution. The room should be large and airy, the head raised, the bed covered with a mattress, and the coverings slight. On the access of a fit, the volatile tincture of valerian may be given, unless the disease proceeds from an affection of the heart; and, in that case, the extremities should be rubbed, and every means tried to assist the circulation in the most distant branches. The stimuli then employed should be chosen with care, and perhaps the camphorated julep with æther will be the best, as it combines an antispasmodic power with a stimulus, not very diffusible. The event of such cases, however, is often sudden and fatal.

See ACTUARIS, HOLLERIUS, SENNERTUS, LOMMIUS, and HOFFMAN; Cullen's First Lines, vol. iii. p. 372. edit. 4; Memoirs of the Medical Society of London, vol. i. p. 77.

PALUDA'PIUM, (from *palus*, a lake, and *apium*, smallage; because it grows in moist places, and near rivulets). See **APIUM**.

PA'LUS SA'NCTUS, (from its woody texture, and the numerous virtues ascribed to it). The HOLY POST. See **GUAIACUM**.

PAMPINIFO'RMES, (from *pampinus*, a tendril, and *forma*, likeness). See **DUCTUS THORACICUS**.

PANACE'A, from *παν*, all, and *αἰς*, a remedy, an universal medicine). There are many panaceas in most of the former dispensaries, for the ancients were particularly anxious to cure all diseases with a single medicine, among which we may notice

PANACE'A DUPLICA'TA. See **NITRUM**.

PANACE'A LAPSO'RUM. See **ARNICA MONTANA**.

PANACE'A MERCU'RII. See **MERCURIUS DULCIS SUBLIMATUS**.

PANACE'A VEGETA'BILIS. See **CROCUS**.

PANACE'A MOSCHA'TA. See **HERBATUM CANNADENSIS**.

PANA'DA, quasi PANA'TA PANATE'LLA, (from *panis*, bread). Bread boiled in water, to a proper consistence, as food for children, in febrile complaints, and in states of considerable debility. It should be made from bread thoroughly baked, from baked flour, or rusks. Salt is a better condiment than sugar.

PANARI'TIA. See PARONYCHIA.

PANA'VA. See GRANA TIGLIA.

PA'NAX. Synonymous with panacea. See PASTINACA OLUSATRA.

PA'NAX ASCLE'PIUM. See FERULA GLAUCA FOLIO and MINOR.

PA'NAX CHIRO'NEUM. See CHAMÆCISTUS.

PA'NAX COLO'NI, *stachys palustris fetida*; *galeopsis angustifolia fetida*; *sideritis Anglica*, *strumosa radice*; *galeopsis palustris betonica folia*, *flore variegato*; *marubium aquaticum acutum*; *tertiola Cæsalpini*, *stachys palustris* Lin. Sp. Pl. 811. CLOWN WOUND WORT, or ALL-HEAL. This and some other species of *stachys* have been used as astringents.

PA'NAX CO'STINUM, HERA'CLEUM, HERCULE'UM, PASTINA'CEA. See OPOPONAX, and PASTINACA OLUSATRA.

PA'NAX QUINQUEFO'LIUM. See GENSING.

PANCHYMA'GO'GUM, (from *παν*, *χυμος*, humour, and *αγω*, to bring away). The name of some cathartic extracts, supposed to carry off fluids of every kind.

PANCRATIUM, (from *παν*, and *κρατω*, to conquer,) a gymnastic exercise consisting of wrestling and boxing. The SEA ONION; named from its power in overcoming all obstructions.

PANCREAS, (from *παν*, and *κρεας*, flesh,) *callicreas*; *pancrene*. The SWEET BREAD; a long, flat, conglomerate gland, situated transversely in the duplicature of the posterior portion of the mesocolon, reaching from the duodenum to the spleen, and in shape resembling a dog's tongue. Its head lies in the first curvature of the duodenum, and from thence it runs across the spine to the spleen, behind and below the stomach, to the last curvature of the duodenum. There is a natural cavity into the epiploon, between the lower sides of the stomach, and the upper side of the mesocolon; and here the arteries, veins, and nerves enter, and the cystic and hepatic ducts come out to form the ductus communis choledochus, which goes into the duodenum near the pancreatic duct. The vessels of the pancreas come from those of the spleen, which run along it. That head next the duodenum hath vessels from the mesenterica and gastrica dextra. The substance of this viscus, composed of united masses which occasion an uneven surface, is that of the conglomerate gland; in the whole length of the gland is a duct called ductus Wirsungii, from its discoverer, but generally spoken of by the name of ductus pancreaticus: it is white and almost transparent, beginning towards the spleen; and receiving branches, it grows larger, and proceeds into the duodenum, in the same canal as the biliary duct. The branches are large near the trunk, and smaller at the edges, but always lie in the same plane. The duct is sometimes double, sometimes winding, and generally nearest the lower side; very thin, without valves; and does not always go out jointly with the biliary duct, but seldom otherwise. Malpighi makes the pancreas a cluster of vesiculæ; Ruysch finds these vesicles to be vascular. The nerves come from the plexus hepaticus, plexus splenicus, plexus mesentericus, &c. The pan-

creatic juice resembles the saliva, but is less viscid, and contains a larger proportion of salts. All the pancreatic juice is sent into the duodenum, and is secreted most when the stomach is fullest. This viscus is subject, like the spleen, to inflammation; but this disease has no appropriate distinguishing symptoms.

PA'NCREAS MI'NUS. Where the great extremity of the pancreas is connected to the duodenum, it sends out an elongation, with a distinct duct in it, which opens into the duodenum.

PANCREA'TICÆ ARTE'RIÆ, (from *pancreas*, the sweet bread). The splenic artery runs from the celiac, under the stomach and pancreas, to the spleen: it adheres to the lower posterior part of the pancreas, to which it gives several branches called *pancreaticæ arteriæ*.

PANCREA'TICÆ VE'NÆ, (from the same). They are several branches from the splenica, which run to the pancreas along its lower side. There are other small pancreatic veins which do not arise from the splenica.

PANCRE'NE, (from the *παν*, and *κρηνη*, a fountain; from its great secretion). See PANCREAS.

PANDALITIUM. See PARONYCHIA.

PANDE'MIUS, (from *παν*, and *δημος*, a people). See EPIDEMICUS.

PANDICULA'TIO, (from *pandicular*, to gape and stretch.) STRETCHING; *distentio*; is that restless stretching and uneasiness which accompany the cold fit of an intermitting fever, and one of the irregular actions from debility.

PANI'CULA. A PANICLE. A stalk diffused into several pedicles, sustaining the flowers or fruits, like the oat, millet, &c. Panicula is also a diminutive of panus, a species of tubercle; and a name for crude bile.

PA'NICUM, (à *paniculis*, from its many panicles,) *elymagrostis*; *elymos*; COMMON PANIC; *panicum dactylon* Lin. Sp. Pl. 85. The spike consists of innumerable thick seeds, disposed in lesser spikes, so as to appear like a cluster. It is cultivated in Germany; and the seeds have been used as food, but are not regarded in medicine. See Raii Historia.

PA'NIS, (from *παν*, to feed). BREAD; *artos*, *fari-nacea panis*. Good bread should be composed of flour well kneaded with the lightest water, seasoned with a little salt, fermented with the yeast, and sufficiently baked. The viscosity of unfermented bread, called *duratos*, is destroyed by fermentation; and the bread is thus rendered more digestible, but at the same time inclines the substances fermented to acidity, whence unfermented bread only can be proper where acidity abounds in the stomach. (See BREAD.) To this article we have little to add except the kinds distinguished by ancient authors. The purest and best bread was styled *panis siligineus*, *mundus*, *athleticus*; *isungia coliphis* and *robys*. The next in quality, from which the bran was not wholly sifted, had the appellations of *secundus*, *smilaceus*, or *smilagineus*; the third containing the whole of the bran, was styled *antophyrus*, *syncomastus*, and *confusaneus*. A fourth kind consisted wholly of bran, and was styled *cacabaceus*, *sordidus*, *furfuraceus*, or *furfurativus*, *bissus*, and *leibo*.

PA'NIS CANINA'CEUS. See CANICÆ.

PA'NIS FURFURA'CEUS, IMPU'RUS, A'TER, CIBA'RIVUS, GREGA'RIVUS. See COLIPHIVUM.

PA'NIS CU'CULL. See ACETOSA.

PA'NIS PORCINUS. See ARTHANITA.

PANNI'CLUS ADIPO'SUS. See CELLULOSA MEMBRANA.

PANNI'CLUS CARNO'SUS. A fleshy membrane which assists the corrugation of the skin, found, with a very few exceptions, only in brutes.

PANNO'NIUM. See ARTHOICUM.

PANNO'NICA, (from *pannus*, a rag). See HIERACIUM ALPINUM.

PA'NNUS, (from *πῆνναι*, to labour). WOOLLEN CLOTH; synonymous also with albugo, and with a venereal spot.

PANO'CHIE. See BUBO.

PANOPHO'BIA, (from *πᾶν*, and *φοβία*, to fear). MELANCHOLY, attended with groundless fear. See MELANCHOLIA.

PANTARBE. An imaginary stone, supposed to be capable of attracting gold as the magnet attracts iron.

PANTI'CES. See INTESTINA.

PA'NULA, or PA'NUS. A sort of crude bile.

PA'NUS. See PHYGETHON.

PAO-A'GULA. See AGALLOCHUM.

PA'PAGA and PAPAGA'LLI. Names for the seeds of bastard saffron, denominated from the magpies eating them.

PA'PAS. See BATTATAS.

PAPA'VER ALBUM; *papaver hortense semine albo; somniferum*, α, Lin. Sp. Pl. 726; WHITE GARDEN POPPY; *papaver somniferum album*. The watery extract of this plant is chiefly used, and it amounts to about one fifth of the weight of the poppy heads boiled. It is said not to produce a nausea or giddiness, which generally follows the use of opium; and the dose is about double that of the latter. It is supposed to check a diarrhoea as well as the Asiatic opium, but does not so powerfully check expectoration; but in reality it seems only to be weaker. The seeds, without a portion of farinaceous, contain a great quantity of oily matter, obtained copiously by expression, which has been employed both in diet and medicine. In the former also the seeds have been used in considerable quantity, without the least trace of a narcotic quality. A cataplasm is formed of the heads, and applied to parts in an irritable or a painful state.

The cataplasm of white poppy is made in the usual way, with a strong decoction of white poppy heads; and may be rendered more sedative, if necessary, by adding a solution of opium, or the extract.

In the fomentation of white poppy, four ounces of the heads are added to six pints of water, reduced by boiling to a quart.

The syrup of white poppy is made in the following manner: take of the heads of dried white poppies, without their seeds, three pounds and a half; of water, eight gallons. Slice and bruise the heads, and boil them in the water to three gallons; in a water bath saturated with sea salt, reduce it by boiling to about four pints, and strain while hot, first through a sieve, and then through a thin flannel: set it by for a night, that the fæces may subside; boil the liquor poured from the fæces to three pints, and dissolve six pounds of double refined sugar in it. Pharm. Lond. 1788.

This syrup is given to children in doses of from 3 ss. to one drachm or more; to adults of an ounce and a half. In general, an ounce of this syrup is equal to one grain

of opium; but it is subject to great variation in point of strength, from the different degrees of maturity, and the soil and seasons in which the poppy heads are produced. See OPIUM.

PAPA'VER CORNICULA'TUM LUTE'UM. See CHELIDONIUM MAJOR.

PAPA'VER NI'GRUM; *papaver hortense nigro semine, papaver somniferum* Lin. var. β. BLACK GARDEN POPPY, as the seeds are black.

These plants are often found wild, and several varieties are produced by culture in our gardens. The head, stalks, and leaves, have an unpleasant smell, and a bitterish pungent taste, like opium. The smell and taste are lodged in the milky juice of the cortical part of the heads, which is collected in the manner already described. (See OPIUM.) It is, however, weaker as a medicine, though stronger in smell and taste. The juices obtained from the white or the black poppy are the same; but the white affords the largest quantity. The seeds contain an insipid oil, obtained by expression, without any narcotic quality.

PAPA'VER RU'BRUM; *rhaas*, and *erraticum; calocatanos*; CORN ROSE; WILD POPPY; *papaver rhaas* Lin. Sp. Pl. 726. This plant hath deep red flowers, dark coloured seeds, hairy leaves and stalks; is common in corn fields, and sometimes varied by culture. The heads contain a narcotic juice similar to the preceding, but in a very small quantity. The leaves of the flowers, on expression, yield a deep red juice, which they impart to watery liquors, and a bright, though pale red to rectified spirit. The London College orders a syrup to be made in the following manner.

Take of the fresh flowers of the wild or red poppy, four pounds; boiling distilled water, four pints and a half: put the flowers by degrees into the boiling water, in a water bath, constantly stirring them. After the vessels are taken out of the bath, macerate them for twelve hours; press out the liquor, leaving the fæces to subside. Lastly, make it into a syrup with double refined sugar. Pharm. Lond. 1788. This syrup has been thought useful as an anodyne and pectoral; but it is more employed for the beauty of its colour.

PAPA'VER SPINO'SUM; *argemone Mexicana* Lin. Sp. Pl. 727. PURGING THISTLE. Its juice is called *glaucium*, and is used as a cooling external medicine.

PAPA'VER SPUME'UM. (See LYCHNIS SYLVESTRIS, BEHEN ALBUM, PEPLION, or PEPLOS.) *Euphorbia pepilis* Lin. Sp. Pl. 652. See EUPHORBIA; Lewis's *Materia Medica*; Neumann's *Chemistry*.

PAPAYA MAS ET FCE'MINA; *papaya Peruviana, papayamarum, platanus mamera mas et femina*. MALE and FEMALE PAPA TREE. *Carica papaya* Lin. Sp. Pl. 1466, nat. order *cucurbitacea*. The fruit resembles a melon; it is eaten raw, sometimes with vinegar, or prepared with sugar, and is said to strengthen the stomach.

PAPILIONA'CEA, (from *papilio*, the butterfly). PAPILIONACEOUS. Flowers are thus called from their resemblance to the wings of a butterfly when expanded; irregular and usually four-petalled. The lower petal is shaped like a boat, and called *carina* or *keel*; the upper petal, which spreads and rises upwards, *vexillum*, *standard* or *banner*; the two side ones separated by the keel are called *alæ*; the keel is sometimes split, and then this corolla is properly five-petalled. These flowers form a natural class, named *papilionaceæ*, and are

chiefly comprehended within the order *decandria*, of the class *diadelphia*, in the artificial system. This is one of Tournefort's classes, and is the *leguminosa* of Ray and other authors. Of this tribe are peas, beans, kidney beans, vetches, and other leguminous plants, hence called pea-blossomed flowers. See Miller's Dictionary; Martyn's Language of Botany.

PAPILLA, (from *pappa*, a dug). The NIPPLE; *mamma* and *mamilla*; the little eminences on the breast. In children of both sexes, and in males of all ages, they appear to be no more than cutaneous tubercles; but, in reality, their structure is the same, but the parts are not evolved. In females arrived at the age of puberty the nipple begins to increase; in pregnant women, and those who give suck, it is large; in old age it decreases, and becomes flabby. The body of the nipple seems to consist of extensive elastic fibres, containing the terminations of the tubuli lactiferi. Their convolutions act as valves: but when distended, as the nipple is drawn out, they become straight; the breast also is equally elongated, and its convoluted vessels become straight, so that the milk flows freely. The lactiferous tubes are about twelve or fourteen in number, and pass out from the apex in as many apertures. Its surface is uneven, wrinkled, and covered, like the inside of the mouth, by a very soft, thin, epidermis.

The nipples are sometimes flat, sometimes drawn in. When flat, which was formerly more common from wearing tight stays, they were with difficulty drawn out, and the suction of a strong child was necessary. The retraction of the nipple seems to be owing to adhesion of some of the convoluted fibres, which has taken place at early age, so that the breast has swelled beyond it. It is drawn out by the suction of glasses, and often with great pain.

Excoriations of the nipples is a most distressing complaint. It is more common in the first than in subsequent nursings, and, when independent of any disease in the child's mouth, is owing to the unusual irritation of the new stimulus. In many instances bathing them with a little port wine or brandy will succeed. A more effectual remedy is the tincture of opium, which can be more easily washed off, while the salts of iron and of zinc are often deposited in the rugæ of the nipple, and with difficulty removed. A remedy extremely simple, and said to be certain, was given us by an old woman. When the child has done sucking, the nipple is to be sprinkled over with equal parts of finely powdered gum arabic and sugar of candy. This absorbs the acrimonious fluid, and defends the breast. When the child also takes hold of the nipple, he is attracted by the sweetness and the irritation given by taking hold, and capriciously dropping the nipple, in which the pain chiefly consists, is avoided. By this term Peyer calls the intestinal glands.

PAPILLÆ CAPITATÆ, LENTICULÆ RES PYRAMIDALES. See LINGUA.

PAPILLÆ MEDULLÆ RES. *Tubercula mamillaria.* Small eminences on the medulla oblongata.

PAPILLÆ PYRAMIDALES, are observable on the surface of the skin. They are longer in some parts, as in the fingers, and called *villi*, appearing in rows, each having two ranks contiguous. They are the organs of touch, being the terminations of the cutaneous

nerves, each of which is inclosed in two or three membranous coverings. See CUTIS.

PAPILLA' RÊ OS, (from its resembling a *papilla*). See SPHENOIDES OS.

PAPILLA' RES CARU' NCULÆ. See CARUNCULA.

PAPILLA' RES PROCE' SSUS. The extremities of the olfactory nerves entering the mucous membrane of the nose.

PAPILLA' RIS HERBA. See LAMPSANA.

PAPILLO' SUS. A leaf, whose surface is covered with little points or protuberances like nipples.

PA' PPAS, PA' PPUS. POTATOES. See BATTATAS. The down also of the seeds of plants, which are hence called *pappose*, or *pappescent*.

PA' PPOS. PATERNAL. The downy hairs upon the chin.

PA' PULA, (a dim. of *pappa*). A PIMPLE or ULCEROUS TUBERCLE. A very small and acuminate elevation of the cuticle, with an inflamed base, not containing a fluid, nor tending to suppuration.

PA' PULÆ. This term is applied to a variety of different eruptions by medical authors; but confined by Dr. Willan to those enlargements of the papillæ of the skin, occasioned by a strong determination of the blood, sometimes attended with a degree of inflammation; the small papillæ, thus enlarged, elevating the cuticle immediately above them, and appearing red. A slight effusion of lymph often takes place in these circumstances, and gives a pustular form to several papulæ; but the fluid does not break the cuticle, and the pimple does not suppurate. The duration of papulæ is uncertain, but they usually terminate in scales. Of this order he enumerates three genera, which, with their species, are STROPHULUS *interinctus*, *albidus*, *confertus*, *volaticus*, and *candidus*: the second, LICHEN *simplex*, *agrius*, *pilaris*, *lividus*, and *tropicus*: the third, PRURIGO *mitis*, *formicans*, and *sensilis*. Vide in verbis.

PAPY' RUS, (from *παπυρος*, an Egyptian term). The PAPER TREE; *papyrus Nilotica Alpina, Egyptiaca; Cyperus Niloticus* vel *Syriacus. Cyperus papyrus* Lin. Sp. Pl. 70. This tree afforded to the Egyptians food, boats, furniture for beds, and other utensils in houses, sails for ships, shoes for priests, and paper. The paper of modern times is, we know, made of flax, first woven into cloth. We have mentioned under ODONTALGIA its oil; and have only to add, that the magma of which paper is made, or into which it may be reduced by maceration in water, is recommended in diarrhœas. See Maryatt's Art of Healing, p. 40, 41.

PAR, (*παρ*, equal, even). A PAIR. Some vessels are called *sine pari*; because there is no corresponding one on the other side.

PAR CUCULLA' RE. See POSTICI.

PAR LINGUA' LE. The ninth pair of nerves from the head.

PAR MENTA' LE. See LEVATORES LABII INFERIORIS.

PAR VA' GUM. The eighth pair of nerves from the head, *nervi vagi*, and *sympathetici medii*. This pair is made up of several small cords which come from almost the whole length of the medulla oblongata, and when joined with the accessorius Willisii, a small cord running up laterally from the medulla spinalis, pass through the foramen to join this pair, which goes out

by that common hole between the temporal and occipital bones, where likewise the internal jugular vein goes out of the cranium. The par vagum goes down the neck, by the side of the carotid arteries, and behind the internal jugular, and is accompanied by the intercostal nerve to the last cervical vertebra. In the neck the par vagum sends off the lingual and superior laryngeal branch; thence passes down into the thorax, gives branches to the pharynx, larynx, &c. and joins many nerves. As they enter the thorax they go across the subclavian arteries, and, as the right trunk passes before the subclavian, it sends off a twig, which bends backwards under the artery, and runs up the side of the *aspera arteria*; called the *recurrent nerve*. Afterwards the par vagum runs down behind the lungs, to which they give a plexus, and then form two cords, one anterior the other posterior, called *nervi stomachici*, which pass along the *œsophagus* through the aperture, in the diaphragm, and are dispersed on the stomach, &c. See *NERVI*.

PA'RA. A Greek preposition, often signifying in composition, *disease* merely; sometimes, *beyond* and *besides*. It occasionally increases and sometimes diminishes the force of the word compounded with it.

PARACE'NTESIS, (from *παράκενσις*, to make a perforation,) *compunctio*, TAPPING; an operation employed for discharging water through the integuments of the belly from its cavity. The place formerly appointed for the perforation is about four fingers breadth from the navel, or rather in the middle betwixt the naval and the upper part of the *os ilium*. The left side is usually preferred, as the spleen does not extend so low as the liver. Mr. Sharp observes that, if the naval protuberates from water only, a small puncture made in the tumour with a lancet will discharge the water, without endangering a rupture. The signs of ascites, and the distinction between it and the pregnant state, we have already considered. (See *ASCITES*.) It is now only necessary to remark, that in the young and robust this operation may be performed; but when fever, scirrhus, or abscess, concur, it should be omitted. In exhausted constitutions, in consumptions when attended with jaundice or with general dropsy, if allowed, it should be only for temporary benefit, and the patient should be apprized that nothing more can be expected.

If the extravasated fluid remains in the same proportion for several years, particularly if the health in other respects is good, the evacuation is a radical cure, provided that the health is otherwise unaffected; but while the bulk of the water increases, there is not that confidence of a radical cure.

Upon a sudden evacuation of the waters in a hydrophorictis, or in an ascites, deliquium ensues, because when the pressure of the water is taken off, the flow of blood into the descending aorta leaves the vessels of the brain not sufficiently supplied.

In this operation, therefore, it is proper to have, 1. A roller of flannel, or a flannel laced about the belly, previous to the evacuation of the water, that it may be tightened at pleasure, and the bowels pressed against the diaphragm. 2. A piece of flannel, for a compress about a foot square. 3. A sufficient quantity of proof spirit, to moisten the roller and compress. 4. A piece of sticking plaster about two inches square, to lay over the pledgets of lint. 5. The trochar with its canula, and a

probe to thrust back any thing that may obstruct its mouth. 6. Two assistants, to keep a proper pressure, observing to press from behind, and on the sides, rather forward, continuing this pressure during the time that the water is passing off, until the roller or the laced flannel is securely applied.

A flat trochar is now preferred; and, when the bandage is prepared, the trochar is introduced, pressing on its end with the palm of the hand. It was usual first to perforate the skin, that the impetus in overcoming the resistance might not carry the instrument too far; but a check is sometimes affixed to the canula, though, in general, pressing on it with the fingers, about an inch from the extremity, will be sufficient, and the want of resistance will show when it has reached the cavity. The trochar should not be small, as the fluid is sometimes glutinous, and a blunt probe should be occasionally introduced, if there is any interruption to the flow. Should the resistance be very great, after penetrating the integuments, it is probable that the water is contained in a cyst; and, in that case, the abdomen will not be completely emptied. It is then advised to tap on the other side, as a cyst is seldom single; but in this variety of the disease, the operation is useless; nor is it certain that on the other side we may certainly meet with another cyst.

Lately it has been more common to introduce the trochar in the middle of the abdomen, between the umbilicus and the symphysis of the pubes, through the *linea alba*. The only advantage is, that we certainly avoid every branch of the hypogastric artery, which sometimes varies its direction in the minuter ramifications. The wound, however, does not contract so soon, and often continues to leak for many days; but though this is perhaps an inconvenience, it is not a disadvantage.

When the water is drawn off, lay the pledgets upon the wound, and secure them with the plaster; over them lay the flannel cloth, and then begin with the bandage or laced flannel, as already mentioned. See *Heister's Surgery*; *Le Dran's Operations*; *Sharp's Observations*; *Bell's Surgery*, vol. ii. p. 337, 354; *White's Surgery*, p. 298, 306.

PARACMA'STICI, (from *παράκμαζω*, to decline.) See *ACMASTICOS*.

PARACO'E, (from *παράκουα*, difficult hearing.) DULLNESS OF HEARING.

PARACOPE, (from *παράκοπιω*, to be delirious.) A slight delirium. Hippocrates.

PARACYNANCHE, (from *παρα, de, κυων, a dog*, and *αγγω, to strangle*, species of quinsy; a distemper to which dogs are subject.) *Juxtangina*. See *CYNANCHE*.

PARACU'SIS, (from *παράκουα, non rectè audio*.) DEPRAVED HEARING, of the order *dysæsthesia*. In Cullen's *Nosology* the species are: 1. *Paracosis imperfecta*; in which sounds are difficultly distinguished. (See *SURDITAS*.) 2. *Paracosis imaginaria*; when the sound is excited within the ear; *susurrus*; *syrigmus*, *syringmos*. See *TINNITUS AURIUM*.

PARADISAI'CA ARBOR. See *THUYA*.

PARADI'SA GRANA. GRAINS OF PARADISE. *Amomum grana paradisi* Lin. Sp. Pl. 2, have been supposed to be the seeds of the larger cardamoms, and called *malegueta*, *maniguetta*, and *cardamum piperatum*. They

are brought from the East Indies, are angular, of a reddish brown colour without, and white within; smaller than pepper; in appearance resembling cardamom seeds. They grow in pods, in shape and size like unripe figs, divided internally into three cells, in each of which are two rows of seeds. They join the flavour of cardamoms to the pungency of pepper; but the latter pungency resides in their resin; the distilled oil possessing only their smell. These seeds are sometimes used instead of pepper, but more often employed to adulterate it. Their medicinal virtues are the same as those of the semina cardamomi, though they are rather more pungent. See Neumann's Chemistry; Lewis's and Cullen's Materia Medica.

PARAGLOSSA, (from *παρά*, and *γλῶσσα*, the tongue). A PROLAPUS of the TONGUE. A SWELLED TONGUE.

PARAGU'A. See CASSI'NE.

PARALAMPSIS, (from *παράλαμπω*, to shine a little). See ALBUGO OCULORUM.

PARALLELA, (from *παρά αλλήλων*). A scurf or leprosy, affecting only the palms of the hands, and running in parallel lines, sometimes occurring in the venereal disease.

PARALOPHIA, (from *παρα*, and *λοφία*, the first vertebra of the back,) the lower and lateral part of the neck. Keill.

PARALYSIS, (from *παρύνω*, to dissolve or weaken). A Palsy; *catalysis*, *attonitus morbus*, and *stupor*; though the last appellations are sometimes confined to the palsy, which follows apoplexy. Dr. Cullen places this disease in the class *neuroses*, and order *comata*, defining it a loss or diminution of the power of voluntary motion, but only affecting certain muscles or parts of the body, often accompanied with drowsiness. He distinguishes four species. 1. *Partialis*, palsy of some particular muscles; 2. *hemiplegica*, of one side of the body; 3. *paraplegica*, of the upper or lower half of the body; 4. *venenata*, when from sedative poisons, external or internal.

The apoplexy, hemiplegy, and palsy, diseases nearly similar, may be considered in one view. In the beginning, the palsy, connected with sanguineous apoplexy, is acute; but it soon becomes chronic, like other palsies.

The most violent form of palsy is that which succeeds apoplexy, and it is usually the **HEMIPLEGIA**, q. v. That which equals it in obstinacy and degree is the *paraplegia*, where the lower extremities are affected; and the rare occurrence of the palsy of the right hand and left foot, which Sauvages would call *hemiplegia transversa*, is scarcely less difficult of cure. The partial palsies are of inferior importance; but we must notice each in the order mentioned.

Hemiplegia might be considered as a consequence of apoplexy, but that it sometimes attacks without loss of sense, and sometimes comes on gradually, the head on one side losing the acuteness of its sensation, then the hand, till the whole side is paralyzed. When preceded by an apoplectic attack, the patient is for a time dull and heavy, with a sensation of cold, trembling, and debility. The principal attack is, however, usually sudden, and with all the symptoms of apoplexy, as stertor, insensibility, a slow pulse, and slow impeded respiration. Even during the insensibility the mouth is drawn

on one side, a certain proof of the nature of the disease; and when recollection returns, one side is usually either insensible, without motion, or both. In general, the whole of the side is affected in unequal degrees; but sometimes the head only suffers, in a few instances the hand and leg, while the head remains free. When the apoplectic symptoms have receded, the power over the voluntary motions of one side is lost, the vital and animal functions are weakened only. This circumstance has been already explained by the connection of the nerves in ganglia and plexuses, where nerves are united, so that the functions are diminished only, instead of the organ losing its power in any given portion. The action of the tongue is impaired; but it is also locally paralytic, for it trembles, and, when put out, is turned to one side. The side affected is in general dry and cold, though sometimes bathed in cold colliquative sweats: the extremities swell, are often affected with cramps or convulsive motion, and the limbs lose their muscular fulness and colour; the flexors are contracted, the nails white and livid; the mouth, wanting the power of the antagonizing muscles, is drawn down on one side.

The mind is affected with the body. The memory is impaired, the recollection fails, the judgment is often considerably weakened. The paralytic patient cries and laughs without an adequate cause, is timid, irascible, violent. The distortion and vacancy of countenance give the air of fatuity to his look and manner; and the tongue hanging from the month, the saliva dropping from the chin, the articulation imperfect, contribute to render him an object highly distressing. It is the most dreadful lot of humanity.

In this state, the paralytics often continue for many years a burthen to themselves, and objects of the highest distress to their sympathizing friends. If, however, the patient be young, and previously in health, (but it is not a disease, in general, of the young,) they gradually recover some portion of strength, and some action of their limbs. The articulation of their words is again, in appearance, learnt, and very gradually acquired; the limbs are moved by the concurrence of other muscles with those affected, though each recovers some share of its power. The amendment comes on with a creeping sensation, and often with violent pain, occasioned by the distention of contracted vessels. A glowing heat, increased power of motion, and a greater degree of sensibility, are slowly and gradually conspicuous. The patient sometimes completely recovers; but we must add, that this rather happens from the powers of nature than from those of medicine.

We saw, in our examination of the nerves, that there were no exclusive branches destined for sensation, except when depending on organization, as in the eye and ear. It is difficult therefore to explain, why sometimes the motion, sometimes the sensation only, is affected. It has been supposed that a greater degree of active power in the nerves is required for the former than the latter office; and it seems that sensation is most commonly destroyed in the lighter forms of the disease. The two defects are, however, so often in different degrees, without any striking connection between either and the violence of the palsy, that we offer this solution with doubt and hesitation. On dissection, we find sometimes an effusion of watery fluids, or extravasation of the

blood, sometimes exostoses at the base of the skull; in a few instances, local abscesses and tumours. In local palsies, the nerve leading to the part appears sometimes shrivelled; but in no instance has any organic change of the brain, in an extensive degree, been found. When the brain is unusually dry, shrivelled, &c. the disease has been rather mania than palsy. Often dissection discovers no alteration in any part of the encephalon. In more partial palsies, the spinal marrow is chiefly affected, but this happens in new born children, from the spinal marrow being deficient in this part. In adults, it is sometimes owing to a shock, but more often to distortion or partial dislocation.

The more immediate cause of hemiplegia seems to be, therefore, some partial compression on the origin of the nerves, or some change in the state of the nervous power. The latter we infer from the absence of any cause of compression, and the nature of the remote cause, which is incapable of producing any organic affection, as deleterious gases or sedative poisons.

The remote causes are such as favour determination to the head, either constantly, or in particular circumstances only. The constant causes of this kind are those which depend on form and constitution, as short necks, or large heads; and, as the effusion is most commonly venous, lax fibres, with large veins. As forms and imperfections are inherited by children, so far hemiplegia is hereditary. The causes which determine to the head, accidentally, or in particular circumstances, are convulsive and epileptic paroxysms, violent passions, the repulsion of cutaneous eruptions, the suppression of the usual discharges, great heat, close or confined rooms, and improper use of warm bathing.

The causes which leave no traces, and which we suppose to have produced some change in the nervous fluid, are sedative poisons, particularly of lead; cold, with moisture, long continued grief, deleterious gases, syphilis, scurvy, and excess of venery.

The prognostics are generally doubtful. A spasmodic apoplexy and sanguineous hemiplegia may be removed, but they are apt to return and end in a fatal hæmorrhage of the brain. In cold weather, palsies are not soon relieved; and it has been said that relief may be less expected, if the muscles of the head and face are affected, if the disease be in the arms rather than in the legs. The other species of palsy, and a serous hemiplegia, do not suddenly prove mortal; but the cure is more difficult the more the senses are injured, and such diseases frequently continue during life. The palsies of infants are sometimes relieved about the years of puberty, but adults rarely recover completely. A palsy in the belly and lower limbs is generally mortal, and often accompanied with a gangrene. If convulsions occur in the parts opposite to those that are paralytic, the danger is greater. When a palsy follows an apoplexy, or comes on in old age, it is scarcely in any instance cured. Palsy, from pressure on the medulla spinalis, is often relieved by art, but slowly yields to the powers of nature. If the part affected is painful, yet capable of sensation, not cold, nor extenuated, there are some hopes of a recovery, which is still more to be expected if there is a sensation of formication and a pricking pain in it.

The indications are, 1. To remove the causes, which interrupt the influx of the fluid into the nerves. 2. To

excite increased action in the parts affected, and the whole nervous system.

Effusion of the brain, the most frequent cause, is, we have said, very frequently venous; but if the disease occurs in a young person, after violent exercise, in consequence of a blow or fracture, arterial effusion is probably the cause, and in this case only is bleeding in any considerable degree admissible. The remote causes, when they can be traced, will point out the probability of serous effusion, and the appropriate remedies can be soon ascertained. Bleeding in this case is improper, though countenanced by Dr. Cullen, from an opinion that the red veins absorb in the brain, since lymphatics have not been discovered in it. The existence of the common absorbents is now, however, admitted, though it has not been demonstrated; and the general state of relaxation in constitutions of this kind render indiscriminate bleeding, formerly so common, highly improper. There are, indeed, very few instances, and these we have mentioned, where this remedy is proper.

Of *emetics* we have already spoken, and the controversy to which they have given an origin; nor can we add to what we have already said on that subject. See *EMETICS*.

Cathartics are remedies of considerable importance in this point of view, and their nature must be varied according to the difference of the disease. The younger and more robust require those of the cooling kind, as the salts; but a mixture of those which are more active is often necessary, as large quantities cannot often be swallowed. In the more lax and debilitated habits, rhubarb, aloes and their tinctures, quickened with the tinctures of senna and of jalap, are useful. The degree of the discharge by stool must be regulated by the strength of the patient, and if that is so much exhausted as to excite apprehension from its excess, clysters must be trusted: in the torpid state of the patient they must not be inert. When nothing can be swallowed, clysters are the only resource, and decoctions of the colocynth, with a large proportion of salt and oil, are most useful: the aloes is also not an useless ingredient. Tobacco clysters are effectual ones; but the languor they induce, and the faintness which often follows their action, render them improper in this disease.

Blisters we consider among the evacuates, since we have found little advantage from their stimulus. They should be applied very near the head; and when the discharge is lessened, others should be applied either to the vertex, or behind each ear. Setons, &c. are applicable to the chronic form of the disease, which we shall afterwards notice.

Diuretics and *sialogogues* are also evacuates, which have been sometimes used. Of the former, the cathartides were for a time highly esteemed; but their diuretic power is inconsiderable. Mercury, the chief sialogogue, is inadmissible, from the debility which any considerable dose of it induces, and it has, indeed, seldom been employed as a remedy for this disease.

Diaphoretics, of the warm stimulating kind, are highly useful in those hemiplegias which arise from effusion. The foundation of their utility we have already seen, vide in verbo; but this subject we shall return to under the second indication.

The next indication is sufficiently obvious; but it must not be followed until the venous congestion or

extravasation, if either appear to exist, are relieved. The imprudent use of stimuli, at a very early period, often produces a fatal apoplexy.

As fever has been sometimes found to relieve palsies, and as some heat and increased action will occasionally come on, after an attack of this disease, we are directed, by some old authors, to excite fever. This need not lead us to any very nice disquisitions respecting the connection between the disease and the remedy; for by exciting fever, was only meant the effects of stimulants in increasing the rapidity of the pulse and the heat; and when fever was supposed to cure palsy, the relief was owing to the stimuli usually employed. There is an imposing simplicity in the direction to relieve the congestion, previous to the use of stimuli, which will mislead the young practitioner; for, such is the tender structure of all the nervous organs, that compression, continued for even a short time, will so far injure their organization as to make every future attempt more hopeless. We have, therefore, found it more convenient to follow the intentions of ancient authors, and not delay, for any long period, the stimulating plan. What that period should be, must be left to the discretion of the practitioner in the peculiar circumstances of the case. In general, the more torpid and exhausted the habit, the more violent the cause, the more urgent the symptoms, the less delay is admissible; nor need we add, that, in cases of sedative poisons, any delay is improper. In general, when some stools have been procured, not mere evacuations from the rectum, but a free discharge through the whole canal, and a blister is found to have begun its action, the stimulating plan may commence; and we ought to reflect, that by this means the torpid absorbents may be roused to action. The whole class of stimulantia have been occasionally employed; but, in general, the aromatics and ammonia are preferred, as more quickly active, more generally diffusible, with less suspicion of acting indirectly as stimuli, than any other medicines. When activity is less necessary, the tetradinamia, the siliquosæ, and the alliaceæ, are employed; and the mustard, the horse radish, the onion, with the whole tribe of their congenères, are called to our assistance. They must be frequently changed, variously combined, and often alternated with gentle laxatives, to prevent returns of accumulation on the brain. In this part of the conduct little skill is necessary; and the medicines may be varied as caprice or fancy may direct, provided no one is continued for a long period.

Though these are the most powerful and active stimuli, yet others have been occasionally employed. These are the essential oils and the balsams. The most active and useful of the former is the ethereal oil of turpentine, and of the latter the balsam of Peru, though this is less useful, as in the larger doses which the disease requires, it is highly offensive to the palate. The oil of cinnamon and the balm of Gilead, often used, are less effectual. The arum, the serpentaria, and the guaiacum are stimulants of a less active kind, and less diffusible, and the latter has perhaps gained a great share of its reputation from the volatile spirit with which it is usually combined in the officinal preparation employed.

External stimulating applications are highly useful with the internal stimuli. Of these the most commonly useful, or from abuse injurious, is the warm bath,

particularly that at Bath. It is easy to understand, why it is so often injurious in hemiplegia depending on congestion; and useful where congestion, together with the tendency to it, is wholly removed; or where the disease arose from sedative poisons. Common warm water, of a moderate temperature, from 92°, for instance, to 96°, is much less dangerous. It has been usual to combine such baths with aromatics, but little advantage is gained by the union, and the heat is more generally efficacious. The cold bath is often more safe, since the repulsion of the fluids from the skin is transitory only, and it excites increased action by giving additional tone; but the other tonics are less generally employed. The tepid salt water baths and sea bathing are very useful remedies. The bitters are of an equivocal nature, and do not seem very essentially useful; and the metallic tonics have not perhaps been sufficiently tried. Even the steel, except in chalybeate waters, is seldom given; but these are so frequently useful, that they have tempted us to try this and some others of the same class, though we have not done so sufficiently to induce us to offer any remarks on their efficacy. If arsenic is so active a tonic in the paralytic state of chronic rheumatism as Dr. Bardsley has represented it, we may expect some efficacy from it in paralysis.

External applications are, however, more particularly useful in partial palsies; and in these the Bath waters may, without hesitation, be freely employed. In the palsy from the endemial colic of Devonshire, from lead, or any other cause, it often relieves; and the mustard, the ammonia, with many other stimulants, are often useful. The acknowledged utility of mustard has been seized on, to render it a vehicle of quackery; but, in reality, the supposed essence of mustard is a superior application, viz. the ethereal oil of turpentine, combined with spirit of wine, some camphor, and apparently opium. Cold and warm pumping is also very serviceable in partial palsies, as well as in particular states of the more general disease, where the congestion is removed, and some organ is peculiarly weak.

Electricity was, for a time, highly fashionable; but it has lost its credit, except when in cases of partial palsy sparks are drawn from the part. It is undoubtedly a stimulus, but a slight and transitory one. All Europe was informed of its success in curing the locksmith of Geneva; but very few heard that he soon relapsed, and died in his former palsied state. Success is usually blazoned, while failures are concealed.

Galvanism has lately been employed, it is said, with great success; but we have often mentioned our distrust of the boasted powers of a new remedy. There is, however, a striking instance in the *Annals of Medicine*, or its successor, the *Edinburgh Medical Journal*, of its success in a considerable disease of a nerve of the leg, inducing epilepsy.

After some time, when little advantage is apparently gained by medicine, the prudent physician will discontinue, to resume it again after some weeks or months. The artful one will, however, persevere to gain the laurels which are due to the activity of nature's powers. 'Tis a dishonest warfare! In these cases, however, nature generally when unassisted, exerts all her energy, and either by the increased activity of the smaller branches, perhaps by the accumulated excitability of the whole nervous system, some degree of strength and

motion is regained. This constitutes what we have styled the chronic form of the disease; and though we have declared medicine useless, yet some slight general regulations will be advantageous.

The diet should be solid, gently restorative, and stimulant; sleep moderate, on a hard mattress, in a large, cool room, situated on a gravelly soil, but not exposed to cold winds. In the summer the neighbourhood of the sea is highly salutary. The bowels should be kept open by gentle laxatives, generally aloetics, or rhubarb; and in torpid habits these should be given in the form of tinctures. Such exercises as can be admitted should be taken daily, and walking so far as the strength will permit, or gestation in a carriage, not too easy, will at other times be advantageous. To avoid congestion, which, if the original source of the disease, will be liable to recur, it is necessary, in addition to the laxatives, to open some drain near the head by a perpetual blister, or by a seton; and friction, particularly on the affected side, should be used morning and evening. When the tongue is particularly affected, an infusion of mustard and horse-radish should be often held in the mouth, or a bit of ginger frequently chewed. The mind should be soothed by cheerful company, and every varied amusement; by prospects held out of recovery, by changes of place and objects, with every other affectionate service.

Paraplegia sometimes arises, we have said, from distortion, sometimes from a violent shock, or, occasionally, from long continued cold. Distortion has its appropriate remedies, and the limbs gradually recover strength and motion; but we must add, that, independent of any remedy, this disease is more often progressive in amendment than any other form of palsy. In the disease from the other causes, blisters to the sacrum, and the warmest stimulants, externally and internally, are necessary. We need not apprehend danger from congestion; so that the bath waters, sea bathing, warm and cold pumping, may be freely employed. Great inconveniences arise, sometimes from an inability to retain the water, or the stools. Each is often relieved by blisters to the sacrum, and the former by the cautious internal use of cantharides. Astringent injections, and bathing the parts around with cold water, will be frequently serviceable in the latter case.

The *hemiplegia transversa* of Sauvages has not been described by any late author, and Sauvages seems often more eager to accumulate the number than the value of his authorities. It was seemingly an accidental occurrence, and probably a combination of two partial palsies. The only author cited is professor Fabricius of Helmstadt, who describes it as arising from a dysentery, prematurely suppressed by opiates and astringents.

We have not, in our enumeration of the remedies, mentioned the mosch, camphor, or castor. These, however, with opium, are sometimes useful, when convulsions, which are not unusual on the affected side, come on. Camphor is sometimes given as a stimulant; but this property rests, as we have said, on a very uncertain foundation. We have sometimes thought that, joined with ammonia, it is more certainly carried to the skin, acting as a diaphoretic.

Some varieties of paralysis are too curious to be wholly omitted. One of these is mentioned by De Haen, arising from *vomica* in the lungs, which com-

presses either the thoracic ganglion, or the brachial nerves above. The *intermittent palsy* is described by Torti, and seemed to depend rather on accumulation and compression on one part of the brain than effusion, since it was at once relieved by the recession of the disease, and was cured by the remedies of intermittents. Its form was that of hemiplegia.

The *arthritic hemiplegia* merits particular notice. It is mentioned by Musgrave, but particularly described in the Upsal Transactions. The peculiarity of the disease consists in its being relieved by cooling medicines, and aggravated by stimuli of every kind. The *syphilitic palsy* appears in many different forms; but it is chiefly owing to exostoses in the inner table of the skull, and is scarcely ever removed; for though the disease be cured, its effects remain.

See *Ætius*, *Celsus*, *Cælius Aurelianus*, *Aræteus*, *Trallian*, *Hoffmann*, *London Medical Observations and Inquiries*, vol. iii. p. 160, &c. p. 257, &c.; *Cullen's First Lines*, vol. iii. edit. 4; *Edinburgh Medical Commentaries*, vol. iii. p. 9.

PARA'LYSIS, (from their use in palsies). *Primula veris* Lin. Sp. Pl. 204. *a. Verbasculum pratense odoratum*; *primula veris odorata, flore luteo simplici*; *primula veris major*, PIALES, COMMON COWSLIPS. This plant is valued for its flowers, which have an agreeable smell, are used to give flavour to a wine, and are gently anodyne, and antispasmodic.

Primula veris minor. P. veris γ Lin. The PRIMROSE, grows in hedges and woods; its flowers are weaker than those of the cowslip; the leaves and roots resemble asarum, and are powerful errhines and emetics.

Primula veris β Lin. *herba petri*; *primula inodora lutea*; *verbasculum pratense*. OXSLIPS, or GREAT COWSLIPS. The flowers are slightly diuretic.

PARAME'SOS, (from *παρα*, near, and *μεσος*, middle). See DIGITUS.

PARANOI'E, from *παρα*, dim. and *νοειν*, to understand). See DELIRIUM.

PARAPHIMO'SIS, *PERIPHYMO'SIS*, (from *παρα*, and *φίμω*, to tie, as with a string). An inflammation of the prepuce, when it cannot be drawn over the glans. See *LUES VENEREA*; *Bell's Surgery*, vol. i. p. 534; *White's Surgery*, p. 345.

PARAPHO'NIA, (from *παρα*, and *φωνη*, the voice). *Cacophonia*. DEPRAVED VOICE, including in general dumbness and difficulty of speech. Dr. Cullen, confining it to the depraved voice, distinguishes the following species: 1. *Puberum*, that change of voice remarkable in boys about fourteen years of age. 2. *Rauca*, the hoarse and rough voice, from the dryness of the fauces. (See *RAUCEDO*.) 3. *Resonans, rhenaphonia*, when the voice seems to come whistling through the nostrils. 4. *Palatina*, from a defect of the lip, the palate, or uvula (see *ASAPHIA*, or *ASAPHODES*.) 5. *Clangens, leftophonia, oxyphonia*, when the sound is shrill or squalling. (See *CLANGOR*.) 6. *Comatosa*, a voice resembling stertor.

PARAPHRENE'SIS, (from *παρα*, and *φρεν*, the mind). See DELIRIUM.

PARAPHRENI'TIS, (because commonly attended with delirium). *Diaphragmitis*. AN INFLAMMATION OF THE DIAPHRAGM. In this disease the pain is very violent and deep seated in the lower part of the breast, under the short ribs, or striking between them and the

back; the fever very acute, and the delirium constant. The belly is drawn up, and kept as much at rest as possible; the respiration excessively quick, erect, small, suffocating, difficult, performed principally by the muscles of the breast; the patient frequently affected with sickness and hiccup, often with involuntary laughter, convulsions, and madness. The pulse is very frequent and small, often irregular; great anxiety; and symptoms of irritation come on, with a rapid, fatal termination. In general, the progress, termination, and manner of treatment, are nearly as in pleurisy. The pain is greatly augmented during inspiration, coughing, sneezing, repletion of the stomach, nausea, vomiting, or in discharging the feces and urine. The termination is often in suppuration; the risus sardonicus, convulsions, and madness, are supposed to be distinguishing symptoms of the disease. Sagar observes, that it is an inflammation, attended with an obscure pain at the spurious ribs, oppression of the breast, often bloody sputum, difficult breathing, anxiety, the sensation of tightness, like the stricture of a cord, at the precordia; a retraction, almost involuntary, of the angles of the mouth; delirium, and sometimes a lethargy. The pulse is unequal, intermitting, irregular, and hard; the hypochondria drawn inwards; respiration without the motion of the diaphragm; the urine sometimes pale, at others, high coloured, with a sensation of burning at the precordia. See PLEURITIS; Boerhaave's Aphorisms; Fordyce's Elements, part ii.

PARAPHRO'SYNE, (*alienation of mind*, from *παράφρων*), is a transitory insanity without fever. See MANIA.

PARAPHYMO'SIS, (*παρά, and φύμω, oblige*). See PHYMOSIS.

PARAPLE'GIA, PARAPLY'XIA, (from *παρά, trans, and πλῆσσω, to strike*). A palsy of all the parts below the neck; but Hippocrates means by this term a palsy in any particular part, from apoplexy or epilepsy. Dr. Cullen confines it to that species of palsy which affects the lower extremities only. See PARALYSIS.

PARAPOPLE'XIA. See APOPLEXIA.

PARARY'THMUS, (from *παρά, and ῥυθμός, number*). See ARYTHMUS.

PARATHRE'MA, (from *παρά, and ἄρθρον, a joint*). (See LUXATIO.) A tumour also from protrusion. See HERNIA.

PARASITICA'LES PLA'NTÆ, (from *παράσιτος, a hanger-on*), are produced from the trunk or branches of other plants, and do not draw their nourishment from the ground; as misleto, ivy, &c.

PARA'SPHAGIS, (from *παρά, and σφαγή, the throat*). The part of the neck contiguous to the clavicles.

PARA'STATA, (from *παρίστημι, to stand near*), any thing situated near another.

PARA'STATÆ. *Assistentes, astites glandulosi*; the EPIDIDYMIS. Herophilus and Galen distinguish this part of the testicle by the name of *varicosa parastata*, while they style the prostate *glandulosa parastata*. See EPIDIDYMIS, and TUBÆ FALLOPIANÆ.

PARASTRE'MMA, (from *παράτρεψω, to distort*). A convulsive distortion of the mouth or any part of the face.

PARATHE'NAR MA'JOR, (from *παρά, near, and*

σιναρ, the sole of the foot). This muscle in each foot is fixed backward by a fleshy body to the outer part of the lower side of the os calcis, from the small posterior external tuberosity, all the way to the anterior tuberosity, where it joins the metatarsus, and at the basis of the fifth metatarsal bone separates from it again, forming a tendon, inserted in the outside of the first phalanx of the little toe, near its basis, and near the insertion of the parathenar minor. It separates the little toe from the rest.

PARATHE'NAR MI'NOR. A muscle in each foot, fixed along the posterior half of the outer and lower side of the fifth bone of the metatarsus; terminating under the head of the bone, in a tendon, inserted in the lower part of the basis of the first phalanx of the little toe. These muscles are sometimes called *transversales pedis*.

PARAU'. See BEZOAR ORIENTALES.

PAREGO'RICA, (from *παρηγορέω, to mitigate*). An epithet for medicines which relieve pain. See ANODYNA.

PAREGO'RICUM ELI'XIR; *tinctura opii camphorata*. Take of hard purified opium, flowers of benjamin, of each one drachm; camphor, two scruples; essential oil of aniseeds, one drachm, by weight; proof spirit of wine, two pints: digest for three days. Pharm. Lond. 1788. It is useful in allaying the tickling sensation from cough, without diminishing expectoration or producing dyspnœa. It is given to children in the chin cough, from five drops to twenty; to adults from twenty to a hundred and twenty.

PAREIRA BRA'VA, (*harcyra, Span.*) *ambutua, caapeba, convolvulus colubrinus, botou*. WILD VINE, *cissampelos pareira, L.* Lin. Sp. Pl. 1473; the root of an American climbing plant, brought from Brasil, generally in crooked pieces of different sizes. The outside is brownish, and variously wrinkled; the internal substance pale, dull, yellowish, and on a transverse section, a number of concentric circles, crossed with striæ, running from the centre to the circumference, are conspicuous. There is a white species, the bark of whose root is white, and the substance within like the root of liquorice.

This medicine has been highly esteemed as an attenuant, expectorant, and diuretic, in suppressions of urine, in nephritic and calculous complaints, in ulcers of the kidneys and bladder, in humoral asthmas, in fluor albus, rheumatism, and jaundice; but is neglected in this country, since it has been found inefficacious. The dose of the powdered root is from ℥j. to ℥ij; in decoction ʒij. to a pint, divided into three doses. It yields its virtue to water or to spirit. See Lewis's Materia Medica; Neumann's Chemistry.

PARE'NCEPHALIS, (from *παρά, and εγκέφαλον, the brain*). See CEREBELLUM.

PARE'NCHYMA, (from *παριγχνω, to pour into*). A term introduced by Erasistratus for the substance contained between the blood vessels of the viscera, imagined to be extravasated and concreted blood. It sometimes means any of the viscera through which the blood is supposed to be strained.

PARENCHYMA'TICI, (from *parenchyma*). INFLAMMATIONS OF THE SUBSTANCE OF THE VISCERA.

PARE'SIS, (from *παρίημι, to relax*). A palsy of the bladder, when the urine is either suppressed or

discharged involuntarily. (Aretæus.) In modern authors an imperfect paralysis, synonymous with ANAESTHESIA, q. v.

PARETU'VIER. See GUAPARAIBA.

PARIETA'RIA, (from *parietes*, because it grows on walls). COMMON PELLITORY OF THE WALL; *parietaria officinalis* Lin. Sp. Pl. 1492, *muralis*, *helxine*, *perdicium*, because partridges feed on it; *vitriaria* and *urceolaris*. This plant hath tender reddish stalks, rough, uncut, oblong leaves, pointed at both ends, and imperfect rough flowers growing in clusters along the stalks, followed each by a small shining seed; perennial; flowering in May. The leaves have been used externally as refrigerants; and internally as diuretic and emollient, though now disused, notwithstanding it is retained in the British Pharmacopœias. See Raii Historia.

PARIETA'RIA O'SSA, (from *parietes*; because they defend the brain like walls,) THE BONES OF THE SINUSIPUT. These bones form an irregular square, whose upper and fore sides are longer than those behind or below. The inferior side is a concave arch, receiving the convex part of the temporal bone. Together they form the sides and upper part of the head.

The external surface of each parietal bone is convex, and about the middle is a transverse arched ridge where the temporal muscle is attached: at its concave side the temporal bone unites with and rises above it, to prevent apparently its starting from blows. Near the upper and the posterior part of each bone is a small hole, through which a vein passes to the longitudinal sinus, and sometimes a branch of the temporal artery. The situation of this hole should be attended to, lest, if a branch of the artery is cut, it retract into the bone, and occasion an incurable hæmorrhage. Internally there are numerous furrows on the concave surfaces of these bones, and they are largest and deepest near the anterior angle of the lower edge. In these furrows there are sometimes passages into the diploe. On the inside of the upper edge there is a large sinuosity, where the upper part of the falx is fixed, and the superior longitudinal sinus lodged. Near the angle formed by the lower and posterior angles of these bones are the depressions of the lateral sinuses. The pits made by the brain are also very conspicuous on the internal surface of this bone.

The parietal bones join the os frontis by the coronal suture; at their long inferior angles the sphenoidal bone by part of the sphenoidal suture; at the lower edge the bones of the temple by the squamous suture; the os occipitis by the lambdoidal suture; and one another by the sagittal suture.

In the new born child none of their sides are complete, and no hole exists in the ossified part near the sagittal suture. The unossified part of the head was supposed to be kept open for the evacuation of the superfluous moisture of the brain, then called the *fountain* (BREGMA, q. v.); sometimes with the epithet *pulsatilis*, for the arterial pulsation is there felt; and accoucheurs judge by this beating, and the fulness of the bregma, whether the child, on the head presenting, is alive. The bregma is usually ossified before the seventh year; and previous to that age, sometimes after it, applications have been made to that part, with a

view to draw off noxious vapours from the brain. We still apply blisters to the vertex, though perhaps without any decided advantage, as the brain is there covered by a thick ligament, scarcely more pervious than bone.

PARIETES. The soft inclosing membranes and muscles of any cavity.

PARI'GUA. See CASSINE.

PA'RI'S QUADRIFO'LIA. See HERBA PARIS.

PARI'STHMIA, (from *παρα*, and *ισθμια*, a part of the throat so called). See TONSILÆ.

PARISTHMIO'TOMUS, (from *παρισθμια*, and *τομή*, to cut). An instrument with which the tonsils were formerly scarified.

PARMENTA'LE. See LEVATORES LABII INFERIORIS.

PARMESAN. A rich cheese made at Parma, from the milk of cows fed on the banks of the Po. See CAUSEUS and ALIMENT.

PARNA'SSIA PALUSTRIS, Lin. Sp. Pl. 391. *Hepatica alba*; *gramen Parnassii*; *cistus humilis*; *pyrola rotundifolia*; GRASS OF PARNASSUS, or WHITE LIVERWORT. The leaves are roundish, and disposed in a circle; it grows in flowery marshy places, and flowers in August. The whole plant is said to be cooling and diuretic; but it is not now used. See Raii Historia.

PARONY'CHIA, (from *παρα*, and *ονυξ*, the nail). A WHITLOE, or FELON, *penaris*, *dogga*, *pandalitium*, *panaritium*, *fassa digitum*, *onychias*, an abscess at the end of the fingers. The symptoms and treatment greatly differ, according to its situation. If, at the root of the nail, an astringent spirituous application, often the camphorated spirit of wine, kept constantly applied, with a moderate pressure will cure it. Should suppuration, however, come on, at its first appearance as a white speck at the base of the nail, the cuticle should be removed, and the spiritus Minderei, or any slight discutient, applied. The appearance of the white spot, however, must be caught at, since a few hours delay will render the attempt abortive.

When it attacks the finger, but is seated only under the skin, it is troublesome in consequence of the thickness of the cuticle. It is, therefore, convenient to disperse it; and this may be done by immersing it frequently in warm water, or applying saturnine lotions. Should these fail, a knife may be at once passed through the prominent point, to relieve the inflammation by a topical bleeding, though the matter be not yet formed. When suppuration has taken place it may be opened early, or the cuticle pared down, so that the natural opening may be more quickly made.

When the paronychia is seated under the sheath of the flexor tendons, it is known by a violent pain, affecting the internal condyle of the humerus; and it is a disease so excruciating as to excite violent fever, and often delirium, with convulsions. The pain is occasioned by the resistance of the compact tendinous sheath, which prevents its pointing outward, and the matter insinuates itself upward to the palm, where it is felt under the aponeurosis of the palmaris, and, passing under the annular ligament, sometimes reaches the fore arm.

When the disease is, therefore, ascertained, as it may be by the pain in the condyle, the abscess should be

immediately opened, and the incision must extend so far as the matter has penetrated. If the tendon should be sloughy, that portion must be separated; but, in general, a part of it must be taken away; for when the distention is taken off, the wound will close in consequence of the elasticity of the tendinous expansion.

It is sometimes necessary to follow the matter beyond the annular ligament into the fore arm; for a cure can only depend on the freest opening. The best dressings are warm spirituous ones, and the oil of turpentine is well adapted to the complaint.

In the last kind, the abscess is formed within the periosteum, and the pain, as well as fever, are considerable, though not so great as in the preceding, and the characteristic symptom of a pain in the internal condyle of the humerus is wanting. The swelling and tension of the fingers are also less; but the latter are often livid, and covered with dark coloured vesicles.

In this case a bistoury must be introduced at the side of the finger, and plunged deep into the bone, through the periosteum. A slight sanious discharge only, in general, follows; but this gives relief, and the next day it is often more considerable, flowing copiously for some time. Should this not succeed, amputation of the finger should not be delayed.

See Le Dran's Operations; Heister's Surgery; Kirkland's Medical Surgery, vol. ii. p. 269; Bell's Surgery, vol. v. p. 431; Pearson's Principles of Surgery, vol. i. p. 82, &c.; White's Surgery, p. 18.

PARONY'CHIA, (from its supposed virtues in curing paronychia). *Sedum, saxifraga, alsine; saxifraga tri-dactylites* Lin. Sp. Pl. 578, WHITLOW GRASS; is said to be emollient, but is of too little efficacy to be trusted.

PARO'PLÆ, (from *παρά*, and *ὤψ*, the eye). See OCULUS.

PAROPTE'SIS, (from *παρά*, and *ὑπταω*, to roast). Sweating from external heat.

PARO'RASIS, (from *παρά*, and *ὁραω*, to see). An IMBECILITY OF SIGHT. See DYSOPIA.

PARORCHI'DIUM, (from *παρά*, and *ὄρχις*, the testicle). A DETENTION OF THE TESTICLES, in the abdomen or at the ring of the muscles, called *criphsorrhis*, or concealed testicles. Usually about the time of the child's birth they descend into the scrotum; but the time of their descent is very uncertain in different persons, and in the same person both testicles will not always descend at the same time; sometimes they never pass into the scrotum. Mr. Pott observes, that he knows not of any particular inconvenience arising from the detention of a testicle within the cavity of the belly; but its lodging in the groin exposes it to be hurt by accidents. When hurt it may be mistaken for a different disease, and occasion very improper treatment. To which considerations he adds, that there is no kind of disease to which the testicle is liable in its natural situation, but what may also affect it in any or all its unnatural ones. In the first cause related by Mr. Pott, a testicle being detained in the groin of a young healthy seaman, who hurt the part by hitting it against a piece of timber, the tumour, became extremely painful, and was mistaken for a bubonocoele, from which it might have been more readily distinguished by the following circumstances, had not the extreme tenderness of the injured testicle prevented any examination by the touch; and the very hard swelling of the scrotum precluded any certainty

of a testicle being there or not. Mr. Pott adds, that the tumour in the groin did not, like the bubonocoele, point obliquely from the ilium towards the pubes, but lay across the groin, and when the scrotum became soft no testicle could be felt; two striking circumstances to determine the nature of the case. In the earlier part of this young man's life, the detained testicle had been mistaken for a rupture, and a truss had been applied to it. In the second case the testicle was detained in the groin; and the patient was also advised to wear a truss, which he could not bear from the pain it occasioned. At last, when infected with a gonorrhœa, this detained testicle inflamed, forming a hernia humoralis, unfortunately mistaken for a bubo. The tumour, however, was moveable, and the scrotum on that side contained no testicle; two circumstances of importance in the diagnosis. Each patient was cured by the remedies for inflammations of the testicles in their usual situation.

PAROTIDÆ'A, (from *παρωτίς*, the parotid gland). See CYNANCHE PAROTIDÆA.

PARO'TIS, (from *παρά*, and *ὤς*, the ear). The PAROTID GLAND, *epharmā* and *epharsis*; together styled *dioscari*. It is seated on each side in a cavity below and before the ear, between the maxillary process, the zygomatic process, and the angle of the lower jaw. Its duct passes over the buccinator to pierce the membrane of the mouth, near the third dens molaris of the upper jaw. It is a secreting salivary conglomerate gland, supplied with vessels from the temporal artery, with an appendice at the tendinous beginning of the masseter muscle. It is also an inflammation, or an abscess of the parotid gland, considered by Dr. Cullen as synonymous with bubo. See ABSCESSUS PAROTIDIS.

PAROXY'SMUS, (from *παροξύνω*, to irritate). A PAROXYSM, chiefly applied to fever or spasm. Sometimes this term is applied to a crisis, or that more acute exacerbation previous to the solution of the disease.

PARTHENIA'STRUM, (from *parthenium*, tansy). BASTARD FEVERFEW. WILD WORMWOOD. *Parthenium hysterophorus* and *integrifolium* Lin. Sp. Pl. 1402, used as a vulnerary in Jamaica and South America, the country of each.

PARTHE'NIUM, (from *παρθένος*, a virgin; from its use in diseases of young women,) *tanacetum, matricaria*, and *artemisia; achillæa atrata* Lin. Sp. Pl. 1267.

PARTURI'TIO, (from *parturio*, to be in labour). LABOUR; the bringing forth of a child.

Women are generally delivered about the end of the ninth month, or very early in the tenth: instances, however, have occurred of the birth of healthy children, at different periods, from seven to eleven months after conception.

Labours are either *natural*, when the delivery is accomplished by the efforts of nature; *laborious*, when protracted beyond the usual time, or requiring extraordinary assistance; and *preternatural*, when any part besides the head presents, requiring also obstetrical aid. When the period of gestation, at which the fœtus can enjoy independent life, is arrived, either the uterus admitting of no farther distention, the active efforts of a stronger and perfect child, the irritation occasioned by the presenting part on the os tincæ, excite this hollow muscle to contraction. Either of these causes, or all combined, may produce this effect; but difficulties and

objections may be made to all. It is, however, sufficient for our purpose, that in the latter months, some days before labour commences, the tumour sensibly falls down. This, however, sometimes occurs twice, in a few instances oftener, before labour really comes on; and in each, the swelling again rises, not from the foetus changing its position, but from its increase of bulk, or from its assuming a straiter posture. When, however, labour is actually at hand, efforts are made by nature, usually called pains. These, in the beginning, are slight, and the intervals considerable: after some of these efforts the uterus begins to contract, and a glary mucus, sometimes bloody, is discharged from the vagina. The pains then become more severe, return more quick, and continue longer. From the pain and agitation, the pulse is affected, the skin becomes hot, the face reddens, and the mucus is more copiously tinged with blood; the os tincæ opens; its edges grow thin; the membranes, with the waters, dilate and widen the orifice. When the pain ceases each time, the womb rises, but not so high as before; the tumour formed by the membranes disappears; the os tincæ is relaxed, and the diameter diminished; the child falls, by its gravity, upon the lower part of the womb; and the part of the body which presents, may be easily distinguished through the relaxed membranes.

Towards the end of labour the succession of pains is rapid, and the efforts violent: at first the pains usually begin in the small of the back, and terminate about the pudenda; but at this period they are perceived in the umbilical region, pressing with a sense of weight towards the fundament. The tumour formed by the waters distending the membranes below the mouth of the womb dilates the parts, until at length it bursts, and the waters are discharged. If the child's head presents fairly, it stops the discharge of the remaining waters: and the same effort which bursts the membranes often expels the infant; though at other times the interval is long before the delivery of the child. The head of the child having passed the os internum, enters the vagina, which becomes wider in proportion as it shortens; the perinæum is stretched by the child's head, and the frænulum sometimes torn in the passage; the nymphæ are obliterated; and the labia pudendi confounded in the general distention. At length the head forces the os externum, and the body readily follows, with the rest of the waters, mixed with blood. At this last period the woman trembles and is convulsed, but is soon relieved by the expulsion of the child. A calm succeeds, until returning efforts are exerted for the exclusion of the placenta, &c. called *secundines*. Parturition, therefore, demands the concurrence of several agents. The cause and determination of labour is in the womb itself, which contracts, and forces its contents by the vagina, where there is the least resistance; for if from any cause that resistance is insurmountable, the uterus itself is lacerated. The womb is muscular and reticulated; some of its fibres run uniformly parallel upon the inner surface, from the fundus to the neck: others diagonally or horizontally, and so closely interwoven towards the fundus, as to have been mistaken for a muscle destined for the separation of the placenta. The uterus, in short, is capable of dilatation and contraction, acting like other hollow muscles, assisted by the diaphragm and the abdominal muscles.

The irritation which the womb suffers at the end of pregnancy is supposed to be the chief cause which determines its action; for before conception its cavity is triangular and flattish; the angles very pointed; and the uterus consequently more thick in the middle, and at the fundus; apparently consisting of fibres, coiled and doubled, as it were, in reserve, to expand with the gradual development of this organ. The expansion once begun, continues with the growth of the foetus until all the fibres are unfolded; so that when farther stretched, pain, contraction, and labour, follow. The prelude to labour consists of gentle efforts of short duration, gradually and almost insensibly expanding the orifice or os tincæ. When this is sufficiently dilated to admit the head, the pain remits, but is renewed when the head enters and extends the vagina. As the neck of the womb varies in length and thickness; as the development of its fibres may be retarded or accelerated by various circumstances; and as the increase of the child may be faster or slower; it will be obvious that the birth will be accelerated or protracted, at least within certain limits. However small the dilatation of the os internum, it will occasion a separation of the chorion from the uterus, rupture the communicating vessels, so that the fluid which circulated between them will escape, and become the source of a mucous discharge at the first period. If the membranes are strong, their progressive separation continues until it arrives at the borders of the placenta, where the adhesion being greater, the bag generally bursts; though in rapid labours, the child and the membranes and the secundines have been discharged together.

When the vertex first presents, as is the case in a natural labour, one ear is turned to the pubis, the other to the sacrum, so that the forehead must be towards one side of the pelvis, and the occiput to the other: thus the broadest part of the head is in the widest of the pelvis; so that, when compressed and propelled, the vertex descends into the lower part of the ischia, where the pelvis is narrower at the sides. The forehead now turns round into the concavity of the sacrum, and the vertex towards the pubis, a position in which advantage is still taken of the width of the pelvis: it is then pushed forwards, turning as on a fulcrum, until the forehead rises gradually from under the perinæum.

With respect to preternatural presentations, see *PRÆSENTATIO*.

Natural labours are, we have observed, when the head presents and is delivered by common pains, requiring no other assistance than what is needful in saving the perinæum from being lacerated. Laborious labours, called also lingering, non-natural, and difficult, are when the head presents; but labour pains being insufficient, some safe contrivance becomes necessary to bring it forward. These are of two kinds; when delivery is effected without destroying the child; or when the head of the child must be opened, that its size may be lessened to adapt it to the passage. Preternatural labours are when the legs or breech are delivered first, the body and head last; or when different parts of the body present, except the head, or the head presents in such a situation that the child must be forced back, turned, and delivered by the feet.

Some pains come on about the time of labour without assisting the progress of the child, and are called false

pains, occasioned by spasm, from the child pressing on some nerve, from costiveness, sometimes from plethora. They are known from the os tinæ continuing shut during the pains. A clyster, followed by an opiate, will relieve them; but true labour pains, after a little interval, are promoted by opium. False and true pains sometimes attend at the same time; but an opiate will relieve the former without impeding the latter. The prognostics are taken from the age, the state of health, and the temperament of the patient; from the force, duration, and recurrence of the pains; from their effect in dilating the os tinæ; from the rapidity with which the child follows the rupture of the membranes; from the bulk and posture of the child.

Until the woman is likely to be soon delivered, she may be up, or in bed; but at the time the most convenient posture is on her left side upon a bed, with the knees drawn up. If asthmatic, the head may be raised, or they may be delivered in a sitting posture.

The assisting powers in a natural labour are particularly the diaphragm, and abdominal muscles. The feet should be placed against a fixed object, to assist the abdominal muscles; and a strong inspiration made at the beginning of each pain, to fix the other extremities of the muscles. A deep inspiration, or an effort to strain, except what nature excites, should be avoided, especially as the pain goes off, since it retracts the fœtus, and lessens its force in distending the parts.

When the child's head forces strongly against the perinæum, which is the consequence of the external orifice not being in the axis of the pelvis, it should be supported by a gentle pressure from the hand with a napkin, during a pain. The palm of the hand should be firmly, but not with too violent pressure, lest inflammation should be the consequence, fixed against the tumour, repressing the passage of the child backward, and endeavouring to conduct the head to the aperture, when the vertex will pass from under the pubes and the forehead, rise over the distended perinæum, which, with a little assistance, will slide over the face.

This part of the process is now completed. The body is not immediately excluded; but after a few moments respite, the whole is gradually concluded, for the body is born without difficulty; except that, of a large child, the shoulders pass with less ease.

After the parts are cleaned and dried, the patient has a little respite till the placenta begins to separate. This process was some time since, under the direction of Dr. Hunter, entrusted wholly to nature; nor was art suffered to interfere, though a day or two elapsed before the separation took place. This was an error in many respects. The mind was kept in anxiety, for the patient was not completely a mother till restored to her former state; nor, till the circulation in the uterus was free, was there any probability of the flow taking place to the breasts. Modern practitioners have, therefore, neither hurried on the separation, nor delayed it many hours, should not nature complete the business. It is usually an operation of nature without assistance; and after about ten minutes from delivery, pains begin; the cord, if kept tense, is elongated, the abdominal tumor subsides into a rounded ball, sinking gradually lower, and the placenta, with little difficulty, is brought through the vagina. If the labour has been long and tedious, or the patient previously debilitated, the contraction of

the uterus, which produces the separation, takes place slowly. We must then wait; and if in five or six hours, gently pulling in the interval by the cord, it does not advance, the hand, guided by the funis, must be introduced into the uterus, and the edges of the placenta separated around. It then soon comes forward, for the centre is first naturally loose. The cake is distinguished from the clots which usually surround it, by its being in the centre of the funis, by its firmer consistence, and by its convex puckered feel. When flooding is violent, the separation must be quickly accomplished; and when the contraction of the uterus is irregular, reducing its form to that of an hour glass, the stricture must be steadily dilated; a work of no little difficulty. In general, the separation should be left to nature; but should hæmorrhage and convulsions occur; should the separation, notwithstanding every effort, be delayed for more than twelve hours; the most steady but determined mode of separation should be adopted. Some authors indeed advise a longer delay, and even to wait the effects of a dose of opium; but this has never seemed, in our practice, to facilitate the contraction of the uterus. We may just add, that after dry warm linen has been put on, all impurities removed, and a little well boiled gruel given, the woman should be left perfectly quiet, the child put by her side, and the room, with a moderate light, kept perfectly tranquil.

LABORIOUS LABOURS form an object of far greater intricacy and difficulty. In the whole practice of medicine and surgery no subject requires greater firmness of conduct, more profound reflection, nor more sound judgment. Delivery may be protracted by causes depending on the mother, the child, or the secundines.

In general, laborious labours are owing to increased resistance, or diminished or irregularly exerted powers. We find an increase of resistance from the rigidity of the parts, the frequent consequence of advanced life; scirrhus or polypous tumours; accumulated water and fæces in the bladder and intestines; a stone in the urethra; a prolapsus of the vagina or rectum. To which some authors have added an obliquity of the uterus; but this cause has not occurred to the most experienced practitioners since the time of Deventer, who first suggested it; an anchylosis of the os coccygis, and a peculiarly short funis, neither of which seem for any considerable period to protract delivery. To ascertain the cause will suggest the best means of relieving the patient; but, when the impediment cannot be at once removed, if the accoucheur has patience, takes a little blood from robust and plethoric women, gives an injection, followed by an opiate, he will find the most ample assistance from the powers of nature.

The powers of the mother are diminished by general or local weakness. General debility, however, while it lessens the power, often in a greater degree diminishes the resistance, and in the last stages of hectic, children are often born, almost without a pain. The local weakness is a torpor of the uterus, by which it fails to contract, or contracts irregularly and inefficiently. Torpor often arises from over distention, sometimes from a want of irritability in the womb; but the former continues no longer than the time when the waters escape; though this part of the process must not be hastened, as we shall find their early discharge one of the most common causes of tedious delivery.

Other causes of delay, depending on the mother, are floodings, epileptic fits, spasms or colic. Floodings are always dangerous; but, when they remit during pains, we may check the discharge by breaking the membranes. If they increase during pains, they probably proceed from the placenta being fixed to the os uteri; and this situation is most alarming. As soon as it is ascertained, which may be done with the finger when the os tincæ is a little opened, and the spongy feel of the placenta presenting points out the cause, the hand must be passed with the most steady firmness, as quickly as is consistent with the patient's safety, to bring down the feet and deliver the child. It is seldom that the forceps and crotchet can be used in such cases. Spasms and colics are removed by opiates; and for the management of epileptic fits, see CONVULSIO and PREGNANCY.

The conduct of the attendants, in time of labour, often renders it tedious. Any sudden intelligence of an interesting kind, whether pleasing or disagreeable, the appearance of danger, a look of uncertainty or peculiar anxiety, will at once stop the pains and the progress of the labour, often inducing worse complaints. Every thing in the room should be tranquil, easy, and cheerful; the spirits should be supported by the most favourable prognostics, by holding out every promising symptom to view, and palliating or concealing whatever may be of a different complexion. The strength should also be supported; and until the appearance of a forcing accompanies the pain, the idea of labour should be kept at a distance. The early pains, styled grinding, which are necessary for the dilatation of the parts, must be soothed by opiates; the bowels kept soluble by clysters, and the strength preserved by avoiding fatigue. The woman should be allowed to walk, sit still, lie down, as is most suitable to her own feelings.

The bulk of the child is sometimes a cause of laborious labours; occasionally the firmer ossification of the head, its less favourable position in the pelvis, the breadth of the shoulders, or an enlargement of the whole body in consequence of mortification. If the pelvis is well formed, these causes occasion only a temporary delay, and nature will accomplish her purpose.

The secundines are often a cause; and a very frequent one is too great rigidity, or the contrary state of the membranes. In a well formed pelvis, and a strong healthy young woman, the child, covered with its membranes, is often at once excluded, when they are too firm; and great inconveniences arise from the flooding in consequence of such a sudden discharge. When too lax, they are ruptured on the slightest touch; and, unless the uterus has been previously over distended, the pains cease, the os uteri contracts, the parts become rigid, and labour is peculiarly tedious, often requiring the use of the vectis or the forceps. When it is necessary to break the membranes, the nail is the safest instrument; but it is necessary to avoid mistaking the child's head, covered with mucus, for them. They are, in general, too tender, and the accoucheur should be cautious of breaking them prematurely, so that in touching he should avoid the moment of a pain, when they are often forced down.

The funis umbilicalis, when too long, protracts labour, especially if twisted round the child's neck. It is seldom necessary, however, to divide it; and when the

head is born, it may be easily slipped over. When too short, it does not protract labour, but pulls the placenta early in the progress, occasioning a partial separation, and the death of the child, unless it soon follows. To divide it during labour is dangerous; and the operator may, with propriety, hasten the birth. Such cases, however, occur rarely. If the funis protrudes before the child, it should be returned before the labour is so far advanced as to fill up the passage; for, unless this be done, if the labour is slow, the child is lost. If this cannot be done, the forceps must be used to hasten delivery, for to turn the child in such circumstances, is to expose it and the mother to the greatest danger.

Though we have represented the powers of nature as able to overcome the greater number of obstacles, yet some are in themselves irresistible, and the woman sometimes sinks. Both mother and child would therefore be lost if additional assistance could not be procured. Various means have been contrived for this purpose, viz. the fillet, the lever or vectis, and the forceps. The fillet is with difficulty applied, except when the child's head is so low that the hand of the operator would supersede its use; nor is it without danger to the child, if the force used be considerable. The lever, the supposed invention of Roonhuysen, was probably, as Dr. Bland, in an excellent paper in the second volume of the Medical Communications, has shown, only a single blade of Chamberlen's forceps, and is, in his opinion, a very convenient instrument. A great advantage is, that it is perfectly safe, and may be easily concealed; a circumstance of no little importance in situations where the mind is so easily agitated, and where agitation is attended with such dangerous consequences. Its inconvenience is said to be, that its fulcrum is the symphysis of the pubes, and that there is danger from bruising the meatus urinarius, of producing inflammation and mortification. We suspect, however, and we are countenanced in this suspicion by some respectable authors, that these disadvantages result from its abuse. When the head of the child is confined at the upper brim of the pelvis, or rather when the head has partly passed through it, the great impediment is at the symphysis, and the great object to bring the occiput below it. In this case, the fulcrum of the lever is not at the symphysis, but at either ramus of the pubis, where there is room for its introduction. On the other hand, the fulcrum of the forceps, when the blades act singly, is at their junction; which would give this instrument a decided preference were there always room for the introduction of both blades, or were the idea of an instrument less formidable to the patient. Either, however, may be occasionally employed, and each is a valuable assistant in labours preternaturally delayed.

A different instrument, though with the name of the lever, is recommended by some of the ablest practitioners; but it is rather an extractor. It is the vectis or lever of Lowther (see Plate), and is used without any pressure, either on the rami of the pubes or the symphysis. It acts slowly and safely; but its chief advantage, in cases of emergency, is its bringing the head within the reach of the forceps, an instrument which should not be trusted beyond the guidance of the fingers. This lever rests on the occiput, and, like Roonhuysen's, with the difference of action mentioned, brings the head down till the face is turned into

the hollow of the sacrum. Its situation must then be changed, and the instrument applied over the chin. The practitioner, in using either, should keep his left hand under the perinæum, for the natural pains, when the head is freed from the edge of the pubes, often propel the child rapidly; to which we must add, that the stimulus, from the introduction of the instrument, often increases them.

The shape of the forceps is also seen in the plate: indeed words will not adequately describe them. They should not, we have said, be trusted beyond the reach of the fingers, and the short forceps should therefore be only used. These cannot be applied till the head of the child is nearly or completely within the brim of the pelvis. The blades are to be placed over the ears, and the convex side of the instrument must be towards the hollow of the sacrum. The handles must then be cautiously brought together, and the forceps locked, which, if the instrument is properly applied, is no difficult task; but should it prove so, the position of either blade is faulty, and it should be altered. When locked, the handles are confined by a fillet. In the employment of every instrument, it should only act during a pain; and, in the more considerable intervals, the fillet should be loosened, that the pressure on the child's head may not be too long continued.

In considering the causes of laborious labours, we mentioned the deficiency of the propelling powers, or the increase of resistance. The unfavourable position of the child's head is a most frequent cause of this increased resistance, and it is one of the causes to which the lever is particularly adapted.

The unfavourable position alluded to, is the presentation of the fontanelle, instead of the vertex (more strictly speaking, the anterior portion of the fontanelle rather than the posterior), the face and the forehead. In the first case, the face is frequently turned under the symphysis of the pubes; and, in the two latter, the chin is placed indifferently towards the pubes or sacrum, most commonly towards the pubes. It is not because the face or the forehead presents, that the case is styled laborious, for in strong, robust constitutions, these presentations occasion little delay; but because they afford increased resistance, which the woman's powers cannot overcome.

When, therefore, such cases prove laborious, there is some doubt whether the lever or forceps is applicable. In general, when the head is advanced about one-third only, or one-half, through the pelvis, the lever is the most useful instrument, and it is introduced over the occiput, to draw down that part of the head which occasions it to occupy much less space than when the face presents. This operation is greatly assisted by raising the chin with the other hand. In some cases, the resistance is increased by a slight diminution of the space at the brim of the pelvis. The lever of Dr. Lowther may be often used in such situations. When convulsions or hæmorrhages require expedition, to save the life of the woman, the lever should not be trusted. In other cases of laborious labours it is in no respect superior to the forceps, though, in many of the instances, equally useful.

The cases in which the short forceps are applicable may be divided into those where the face is in the hollow of the sacrum, to one side of the pelvis, or under

the symphysis of the pubes. In the first case, one blade of the forceps, guided by the finger, is to be carried forward over one ear, and the other in the same direction on the opposite side. The line of traction must then be first downwards and backwards to disengage the occiput, next upwards and forwards to disengage the chin from the breast. In the second case, the blade which is to pass under the symphysis of the pubes is to be first introduced; and if the face be to the right hand, the right hand blade must pass under the symphysis. The other blade is introduced at the opposite side; and the action of the instrument is not only directed downwards, but in part so as to turn the face to the hollow of the sacrum. In the third case, the blades are to be applied as in the first, but the line of traction should be upwards and outwards, to bring down the occiput before the face.

The safest instruments, however, should not be rashly employed; and it requires no less of skill than of steadiness and resolution, to determine the proper period of our active exertions by their means. The accoucheur is attacked equally by the impatience of the sufferer, and the clamour of the female attendants. To suffer her to die undelivered would fix an indelible stigma on his character; to employ instruments rashly and unnecessarily would be equally discreditable; and should the woman at last die, the disgrace would be equal. The accoucheur should, therefore, carefully weigh the state and constitution of the woman with the work which remains to be performed. Should the pulse continue firm, should the patient be able to take nourishment, however slight and attenuated, should she have intervals of easy repose, he may still wait, whatever is the length of time. Yet he should cautiously attend also to one circumstance, whether nature endures only without exertion, or whether the intervals of repose are alternated with periods, however short, of pain. While such periods are observable, and the strength is in other respects preserved, he may safely wait; and he may be assured, that a comparatively rapid and easy recovery will amply repay his patience and anxiety. When, however, the periods of exertion are few and slight; when the pulse begins to flag, the features to sink; when nourishment is taken in with difficulty, and fainting comes on, we must hasten our exertions to preserve two lives. Should we not succeed with the lever or forceps, and it be at last probable that one must fall, may we not depart from the general rule, and attempt the delivery with the long forceps? It is the less desperate step, but should only be taken with those well acquainted with the use of the former instrument. For the particular directions in the application of the forceps, see EMBRYULCIA.

Should we, however, fail, the last desperate step remains, to open the child's head, and thus to lessen the diameter of the cranium, and afterwards draw it down with the crotchet; an instrument resembling the forceps, but terminating in a hook, sharp at the point, and bent to an angle most convenient for holding (see plate of the Instruments of Midwifery); and we may here add, that the references to the old instruments in the article EMBRYULCIA, q. v. should be expunged, as it was judged unnecessary to represent objects now no longer used.

The crotchet must not be employed while there is any possibility of delivery by the powers of nature, the

lever, or the forceps. The cause of this impossibility is the smallness of the pelvis, or its distortion; for in no instance, in a well-formed pelvis, is the size of the head an insurmountable obstacle. The diameters of the pelvis have been measured with geometrical precision; but in the living body we cannot be exact, nor can we determine it often within a quarter of an inch. In general, the great difficulty is at the brim; and if its diameter is within two inches, the danger is considerable. The smallest space through which a child has passed is about an inch and three quarters. When the capacity of the pelvis is so small, after every obstacle from accumulated urine or fæces has been removed, when the lever and the long forceps have failed, embryotomy must be attempted.

The *perforator* (see plate) must be first introduced, guided by the fingers to the child's head, and in its closed state must be pressed into it so far as the rests. The blades must then be gradually opened, so that the points shall be in the direction of the largest diameter of the pelvis, guarding them with the fingers of the left hand. That these shall be sufficiently disengaged, an assistant should support one ring of the handles. By opening and shutting the perforator, if necessary, in different directions, a large hole is made in the cranium, through which, by a crotchet or a small scoop, the brains may be extracted. The rough edges of the bones should be removed, or covered with the remaining pericranium. Experience has shown that the extraction of the child, now that the bulk of the head is lessened, may be delayed from twelve to twenty-four hours; for the injurious pressure being removed, the patient recovers strength by a little sleep, and by taking nourishment, while the child, less rigid by supervening putrefaction, passes more easily. The crotchet, guarded by the fingers, must be introduced at the aperture formerly made, and fixed to any portion of the side or basis of the skull which it meets. The force employed to extract the remains of the child must be steady and gentle; if any pains occur, the efforts must be synchronous, and co-operate with them. If the instrument loses its hold, it should be carefully again fixed, guarded with the fingers, as before.

When the superior part of the cranium is thus brought down, the instrument may be more securely fixed in the foramen magnum, or on the outside. In many cases, the force used must be considerable, and the natural turns imitated to accommodate the larger diameter of the head to the greater space in the pelvis. When the shoulders or the sternum cannot pass, the arm has been taken off at the shoulder joint, or the contents of the chest evacuated by means of the crotchet. In general, however, where the head has passed, the shoulders do not form an insurmountable obstacle; but where the cranium must be in part destroyed to secure its exit, the shoulders may be impeded. Should the cavity of the pelvis not exceed an inch, or at least be within an inch and a half, the CÆSAREAN SECTION, q. v. is the only remaining expedient which offers any probability of preserving life.

Yet we ought not to pass over a confident proposal, not offered as a hint, as a suggestion, as a probable means, but at once ushered in with the most splendid encomia; honoured by a medal, by a pension, by accla-

mations, which all Europe was expected to join; we mean the division of the symphysis of the pubes, by M. Sigault. The idea was suggested in 1768, successfully executed, it is said, in 1777. The new operation was seized with avidity by the enthusiasm of the inventor's own nation; praised by Camper, and performed at Wurtzburg and Dusseldorpe. First experiments, by some fatality, we have said, frequently succeed, and the inventor is sure to find his own plans infallible. It was not, however, an idea wholly new. The ancients suspected that a relaxation of the ligaments probably took place in labours, to facilitate the delivery; and subsequent authors had hinted at the necessity of the containing parts yielding as well as the contents. Pinæus had expressly mentioned their division as parts of beings less noble, compared to the boys, which were thus prevented from seeing the light. We must not, however, enlarge on the subject. It has been repeatedly tried and abandoned. The space gained was found to be inconsiderable, particularly at the brim of the pelvis, where the contracted space was most sensibly felt. It did not preclude the use of the scissors and crotchet; and was, in general, equally fatal to the mother and child. See Osborne's Essays, and Hamilton's Outlines of Midwifery.

PRETERNATURAL LABOURS are those in which any other part besides the head presents, and is generally first excluded. In the advanced periods of gestation, the child, from its increased bulk, is confined by the uterus, and struggles with difficulty in its narrow circle; but at an earlier period he is more at large, though with less power over his voluntary muscles. To this period, however improbable, the preternatural position has been attributed; and, as subsidiary causes, the quantity of the liquor amnii, the size of the pelvis, and the length of the funis, have been enumerated. Any violent agitation of the mother has been also considered as a cause, and her peculiar sensation, in such circumstances, considered as a proof of its action. Yet neither seems to explain satisfactorily the change of situation. While the fœtus has space in which it can move, it is apparently incapable of voluntary motion; and, if there is room for a change of position, there is room also for the recovery of its former station. We do not seek for a cause of a long, a short, or a knotted funis; for the uterus expanding to the right or left side; for the placenta fixing to the fundus, sides, or mouth of the womb. Why then must we explain the situation of the fœtus? Are we sure of satisfactorily explaining the natural presentation? There is reason to suppose the position of the child to be unnatural, if the pains are weak; the membranes protruded like the finger of a glove; if no part of the child can be felt, when the os tincæ is dilated; or if the part felt be small, irregular, and not strongly resisting, like the head. If the fæces are excluded, the breech most probably presents. We form our prognosis, in such circumstances, from the constitution and shape of the woman, the bulk of the child's body, and the manner of presenting; from the time that has elapsed since the breaking of the membranes; for, in the same proportion, the child's body is more firmly fixed in the pelvis, and from the different circumstances, which would be a source of alarm in other labours. In general, in such cases delivery is dangerous.

The varieties of preternatural labours are, first, when one or both lower extremities present; including, in this enumeration, the breech; secondly, when the child lies across the pelvis, offering the shoulder, side, back, or belly; thirdly, when either one or both arms present.

Authors usually commence with what are styled the footling cases, since the others are reduced to it, and they are the easiest as well as the most simple forms of preternatural labours. They are styled *agrippian*, either as *aggre partum*, or from the tale of Agrippa having entered the world in this posture. The case is easily understood; the shortness of the toes, the projecting heel, and the weight of a foot, will distinguish it from the hand.

In this case we wait, as in natural labours, till the presenting part reach the os externum. The woman is then placed on her side, with the breech towards the edge of the bed, and when the operator can take hold of one leg, he should gently draw it forwards, moving it from pubes to sacrum during the pain only. In the interval, the os externum and the protruded limb should be covered with a warm cloth. When the foot is without the os externum, the other leg should be drawn down; and when within reach, it will be safer to draw first with one, and afterwards with the other leg, than with both at once; as the parts are thus more distended, and better prepared for the passage of the shoulders. When the legs are born, they should be covered with a warm cloth, without concealing the toes, which afford the necessary directions for turning the body. These should be turned to either side, and if directed to the back or belly, a little before the breech advances to the os externum, the legs should be covered with a warm cloth, and pushing a little upwards, the toes should be steadily and gradually turned towards either sacro iliac ligament. This is seldom accomplished during one pain. As the breech advances, the operator has a firmer hold, and he must move the child a little from side to side, pressing towards the perinæum. When the navel approaches, the umbilical cord should be gently brought down; and when the cord is compressed by the os tincæ, the operator must hasten the operation. In this mode of delivery the arms are drawn up by the side of the head. At this time, then, the child, resting on the arm, or one hand of the operator, is to be drawn a little aside, to afford room for the passage of a finger or two on the opposite side over the shoulder. The arm is by these fingers to be drawn down obliquely over the breast, bending the fore arm. The other arm must be brought down in the same way. The woman may now rest for a little while; and after a pain or two, the head, in many instances, is excluded. If it is not, and the woman is much exhausted, the remainder of the process must be accelerated, as the child will be otherwise lost from pressure on the cord. The pulsation and the woman's strength will determine the proper period of waiting. When it is necessary to deliver the head, the child must rest on the arm of the operator, and two fingers of the hand on that side be passed into its mouth to draw down the lower jaw; while pressing on the shoulders with the other hand, the accoucheur, rising from his seat, must endeavour to turn the face into the hollow of the sacrum, and then draw in a direction from pubes to sacrum, with a

VOL. II.

steady force, raising and depressing the head till it begins to yield. The face will then descend from the hollow of the sacrum, and the occiput be brought from under the pubes by a half round turn. During the whole time an assistant must press on the perinæum, and the operator coincide in his exertions with the pains.

If the mouth cannot be reached, a pressure should be made on the lower jaw, with great caution, as this bone is very tender; and the convolutions of the cord round the child's body or neck, if possible, disengaged. If the feet are not pulled down too early, the contraction of the os tincæ seldom proves an insurmountable impediment to the delivery of the head. By a little delay, where sufficient strength remains, the head is delivered, though for a time it resisted all attempts. In natural labours, the upper part is exposed to the pressure, and it yields easily: in these cases the firmly ossified basis which first presents is incapable of altering its shape; though when it has begun to pass, the superior bones yield, and facilitate the remaining part of the operation. If we find the delivery hindered by the very large size of the head, or a size greatly disproportioned to the pelvis, and perceive that there is no longer room for delay, if we would preserve the mother; its contents must be evacuated by the perforator introduced at the basis of the skull, and the head at last brought forward by the blunt hook or crotchet. In general the forceps are of little use, for a head which can be brought forward by these may be delivered by a very little assistance to the powers of nature.

If one leg should be entangled by catching on the pubes, it may be easily brought down; but if folded along the child's body, it should be left to pass down with the breech and body. When one or both knees present, the legs often cannot be brought down till the breech be slightly raised and pushed gently back into the pelvis. If the feet should offer with the breech, the latter should be gently pushed back.

When the breech presents, the child's breast may be towards the pubes, sacrum, or either side of the mother. The breech may be easily distinguished by the touch, and is rendered probable by an early discharge of meconium. In each case the delivery should be left to nature, till the breech and feet have advanced beyond the os externum. In the two first cases the labour must be then managed as directed, turning gradually the child to accommodate it to the varying diameter of the pelvis. The last is more simple. In general there is less inconvenience, danger, and pain, in suffering the child to come forward double, than to push it back and turn it. The pains, in such cases, are usually more violent; and, after some continuation, should they remit, and the strength lessen, the parts will be better prepared for the more active exertions of the operator. Delay is, however, inadmissible when the mother's strength is inconsiderable, the pains slight and inefficient; when the child is large, the pelvis narrow, the umbilical cord compressed between the thighs of the child, and in cases of flooding and convulsions. In such circumstances the feet must be brought down as soon as possible.

The navel string most commonly falls down where the fore parts of the child are opposed to the symphysis of the pubes; and if the breech be far advanced, and

P

the pains strong, it cannot be reduced, nor can the child be pushed back. In such cases the child can be preserved only by the labour coming on rapidly: to attempt bringing down the feet would greatly endanger the mother without saving the infant. In breech cases, care must be taken not to mistake the buttock for the shoulder, and to touch with caution, lest the genitals may be injured.

When the child lies across the pelvis, offering the arm, shoulder, side, back, or belly, the powers of nature are insufficient for the delivery. If the practitioner is early aware of either presentation, it will not be difficult to turn; but if the waters have been for some time evacuated, and the uterus is contracted round the body of the child, each case is highly dangerous. Fortunately some little water is often retained, and then turning is not difficult.

As we have often mentioned this operation, we shall now give a few simple directions for its execution, as in the cases before us it is indispensable. We must, in general, wait till the *os tincæ* is so much enlarged as to admit the hand of the operator freely; and till the pains have in a great degree abated. We shall then be able to ascertain, with some certainty, the position of the child, the shape and dimensions of the pelvis. The waters should, if possible, be preserved; but if they should break, the hand may be immediately passed to retain some portion of them, and the turning may be immediately executed. Should this, however, be impracticable, a large dose of opium should be given, to procure some relaxation of the contraction previous to the attempt. No other narcotic has been tried, though several, particularly the belladonna, seem to have greater power in diminishing irritability.

The hand should be introduced with the fingers closed in a conical form, after being well lubricated with pomatum, steadily and resolutely, during the remission of a pain, on the fore parts of the child, as the feet are usually folded on the belly. In pushing back any part of the body of the child the hand should be expanded; and though, on the introduction of the hand, the remission of a pain be waited for, the efforts in drawing the child down should co-operate with those of nature. If both legs are within reach, both should be brought down; and should there be reason for concluding the child to be dead, as this is by no means certain, the operation should be conducted with the greatest tenderness. When it is necessary to pass the hand high up in the uterus, it is more convenient to avoid the projecting sacrum by passing it on one side; and if the presenting part opposes its introduction, it should not be pushed back till we have tried to raise the hand, and pass it round to the other side, where the space may be greater. When both feet cannot be brought down, one will be sufficient, and we thus obtain room to search for the other; but should it be impracticable to bring down the other, the delivery, by a little care, may be completed by means of one only.

From the rashness or unskilfulness of the operator, the putrid state of the child's body, the size of the head, or the narrowness of the pelvis, the head is sometimes separated from the body. When the child is known to be putrid, no great effort should be exerted till the finger is fixed on the lower jaw. If already

separated, it may be sometimes extracted by the fingers in the lower jaw, or by the forceps; pressing, in either case, on the woman's abdomen, to keep the head steady. Should these methods fail, it may be opened by the perforator, and at last extracted by the crotchet.

When the arm presents, a skilful practitioner may often prevent its coming down, or return it when it has protruded. If the shoulder is, however, locked in the pelvis, the hand can be introduced into the uterus, by the side of the arm; and when the feet are brought down, the arm of course returns. When the hand is introduced, it is conducted by the breast and belly of the child to the feet. If any difficulty occurs in finding them with one hand, the other will often succeed. But if the shoulder and head prevent the introduction of the hand, the presenting part must be raised or shifted to one side, that one or both feet may be taken hold of, which, by gently pulling while the shoulder is raised, may be brought so low as to be surrounded with a noose, and then the delivery will be easily completed.

The *shoulder*, when *presenting*, feels more bony, hard, and irregular than the buttock; and when the *os tincæ* is dilated, the arm often comes down. They are then together locked in the pelvis, and turning will be more difficult and hazardous; unless the child is small, the pelvis unusually capacious, or the hand pressed close to the side of the head, the arm and head will not be excluded together. By attempting to bring both forward the latter is often torn off.

The side, the back, and the belly, are easily distinguished; and when they present, do not come beyond the brim of the pelvis, so that turning is by no means difficult. When the case is ascertained there should be little delay, for the child should be turned before the uterus is too closely contracted round it.

A case of peculiar difficulty sometimes occurs, when the child lies straight in the uterus, with the feet above, the arm and shoulder presenting, and the head resting on the pubes, or on one side of the brim of the pelvis, while the uterus is contracted around it. In this case, the arm must be reduced by passing the hand along it till the operator reaches the shoulder, which he must shift a little to the opposite side, bringing the head more nearly opposite the *os tincæ*. Should this method fail, the fore arm may be pushed up at the elbow, and in bending it the joint must be carefully attended to. When the arm is reduced it must be kept in the uterus till, at the next pain, the head is brought down and prevents its return; for if this be not done, the arm will be protruded as often as it is returned.

If the *os tincæ* be not sufficiently dilated to return the arm, and if the head by the labour pains is carried still farther to the side; while these are violent and almost unremitting, every attempt must for a time be given up, and a very large dose of laudanum administered. The former efforts may be then repeated, or by fixing a noose to the child's arm, the head may be drawn by this means nearer the *os tincæ*, or more space may be gained for introducing the hand. This is the very judicious and probable plan recommended by the late Dr. Hamilton, by which he repeatedly succeeded. Should this fail, as the head is without the reach of the perforator, the crotchet must be fixed on the trunk or thorax to bring down the breech or feet, and the delivery may be then accomplished, as in these cases. This practice

is, however, only justifiable when the pelvis is faulty, or the mother's life in imminent danger.

Dr. Denman has remarked, that when the arm presents, if it is drawn down, and the patient left to the efforts of nature, the child, by the action of the uterus, will turn as on an axis, the breech come down, and the arm be necessarily drawn back. This, however, will only be the case when the child is dead; and the method recommended by Dr. Hamilton will often save the life of the child; nor has this spontaneous evolution succeeded within the observation of other practitioners.

When both arms present, the case is not more difficult than when one protrudes. They prevent the head coming down, and may be either reduced, or there is room to bring down the feet. It is possible, however, that the head, with a hand on each side, may be locked in the pelvis. If the woman's strength begins to decay, for by delay in a well formed pelvis the delivery may be completed by the efforts of nature, the lever and the forceps must be tried; and if these fail, the only resource is the crotchet.

When the head is locked fast at the brim of the pelvis, and the uterus is contracted round the body of the child, a tumour is perceived on its head, if it be living, but not, if dead. When a child is locked fast, the face is usually towards the sacrum. Sometimes the face of the child is turned upward, from its progress being stopped by the sagittal suture resting on the brim of the pelvis. In a case of this kind Levret advises passing a fillet through the perforation of each blade of the forceps, before they are introduced. When the handles are fixed, the ends of the fillets must be tied together, so as to hang down in a noose, about six or seven inches. If, then, the handles are raised with the right hand, and the fillet pulled down with the left, the forceps will be converted into a lever of the third kind, and bring the head into the hollow of the sacrum. This is, however, only practicable with the long curved forceps.

After the delivery, the accoucheur should pass his hand into the uterus, or press on the abdomen, to examine whether another child may not remain. Should the child, with the waters, be in a small proportion to the bulk of the abdomen; should the umbilical cord, after being divided, continue to bleed beyond the usual time; labour pains recur; a tumour remain a little below the scrobiculus cordis, he should certainly introduce his hand into the uterus; for these circumstances are often, from different causes, fallacious. When a child is known to be in the uterus, and natural pains come on, the membranes soon force down. If the head or breech present, the membranes may be broken, and delivery will soon be completed. If the feet present, they should be immediately taken hold of and brought forward. As in such cases the uterus is usually over distended, the pains are often slow and inefficient, the woman agitated in uncertainty, and weakened by flooding; so that it is better to pass the hand, break the membranes, and expedite the delivery. Cases of twins are uncommon; of triplets and quadruplets proportionally more rare. A very few instances have occurred (Garthshore, Philosophical Transactions) of five at a birth. It is singular, that of far the greater number of twins and triplets, the father has been in an infirm state of health.

When the labour is completed, the linen, &c. must be changed, and the woman left to repose, after having taken some gruel, seen her child in health, which should be placed at her side. She may then be left to rest for two or three hours; while the room is kept cool, airy, and with the utmost tranquillity around. It has been usual to give various medicines, particularly spermaceti, "the sovereignest thing on earth for an inward bruise;" but this, and all other medicines, are now disused. Should there be inflammation from bruises, fomentations or astringent applications may be used; and should not a stool occur in twenty-four hours, a clyster or a little castor oil may be given. Should after pains, as they are called, be troublesome; pains arising from spasmodic contractions of the uterus in consequence of the discharge of clots of blood, an opiate may be given, and repeated, if necessary.

The peculiarly irritable state of a woman in child-bed renders the continuation of the utmost tranquillity and caution necessary till after the third evening. It may afterwards be gradually relaxed. The secretion of milk will then have begun; the period of the formation of fever is passed; the irritability, the constant attendant of changes in the balance of the circulation, greatly diminished. Popular prejudice has prolonged this caution to the ninth day, and in some families it is still common to confine the woman to her bed on that day; and, indeed, such is the prejudice which fills every female mind respecting its importance, that from apprehension alone some little irritation is occasionally observable on it.

The child, from the delay, the pressure on the head, or the cord, is sometimes born apparently without life. In this case the cord is allowed occasionally to bleed a little; air is blown into its mouth, closing the nostrils; embrocations of warm brandy applied to the pit of the stomach, and a clyster thrown up. A tobacco clyster sometimes given, or tobacco smoke injected into the rectum, seems, from the narcotic quality of the herb, rather injurious than useful. A little soap is always at hand, and will form a more convenient laxative in this form.

See Smellie's, Le Motte's, Denman's, and Hamilton's Midwifery. See ABORTIO MENORRHAGIA, PRÆSENTATIO PERITONITIS.

PA'RTUS, (from *partio*). See PARTURITIO.

PARU'LIS, (from *παρεν*, and *αλον*, a gum). AN INFLAMMATION, BOIL, OR ABSCESS IN THE GUMS. (See ABSCESSUS GINGIVARUM.) From similar causes, viz. decayed teeth, excrescences of different consistences, from the fungus to the wart, grow on the gum. A decayed tooth, if suspected as the cause, should be removed, and the excrescence removed by the ligature or the knife. After the operation, the wound should be allowed to bleed for some time; after that astringent washes, at first more strong, to act as styptics, and at last milder, to heal the sore, should be frequently used.

PA'SMA. See CATAPASMA.

PA'SPIER. See CRITHMUM.

PA'SSA, (from *pando*, to spread). A FIG OF GRAPE, hanging down from the limb or bunch; generally used as an epithet, as in *uva passa*, the raisin. See PARONYCHIA.

PASSIFLORA LAURIFOLIA and MALIFORMIS, Lin. Sp. Pl. 1355 and 1356. The fruits of

these species of granadella are cooling, and gently laxative.

PA'SSIO, (from *pati*or, to suffer). A PASSION, AFFECTION, OR DISEASE. See AFFECTIO, and HYPOCHONDRIACUS MORBUS.

PA'SSIONS. See PA'THEMA.

PA'SSUDE, (dim. of *passa*, a fig). See UVÆ PASSÆ.

PA'SSUM, (from *passa*, a grape or raisin). See VITIS.

PA'STA RE'GIA, and PA'STILLUS, (from *παρσσω*, to sprinkle). See COLLIX, and TROCHISCI. PASTE, as an article of diet, has been highly reprobated, and indeed it is somewhat unwholesome, though we cannot accuse it with some eager dietetic reformers of producing obstructions in the mesentery, atrophy, and dropsy. If boiled without suet or fat, it is not easily digested; and if baked insufficiently it is equally insoluble. With suet or butter it is light, and not peculiarly injurious; but the oil when baked is an empyreumatic state, and rises inconveniently on the stomach of those subject to indigestion. As an article of diet it should be used sparingly and with caution; should be thoroughly baked, but not burnt.

PASTINA'CA, *pastinaca sativa*, α, Lin. Sp. Pl. 376, (from *pascor*, to feed; useful as food). PARSNIP. The root is thick, fleshy, and juicy; the leaves large, broad, and strengthened by a thick rib; the seed oval, large, thin, marginated, casting its husk. It grows in meadows, and on the borders of fields, flowers in July, and is chiefly noted as a food most agreeable to rabbits. The name is given to several vegetable products, *branca ursina Germanica*, *spondylium*, cow parsnip, a species of *sium*, *daucus*, *tordilium*, and *cuminoides*.

PASTINA'CA HORTE'NSIS. See PASTINACA SATIVA.

PASTINA'CA OLUSA'TRA, *opoponax pseudocostus*, *panax heracleum majus*, *panax pastinacea*, *spondylium vel pastinacæ Germanicæ affinis panax*. HERCULES' ALL-HEAL, or WOUND WORT. The leaves are entire, heart shaped, but with one side lower than the other; the middle ribs bearing the several sets of leaves, which stand in pairs along a larger rib. It is a native of the warm climates, but bears the cold of ours, and produces the gum OPOPONAX, q. v. The seeds are much warmer than those of the wild or the garden parsnip.

PASTINA'CA SATI'VA, Lin. Sp. Pl. 376, β, *pastinaca hortensis*. GARDEN PARSNIP. The leaves are paler coloured than the wild, smooth, and indented. The roots are sweet, contain much mucilage, and are very nutritious: they yield with rectified spirit of wine a sweetish extract, and in distillation with water a small portion of essential oil, with the flavour of the root; the seeds are aromatic, but inferior in this respect to those of the wild species.

PASTINA'CA SYLVE'STRIS, *elaphoboscum*, *elaphicon*, *banica*, and WILD PARSNIP, a variety of the *pastinaca sylvestris*, as authors have supposed, but more probably a species of *ananthe*, perhaps the *æ. pimpinelloides* Lin. Sp. Pl. 366.

It hath dark green indented leaves, and slender woody roots; is common about the sides of fields, flowers in June and July, and ripens its seeds in September. On eating the roots a heat is complained of in the mouth, soon followed by thirst; the pupil gradually di-

lates, the sight is lost, and a delirium comes on. When discharged by vomiting these symptoms abate; but the dilatation of the pupil is the last which disappears. These wild parsnips are harder when boiled than the good ones, and may be thus easily distinguished.

PATE'LLA, (a diminutive of *patina*). The KNEE PAN, *rotula*, *mola genu*, *scutiforme*, *cartilagosum*, *et disciforme os*, *oculus genu*, *caucaloides*, *epigonatis*, *epimulis*, *mylacris*, *myle*, and CAP OF THE KNEE. It is a flattened bone, situated at the anterior part of the joint of the knee, broad upwards, and pointed downwards. Its anterior surface is smooth, but perforated with many holes, formed by the attachment of ligamentous fibres: its posterior surface is covered with a cartilage; divided internally by longitudinal and transverse ridges, into four cavities, the two lower of which move upon the femur in the extension, the two upper in the flexion, of the leg. The upper cavities are adapted to the pulley of the os femoris, on which they rest when the leg is in an ordinary unrestrained posture; but when bent, the patella descends on the condyles, and when extended rises above the pulley. The edges and lower points of the bone are rough, for the attachment of the tendons or ligaments.

The knee pan is cellular, but the cells are so small that it is a strong bone, and can resist a smart blow; but it is broken by a violent contraction of the muscles when the leg is extended. (For fractured knee pan, see vol. i. p. 683.) The tendons of the extensors are inserted into the upper part of the patella, and a ligament runs from the lower part to be connected to the tibia. The patella suffers the leg to have some degree of rotation, which if it had been a fixed process like the olecranon it would not: it likewise is less incident to fractures than if it had been one solid bone with the tibia. At the time of birth it is cartilaginous.

PATE'LLA DOCUMA'STICA. See CUPELLA.

PATE'TÆ UVÆ, or PATETHEISÆ. See UVA PASSA.

PATHE'CA. See JACE BRASILIENSIBUS.

PATHE'MA, (from *παρχω*, to suffer). See AFFECTIO.

It is not our present object to engage in minute disquisitions on the subject of the passions; for the question, so far as it is medical, lies within a narrow compass. It has been confused rather than illustrated by the metaphysicians, whose speculations we need not follow.

Much inconvenience seems to have arisen from the metaphorical language employed. Affections, emotions, and passions, have not been clearly distinguished, nor has it been carefully pointed out that they are degrees only of similar changes in the brain. That pleasing sensation, for instance, which arises from the contemplation of objects of taste is an affection, which, arising to admiration, is an emotion, and in a still greater degree styled ecstasy, becomes a passion. The inaccuracy of language is felt also in the first step. Emotions and passions imply active energy, and can scarcely be proper terms to characterize fear, which depresses; terror, which for a time annihilates all the functions; or grief, which kills. The error arises from considering them as distinct mental affections; but they are so only in a remote degree. They are occasioned by the sensible impressions, which excite ideas;

by the associations or reminiscence, which recal them; and are interposed between the idea and volition, influencing the latter apparently as distinct causes. Thus the passionate man, in his violent fury, is not agitated by the cause, which is often trifling, but by the passion of anger excited by the idea; the jealous man, not by the actions or words of his mistress, but by the suspicions which these excite. In the common mental operations there is a step between the idea and volition, distinguished by the term motive; but we proceed often so rapidly from the impression to action, that volition and the motive are not observed, though each exist. In this intermediate period the connections and associations have often a considerable effect in changing the views and objects, sometimes exciting to violence, depressing to despondency, or composing the mind in the pleasing delusion of contemplative admiration. These different and opposite mental affections produce corresponding changes in the body, and act as exciting and depressing powers. We see their distinct effects only as corporeal; for they produce the same consequences as the more material agents. Thus the excitability is destroyed by grief as well as by the slow action of a narcotic poison, or more suddenly exhausted by passion, as in the case of the death of lord Chatham. Moderate joy acts exactly like a gentle stimulus, and the admiration excited by beautiful objects, either of nature or art, like those gentle narcotics which diffuse calmness and serenity, though undermining the more active energies of our constitution. So true is the general position, which we have often endeavoured to inculcate, that we see in medicine nothing but what is corporeal; our agents and the changes produced are the same, at least in their effects.

Passions are divided into the exciting or depressing: each again, in a medical view, into such as excite suddenly, and with temporary violence, or more slowly and permanently. Were we, therefore, to draw out a short scheme of this kind, it would be the following, which, though in itself imperfect, may be of use when we consider the subject in a medical view. Passions are either,

I. EXCITING.

- α In a violent degree, as ANGER, PASSION, ECSTASY.
- β More moderately. JOY, EMULATION, DESIRE, HOPE, BENEVOLENCE, LOVE.

II. DEPRESSING.

- α In a violent degree. TERROR, GRIEF.
- β More moderately. FEAR, JEALOUSY, ENVY, RESENTMENT.

III. CALMING.

VENERATION, ADMIRATION, CONTEMPLATION of the excellent or beautiful in nature or art.

1. Music.
2. Painting.

Persons of strong active imaginations, sanguine in their temperaments, eager in their pursuits, and expectations, are most liable to, and suffer most from, the violently *exciting passions*. The effects are often

apoplexy, palsy, hæmoptoe, jaundice; or if they escape from such severe diseases, they experience all the consequences of too great excitement in subsequent depressions. The passions which excite moderately are peculiarly conducive to health. They keep up the balance of the circulation, by which the blood is regularly distributed to the surface, increase the active powers of mind and body, render the sleep sound and refreshing, the appetite and digestion excellent. Yet these effects are only the consequence of the sunshine of prosperity; for when emulation is followed by disappointment, or even not cheered by due encouragement, hope long delayed, benevolence rewarded by ingratitude, each degenerates into its corresponding depressing passion. The more violent passions are the ocean in a storm; the less violent, the salutary breeze, which gently agitate the waves, and prevent stagnation and putridity.

The *depressing passions* are, in different degrees sedative. The more violent ones are sometimes fatal in a moment. The others slowly undermine the constitution, weaken every function, and induce dyspepsia, palsy, dropsy, with the whole train of asthenic diseases.

We have added the *calming passions*, to point out the injurious effects of their indulgence. It was the remark, we believe, of Mr. Burke, that they were sedative; and they certainly are so, perhaps in consequence of their not so powerfully engaging the more active intellectual exertions: yet we think the resemblance to those narcotics which give serenity, offered lately rather as an illustration than as an argument, is so striking, that we would call them the mental opiates. People of acute sensibility and refined taste, of indolent habits and less inclined to active exertions, are most liable to take copious draughts of these intoxicating engagements.

In the early periods of these respective mental diseases, when they become such, the treatment must be moral and intellectual. It is of the utmost consequence, therefore, to trace the passions in the infant state, for they may be observed at a very early period of life, and to apply due restraints on their excess. Even the most salutary passions should be moderated, or emulation may arise to envy, desire to greediness, benevolence to a painful refinement, joy to ecstacy, love to jealousy. The suitable mental treatment requires little discussion; for it must be varied according to the temperament, the disposition, the situation of the patient. When they induce corporeal disease, they belong to the different parts of the work.

PATHE'TICI, (from the same). See DYSOREXIE.

PATHE'TICUS, (from the same). An epithet of the fourth pair of nerves, because they direct the eyes to intimate the passions of the mind. They are the smallest pair in the body, and appear below the edge of the transverse processes; they pass by the side of the sella turcica, and go through the foramen lacerum orbitale superius, to the superior oblique muscle.

PATHOGNOMONICUS, (from παθος, a disease, and γινωσκω, to know). An epithet for a symptom or a concurrence of symptoms inseparable from a distemper, and found in no other. *Quod convenit omni, soli et semper*. Pathognomonic symptoms are, therefore, those by which a disease may with certainty be distinguished, the enumeration of which forms the most concise definitions.

PATHOLO'GIA, (from *παθος*, a disease, and *λογος*, a discourse).

We have already observed that the institutions of medicine were usually divided into the physiology, pathology, hygiene, and therapeutics. The more general division was, however, into the hygiene and jatrike; the latter including the pathology, the prognostics, and the therapeutics. In this view the pathology includes the differences, the nature, the causes, and effects, of diseases; but even this division is now neglected. The differences of diseases are referred to nosology, though this, at the period of the publication of Sauvages' first edition, was styled *pathologia methodica*. The particular causes and effects of diseases are referred also to the particular description, so that little remains under this head in modern authors but the general doctrines.

We have already anticipated the greater part of the disquisitions respecting the general doctrines under the article *MORBUS*, q. v.; for there, in a work of this kind, the reader would look for the diseases of the fluids, of the simple and the vital solids. The diseases of the containing solids, of the organized solids, and the particular secreted fluids, could not be separated from the particular diseases.

The distinction of the causes of diseases in general we have also noticed (see *CAUSA*), and the particular causes might perhaps be referred to the diseases which they produce. We have certainly anticipated almost every part of such disquisitions, as they rest on the more improved chemical knowledge of modern times, and to combat ancient fancies would form a very uninteresting part of the present work. It is sufficient then to observe, that the causes of diseases as distinguished by the latest pathologists, are those from the injurious effects of the atmosphere; from food and drink; the improper use of remedies; poisons; errors in the animal motions; injuries from particular positions or motions; immoderate mental exertions; perturbations of mind; excesses of sleep and watching; unnatural excretions and retentions; causes of calculus; diseases from animated beings, or other external causes, as clothing; accidents from bruises or fire; substances swallowed, or in any manner introduced into the cavities.

The predisposing causes, *seminia*, are those common to each sex or age, or those peculiar to particular temperaments and constitutions. To which are sometimes added preternatural predispositions, which are little else than concealed idiosyncracies excited to action by accident. See *AIR*, *ALIMENT*, *VENENUM*, *HYPOCHONDRIASIS*, *SOMNUS*, *CALCULUS*, *VESTITUS*, *AMBUSTIO*, *PROGNOSIS*.

PATIE'NTIA, (from *patior*, to bear, from its gently purging qualities). See *LAPATHUM HORTENSE*.

PATIE'NTIÆ MUSCULUS, (from the same,) because its action is expressive of patience. See *LEVATOR SCAPULÆ*.

PA'TOR NA'RIUM, (from *pateo*, to be open). See *NARES*.

PATRA'PIUM. See *APIUM*.

PA'TRUM CO'RTEX, vel *PU'LVIS*, (because it was introduced by the Jesuits). See *CORTEX PERUVIANUS*.

PATU'RSA. See *LUES VENEREA*.

PAU DE SA'NGUE. See *GUMMI RUBRUM AS-TRINGENS*.

PAULI'NA. *Confectio*, (from *paavo*, because it pro-

cured rest). A warm opiate; the *paolina* of Aristarchus, and the same with the *confectio Archigenis*. The London college have rejected it from their *Pharmacopœia* of the year 1788.

PAVA'NA, i. e. *MOLLUCCE'NSE LI'GNUM*. See *CATAPUTIA MINOR*, under *GRANA TIGLIA*.

PAVA'TE, PAVETTE. See *MALLEAMOTHE*.

PAVI'NA. See *HIPPOCASTANUM*.

PA'VOR, (from *haveo*). FEAR. See *PRURITUS* and *PATHEMA*.

PECHE'DION, (from *πηχιδιον*). See *PERINEUM*.

PECHURIM CORTEX. (See *FABA PECHURIM*). It agrees in quality with the bean, and is used in dysenteries and dyspepsia.

PECHYA'GRA, (from *πηχυς*, the elbow, and *αγμα*, seizure). See *ARTHRITIS*.

PE'CHYS, (from *πηχυς*, the elbow). See *OLECRANON*.

PECHYTY'RBE. See *SCORBUTUS*.

PE'CTEN. See *PUBIS OSSA*.

PE'CTEN VENERIS. See *SCANDIX*.

PECTINA'TIO, (from *pecten*, a comb). COMBING; a species of friction.

PECTINE'US vel **PECTINA'LIS MUSCULUS**, (from *pecten*, the pines,) from the colour *lividus*, rises from the upper part of the os pubis, on the outside of Poupart's ligament, runs downwards, backwards, and outwards, and is inserted into the linea aspera below the little trochanter: it draws the thigh outward and inward, and assists in rolling it.

PECTINATI MUSCULI, (from their resemblance to *pecten*, a comb,) the fasciculated muscular fibres of the right auricle of the heart.

PECTORA'LE DECO'CTUM. See *HORDEI DECOCTUM COMPOSITUM*.

PECTORA'LIS, (from *pectus*, the breast,) an epithet for medicines appropriated to disorders of the breast. Employed in this general sense the term is improper, and the more limited one of modern authors, viz. *expectorantia*, should be commonly used. If the pectoralia may, with M. Lieutaud, be of three kinds, demulcents, astringents, and resolvents, it will be very obvious that the general term will lead to confusion.

PECTORA'LIS MAJOR, vel **ADDU'CENS HU'MERI**, rises in a radiated manner from the anterior and inferior part of the clavicle, then from the sternum, and at the lower part from the third, fourth, and fifth ribs from the cartilage, and partly from the bony portion of the sixth rib, sending its tendinous fibres over the upper part of the external oblique and rectus abdominis, passes towards the arm with its upper edge contiguous to the deltoid, and between them the cephalic vein penetrates. Near its insertion the pectoralis doubles in on its lower edge, forming a posterior and anterior lamella, and runs to be inserted into the anterior part of the biceps groove. This doubling has occasioned Winslow to divide the muscle into two parts. From its tendon it sends off fibres, which contribute to form the fascia that covers the muscles of the arm; and this muscle, with the latissimus dorsi, forms the cavity of the axilla. The pectoralis is partly a rotator of the arm, but its great use is to bring the arm forward close to the body. It assists also in moving the trunk of the body when the arm is fixed, and Haller thought that it assisted respiration.

PECTORA'LIS MI'NOR, *serratus anticus* and *serratus*

anticus minor, lies beneath the pectoralis major, rises by three digitations from the third, fourth, and fifth ribs, then passes obliquely upwards and outwards, and joins with the short head of the biceps, to be inserted into the coracoid process of the scapula. It is sometimes called a muscle of the scapula, or of respiration, according as the one or the other termination is considered to be the fixed point.

PECTORA' LIS INTE' RNUS. See TRIANULARIS STERNI.

PECTORA'RIA HE' RBA, (from its use in affections of the breast). See ANGELICA SATIVA.

PE' CTORIS OS. See STERNUM.

PE' CTUS, (from *πηκτος*, compact). The BREAST; *chelys*; from its resemblance to the back of a tortoise, *χελωνη*; also the *metatarsus*.

PECTU' SCULUM, (dim. of *pectus*). See META-TARSUS.

PEDICULO' SUS MO' RBUS, (from *pediculus*, a louse). See PHTHIRIASIS.

PE' DIBUS BO' VUM O' LEUM EX. NEAT'S FOOT OIL, prepared by boiling the joints of horned cattle in large vessels. See ANCHYLOSIS.

PEDI' CULI INGUINA' LES et PU' BIS. See MORPIONES.

PEDICULA'RIA, (from its destroying lice.) See STAPHISAGRIA.

PEDICULA' TIO, (from the same). See PHTHIRIASIS.

PEDI' CULUS, (from *pes*, a foot,) from their great number of feet. A LOUSE. *Pediculus humanus* Lin. Systemæ Naturæ, vol. ii. p. 1016; an animal "familiar to man," though often inconvenient from its bite. Lice have been supposed hermaphrodites; and are certainly oviparous. A louse will lay, in six days, fifty eggs, without exhausting its store, and in twenty-four days the young ones are capable of laying eggs themselves. From calculation, it is supposed that two female lice may produce eighteen thousand in two months. The largest animals of this kind were discovered by Linnaeus, in the warm caverns of Falhum, in Sweden. Those which conceal themselves in clothes are apparently different from the lice of the hair; for in India, however dirty the person, he is only infested with the latter. It is a common remark, that navigators lose them in the tropics, and recover them on their return to the same spot; but it is not supported by observation. Monkeys, the Hottentots, and some races of negroes, are said to eat them; and in some receptacles of lunatics, it is reported that they are put into the hair to produce irritation. When new-born children were affected with a suppression of urine, a louse was formerly introduced into the urethra; and the same remedy has been used, in similar complaints of horses. It acts, as is supposed, by its irritation.

It is said also that they quit any person ill of an infectious disease, multiplying most in the strongest constitutions. It is at least certain that animals, particularly fish, are seldom infected with them but at the period of their greatest perfection. They are said to be useful to children in epilepsies, diseases of the head, and in scrofula, by producing sores; and it is added, that the worst consequences have arisen from drying these sores. As a remedy, this animal is not likely to be again employed, and it is carefully destroyed, when discovered.

The most fatal poisons to it are the mercurial calces, the seeds of veratrum, staphisacre, menispermum, rue, opium, angelica and laurel, saffron, pepper, sedum, lycopodium, pinguicula, and nicotiana. In botany, the term is synonymous with *pedunculus*.

PE' DICUS, (from *pes*, a foot). See EXTENSOR DIGITORUM BREVIS.

PEDI' LUVIUM, (from *pedes*, and *lavo*, to bathe), *lavapedium*, A BATH FOR THE FEET. The extreme vessels of the feet sympathize with those of the rest of the system, the stomach, and the head. If the feet are cold, colic pains come on, the skin is rough, perspiration defective, and the salutary evacuations from the uterus and hæmorrhoides checked. Pediluvia are consequently extensively useful. Baths for the feet should be used at bed-time, to procure a general perspiration. If used a few days before the menstrual discharge, they are said to promote it, and are particularly useful in affections of the head, as well as the commencement of febrile complaints. It is sometimes injurious, by determining too powerfully to the head, and should be used with caution in its diseases, or the temperature should not be raised above 98°. See BALNEUM.

PE' DION, and PELMA, (from *pes*). The sole of the foot. See PES.

PE' DORA, (from *pes*). The sordes of the eyes, ears, and feet.

PE' DRO DEL CO' BRA. See COBRA DE CAPELLO.

PE' DRO DEL PO' RCO. See BEZOAR HYSTRICIS.

PEDU' NCULÆ CEREBE' LLI. See CEREBELLUM.

PEDUNCULA' TUS, (from *pedunculus*). Growing upon foot-stalks.

PE' GANON, (from *πηγνω*, to condense). See RUTA.

PE' GE. A FOUNTAIN. See OCULUS.

PE' LADA. A loss of hair from a venereal cause.

PELECA' NUS, the name of an instrument for drawing the teeth; and of a glass vessel, formerly used for the digestion and circulation of liquors, poured in at their narrow necks, which were afterwards hermetically sealed: at present two mattresses are used, instead of a pelecen, the neck of one being inserted into that of the other.

PELIO' MA, (from *πηλος*, black). See SUGILLATIO.

PELLAGRA, (from *pellis*, the skin, and *αγρα*, a disease). This singular disease has attracted particular attention, within these last thirty years, not wholly from its novelty, but from its becoming more violent, and from its being more generally accompanied with peculiar nervous affections. It comes near the *lepra asturiensis* of Sauvages, but seems more closely to resemble the *elephantiasis*, as we have described it, vol. i. p. 598. As a new disease, it is necessary to notice it with some minuteness, but we shall, at the same time, confine our account within limits of no great extent, and refer, at the end, to a numerous list of authors, who have treated of it, in a chronological series, from the era of *Frapolli*, who first publicly noticed it, in a tract, published at Milan in 1771.

The symptoms which show the approach of the disease are those of debility only; languor, listlessness, gloom, a weakness and stupor in the legs, unsteady walking, imperfect ideas, and vertigo. After these

appearances, which are, however, sometimes absent, at the approach of summer, a sense of tension, burning, and itching in every part exposed to the sight, except the head, is felt, and followed by an inflation of the epidermis, and tubercles of a shining red colour. If exposed to the meridian sun, those affected become languid, faint, and fall down insensible, though they soon recover, on being carried into the shade. After some days, the tubercles desquamate, the skin appears at first red, but soon recovers its natural colour. The advancing summer removes every complaint; and, though some relapse in autumn, in the winter every disagreeable symptom vanishes. While the disease continues, the pulse is small and weak; when it recedes, the usual strength returns; and no return of the complaint is, in many cases, observable for several years.

In the second stage, every symptom is exaggerated; the itching is more pungent, the heat more fiery, the skin harder, cracked, and chapped, the debility greater, the mental functions disturbed, with peevishness and impatience, the sleep broken, the appetite irregular and unequal, pain of the head and spine, with delirium and confusion of ideas. The local disease is not now troublesome; but the nervous complaints are greatly exasperated. Vertigo increases, the patient is sad, loves solitude, and the melancholy delirium occasionally alternates with the more violent: the tedium vitæ is insupportable, and self-murder is a frequent consequence. Strambio remarks, that those who labour under pellagra have the greatest tendency to drown themselves, "as by a delirium opposite to the hydrophobia." Coercion is at last necessary; and a diarrhoea, atrophy, or dropsy, closes the dreadful scene, if the patient does not sink, from a loss of both mental and corporeal power.

It is necessary to mark a few of the symptoms more distinctly. The affection of the skin first appears truly erysipelatous; but with different degrees of burning heat, redness, and desquamation, sometimes attended with large phlyctenæ, full of an acrid, often a yellow, fluid, as from burns. The crusts on the hands appear first to resemble the effects of heat and hard labour, though, when minutely examined, they are very different. They affect the parts exposed to the sun, particularly the backs of the hands and feet, seldom the head, except on the tip of the nose or the forehead. Those who have dreaded the disease have avoided the sun; but though they have escaped the cutaneous affection, have suffered in the other respects, and scarcely in any instance have the lips escaped being dry and chapped.

The pains of the head and back are almost constant attendants, and often even precede the cutaneous affections. Those of the head are pungent, lancinating, piercing, gnawing, with a sense of burning, as if flames were kindled in the brain, with a most troublesome singing in the ears, and a pulsation in the substance of the brain. The spine suffers from an uneasy titillation, and occasionally from a stroke resembling that of electricity. The pain passes through every part to which nerves are distributed, and from this pain the weakness of the muscles, and the spasms which affect different portions of the body in all their varied forms, occasionally rising to epilepsy or syncope, seem to proceed. Hemiplegia sometimes attacks one side; sometimes the palsy is more general.

Vertigo was also a very early symptom, but most conspicuous in those who exposed themselves to the burning sun. From this the double vision and the tinnitus aurium apparently arose. The delirium sometimes proceeds like an acute disease, terminated by a most offensive sweat, resembling mould, or the cocoons of silk-worms macerated in water. At other times it is chronic, and gives a fierceness to the countenance not to be described. From this description, the essential or pathognomonic symptoms are obvious, and pellagra may be defined, "inflation of the skin with tubercles, in parts exposed to the air, except the face; at first remitting; preceded by melancholy and debility; at last constant, with increased irritability and alienation of mind. It is thus related to lepra, elephantiasis, &c.

Pellagra is sometimes complicated with nervous fever, with inflammations, and, towards its close, with dysentery. It is sometimes, from the descriptions of Odoard and Soler, accompanied with every variety of scorbutic symptoms; an union which appeared to them more singular, as scurvy is almost unknown in the duchy of Milan, though occasionally observed at Venice, and in both districts it is endemic. These appearances are, however, symptoms of debility only; and with them may be united petechiæ, vibices, &c. which often attend the disease. Strambio mentions an herpetic affection as a concomitant, and Soler the Grecian elephantiasis. Dissection seems only to have shown the effects of the disease in numerous visceral obstructions.

The pellagra is indisputably hereditary; and, though it seldom appears till after puberty, even in infancy the experienced eye can, it is said, trace the germ of the complaint. It is not always, however, conveyed to the offspring; but the means by which it is avoided are by no means clear. It does not depend on air or situation, though an endemic disease; for in every variety of soil and situation, in the districts of Milan and Venice, it is observable. The condition of the peasantry is, indeed, in these truly miserable. Their strength is exhausted, at a very early age, by labour, to which they are unequal; and their diet chiefly consists of bad, ill fermented bread, made of maize; their drink of stagnant water, or, on the mountains, an inferior kind of wine, *la posca*. Their habitations are close, confined, and filthy in excess, which they share with their cattle. Their countenances are, consequently, gloomy, their complexions yellow, face tumid or contracted, the limbs stiff, the catamenia irregular, abortions frequent, births laborious, old age premature. The foundation of the disease is certainly debility, and causes of debility often induce it, when dormant; but similar causes frequently occur, without producing pellagra. Weakness is, therefore, a predisposing cause only, and the activity of some latent contagion is necessary; a contagion constitutionally conveyed to the offspring. Though very unusual, persons, otherwise firm and strong, are sometimes affected; nor is it, apparently, communicated, by infection, from husbands to wives, or the contrary. Yet it is singular that, at the little town of St. Rivolta, in the district of Lodi, after a man, infected with the disease, had resided there, it became comparatively frequent, though unknown before. Titius seems to suspect that it may have been originally communicated by cattle.

Some authors have attributed the pellagra to the

influence of the sun, and supposed similar to a *coupe de soleil*; but the disease begins in the spring; and those, we observe from authors, who endeavour to escape it by avoiding the burning heat, only experience a slighter cutaneous affection. The other symptoms come on with equal severity. It seems probable that the virus is collected in winter, and produces its effect in spring, drawn to the surface by the warmth; and it is certainly connected with the manners and habits of a country life, since the inhabitants of villages are very rarely, those of cities scarcely ever, affected. If evacuated by the skin, that is, if the tubercles discharge and desquamate regularly, the nervous symptoms do not appear, or are more slight; but when the skin is more hard and solid, the worst consequences follow; and if the tubercles are repelled, sudden death is often the consequence. To this must be added, that persons not exposed to the sun often experience the nervous symptoms without the impetigo. The solar light, therefore, only produces the eruption.

Authors have divided this disease into hereditary and acquired, into moist and dry; but these distinctions do not contribute to our knowledge of its nature or treatment. Each is little understood. It has been considered as a particular species of scurvy, from the spots on the surface; as hypochondriasis, from the visceral obstruction, and the gloomy delirium; as elephantiasis, from the tubercles; as the *lepra asturiensis* of Thierri; and as a periodical chronic nervous erysipelas. The two first opinions are wholly without foundation; but as we have stated the pellagra to be of the family of elephantiasis, we must now notice the distinguishing marks.

They agree in being founded in an exhausted constitution, in the pustules being symptoms rather than essential marks of the original disease, in their fatal termination by dropsy, atrophy, or some other asthenic disease. They differ, as the elephantiasis affects the face, the roots of the hair, the palate bones, and as the disease of the skin increases with the increase of the other complaints. In pellagra, it lessens when the nervous symptoms are most violent. The pellagra also is distinguished by the thick urine, double vision, and the peculiar mouldy smell of the sweat.

The *lepra asturiensis* agrees with the pellagra in many of its symptoms. The pustules are, however, very painful, offensively fetid, and attack the head indiscriminately with other parts, as well as the roots of the hair. The mind is but slightly affected, and its disease is that of timidity rather than delirium. The last opinion, that of Titius, is not supported by any conclusive evidence. It must, therefore, as we have said, be placed among the impetigines, between the lepra and elephantiasis.

The cure, unfortunately, is very difficult: indeed, when the disease has proceeded so far as to affect the nervous system, it is impracticable. All the evacuants are injurious, and the tonics have not been sufficiently tried. The metallic tonics, as mercury or arsenic, promise most success, if given with medicines which assist the cuticular discharge. Mercury, conducted so as to salivate, has been found injurious. When the first symptoms have appeared, persons have escaped by removing into towns, or wholly leaving the district. Perhaps removing into a warmer climate, without being exposed to the sun, might be useful.

PELTA' TA CARTILA' GO, (from *pelta*, a buckler). See ASPERA ARTERIA.

PELVIMETER. An invention of M. Coutonli to measure the different diameters of the pelvis; and another in the form of calipers is recommended by M. Baudelocque. Each is, however, more curious than useful, and neither is much used in this country. The form and shape of the woman shows deformities from irregularity of the brim of the pelvis, and the operator, used to the measure of his fingers, can ascertain, in touching, the distance from pubes to sacrum, as well as any irregularities of shape at the lower diameter.

PE'LVIS, (from *πελος*, a basin). A name for the inferior part of the cavity of the belly, bounded forward by the os pubis; backward by the os sacrum above, and coccygis below; laterally by the ilia above, and ischia below. In infancy the bones are more numerous than in the adult state, and the edges of several are cartilaginous, so that the pelvis of the child may yield a little in difficult labours. Yet the motion of the parts on each other is so inconsiderable, that no great advantage can be this way obtained.

The pelvis consists of the os sacrum, os coccyx, and the ossa inominata: the latter contain the ossa ilia on

Q

the sides, the pubes, branching from the front above and below; and the ossa ischia, joining the lower ramus of the pubes to the sacrum. See plate.

The union of these bones is more or less perfect. In adults the sacrum is sometimes ankylosed with either os inominatum; and, from long confinement, violent shocks, or diseases on the other hand, it is considerably loosened, so as to make walking unsteady and difficult. The os coccygis, which in adults consists of bones separated by cartilage, sometimes coalesces into one bone, and is also firmly united to the sacrum. In this process its length is diminished, and it usually turns inward, forming a very considerable impediment to the progress of the child. This impediment is sometimes overcome by the propelling pains, and some motion between the sacrum and the coccyx is restored. Lateral motion is prevented by strong muscles and ligaments. The ossa pubis are connected in front, it is said, by a cartilage, but it is rather by a mixture of cartilage and ligament. The former belongs to each bone, and at their junction unites. It is thicker in front, from the upper to the lower part, than behind; and the ligamentous fibres, mixed with it, are, of course, longer in front. In their reticulations they leave intervals, which contain small red bodies, described as resembling synovial glands; and some authors have mentioned a kind of capsular membrane in its back part, while the cartilages on each side seem calculated, by their separation, to admit of a small motion. This cartilaginous separation is, it is said, discovered near the middle of the symphysis, extending a little lower behind. Other authors have denied the existence of this apparent joint; and though we have seen a cavity in the cartilage, it did not appear to be regularly organized, at least in that instance. The ligamentous fibres, which we have described, are reinforced by others, and by tendinous expansions from all the muscles on either side; so that if Nature designed by this structure an obscure motion, she has taken anxious care to prevent its being considerable, apparently to prevent it entirely.

The union of the sacrum with the ossa inominata is more close and compact; nor do we find that when the connection is loosened, that the former intimate union again takes place. The os sacrum is united to the lowest lumbar vertebra, nearly in the usual manner; but there are two little articular masses fixed in the posterior edge of the impression, by which they are mutually received into each other, which answer to similar substances in the vertebra. The union of the sacrum with the spine is secured also by ligamentous fibres, so that the motion is inconsiderable; but the convexity of the spine in the loins is in part lessened by the small motion which each vertebra admits; and by altering the angle at which the woman reclines, or by bending forward, we can thus often effectually change the direction of the axis of the pelvis.

In midwifery the knowledge of the structure and peculiarities of the pelvis is an important circumstance. The brim of a well shaped pelvis represents an irregular oval, or something that approaches to a triangle; if it is considered as an oval, its greatest axis is from side to side; if we consider it as a triangle, the posterior part is far longer, and the ossa pubis constitute the other two sides of the triangle; the lower circumference

is formed behind by the sacrum and os coccygis, on each side by the ischium and sacro sciatic ligaments, and before by the lower part of the pubes. When the body is gently reclined, the brim of the pelvis is horizontal, and a line would pass from the navel through the middle of the cavity; but when a woman is in labour, or near her time, this imaginary line must fall from between the navel and scrobiculus cordis; and accordingly we find that the head of the child presses behind the anus, and gradually advances from thence up the perinæum, until it comes to the lower part of the symphysis of the ossa pubis. The chief use of this supposed line is to place the woman in the most favourable position during labour, that she may act more advantageously with her abdominal muscles, and that the child's head may fall more directly into the middle of the pelvis. It will be a rule also to direct the forceps on the child's head, and the hand into the uterus. The obliquity of the pelvis from behind forwards is equal to an angle of nearly 40° .

In considering the pelvis, we should observe its width, the depth and form of its cavity, and the extent of its brim from the fore to the back part, which, in a well-formed pelvis, is an inch less than it is from side to side; four inches and a half from the fore to the back part; and five inches and a half from side to side.

The lower circumference of the pelvis is nearly equal; but when we allow for the os coccygis being moveable, it makes a quarter of an inch more in its longer direction from the os coccygis to the os pubis than from ischium to ischium. The depth of the pelvis, from the upper edge of the sacrum, where it articulates with the vertebræ lumborum, to the lower part of the os coccygis, is about five inches in a straight line. When the os coccygis is pressed back, it is then six inches: from the brim of the pelvis, to the lower part of the symphysis of the os pubis, is only two inches; while from the under part of the ischium it is four inches. The brim is concave internally all round.

The inferior aperture is usually, in the natural state, smaller, and of a more irregular figure than the superior, as it is not wholly formed of bone. The base is broken by the coccyx, the tuberosities of the ischia, &c. into different angles, which are filled up by ligaments, forming in front what is styled the *arch of the pubes*, which expands from an inch and a quarter to four inches in breadth in a well formed pelvis. The transverse diameter is largest in its natural state; but, from the yielding of the coccyx, is the smallest in delivery. The largest diameter also of the inferior aperture is opposed to the smallest of the superior; and from hence arises the necessity of the half turns in delivery, which we have mentioned as necessary in PARTURITION, q. v.; and the greatest diameter of the superior, crosses the smallest of the inferior at an angle more or less acute. From an attention to this circumstance, we can often, with the finger alone, remove apparently insurmountable obstacles. The curvature of the sacrum also removes many inconveniences if attended to; and on this account the child comes with so much facility when the face is in that hollow. This concavity also prevents pressure on the sacral nerves.

The pelvis may be faulty either from too great or too small a size. In the former case the child is often too suddenly excluded, and dangerous hæmorrhages are

the consequences. In this case also the uterus is often propelled with the child, particularly when the woman has had many children; in the earliest and latest months also the child rests on the rectum or meatus urinarius, producing constipations and strangury: in the intermediate period it rests on the edge of the pelvis.

The pelvis is, however, more often faulty from its narrowness. This defect is seldom conspicuous in every part of the basin, and most generally in the superior aperture. The small diameter is most commonly contracted, and sometimes one side only of the bony circumference is pressed in. When the inferior diameter is lessened, it is usually effected by the approach of the tuberosities of the ischia. M. Baudelocque accounts for the former deformity, by attributing it to a softness of the bones in the early state; and he remarks, that the direction of the weight of the body carries the sacrum forward, and the ossa pubis backward. This is not, however, a perfectly correct view of the circumstances. The disease arises from the prominence of the abdomen, usually attendant in such cases, which renders it necessary to throw the shoulders back to preserve the equilibrium. In consequence, the line of pressure is upwards and backwards, instead of being upwards and a little outwards. In weak states it is common to recline on one side to relieve often the weaker leg, or to change the position. From this it arises that one ramus of the pubes is chiefly pressed in, that one of the acetabula often approaches nearer the sacrum, and that a line drawn perpendicularly from the symphysis of the pubes towards the sacrum, divides the pelvis into two very unequal parts. The inferior aperture in the same softened state of the bones will be affected by the child's sitting, lolling on one side in preference to the other, or twisting the body into unnatural attitudes for the sake of present relief.

The dimensions of the pelvis itself often greatly vary. In the diameter from pubes to sacrum the diminution sometimes scarcely exceeds half an inch; in others the bones approach so near, that often scarcely an inch of aperture is discovered. A pelvis cannot, however, be considered as *very* narrow, unless each diameter be less than three inches and a half. M. Baudelocque informs us that he has seen pelvises, where the distance from pubes to sacrum above was not more than six or eight lines; and in one which he possessed, the distance from the right acetabulum to the sacrum was only between three and four lines: in another the distance from the projection of the sacrum to the symphysis of the pubes was but fourteen lines. An increased projection of the sacrum, from the causes assigned, viz. a swollen abdomen, in consequence of great debility, contracts the superior aperture to very small dimensions; and this projection is sometimes straight forward, sometimes to one side only. In the latter case an aperture is often left on the other side sufficient for the passage of a child.

Labour will be tedious when the aperture is little more than three inches; yet the bones of the child's head, by yielding, may be moulded into an oblong form, and at last pass, and the head will soon recover its natural shape. If within three inches, the difficulty is greater; and when so little as two inches and a half, the mother and child are in a dangerous situation. The difficulty from the diminished aperture of

the superior part appears very early in labour. The pains, though strong, do not propel the child, and the woman's strength is exhausted before the child's head can pass into the pelvis. Nature, however, is all powerful in this respect, and the head will pass through an almost impermeable strait. It is then more within reach; and the difficulty arising from a deformity in the inferior aperture is more easily removed, as the head is often within reach of the shorter forceps.

When the head comes into the cavity of the pelvis the pains for a time cease, and the head, recovering its former shape, requires the renewed action of the propelling powers to protrude it beyond the second obstruction. When the deformity is only at the inferior aperture, the symptoms of difficulty appear later, and labour is peculiarly difficult. The practitioner must, therefore, be cautious in his prognostic, not to promise a quick termination from a prosperous commencement, nor a particularly tedious one from difficulties in the earlier period.

The middle of the pelvis is more seldom faulty than the superior or inferior diameters. The defect in this part is sometimes owing to exostosis, and more often to the direction of the sacrum, which is straight, or occasionally convex instead of concave.

Another variety in the form of the pelvis, which renders labours tedious, is the less elevation and sweep of the arch of the pubes, in fact, an approach in form to the male pelvis. A different direction of the spines of the ischium, their too great length, or an ossification of the coccyx, may have a similar effect; but the latter is not often the cause of any considerable delay.

In the article on parturition we have stated that the operation of the symphysis of the pubes is no longer practised in this country, and that the separation of these bones by an operation is calculated to gain but little space. The great question, however, which we have not yet noticed, is, whether all or any of the cartilages yield during labour. Should they do so, considerable space may be gained. It is contended that this separation is possible; by others that it is the effect of disease only; by others again that it is natural, and very commonly takes place. Truth, as usual, lies between. It is certainly not common; but there is much reason to suppose that it does occasionally take place, independent of disease. That the bones do sometimes separate we know, since, in consequence of the disunion, abscesses occasionally form in the interstices. These abscesses are formed chiefly at the union of the ossa inominata and sacrum, or at the symphysis of the pubes. The former is the less violent disease, and is often cured. The latter produces hectic fever, and the cause is often not discovered till after death. The matter sometimes bursts into the cellular substance, occasionally into the bladder; sometimes passes down under the periosteum to the acetabulum, and from thence to the surface on the upper and inner part of the thigh.

A straight pelvis will cause a difficult labour; and it is known by introducing the finger up the vagina: if you can feel the os sacrum, the pelvis is straight; or if you can touch the ossa pubes with your fore finger, and the vertebræ of the loins with your middle finger, it is considered as narrow, and vice versa.

Pelvis is also the name for a cavity in the kidneys, for the cochlea of the ear, &c.; and hence *pelvis renum*,

aurium and cerebri. See Denman, Baudelocque, and Hamilton's Midwifery.

PE'LVIS. See also CEREBRUM and RENES.

PEMPHIGO'DES, or PEMPHINGO'DES, (from *πυμφοξ*, a blast of wind). Fevers distinguished by flatulencies and inflations, in which an ærial effluvium seems to pass through the skin of the patient, and to strike on the finger. (Galen's Commentaries on 6 Epid. sect. i. aph. xvii.) Other authors give this name to a fever, by the intenseness of whose heat aphthæ are excited in the mouth. It is supposed, according to Fæsius, to be a synochus, in which the blood vessels are inflated, and consequently called an inflated fever.

PE'MPHIGUS, (from *πυμφοξ*, bulla, a vesicle). The VESICULAR FEVER, *febris bullosa, exanthematica, serosa, mortua*. Dr. Cullen places it in the order *exanthematica*, defining it a contagious typhus: on the first, second, or third day of the disease, little vesicles, the size of a nut, appear on different parts of the body, continue a few days, and at last exude in the form of a thin ichor. To this he annexes the following observations: "From the opinion of others, rather than my own, this character is taken; because I have seldom seen this disease, and never have observed it epidemical, or pursuing a regular course, as is here described."—With regard to the species, he says, "Since I never have seen a pemphigus which I could consider as an exanthematic fever, and have found only very few observations in the writings of physicians concerning a disease of this kind, almost every thing inserted in our Nosology must necessarily be taken from Sauvages; therefore, I have followed him, though I would willingly have omitted this malady, since almost all that has been said about it appears to me doubtful, obscure, and ambiguous. Francis Home, however, my eminent colleague, shewed me a man slightly feverish, in whom vesicles, the size of a hazel nut, arose first on his arms, and afterwards, successively, on his whole body, which, in two or three days after, exuding a little serous humour, collapsed. But this fever discovered no peculiar disposition or type, and, being by no means contagious, soon disappeared." Synopsis Nosologia Methodicæ, p. 148, 149.

Dr. Withers remarks, that "in the case of E. P. the vesicular eruption, which was very sore and painful, was preceded and accompanied with some feverish symptoms, evidently of the low kind. It continued only for a few days, and then gradually went off." By tonics and antiseptics, he adds, that he cured two patients, not long before, of the pemphigus, in which the fever was extremely putrid, with many gangrenous sloughs, of a fetid smell and most dreadful appearance, following the eruption of the blisters, attended with a low delirium for many nights, the greatest dejection of countenance, and prostration of strength. Since this time it has been noticed by different authors, though the most distinct account of the disease is given by Dr. Dickson in the Irish Transactions. From his description it appears to be a true exanthema, not constantly attended by fever of a given kind, but occasionally mild, though often highly putrid. The treatment is varied according to the nature of the fever; and when the pustules appear on the internal parts, which sometimes happens, irritation must be guarded against by opiates and demulcents. See Acta Helvetica, vol. ii. p. 260; Cullen's First Lines, ed. 4. vol. ii. p. 254; Edinburgh

Medical Commentaries, vol. vi. p. 79; Withers on the Asthma: Gaitshell and Upton in the Memoirs of the Medical Society, London; Dickson in the Transactions of the Royal Irish Academy; and Christie in the Medical and Physical Journal.

PEMPTÆ'US, (from *πεντες*, the fifth). See INTERNITTENS FEBRIS.

PENÆ'A SARCOCO'LLA. See SARCOCOLLA.

PENICILLUS, (dim. of *peniculum*, a brush). A TENT, or PLEDGET.

PE'NGUIN. See KARATAS.

PE'NIS, (*à pendendo*, from its hanging down,) *caulis, coles, mentula, friapus*, is composed of three parts, viz. the two corpora cavernosa, and the corpus spongiosum urethræ. Its skin, which is thin, and without fat, is doubled at the top, forming a hood, the præputium, which covers the glans penis, *cuspis* or *balanos*: the small ligament, by which it is tied to the under side of the glans, is called *frænum, canis*, and *filettum*. The prepuce keeps the glans soft and moist, prevents excoriation, and preserves its sensibility. The penis, where it joins the body, is connected by a small ligament, which arises a little from its root on the back part, and ties it to the upper part of the os pubis. It receives two branches of veins from the hypogastric vessels, and its arteries from the hypogastriæ and pudicæ; the two veins unite towards its root, and make one trunk, which runs on the back of the penis. It hath two nerves from the sacrum, several lymphatics, which pass through the inguinal glands, and three pair of muscles, viz. the erectores, acceleratores, and transversales. Cowper observes, that the cuticle on the glans is villous or downy, and that the cutis is thinner on it and the scrotum than any other part. See Cowper's Observations on the Penis, Ruysch, and de Graaf.

PE'NNA, (from *πτερουσαι*, to fly,) *mentula alata*. A FEATHER. In the third volume of the London Medical Observations and Inquiries, p. 7, &c. is an account of a successful attempt to recover a fibre of a feather from the œsophagus, by means of a whalebone, with a sponge at each end. By threads loosely connected with both, the feather was entangled and brought up. If, however, it can be forced into the stomach, no inconvenience will probably arise.

PENNATIFO'LIUS, (from *penna*, and *folium*). Having leaves resembling feathers.

PENO-AB'SOU, *piné obsou*. A tree in America, whose bark is very fragrant, and whose fruit, about the size of an orange, contains from six to ten nuts, from which an oil is expressed. The fruit is poisonous, but the oil is said to cure the wounds received by poisoned arrows. Its genus is unknown.

PENTADA'CTYLON, (from *πεντε*, five, and *δακτυλος*, a finger, because it has five leaves upon each stalk). See CATAPUTIA.

PENTAGY'NIA, (from *πεντε*, and *γυνή*, a woman). The name of an order in the 5th, 10th, 11th, 12th, and 13th classes of the Linnæan system, containing those plants which have five pistils in an hermaphrodite flower.

PENTA'NDRIA, (from *πεντε*, and *ανδρ*, husband). The fifth class in the Linnæan system, comprehending those plants which have hermaphrodite flowers with five stamens.

PENTANEU'RON, (*πεντε*, and *νευρον*, a nerve, from its five ribbed leaves). See PLANTAGO MINOR.

PENTAPHA'RMACUM, (from *πεντε*, and *φάρμακον*, a drug). A medicine consisting of five ingredients.

PENTAPHY'LLUM, (*πεντε*, and *φύλλον*, a leaf; from its five leaves on each stalk). CINQUEFOIL. See QUINQUEFOLIUM.

PENTAPLEU'RUM, (from *πεντε*, and *πλευρον*, a rib; synonymous with pentaneuron). See PLANTAGO MINOR.

PENTO'ROBUS, (*πεντε*, and *οροβος*, the wood pea; from its five seeds resembling the wood pea). See PEONIA.

PEPA'STICA, PE'PTICA, (from *πεπαινω*, to concoct). DIGESTIVE MEDICINES, supposed to promote the production of a proper pus in wounds and ulcers. It, however, seems doubtful whether this general term be proper or necessary; because, though there are medicines which certainly seem to answer this purpose, yet as they act on general principles, for they are chiefly stimulants, or correct those circumstances which impede the operations of nature, they ought not to form a separate class from one effect.

PE'PITA NUX. See NUX VOMICA SERAPIONIS.

PE'PLION, or PE'PLOS, (*πεπλος*, a purple veil, from their colour). Purging medicines formerly used for evacuating bile and phlegm; styled also *mecon*, *meconium*, *chamæsyce*, *hahaver spumeum*, *symphytum*, and *tithymalus*. See MEDICINE. History.

PE'PLIOS LUTETIANO'RUM. See FABAGO.

PE'PO, (from *πεπλω*, to ripen). COMMON POMPION. As an aliment it is cold, flatulent, and indigestible; but by pressure an oil is obtained from the pulp, which softens the skin. See Raii Historia.

PE'PTICOS, (from the same). See PEPASTICA.

PEQUE'TI RECEPTACULUM, (from *Pequet*, the discoverer). See RECEPTACULUM CHYLI.

PERA'GU. *Clerodendrum infortunatum* Lin. Sp. Pl. 889. A shrub in Malabar whose juice kills worms, and its roots are said to cure the lientery, colic, &c. See Raii Historia.

PERCOLA'TIO, (from *percolo*, to strain through). A term sometimes applied to secretions, sometimes to the transudation of fluids through their coats. See DEPURATIO.

PER DELIQUIUM. An old chemical term expressive of the fluidity which salts acquire by exposure to air.

PER DESCENSUM. A kind of distillation, in which the vapour has a descending course.

PERDE'TUM. See SISARUM.

PERDI'CIUM, (*perdix*, partridge; because that bird feeds upon it). See PARIETARIA.

PEREGRI'NUM LIGNUM. See NEPHRITICUM LIGNUM.

PERETE'RION, from *περαω*, to dig through). See TREPANUM.

PERE'XYL LUSITA'NIS. See CAAPONGA.

PERFE'CTI MAGISTE'RII O'LEUM. See LATER.

PERFOLIA'TA, (from *per*, and *folium*, a leaf; because its stem surrounds the leaf like a cabbage). See BUPLEURUM. This plant was sometimes celebrated for curing ruptures.

PE'RFORANS MA'NUS, (from *perforo*, to pierce through). See FLEXOR TERTII INTERNODII DIGITORUM MANUS.

PE'RFORANS PE'DIS. See FLEXOR LONGUS PEDIS.

PERFORA'TA, (from *perforo*). See HYPERICUM.

PERFORA'TIO, (from the same,) penetrating by an instrument into any of the cavities of the body, as into the abdomen by a trochar. See also SETACEUM.

PERFORA'TUS MA'NUS. See FLEXOR INTERNODII SECUNDI DIGITORUM MANUS.

PERFORA'TUS PE'DIS. See FLEXOR SUBLIMIS PEDIS.

PERFORA'TUS CASSE'RII. See CORACO-BRACHILEUS MUSCULUS.

PERFRICA'TIO, (from *perfrigeo*, to be very cold). See HORROR.

PERFU'MES. See MATERIA MEDICA; ODOURS, aromatic, fragrant, and ambrosiacal, p 134.

PERIA'MMATA, and PERIAPTA, (from *περιαπλω*, to hang round). See AMULETA.

PERIADY'SMIA. See GASTRODYNIA.

PERIA'NTHIUM, (from *περι*, around, and *ανθος*, a flower). The calyx, when contiguous to the fructification. When it includes the stamina and germen, it is the perianthium of the fructification; when the stamina without the germen, the perianthium of the flower; when it contains the germen and not the stamina, the perianthium of the fruit. See CALYX.

PERI'ANTHIUM ABBREVIATUM. Shorter than the tube of the corolla.

PERIBLE'PSIS, (from *περιελεπω*, to stare about). The wild look of delirious persons.

PERI'BOLE, (from *περιβαλλω*, to surround). Sometimes it signifies dress; at others, a determination of fluids to the surface.

PERICA'RDII ARTE'RIA, (from *pericardium*, the membrane surrounding the heart). The ARTERY OF THE PERICARDIUM, rises from the anterior middle part of the common trunk of the subclavian or the carotid, runs down upon the pericardium to the diaphragm, to which it sends some branches.

PERICA'RDII VENA. The VEIN OF THE PERICARDIUM, sometimes springs from the trunk of the superior cava, at others from the origin of the right subclavian. The left vena pericardii comes sometimes from the left subclavian before the mammaria, sometimes from the mammaria or diaphragmatica superior on the same side.

PERICARDI'TIS, (from the same). See INFLAMMATIO PERICARDII.

PERICA'RDIIUM, (from *περι*, about, and *καρδια*, the heart,) *capsula*, *involucrum*, and *succulus cordis*, the membrane which surrounds the heart filled in the living body with an halitus, which is condensed in a watery fluid after death. The first membrane of the pericardium is formed by the pleura, which leaves it where it adheres to the diaphragm. The substance of the *pericardium* is a firm membrane, composed of two lamellæ, the external of which is the stronger, and apparently composed of tendinous fibres crossing each other in every direction: the internal is a complete bag, without perforation, being reflected over the heart itself, and nearer a spherical than a conical figure. This internal coat contains the liquor pericardii, supposed to be secreted by glands, but more probably exhaled from the small continuations of the arteries. In healthy persons, the quantity of fluid is small, in others more copious, generally resembling serum tinged with blood, owing to the transudation of blood through the muscular cavities of the heart, for the longer the body is kept, the redder is

the liquor. The use of the pericardium is to supply the fluid, and to confine the heart; and it is very intimately connected by a great surface to the diaphragm, near the middle, where it has little motion in inspiration or expiration. The pericardium is much larger than the heart; it is not fixed to the basis of the heart, but round the large veins above the auricles before they send off the ramifications, and round the large arteries before their divisions, which alters the general rotundity of its figure. This membrane is subject to different affections; particularly dropsy, inflammation and suppuration. See HYDROPS, INFLAMMATIO, and ABSCESSUS PERICARDII.

PERICARDIO-DIAPHRAGMATICÆ VE'NÆ. See DIAPHRAGMATICÆ SUPERIORES.

PERICARPIUM, (from *περι*, about, and *καρπος*, the fruit). The germen, or seed vessel, from which the seeds drop when they are ripe. It is analogous to the ovary of animals; but its place in the vegetable kingdom is occasionally supplied by the calyx. It is distinguished by several appellations, according to its nature or shape, as *capsula*, *siliqua*, *legumen*, *conceptaculum*, *drupa*, *pomum*, *bacca*, *strobilus*, *folliculus*. See also CATAPLASMA.

PERICHO'NDRIUM, (from *περι*, and *χονδρος*, a cartilage). The perichondrium is said to be only a continuation of the periosteum, which, according to Dr. Hunter, may be true of that which supplies the place of bone in an adult, as the trachea; or in such as in maturer age become bone, as the epiphyses of infants; but on the cartilages that are expanded over the extremities of articulating joints, the perichondrium is the inner layer of the capsular ligament reflected over them. This is only discoverable in young subjects, where the parts are capable of separation.

PERICHRISIS, (from *περι*, and *χρισω*, to anoint). See LINIMENTUM.

PERICHRISTI, (from the same). An unguent applied to the eye lids in ophthalmia.

PERICLASIS, (from *περι*, and *κλαω*, to break). A fracture with a considerable wound, wherein the bone is laid bare.

PERICLY'MENUM, (from *περικλυζω*, to roll round). A climbing plant. See CAPRIFOLIUM.

PERICLY'MENUM PARVUM. See IPECACUANHA.

PERICRA'NIUM, (from *περι*, and *κρανιον*, the head). The membrane which immediately invests the bones of the skull, under the hairy scalp, made up of two laminae, closely united. The external lamina parts from the internal at the semicircular plane surrounding the temples, and becomes a very strong aponeurotic or ligamentary expansion, which covers the temporal muscle, and is afterwards fixed in the external angular apophysis of the os frontis, in the posterior edge of the superior apophysis of the os malæ, and in the superior edge of the zygomatic arch, as far as the root of the mastoid apophysis. At this place the aponeurotic coil seems to form the external lamina of the pericranium, and they both communicate with particular aponeurotic expansions of the mastoid, masseter, zygomatic, and other neighbouring muscles.

PERIDESMICA, ISCHU'RIA, (from *περι*, and *δεσμος*, a ligature). A suppression of urine from stricture in the urethra. See ISCHURIA.

PERIDRO'MOS, (from *περι*, and *δρομος*, a course). The extreme circumference of the hairs of the head.

PERIESTECOS, (from *περιεστειναι*, to surround).

An epithet for salutary symptoms, prognosticating the recovery of the patient.

PERI'GRAPHE, (from *περιγραφο*). An inaccurate, circumlocutory description or delineation. See also RECTUS ABDOMINIS.

PERI'GUA. See CASSINE.

PERIN, (from *πηρα*, a bag). See TESTES, PERINÆUM, and ANUS.

PERINÆOCE'LE, (from *perinæum*, and *κελη*, a rupture). A rupture in the perinæum.

PERINÆ'UM, (*περινω*, to flow round; from its moisture,) *interfemineum*, *gressura*, *pechedion*; the space between the anus and the parts of generation; divided into two equal lateral portions by a distinct line, called RAPHE, q. v., longer in males than in females.

In midwifery, when the os externum is so much dilated by the head of the fœtus as to allow of its delivery, the perinæum is generally stretched to the length of three, and sometimes of four inches, so that without care, a laceration would be often the consequence. Instead of stretching back the perinæum with the finger, it should be supported with the palm of the hand, and the head of the child at the same time moderately opposed in its force, that the distention may be made gradually, until sufficiently dilated for delivery. Inflammations and lacerations of the perinæum, if they occasion vomiting, are soon fatal. When this accident happens, the woman should be kept long in bed, with her knees constantly closed, and her bowels should be kept soluble.

The puncture of the perinæum was an operation usually performed in cases of a suppression of urine, which cannot be relieved by gentler methods. The operation was performed by pushing a trochar at the place where the external wound in the old way of cutting for the stone was made, into the cavity of the bladder. At present the water is evacuated by pushing the trochar into the bladder, from a little above the os pubis, or through the rectum. This method of discharging the urine hath succeeded, but when the suppression has been of long continuance, the operation is dangerous; for the bladder, by distention, has lost its tone, and mortification, at least an incontinence of urine, is the usual consequence. See Le Dran's Operations. Sharp's Operations. Sharp's Critical Enquiry. White's Surgery, p. 466. There are also abscesses formed in this part. See ABSCESSUS PERINÆI, and FISTULA IN PERINÆO.

PERINÆA'LIS ISCHU'RIA. See ISCHURIA; the varieties of the fourth species.

PERINENEUCOS, (from *περι*, and *νεω*, to nod). See EPINENEUCOS.

PERI'N PANEL. A bacciferous Indian shrub, the leaves of which are used in fumigations in hysteria. It has yet found no place in the systems of the botanists. See Raii Historia.

PERINY'CTIDES, (from *περι*, and *νυξ*, the night). PUSTULES, or PIMPLES, which break out in the night.

PERIOSTEUM, (from *περι*, about, and *οστειον*, the bone,) *circumossalis*, is that membrane which covers the bone, divided by authors into two layers. The internal or proper periosteum lies close to the bone, and appears furrowed like it. This is a very fine membrane, and appears, on a successful injection, to be extremely vascular, from the ramification of vessels which run to the bone. The external layer is of a white glistening

appearance, composed of the fibrous expansions of membranes, ligaments, and tendons, running in various directions according to the insertion of these tendons. The periosteum is not elastic: Dr. Hunter thinks it is not very sensible; and advises, in amputations, not to scrape it, but only to pass the knife round it, a little above the place where you intend to saw. The periosteum is wanting on those parts of a bone where strong tendons enter, as in the trochanter. Its uses are, to prevent the bad effect of friction on the bones; to protect the vessels running into them; to connect epiphyses; and to give origin to muscles. See *ABSCUSSUS PERIOSTEI* and *INFLAMMATIO*.

PERIPHYMO'SIS. See *PARAPHIMOSIS*.

PERI'PLOCA, (from *περιπλέκω*, to twist round). Italian and French *SCAMMONY*; *scammonia Monspelica rotundioribus foliis, apocinum latifolium; cynanchum monspeliacum* Lin. Sp. Pl. 311. Its concreted juice purges in somewhat larger doses than the scammony of the shops.

PERIPNEUMO'NIA, *PERIPLEUMO'NIA*. *PERIPNEUMONY*, from *περι*, about, and *πνευμων*, the lungs; *pulmonia, pneumonia*. Dr. Cullen defines it a *peripneumonic pneumonia*, attended with a pulse not always hard; sometimes soft; an obtuse pain in the thorax; a constant difficulty of breathing, often not perceived unless in an erect posture; the face swelled, and of a purple colour; most commonly with a moist cough, and often bloody sputum. Of this he makes three divisions. 1. Simple idiopathic peripneumony. 2. Idiopathic peripneumonies, complicated with fever, as the putrid, ardent, and malignant peripneumony. 3. Symptomatic peripneumonies, viz. the arthritic, exanthematic, phthisical, hydrophobic, and rachialgic. Other authors distinguish three kinds of peripneumony: the true, or inflammation in the lungs; the spurious, or when mucus obstructs the vessels of the lungs; the catarrhal, from a thin acrid defluxion on the lungs.

The true peripneumony is produced by cold applied to the skin, mouth or stomach; an over exertion of the lungs; or by any of the general causes of inflammation.

The disease commences with the usual symptoms of fever. The cold fit is violent, succeeded by great heat, head ach, dryness of the tongue and skin, urine of a dark or a yellowish redness, countenance full and of a purple colour. These symptoms occasionally continue for a day or two before any pain in the chest comes on, though sometimes the pain attacks on the first accession of heat. The pulse is at first hard and strong; but in the true peripneumony frequently soft, and apparently labours with a distressing load; at last it is weak, fluttering, irregular, and indistinct. When the pain is felt, a short, dry, distressing cough soon follows, which greatly exasperates it, and continues during the whole complaint; but, on its salutary decline, is freer, easier, and looser. In the beginning of the disease scarcely any sputum is discharged, but a little frothy saliva, followed by a yellow viscid gluten, and at last by a whiter softer matter if the disease proceeds favourably. The pain is occasionally in almost every part of the chest, but usually between the ribs of either side, more frequently, it is said, on the right side than the left. It is increased on laying down, and considerably more so by laying on either side, whether it be the side affected or not. It is singular that this symptom should vary so considera-

bly in different cases; nor could all the anatomical dexterity of Morgagni, or the pathological ingenuity of Dr. Cullen, explain satisfactorily the reason of what is styled the varieties of the *decubitus difficilis*.

The difficulty of breathing is chiefly felt on inspiration, but the expiration is performed frequently by a convulsive effort, and often an obscure sound. The bowels are generally constipated, though in a few instances a diarrhoea attends.

If peripneumony proceeds favourably, the pulse becomes slower and softer; the yellow, tenacious, and often bloody, sputum is mixed with points of a whiter matter, and the proportion of this more salutary expectoration gradually increases with the amendment of every symptom, for the cough is less violent and straining, the breathing freer, the skin more moist, and the tongue cleaner at the edges. If less favourable in its progress, the sputum becomes more dark and viscid, the pulse lower, indistinct, and often intermitting; a wandering low delirium comes on, with subsultus, and the patient dies, apparently suffocated, from the oppressed vessels no longer permitting the expansion of the lungs.

Peripneumony is, in general, confounded with pleurisy; with inflammation of the other contents of the thorax; with rheumatic affections of the muscles of the chest; with catarrh, and asthma. It is, however, an active inflammation, which at once excludes the two latter diseases. The rheumatism in the side is attended with acute pain, but with scarcely any cough, and with a hard pulse, nor is the face full and flushed. True pleurisy resembles, in many respects, peripneumony; but, in general, the face is less flushed, the pulse harder, the cough less violent, and without, at any period, expectoration.

Pleurisy and peripneumony, however, are seldom wholly distinct, and the diagnosis is of less importance, as the remedies are nearly the same. (See *PLEURITIS*.) Where cough exists, whatever be the name of the disease, expectoration must be brought on, if possible. Various other inflammations of the chest, as of the pericardium and diaphragm, are attended with similar symptoms, but the treatment differs so little, that no injury can arise from mistake. It is necessary, however, to remark, that the seat of peripneumony is often changing, that it shifts from one side to the other, to different parts of the same side, and when the lower part of the right lung is inflamed, a similar affection is communicated to the liver, occasioning pain in the right epigastrium, with an expectoration yellow, copious, and frothy. See *HEPATITIS*.

Peripneumony terminates, like other inflammations, in effusion, suppuration, or gangrene. It has, however, a termination peculiar to itself, viz. hæmorrhage in the lungs, from the increased vis a tergo. Effusion is the salutary termination; and when we perceive an apparent resolution by expectoration, some effusion always accompanies it; for after violent peripneumonies, adhesions are often found between the lungs and pleura, or watery effusions take place in different parts of the chest. Suppuration is known, as in other parts, by a remission of the pain and shivers, followed after some time by heat and increased perspiration. Throbbing pain is seldom felt, except when the seat of the disease is just within the intercostal muscles; and in that case a fullness, as well as pain, on pressure, point out very

distinctly the part affected. Gangrene is shown by the sinking pulse, general debility, with a sunk countenance, and the usual placidity, or occasionally with a ghastly stare. The termination by hæmorrhage is sudden; and it is discovered by dissection, since the lungs are found to resemble in substance the liver.

If we perceive, on the fourth or fifth day, the spitting more free, less glutinous, whither, approaching in the distinct clots to a globular form, the disease is evidently remitting. The usual signs of a freer, slower pulse, a white sediment in the urine, and a soft clammy moisture on the surface, are equivocal, without some change in the expectoration; for unless the sputum assumes the salutary appearance, should even the fever remit, suppuration or phthisis are frequent consequences. The suppuration, however, from peripneumony, is very different from that which constitutes consumption, and we have in one or two instances suspected that a salutary termination of the former has checked a beginning hectic. On the other hand, however, inflammation of the lungs often excites a similar state in a previously indolent vomica, and consumption is thus the consequence of peripneumony. It has been doubted whether the salutary effusion may not by absorption, perhaps by the drying power of the air, assume the purulent appearance; because purulent matter is sometimes said to appear independent of any abscess, or indeed of any loss of substance. This induced De Haen to consider pus as a secreted fluid; but though we have admitted that secretion may take place from arteries without any glandular apparatus; yet, on the whole, there is no evidence, at least in this disease, that pus is secreted, or that the dried effusion assumes its semblance. (See Pus.) If pus in peripneumony appears, suppuration has preceded.

A bloody sputum is often alarming, as the forerunner of an hæmorrhage; but such consequences seldom follow: on the contrary, we have often found it a salutary symptom, not differing in its effects from a topical bleeding. A diarrhœa coming on about the fifth or sixth day is often a highly dangerous event, as it prevents the salutary discharge by expectoration, or if the latter has appeared, checks it, without supplying its place. A moist skin, with an improving sputum, is often advantageous; while a dry heat, oppressed breath, with great anxiety, are alarming. To be able to lie low for a little time on either side is favourable; but the prognosis is always peculiarly uncertain, since the disease is so often exasperated unexpectedly, and changes its seat, with a new accession of fever frequently in its course. The cough is often most distressing, which we dare not mitigate, as every remedy for this purpose checks expectoration. We have not, however, found that the most incessant cough is a prognostic of a peculiarly dangerous state of the disease. Delirium is often a dangerous symptom; but we have sometimes seen peripneumony alternating with delirium, and in that case the disease has yielded with little trouble. Favourable signs appearing on the seventh day give a probability of a safe termination, should no metastasis occur; but in no disease is the strictest caution more necessary, since in none are there more unexpected changes, in none is the fatal event frequently so sudden, while our apprehensions are lulled by promising symptoms. If we pass the seventh day without any favourable change the patient seldom recovers. If the

changes are not decisively salutary before the fourteenth, complete recovery cannot be expected.

The remote causes of peripneumony are those of inflammatory fever in general. An inflammatory diathesis, by which we understand increased tone of the arterial system, is usually necessary to give the usual active form of the disease; but we shall find that it may take place when this state is in an inconsiderable degree, or when it is wholly absent. That more topical causes, as straining, obstructions, or any injuries of the lungs, may induce it, appears doubtful. They may perhaps predispose to it, or, on the accession of exciting causes, may render the subsequent complaint more violent. The effect of the causes of inflammatory fever directed to the lungs is the constriction of the extreme vessels, and this, with the increased vis a tergo, as explained in the article INFLAMMATION, q. v. will explain all the symptoms.

Dr. Fordyce, in the second part of his Elements, observes, that nature without assistance sometimes relieves the complaint by an increased secretion of mucus from the lungs, which at first is spit up thin, and with uneasiness, becomes gradually thicker, of a yellowish or greenish cast, and at last white. It is often, he adds, mixed with blood, relieving, and gradually diminishing, the symptoms, so as to remove the disease before the fourteenth day. Peripneumony is sometimes cured by an hæmorrhage, or by an inflammation arising in some other part of the body.

The artificial cure depends on the same principles. Expectoration, we have observed, is the only salutary evacuation, but to procure it, the inflammatory stricture must be first taken off. To these views every part of the curative plan must be directed. Indeed, in true peripneumony nature can seldom relieve without the aid of art; and in those cases in which disease has spontaneously or with little assistance yielded, it has probably been rather catarrhal than peripneumonic. Catarrh, we have seen, consists in an inflammation of the bronchial glands, and if it extends farther into the substance of the lungs becomes peripneumony, though in that case the disease is seldom of the more active, the more acute, kind.

BLEEDING is the only remedy for the former purpose, and it has been often employed with freedom, often with temerity. In the use, however, of this mode of relief, we must anxiously consider the patient's constitution, habits, and situation. The strong and robust; those who have lived full, and been subject to inflammatory diseases; the laborious rustic, who breathes the pure air of a mountainous district; will bear very large and repeated bleedings. In such cases it is often necessary to take from eighteen to twenty-four ounces at once, to repeat the operation after twelve hours, scarcely to a less extent, and again after twenty-four or thirty hours. The limits in these cases are the relief of the pain, some mitigation of the hard pulse and burning heat. We have proceeded even farther with this evacuation in particular circumstances; but when in the constitution we have described, the attack is violent, the discharge of blood must be considerable within a short period, and it should be taken from a large orifice. The appearance of the blood affords us also some criterion for the propriety of the repetition. If the clot is dense, of a buffy surface, contracted round the edges,

resembling in form a cup, the patient will usually bear with ease farther evacuations. The buffy appearance, however, is often seen when the texture of the clot is loose, sometimes even in the blood from scorbutic persons, so that the density must also be examined. A convenient method for this purpose is the pressure of any substance of a given weight, as of a key kept constantly in the pocket.

The evacuation must be more guarded in different circumstances, and, in all, the shades from the extreme case already described to the indolent inhabitant of a crowded town, or the sedentary mechanic, exhausted by labour and poverty, our conduct must be cautiously varied. The practitioner must recollect, that this remedy is designed to obviate the inflammatory diathesis, which is chiefly distinguished by the general firmness and vigour of the whole habit, and by the hardness of the pulse. The former is not always to be certainly ascertained, and the latter is still more equivocal. The resistance formed by the obstruction of the larger vessels will often give a seeming hardness where there is a slight degree only of inflammatory action, and the pulse has been denominated harsh rather than strong. In all doubtful cases, therefore, the greatest care is requisite, particularly in ascertaining distinctly the effects of the first bleeding. If these are doubtful, we should lessen the subsequent evacuation, even should symptoms appear to require it. In these uncertain cases we seem to relieve pain; but the pulse, instead of becoming fuller and softer, is often more contracted, or more weak; the countenance may, indeed, appear less flushed, but it is also sunk; the difficulty of breathing is greater; and the little expectoration which might have appeared is checked. The disputes, whether blood should be taken from the side affected, or the opposite side, chiefly relate to the use of bleeding in PLEURISY, q. v., and we shall notice them under that article.

When we feel doubts respecting the propriety of general bleeding, we may still evacuate blood from the part affected, by means of cupping glasses or leeches. The latter are often preferable, as they do not render the subsequent applications of blisters inconvenient. If the disease is violent, the number of leeches to the side should not be less than eight or ten; but in exhausted constitutions the less number may be more advisable. If cupping glasses are applied, not more than five or six ounces should be taken, as the evacuation is more rapid.

When the increased tone of the arterial system is thus in part removed, it may be farther lessened by *laxatives* and *refrigerants*. Whatever may be the inconvenience of *laxatives* in the advanced stage, they are highly useful in the earlier periods, and in the three first days may be freely employed: the milder saline *laxatives* are preferable. The most useful refrigerant is nitre, which may be combined with the citrat of potash, or determined more certainly to the skin by the addition of camphor, and of antimonial wine, or by a combination with the citrat or acetat of ammonia.

Emetics may be given in the earliest stage; but when the violent obstruction of the vessels of the lungs has taken place, they are doubtful remedies, and the nauseating antimonials are preferable. These, with the refrigerants, are the only safe and most effectual diapho-

retics. Of the antimonials, the Kermes mineral has been preferred, though without any peculiar advantage.

The more violent fever will be, in some degree, lessened by these plans, and the local affection will be alleviated by *blisters*. These have been objected to in the earlier period of the complaint, as danger was apprehended from their stimulus; but there is little foundation for the caution. If bleeding be necessary, it should always be premised; and in the extreme case of highly inflammatory diathesis first mentioned, two bleedings at least are required before the blister will act with advantage. It should then be applied on the part affected; nor, as we have said, are the wounds from leeches any impediment. Should cupping glasses have been applied, a little delay is necessary, before the wounds are closed by an inflammation of their lips. If blisters are applied very early, they sometimes drive the pain to another part, often to the opposite side, and it will be necessary to follow it with another blister, though, if the inflammatory diathesis is violent, bleeding must be repeated.

The cough may be alleviated by oily emulsions, by demulcents, or by inhaling the steam of warm water. Opiates, however, during the whole course of the disease, seem to be injurious; yet De Haen gave, as we have remarked, the tincture of opium, with olive oil; and other authors have occasionally employed this medicine; but, except when a sudden check is necessary for a diarrhoea, we have seldom used it, and even then with disadvantage in other respects. The extract of the white poppy has been given by Dr. Saunders; but this is so slight an opiate as scarcely to militate against the general opinion; and Dr. Hamilton, of Lynn, combined it with calomel, he thought with advantage; but his practice has not become very general. We cannot speak of this combination from our own experience.

The *expectorants* are the chief remedies; and the most effectual of these, in the first days of the disease, are the remedies already recommended for the fever, particularly the camphor, and the nauseating doses of antimonials. When the inflammatory obstruction is in some measure removed, when the expectoration is less glutinous, and assumes a more globular form in the basin, with a whiter colour, a gentle stimulus on the bronchial glands is useful. The gum ammoniac is less irritating than the squills, and it was formerly combined with soap, to render it was said, the sputum whiter. However ridiculous this language may appear, we have suspected that the effect had some foundation, and that with soap the expectorants were more effectual than in any other form. Those who are fond of pursuing analogies may, from the same source, explain the little inconvenience experienced by De Haen from opium when combined with oil. After a day or two the squills may be combined with the gum, and the dose gradually increased.

When every circumstance seems, in this way to be favourable, and every symptom to assume a more salutary appearance, our progress is often checked by two events. The expectoration will sometimes suddenly stop; or a diarrhoea coming on will have the same effect. The expectoration stops occasionally from some irregularity, from the strength having been exhausted by previous bleeding in excess, or without our being able to trace the suppression to any cause. In this

case, breathing the steams of vinegar, the ammonia added to the medicines, increasing the dose of the squills, or a blister to the back part of the neck, will often bring it back. Whatever is attempted must be closely followed, for the danger is imminent; nor is there any great impropriety in adopting, nearly at the same time, each means of relief, provided the doses are not so considerable as to exhaust the excitability. In this situation, also, we are advised to put blisters to the inside of the thighs or legs; and, though it is not easy to explain their effects on any principle but the erroneous system of revulsion, we have thought them serviceable. In reality, when nature is sinking, the obstruction often yields, and the last remedy gains the credit; so that when medicine seems to fail, if we support the patient with good broths, or jellies, interposing, when necessary, a little wine, we shall often succeed. Slight emetics will be frequently of service at this time, and restore the expectoration, whose return was before hopeless: the seneka root seems to have gained reputation from its effects in these emergencies.

A diarrhœa supervening is a more distressing event; and it is not uncommon either from some irregular and erroneous exertion of nature, or from the medicine. It has been usually attributed to the squills, but these will not produce this discharge when most wanted; to the gum ammoniac, which is scarcely in any case laxative; to the oily emulsions, the usual vehicle which contains a proportion of oil inadequate to the effect. Whatever be the cause, the event is equally distressing and dangerous. We have in emergencies interposed opium, but the expectoration is by this means more effectually checked; and if we attempt to restore it by emetics, we incur the risk of their operating on the intestines rather than the stomach. The seneka is liable to the same inconvenience; and the effects of vitriolated zinc and copper are too uncertain, often too violent, to be trusted in such a dangerous situation. Difficulties, so painful we have more lately endeavoured to elude; and by adding the pulvis à creta c. cum opio in the dose of about five grains, often with a drop, or more, of the oil of cinnamon to each draught, we have patiently waited the event. This plan, when a diarrhœa seems to impend, we often had reason to be better satisfied with than the more active opiate. The extract of logwood is an useful addition, and will sometimes alone check the diarrhœa, but cannot alone be trusted.

Through the whole course of the disease warm diluting liquors should be freely given, the room be airy, the curtains open, avoiding equally too great heat, or a current of cold air. An erect position is generally recommended; but sitting up occasions fatigue, and a half erect posture, supported by pillows, is equally advantageous. Bathing the feet and legs is an equivocal remedy, and should not be attempted without the greatest caution. If the water is too warm, the stimulus will be too great; if too cold, it may produce a shiver. Every means of avoiding either should be carefully guarded.

Many slight remedies have been spoken of with high commendation. If such have succeeded, it is fortunate for the patient and the practitioner. We have found, however, peripneumonies so intractable and so dangerous, with every precaution, that we have suspected vio-

lent catarrhs to have been raised into importance under this more formidable title.

See Baroni de Pleuro Peripneumonia; Huxham on Fevers; Stoll Ratio Medendi, 1776, and Aphorismi de Febris; Morgagni de Sedibus et Causis Morborum; Baglivi Opera; Lancisi Opera; Vogel Prælectiones Academicæ; De Haën Ratio Medendi, tom. ix. et xi.; Sarcione Istoria Ragionata de Mali osservati in Napoli, part ii.

PERIPNEUMONIA PUTRIDA. Inflammatory peripneumonies do not merit the appellation of an epidemical disease; for, though frequent about the same time, they seem rather to arise from the severity of the weather than any peculiar miasmata. The putrid peripneumony, on the contrary, proves often a very formidable epidemic, and its nature is that of the typhus, with which the peripneumony is accidentally combined. It is the property indeed of every epidemic fever to assimilate each accidental disease to its own nature.

The putrid forms of inflammatory diseases have not shared the attention of nosologists, because their systems would not always consistently admit them. They claim, however, particular notice, not only on account of the diagnostic, but of the very different and opposite treatment which they require. When lately speaking of measles, we mentioned Dr. Willan's opinion, that the supposed putrid form of the complaint was really a different disease, the scarlatina. We then observed, that though we had not seen such a disease, from analogy its existence was highly probable; and the sheet had scarcely passed the press, when measles, in its least equivocal form, but attended with putrid fever, and every mark of debility, occurred to us. In short, it was exactly such a complaint as we supposed in that article it might be. (See MORBILLI.) The putrid peripneumony we have had occasion to see in four distinct epidemics, and shall now shortly describe.

It begins with coldness, like other peripneumonies; but the cold continues long, without being followed by heat: the depression of strength is perceived very early, and the countenance, though sometimes reddish, is usually sunk. The pain of the side is highly distressing, and the cough almost incessant. The pulse has the semblance of strength, but beats with a stroke less firm and full than in the inflammatory peripneumony, and may be distinguished from the oppressed pulse lately described, by its being soon stopped when pressed. The rest of the scene is soon concluded. Debility hastens rapidly on; the pulse flutters; the countenance becomes truly hippocratic; and life soon ebbs, without our having the power to recall it.

Expectoration scarcely in any instance comes on, for the final scene anticipates the period of its approach; and the vessels, even when the duration of the disease is prolonged, are no longer able to propel it. Every evacuation hastens the event; nor is there often room for the mildest emetic, or the most gentle laxative. The disease is usually fatal on the fourth or fifth day; and if any blood is incautiously drawn, or any laxative has a violent effect, on the third, frequently on bleeding, the patient has sunk in twenty-four hours.

The best remedy is camphor, with the aromatic confectio, and wine in large quantities. After a day or two the bark may be given in doses as large as in the

most putrid fever; nor has it appeared to increase the difficulty of breathing. A gentle salutary moisture on the skin, the diapnoe of Chenot, is the most favourable symptom, together with a return of the natural character of the countenance. Should an evacuation by stool be necessary, a clyster only should be trusted. In fact, every rule in the treatment of the true peripneumony must be abandoned, and the strength by every means be supported.

Dr. Cappel, a pupil of Frank, the great admirer of Brown on the continent, has described an epidemic of this kind which occurred in Dr. Frank's institution, but not so acutely putrid as it has occurred to us. Purgatives were useful in the early state; and where the debility was not very great, we have found them in the very earliest stages salutary, if given with caution. He enumerates also the Kermes mineral, seneka, camphor with calomel, and all the medicines which he could find had been recommended in inflammatory peripneumony as likely to be useful. With no little inconsistency also he prefers the Brunonian doctrines, though Brown speaks only of bleeding and purging as remedies for peripneumony, while bleeding, even with leeches, is pronounced fatal, and purges only admitted in the earliest periods. Such perhaps were the commands of Frank.

Authors generally speak of this disease as an erysipelatous inflammation of the lungs. See Sarcone Istoria Ragionata; Ludwig Adversaria, part i. p. 52.; Huxham de Aere, &c. vol. i. p. 324, 326; Forestus, lib. i.; Obs. 16, 17, in scholio; Huxham, vol. ii. p. 63; Baglivi Appendix de Pleuritide.

PERIPNEUMONIA NO'THA. The SPURIOUS or BASTARD PERIPNEUMONY; *catarrhus suffocativus* of authors, may appear at any time in the year, but it usually approaches early in the spring, particularly after a very sharp winter. This kind of peripneumony resembles the true, but the heat, pain, and thirst, are not so considerable, and the accumulations of mucus in the lungs are more considerable.

This disease is strictly and originally catarrhal, affecting those advanced in years, or who have weakened their constitution by any excesses. It is brought on by cold, and particularly by the north-east winds of early spring. The catarrhal accumulations are not readily thrown off, and the obstruction excites fever and inflammation; but, as may be expected in such constitutions, of a languid, sluggish kind. It is said to be occasionally produced by drying up an old ulcer, or by a dropsical disposition; but it is then apparently confounded with hydrothorax.

Boerhaave observes, that the bastard peripneumony steals upon the patient with a slight weariness, weakness, debility of the intellectual functions, dyspnoea, and an oppression of the breast. The uneasiness it excites is so small, that the heat and fever are scarcely sufficient to make the patient sensible of his disorder: afterwards slight shiverings, returning in paroxysms, and the attacks of a gentle fever suddenly increasing the dyspnoea and debility, bring on death, without any particular change in the pulse or urine. Sydenham, who first distinguished this disorder from the catarrh, gives the following account of its attack and progress. The patient is hot and cold alternately, giddy, complains of an acute pain in the head, when the cough is most

troublesome. He vomits all liquids, sometimes with and at others without coughing; the urine is turbid and intensely red; the blood taken away resembles pleuritic; the patient breathes quick and with difficulty; if advised to cough, his head aches, as if it would burst; a pain is felt in the whole breast; and a wheezing is observed by the attendants whenever the patient coughs. To this may be added that the patient's cheeks and eyes often appear slightly inflamed, the pulse is small, often intermitting. Lying low, or on one side, is peculiarly painful.

If the strength does not return after the disease is removed, the pulse continues quick and weak, breathing difficult and oppressed, with at times shivers, followed by flushing in the cheeks: if the lips are dry, and the appetite defective, the patient soon sinks with suffocation.

The disease is therefore in every view catarrhal, and peripneumonic only from obstruction or accidental cold. Its most frequent termination is in hydrothorax, and, indeed, in the description of every author symptoms of hydrothorax are occasionally mixed. It is undoubtedly difficult to avoid confounding diseases similar in their symptoms, and rapidly changing, to each other; nor is it of consequence, since the treatment differs so slightly. The very inconsiderable degree of inflammation which occurs in peripneumonia notha requires no very peculiar conduct. It arises from accumulation of mucus, and is relieved by lessening the load.

The indications of cure will be to expel the accumulated mucus, and to strengthen the habit in general. The warmer expectorants, with those which gently stimulate the bronchial glands, are the principal remedies. The former are the balsam of Peru, and the different turpentine; the latter the gum ammoniac and the squills. Perpetual blisters to the breast are often essentially serviceable, and issues or blisters on the legs or thighs have been recommended, though it is not easy to ascertain the principle on which they act, or, indeed, whether they are really advantageous.

If the cough is violent, opiates may be given as soon as expectoration is tolerably free; a mixture of the pil. ex opio and pil. ex aloe cum myrrhâ may be safely given in such doses as circumstances may require. To keep the bowels lax is essentially necessary, and in giving the opiate we must never interfere with the discharges by stool.

The tetradynamiaë are very useful as stimulant expectorants, and the mustard whey is a common as well as a salutary drink. The seneka is often too violent in its operation, but in moderate doses may be useful, for active emetics are often injurious. Warm weather or a warm climate are often useful auxiliaries.

The strength is restored by the warm balsams, with the purer bitters; by chalybeate waters; moderate and constant exercise; by a strict attention to diet, which should be generous, without being too rich or flatulent; and by a steady moderate discharge from the bowels. For this purpose the warmer laxatives, in the form of tincture, are useful, and none are more so than the tinctures of rhubarb, senna, and jalap, in equal proportions.

When the disease is apparently combined with hydrothorax, or, in other words, when the mucus or water is in the cells of the lungs, the active expectorants and

diuretics must be joined with brisker purgatives. The squill and the gum ammoniac are the chief remedies in these circumstances, and they may be conveniently combined with a proper proportion of the extract of jalap.

See Sydenham's Works, part i.; Huxham, vol. i. p. 163: Grimm on the Epidemics of Eisenach; Boerhaave's Aphorisms, with Van Swieten's Commentary.

PERIPYEMA, (from *περι*, and *πυρ*, *pus*). A collection of matter surrounding any part.

PERIRRHOEA, (from *περίρρεω*, to flow from every part). A copious flow of humours from every part.

PERIRRHOE'XIS, (from *περι*, and *ῥήγνυμι*, to break). See HEMOPTYSIS.

PERISCEPASTRUM, (*περι*, and *cepastrum*, a wild onion; from its encircling the head in successive folds like the coats of that bulbous root). See FASCIA.

PERISCYPHISMUS, (from *περι*, and *κυφος*, *gibbous*). An incision made across the forehead, or from one temple to the other, over the coronary suture; formerly used in considerable inflammations of the eyes. The lips of this wound were kept asunder with lint; and when the disorder abated, the denuded bone was rasped, and the wound healed. P. Ægineta, lib. vi. c. 7.

PERISTALTICUS, (from *περιστῆλλω*, to contract). The vermicular motion by which the intestines protrude their contents.

This motion is not apparently downwards, but the contained matter is moved backwards and forwards, though, on the whole, the tendency is to the inferior portion of the intestine. This kind of motion is evidently designed to expose the alimentary mass more completely to the mouths of the lymphatics. In the large intestines, where the hardened mass is moved with greater difficulty, the contractions are stronger in consequence of the fixed points which the plaits of the intestine afford, and the contracted portion forms a valve to prevent regurgitation.

PERISTAPHYLINUS EXTERNUS, (from *περι*, and *σταφυλη*, *uvula*). See CIRCUMFLEXUS PALATI.

PERISTAPHYLINI INTERNI. See PETRO-SALPINGO-STAPHYLINI.

PERISTAPHYLO-PHARYNGÆI, (from *περι*, *σταφυλη*, and *φαρυγξ*). Two small muscles inserted between the uvula, and lower extremity of the internal ala of the apophysis pterigoidæus, and running obliquely backward on the sides of the pharynx. They are difficult to find in very lean subjects, and seem to be what Santorini calls *hypero-pharyngæi*, or *palato-pharyngæi*.

PERISTERIUM, (from *περιστῆρες*, a pigeon, because pigeons are fond of it). See VERBENA.

PERISTROMA, (from *περιστρίνω*, to strew about). See INTESTINA.

PERISTO'LE, (from *περιστῆλλω*, to compress). The interval of rest betwixt the systole and diastole of the heart.

PERITERION, (from *περι*, and *τηρῶ*, to preserve). See TREPANUM.

PERITOMATICOS, (from *περιτῶμα*, an excrement). See APERITTOS.

PERITONÆORE'XIS, (from *περιτοναϊον*, the peritonæum, and *ῥήσσω*, to break). A bursting of the peritonæum, and consequent hernia.

PERITONÆUM, (from *περιτείνω*, to extend round). This membrane, which lines the belly, and invests all

the viscera contained in it, is of a close texture, though very pliable, capable of great extension, and so elastic as again to recover its ordinary size, as appears in pregnancy, &c. It is connected to all the circumambient parts by a cellular membrane, generally called the *external lamella of the peritonæum*, which forms what are styled the *processes of the peritonæum*. The peritonæum, nevertheless, hath productions peculiarly its own, which run from without inwards, and cover externally the contained parts. (See ABDOMEN.) The cavity of the peritonæum is the receptacle of effused water in ASCITES, q. v.

PERITONITIS, (from *peritonæum*). INFLAMMATION OF THE PERITONÆUM, including the mesentery and omentum, inflammatio mesenterii. Dr. Cullen defines it to be a fever, with pain in the belly, increased when the body is erect, but without the proper signs of abdominal inflammations; and places this disease in the class *pyrexia* and order *phlegmasia*. The species are: 1. *Peritonitis typhosa*; 2. *Peritonitis omentalis*, *omentitis*, or *epiphloitis*; 3. *Peritonitis mesenterica*. See INFLAMMATIO MESENTERII, and PUERPERALIS FEBRIS.

The general directions for the cure of peritonitis are the same with those of ENTERITIS, q. v. But it is necessary as we have already observed, to distinguish them, since stools, though necessary, are not equally essential, and the application of a blister is more so. Opiates also may be given more freely, and, with the addition of the ipecacuanha to determine to the skin, they are often highly useful. The deeper seated species, as they are more difficultly distinguished, cannot be opposed by any particular plans. They must be in general treated as enteritis.

PERLE. See ALBUGO OCULORUM.

PERLÆ, (Ital. and Span.; *perl*, Welsh; *perlea*, Germ.). See MARGARITÆ.

PERNIO, (from *πῆμα*, the heel,) *chimetlon*, *erithema à frigore*, *bessamen*, *bugantia*; a variety of phlogosis erythema, in Dr. Cullen's system; KIBE or CHILBLAIN: this disorder attacks the hands, feet, heels, ears, nose, and lips, usually of children, and those of a sanguine habit and a delicate complexion. It arises from severe and continued cold, or from heat too suddenly applied after it.

The parts affected are inflated, and afterwards heat, redness, pain, and itching come on; small blisters are formed, which soon burst, leaving a slight excoriation, which at length becomes a deep and obstinate ulcer, discharging a sharp sanious matter; in the worst degree degenerating into a gangrene.

Its immediate cause is a diminution of the excitability of the extreme vessels, and the erysipelatous appearance of the earliest period is only the first stage of gangrene. It seems chiefly to occur to children whose vessels are full; and, in many instances it has appeared to be an inflammatory deposition, which it has been injurious to repel hastily. If it be a deposition, the nature of the complaint will be easily known by the fulness of the habit, and the relief of some general indisposition; and in that case laxatives, alteratives, and a simpler diet, will be necessary.

If from cold, the constitution should be gradually strengthened by the cold bath, bathing the feet and legs frequently in cold water; avoiding too much heat, when the feet are cold, and particularly warming the

feet when without shoes. It may be for a time prevented by warm socks, &c.; but these only render the person more subject to the complaint when they are neglected.

When a cough, or other circumstances, forbid the application of cold to the extremities, the best substitute is, to wear dog skin socks, or gloves, day and night, until the inflammation is removed. Linnæus recommends bathing the part with diluted marine acid; and the following embrocation is often an efficacious remedy. R. aceti, sp. vini tenuioris aa 3 vi. aluminis 3 ij. m. In greater degrees, when the part is frost-bitten, the treatment must be the same as directed in the article CONGELATUS.

Oil of turpentine, camphorated spirit of wine, camphorated oil, and volatile liniment, are often useful applications; and electricity has been employed, it is said, with success. In Scotland the fungous ulcerations which sometimes ensue, are destroyed with a hot iron; and in other places, alum beat up with the white of an egg is applied with advantage.

Vapours are sometimes more effectual than baths, and the vapours from vinegar are the best; but cold and astringent applications should follow, as these applications relax the vessels of the part. When ulcerated, the steams of vinegar and a warm digestive should be applied to the sore.

See Heister's Surgery; M. A. Severini Dissertatio de Pernionibus in Libro de Abscessibus; Tissot's Advice to the People; Bell's Surgery, vol. v. p. 440; Pearson's Principles of Surgery, vol. i. p. 142; White's Surgery, p. 22.

PERONÆA ARTERIA, (from *perone fibula*), is the smaller division of the posterior tibialis, passing down behind the fibula, between the soleus and the flexor pollicis. It then crosses the interosseous ligament, and about the upper and back part of the os calcis forms an arch with the tibialis posterior.

PERONÆUS BREVIS, (from the same,) *peronæus anticus* of Douglass, and *medicus* or *anticus* of Winslow; a muscle covered in part by the peronæus anticus. It rises from the outer part of the fibula, its fleshy fibres continuing to adhere to that bone, lies in a groove in the malleolus externus, and is inserted in the basis of the last metatarsal bone of the little toe.

PERONÆUS LONGUS; *primus* or *posticus* of Douglass, rises from the external lateral parts of the head of the tibia, and from the anterior outer surface of the fibula; its tendon is turned back under the tarsus, bound down by an annular ligament with the brevis, passing over the os cuboides, at which place it hath a sesamoid bone, and runs across the sole of the foot to be inserted into the basis of the first metatarsal bone, being an abductor. Near the insertion of this muscle there is a small bursa mucosa.

PERONÆUS SECUNDUS, *semifibularis*, rises about the middle of the outer part of the fibula, and, as it runs under the malleolus externus, becomes tendinous, and is inserted with the tendon of the peronæus brevis into the metatarsal bone of the little toe.

PERONÆUS TERTIUS, *nonus Vesalii*, is situated at the anterior inferior side of the lower part of the leg, closely connected with the outer edge of the peronæus longus. Its tendon passes under the annular ligament, and running obliquely outward, is inserted into the

metatarsal bone of the little toe. It is by late authors considered as a portion of the extensor longus digitorum pedis.

PERONÆA VE'NA is one of the divisions of the poplitea; and runs nearly the same course with the artery of the same name.

PERONE, (from *πείνω*, to fasten; because it fastens the tibia and muscles together.) See FIBULA.

PERONE'US BRE'VIS, (from *perone*; see above). See EXTENSOR DIGITORUM LONGUS.

PERSEA, (from *Persia*, whence it was brought). See MALA ARMENIACA.

PERSICA, (from *Persia*, *Rhodacinea*, from *Rhodes*). The PEACH TREE; its kernel is called *machærna*; the fruit *malus Persica*, *amygdalus Persica* Lin. Sp. Pl. 676. The fruit is spongy, cold, and watery, but not unwholesome, except in weak flatulent stomachs. The leaves are a narcotic bitter, and perhaps nearly as deleterious as the laurel leaves. These, as well as the flowers, are given as a vermifuge, sometimes with success. Half an ounce of the recent flowers, or one quarter of this quantity, when dry, is considered in infusion as the proper dose.

PERSICA'RIA U'RENS, (from *persica*, as its blossoms resemble those of the peach,) *hydropiper*, CULRAGE, LAKE WEED, WATER PEPPER, BITING ARSMART, *polygonum hydropiper* Lin. Sp. Pl. 517: is an annual, aquatic plant, with oblong uncut leaves, pointed at both ends, and with imperfect flowers set in spikes on the tops of the stalks. The cup is thick and fleshy, divided into five oval segments, which closing, form a cover to an angular glossy seed. The leaves have a burning taste, nearly allied to the arum; but their acrimony is dissipated or destroyed in distillation. They are said to be antiseptic, diuretic, and aperient; but are not used in the present practice. See Raii Historia.

PERSICA'RIA MACULA'TA. DEAD OR SPOTTED ARSMART; *persicaria mitis*, *polygonum persicaria* Lin. Sp. Pl. 518; grows also in wet grounds, and is said to be antiseptic, but is not in use as a medicine. See Raii Historia.

PERSICA'RIA SILIQUO'SA; *balsamina lutea*, *noli me tangere*, *impatiens herba*, *mercurialis sylvestris*; QUICK IN HAND, TOUCH ME NOT; is not a species of persicaria, but of the *impatiens*. It is the *impatiens noli me tangere* Lin. Sp. Pl. 1329; and is said to be a forcible diuretic, but is never used. See Raii Historia.

PE'RSICON, (from *Persia*). See JUGLANS.

PE'RSICUM BALSAMUM. See BENZOINUM.

PE'RSICUS I'GNIS. See CARBUNCULUS.

PERSI'STENS FE'BRIS, (from *persisto*, to persevere). A REGULAR INTERMITTING FEVER.

PERSONA'TA, (from *persona*, a mask, because, on the Roman stage, the leaves were used as a mask. Pliny). See BARDANA MAJOR, and BARDANA ARCTICUM.

PERSONATÆ, (from *persona*, a mask). One of the natural orders of Linnæus' Fragments, distinguished by an irregular ringent corolla. The greater number of genera agree with those plants which have two stamina longer than the others, and seeds in a silique.

PERSPIRA'TIO, (from *perspiro*, to breathe through). PERSPIRATION, *transpiratio*, *anapneusis*, *discussio*, *diaphoresis*, *diapnoe*, *difflatio*. The importance of this evacuation from the skin is very generally understood and

acknowledged. Cheerfulness and hilarity accompany its free discharge, languor and distress its suppression. We anticipated this subject under the article *DIAPHORETICA*, q. v., where we noticed the different forms in which the perspirable matter is discharged, as well as the sources from which it is produced. We there distinguished the halitus that forms the salutary, insensible perspiration thrown off probably in a gaseous form, from that more sensible discharge whose form is seemingly a vesicular vapour; and again from a decidedly fluid sweat. The two former are from the same sources, either exhalent arteries or cuticular follicles; the latter more probably from exhalent arteries, as it is apparently serum unchanged, and as the skin sometimes feels harsh and hard, though bathed in sweat. Perspiration also, in the two former states, is attended with cheerfulness and serenity; sweat, even when it relieves pain, leaves the patient languid and oppressed. It is not an objection to this opinion that anatomy has not discovered any glandular apparatus under the skin for either evacuation, since it is evident that the extreme vessels can alone separate, perhaps form, peculiar fluids; and there is not a greater difference between the rarest halitus and the most fluid sweat, than between the mild mucus of the Schneiderian membrane, and the acrid discharge, when this membrane is inflamed by a catarrh, or between the tears in the natural state, and the burning streams which flow from the eye in ophthalmia.

From the consequences of perspiration in excess or defect, it is evident that the state of the extreme vessels is intimately connected with that of the stomach and the brain; nor does the commonest observation require any aid to explain fully the changes in the functions of the latter, when in the access of fever perspiration is retained either by a spasm or a quiescence of the capillaries. Various other appearances show a similar connection with different parts of the nervous system. When a catheter or a bougie, for instance, is introduced into the urethra, a shivering is often induced, sometimes so great as to excite a hot fit, and a single paroxysm of fever. A dislocated ankle, Van Helmont informs us, produced in himself a shivering. Violent pain, a harsh sound, terror, and many purely mental affections, will have a similar effect; so that it was not inaptly said, that, like some insects, we live on the surface almost exclusively.

The perspiration, when fluid, contains a large proportion of water, some gluten, and a small quantity of muriated ammonia. When in the form of air, its chief ingredient is carbonic acid gas, sometimes azotic gas. It is highly probable that the nature, at least the proportions, of each vary in different constitutions, and in different circumstances; but experiment has not pointed out what these are, nor indeed are physiologists perfectly agreed which is the most common discharge. Azote, we have reason to believe, is taken in with the air in respiration; so that it is scarcely probable it should be discharged by an organ similar in its office to the lungs. The proportion of carbone in the system is constantly decreasing in the process of animalization, and therefore it is the more excrementitious fluid. It will not also have escaped the reader, that the difficulty we felt in tracing the changes of the diet in its assimilation, were those chiefly connected with the proportion of azote in the animal fluids.

We hinted in the article *MEDICINA STATICA*, that during the reign of the mechanical physiology, the state of health was measured by the weight; and if the egesta were equal to the ingesta, all was supposed to be well. When the balance turned, showing that the former were supplied, the morsel raised on the fork was rejected. In this inquiry, it was found that of eight pounds of aliment, five passed off insensibly; for the excrementitious matters amounted only to three. It appears, however, by subsequent experiments, that the smallest proportion of the quantity lost is discharged by the skin, and, from calculation, the surface of the lungs greatly exceeds that of the body, so that its perspiration, from this view also, is probably more considerable; and in colder climates than those of Italy, where Sanctorio's experiments were made, the quantity passing off by the lungs is probably far greater than the calculation. Is it that the skin is chiefly destined to convey the halitus, and the lungs the watery fluid? This is not very probable, since carbonic acid is discharged from the latter; nor is there more probability in the supposition, that azotic gas is separated exclusively by the skin.

Perspiration may either be in excess, defective, or altered in its qualities. Perspiration in excess is often partial in the feet and the axillæ; and the fetid odour, as well as the inconveniences from the suppression, shows that the quality is also altered. It is apparently in excess also in hectic; but as for a great portion of the twenty-four hours it is retained, there is some doubt whether it may be, on the whole, too great, and whether the debility may not arise from the loss of the gluten, combined with the perspiration when in a fluid form. In the *sudor anglicus* it seemed to sink the patient from the excess of the discharge, perhaps combined with the sedative nature of its cause. In weak states of the system the perspiration is usually too great, and the debility is increased by its excess. Wearing flannel next the skin occasions also, in warm weather, too copious an evacuation: it was formerly supposed that the too frequent change of linen was injurious in the same way. The means of obviating this excess is to remove its cause when known; to strengthen the system, particularly by cold air and the cold bath, except in cases of hectic. In the partial sweats, however, every astringent should be carefully avoided: the offensive smell may be lessened by the strictest attention to cleanliness; but to stop the discharge would be often fatal, always dangerous.

Excess and defect of perspiration are, in many persons, habitual, so that unless they produce disease, they never require any attention; and we have already shown that, in consequence of the balance of the secretions, neither viscosity nor tenuity of the fluids can arise from either. The latter is distinguished by a dry chapped skin, and by scaly eruptions, often leprous. It is induced, occasionally, by the drying powers of the harmattan; and in some peculiar occupations, as in dyeing, where the astringency of the dyes produce it topically in the hands; and in millers, as the hygrometric affinity of meal is so considerable, as often to split the planks of mill houses. In these circumstances the disease is scarcely produced till the skin is hardened, for the perspiration is not originally defective, but too hastily carried off. When it is established, little real inconvenience seems to result,

for the excess of fluids is carried off by other organs; and as the change is gradual, and the state of the vessels unaltered, no disease is the consequence.

The altered quality of the perspiration is a subject which requires greater attention than it has received. We find from the peculiar smells of small pox, miliaria, pellagra, and many other diseases, that some alteration has taken place; but its nature is unknown. In cancer, for in such cases the perspiration also is tainted, it seems to be the hepatised ammonia; in gout, the phosphoric acid. The nature of the odour of excessive partial perspirations in the feet, axillæ, &c. has not been ascertained. If it were more purely alliaceous, we should suppose it to be phosphoric, without such a proportion of oxygen as gave it acidity; but it is rather hircine, whose peculiar nature we cannot understand. But as all hircine odours show a sedative and deleterious power, this will sufficiently point out the necessity of assisting its discharge.

PERTURBATIO A'LVI, (from *perturbo*, to disturb much). See **DIARRHŒA**.

PERTUSSIS, (from *per*, and *tussis*, a cough,) *tussis ferina*, *convulsiva*, *rheumatica*, a KINK COUGH, HOOPING or CONVULSIVE COUGH; is an epidemic, contagious, spasmodic disease, resembling often an intermittent in the regular return of the fits, and recurring often in the returning spring. See Huxham de Aëre, &c.; Morb. Epid. p. 76, 77.

The whooping cough usually begins with hoarseness, a cough of the common kind, with sometimes a slight fever. This cough becomes by degrees more harsh, and on inspiration a ringing sound is occasionally perceived; at first perhaps once only in two or three days, then more frequently, till it attends every fit. Previous, however, to this sonorous inspiration, the cough will appear peculiar in its violence, and by the convulsive rapidity of the inspirations threatening suffocation. In many cases these convulsive efforts alone mark the disease, for the whooping never occurs. The violence of the cough frequently brings on vomiting, which terminates the fit, and is a favourable sign. The fits frequently occur irregularly, and are often numerous in a day and night. It is almost constantly observable that, within two or three minutes after a violent fit, a slighter will occur: a circumstance which points out the nature of the disease at a very early period.

The duration of the complaint is various; and it often recurs with violence, after it has appeared to remit, and almost to vanish. This is sometimes owing to taking cold; but occasionally happens without any assignable cause. The general health of the children is often unimpaired; and they will rise from their knees, where they usually throw themselves on the approach of a fit, and with a face of a dark purple from the straining, the eyes staring from their sockets, return with unimpaired spirits to their play. After a violent fit also, terminated by vomiting, they will eat greedily and voraciously. Some uneasy sensation precedes the paroxysm, which occasions crying in infants; and the elder children, as we have said, often fall on their knees at a chair. Though we speak of children, persons of every age are affected; but in adults it is usually slight.

After a short time, the whooping cough is attended with expectoration, frequently tinged with blood, which

infants often swallow, and even children do not always fairly expectorate. This produces a diarrhœa, or renders occasional laxatives necessary. The disease affects children only once in their lives; and should there be exceptions to this position, we believe they are equally rare with a recurrence of small pox. It is generally epidemic, and certainly contagious, though not highly so. Pertussis is not in itself dangerous, but it sometimes becomes so in infants by the debility it occasions, and in the more adult state by inducing peripneumony and hectic. In very weak children a fit has been fatal, apparently by occasioning a rupture of a vessel in the brain, sometimes by producing suffocation.

Whooping cough has been supposed to arise from acrimony in the stomach, on the diaphragm, or in the mucous follicles of the lungs. No satisfactory argument in support of either cause has, however, been adduced. It is apparently a spasm, purely nervous, from a miasma conveyed by the air, whose effects continue till the constitution is habituated to its stimulus, and again return, from any cause which increases irritability. The discharge of mucus is apparently not critical, but the glands are emulged by the violence of the cough, and the expectoration, at least, contributes to relieve the over distended vessels.

This disease is not subdued by medicine: it will run its course, in spite of every effort. Medicine is not, however, useless; and we shall point out the foundation of our most salutary exertions.

We have said that the chief source of danger is from accumulation and inflammation of the lungs. In the robust and plethoric, therefore, bleeding is sometimes necessary, and a perpetual blister to the side or back is often useful in this view. Expectoration should be encouraged with the same intentions, and this renders frequent emetics very advantageous. In infants, for reasons already stated, occasional laxatives are also necessary.

Opiates may be given safely in moderate doses, but it is necessary to prevent their constipating effect by interposing laxatives. The tinctura opii camphorata is a safe and useful medicine.

Various antispasmodics have been at different times employed. The hemlock proposed by Dr. Butter has not succeeded in other hands; and the castor, combined with bark, in the proportion of one part to two, recommended by Dr. Morris, is scarcely more effectual. The asafœtida, spoken of with confidence, often fails; and the tincture of bark, with opium and tincture of cantharides, has been given for a long period with little success. The proportions are, ten parts of tincture of bark, four of elixir paregoric, and one of the tincture of cantharides, given by tea spoonfuls. The white vitriol seems a more powerful medicine; and as it often excites vomiting, may perhaps be useful: it is apparently the active ingredient in a celebrated quack medicine, the *anti-pertussis*. The *Moschus Artificialis*, q. v. has been lately recommended, but has not been very successful. The arsenic has not, we believe, been tried. External applications have been numerous. In Poland, where the disease is endemic, oil of amber, with the aqua ammoniæ, sometimes diluted, is rubbed in on the spine. The old women of this country improve on the plan by rubbing it on the spine, the palms of the hands, and the soles of the feet, three times for three nights

successively. Garlic is also sometimes rubbed on the spine and sides, sometimes applied in the form of cataplasms to the feet. Change of air is highly commended; and repeated changes are sometimes apparently useful. We have thought the more high elevated situations less useful, and the lower damp ones more serviceable; but in the whole of the practice there is great uncertainty. Whatever determines to the surface is useful, so that exercise and cheerful society are often salutary. In some instances the sea air, and keeping the feet wet with sea water, has been apparently beneficial.

Dr. Cullen places this disorder among the spasmi, defining it a contagious disease, attended with a convulsive strangulating cough, and sonorous, reiterated inspiration, often with vomiting.

In general, however, numerous medicines have, as usual, gained the credit due to nature. The disease will run its course, and at last disappear; and the last medicine, consequently, gains the credit. We may mitigate the effects, but we cannot cure.

See Sydenham's Works; Huxham de Aëre et Morbis Epidemicis, p. 76, 77; London Medical Observations and Inquiries, vol. iii. p. 281—286, 319—325; a Treatise on Kink cough, by W. Butter, M. D.; Dr. Cullen's First Lines, vol. iii. edit. 4; London Medical Journal, vol. ii. p. 398.

PERUANUS CORTEX, (from *Peru*, the place of its origin). See CORTEX PERUVIANUS.

PERUVIANUM BALSAMUM, (from the same).

BALSAM OF PERU; *hoitziloxitl* of Hernandez; *Mexican balsam*; *Indicum* and *Americanum balsamum*; *cabureiba* of Piso; *myroxylon peruvianum* Lin. Sp. Pl.; Willdenow, vol. ii. p. 546. There are three kinds of this balsam; viz. the pale yellow, the balsam of incision, which is the best, but very rare, and of the consistence of honey. The shell balsam, the yellow sort inspissated by the sun's heat in gourd shells, in which it is sometimes brought to Europe, of a reddish colour, a very agreeable smell, and semi-transparent. The common or black Peruvian balsam is the kind we usually receive. It is extracted from the bark, branches, and leaves of the tree, by boiling in water; in consistence resembling honey, of a dark black colour in the mass; but, in small portions, of a clear reddish or yellowish brown, an agreeable smell, approaching that of a mixture of benjamin and storax, and of a bitterish pungent taste; easily inflammable, not in the least miscible with water.

Distilled in a retort with an open fire, it yields a butter like that of benzoin, and sometimes a considerable quantity of concrete saline flowers similar to those from the same resin. If this balsam is rubbed with sugar, the white of an egg, or with the mucilage of gum-arabic, it is suspended in water in the form of an emulsion.

It is applied to wounds in nervous and tendinous parts; strengthens the stomach; is an useful expectorant in cases where the circulation through the bronchial glands is languid; consequently of service in peripneumonia notha, in asthmas, and, if the dose be moderate, in those cases of hectic where the expectoration is diminished from a want of irritability.

As a tonic it is useful in suppressed or asthenic gout; and according to Sydenham in the colic of Poitou: a

tincture of it in spirit of wine is warmly recommended by Hoffman.

It has been recommended as an antispasmodic; but has no claim to extraordinary powers in this respect. It is sometimes adulterated with turpentine, a fraud not highly injurious, as the latter is an useful medicine for the same complaints.

See Tournefort, and Lewis's *Materia Medica*; Neumann's *Chemical Works*.

PERVER'SIO UTERI, (from *perverto*, to turn over). See PROCIDENTIA UTERI.

PERVIGILUM, (from *pervigilo*,) *Agrypnia*; a WANT OF SLEEP; a symptom very common in fevers, and always a bad presage. Sleeping with the eye lids half closed is equally dangerous, as it shows considerable insensibility. When the watchfulness is intense, it shows that a considerable irritation exists in the brain; often owing to increased circulation through its vessels, but sometimes purely nervous from excess of excitement.

PERVINCA MAJOR, (from *pervincio*, to tie together; because its roots were used as cords.) See VINCA PERVINCA.

PES. The FOOT is divided into the tarsus, metatarsus, and toes. The tarsus consists of seven bones, viz. the astragalus, whose upper head is received into the cavity of the tibia; the calcaneum, or bone of the heel: the naviculare, or naviforme; the cuboides, the external of the anterior bones; the cuneiforme externum; the cuneiforme medium; and the cuneiforme internum. These bones being convex above, and concave below, make the tread more secure, and from their number the shock is broke in jumping. A caries in those parts is dangerous on account of their spongy substance, size, and number. The sole of the foot is called *peza*, *thenar*, *pedion*, or *felma*, a term applicable also to a sock.

Children's feet are sometimes distorted at their birth, or turned into a bad position. This often arises from a faulty position of the child in utero, and consists only in distortion, which may be easily remedied by bringing the diseased foot as near as possible to a natural position; then, with a bandage dipped in flour and the white of an egg, confining it by rolling from near the knee to the toe. When the egg has coagulated it will preserve the position. The bandage should be changed every fortnight.

Other methods of curing this imperfection have been, to bring the foot into a natural position, and confine it by leg irons of different constructions; confining the foot in a natural position in boxes of tin or copper; binding them in strong leather boots; or by a more complicated apparatus, after confining them in metal shoes, to turn out the toes by a wheel, which is fixed by a ratchet. Either method may succeed where the foot can be easily reduced to its proper situation, but if the bones are defective or the distortion is considerable, each is useless.

A deficiency of some bone often occasions the disease, and in that case these methods will not remove the complaint; but they will assist in reducing the position of the foot, and nature will accommodate the other parts, so that no inconvenience will remain but a slight limp, unless the deficiency be considerable. This, however, rarely happens.

The inconveniences of all these plans are, that if sufficient room for loco-motion is not given, the joint becomes stiff: if there be, the support is not sufficient. Mr. Sheldrake has ingeniously contrived to lessen these inconveniences by substituting a spring for the acting power; which is so contrived, that when the limb is moved the spring is excited to stronger action. This undoubtedly is a very ingenious idea, and the plan has often succeeded. It should, however, be attempted early, for after the child has begun to walk, the cure is more difficult.

PESSA'RIMUM, (from *πῆσσω*, to soften). A PESSARY; *balanos*, and *balanocastanum*, from its original shape resembling an acorn. Among other external remedies used by Hippocrates were pessaries, introduced into the vagina; and they were much used amongst the ancients, formed of different ingredients, according as the diseases which required them. P. *Ægineta*, vii. 24. At present their use is chiefly confined to the support of the uterus, when it falls into the vagina. They are useful to women, also, who labour under an incontinence of urine from that cause. Sponges of such a size as, when expanded, fill up the cavity of the vagina, are very good pessaries; and they may be dipped in any liquor that will assist the intention of using them. They support the uterus; and, by a string, the woman can remove and again apply them herself.

Commodious pessaries are described in Heister's Surgery, in the article *Procidencia Uteri*. Dr. Simpson described one, which he invented, in the *Edinburgh Medical Essays*, vol. iii. p. 313.

Some authors suspect that pessaries, by the pain and irritation they occasion, may produce leucorrhœa. It is evident that pessaries only prevent the descent of the womb, by obstructing the passage; and while a part is continually distended, it never can be strengthened by the power of art or nature. If the pessary is introduced too small, it will soon be forced away by the first fit of coughing or straining, and if too large may bring on the *fluor albus*. It generally is painful, and often injurious; so that, except where the irritation it produces is inconsiderable, and the woman obliged to exert her strength, it should be avoided.

Pessaries sometimes produce violent inflammations; and instances have occurred of their passing into the rectum by the inflammation and suppuration excited. In some persons, however, they are worn without irritation; and the simplest, which are rings of cork or ivory, are the best.

PESSOLA'TÆ. See MORPIONES.

PESTILENTIA'LIS, (from *pestilentia*, pestilence). A high degree of malignity in a fever, and hence generally applied to the plague.

PE'STIS, (from the Hebrew term *pasat*, to despoil). The PLAGUE. Dr. Cullen places this disease among the exanthemata, defining it a typhus, very highly con-

tagious, attended with extreme debility, adding that contentions have arisen among physicians concerning the character of the plague, which are easily cleared, so that the characteristic signs which occur in every case of the plague may be assigned with perspicuity: it, therefore, will be sufficient to give such as happen in the greater number. It is chiefly varied by its degrees of violence; hence the *pestis benigna, vulgaris, Ægyptiaca*, &c.

The plague is the most violent, rapid, and suddenly fatal degree of putrid or asthenic fever. In the beginning it is sometimes attended with inflammatory symptoms, particularly in the higher latitudes, but it speedily becomes very highly putrid. Whatever be the nature of its miasmata, the effects are immediately to diminish, and, according to the degree of its power, to extinguish, the vital power, dissolving the texture of the blood, from whence arise the purple spots.

The plague approaches with a chilliness and shivering, often with coldness only, which continues for a long time; soon after, a violent vomiting, a painful oppression of the breast, and a burning heat, particularly in the internal parts, come on, which continue till death changes the scene, or till the eruption of a bubo or a parotis appears to relieve. Sometimes the disease is mortal before the signs of fever approach; the broad purple spots, which denote the highest degree of malignity, coming out even while the person is engaged in business: these spots recede and return before death's approach. Sometimes swellings appear, without having been preceded by a fever, or any violent symptom. The breath and sweat are very offensive. The pathognomonic symptoms are the buboes and carbuncles, which appear in various parts of the body. If these are absent, the disease is generally styled a putrid or a malignant fever.

The more particular symptoms are, very early and considerable prostration of strength, with every mark of debility in the vital and animal actions, frequent hæmorrhages, or a colliquative sweat, muddiness in the eyes, coma, and loss of speech. On dissection, the heart and liver are found to be greatly enlarged. The whole train of symptoms marks excessive debility, but the disease is seldom highly putrid: in many cases it is in no respect so. Since the inflammations and abscesses of the glands, usually the parotid, the axillary or the inguinal appear at no determined period of the fever, sometimes even without a regular febrile attack, and are occasionally wanting, there is no foundation for arranging plague among the exanthemata, and it should be reduced to the asthenic remittents. We say remittents, because, in the beginning, remissions are sometimes observed, and because the most dangerous asthenic fevers are usually of this kind.

The disease is not, as supposed, highly infectious. It is described as propagated like the epidemic catarrh, by miasmata conveyed through the air, and re-appearing in places to which this scourge is familiar at regular seasons, but by no means at the periods of extreme heat: on the contrary, in the hottest seasons it often vanishes. When not depending on miasmata it is conveyed in what pathologists style *fomites*, goods generally of woollen or cotton, which contain the contagious matter from an infected person, and becomes more virulent by confinement. The infection is not readily conveyed

by the atmosphere, and contact, or confinement with the patient in a close room, is necessary for its activity. Our campaigns in Egypt have rendered us more familiar with the disease, and divested it of a great part of its terror. Many fevers are more general; many more fatal.

The plague used to visit England every thirty or forty years; but one hundred and thirty have now elapsed without its occurrence, and during this period our connection with the east has been more considerable. This will not be readily attributed to the practice of quarantines, which appear to be carelessly executed, and indeed the directions are highly injudicious. The period is too long for the disease to lie latent in the crew; and too short for the ventilation of the goods. Our escape may, therefore, be owing to different habits, to a diet more antiseptic, to more free air, &c.; but these would probably prevent only its spreading. If imported, some victim would fall the sacrifice, but there is little reason for thinking that it would ever be general, or very generally fatal.

If we look to the later experience in Egypt, we shall find these ideas strongly confirmed. Assalini, attached to the French army, calls it only the epidemic fever; yet if the plague is to be distinguished by any concurrence of symptoms, it was undoubtedly the same disease.

If this author's observations, and indeed those of the French and English surgeons who attended the armies in Egypt, be true, the nature and source of the disease will appear to be very different from the representations of former practitioners. All these concur in the opinion that it is not highly infectious; many that it is slightly, if at all, so; and, instead of deriving it from peculiar miasmata, of considering the eastern countries as its great source, they attribute its appearance to common marsh miasmata, and its propagation to superstition, filth, and inattention. Assalini traces its progress in the French armies with great care; and if his facts are true, of which there is little doubt, these positions follow as rigorous conclusions. We have said that it is not *highly* infectious, of which a strong proof is, that those connected with the sick are seldom infected unless confined in the rooms. Casual intercourse is certainly by no means dangerous, as is shown by the medical attendants having very seldom suffered. When they appear to be infected, it is by no means certain that they may not suffer from its original cause, miasmata, since the strictest confinement does not insure perfect security. In one point of view it is, therefore, epidemic, in another, endemic; for the miasmata, which, in Germany and England, produce tertians, in Hungary petechial fevers, in Italy remittents, in Syria and Egypt seems to occasion the plague. Many of the absurdities detailed by Thucydides, Lucretius, and Boccaccio, appear to have no foundation; and to all may be applied what Galen said of the first, Thucydides, *quæ agrotis contigerunt tanquam idiota idiotis scripsit; Hippocrates vero tanquam artifex artificibus*. Negroes, who resist the yellow fever of America and the West Indies, an epidemic apparently more violent and fatal than the plague, yield easily to the latter. It has been disputed whether this disease attacks the same person twice; and it is in general supposed that it may, though a second seizure rarely occurs in the same epidemic. M. Sortira, one of the attendants on the French army, seems to think that

when the bubo freely suppurates, the patient is afterwards invulnerable from this poison.

In Europe the disease is only spread by infection: it cannot be styled an epidemic, for the separation of the healthy invariably preserves them. During the plague at Rome, in 1656 and 1657, all the monasteries escaped. The prisons were equally free, notwithstanding their closeness and filth. From the certificates annexed to the treatises on the plague of Marseilles, a similar security was obtained, by separating the healthy from the diseased. Even in its native country seclusion is of service, since it inspires confidence, and the night air is avoided.

The plague, we have said, consists in extreme debility in every function. "I drank neither wine nor spirits," said General Menou, "yet I am as giddy as a drunken man: the taste in my mouth is insupportably offensive, and I am so weak that I can no longer walk: my legs seem as if they were made of cotton." The eyes are red and muddy, the head heavy, and the sensibility often extinguished. The patient feels an anxious wish to sleep. If you even tell him what his disease is, when in a violent degree, he will rather sleep, though informed that it will be his last. The anxiety soon increases to palpitation, and that to syncope; the pulse is peculiarly irregular, the vomitings of bile often incessant; petechiæ quickly extend to vibices; the diarrhœa is colliquative; the speech faltering; the motions unsteady, with a wandering delirium and convulsions. It is impossible to accumulate symptoms which would together show a greater deficiency of the vis vitæ, and its consequence, the accumulation of blood in the heart, the lungs, the biliary system, and the brain. The marks of putrescency are less striking, for debility is more often the cause of extravasations under the skin than a putrid dissolution of the blood. The elegant lines of Lucan formerly quoted, in which poetical hyperbole has only perhaps a little overcharged the picture, show that such effusions may take place suddenly, before putrefaction could be communicated to the whole mass (see HÆMORRHAGIA). In the plague, persons often walk out, with the spots, as they are called, on the skin, not feeling any disease but debility.

The cure of the plague was formerly supposed to be a desperate attempt. We now know that, though a dangerous disease, it is more often conquered than victorious; nor is there the slightest doubt, but, if it should ever be again introduced into this kingdom, that it would soon excite little alarm. We have seen many epidemics which have been, for a time, more fatal than the plague would probably be, in the present state of society, with judicious political regulations.

The great source of difficulty to the practical physicians has been the good effects of *bleeding*. Sydenham employed it to a considerable extent, preceded only, as he tells us, by Botallus, who bled largely in almost every complaint. Yet Oribasius, long before, had employed this remedy on his own case; for, when the plague was epidemic in Asia, he was seized with the disease; and on the second day, *during the remission*, scarified his legs, taking off two pounds of blood. Modern authors, and particularly Dr. Russell, have been more cautious, limiting the evacuation to a single bleeding, and then only when the disease attacks with symptoms of inflammation. Chenot confines it to those

cases where the turgescence of the vessels seems to impede the diapnoe; and the Russian physicians, De Mertens and Samoilowitz, scarcely mention it. When, therefore, in a strong robust habit, the face is flushed, the skin hot and dry, the pains violent, particularly in the side, bleeding by general consent may be employed. But must we wholly resign the observations of Sydenham? We should do it unwillingly; and for this purpose, under the article FEBRIS, q. v., we have mentioned the facts, and stated the principle on which we would reconcile the supposed utility of bleeding, with symptoms of considerable debility. (Vol. I. p. 652.)

When symptoms of indigestion appear, and even when the disease has attacked, after a full meal, it has been usual to give an *emetic*. Probably in every case this remedy is proper, since, from the accumulations in the liver, bilious discharges are common and useful. These are usually directed so as to keep up a slight diarrhoea; but excessive evacuations in either way are injurious. Samoilowitz, and the Russian practitioners, are very fond of the early use of emetics. Slight purgatives of the saline or acid kind are also useful through the whole course of the disease.

Diaphoresis is the evacuation which relieves most certainly and effectually; and this is usually kept up by warm liquids, vegetable acids, often by opium. In cases of greater languor and debility, the warmer opiates, as the *confectio opiata*, are employed, assisted often by camphor and ammonia. Yet on the whole these appear, on comparing the testimony of different authors, to be less generally effectual, though sometimes essentially necessary, from the debility which prevails. In the early stages, to drink freely of the camphorated julep, with a large proportion of the vegetable acids, seems particularly useful.

Blisters have been freely employed from the observation of Galen, that those cases have best succeeded in which there were eruptions or ulcers on the skin; but later authors have found them less effectual, and generally confine the application to cases where topical pains are violent, or partial congestions considerable.

External applications have been various. The *oily frictions* have numerous advocates; but Sortira suggests, that advantage was taken of Mr. Baldwin's benevolence, and the cures by the oil exaggerated and multiplied by those who wished to have oil gratis. Mr. Baldwin is not, however, the only evidence, nor are his representations unusually strong. Father Louis of Padua, director of the hospitals at Smyrna, is still more pointed in his recommendations of this remedy; and Assalini thinks it may be useful. If the other French physicians speak slightly of it, there is reason to suppose that they have not employed it properly, or that its effects in different epidemics, perhaps in different constitutions, may vary.

Frictions with ice seem to have been employed, exclusively, in Russia, and Samoilowitz gives several cases in which it succeeded. His patients were, however, chiefly among the strong and robust. If we estimate the utility of this remedy by what we have been told of the effects of cold applications in typhus, we should consider it as dangerous in a disease of so great debility. He used a large piece of ice with a polished surface, formed by friction against another piece, and rubbed the arms, the legs, and thighs chiefly, the belly slightly,

and the breast scarcely at all. Rubbing the spine with alcohol, impregnated with aromatics, is recommended by Sortira, who remarks, that animals wounded in the vertebrae are recovered by spirituous and aromatic injections on the membranes of the spinal marrow. From these effects, he supposes that aromatics were employed in the temples of the gods, and he derives the appellation from the Ionic verb *αρωμαίνω*, I pray.

In every stage of this complaint, wine given in proportion to the debility is useful; and in the highly asthenic cases, bark, with the mineral acids, has been freely employed. These, however, are spoken of so vaguely, that we suspect they have been seldom necessary. They must often, however, be the only resources.

The conduct of the buboes has been the subject of much controversy. It is necessary, however, to remark, that these are not the only external affections in this disease. Carbuncles (see ANTHRAX,) and vibices, (see PETECHIAE,) often covering a deep putrid ulcer, are occasionally observed at the conclusion, sometimes in the commencement, of the plague. These were usually called *tokens*. Whatever may therefore be thought of buboes, neither the carbuncles nor the vibices can be supposed critical; and on the whole it is highly probable, that the last are rather accidental symptoms than critical depositions. It is in general advised to bring the bubo to a suppuration. This is, however, always difficult; and to open it, before this process is at least begun, appears to be an useless torture. Poultices, cataplasms, and even the actual cautery, often fail; and, if the bubo does not suppurate, the danger is supposed to be more considerable. This may, however, be the case, though the tumour is not critical; for the want of suppuration is often a symptom only of considerable debility. Friction, with warm tepid oils, was found the most easy and effectual method: perhaps mercurial ointment might have been more successful.

To guard against the plague is an object of no little importance; and this subject divides itself into the means of preventing its importation from the countries where it is occasionally epidemic, and those of preserving the health of individuals during its ravages. The late observations have greatly assisted us in each respect.

The regulations of quarantines are vexatious and ineffectual; nor can there be a doubt, but that if the fomes of the plague was contained in any vessel from the Levant, the disease would be propagated in this country. But, as we have said respecting the yellow fever of America, unless an eastern constitution and eastern manners were at the same time imported, the danger would be inconsiderable. The period of forty days, originally perhaps determined by religious observances, is not necessary to ascertain the state of health of individuals, when we reflect that they have been already more than a month on their voyage, and in varied climates. A medical man would not run the slightest risk in examining individuals, and these in fresh clothes might be immediately liberated. The goods would require a much longer time, unless ventilated; but if in a raw unmanufactured state, a very slight ventilation would be sufficient; nor might any one fear to engage in the task if he took advantage of a fresh breeze, and

stood to the windward. The great danger would arise from manufactured apparel, unless it were of leather. These should be ventilated with the utmost care and caution. Yet the clothes which the author wore during the voyage would be probably incapable of conveying the disease, if he himself were in health. Perhaps it would be less expensive, and would be infinitely less vexatious, if all the wearing apparel of the crew were destroyed in case of the slightest suspicion of infection.

If the plague were to reach a town, it would be easy, we think, to avoid its spreading, if the family were not permitted to mix with others till their health was ascertained; and if the nurses or necessary attendants on the sick were cautiously to avoid communication with others, except at some distance. This we add for the sake rather of calming the mind than from necessity, since the disease is certainly not infectious in any considerable degree. Every thing from the house should be cleaned and aired; the linen immersed in water, and kept there for some time, and exposed to the air before the operation of washing begins. It has been the common error of physicians to disbelieve the existence of a plague till its mortality has forcibly evinced the truth. If then an epidemic fever has continued, and it is uncertain how far its seminum has been dispersed, all crowds should be avoided. Those most certainly free should be suffered to leave the town, after perhaps a slight quarantine in the neighbourhood; and all suspected goods should be destroyed. To assert that the disease is not infectious, is to lull persons into an incautious security; to say that it is highly so, renders the fever most highly dangerous, by depressing the spirits. In this country it is propagated by infection only, and with moderate caution may be avoided, notwithstanding an occasional communication with those who are diseased.

The necessary rules for this purpose are not numerous. If the mind is busily engaged, and the person has little time to reflect on his danger, it is greatly lessened. The good bishop of Marseilles escaped, by his hourly engagements in the works of benevolence. If not engaged, cheerfulness, confidence, and serenity, are the best guardians; and it is a pious fraud to tell those who must remain, that with moderate caution there is not the slightest danger, and to make light of any accidental ailment, or even the first attack of the disease. To tell a person that he had not the plague was the most certain mode of curing him, when he was really infected.

Another rule of no little importance is to be often in the open air; to change the linen and the clothes frequently; and not again to put on the woollen garments till they had been freely ventilated. The diet should be generous, and the wine in a larger quantity than usual. The bowels should be kept free; and perspiration, at night, be induced by warm liquids, with vegetable acids, and some portion of spirit. Every depressing passion should be avoided, as well as every cause of debility. Diemerbroeck remarked, that newly married persons were peculiarly subject to the infection of this disease.

Tonics are sometimes necessary, and the occasional use of the cold bath, of bark, and the mineral acids, have been found useful. Camphor, an excellent antiseptic, palliates the appetite; and its effects in a bag round the neck are at least equivocal, probably imaginary. Above

all, free open air is the best method of rendering the infectious matter effete; and a cheerful serenity, with the most frequent changes of clothes, every mode of supporting the strength, and a free discharge from the different excrementitious glands, the most certain means of preventing its effects.

The earlier the tumours appear on the surface of the body the better; for thus all other symptoms are removed. See BUBO and CARBUNCULUS.

When the plague is fatal, some die of a fainting the first or second day; others, in whom the poison is not thrown out upon the external surface, or, if thrown off, returning back, of a mortification of the nervous coats of the more important organs, as the œsophagus, pleura, stomach, intestines, &c. whence the bodies swell, and have an intolerable stench. Sometimes, when the tumours are too numerous, the patient dies of a symptomatic fever, from the inflammation, pain, and heat.

See Samoilowitz sur la Peste en Russie, 1771; Mead on the Plague; Cullen's First Lines, edit. 4, page 200, vol. ii.; Sydenham's Works; Dr. Russell on the Plague; Chenot de Peste Transylvanica; Memoires Medicales d' l' Armee de le 'Orient, par Bruant; Memoires sur l' Egypt, vol. iv.; Observations on the Plague, &c. by Assalini; De Mertens' Account of the Plague, which raged at Moscow in 1771; De Foe's Account of the Plague in London, an imaginary narrative, which has been quoted as the result of real observation. The facts, however, preserved respecting that epidemic are often new and important.

PE'TALA, (from *πτεῖλαι*, to extend or unfold). PETALS. The flower leaves distinguished from folia, the leaves of the plant. Flowers with one leaf are called *monopetalous flowers*; with two, *bipetalous*, &c.; with more than six, *polypetalous*.

PETALO'DES, (from *petalum*, and *ειδος*, likeness). A scaly or leafy sediment of the urine, sometimes attending an ulcer in the bladder. In botany an epithet for plants furnished with petals.

PETASITES, (from *πετασος*, a hat, because the leaves are large, have a hollow in the middle, and extend horizontally round it). TUSSILAGO MAJOR, GALERITA, PESTILENT WORT, BUTTER BUR; *tussilago petasites* Lin. Sp. Pl. 1215; a perennial plant, found by the sides of ditches and in meadows, producing early in the spring a thick, naked, roundish stalk, with a spike of small naked purplish flosculous flowers on the top: the flowers and stalks soon wither, and are succeeded about May with very large roundish and heart shaped leaves, standing on long pedicles, somewhat hollowed in the middle, so as to resemble a bonnet; the root is long, thick, of a dark brown or black colour on the outside, and white within.

The roots are said to be aperient and alexipharmic; have a strong smell and a bitterish acrid taste, of the aromatic kind, very durable and diffusive, scarcely to be concealed by a large admixture of other substances. Their virtue is in the resin, distinguished by the eye in the dried root, and readily extracted by spirit of wine. See Lewis's Materia Medica.

PETE'CHIA, (from an Italian word, signifying small pox of a purple colour). It originally signified elevations of the skin; but custom hath now confined it to spots diffused on the skin without raising it. (See

STIGMA.) Their appellations are various, viz. *punctula*, *lenticula*, *fulicaris morbus*, *purpurata* by the French physicians, and *taberdillo* by the Spanish. The term *lenticularis*, however, usually confined to pimples rising above the skin, is peculiarly improper. Commonly they are reddish, purple, or blackish spots in the skin, like small points, but soon spread, and gradually grow broader: when extensive, they are often styled *vibices*, and have different appellations, according to their forms.

These spots are not uncommon in fevers; see Pringle's Observations, p. 287; Monro on Military Hospitals; and Cleghorn on the Diseases of Minorca, p. 147. In the intervals of the pustules of small pox, and of the efflorescence of the measles, they are frequently observable, sometimes without any danger, though their appearance is always a source of alarm.

Their nature is sufficiently obvious. They are little ecchymoses, often arising from a putrid dissolution of the blood, sometimes from debility, independent of putrefaction. In general, on their appearance, bark is given, and it usually renders their colour more florid; but when the bark might be injurious, as in asthma, or in measles, we have found the vitriolic acid equally useful.

Petechiæ sometimes occur alone, without any evident cause, of which there is an instance in Dr. Duncan's Cases, page 90, and we have recorded another, under the article *HÆMORRHAGIA*, as it was peculiarly violent; but, in slighter degrees, if no peculiar disease attends, we have usually disregarded it, and, in numerous cases, have seen it spontaneously vanish. This is the *morbus petechialis sine febre* of the German physicians, which they represent in very formidable colours. Richter, the great oracle of our predecessors, supposed petechiæ to be from bile, because, when attended with fever, emetics cured it, with the addition of vitriolic acid. Either or neither would have been equally successful.

PETECHIA' LIS FEBRIS, (from the *petechiæ*, which sometimes attend). The **PETECHIAL FEVER**; which, though often treated as a distinct species, is only the low or the putrid fever, attended with purple spots, as a symptom. See **PUTRIDA FEBRIS**; Hoffman, Pringle, and Huxham, on Petechial Fevers.

PETI'GO, (quod semper vicina serpendo petat). Synonymous with impetigo. See **LICHEN**.

PET' TRÆ O'LEUM. See **PETROLEUM VULGARE**.

PETRIFA'CTIO, (from *petra*, a stone, and *facio*, to make). A disease of the eyes. See **ANCUBITUS**.

Petrifications, in the nomenclature of the natural historian, are animal or vegetable productions, incrustated with stony matter, or become actual stone. Petrified wood is an exact imitation of real wood, so that from the concentric laminæ the species of tree can often be ascertained. In these changes, the stony matter is gradually substituted to the vegetable, till the latter is decomposed; and as the substitution is gradual, the stone is moulded on the original cavities, and the organization is exactly copied. Though each earth may form petrifications, they most commonly consist of the siliceous, as its molecules are much smaller, and may be suspended in water. Indeed, they are, at times, deposited on the addition of water, when contained in fluor acid air.

The mineral kingdom has also its peculiar changes, to which the appellation of petrifications can scarcely be applied, so that, in the latest works, they have been styled *pseudomorphoses*. As none of these have been ever employed as medicines, we must not enlarge on the subject, but refer to Cronstedt's Mineralogy, by Magellan, Appendix; Haüy, i. 142. For the theory to the younger Monges, Journal de Physique, 1781, page 255; and Daubenton's Leçons de l'Ecole Normale, iii. 393.

PETRO'LEI O'LEUM. The purer substance of petroleum: the British oil, extracted from a species of stone coal, is of this kind; and every species is recommended externally, in chronic rheumatisms and paralytical complaints, as powerful stimulants. See **PETRO'LEUM BARBADE'NSE**.

PETRO'LEI BARBADE'NSE AMMONIA'TUM LINIMENTUM. See **AMMONIA**.

PETRO'LEUM, (from *πέτρα*, a rock, and *oleum*, oil, because it sometimes distils from rocks,) *callicola*; *terreæ oleum*. Petroleum, in consistence, is next to naphtha, but grosser and thicker, of a yellowish, reddish, or brown colour, but so light as to swim on spirit of wine. It is inflammable, less fluid and transparent than water, of a pale yellow, with a shade of red or green, sometimes of a reddish brown or black, specific gravity 0.8783, yields, when burnt, a soot, and a small quantity of an oily residuum. (Hatchett, in Nicholson's Journal, ii. 201, &c.) Its taste is bitter, its smell strong and penetrating; qualities greatly diminished, when it assumes its solid form and black colour.

Petroleum, like oil, is composed of hydrogen, carbone, and azote, in a peculiar state, and modified by oxygen. These principles, and the marine bodies often found in bituminous strata, lead to the suspicion that the origin of bitumens is organized bodies, chiefly marine ones, decomposed. The rare occurrence, however, of these marine bodies in bitumens, and the numerous marine strata, which contain not an atom of bitumen, render the conclusion doubtful, though supported strongly by the azote, an animal ingredient.

The liquid bitumens are the pure *petroleum*, and the *white*, or the *naphtha*. The solid are the *mineral pitch*, or *maltha*, the *asphaltum*, the *mineral choutchouc jet*, *canal coal*, *common* and *spurious coal*, and *amber*. The last only of the solid bitumens is used in medicines. See **SUCCINUM**.

PETRO'LEUM A'LBUM. **WHITE PETROLEUM**. It is nearly colourless, almost as fluid and limpid as water, of a strong, penetrating smell, not disagreeable, somewhat resembling that of the rectified oil of amber. It is found only in the duchy of Modena.

PETRO'LEUM BARBADE'NSE. *Bitumen Barbadosense*, *pisæleum Indicum*, **BARBADOES TAR**, is a species of petroleum, of a reddish black colour, a thick consistence, approaching to that of treacle, or common tar, and found in the American islands, particularly in Barbadoes.

These different kinds issue from the clefts of rocks, chiefly in Persia, near the shores of the Caspian, or swim on the surface of lakes, in volcanic countries. They are often obtained, by distillation, from bituminous substances, but we rarely meet with them genuine. Fine petroleum catches fire, at the approach only of a

flame, and burns, without leaving any residuum: concentrated mineral acids, mixed with petroleum, effervesce with violence, and often flame; and their addition increases its consistence and odour. Petroleum does not readily mix with alcohol, but is easily united with the essential oil of vegetables.

The finer petrolea are more agreeable than oil of amber, and more mild than oil of turpentine: they have been used, in nervous complaints, as antispasmodics or diuretics, but chiefly as external applications, in rheumatism, palsy, and chilblains, &c. For these purposes, the British oil, and similar productions of our own, are equally efficacious. The Americans use the Barbadoes tar internally, as a sudorific; externally, as a discutient and stimulant. On distillation, the Barbadoes tar yields an empyreumatic oil, which, when placed between the eye and the light, appears of an orange colour, but, in other positions, of a blue; though, by long keeping, it is yellow in all situations.

See Neumann's Chemical Works, and Lewis's *Materia Medica*.

PETRO'LEUM FLA'VUM, *naphtha Italica*, ITALIAN ROCK OIL, or YELLOW OIL OF PETRE, is of a clear yellow colour, less fluid, less penetrating and agreeable than the white, more nearly approaching oil of amber. It is found in the duchy of Modena.

PETRO'LEUM SULPHURATUM. See SULPHURIS BALSAMUM BARBADENSE.

PETRO'LEUM VULGA'RE, *petræ oleum*, *petroleum rubrum*, *petroleum*, and *oleum Gabianum*, COMMON ROCK OIL, RED PETROLEUM, is of a blackish red colour, of a thicker consistence, and a less penetrating, and more disagreeable smell, than either the white or the yellow kinds. It is found in Italy, and about the village Gabian, in Languedoc.

PE'TRO-PHARYNGÆ'I. These muscles rise from the lower part of the extremity of the apophysis petrosa, and run backwards, to be inserted into the linea alba of the pharynx.

PETRO'SA APOPHY'SIS, (from *πετρα*, a rock). The rock, or harder portion of the temple bones; in children, easily separable from the mastoid and squamous portions.

PE'TRO SALPI'NGO-STAPHYLI'NI, *peri-staphylini interni*; *salpingo-staphylini interni*. Each of these muscles is fixed by one extremity, partly to the inner side of the bony portion of the Eustachian tube, or to that next the apophysis petrosa, partly along the cartilaginous portion of the same tube. It passes a little way under the soft membranous part, and then turns towards the septum palati. See Winslow's Anatomy.

PETROSELI'NUM, (from *πετρα*, and *σειλιον*, *fiarsley*). See APIUM HORTENSE.

PETROSELI'NUM MACEDO'NICUM. See APIUM MACEDONICUM.

PETROSELI'NUM MONTA'NUM. See OREOSELINUM.

PETRO'SUM OS, (from *petra*, a rock). See TEMPORUM OSSA.

PE'TUM. (Indian.) See NICOTIANA.

PEU'CE, (from *πεικη*). See PINUS.

PEUCEDA'NUM, (from the resemblance of its leaves to those of *peuce*, a pine tree). *Feniculum porcinum*, *cauda porcina*, *pinastellum*, *agrion*, *agriophyllon*, *marathrophyllum*, SULPHUR WORT, HOG'S FENNEL;

peucedanum officinale Lin. Sp. Pl. 353. It is perennial, grows wild, by the sea shores, and in moist, shady places, flowering in July. The roots have a strong, fetid smell, with an unctuous, acrid, bitter taste; and, when fresh, in spring or autumn, yield a considerable quantity of yellow juice, on incision, which soon dries into a solid gummy resin, retaining the taste and smell of the root. It is chiefly recommended in hysteria, and is supposed to be also an aperient. See Lewis's *Materia Medica*.

PEUCEDA'NUM SILA'US. See SAXIFRAGA ANGELICA.

PEW'TER, a compound metal, composed of tin, lead, and copper. It is supposed to be dangerous, from the mixture of lead, but without foundation. The lead is too minutely covered with the other metals, to be affected by beer, cider, acid fruits, or animal fats. Vinegar will dissolve no portion of it. The horrible phantoms raised by the apprehensions respecting lead begin to disappear.

PEY'RI GLA'NDULÆ. PEYER'S GLANDS. See BRUNNEIRI GLANDULÆ.

PE'ZA, (from *πῦς*, a foot). See PES and ASTRAGALUS. It sometimes means every part of the leg under the tibia.

PEZI'ZA, (from *πεζα*, the sole of the foot, because it sometimes rests without a pedicle). A species of fungus, whose edges are so divided as to form a remarkable cavity. It is of an uniform substance, neither distinguished by lamellæ nor pores.

PEZI'ZA AURI'GULA. See AURICULA JUDÆ.

PHA'CE, or PHA'COS, (from *φακη*, a lentil). See LENS.

PHACOI'DES, (from *φακη*, and *ειδος*, likeness,) resembling a lentil. See OCULUS.

PHACO'SIS, (from *φακη*, a lentil). A black spot in the eye, resembling a lentil.

PHAGEDÆ'NA, (from *φαγω*, to eat,) is sometimes taken in an extensive sense, for every ulcer which eats away the sound parts contiguous to it, and is called *dehascens ulcer*; sometimes in a more limited one, for a deep, tumid ulcer, which destroys the flesh underneath, as well as the neighbouring parts. It is occasionally described as only destroying the skin; at other times, as a particular species of ulcer, called *herpes phagedæna*, or *exedens*. There is a considerable confusion in authors, respecting the distinction of phagedenic ulcers, and Celsus includes under this term even a spreading gangrene. Wiseman distinguishes phagedenic ulcers from herpes, defining them deep, eating ulcers, with swelled lips, beginning in the flesh with matter; while herpes begins in the skin, and is comparatively dry. Dr. Adams, in his morbid poisons, divides them into two species, viz. successive ulcerations and sloughings; secondly, ulceration kept up by the irritation of newly formed pus. The treatment of Dr. Adams' species we must consider under the article of ulcers; the second species of Celsus has been already noticed, under MORTIFICATIO, q. v. It is the appellation, also, of an affection of the stomach, requiring an immoderate quantity of food. See BOULIMUS.

PHA'LACRA, (from *φαλακρος*, bald). *Calvata*. Blunt and smooth surgical instruments, as a probe, or any other, with a button at the end. Hippocrates.

PHALACRO'TIS, (from the same). See ALOPECIA.

PHALA'NGIUM ALLOBRO'GICUM, (from *φαλαγγξ*, a joint in the finger). See LILIASTRUM ALPINUM MINUS.

PHALANGO'SIS, (from *φαλαγγξ*, a row of soldiers). A disease in which the eye lid turns inwards, so that the hairs stimulate the eye. (P. Ægineta, lib. vi. c. 8.) The eye lid is tumefied or relaxed, proceeding either from a paralytic disorder of the musculus elevator palpebræ, or from the relaxation of the skin above. An œdematous tumour is sometimes formed in the eye lids, but this should be distinguished from the disease which proceeds from relaxation, and requires an excision of the skin. The disorder sometimes returns, notwithstanding the operation. See Hippocrat. lib. de Victus Ratione; Celsus, lib. vii. c. 7. V. PROSIS.

PHALANGO'SIS TRI'CHIA. See TRICHIA.

PHA'LANX, (*φαλαγγξ*, an army of soldiers). The bones of the fingers, called from their regular disposition. See DIGITUS.

PHA'LARIS, *Canariensis* Lin. Sp. Pl. 79, (from *φαλος*, shining). *Gramen spicatum*. CANARY GRASS. It grows amongst corn, and is found in many places besides the Canary Islands. The seeds are diuretic. See Raii Historia.

PHANTA'SMA, (from *φανταζω*, to make appear). See PSEUDOBLEPSIS.

PHARMACEI'A, (from *φάρμακον*, a medicine). A discharge from the abdomen, from the exhibition of a cathartic.

PHARMACEUTICA, (from *φάρμακον*, to exhibit medicines). PHARMACEUTICS constitute that branch of our art which teaches the method of rightly preparing and exhibiting medicines.

PHARMACEUTICÆ, *φαρμακευτική*, MEDICINE, (from the same). The art of healing by medicines. See MEDICINA. History, and Kirkland's Inquiry, vol. i. p. 64, &c.

PHARMACI'A, (from *φάρμακον*, a medicine,) is the art of preparing and compounding medicines, and may be traced to the earliest eras of medical records. When medicines were first given, some preparation was, of course, necessary; and we find in Hippocrates not only ointments, but infusions of different vegetable substances in oils, called from the basis, *myrtinum, rosatum*, &c. In fumigations he employed troches, *φθοιςκοι*, which required preparation. It is probable that this union of pharmacy with the practice of medicine continued for many ages; for we first find it as a separate profession at Rome in the time of Theophrastus. (MEDICINA, vol. i. p. 945.) To the Arabians we are, however, indebted for the more complicated processes of pharmacy; though, as we studiously pointed out, MEDICINA, vol. i. p. 951, some parts of pharmaceutical practice were known to Actuarius, whom we have styled the last of the ancients. See MODERNI.

The Arabians first rendered pharmacy more complicated by increasing the number of distilled waters, preparing tinctures and syrups, and accumulating the ingredients of their formulæ. The first great division of pharmacy was, however, effected by the chemical sect, early in the sixteenth century. This introduced the distinction of preparations into *galenical* and *chemical*; the former containing the decompositions and preparations, in which the heat was inconsiderable, not greatly superior to that of boiling water; the latter, those pro-

duced by the greatest violence of fire; but neither this nor any other distinction is followed very closely in terming a preparation either galenical or chemical. The earliest code for preparing medicines, we have said, was published by the authority of the senate of Norimberg in 1542; but we have since seen an earlier account of lists published at Lindau, settling, by authority, the price of drugs. The progress of pharmacy, as ascertained by authorised codes, we have already traced with some care in the article DISPENSATORIUM.

Pharmacy must necessarily go hand in hand with chemistry; but it has only become a science since the introduction of the pneumatic chemistry, and we must regret that we have received no work which embraces its whole extent since that period. The new Dispensatory of Dr. A. Duncan is the most valuable and complete of this kind, but it is limited to the preparations in the established dispensaries of Great Britain and Ireland.

The objects of pharmacy are obvious from the definition; and we shall consider in their order the general rules by which medicinal substances are PRESERVED, PREPARED, and COMPOUNDED: the particular ones must be learnt under the proper heads.

To separate decayed from sound portions of vegetable substances, for to these our attention is now chiefly directed; to dry them with care; to prevent the dissipation of volatile parts, the access of insects or impurities, are obvious precautions. Vegetable substances should be collected in the countries where they are indigenous, and in soils and situations where they naturally flourish with the greatest luxuriance. Annual roots are in the greatest perfection just before their shoots spring forth, biennial ones in the spring of the second year. In the autumn of the first their virtue is not greatly inferior; but there is danger of gathering the effete exhausted root, hastening to decay, by mistaking the second for the first year. Perennial roots are best in the spring, just before the period when the sap begins to rise. Juicy roots, if their medicinal portion be not volatile, may be rapidly dried by a heat of from 90° to 120° of Fahrenheit; but if aromatic, in a current of cold dry air, not exposed to the sun. Thick roots should be sliced and hung on strings. Some roots should be kept moist; and these must be buried in damp sand.

Herbs and leaves in general acquire activity from their age, but mucilaginous ones become woody. No very great nicety is required in their collection but what this hint will supply, except in the cases of helleboraster and digitalis. The former has the leaves of the first and the second year at the same time, distinguished by their colour and their acrimony. It is necessary, therefore, to select one kind only, and the oldest are the most active. The digitalis is a biennial, and the leaves, previous to the flowering of the second year, more active than those of the first: they should, if possible, be distinguished. Aromatic leaves are to be collected after the flower buds are formed; annuals about the time of flowering; biennials before the sap mounts; and perennials before they flower. They should be dried rapidly in a current of free air, and, if succulent, by artificial heat.

Resinous barks are best collected in spring, gummy ones in autumn; and of the former the heaviest are the best. Flowers, as well as herbs, should be collected

in dry weather; and, in a few instances, it is unnecessary to separate them from the calyx, if small, as the whole plant has similar virtues. If any peculiar advantage is expected from small doses, however laborious, the separation is proper. In general, they should be dried with artificial heat, though not to such a degree as most slightly to destroy their colour.

Seeds and fruits should be gathered when ripe, but before they would fall spontaneously. Pulpy fruits are compressed, or deprived of their cores or kernels. In general their natural coverings should be preserved; but in the nicer sweet meats they are taken off. In some medicinal substances, also, they are taken off, as in the colocynth, &c.

Every vegetable substance should be kept dry. Herbs and leaves, which, when friable, appear to have lost their odour, regain it by keeping in a close box. Oily seeds and fruits should be kept in a dry cool place, but not beyond the season of again collecting them. Those vegetable substances are best preserved, in every form, which have grown and been gathered in a dry season.

Animal substances in a moist state should be preserved with care, so as not to be more or less dry. Those which are solid, and minerals, require no peculiar attention.

Medicines are PREPARED, if solid, by *mechanical division*. The means are, pulverisation, trituration, levigation, granulation, and sifting; if fluid, by decantation, filtration, and despumation: if moist, by expression. Compound formulæ are prepared by mechanical mixture; by solution, either simply or with the assistance of a third body; and by heat.

Mechanical mixture is performed by agitation, by trituration, or beating in a mortar; but if the substances are fluid and incapable of chemically uniting, they soon again separate; an inconvenience lessened by employing an albuminous or a mucilaginous intermede. The union, however, though more lasting, is only temporary. Trituration is a more steady and continued agitation; but when employed to assist solution, the weight of the pestle contributes to a further mechanical division. The mechanical mixture, by beating or kneading, is more lasting, because the substances employed, at least one of them, is in a semi-fluid state, and the heavier body cannot subside.

Solution requires some time, assisted by agitation and a gentle heat. It is effected by chemical affinity, and sometimes a third body united to the menstruum is necessary before its attraction is sufficiently strong, as salt is added to the nitrous acid to render it the proper menstruum for gold. Heat is necessary not only in simple solutions, but often in so great a degree as to raise both the solvent and the menstruum in vapour when their union will only take place. Thus, water and the essential oils of vegetables unite in a state of vapour, when a very slight, imperfect union would take place in a fluid form.

Pharmaceutical operations chiefly depend on a change of form, on combination or decomposition. THE FORM IS ALTERED by solution, fusion, a change into a state of gas, vaporisation, exciccation, condensation, congelation, and coagulation. In each, however, some decomposition takes place.

Solution is a common pharmaceutical operation; but under this title we include the fluid forms of every sub-

stance, whether vegetable or mineral. The most simple form is a solution of the common neutrals, whether alkaline or metallic salts, and the various combinations found in mineral springs. Infusions are solutions of the vegetable extractive matter, and decoctions are solutions by means of heat; the various vinegars, wines, elixirs, and tinctures, are similar preparations: but while infusions contain the vegetable substance, separated only from the woody fibres, in the decoctions, some decomposition apparently takes place, and a part of the extractive matter, or the oil, by the union of oxygen, becomes resin. Vinegars contain the vegetable matters with little change, but they are adapted chiefly to what are styled the alkalescent plants, the tetradynamia; while in the wines, elixirs, and tinctures, the vegetable is decomposed in proportion to the diminution of the quantity of water in the menstruum. The spirit extracts principally the resin, and the form of tincture is adapted to those medicines which are chiefly resinous. Even to the strongest spirit the resin, however, conveys some portion of gum; and, on the contrary, the cold watery infusions are not without some, though a very small, proportion of resin. Water is the appropriate menstruum of salts and mucilages; but some portion of each may be combined with a weak spirit, though not in a quantity to be effectual, unless in the metallic salts, where the dose is inconsiderable in bulk.

Fusion is scarcely a pharmaceutical operation. It may be termed a solution by means of caloric, and is chiefly employed for the purpose of *granulation*; a method of powdering metals by continued agitation while cooling. Modern practice only employs this process in preparing the filings of tin.

A change into a state of gas is employed to impregnate water with some ingredients in imitation of the mineral waters. Hepatized hydrogen, carbonic acid air, and other gaseous fluids, are employed in this way. (See *AQUÆ MINERALES ARTIFICIALES*.) The pneumatic chemistry, though it has thrown considerable light on numerous pharmaceutical processes, has, however, added little to our stock of resources.

Vaporisation is a very extensive operation. It is employed to separate substances which differ in volatility, and, as we have said, to facilitate chemical action. In *deflagrating* metals, the acid of the nitre in part is volatilized, while its oxygen is combined with the metal, forming a calx. Thus the flowers of zinc, diaphoretic antimony, &c. were formerly prepared; and in *ustulation*, the roasting of metals, the sulphur and arsenic are dissipated. When, however, it is proper to retain the volatile portion, we apply a receiver, as in the various modes of *distilling* fluid and *subliming* solid substances. When the operation is more simple, consisting in exposure of the fluid to heat in a shallow vessel, it is styled *evaporation*. Saline solutions are to be *concentrated* when evaporated in order to crystallization; other moist bodies to be dephlegmated; but alcohol must be dephlegmated by other means, for its volatility requires distillation. It is sometimes, however, dephlegmated by chemical affinity, when, by adding pot ash, the solution is very slightly soluble in the pure spirit.

Exciccation is often performed by vaporisation, as in making extracts from vegetable substances, when some decomposition always takes place. It is sometimes effected by placing the moistened body on blotting paper, or a chalk stone. The heat is sometimes

considerable, as in calcining alum, and depriving salts of their water of crystallization. When some salts, particularly common salt, are exsiccated, they crackle: a sound called *decrepitation*.

Condensation is applied only to vesicular vapour, for the permanently elastic gases cannot, by any pressure or change of temperature, be reduced to a solid form. It is the second part of the process of *DISTILLATION*, q. v.; and when, by the position of the vessels, the condensed vapour repeatedly returns into the receiver, to be as often again raised in vapour, the operation is called *circulation*. When a fluid is repeatedly distilled in fresh vessels, the process is called *rectification*; and if the distilled fluid be repeatedly distilled from fresh materials, *cohobation*.

Congelation is chiefly used to concentrate vegetable acids, occasionally alcohol, and is performed by the natural cold, in higher latitudes, and by evaporation, or freezing mixtures (see *COLD*), in these climates.

Congelation is effected by means of heat, sometimes by chemical affinity, by abstracting water, by acids, rennets, &c.

COMBINATION is one of the most important pharmaceutical operations, and chemical combination consists in an intimate union of the particles of two or more heterogeneous bodies. To unite chemically, the bodies must possess an affinity for each other greater than the attraction of aggregation, and their particles must approach within a given distance. It is not always necessary that they should be in a fluid state, but they must be mechanically divided into very small particles; and the operation is assisted by caloric, by agitation, sometimes, though not in every instance, by compression. Some air is generally separated in solutions, which compression impedes.

Gases generally mix with gases; and they seem, in very few instances, to combine, unless from the impulse of electricity or galvanism. They appear to be mutually diffused; each given portion of the gaseous compound containing the same proportions of each. They dissolve fluids or solids: thus the hepatic air is sulphur, dissolved in hydrogen; or are absorbed by them, as the carbonic acid air by water or lime. Fluids dissolve solids, or are rendered solid by them, as a supersaturated solution of salts, by rapidly crystallizing, becomes a solid mass, or, more simply, as chalk absorbs water, without showing the slightest humidity. What we have said of the diffusion of gases, however, does not apply to known bodies, in a gaseous form, for the muriatic acid and alkaline airs exert their mutual affinity in this aerial state; nor is it quite certain, though probable, that no union takes place between the discordant ingredients of our atmosphere.

Solution is evidently a chemical combination, and of extensive operation in the practice of pharmacy, at least in the way we have explained it. The degree of affinity of bodies for the most common menstruum, water, is various. Some salts, as potash, will extract it from the driest atmosphere, and they are then said to *deliquesce*: others will yield readily the water which they entangle in their crystals, and are then said to *effloresce*. We sometimes employ solution, to separate salts from insoluble impurities, and the process is called *lixivation*; sometimes to separate soluble impurities, and it is thus called *edulcoration*. When one portion only is separated from

an heterogeneous compound, it is styled *extraction*. Different kinds of solution, as already explained, are styled *infusions*, *decoctions*, &c. *Maceration* is infusion long continued, often interposing triture; and *digestion* is infusion with a continued heat below the boiling point. The solution of metals in mercury is termed *amalgamation*. *Absorption* is the condensation of gas, in consequence of its union with a fluid.

There are, however, combinations, independent of chemical affinity. The suspension of oils in water, by means of an intermede, styled *emulsions*, is one of these; and the solution of resins with water, by means of gum, as in the gum resins, galbanum, asafetida, &c. is another instance. The union of oils with mucilages, in a *linctus*, is a simple mixture, and the greater number of combinations, in extemporaneous prescriptions, are the same.

DECOMPOSITION is chiefly effected by the superior affinity of some added substance to that by which the bodies were previously united, the abstraction of one of the bodies, or an alteration of the circumstances connected with their union. Thus vitriolated potash is decomposed by adding the smallest particle of barytes; salts are deposited from water, by evaporation, or by the abstraction of caloric.

Dissolution, by some late authors, is opposed to solution, and it is applied when, in the solution of two bodies, a previous union is destroyed. It is a solution of pure calcareous earth, in muriatic acid, but a dissolution of carbonated lime in the same acid, since the carbonic acid is separated in the form of gas. This separation of gas is called *effervescence*.

Precipitation comprehends those processes in which the body, previously dissolved, becomes solid. Thus flint is separated from fluor acid air, in a solid form, and magnesia from Epsom salts. This, however, commonly styled a *precipitate* when heavy, is cream when it swims on the surface, as the lime separated from lime water is called cream of lime. Precipitation is effected by abstracting a portion of the menstruum, or diminishing its powers. The latter is sometimes effected by dilution; as when alcohol dissolves resins they are precipitated by adding water, while the abstraction of water produces the precipitation of salts. Another cause of precipitation is the addition of a body which has a superior affinity to the menstruum, or to the dissolved substance; but the latter is not precipitated, unless it is insoluble in the new fluid.

Precipitation is employed to procure substances which nature offers in a compounded state, as magnesia from Epsom salts; sometimes to separate impurities, as lime is separated, in a considerable degree, from neutrals, by the vitriolic acid. The whole system of chemical re-agents, in the analysis of mineral waters, is connected with precipitation. The conduct of this pharmaceutical operation requires minute attention. The re-agent must be peculiarly pure; it must be added slowly, and never in excess. We must be cautious also in our examination of the precipitate, that other bodies may not be accidentally mixed; for the whole may be a solution in a compound menstruum, and, destroying the combination, may precipitate other bodies besides those which are affected by the chemical affinity of the re-agent.

Crystallization is a slow precipitation; and in this gradual process the particles of salts assume particular

forms, perhaps from a certain polarity in the minute particles. Though we find crystallizations particularly in salts, yet every body, when the attraction of aggregation is completely removed, and the menstruum is sufficiently fluid to admit of its motions, seems capable of assuming a regular form, except perhaps the fat oils. The experiments, which seemed to show some determined forms in their particles, were probably optical delusions.

M. Hatty has rendered it probable that there are only three forms of integrant particles, the parallelepiped, the triangular prism, and the tetrahedron. The primitive forms of crystals are, however, six; the parallelepiped; the regular tetrahedron; the octaedron, with triangular faces; the six-sided prism; and the dodecahedron, terminated by rhombs, or by faces of isosceles triangles.

It has been observed that the menstruum should be so attenuated as to give perfect freedom of motion to the particles; nor, perhaps, is there an instance of bodies perfectly dry crystallizing. Gunpowder is sometimes decomposed by the nitre crystallizing, but only when it has previously deliquesced. In this case we perceive that the operation of crystallization is effected with some momentum, as it overcomes the attraction of aggregation; and we recollect an observation of Vauquelin, that in one instance it appeared to break a thin vial. When, from the deposition of some impurities, the fluid becomes thick, the crystals are no longer formed, and the fluid is then called the *mother water*, *mater crystallorum*.

The liquefaction by fusion is equally favourable to crystallization, if conducted with care, as by solution; but the crystals first formed should be removed, or the future ones will fill up the interstices. In the formation of all crystals by solution, some water is entangled between the crystals, called their *water of crystallization*; and, in the experiment before alluded to, where many salts, rapidly crystallizing, form a solid mass, it is from the whole of the water being entangled between crystals, of many different shapes. Those salts which are far more soluble in boiling than in cold water, contain the greatest proportion of the water of crystallization; and those which differ little in this respect, the least. For the crystallization of the latter, evaporation is always necessary.

In many respects, crystallization is an object of curiosity, rather than use; but it is employed to separate salts from impurities, and from other salts which differ greatly in solubility, or their different affinities to hot or cold water. It is probable, also, that some of the metallic salts only crystallize when they contain the acid, or rather are oxydated in a given proportion. Hence, emetic tartar, in the form of crystals, is a more certain medicine than when confusedly crystallized in powder. The perfection of the needle-like crystals in the sublimation of calomel is a test also of its goodness.

Oxygenation is frequently a necessary pharmaceutical operation. It was formerly styled combustion; but this operation, attended with the production of heat and light, is only one mode of oxygenation. When the saccharine acid, for instance, is formed by the addition of the nitric acid to sugar, the process is called oxygenation, though neither heat nor light are produced.

Combustion is a process sufficiently known. It is em-

ployed to procure the alkaline salts of vegetables, and more partially in *charring*, where the heat, and perhaps the light, are forced to combine again with the wood, in a looser union. When attended with flame, in the usual manner, it is styled *inflammation*; when with violent heat and light, rapidly separated, *deflagration*. In the latter process the materials must be dry, they must be projected in small quantities, and the deflagration must be completely over before more is added, or the metal will not be properly oxygenated. The operation is assisted by stirring, when the first violence of the explosion is at an end. In all these processes the oxygen is derived from the air, from the decomposition of water, or from acids, when they are employed. When the various modes of oxygenation are designed to produce an oxide, modern refinement has styled it *oxydizement*; when an acid, *acidification*.

In medicinal pharmacy, metals are the common subjects of oxydizement or acidification; for many of the metals, as we have seen, are acid when in the form of oxyds. Iron and manganese are oxydized merely by the action of the air. Gold and platina scarcely undergo this change, in the most violent heats. The action of the air greatly assists the operation of water, in producing oxydation. When acids are employed, they are sometimes decomposed, and afford the oxygen; but most commonly enable the metal to decompose water. The sulphuric acid is decomposed by few metals, but powerfully promotes the decomposition of water. The nitric acid, on the contrary, in almost every oxygenation, is itself decomposed. The muriatic acid is never decomposed, and only acts on metals capable of decomposing water. When oxydized, it readily yields the superabundant oxygen, but no portion of that which contributed to its original formation. The more rapid the process, the more complete is the oxygenation; and when it proceeds too slowly, it may be accelerated by heat; when too rapidly, diminished by cold. When metals are oxygenized by acids, they are generally united in the form of salts; but, if oxygenized in a great degree, they are insoluble in acids.

The *disoxygenation* of metallic oxyds is seldom required in medical pharmacy; but compound oxyds may be farther oxygenized by treating them with nitric acid. In this way various acids are formed; but scarcely any of these are employed in the practice of medicine. The combination of oxygen from the atmosphere with various vegetable matters, which takes place in the different forms of *FERMENTATION*, we have already considered. Vide in verbo.

If we were to arrange more regularly the objects of the pharmacist's attention, we should propose the following plan. In the usual dispensaries no scientific arrangement has yet been attempted; and this, as a first attempt, may be found imperfect.

I. MEDICINES IN A FLUID FORM.

a Not decomposed.

EXPRESSED JUICES, SYRUPS, SOLUTIONS, INFUSIONS, VINEGARS.

b Partially decomposed.

WINES, DECOCTIONS, TINCTURES.

c Completely decomposed.

DISTILLED WATERS and SPIRITS; ESSENTIAL and EXPRESSED OILS.

II. IN A MORE SOLID FORM.

CONSERVES; INSPISSATED JUICES; RESINS;
POWDERS.

III. CHEMICAL COMBINATIONS.

SALTS; *neutral, earthy, and metallic.*
OXYDS.

INFLAMMABLES.

IV. MIXTURES.

*a Fluid, JULEPS, EMULSIONS, LOTIONS, LINI-
MENTS.*

*b Semi-fluid, CATAPLASMS, OINTMENTS, CE-
RATES.*

c Solid, PILLS, TROCHES, PLASTERS.

Medicines in a *fluid form*, not decomposed, or at least the juices only separated from the woody fibres, soon spoil. A little fermentation commences, they become foul and ropy; so that they should be quickly used, unless preserved by a mixture of spirit. The *syruhs*, from their inspissated form, are not equally susceptible of fermentation, but in a cool place may be long preserved; though the sugar, after a certain period, begins to crystallize. The *vinegars* are less liable to change; and the *solutions*, in which we chiefly include the salts in a fluid form, appear to be less so. The metallic salts, however, are sometimes deposited when the phial is frequently opened; and the solutions of emetic tartar, of muriated barytes, and quicksilver, are stronger at the bottom if shaken, but weaker if dropped out without any agitation. Under the head of solutions we include all mineral medicines in a fluid form, though the menstruum be wine, as in the antimonial wine, or spirit, as in Van Swieten's solution of sublimate, or the *tinctura ferri muriati*.

In the *wines, decoctions, and tinctures*, vegetable substances, we have said, are partially decomposed; the least in the wines, and most considerably in the tinctures, which, if the spirit be rectified, contain almost the pure resin. In the wines and decoctions the depositions are considerable, and they should not be long kept: in the tinctures they are less; but as the spirit evaporates, and the closest stoppers will not wholly prevent it, the dissolved substance is no longer suspended. No means can wholly prevent the deposition, and tinctures are always unequal unless when recent. Fortunately the dose is usually not small, and no great dependence is placed on them. To this, however, the tinctures of opium and digitalis are exceptions.

A more complete decomposition takes place in *distilled waters, spirits, and oils*. These, in fact, are the essential oils of vegetables, combined with water or alone. The water in these cases is free from impurities, and will not spontaneously change; but in the simple water the oil sometimes separates, rising to the top; so that, if long kept, they should be frequently shaken. In the spirit the oil continues without any separation. These are the liqueurs of the French and Germans, in which the spirit is disguised by the sugar, and softened by the oil which communicates the flavour. The least hurtful are those which are flavoured by aromatics; but all are seductive, and accustoming the palate to a stimulus, it soon requires a much stronger one, regardless of the flavour which first allured. The expressed oils are well known, but when the separation is assisted

by heat, which is usually applied by heating the plates of the press, they soon become rancid. This is the foundation of the direction, when *cold drawn* linseed oil is prescribed. Essential oils are subject to a change in consequence of the formation of crystals (see GAUBII ADVERSARIA); but their nature and source is not known; and as they form gradually without being conspicuous till after many years, it is sufficient to mention the change only in this place.

Medicines in a *solid form* are the *conserves*, which, after a little time, ferment, if not kept cool; the *inspissated juices*, which, if moist, contract a mucus, if hard, become friable, and not very distant from the form which follows, the *resins*. The *conserves* and *inspissated juices* should be in a moist state, and covered with paper, dipped in spirit. Powders should, in general, be kept dry, and in bottles closely stopped.

The *chemical combinations* require no particular remark. The oxyds are sufficiently known, and under the inflammables we include the hepatised ammonia, and the preparations of sulphur.

The *mechanical mixtures* in a fluid form can seldom be so accurately mixed as to prevent separation, and they are not adapted for long keeping. Those which are of a greater consistence do not separate, but the oils of the *plasters* and *cerates* often become rancid, and irritate the wounds they are intended to sooth. In general they are in a very imperfect state. The *plasters* and *ointments* we have styled mixtures; but in the articles EMPLASTRA and NUTRITUM we have given more correct views of these formulæ: as the chemical action, however, is apparently confined to the calces of lead, we thought it better to follow the more common ideas in this place. *Pills* and *troches* are undoubtedly mechanical mixtures; but it is necessary to remark that the first are usually so soft as not to preclude chemical action. By keeping, therefore, they often lose their virtue, or acquire different qualities. They often, also, become so hard as to be insoluble in the stomach.

An abstract of ancient pharmacy would have afforded some subjects of curiosity, but would not have been particularly interesting, and certainly of no utility. To assist, however, the reading of a few ancient authors which still hold their place in libraries, it will be necessary to notice some of their terms, and the same arrangements of medicines peculiar to the language of pharmacy. Thus the term *julepum* is often confined to medicines used as alteratives; *distillatio instaurans*, or *jusculum*, to a nutrient mixture; *bochetum* to a diaphoretic; *hordeatum*, or *ptisana ex hordeo*, to a diluent; *potio* to a laxative. *Opiatum* is often the term for a bolus, as resembling in consistence the theriac; *morselli* and *mandaleones* for pills; *drophaces* for stimulating plasters; and *spanadrafti* for adhesive ones. A semi-fluid application to the head is often called *frontale*, or *apophlegmatismus*; a more solid one, *cucupha*. To the stomach an application of the solidity of a plaster is called *scutum*; and the softer kind of pessary, *nascate*.

The pharmaceutical classes of medicines are,

THE FIVE EMOLLIENT HERBS; malva; althæa; violaria; mercurialis, and parietaria. To these are sometimes added branca ursina; beta, and atriplex.
THE FIVE CAPILLARY HERBS; adiantum nigrum et

- album; polytricon aureum; tricomanes, and ceterach.
- THE FOUR GREATER WARM SEEDS; semina anisi, fœniculi, carui, and cumini.
- THE FOUR LESSER WARM SEEDS; semina ammeos, amomi, apii, and dauci.
- THE FOUR GREATER COLD SEEDS; semina cucumeris, cucurbitæ, citrulli, and melonum.
- THE FOUR LESSER COLD SEEDS; sem. endiviæ, scariolæ, lactucæ, and portulacæ.
- THE FIVE GREATER APERIENT ROOTS; radices opii, fœniculi, asparagi, petroselini, and rusci.
- THE FIVE LESSER APERIENT ROOTS; rad. graminis, rubiæ, eryngii, capparis, et ononidis.
- THE FIVE KINDS OF MYROBOLANS; citrini, chebuli, indi, emblici, and belerici.
- THE FOUR CORDIAL FLOWERS; flores boraginis, buglossi, rosarum, and violarum.
- THE FIVE PRECIOUS STONES; lapides saphyri, granati, smaragdi, hyacinthi, and carneoli.
- THE FOUR PLEURITIC WATERS; aquæ eardui b. mariæ, taraxaconis, cardui benedicti, and scabiosæ.
- THE THREE STOMACHIC OILS; oleum absynthii, cydoniorum, and mastichinum.
- THE FOUR WARM OINTMENTS; aregon, martiatum, altheæ, et agryppæ.
- THE FOUR COLD OINTMENTS; album camphoratum, rosatum mesue, populeon, and infrigidans Galeni.

These classes the young pharmacist was directed to commit very carefully to memory, and was frequently examined on the subject.

We had intended to have enlarged farther on the modern NOMENCLATURE of pharmacy, vide in verbo; but the few remarks already offered are probably sufficient. We wish they may be so to correct redundancy in titles. The botanist was glad to escape from the descriptions of Ray and Caspar Bauhine, by the substitution of a trivial name for each species; and when custom had established such, a change was sacrificing convenience to accuracy, and to accuracy misplaced. It is the object of the pharmacist to point out the species employed, in his list of the materia medica, not to repeat it on every occasion in his title.

As we have enlarged on the distinguishing characteristics of the skilful surgeon and judicious physician, we may be expected to speak also of the character of a pharmacist. We supposed, however, that common honesty, and an acquaintance with the properties of each medicine, was sufficient. Yet these are enlarged on with some originality, quaintness, and energy, by an old author on the subject, now lying before us (Renodæus), that we are tempted to extract a small part of it.

"Probity is no less necessary in a pharmacist who prepares medicines for the preservation and recovery of health, than in a philosopher; for in his hands are disease and health; death and life. If ignorant or malicious, he is able essentially to injure, or to kill. A pharmacist should, therefore, be as conscientious as Socrates.

"Principally he ought to be religious, to reverence the Almighty; wholly free from envy and malice;

sound in mind; acquainted with grammar; neither indigent nor covetous; and able to bear fatigue both by day and night. The atheist is equally regardless of the Creator and the creature; and the invidious man pines at his neighbour's prosperity. The fool is anxious to do mischief; and the unskilful man thinks nothing right but what he does himself; and no one is more unjust. The covetous man benefits nobody, and is most unjust to himself: the poor man is easily tempted to poison. His poverty but not his will consents. (Ad turbia enim cogit egestas.)

"Drunkards, buffoons, mimics, chatterers, impostors, and mountebanks, who deceive by trifling, fraud, boasting, vain promises, flattery, and lies, who thus exhaust the purses of the common people, are unworthy the name of *pharmaceutists*. Nothing is more injurious in a state than such reptiles. (Cane quovis potioribus et angue.)

"Since the subject of pharmacy and medicine is the same, viz. the human body as susceptible of either disease or health, the physician and apothecary must have many common qualities, such as prudence, probity, diligence, and a knowledge of medicine; but since pharmacy is subservient to physic, and has only for its object the medicine itself, or its due form, when the pharmacist proceeds farther he becomes a quack and a cheat.

Nor must we trust pretenders, who assert that gentle medicines may be given at any time without danger; for lettuce at an improper season, and in too large a quantity, is as fatal as hemlock; and though wine is familiar to the constitution, it is often more destructive than the sword: though a cordial, the milk of old men, the restorer of the principles of life, if given at an improper time it is highly injurious.

"The duty of the apothecary is confined, therefore, to the medicine, to apply it to the purpose of restoring health. That he may execute this office with success, he must select, prepare, and compound the remedy; but before he selects it he should know what it is." J. Renodæi Institutiones Pharmaceuticæ vel Dispensatorium Galeno-Chimicum, quarto, Hanoviæ, 1631. Lib. 1. cap. 2. page 3.

A. Duncan's Edinburgh Dispensatory; Renodæi Dispensatorium; Pharmacopeia Augustana Zwelferi; Schroeder Pharmacopeia Medico Chimica; Lewis's Dispensatory; Dossie's Elaboratory laid open; Baumé Elemens de Pharmacie; Gaubius de Formulæ; Annales de Chymie.

Pharmacia extemporanea. If pharmacy, in one view, be the art of compounding medicines, extemporaneous prescriptions may be properly distinguished by this title. We long hesitated about introducing an article of this nature; and it may be easily supposed that the accomplished physician, when he has ascertained the nature of a disease, and sees the changes necessary in the constitution for the restoration of health, will be readily able to adapt his means to the end in view. This, however, is not always an easy task. A young physician, anxious for his patient, perhaps for his own credit, feels this part of his duty difficult; and it is unfortunately that which the apothecary can best judge of, and in which mistakes will be most readily caught

at and ridiculed. We conclude, of course, that he has not been bred in the dull circle of an apothecary's shop; yet it is singular, that those who have climbed over the counter into their chariots have not appeared always the most ready in this part of their duty. A few remarks on this subject may not be, therefore, improper; and we shall translate them from a little manual, which, in early life, we wrote for our own use, with such additions as a long experience has suggested.

It is not our present object to point out the doses of medicines, as it is our design to enlarge farther on this subject under the article *Posologia*, q. v. We may remark, however, in this place, that the rules laid down on this subject by authors, when they teach us how to vary the dose according to age or sex, are liable to numerous exceptions. Thus a child of a year old will often bear a larger dose of calomel than an adult; and a weak female a larger dose of rhubarb than a robust labourer. Gaubius, Wedelius, and Boerhaave have, however, regulated the doses with mathematical accuracy, from the age of fifty-six, the standard, to ninety-eight on one side, and to seven weeks on the other. We need not add, that such tables are wholly useless.

It is scarcely necessary to remark that the general qualities of each medicine, and of its most common forms should be known. An emulsion, for instance, will be decomposed by a variety of medicines which it is sometimes necessary to add, particularly by the camphorated tincture of opium. The physician should know also the effects of mixture, that camphor, v. g. will soften the fetid gums, and different ointments, reducing what may be ordered to be spread on cloth, to the consistence of a liniment. It is needless to add that practitioners should be acquainted also with the chemical properties to prevent decompositions; and for this purpose we anxiously pointed out in the article *Chemia*, q. v. the different preparations which would destroy each other's properties. Sometimes, indeed, decompositions are apparently intended; for if Griffith's mixture be given in the form of pills, they are of a very imperfect consistence, but harden as the different ingredients act on each other; and in the mode we have recommended for making Plummer's pills, the calomel and the sulphur auratum evidently combine in the mass. It sometimes, however, happens that this combination of different ingredients renders the pills hard and insoluble; an inconvenience severely felt if the pills are kept for a long time.

The taste, the smell, and the general appearance of the medicine, require particular attention in an age so luxurious as the present. Unfortunately, active medicines cannot always be rendered pleasant, and the most disagreeable are usually given in the form of pills. If these cannot be swallowed, for some people are unable to swallow what they have not masticated, the inconvenience of the taste cannot be avoided. It may, however, be often lessened by choosing a proper vehicle. Thus milk covers the taste of bark, of volatile tinctures of guaiacum and valerian. A solution of the juice of the liquorice, or a light decoction of the root, covers more effectually than sugar every bitter taste; and a small proportion of kali changes it at least to a different, often a more agreeable one. Any change is sometimes sufficient to reconcile a delicate taste to the continuance of a medicine.

It is easier for some individuals to swallow a small bolus than pills, and a bolus wrapt in wafer paper slightly moistened, slides often with ease through the œsophagus. Some unpleasing medicines, if the bulk be not large, may be conveniently conveyed into the stomach in this form. It is highly necessary, however, if we regard elegance or convenience in prescriptions, to be aware of the different specific gravities of medicines. The bulk of some medicines in moderate doses renders their exhibition in pills or boluses inconvenient, while the weight of others in small ones subjects them to be lost, if given in a liquid form. Yet we once saw two grains of calomel ordered in a four ounce mixture to be taken by table spoonfuls.

The forms of fluid internal medicines extemporaneously prescribed are *draughts*, *mixtures*, *juleps*, *emulsions*, *infusions*, *decoctions*, *solutions*, *tinctures*, *drops*, and *clysters*. The solid forms are, *powders*, *boluses*, *electuaries*, *lozocs*, and *pills*. The ancient pharmacutists employed many others, and were minute in their distinctions.

Draughts and *mixtures* differ only in the quantity sent; as the draught is usually taken at once, and should not exceed an ounce and a half. In a larger quantity it has been styled a *potion*; but this term was almost exclusively confined to a purgative, and is now disused. The young practitioner will endeavour to make his draughts as pleasant as possible, combining the more nauseous ingredients in pills. At all events they should not be too thick, and a single draught should never contain more than two scruples of a powder, seldom more than half a drachm; of electuaries and conserves not more than a drachm; of inspissated juices or extracts, a scruple. The mixture may vary from three to six ounces; but in this form we should avoid oils, which soon become rancid in warm weather; conserves, which will ferment; and such combinations as will not be permanent. In general, mucilages are more convenient media to combine oils with water than the yolk of an egg; and the mucilage of gum tragacanth is apparently better than that of gum arabic. If oil is employed, about half the quantity of mucilage is necessary; if balsams, an equal; and if resins, a double quantity. *Spermaceti* requires nearly an equal quantity; wax (previously rubbed with spirit of wine), and balsam of sulphur, double; camphor, it is said, four times, and musk five times, as much. Camphor may, however, be conveniently suspended by rubbing it previously with magnesia; wax, by a mixture of soap; magnesia itself, by previously rubbing it with sugar; and resins, by trituration with almonds.

Juleps, in the strictness of the ancient pharmacutists, is a sweet mixture, as the Persian name imports, to disguise or carry off the taste of the more disagreeable medicines. Its characteristics are pellucidity and sweetness; but at present the name is employed without any determinate meaning, or as synonymous with mixture.

Emulsions are oils united with watery fluids, by means of mucilage, sometimes by ammonia. The latter are, however, easily decomposed, and seldom continue in perfect union many hours; so that they are chiefly adapted for draughts, or at least no more should be ordered than can be taken in twenty-four hours. The others are more permanent in their union; but even of

these no very large quantity should be directed, unless intended for a common drink.

Infusions are made with cold or with boiling water. Many bitters yield a pleasant impregnation to the former, and a harsh disagreeable one to the latter. Camomile flowers, the carduus, and some others, are of this kind, and probably the bark may be added. We now know that cold water dissolves the extractive matter only, boiling water the resin, probably increased in quantity by the oxygen absorbed from the air if the vessels are not close. It has been supposed that previous trituration with magnesia will enable the water to dissolve a larger portion of the bark, but the colour only is apparently heightened, for the same effect will be produced if the magnesia or kali is added to the strained fluid. Infusions, however, are not to be depended on in emergencies: they are chiefly adapted to a medicine which must be long continued, and are seldom given alone without some medicine to add to their warmth. From what we have remarked under the article COMBINATION OF MEDICINES, it is probable that the formula will be more effectual if the addition is of a different kind.

Decoctions are prepared by boiling; but, for the reasons assigned, the proportion of the ingredient should be increased, the time of boiling shortened, and the vessels carefully closed. In many instances, when we wish to preserve their strength unimpaired, they should be strained warm, and those ingredients which yield their virtues readily should be added only at the end of the process; for the water might be otherwise saturated and the more useful ingredient yielded in a less proportion. It was formerly not unusual to add a neutral salt, as in the decoctum bardanæ. This should be guarded against if we ever wish to unite a mercurial with it. The usual proportion of the vegetable is from one ounce to two, to a pint and a half of water, to be boiled to a pint, if not of a resinous nature.

Solutions are, as may be supposed from the term, saline bodies dissolved in water, and may appear to require no particular directions. The first and most obvious remark is, that the water should be pure. Distilled water is necessary in many solutions, but rain water, carefully filtered, is pure enough for almost every purpose. Muriated barytes, for instance, is decomposed by all water containing selenite; nor are the solutions of tartarised antimony or muriated mercury wholly unaffected by the common contents of water. A reason already assigned renders it inconvenient to order a large quantity of these solutions, since, by frequently opening the bottle, the access of air occasions same decomposition, so that the latter part differs greatly in strength from the former. The aqua ammoniæ is from this cause very unequal in strength; and it is always safer to order the salt. Arsenical solutions are subject to the same inconvenience; and we have found it safer to add these in a determinate proportion to a small mixture composed chiefly of distilled water, and in a quantity no larger than is sufficient for three or four days. In solutions of neutral salts we find the cathartic power often increased in proportion to the quantity of the menstruum, so that three drachms of Rochelle salt in a pint

and half of water will often have more effect than twice that quantity in three ounces. The deposition of any portion of muriated mercury is prevented by adding the muriated ammonia; but, in general, if we wish to prevent precipitation, it is best effected by adding the acid which has the greatest affinity, not to the metal, but to its oxide.

Tinctures are officinals, and scarcely the object of extemporaneous prescription. We notice them only to remark that if the weaker spirit is combined with the stronger, some decomposition will ensue, and injure the elegance of the formula. A small proportion of alcohol should, therefore, be occasionally added. It is not common to add any other ingredient to tinctures; but laxative ones are rendered occasionally more active by a small proportion of emetic tartar, and the tonics somewhat altered in their appearance, if not improved in their power, by a fixed alkali. No prudent physician will neglect occasional changes in appearance, to inspire confidence: no skilful, we had almost said, no honest one, will alter the essential parts of plans which he finds advantageous.

Drops. If these are in small doses, the size of the mouth of the phial and the quantity of fluid in it may make a material difference in the quantity taken. It is necessary, therefore, to dilute it with at least a triple quantity of the fluid, that the little variation, from the causes mentioned, may not essentially alter the real dose. Some colouring matter in this form is often necessary. The precautions suggested under the two last heads will require attention in the prescription of drops.

Clysters. Elegance of the formula is in this mode of relief less important when given with a view of evacuating merely; but when medicines of a different kind are injected, some attention to their mixture is requisite. Camphor, for instance, should be carefully divided, lest portions should adhere to the rectum, and produce unpleasant consequences. Turpentine we have also found it necessary to mix with care, to avoid an inconvenient stimulus. When mucilage, or the yolk of an egg fails, we have found the coarsest brown sugar contribute to its union with the watery fluid. Clysters, for the purpose of procuring a discharge, should exceed a pint: if they are to be retained, they should not be in a larger quantity than three or four ounces. If intended as nutrients, the latter quantity is fully sufficient, and some opium should be added to retain it. Antispasmodic clysters should be equally restrained from passing off, by opium; and these in children should never exceed two ounces, though their purgative clysters may be more than six. In general, the dose given in clysters is allowed to be triple that taken by the mouth.

Powders is a simple form scarcely requiring a remark, except that deliquescent salts should be avoided. There are some powders also which decompose each other in a dry state, or at least render each other inert: sulphur, for instance, destroys the activity of mercury, and lime will decompose muriated ammonia. In prescribing powders, this circumstance requires very particular attention.

An *electuary* differs from a *bolus*, as a draught from a mixture, in the quantity being either a single dose or several together. Each consists of powders or extracts

brought to this semi fluid form by means of syrup. Other fluids will not give it sufficient cohesion; and if the dose of the powders is large, conserves will add too much to the bulk. All essential oils, however, including camphor, require conserves: turpentine is best covered by honey; but all these are more safely and properly combined in draughts, if we except camphor, which should, if possible, be directed in a bolus or pills. The interest of the apothecary is not injured in this way, as he has learnt to charge a bolus in a draught. Conserves in general are best adapted to the metallic oxyds, many of which are heavy; but such electuaries should be sent in small quantities, lest they be injured by fermentation, or rather in boluses, as an error in the quantity may be injurious. In general, every medicine to be taken in a precise dose should be sent in a bolus or a draught.

Lohoc is a form of Arabian invention, as the title implies. It is generally composed of oils with mucilages, but any of the mucilaginous conserves, as that of hips, may be employed. It is of an intermediate consistence, between an electuary and an emulsion, and should be so dense as not to be immediately lost on the fauces, and so fluid as not to excite deglutition; for when it has passed the fauces its utility is at an end. Small quantities of a mild fluid seem in general equally efficacious, particularly the common emulsion with nitre, or barley water sweetened with capillaire.

Pills are sufficiently known; but we have already remarked that whatever decomposition may take place by time, should be considered, and the change, whatever it may be, guarded against. The various extracts, the fetid gums, camphor united with the conserve of hips, metallic salts, are best adapted to this formula. Few persons will swallow more than four or five at a dose, but many swallow them so easily that they make little difficulty of taking ten, fifteen, or twenty. When this is the case, almost every medicine, except deliquescent salts, may be given in this form; and these may be easily avoided.

The external formulæ are, GARGLES, FOMENTATIONS, CATAPLASMS, LINIMENTS, OINTMENTS, and PLASTERS; but they require no particular remarks. The gargles are mixtures; the fomentations, decoctions; the liniments, like the lohocs, of a consistence between a solid and a fluid.

Various other formulæ are chiefly officinal: the different distilled waters of former dispensaries, lozenges, syrups, and vinegars, are seldom the objects of extemporaneous prescription.

Before we conclude this article, it will be necessary to enumerate and shortly explain the various terms of former pharmaceutical authors, and we shall, for the convenience of referring, adopt an alphabetical order. Though many of these have already occurred in our pages, it may be useful to bring them together in one view.

Anacollema, a glutinous cataplasm, applied to the forehead to intercept, according to the ideas of the ancients, the flow of blood to the nostrils in cases of epistaxis. *Apozema*, a decoction.

Bacilli; small sticks for the production of smoke, or for inhaling. *Claretum*; wine rendered aromatic by the infusion of spices, sweetened with sugar; vide in verbo. *Collutiones*; washes held in the mouth. *Crœcus*; any

calx of a bright yellow colour. *Cucupha*; a bonnet filled with cephalic medicines, vide in verbo. *Dropax*; a strongly adhesive plaster, whose chief ingredient was pitch. *Eclegma*; a lohoc. *Elixir*; a tincture. *Embrocha*; a stillicidium, dropping or pouring water. *Essentia*; besides its common meaning, sometimes signifies inspissated juices, sometimes eleosacchara. *Epi-thema*; a liniment. *Frontale*; a liniment applied to the forehead. *Galreda*; an inspissated animal glue. *Glandes*; see SUPPOSITORIA. *Holipha*; sweet cakes rendered medicinal by some infusion. *Lapis vegetabilis*; any fluid medicine inspissated by evaporation, and dried to the hardness of a stone. *Liquor*; the fluid of deliquescent salts, often a distilled fluid. *Lonzoga*; lozenges. *Malagma*; cataplasma. *Magisterium*; vide in verbo. *Martius panis*; almond bread, made also of pistachio and other nuts. *Masticatorium*; any acrid medicine chewed to promote a discharge of saliva, or as was said of PITUITA, q. v. *Mel*; not only honey, but any preparation in which it was used, or of the same consistence. *Morsuli* or *morselli*; lozenges usually of a square form. *Moretum*; a preparation of mulberries joined with aromatics, and some absurd ingredients, which was formerly supposed useful, and cordial to the fœtus, but capable of expelling a false conception. *Nascale*; see PESSUS. *Opiatum*; an electuary of the consistence of the confectio opiata. *Oxyrrhodynon*; an application consisting of vinegar and roses, designed to relieve pain, formerly applied to the head, forehead, or neck.

Pandaleum is a lozenge poured, while fluid, into a box as a mould. *Pasta regia*; see MARTIUS PANIS. *Pastilli*; lozenges. *Pessus* vide PESSARIA in verbo. *Perramma*, and *periapton*, an amulet hung round the neck. *Phænignus*; a slight rubefacient. *Pineatum* and *pineolatum*, martius panis, made of pine nuts. *Pomum ambra*; an odoriferous mass, supposed to ward off infection. *Rotula*; lozenges of a round form. *Sacculus*; an application consisting of dry medicines, sometimes odoriferous ones, included in a bag. *Sapa*; inspissated must; sometimes a conserve. *Saponca*; a linctus made of almonds. *Sief*; a dry collyrium. *Smegma odoratum*; an odoriferous soap. *Spanadrapus*; linen dipped in a fluid plaster, chiefly adhesive. *Stymma*; the dry mass which remains after expressing the oil, in which flowers have been macerated. *Suppositorium*; a solid, round, conical body introduced into the anus, often to excite its action and procure a motion. *Tragea*, *tragema*; a pleasant powder. See MEDICINA. *History*, and Kirkland's Inquiry, vol. i. p. 64, &c.

PHARMACI'TIS, (from *φάρμακον*, a drug; because as a drug it was formerly used). See AMPELITIS.

PHARMACOCHEMIA, (from *φάρμακον*, a drug, and *χημία*, chemistry). Pharmaceutical chemistry in contradistinction to the spagirical art, which treats of the transmutation of metals.

PHARMACOPŒIA, (from *φάρμακον*, a medicine, and *ποιω*, to make). See DISPENSATORIUM.

PHARMACOPOLÆ, (from *φάρμακον*, a drug, and *πολεω*, vendo). See AGYRTÆ.

PHARYNGÆA CYNA'NCHE, (see ANGINA PHARYNGÆA, *pharynx*).

PHARYNGÆUM SA'L, (from *φάρυγξ*, *pharynx*). A salt used in quinsies, thus prepared: R Crystal. tart. sal. nitri $\bar{a}\bar{a}$ $\frac{3}{4}$ i. alum. ust. $\frac{3}{4}$ ss. dissolve in distilled

vinegar, and coagulate the solution. This salt was formerly dissolved in water for gargarisms.

PHARYNGE'THRON, (from φαρυγγεθρον). See PHARYNX.

PHARYNGO-STAPHYLI'NI, (from φαρυγγ, and σταφυλη, uvula,) are two small muscles fixed to the lateral part of the muscoli thyro-pharyngæi, as if they were portions detached from these muscles, running obliquely forward along the two posterior half arches of the septum, and terminating in the septum above the uvula, where they meet: the thickness of the posterior half arches is made up by these muscles. See Winslow's Anatomy.

PHA'RYNX, (απο το φερειν, because it conveys the food into the stomach,) *infundibulum*, *pharyngethron*, a muscular bag fixed behind to the basis of the skull at the cuneiform process of the occipital bone, laterally to the bottom of the face, and below to the larynx. The muscles which cover the first vertebra of the neck are behind: on the sides the upper portions of the carotids and jugulars, the apophyses of the sphenoid bone, and the pterigoid muscle.

The pharynx in shape resembles the wide part of a funnel, of which the œsophagus, q. v. is the lower portion. The top is styled the *arch*, which opens to the nostrils; the body communicates with the mouth, and the extremity with the stomach. The arch on each side terminates in a point towards the jugular cavities of the basis of the cranium. It afterwards contracts on each side, and behind the larynx is again enlarged. The muscles which constitute the pharynx are sufficiently described by their names: they are the *crico-pharyngæus*, from the cricoid cartilage to the *pharynx*; *thyro-pharyngæus*, from the thyroid cartilage to the *pharynx*; *hyo-pharyngæus*, from the os hyoides to the *pharynx*; *stylo-pharyngæus*, from the styloid process to the *pharynx*; *pterygo-pharyngæus*, from the pterygoid process to the *pharynx*; *mylo-pharyngæus*, from the dentes molares to the *pharynx*; *salpingo-pharyngæus*, from the Eustachian tube to the *pharynx*; *cephalo-pharyngæus*, from the basis of the skull to the *pharynx*; *syndesmo-pharyngæus*, from the white ligament to the *pharynx*; *chondro-pharyngæus*, from the cartilaginous appendage of the os hyoides; *glosso-pharyngæus*, from the root or upper part of the tongue laterally. Some anatomists have limited the muscles of the *pharynx* to two or three; and others have multiplied them to thirteen or fourteen on each side. Albinus divides them into six pair, viz. the *stylo-pharyngæus* of Douglas; *constrictor inferior*, the *crico-pharyngæus*, and *thyro-pharyngæus*, of Douglas; the *constrictor medius*, the *hyo-chondro*, and *cephalo-pharyngæus*, of Douglas; the *constrictor superior*, the *glosso*, *mylo*, and *pterygo-pharyngæus*, of Douglas; the *palato-pharyngæus*, *thyro-staphilinus*, of Douglas; and the *salpingo-pharyngæus* of Douglas. The lowest of these muscles between the sides of the cricoid cartilage form the first muscular circle of the œsophagus, which is continued in complete muscular circles to its extremity. Some of the upper ones, according to Santorini, contribute to modulate the voice.

In their various actions they enlarge and compress the gullet, so as to forward the aliment into the stomach.

The pharynx is made up partly of several distinct

fleshy portions, which are looked upon as so many distinct muscles, so disposed as to form the large cavity mentioned, and partly of a membrane which lines the inner surface of this whole cavity, a continuation of that of the nares and palate. This membrane is wholly glandular; and it is thicker on the superior and middle portions of the pharynx, than on the bottom or lower portion. Immediately above the first vertebra it forms several longitudinal rugæ, very thick, deep, and short, and we generally find in them a collection of mucus in dead bodies. In the great cavity there are no rugæ, the membrane adhering, as well as in the upper part, very closely to the muscles. At the lower part, where it is the thinnest, it covers the posterior part of the larynx, and is very loose, formed into irregular folds.

In the London Medical Observations and Inquiries, vol. iii. p. 85, &c. is an instance of a difficulty of swallowing, occasioned by a dilatation of the pharynx.

PHASE'OLUS, (from φασηλος, a little ship, which its pods were supposed to resemble). The BEAN, *vicia faba* Lin. Sp. Pl. 1039; *bona*; hath a long pod full of kidney shaped or oval seeds, which as a food are flatulent, though more nutritious than the other legumina.

PHASE'OLUS MAJOR, *smilax, hortensis, faba major, phaseolus vulgaris* a Lin. Sp. Pl. 1016. FRENCH BEANS, or COMMON KIDNEY BEANS, are cultivated in gardens; flower in July; the pods are used as aliment, and said to provoke urine. They are less nutrient and less flatulent than beans or peas.

PHASE'OLUS ZURRATE'NSIS, vel BRASILIA'NUS, *phaseolus pruritus excitans, nai corona, cow HAGE, cow ITCH, and STINKING BEAN, dolichos pruriens* Lin. Sp. Pl. 1019. The hairs upon the pods, if scraped off and mixed with syrup, may be given to children in doses of a tea spoonful, and two to adults, for destroying the long round worms. If ten or twelve pods are steeped in a quart of beer, and $\frac{3}{4}$ iv. of the infusion taken every morning, they are said to act as a diuretic, and to be useful in dropsies. See Raii Historia; London Medical Journal, vol. vi. p. 313. Vide STIZOLOBIUM.

PHASE'OLUS. See CAJAN FABIA MUCUNA GUACU.

PHASIA'NUS, (from Φασις, a river in Colchis; upon whose banks they abound). PHEASANT. See ARGUS.

PHAUSI'NGES, (from Φαυσις, fire). Red circles in the legs, excited by fire; sometimes used to signify spots from other causes.

PELLA'NDRUM, (from φελλος, cork, because it floats upon water). See MEUM ALPINUM GERMANICUM.

PELLA'NDRUM AQUATICUM, Lin. Sp. Pl. 366. *Cicutaria palustris tenuifolia*, SKELETON WATER WORT, WATER HEMLOCK, FINE LEAVED; when not thus distinguished it is often confounded with the *cicuta virosa*. Withering, Bot. Arrang. i. 176, gives the following description of the *phellandrium aquaticum*: the rundle with many spokes; rundlets, the same; general fence, none; the empalement, a partial fence of seven leaves, sharp, as long as the rundlet; cup, of five teeth, permanent; the blossoms general,

nearly uniform; florets, all fertile, individually unequal; petals five, tapering, heart shaped, bent inwards: *chives*; threads, five, hair like, longer than the petals; tips roundish: *pointal*; seed bud beneath; shafts two, awl shaped, upright, permanent; summits, blunt: seed vessels, none; fruit, egg shaped, smooth, crowned with the cup and the pointals, divisible into two parts; seeds, two, egg shaped, and smooth; florets in the centre smaller than the others. The branchings of the leaves are straddling, the stem very thick, hollow, scored, petals white.

Withering observes that the seeds are recommended in intermittent fevers; and the leaves sometimes added to discutient cataplasms: the plant is generally esteemed a fatal poison to horses, occasioning palsy, owing to an insect (*curculio paraplecticus*) which generally lurks within the stems; the usual antidote is pig's dung.

PHE'LLODRYS, (from *φελλος*, the cork tree, and *δρυς*, an oak; because its bark is a kind of cork, and its appearance that of an oak,) *ceris*; *quercus ceris* Lin. Sp. Pl. 1415. The LAUREL OAK, grows in Dalmatia and Greece. The leaves, bark, and acorns, agree in virtues with the common oak. See *QUERCUS*. Raii Historia.

PHE'NION. See *ANEMONE*.

PHI'ALA. A large round glass vessel with a long neck, often used for chemical solutions. The common phial also of the apothecaries.

PHILADY'NAMOS, (from *φίλος*, a friend, and *αδυναμис*, weak). An epithet of water, as a salutary diluter.

PHILA'NTHROPUS, (from *φιλειν*, to love, and *ανθρωπος*, a man; because it sticks to the garment of those who touch it). See *APARINE*. Sometimes the appellation also of a compound antinephritic medicine.

PHIL'LITIS. See *LINGUA CERVINA*.

PHILLY'REA. See *LIGUSTRUM INDICUM*.

PHILO'NIUM. An opiate, called from its inventor Philo; one of the oldest of its class, except perhaps the mithridate. The *philonium Romanum* is originally a prescription of N. Myrepsus. There are different prescriptions for this medicine in various pharmacopœiæ; but in that of London, 1788, it is made in the following manner, styled *confectio opiata*. Take of hard purified opium, powdered, six drachms; long pepper, ginger, and caraway seeds, of each two ounces; syrup of white poppy boiled to the consistence of honey, three times the weight of the whole. Mix the purified opium carefully with the heated syrup; then add the rest previously powdered.

PHILOSOPHO'RUM MERCU'RIVS, *arca arcanorum, mercurius metallorum*, is a pure fluid substance, said to be found in all mercury, and capable of being extracted from it. The existence of this principle was founded on the idea that quicksilver, fixed by sulphur, was the basis of all metals.

PHILOSOPHO'RUM O'LEUM. See *LATER*.

PHILOSOPHO'RUM LA'PIS. See *ADAMAS*.

PHI'LTRON, (from *φιλειν*, to kiss). *Amatoria veneficia*. A medicine to excite love. We need not add that no such exists, except in the imaginations of the credulous: lust may be excited, but never love. It also signifies the depression on the upper lip, situated immediately under the septum of the nose.

PHIMO'SIS, (from *φίμων*, to tie up). *Capistratio*, a disease in which the prepuce cannot be drawn back so as to uncover the glans penis. Dr. Cullen places it as a variety of the phlogosis phlegmone.

This disease is not exclusively confined to syphilitic affections, though then most troublesome, and more peculiarly dangerous. It is sometimes natural, from a contraction of the prepuce at its termination, as if drawn together like a purse by strings; and in that case at once relieved by separating the extremity, suffering it to bleed, and dressing it as a common wound. It sometimes arises from inflammation, in consequence of an acrimony in the mucus of the odoriferous glands; but then the prepuce is not straitened, the glans only is inflamed and swollen, and to draw back the skin is consequently painful. In such circumstances the steam of warm water, or its opposite, cold applications, will often relieve. To inject a fluid between the glans and the prepuce is in such states more easily advised than executed; but if it can be done, it will be often beneficial.

The principal cause is inflammation, excited by gonorrhœa or a chancre, and it is then a more formidable complaint, because the mischief is confined, and we know not its nature and extent, nor can we apply a remedy. If the constitution is robust, and much fever present, bleeding, low diet, and frequent saline laxatives, are useful. Cold applications to the penis are more beneficial than warm, and topical bleeding, with leeches, is occasionally useful. These, however, often fail, though assisted by opiates, a recumbent posture, and absolute rest. The operation then becomes necessary. It is simple, and by no means dangerous. A sharp pointed knife, concealed and defended by a grooved directory, which must be previously introduced between the prepuce and the glans, are the only instruments. The point of the knife should pass through the prepuce at the bottom, and the section be made by drawing it towards the operator. Common dressings are sufficient; but linen or lint should be interposed between the glans and the prepuce, to prevent adhesions. The treatment of the affection of the glans is connected with its cause, the *LUES*, q. v.

Paraphimosis is the opposite disease, where the prepuce cannot be drawn over the glans. Warm relaxing applications will sometimes assist; but it is rarely so troublesome as to require an operation. See Bell's Surgery, vol. i. p. 528; and White's Surgery, p. 343.

PHLA'SMA, (from *φλαω*, to bruise). See *CONTUSIO*.

PHLEBOPALIA, (from *φλεψ*, an artery, or vein, and *παλλω*, to leap). See *PULSUS*.

PHLEBORRHA'GIA, (from *φλεψ*, and *ρηνω*, to flow). A HÆMORRHAGE FROM A VEIN.

PHLEBOTO'MIA, (from *φλεψ*, a vein, and *τεμνω*, to cut). *PHLEBOTOMY, venæsectio*, the cutting or opening a vein. When several veins were opened in a day, the operation was formerly called *neroniana*.

The first instance of bleeding on record is that of Podalirius: Hippocrates did not often direct this operation; Aretæus, Celsus, and Galen, used it more freely; but at different periods, and by different professors, it was encouraged, or nearly prohibited. Until the circulation of the blood was demonstrated, the principles

of this practice were unknown, and indeed at present they are not, we think, clearly understood.

The discharge of blood procured by this operation is inconsiderable in proportion to the whole mass, so that, though it lessens the whole, the diminution only can produce no effect. The relief which, therefore, follows from bleeding, when properly employed, must arise from another source, and is connected with that state of the system characterized by the term *diathesis phlogistica*. This is the state of the strongest and most robust constitutions, marked by a full strong pulse, florid look, great firmness of the simple solids, and activity of the muscular system. In such habits tension is followed by a proportional reaction, and the fulness of the vessels produces a more powerful contraction of their coats.

The first effect of bleeding, therefore, is to lessen this tension; and as will be obvious from our remarks on INFLAMMATION, q. v. this diminution will lessen the power of the vis a tergo, and the congestions will be relieved by the action of the affected vessels only. Another effect must also be considered. The relief of this tension will take off from the excessive excitement of the brain; for we have shown (see NERVI) that nervous excitement is intimately connected with the state of that part of the arterial system dispersed on the nerves, or in the brain. This is the source, then, of that fainting which follows a moderate bleeding; and the fainting is in a greater degree, and comes on more quickly in irritable constitutions, where this tension is least, as well as in an upright posture, where the heart acts with disadvantage, as opposing the power of gravity. This general relaxation is attended also with a proportional relaxation of the smaller vessels, and pains are relieved, the general feeling of oppression removed, a sweat breaks out, and a quiet sleep is often induced. Similar consequences, as we have seen, probably follow (see FEBRIS and PESTIS) when the viscera are overloaded, even in asthenic or putrid fevers, and explain the apparently inconsistent practice of Sydenham, Dover, and Rush.

This view of the effects of bleeding will explain the peculiar advantages of topical bleeding. In this case the vessels are emptied near the part affected; and vessels, thus depleted, gradually again filling from the trunks, will lessen the tension of the inflamed arteries, without diminishing the general tension of the vessels of the brain. We must look then to the advantages, and indeed the injuries, which result from bleeding, as connected with this more general or more particular relaxation of the system, and with the assistance of these views we shall examine its effects in the various diseases for which it has been recommended. We may be accused, however, of neglect and inattention in not noticing, with therapeutical writers, the diminution of the actual quantity of blood, or of its crassamentum. The diminution of the absolute quantity, however, is so inconsiderable, that in animals bled to death the redness of the muscles is scarcely, if at all, changed; and in young animals bled repeatedly to whiten the flesh, the effect is rather from the debility excited than the abstraction of the red particles. In these cases, however, the latter circumstance has some effect; for, by whatever mechanism these particles are formed, their

formation is not rapid; and if we regularly detract these while the vessels are filled with gelatinous and albuminous fluids, after some time the colour will be necessarily changed. Repeated bleeding may have the same effect in the human body; but we can connect this alteration only with chronic weakness, not with the salutary changes from bleeding. In the same way debility may arise from the abstraction of the gluten or fibrin of the blood, and we may thus attain the object of former pathologists, of rendering it thinner; but till we can trace diseases to viscidities, we shall not employ bleeding for this purpose, which will at the same time gradually destroy the vigour of the system. When regularly repeated in cases of asthma, or from the frequent recurrence of inflammation, we find no benefit resulting from this effect. Anasarca or other dropsical effusions, the effects of debility, are, on the contrary, frequent consequences.

Bleeding was employed in excess by the mechanical physicians, who thought to lessen the moles movenda by this means, and, consequently, to restore the equilibrium between the weight and the power. We usually employ it inversely to lessen the power. As the mechanical system continued to prevail till a very late era, and the practice founded on these doctrines is not yet obsolete, it is not surprising that bleeding is still frequently and indiscriminately employed. The humoral pathologists used it constantly with another view. As they supposed the cause of diseases existed in the blood, they were anxious to examine its state. Eight or ten ounces were often taken with this view; and if the operation was not carefully attended to, the appearance of a slight buff on the surface would determine the repetition of the evacuation. While both views were adopted in the widely extended system of Boerhaave, the remedy was, of course, more fashionable, and the error very generally infected the schools of medicine even in our own era. If, as a late author observes, the practitioners of this country are in general Boerhaavians, we shall be less surprised that it is not yet reformed.

Bleeding is supposed to be indicated by a full strong pulse, by difficulty of breathing, and by local pains, in almost every fever of the young, the strong, and plethoric. Various views will, however, limit its use in each state. A full strong pulse will often usher in fevers most purely asthenic; nor is it true that if, with the Cullenians, we diminish the reaction, we shall relieve the consequent debility. If we succeed at once in checking the fever, as is certainly sometimes the case, it is a remedy highly useful; but, in ninety-nine out of a hundred cases, perhaps in ten times that number out of a thousand, the pulse sinks; and in the latter part of the fever we have to regret the loss of that strength which we so improvidently wasted. In all such cases we must bleed with boldness, or not at all: when we draw the sword, we must throw away the scabbard.

Again: every practitioner, we suspect, is not able to distinguish the really strong pulse from that which is hard in consequence of irritation. In the epidemic now approaching in this country, the pulse in the earliest period is reported to be full and strong; but the fever is in its nature truly asthenic, and from the time, the previous seasons, and the nature of the other prevailing complaints, we are convinced that the report is fallacious;

but a physician seldom sees fevers on their first attack, and must act from a comparison of many cases. We recollect well the first case we saw of putrid peripneumony: the pulse felt strong, and the fatal fiat was issued to bleed; but a source of doubt arose from the other appearances, and the operation was suspended: the patient was preserved at last, with difficulty, by bark and cordials. In general, therefore, to a full strong pulse we must add a firm constitution, a flushed face in which the character of the features is not lost, and considerable bodily strength. The origin of the disease from cold, without any prevailing asthenic epidemic, the situation of the patient in a dry elevated spot, and the season of spring, will contribute to render bleeding more certainly a proper remedy.

Difficulty of breathing, from any cause, or a fit of asthma, has always been supposed a proper indication for drawing blood, and we have more than once seen it employed in the middle of asthenic fevers from this occurrence. The event was in every instance fatal. On better grounds, and on the sanction of more approved authority, it is employed in the violent asthmatic fits. The relief is, however, purchased, if the fits frequently recur, by exhausted strength and anasarctous swellings. The remedy, which is borne with advantage in youth, is injurious in a more advanced period; but unfortunately before this time it has become a habit, which cannot without danger be broken. In nervous asthmas we can often attain the end by a less dangerous remedy, and it is not the natural cure of a disease which is relieved chiefly by expectoration.

Local pains more decidedly call for this remedy; yet it is often not only ineffectual but injurious. In the weak, the nervous, and the irritable, these pains are common; and it will appear, in a moment, absurd to employ with them a remedy adapted to the firm and robust constitution. Even local discharges of blood will frequently weaken, when with irritability plethora is combined. The latter coincidence often takes place, and on this account we did not mention the full pulse as an indication for bleeding. In fact, we would confine bleeding only to local pains on the access of fever, with the former limitations. It is used also with propriety when these pains attack robust constitutions, though without fever, as in colics; in hernia, in sciatica, in jaundice from calculus; for in such constitutions fever soon comes on, from the causes of inflammation, and proceeds with rapidity to some of its most dangerous terminations.

Fevers of every kind in the young, the strong, and plethoric, are supposed to call for the use of this remedy; but we have already shown the dangers of such indiscriminate conduct. We should not have spoken of this practice distinctly, for, in fact, it has been already noticed, except to guard against what we think a radical and widely extended error. We remember the former Dr. Gregory, than whom no man was more accurate and cautious, speaking of bleeding as safe, and often useful, in the beginning of all fevers, if the patient were young and strong. Dr. Cullen, the antagonising spring to every part of the Boerhaavian practice, was led to the same plan from his system of reaction. Both practised in a northern latitude, where it was not considerably injurious; and without noticing this distinction, disseminated, we fear, a dangerous

mode of proceeding. Brown was led to violent indiscriminate bleeding in his revival of the methodic system, and he could not discover his error, as he had little experience. His pupils have unfortunately not always been enlightened by their errors.

If, on the principles laid down in the beginning of this article, we consider the use of phlebotomy in distinct diseases, we must begin with *FEVERS*, and, of course, with *INTERMITTENTS*. In these, bleeding is seldom useful. The effects of relaxation may appear to indicate it in the hot fit to bring it sooner to a conclusion; but we shall gain little in our ultimate object, the cure of the disease, by preventing the return of the paroxysm. If, however, the delirium in the hot fit is violent, if the circulation is so rapid as to endanger hæmorrhage in persons predisposed to an hæmoptoe, bleeding will be necessary to prevent the occurrence of such an event. In general, however, it is unnecessary; and evacuations, with low diet in the interval, and opium on the access, or near the termination of the heat, will conduct the paroxysm more safely to its conclusion. In those irregular intermittents, which attack with local inflammation, it may be useful in the same view; but the great object is to prevent the return. Those which attack with syncope and apoplexy also sometimes require it.

Remittents are seldom of the inflammatory kind; but these are the fevers in which the American practitioners have bled copiously. The principles, however, on which this practice rests have been often mentioned.

Continued fevers of the inflammatory kind, with the limitations lately stated, certainly require bleeding, particularly as we have remarked that local inflammations often begin with fevers, which show no tendency to the subsequent complaint. The great difficulty arises from asthenic fevers often beginning with inflammatory symptoms, and our former distinctions must be here applied. In cases of the slightest doubt it is better to abstain; for it is an error that may be remedied: its opposite cannot. When local affections arise during the continuance of a fever, we must first examine if the disease be such as, in its progress, might be attended with inflammatory congestions. If it be, we must inquire whether any marked exacerbation has taken place, whether the pulse has become suddenly full and strong, the eyes red, and the face flushed. If the circumstances are such as to afford the slightest doubt, we may employ topical bleedings; and if still more doubtful, a blister. In other circumstances the camphor with opium will very effectually relieve.

In the *phlegmasie* we find this remedy most generally necessary, and have already explained the foundation of its use in the article *INFLAMMATION*, q. v. The great object is to relieve the general affection, the diathesis phlogistica, which is shown by a remission of the hardness of the pulse, and some relaxation of the surface. The topical affection may, in this way, be alleviated; but the evacuations would be much too copious were they continued till it was removed. This purpose topical bleedings and blisters will supply. The discharges of blood in these cases were formerly enormous. From altered manners and constitutions, such considerable bleedings are now neither necessary nor useful; and under the articles *PERIPNEUMONIA* and *PLEURITIS*

we have pointed out the utmost extent to which they are at present practised. With a view to facilitate this discussion, we attempted (see INFLAMMATION) to arrange the phlegmasiæ according to the violence of the inflammatory diathesis, and consequently to point out the comparative necessity of bleeding. Some practical doubts may arise respecting gastritis, enteritis, and a few others, where late practitioners, particularly Dr. Pemberton in his very valuable work on the Diseases of the Abdominal Viscera, have carried the evacuation farther than we have proposed in the separate articles, supported by the observation that the pulse rises on bleeding; but, in general, we have offered what has been the result of our own practice. In this second class of active inflammations we have not often seen a second bleeding necessary; but, in a robust, strong constitution, where the pain continues violent, the pulse firm, full, and strong, a second and a third are sometimes required. We have seen enteritis requiring bleedings as copious as pleurisy. In medicine there are no universal propositions.

In the *erythema* (for we must now take leave to follow our own arrangements) bleeding is highly injurious, if we except the peritonitis puerperarum, where it has been employed, it is said, with success. But this subject we shall soon resume in the article PUERPERALIS FEBRIS, q. v. In *catarrhus* the extent of the remedy must be proportioned to the violence of the fever, but this is seldom considerable, and in very few instances is the loss of blood requisite. When coryza becomes peripneumonic, or when dysentery threatens enteritis, it may be admissible; but either happens very rarely. In phthisis, as we shall soon find, it is not an appropriate remedy. Of the species of *arthritis* rheumatism only requires bleeding, and this is often necessary to a considerable extent in all its varieties. Indeed no disease in many cases demands larger and more repeated evacuations. Even in arthrodynia, from the violence of the pain, it is occasionally necessary; and some practitioners employ copious bleedings on the accession of gout. We have known instances in which they have lessened the fit repeatedly, without injuring the constitution; but we dare not recommend the imitation of the practice, especially in the weaker or more irritable habits.

In the *exanthemata* (order *eruptiones*) it is only adapted to the epidemic exanthemata; and from among these we must except all but the *variola* and *rubeola*; for of the *pestis* we have lately spoken. In the former it is only used in excessive inflammatory action, with a determination to the head. In the latter, from its peripneumonic tendency, it was formerly supposed to be the principal remedy, and especially in the diarrhœa, which often follows. Since, however, we have learnt the good effects of laxative medicines, we have found bleeding less necessary, and have indeed very few cases which have required it.

In the *profluvia* the use of this remedy is confined to the active hæmorrhages, those discharges which agree with phlegmasia in their connection with increased activity and tone in the arterial system; and in these at times it must be employed to a considerable extent; for the more rapid evacuation diminishing the tone of the arteries and the tension they impart to the nervous system, brings on fainting, during which the hæmorrhage stops, and the ruptured vessel heals. We have

said that some increased action occurs in even the passive hæmorrhages; and bleeding has sometimes been directed in these, or at least in cases which partake of the nature of each.

In the genus *constrictoria* (order *suppressorii*), asthma only, at times, requires this evacuation; but it must be confined to the strong and plethoric, where there is danger of violent inflammation, or of immediate suffocation. The usual conduct of practitioners, in this respect, we have already noticed. The *suppression of sanguineous evacuations* sometimes depends on spasm, from increased inflammatory action; and when a suppression of the menses, the lochia, or of the hæmorrhoidal discharge, is attended with great load, a flushed face, and other symptoms of inflammatory fever, bleeding is essentially necessary. It should not, however, be hastily employed, or frequently repeated; for it soon becomes an inconvenient, if not a dangerous, habit. In *icterus*, *ischuria*, and *dysuria*, it is only useful when the pain is attended with fever, and inflammation is threatened, or has come on.

Adynamie. In the genus *coma*, violent apoplexy and palsy, depending apparently on active hæmorrhage, alone require bleeding. It has been lately advised in the variety styled *hydrocephalica*; but the practice is confined to a few individuals only: and we have not found that it has been eminently successful, though perhaps suggested by the early appearance of irritation. In the variety of syncope, from affections of the heart, small bleedings have been sometimes repeated with success.

Spasmi. In this order also it is scarcely ever employed but in the more violent convulsions of the plethoric and robust, to prevent the consequences of too great determination to the head during a paroxysm; in *fertussis*, for the purpose of avoiding peripneumony, when it impends; in colica, to prevent inflammation; and in hydrophobia, from an idle theory. The few diseases which remain we shall mention, without any attention to arrangement, in their order. In *hallucinatio* it is sometimes beneficial to lessen irritation; in *mania* when the determination to the head is violent and apparently inflammatory; in *hydrothorax*, as a temporary expedient to prevent suffocation; in the various *hernia*, to prevent inflammation, sometimes to produce deliquium; and in all violent wounds and contusions, for the former purpose.

We have mentioned bleeding generally in convulsions, to prevent determination to the head; but in one disease of this kind, the convulsions of puerperal women, it has been employed with little reserve, and, we may add, little discretion. It sometimes appears at first to relieve; but there are few practitioners who have adopted this plan but have regretted, in the sequel, the loss of that strength which they were unable to restore.

Bleeding has also been recommended to preserve health, and the custom of letting blood regularly in the spring is not yet quite obsolete in the county where the author of this article resides. In females, at the cessation of the menses, it is sometimes empirically employed, and occasionally to procure abortion. It were well if no more active means were used; for this is totally ineffectual. On any sudden terror and surprise it was formerly employed, apparently to prevent any

irregular determinations to the different parts, or probably accumulations in the heart: in such cases it is at least not injurious.

When we treated of the BLOOD, q. v. we described its constituent parts, and their spontaneous separation. It appeared that the buffy stratum on the top was not the effect of viscosity or lentor, but owing rather to tenuity of the blood, which allowed the red particles to fall down before the gluten coagulated. This sometimes arose from a more intimate mixture of the parts of this heterogeneous mass, sometimes, as in scurvy and typhus, from a real tenuity. Since this sign, however, has been greatly depended on, it is necessary to make some distinctions which will render it less equivocal.

As this appearance is owing to the time in which the coagulation takes place, it is necessary to ascertain its existence, that the blood should not be too quickly or too slowly cooled. Blood does not coagulate readily in cold or in warm weather. Either extreme, therefore, should be avoided. It coagulates more rapidly in small masses, and when exposed with an extensive surface: it should consequently flow freely from a large orifice, not drop from the arm, and be received in vessels of a moderate depth, and of no large surface, as a tea cup. The bleeding dishes of our ancestors were too wide and shallow. The blood would too often appear buffy; and this may have been among the reasons for the frequent repetition of bleeding.

A circumstance which formerly appeared inexplicable, will, on these principles, be easily accounted for. In inflammatory diseases the first drawn blood was not buffy. The second tea cup, or the second discharge, was covered with a crust. In such cases the pulse labours, and is oppressed with the load; though the fever is considerable, the face flushed, and the pain, for instance, in the side violently acute, the pulse continues soft, and not peculiarly strong. From considering the constitution, the cause, and other circumstances, bleeding may appear indicated, and in such cases the first cup appears natural. When the load is removed, the pulse becomes fuller and stronger, the circulation more free, and the heterogeneous ingredients more intimately mixed; of course the blood becomes buffy: and though there is sometimes no time for the production of this change in the first bleeding, it is constantly found when the operation is repeated.

This increased fulness and strength is the change expressed by the language, that the pulse rises on bleeding. It is followed by a relief of the load, a remission of pain, a diminution of the burning heat, and the appearance of a gentle moisture on the surface. But because one bleeding has relieved, it does not follow that the operation must be repeated. We must take advantage of this remission to procure a continuance of the favourable change by other means (see FEBRIS and INFLAMMATIO), nor again repeat the operation, unless the former symptoms of diathesis phlogistica recur. On the contrary, if the first bleeding has been injurious, languor, paleness, a rapid, weak, and almost indistinct pulse, with frequent returns of syncope, are the consequences, indicating a state of debility, which, in many cases, we cannot conquer. Bleeding should, therefore, be employed with caution.

Blood is usually taken from the subcutaneous veins in the flexure of the fore arm. It is sometimes drawn

from the jugulars, sometimes from the saphæna in the leg, and in a few instances from the veins in the back of the hand. The last part is selected from necessity only, as the veins of the arm are sometimes very small. Blood is taken from the jugulars in children, as the vein is large, and will admit of a rapid depletion; but the chief advantage supposed to be derived is from the vicinity of the parts affected. In affections of the head a discharge from the jugulars appears to combine the good effects of a general and a topical evacuation; but in diseases of the throat it seems to possess no very striking advantage, except from the size of the vein in children. We are not aware that it produces faintness more quickly than when the blood is taken from other veins. Bleeding from the saphæna is a branch from the obsolete stock of derivation or revulsion, where an evacuation at a distance was supposed to have an effect greater in proportion to the distance. Had the mechanical physicians, with whom this was a favourite doctrine, employed their mathematics, they might have soon found it less. In uterine complaints the choice had a better foundation, as to lessen the quantity of blood in the lower extremities would probably assist the circulation through every branch of the descending aorta; but it would have been more reasonable had practitioners used it in abundant rather than deficient menstruation.

The operation itself has been detailed with a formality which would be only excusable in describing that of lithotomy, or dividing the ring of the abdominal muscles for the reduction of hernia. We shall suppose the minutiae known, and notice only the more important circumstances.

The ligature should be moderately tight, so as to stop the circulation in the veins, but not in the artery, which should be felt at the bending of the arm, after the ligature is applied. When the veins have swollen, the operator, with a spear-shaped lancet, which is preferable, since it makes the wound of the integuments scarcely larger than that of the vein, divides the skin, and immediately plunges the lancet into the vein itself, in an oblique direction, to prevent its passing through the inferior parietes of the vessel. In general, the operator chooses the vein most remote from the artery or tendon; but should no such be found of a proper size, it will only require a little additional caution. He should, in that case, press his lancet only so low as to be sure of wounding the vein, and then divide it in a direction more near to a horizontal one. Veins that do not roll are preferred; but this is an useless refinement, since it is necessary to confine the vein a little below the part where the puncture is made by the thumb of the left hand.

When the blood begins to flow, the posture of the arm should not be changed, as it may occasion the wound of the integuments no longer to coincide with that of the vein, so that the position should at first be an easy one, that is, half bent; and the operator, if he sees that the apertures do not coincide, can easily draw the skin, so as to correct the error. If the blood stops from faintness, fresh air and a horizontal posture will restore the flow. If from too tight a ligature, it should be gently slackened. Moving the muscles of the hand by rolling any thing in it promotes often the discharge. After the operation, a bit of lint, with some sticking plaster,

is only necessary, unless the orifice has been large, or the bleeding has appeared to continue after the ligature is removed. In that case the usual bandage with a compress is necessary. In the choice of veins the median basilic is usually preferred, as the largest, nearest the surface, and the integuments are thinnest over it; but it must be recollected that the artery often lies under it, so that, though bleeding is less painful, the danger is greater.

Simple, however, as this operation is, various inconveniencies, and some very dangerous affections, often follow it. The tendinous aponeurosis of the biceps passes under the integuments, and though this is thinner over the median basilic than the other veins of that part, wounds in it seem to produce inconveniencies. The tendon also of the muscle is sometimes punctured, and occasionally a subcutaneous nerve wounded. The pain sometimes immediately felt on the introduction of the lancet is probably, as we shall soon find, caused by a wounded nerve; for the tendons, in a sound state, are insensible, and in every instance of bleeding the aponeurosis is necessarily cut. When, however, the acute pain just mentioned does not soon recede, but continues to increase, there is always reason to fear the most disagreeable consequences. The wound inflames, its lips become sore and hard, and, after a few hours, a watery serum or a bloody sanies oozes from them. After the continuance of these symptoms for a few days, with little variation, the acute pain is changed to a burning heat, which increases to a very violent degree. The lips of the wound swell still more, and the tumour is communicated to the whole limb, which at last appears erysipelatous. The pulse then becomes hard and quick, the pain is intense, the patient restless, and subsultus, convulsions, or a locked jaw, close the scene.

Events so distressing, from causes apparently inadequate, have excited the attention of pathologists, who have hitherto laboured with little success to explain them. The original idea was, that the wound of the tendon occasioned all the subsequent distress. In vain was it alleged that tendons were insensible, that nerves could not be traced to them, that they must be cut and wounded in a variety of operations, as well as by numerous accidents: equivocal facts were still produced in opposition, nor, till within a few years, was it concluded that such consequences could not arise from any wound of these organs. A partial wound of a nerve often produced similar complaints; and nervous irritation was the forerunner of the inflammation and the spasm. In this state of contending opinions, Mr. Hunter, active and ingenious, though occasionally whimsical and eccentric, suggested a very different cause. He had found in horses, who died in consequence of venesection, the internal surface of the vein inflamed, and similar effects had occurred in the human frame. Air then admitted into the cavity of the vein was followed by inflammation, and its usual attendant suppuration, while the pus, thus mixed with the blood, produced all the symptoms of irritation. Without doubting the facts, we may, however, arraign the consequences. The access of air to the coats of the vein is at best improbable, since it always continues full; but, if admitted, the pungent pain at first, the rapid appearance of the inflammation, and its pro-

gress, precludes the idea of a cause always slow, and, in general, gradual in its effects. If still allowed, symptoms of nervous irritation do not follow the absorption of pus, and a locked jaw is never the consequence of absorbed purulent matter. In fact, all the circumstances coincide in the idea of a nervous irritation, from a wound in the medullary organ; and, from the facts adduced, we must admit that an inflammation of the internal surface of the vein is a frequent consequence of this irritation.

The remedies usually advised for this complaint seem to be in part derived from the idea of an inflammation on the internal surface of the vein. Their operation, however, equally admits of another explanation. When an unusually acute pain is felt in the operation, which does not subside in a few hours, the arm should be kept in a perfectly relaxed state; emollient poultices which would perhaps be rendered more effectual by the addition of opium, applied; the patient's diet below; a large dose of opium given, followed soon afterwards by a purgative. If the pain still continues and the inflammation of the wound increases, leeches, near the part, are recommended, with a liberal bleeding from some other vein. In this state warm emollient applications often increase the heat as well as the pain; and the sedative astringent ones afford most relief, particularly solutions of vitriolated zinc applied cold, and Goulard's cerate. Applications of opium seem not to have been sufficiently tried, and no case of this kind has occurred in our practice to enable us to speak for ourselves.

When the symptoms, however, have increased to a dangerous degree, opiates have been given freely, and every means of allaying irritation attempted; but these means have been usually found inefficient, and the only alternative is dividing all the subcutaneous nerves above the wound, or an amputation of the limb. In this case the wounded vein must be tied above and below, and the intermediate part cut out. If then we dissect down to the tendon of the biceps, and a little on each side the injured nerve, if such has been the cause, must have been divided. Amputation is, however, our last resource; and it would probably have been more often effectual if attempted earlier.

It must not, however, be concluded that every inflammation of the arm, or the neighbouring parts, after bleeding, is so dangerous and fatal in its consequences. A phlegmon will sometimes form on the part from an inflammation of the cellular substance, and this inflammation in many instances becomes erysipelatous. Each is removed by the common remedies, and, after the suppuration, the coat of the vein is found to be free from induration: its substance was never affected.

We have observed, also, that inconveniencies have arisen from the wound of the integuments not perfectly coinciding with that of the vein. The consequences have been, that the blood has passed into the cellular substance, and enormously distended the arm. The sudden appearance of this distention, and the absence of acute pain, sufficiently point out its cause, and the little comparative injury to the constitution likely to result. If from want of caution the lancet is plunged *through* the vein, the injury is more considerable, and mortification has been the consequence. The coagulation of the blood, however, opposes a sufficient

obstacle to the discharge; but the blood itself must be removed by an operation, sometimes the wounded portion of the vein cut out.

Among the accidents from bleeding, an irritation and a consequent inflammation of the absorbents have been enumerated. These vessels we know to be muscular, and they become, by inflammation of their coats, hard and acutely sensible cords. Inflammations of this kind are distinguished from those which arise from the absorption of acrid matter, from the glands not always enlarging, and from the hardness being felt below as well as above the source of the disease: sometimes indeed the gland is affected; but the pain is greatest at the first appearance of the tumour, and it has little tendency to suppurate.

Though inflammation of the vein be not the cause of the dangerous symptoms before enumerated, it certainly sometimes takes place, at least as an effect, and Mr. Abernethy has recorded three cases of the kind. The symptoms of general inflammation were considerable; but the disease yielded to common remedies. The sides of the vein apparently adhered above and below. Our author advises a compression on the vein above, to assist this adhesion, since inflammation is speedily communicated along membranes, and may otherwise extend to the heart, of which, if our memory does not fail us, we recollect one or two instances.

A consequence of bleeding not sufficiently discriminated in the general systems, is the injury which the tendon of the biceps receives from a puncture. The effects of such a wound would alone disprove the symptoms formerly attributed to it; for they are very different. The general distinguishing symptom is the sensation of a cord bound tightly round the arm, with an inability to move it. This seems in some instances to arise from matter confined under the aponeurosis; and in one case an opening made at a small point, near the external condyle, discharged a considerable quantity of pus, by which the patient was immediately relieved. At other times, however, this sensation of tightness really arises from spasm. We know that the tendons are incapable of contracting; but they seem to communicate irritation to the muscular fibres, by which contraction is excited. In the case recorded by Mr. Colby (Medical Communications, vol. ii. p. 18.) there was no suppuration; and in those described by Mr. Watson, though an obscure sense of fluctuation was communicated to the finger, there was no purulent matter. The latter seems to attribute the contraction to a thickening of the aponeurosis from inflammation; but the symptoms, from the description of the patient, evidently point out the source to be a spasmodic contraction; and it is highly probable that as this has occurred in so few cases, while the aponeurosis must be divided in every operation, that a nerve distributed on the tendon was wounded. In the first case an incision was made between the brachialis internus and supinator radii longus (Medical Communications, vol. ii. p. 236), where an obscure fluctuation was seemingly felt. Various other incisions were tried with little effect, till one was made into the middle of the biceps, carried deep into the body of the muscle down to the tendon, in the direction of the fibres, and so low into the latter

as could be done with safety. The relief was immediate, and continued.

In all such cases it seems that opiates have not been tried to a sufficient extent, if we except that recorded by Mr. Colby of Torrington, and his success seems owing to his bold and very judicious exhibition of this remedy. Opium would be apparently useful, not only internally but as an external application, and we could wish that in future events of this kind it might be tried.

We recollect only one other accident from bleeding, viz. the wound of a lymphatic. It continues to discharge lymph for a few days, but is soon cured. At least a watery solution of sulphurated copper will produce this effect. See CUCURBITULA and HIRUDO.

On the subject of blood-letting, see Galen de Sanguinis Missione; Botallus de Venæsectione; M. A. Severinus on Bleeding; An Essay concerning Blood-letting, by R. Butler, M. D.; Bell's Surgery, vol. i. p. 63, &c.; White's Surgery, p. 167; Abernethy's Surgical Essays; Mr. J. Hunter's Works; Medical Communications, vol. ii.

PHLEBO'TOMUS, (from φλεψ, *a vein*, and τεμνω, *to cut*). A LANCET, or a FLEAM, for bleeding.

PHLE'GMA, (from φλεγω, *to excite*). PHLEGM, a mucous or excrementitious fluid discharged from the bronchiæ. Galen gives this denomination to every cold humour: in Hippocrates it often signifies inflammation.

In chemistry phlegm signifies the water obtained by distillation.

PHLEGMA'SIA. See INFLAMMATIO.

PHLEGMA'TIA, (from φλεγω, *to burn*). See ANASARCA.

PHLEGMA'TIA DOLENS. See LYPHÆDUCTUS.

PHLEGMATORRHA'GIA, (from φλεγμα, *mucus*, and ρεω, *fluo*). A discharge of thin phlegm from the nostrils. See Salmuthus, obs. 37.

PHLEGMONE, (from φλεγω, *to burn*). See INFLAMMATIO.

PHLEGMONE ARTICULI. See ARTHROPOUSIS.

PHLEPS, (from φλεω, *to abound*; because it is filled with blood. See ARTERIA.

PHLOGISTICI, (from φλογίζω, *to burn*). Inflammations and fevers, with a hard pulse and topical pain.

PHLOGISTON, (from φλογίζω). INFLAMMABLE PRINCIPLE, on which the ignition of all bodies was supposed to depend. The existence of this element was first asserted by Becher, an opinion adopted by Stahl, and since by other chemists; but the late discoveries of Lavoisier and others have wholly disproved its existence. The opinion since the death of Dr. Priestly has not one scientific advocate; and the addition of oxygen is now established to explain all the changes attributed to the separation of phlogiston.

See on this subject Lavoisier's, Chaptal's, and Fourcroy's Elements of Chemistry. In Mr. Nicholson's Elements the reader will find the fairest representations of both theories, as applied to different processes.

PHLOGOSIS, (from φλογω, *to inflame*). See INFLAMMATIO, and ÆSTUS VOLATICUS.

PHLO'MIS, (from φλοξ, *a flame*; from its flame-like colour). See SALVIA SYLVESTRIS.

PHLYCTÆ'NÆ, (φλυκταίναι, *small bladders*, from φλεγω, *to be hot*), *holophlyctides*, *phlyzacion*, applied by

Linnæus and Vogel to *hydatidæ*. (See BULLA.) Pustules on the tunica cornea of the eye, including the *unguis* and *phlyctenæ*, strictly so called: when they arise in the conjunctiva they are reddish at first, and afterwards white; but when on the transparent cornea, dusky, at last white. Their seat is usually under the external coat of the cornea, and they have been cured by taking off its external lamina, to remove the stagnating matter. They are generally occasioned by inflammation, and should be dressed three or four times a-day with six or eight grains of cerussa acetata, dissolved in three ounces of aq. rose water, and when they yield, washed with equal parts of brandy and water. If they neither disperse nor break speedily they must be opened with a lancet, and dressed with the aqua saphirina. Little watery pustules, full of a hot acrid fluid, are styled *phlyctenæ*; but we shall consider this complaint under the two following articles, q. v.

PHLYCTIS, (from *φλυζω*, to be hot). A watery pustule or eruption on the skin, with a circular base slightly inflamed, containing a lymph, sometimes clear and pellucid, but more frequently whitish, like whey, or pearl coloured. The pustule terminates in a laminated scab. Under this head may be ranked the hydroa or hidraea, boia, and sudamina, of authors.

PHLYXA'CION, or PHLYZA'CION, (from *φλυζω*, to be hot). A pustule or vesication on the skin, excited by fire or heat. Dr. Willan defines it a pustule (the size of a pea) containing pus; and raised on a hard, circular, inflamed base, of a vivid red colour. This disease seems to be only a greater degree of phlyctis, and each may be readily understood by what has been observed under MORBI CUTANEI, q. v. It is succeeded by a thick, hard, dark coloured scab.

PHŒNICIUS MORBUS. See ELEPHANTIASIS.

PHŒNIGMOI, (from *φαισσω*, to become red). See EPISPASTICA.

PHŒNIX, (from *Phœnicia*, its native soil). See LOLIUM.

PHOS, (from *φωσ*, to shine). LIGHT. See PUPILLA.

PHOSPHATS, (from *phosphorus*). Salts formed by the union of the phosphoric acid with different bases: those with the phosphorous acid are called *phosphites*.

PHOSPHORIC ACID. (See CHEMIA.) It has, we observe, been used in hectic, and as a tonic in cases where mineral acids have been recommended. Though found, however, in the mineral kingdom, we would rather consider it as an animal acid. It occurs in the blood, in the bones, in the enamel of the teeth, and the gluten of seeds, particularly of maize. The Bolognian stone is the radiated sulphurated barytes. Hallé, ii. 332.

PHOSPHORUS, (from *φωσ*, light, and *φωσ*, to bring,) *autophosphorus*, the name of a collyrium in Galen. Phosphorus was first discovered in 1669 by Brandt, but kept as a secret, and in 1674 by Runckel, and afterwards by Boyle, from whom it was called the English phosphorus, as it was supplied by a London apothecary, to whom he taught the secret. It is an oxide originally prepared from urine; nor was it discovered till the year 1769 that its acid was contained in bones. For its chemical properties, see CHEMIA, vol. i. p. 420.

It was given many years since, according to the ac-

count of Hankwitz, the apothecary to whom Boyle communicated the secret, in France, in colics; afterwards by Mentz in low fevers, as a cordial and sudorific; and by Le Roi, in rheumatic and nervous diseases. It is, however, a medicine of considerable acrimony, and, from Le Roi's experiments, highly dangerous (Memoires de la Societé d'Emulation, vol. i.) He found the most painful and distressing effects from three grains of this oxide, though it is the dose given by Mentz in petechial fevers as a cordial. Wackard has cautioned us by relating the dangers and inconveniences which resulted from its use. A similar case is recorded in the Medical and Physical Journal; and others might be offered from the records of private practice.

The exhibition of phosphorus is not an easy task. It must be reduced to powder, but the slightest heat inflames it. If put into warm water, and agitated, it diffuses itself like oil, and, on the sudden affusion of cold water, is precipitated in a powder. This may be rubbed with mucilage into a lohoc, with powder of gum arabic into pills; but, camphor, in general, assists its union. A quarter of a grain is now considered as a sufficient dose. The exhibition of phosphorus has again of late been attempted in the cure of rheumatism; but it is a remedy so truly dangerous, that we should earnestly dissuade any future trials.

Combined with soda it is a tasteless neutral, recommended by Dr. Pearson as a laxative for children, and highly useful in their complaints. The other phosphates have not been used, except the phosphorated mercury, which we noticed vol. i. p. 176, and the phosphorated and oxyphosphorated iron, lately recommended in cancer by Dr. Carmichael, of Dublin. See BONONIENSIS LAPIS.

See the different processes in Chaptel's Elements of Chemistry, vol. iii. p. 350, &c.; Thompson's Chemistry; Fourcroy's Chemistry, ix. 245.

PHOSPHORUS BONONIENSIS, and KIRCHE'RI. See BONONIENSIS LAPIS.

PHOSPHORUS LIQUIDUS. One grain of the phosphorus, in powder, cautiously mixed with ten of camphor, dissolved in the oleum caryophyllorum, make a liquid phosphorus, which may be rubbed on the body without danger of inflammation. It is chiefly used as an amusing experiment, since it is luminous in the dark.

PHOSPHURETUM, (from *phosphorus*). PHOSPHURET. Combination of phosphoric acid, with different bases. (See PHOSPHATS.) In these the oxygen is in a still less proportion.

PHOTOPHOBIA, (from *φωσ*, light, and *φοβία*, to dread). Too great sensibility of the retina, either from inflammation, increased nervous sensibility, as in hydrophobia, or from a disuse of light.

PHOXOS, (*φοξος*). The sugar loaf shaped head.

PHRAGMOS, (from *φρασσω*, to enclose). An anatomical term for the double series of teeth.

PHRAS'IUM VIRIDE. See ÆRIS FLOS.

PHRENES, (from *φρην*, supposed to be the seat of the mind). See DIAPHRAGMA.

PHRENE'SIS, or PHRENETI'ASIS, (from *φρην*, the diaphragm). See PHRENITIS.

PHRE'NICÆ ARTE'RIÆ, and VE'NÆ, (from

the same.) See DIAPHRAGMATICÆ ARTERIÆ, and VENÆ.

PHRENI'SMUS. See PHRENITIS.

PHRENITI'CI NE'RVI. The nerves which run in the diaphragm. See NERVI.

PHRE'NITIS, (from *φρενις*, *diaphragm*.) *cephalitis*. Phrenitis was formerly supposed to arise from inflammation of the diaphragm, which was called *phrenes*, as if assistant to the intelligent principle. The term is now applied to an inflammation in the brain, or rather its membranes, with a violent delirium, and an acute continued fever, named *cephalalgia inflammatoria*; by the Arabians *karabitus*; by the Greeks *phrenesis*, *phrenismus*, and *sphacelismus*. Dr. Cullen places this disease among the *phlegmasiæ*, defining it a violent febrile affection, attended with pain of the head, redness of the face and eyes, incapability of bearing light and sound; pervigilium; fierce delirium; and typhomania.

It is idiopathic when the head is primarily affected; and symptomatic when the morbid affection is translated to the head, from some other part, as from the side in pleurisy. The former is inseparably accompanied with an acute fever; the latter is followed by the fever, and styled *desipientia*.

The idiopathic is rare; but the symptomatic is sometimes met with, and most frequently appears about the crisis of other fevers, attended with a rigor, a tremor of the joints, tension of the precordia, coldness of the extremities, thin urine, discharged either in too sparing or too large a quantity. The symptomatic phrensy scarcely differs even in degree from the idiopathic.

An approaching phrenitis is announced by intense continual watchings: or, if the patient sleeps, his sleep is interrupted and troubled; he starts, and is affected with terrible dreams; soon forgetting what is said. If at any time he returns an answer to a question, his fierceness and anger seem to be increased; the pulse is small and hard, a pain is constantly felt in the occiput, and as the disorder increases the eyes become more fixed and red, tears, at the same time, flowing from them. The phrenitis is marked by an acute fever, a pulse low and tense, sometimes hardly perceptible; but in most instances full and strong. The sleep is disturbed, the delirium violent, with noise in the ears, and excessive headach. The tongue is dark and black; the urine high coloured, and in small quantities.

In many instances the violence of these symptoms is less; and unsteadiness, want of recollection, tremblings of the limbs, are the principal symptoms. In short, if there is a distinction between an affection of the membranes and the substance of any part, it appears to be found in the brain. Thus the *membranous* or *parenchymatous* inflammation of nosologists is established; and though the distinction in some respect takes place, yet it is not fully ascertained by dissection, nor is it universally applicable.

The principal distinction necessary to point out is that of phrenitis from mania. The sudden attack of the former, the violent fever, and an evident exciting cause, will, however, be sufficient for this purpose; but the second variety noticed is distinguished with more difficulty. If, however, the symptoms be carefully examined, neither false perception nor erroneous judgment will appear, and the whole complaint be found to consist in weakness and unsteadiness of mind, in con-

fusion, when the intellectual powers are exerted, a want of memory, and a difficulty of discrimination. We have known a man, from this disease, not able to count five in succession for many months.

But while phrenitis appears in these two distinct and opposite forms, various affections of the head have been attributed to it, and treated like true inflammation of the brain. In various articles, particularly in *Concussio*, we have pointed out the difference between active inflammation from increased action, and a similar state from atony and congestion. At the end of fevers an increased fulness of the vessels is found, and each state has been styled inflammation of the brain. Yet the causes, the symptoms, and the cure, are essentially different. It is necessary, therefore, to limit the *true phrenitis* to the active inflammation, with increased action of the vessels, depending on phlogistic diathesis. Of this then we must first treat; and we shall next point out the distinction between the two states, with the variety of conduct which the symptoms suggest.

The remote causes are those of inflammation in general, cold topically applied after great heat, or cold liquors incautiously drank when heated: violent excitement from excess, particularly excess in drinking spirits, is sometimes also a cause. Those subject to the disease are the strong, the robust, and the plethoric; and it seems that the predisposition is hereditary. The treatment is nearly the same as of general inflammation. As resolution is, however, the only safe termination, bleeding is an indispensable remedy. From its effects, as explained in the article *PHLEBOTOMIA*, q. v. it will appear peculiarly applicable to this disease, as it lessens the tension of the nerves by most powerfully diminishing that of the arterial system. Even general bleedings, however, carried to their utmost extent, will not always succeed. Fainting sometimes takes place, while the increased tension continues, with little diminution; and topical bleeding must supply its place. It is recommended to bleed in a standing posture, that faintness may be more readily induced. This is, however, a mistaken direction. Fainting is the impediment to a sufficient bleeding, and the contrary direction has better foundation. Bleeding from the jugulars, as has been explained, seems better adapted to the complaint; but in this climate the disease is seldom so acute as to require these extreme measures. In aid of general and topical bleeding by leeches or cupping glasses, *blisters* are generally necessary; but as cold applications to the vertex are peculiarly useful, the blisters should be first applied to the nape of the neck, and afterwards behind the ears. The head may then be shaved, and cold oxycrate constantly applied to the vertex. The cooling saline purgatives should be given freely, so as to produce copious watery discharges, and nitre in as large doses as the stomach will bear. The room in which the patient lies should be cool and airy, not too light. When this plan has been adopted for a short time, if the delirium be not relieved, the disease is at least brought to that second stage which we must next consider.

The milder delirium, already described, depends on the more languid inflammation, probably in the substance of the brain, and, as we have suspected from dissection, chiefly at the base of the cerebrum. Different degrees of this form of the disease are owing to

suppressed evacuations, sometimes of the menstrual, at others of the hæmorrhoidal, discharge; occasionally to repelled eruptions and gout, though each occasionally produces a degree of phrenitis of a more violent kind, particularly in those constitutionally predisposed to it. Yet even in its greatest violence it must be distinguished, since the very active remedies of the former variety are unsuitable to the present. The inflammation from CONCUSSION, q. v. is of this kind, as well as from ICTUS SOLARIS, q. v. and require the milder plan of cure.

General bleeding is not always necessary, and then not to a great extent. Its degree must be limited by the violence of the symptoms, particularly the delirium. Topical bleeding is more useful, but by no means always necessary; and blisters are better adapted, by a slow, steady discharge, to lessen the accumulation. Each, as general bleeding, must be proportioned to the delirium. The camphor, with nitre, is often useful; and a steady discharge from the bowels equally necessary. The coolest free air, rest, with the utmost tranquillity of mind, are indispensable. When the accumulation is removed, its effect, unsteadiness of mind, often continues. This is sometimes supposed to be owing to remaining inflammation, and the violent evacuations are, with little discrimination, employed: a plan which increases instead of mitigating the disease; for it depends on the too great previous excitement. We have found no mode of conduct particularly serviceable, except absolute rest of mind, with moderate exercise of body. The camphor, bark with valerian, and some other medicines of this tribe, with cold bathing, and gentle alvine evacuations, seem occasionally to have contributed to the relief; but from time alone a cure may be expected.

See Alexander Trallian; Cælius Aurelianus; Ætius; Willis's *Pathologia Cerebri*, cap. x.; Hoffmann; Boerhaave; Baglivi; Fordyce's *Elements*, part. ii.; Cullen's *First Lines*, vol. i. p. 272, edit. 4; Bell's *Surgery*, vol. iii. p. 147.

PHRENI'TIS APYRE'TA. See MANIA.

PHRENI'TIS VOGELLI. See SYNCHUS.

PHRI'CASMUS, (from φρικα, horror). See HORROR.

PHRI'CODES, (from the same,) *carcaros, querquæra*. A fever described by the ancients, attended with horror, rigor, and tinnitus aurium, apparently a semitertian.

PHRY'CTE, (from φρυα, to parch or dry up). See COLOPHONIA.

PHRY'GIUS LAPIS. The PHRYGIAN stone, from its being used by the dyers in Phrygia, rises in Cappadocia, is pale and ponderous; but when calcined, reddish. Its virtues are similar to those of the lapis calaminaris; in fact, it is an earth of alum, and simply an astringent.

PTHHA'RTICOS, (from φθειρα, to corrupt). DELETERIOUS, DEADLY.

PTHETIRO'CTONON, (from φθειρα, a louse, and κτενω, to kill). See STAPHISAGRIA.

PTHIRI'ASIS, (from φθειρα, a louse,) *morbis pedicularis, pediculatio*, a rapid increase of lice, most frequent in warm moist situations. Besides the PEDICULI and MORPIONES, q. v. there is a kind which chiefly breed in dirty clothes. It is this species which forms the morbus

pedicularis, as La Treille asserts; and it is this kind which probably at times burrows in the skin, producing violent itching, and from this cause even insanity. They are called *acari, cyrones, and pedicelli*; but it is probable that these are insects of a different kind.

A decoction of the seeds of stavisacre or coculus indicus, or the powder of either scattered among the hair every night, is an effectual remedy. The last is said to exceed all other means, and it may be mixed in lard, and applied every night to the hair. The pulvis corticis radice sassafræ sprinkled on the head, and confined with a handkerchief, is said to destroy the lice in one night. The neatest and least offensive applications, however, are the mercurials. The white oxide, the mercurius precipitatus albus, may be easily disguised in pomatum, and is a certain remedy for the lice in the hair. The coculus indicus is equally effectual for those of the clothes.

The black soap and the flowers of the *cardamine pratensis* are said to be specifics in all cases of lice on the human body.

PHTHI'SIS, (from φθω, to corrupt). This word, expressing generally *corruption* or *emaciation*, is commonly limited to those states which arise from a previous disease of the lungs; and the term *phthisis pulmonalis* generally means what is styled a consumption, sometimes distinguished by the term *pulmonary*.

Various distinctions of what have been styled species of this disease are found in authors; but we must consider it as one simple complaint from a known cause, viz. an ulcer in the lungs.

The ancients, aware of the cause, could not readily account for the difficulty of healing the ulcer. They found their boasted balsamics useless, and suspected that the constant motion of the organ destroyed the union as fast as it was formed. But we find wounds in the lungs heal with little difficulty; large abscesses, from other causes, even from peripneumony, often yield to common treatment, and the patient perfectly recovers; but when the disease approaches in the manner to be described, recovery is peculiarly rare. We have now probably ascertained the real reason, and must, with Dr. Cullen, attribute this intractable ulcer to the supuration of a strumous gland, which, we know, heals with peculiar difficulty, for reasons to be afterwards explained. See SCROPHULA.

The disease is chiefly confined to the young, the fair with light skins and blue eyes, florid complexions, contracted chest, and high shoulders. In constitutions disposed to hectic, the fingers are often long, and the nails bent; they grow rapidly, but seldom expand in breadth and bulk. From the age of twelve or fourteen to that of about thirty-five is the hectic period; more generally from sixteen to twenty-four; and the tendency seems to return about forty-five or forty-six, especially in women at the period of the cessation of the catamenia.

This disease often attacks insidiously. The patient continues, as we have said, to increase in height without expanding at the shoulders and chest. He becomes languid, loses his appetite and spirits. He is supposed to have grown too rapidly, and the case is neglected, or supposed to be within the reach of the exertions of nature. In the mean time, a slight cough comes on, often only a slight heck, as if a little phlegm hung at the edge of the

epiglottitis, which is generally disregarded. Yet, at this time if the state of the patient be carefully examined, the pulse will be found quick, and above eighty in the most favourable state; after meals, and towards night, more nearly 100. He will not be able to lie on one side with the same ease as on the other, and will experience slight chills. If in females these symptoms appear about the period of menstruation, the catamenia do not come on, and every inconvenience is attributed to this cause. Medicines are directed for this purpose, which are often injurious to the real complaint. Its approach is sometimes more rapid; and a neglected cold is followed by a slow fever, with a continuance of the cough, emaciation, &c. Peripneumony, is sometimes followed also by hectic, but in constitutions only which are predisposed to it; for we have seen many cases of peripneumony terminating in abscess where the matter has been freely discharged, and the patient has recovered. The far greater number of phthises may be referred to neglected colds.

Another precursor of phthisis is hæmorrhage from the lungs. It often appears to be accidental, and is little noticed. The patient seems to recover perfectly; but it returns, and each time in a greater degree, leaving the strength more exhausted, and a slight fever, which soon comes on, more obvious. If hæmorrhage from the lungs often recurs, or continues for any time, however slight the discharge may appear, the danger is considerable.

After the state already described has continued for a few weeks, shooting pains are felt in the chest, sometimes wandering and uncertain in their seat, at others more fixed. It is difficult to fix the source of the pain; for the patient with the greatest dexterity eludes every inquiry. It is in the stomach, in the bowels, from wind, from indigestion, from straining of the cough, &c. When it is ascertained that the patient cannot lie with so much ease on one side as on the other, we may soon discover a pain in that side more fixed and constant than in any other part. Whatever be the difficulty which in cases of peripneumony attend the decubitus difficilis, there is little doubt in the present case. If there is a pain in the side, and the patient can best lie on it, the case is not phthisis. Even when these symptoms have increased to an alarming degree, there is often no expectoration; sometimes a little frothy sputum is discharged, at others a greenish mucus, like that which accompanies recent colds. After a little time, however, some spots of a more suspicious appearance are observed, and at last the spitting becomes decidedly purulent. In many cases of phthisis a caseous matter is discharged very early in the complaint, which curdles in water, while round the edges of the curd pus is often conspicuous.

At this time the chills, frequently observable at a very early period, are strongly marked and followed by burning heat, terminated by a copious sweat. In fact, a true hectic fever is formed. The cough is now often incessant, aggravated by the access of fever; it is in the early part of the night almost incessant.

During the fever, the cheeks have a circumscribed spot of pure florid red; the lips and tubercles in the canthus of the eyes are also brighter than when in health. The fever is augmented after eating, particularly solids, with flushing in the face, and burning heat

in the palms of the hands and soles of the feet. In the morning patients find themselves relieved, but rise languid, pale, and unrefreshed by their sleep. Though the pulse is always quicker than natural, yet there is a remission of the fever for some hours in the forenoon. The countenance now gives evident signs of wasting, the eyes are hollow and languid, the cheeks prominent, the nose sharp, the patient's flesh wastes, and the strength fails; the breathing is short, quick, and offensive; sleep little and disturbed; morning sweats more profuse, and the interval from fever less distinct. The spitting is more loaded with matter, brought up more easily, and in greater quantity, sometimes a pint in twenty-four hours. The menses usually cease, when the hectic exacerbations are strongly marked. From the beginning the body is in general costive, particularly after the morning sweats take place; but about this time also patients, from being costive, have frequent motions, and soon a confirmed diarrhœa; every thing taken into the stomach quickly running off by the bowels. The fever, heat, and cough, abate of their violence, and the morning sweats become less profuse; but if the diarrhœa is checked, these return. The strength totally fails; frequent fainting at last comes on, sometimes a slight delirium; the sputum becomes of a dark brown colour, and sometimes sanious; the lower extremities swell, and at last death closes the scene.

The distinction of consumption, particularly in its early stages is of great consequence; nor is it an object of small utility to point out its original source. At the age of about fourteen in each sex, while the genital organs are evolving, there is often a considerable debility and irritability. The debility in females, as we have seen (see *Menses*), is often formidable, and a slight cough is no uncommon attendant. At this time phthisis may come on, and often does so, with little suspicion: all the symptoms are referred to the great change that then takes place. Similar states of languor are occasionally observed in males, and the same mistake often occurs. In general, in such cases, if either a slight fever from cold, or an hæmorrhage from the lungs, has preceded, it will lead to a suspicion of the truth; and if it should not, the patient may find it difficult to lie on one side, or on taking a deep breath a slight spasm or a cough will come on. No diagnosis can arise from the existence of fever, since in the chlorotic state, coldness, with occasional flushing, are not unfrequent. In general, however, the fever of phthisis attacks most pointedly in the evening; that of chlorosis in the morning: the appetite of hectic patients is best in the forenoon; of chlorosis at night; and the latter can eat meat suppers frequently with impunity. If these diagnostics fail, we must rest till each disease appear more distinctly, or, in the mean time, give only the slight bitters of the purer kind, with such laxatives, generally rhubarb, as will keep the bowels free. Change of air, cheerful company, with a light easy diet, will relieve, if either be the disease.

Syphilis at times assumes the form of phthisis; but, in general, the chest is free, while pains are more violent at night, and more frequently in the middle of the bones of either extremity, or deep seated in the head, than in the trunk. It has also seldom proceeded so far as to mislead, without showing its nature by eruptions, or by an affection of the throat. From the state of

mind we may draw some distinction; for cheerful hope illumines every hour of the hectic, despair darkens each moment of the syphilitic, patient.

Atrophy, from induration of the mesenteric glands, or from abscess in the liver, resembles in its effects, rather than its appearance, the true phthisis. Each is attended with fever, often with regular evening exacerbations, and in the latter we often find a dry short cough. The distinction is not, however, difficult. In the former, the absence of cough, the tumid abdomen, and lying with equal ease on both sides, sufficiently point out the disease: in the latter the dark yellow complexion, and the symptoms of dyspepsia.

After a catarrh, a cough, with a discharge of thin acrid mucus, often threatens consumption, and our apprehension is only relieved by reflecting on the period of life, the absence of hectic fever, the ease with which the patient lies on either side, and, in general, the nature of the expectoration. Truly purulent matter is often also discharged, with such an equivocal exertion that we can scarcely pronounce it either expectoration or vomiting. In this case we have found some foundation of distinction from the nature of the pus. If such as is usually discharged from a common abscess, if in large quantities at once, and not attended with the gradual progress of a hectic, we have usually prophesied a favourable termination, and such has been the result, though in one instance the Solar Tincture, privately taken gained all the credit.

When we spoke above of the source of the disease, it was with a reference to the opinion of a late author, that pulmonic consumption originated in disorders of the liver. It was not an idle nor an unfounded suggestion; for in many instances we have found infarctions of the liver to have preceded; and, when authors speak of consumption arising from a sedentary life, hard study, and distress of mind, we strongly suspect that the foundation of the disease has been laid in the liver. We have mentioned it to direct the attention of practitioners to the early stages of the complaint; nor was it without a view of this kind that, in doubtful cases, we mentioned as a remedy the pure bitters, with rhubarb, to which the fixed alkali may be advantageously added. Is it from this connection that the idea and the term of "a stomach cough" are derived? Stoll has pointed out its connection with a sedentary life; and many authors have enlarged on the injuries which result from the exhibition of astringents in this complaint, which are peculiarly injurious in diseases of the liver: we can add, from observation, that coughs of this kind which have degenerated into phthisis, have been found to originate from a disease of that organ.

We have limited our consideration, however, of phthisis to a consumption arising from an abscess of the lungs, and have expressed our opinion that it is such an abscess as arises from the suppuration of a stumous gland, generally distinguished by the name of *tubercle*, or, when in a suppurating state, of *vomica*. Yet the opinion of other authors must not be passed over without some consideration.

As phthisis follows by hæmoptysis, it has been supposed that the wound arising from the rupture degenerates into a foul ulcer, which heals with difficulty. If, however, the habit is not previously injured, it is not easy to say why a wound from hæmoptoe should not

heal as easily as one from a small sword, pistol bullet, or from the vicarious hæmorrhage from suppressed menstruation. It is, therefore, more probable that the bleeding is the consequence of the contraction of the chest from tubercles, sometimes from a diminished cavity in consequence of deformity.

Suppuration from protracted peripneumony, has also been accused, in general, with less reason. We have seen this happen in several instances, without consumption following. The matter has been fairly spit up; the abscess has pointed externally, and the matter been discharged by a wound; it has been absorbed and carried to the kidneys, within our own observation, with a favourable termination. It is, therefore, probable that this cannot be a cause, except, as already hinted, when the inflammation has been communicated to an indolent tubercle. Peripneumony is indeed a comparatively rare disease; but our recollection does not furnish a fair instance of phthisis originating from it, though so frequently arising from a catarrh, a less degree of the same complaint.

Yet even this view of the case is not without its difficulties. Catarrh is a mild disease, originating from cold, and producing only a moderate degree of inflammation, in a part far above that affected in consumption. We know, too, that catarrh has continued for a series of years without terminating in consumption. The difficulty may be reconciled in two ways. Catarrh, we believe, is never the precursor of phthisis, unless attended with fever, and the fever may be as much the exciting cause, as the inflammation of the bronchial glands; or the supposed catarrh may be only the first symptom of the disease. The former is, we believe, the fact.

Another opinion has been, that the discharge of a continued catarrh has become acrimonious, and produced ulcer. This is, however, truly imaginary. We know no situation in which the discharge is so acrid as during the first inflammatory stage, and this, it is admitted, does not produce consumption; and the discharge of a catarrh in a thin serous state has continued for many years, without a phthisis following.

There is little doubt, therefore, that the true pulmonary phthisis arises from tubercles, and from these exclusively; and the enquiry will remain of what nature these tumours are. External causes of obstruction have been sought, and been found in the dust raised in grinding scythes, in the meal from mills, &c. Dust in innumerable instances is breathed; and were this the cause, Hyde Park, and every frequented turnpike, would in the summer be the prolific source of consumptions. We have never seen calculous concretions in either trade; but we have found them in cork-cutters, and in one instance in a delicate young lady, where the hectic was connected with cutaneous eruptions. Added to this, it must be remarked that, from the analysis of these concretions, they appear, like other calculi, to be formed from the animal fluids.

The tubercles then are conglobate glands, enlarged in consequence of that state of the constitution which constitutes SCROFULA, which we have often hinted consists in a want of irritability to propel their contents, and which we shall soon explain at some length, *vide in verbo*. Their original formation, and their excitement to action, depends on different circumstances.

They are evidently formed in contracted chests, perhaps from the pressure of the crowded parts around obstructing the passage of their fluids; sometimes apparently in consequence of an acrimony. Consumptions are not uncommon in those constitutionally subject to cutaneous diseases from inheritance. When thrown on the surface in a sufficient proportion, the constitution is safe; but where, from debility or external applications, this is prevented, the internal organs suffer, and the inconvenience is particularly felt in the lymphatic system; not that the acrimony is thrown on them, but infecting the fluids exhaled into different cavities, and probably separated in a more acrid state by the conglomerate glands, it is taken up by the lymphatics, and stagnates in the conglobate. Thus we find, in similar circumstances, sometimes the conglobate glands of the lungs, sometimes those of the mesentery, and the lymphatic system in different parts, suffering from obstruction. Infirm health, with atrophy, is the constant consequence, when pulmonic affections are not induced.

Damp air, acrid vapours, and various causes connected with the atmosphere, have been accused; but with little reason except when connected with scrofula, in which case damp situations seem to act as a predisposing cause. Of a sedentary life, of vexation, &c. we have already spoken, and attributed their influence to their effect on the liver.

It remains to consider phthisis as hereditary and infectious. It is useless to engage in a war of words with the partisans of Mr. Hunter respecting the real meaning of hereditary diseases. We only use the term in its common purport—are persons born of consumptive parents particularly liable to the disease? They undoubtedly are so, and it is the consequence of every day's experience. Yet to this there are some exceptions. As in scrofula and other diseases the complaint pursues those children only which resemble in form, in complexion, or temperament, the parent afflicted. The others appear in no respect influenced by the hereditary taint. It is singular, however, not only that the general predisposition but the period of life at which they are affected are the same, independent, with a few exceptions, of the external causes. These exceptions are, removing into a warmer climate previous to the critical period, or in a female being in the increasing state. We have seen the phthisical tendency constantly recurring, and as often removed by pregnancy. The unfortunate patient is, however, at last the victim of a complaint, which may be retarded, but which cannot be subdued.

That phthisis is infectious the medical opinions of southern Europe incontestably show, since it is forbidden to open those who die of the disease, and the bedding and clothes are burnt. We do not interfere with the practices of countries in which we have no experience. In Great Britain we suspect it to be infectious, though not in a considerable degree. The physician who visits, the nurse who attends, the friend who assists, are in no danger. Yet to live in the same room, or to sleep in the same bed, is dangerous, if continued. We have often traced infection; yet where the communication is not constant or intimate, we have thought that the communicated disease is not peculiarly violent or dangerous. Where it has appeared so it has been communicated from parents to children, and the con-

trary; but who can say that in such cases hereditary predisposition may not have had its powerful influence? Let us not deprive the sufferer of the consolations of friendship and humanity; for the disease, we must repeat, unless in similar constitutions, is not highly infectious. It is sufficiently so to inspire caution with respect to too constant confinement, but not to justify neglect.

The course and the progress of the symptoms are not very readily explained. They are in the early stages too considerable for the cause, and in the latter too slight. We have mentioned, not without design, the tall stature, without a proportional expansion, which according to the explanations of the progressive evolutions of the body, shows some primordial defect. To which we must add, that constitutions of this kind generally show a premature expansion of the intellectual faculties, with peculiar debility of the corporeal functions. Deformity, a frequent attendant of each, though it sometimes precedes pulmonic affections, is by no means a necessary attendant. The first marks of indisposition, except those just mentioned, are the symptoms of impeded circulation through the lungs, followed by a slight irritation felt at the top of the epiglottis. These are generally signs of the existence of tubercles, and ought to inspire serious alarm. The former are pointed out by pain and dyspnoea on rapid motion; by a fixed, florid red on the cheeks; by an inability to lie on one side rather than the other: the latter by a hecking cough frequently felt during the day, particularly on motion. The decubitus difficilis is constantly on the affected side; indeed so constantly, that we consider it as a distinguishing mark of the complaint. The explanation, however, is difficult. It might be supposed that respiration would be carried on more easily by the sound lung, if not compressed; and as pain is no part of the symptoms, the pressure on the affected side would produce no inconvenience. We have not pretended to explain any of these appearances which respect the facility of lying on either side. With the fullest collection of the facts before us we have sometimes thought that we had found a clue, when some unfortunate well founded observation has dissipated the visionary fabric. We shall rest on the circumstance as stated, therefore, as a fact, and determine that the side on which the patient *cannot* lie is that which is diseased.

Whether obstruction will alone produce fever is doubted; but the debility, with the obstructions, may undoubtedly occasion an evening hæmic, q. v. The tubercles themselves do not admit of suppuration; and in this respect also resemble scrofulous swellings. The expectoration, we have said, is a caseous substance, *fringed* often with a little true pus, apparently the production of the cyst. Yet in the progress the discharge is truly purulent, and often in considerable quantities; but in such cases the whole substance of at least one lobe of the lungs has apparently suppurated. That the respiration will be affected from such causes must be evident; yet at times it is not so, and in a few cases the patient has been able to lie with equal ease on each side. In such circumstances we have suspected that the glands at the root of the lungs are chiefly affected, but dissections have not been sufficiently numerous to ascertain the fact. The exceptions do not, however, contradict the general cause so frequently observed, and

so often incontestably established. The effect of the more frequent inspiration, and the more rapid circulation, is to expose the blood more frequently to the access of atmospheric air; and consequently to increase its oxygenation: hence the more florid complexion, probably the stronger pulse, and of course the phlogistic diathesis. From the fever arises the increased heat after eating, which is so striking an effect of phthisis, that on its degree we have rested the determination of the digestibility of food (see ALIMENT): from the fever also arises the heat on first going to bed, and the perspiration on the solution of the paroxysm. The febrile exacerbations, we have said (see HECTICA), is owing to the absorption of purulent matter; and when this is not carried to the skin it falls on its vicarious organs, the mucous glands of the bowels, so that the perspiration and diarrhoea counterbalance each other.

In the advanced stages the irritation of the cough is incessant; the heat or perspiration almost constantly distressing; and when these are absent the life seems exhausted from debility. What then affords the cheering ray of expected relief? Such, however, is afforded, for ingenuity invents every fallacious mode of eluding inquiries, and of giving the most favourable view of every symptom. The patient sinks to the grave with the constant assurances of having attained greater strength, and a relief from every dangerous symptom; with eager expectations of the events of another year, when life is limited by another day. Such we would say is the kind interposition of Providence, was the same cheerfulness found in every disease, and was not in many the gloom as distressing to the patient as the ill-founded expectation of the consumptive victim is to the well informed anxious friend. This cheerfulness is said to be owing to the absence of pain; but pain is not always absent; and the difficulty of breathing, the incessant cough, the burning heats, the deluging perspiration would appear worse than the most poignant pain. Yet these are disregarded, represented as trifles, lessened in the report to the most inconsiderable inconveniences: it is truly singular!

The *prognosis* in hectic is always unfavourable. We this day saw a lady whose parents in a long succession have died hectic, and whose brothers have yielded to the same complaint. She feels scarcely more than a slight irritation at the epiglottis, with a delicate nervous habit. Yet the experienced eye must see in a moment her fate, when the breeding period is at an end; for she is now pregnant, and may be again so. Nature assumes her rights, and combats every disease while this important process goes on. We may find no proper place to mark the conclusion of the scene. Each successive pregnancy is attended with greater debility, and the period of suckling must each time be abridged. At last, during the whole pregnancy, the debility is extreme: a healthy offspring, however, is often produced, but with little or no pain in the labour, and the mother dies without a groan within a few days. If the hectic has come on rapidly, the children are often healthy: if it has gradually approached, they soon sink from apparent debility only.

In other respects the prognosis is influenced by the rapidity of the progress, and the degree of the symptoms. A purulent expectoration, with considerable hectic fever rapidly hastening, leaves little hope. If the

pulse in an apparently early stage, exceed in the morning 100, and at night 120; if at the same time the expectoration is purulent and copious, the night sweats constantly repeated and violent, the debility hastening on, and the emaciation following with similar rapidity; much expectation of relief cannot be entertained. If in females who have already experienced a regular return of the menstrual discharge this evacuation should disappear, we must equally despair. While this discharge however continues, while the pulse is at no period more than 90 or 95, while animal food is borne with ease, we have generally indulged a hope of relief: a hope, alas! sometimes disappointed.

Is phthisis then never cured? Whence can arise the confident promises which every newspaper offers, which the most respectable authorities confirm? The deception arises from two sources. Catarrhal complaints are, in many instances confounded with consumptive, and the most experienced eye is occasionally deceived. In some cases also vomicae are completely evacuated by expectoration, and the wound heals. So insidious is the attack of phthisis, that we have mistaken it for catarrh; and, on the contrary, so violent is often a catarrh, that we have apprehended phthisis; nor has the delusion been destroyed but by the expectoration. From such errors many medicines have gained credit; nor can we wonder at the decision of those whose testimony appears convincing, when we own that an extensive experience of thirty five years does not always enable us to avoid error. Confidence is, however, the general companion of ignorance, and those who know of no sources of fallacy conclude that there are none. To say that phthisis is cured may appear equally confident and rash. We shall perhaps be credited when we claim no merit from the cure; but if the same experience which has enabled us to decide on one point will be allowed on the other side, we can say that in six distinct instances we have seen a recovery perfected by nature. The greater number of these were seen and pronounced to be truly phthisical by practitioners of rank, judgment, and experience. We claim, we have said, no merit, and have mentioned the cases to prevent despair: they are so few, that they can scarcely inspire hope.

As the remote causes of phthisis, at least those styled predisponent, are constitutional, we can scarcely expect to be able to avoid them. The exciting causes should occasion the most anxious caution. When, therefore, an hereditary or a constitutional predisposition is suspected, we should with the utmost care avoid every cause of catarrh, every cause of fever, at least during the period of predisposition. To avoid colds, it is not however, necessary to enervate the constitution by heat: on the contrary, the exotics of the conservatory suffer most from every blast. To guard against such a state of febrile irritability on one hand, and to avoid, on the other, too great exposure to cold, is a difficult task. No rules can be laid down. In general, to guard against the sudden impulse of cold by moderately warm clothing; to remove to a warm climate, is the best security; but where, in the present state of Europe, is *personal* security to be found? If we seek for warmth in the Antilles, or in America, we encounter diseases equally dreadful, and we may, perhaps, with equal safety, and more comfort, find it in the warmer spots of this island

in the winter and spring; removing, from the months of July to November, to the inland parts, to avoid the relaxation of too great heat. Cornwall and Devonshire afford retired secluded spots, where the bleak east scarcely intrudes, and where the frost seldom binds the earth for any continued time, even in extreme winter. In these retreats careful exposure to the air will prevent an unnatural tenderness; the strength may be recruited by exercise on horseback, visiting the neighbouring shores in the mildest days, and keeping in the sheltered spots on the coldest; guarding, by a cautiously regulated diet, and a moderately warm dress, against every stimulus, and yet by admitting an admixture of animal food, at the period when exacerbations are less expected, supporting the general strength. When the predisposition is stronger, and when the disease may be said to have commenced, if any pain of the side shows a local affection, a blister should be immediately applied; and the pain shifting to different parts of the thorax, should be followed by the same remedy, wherever it may appear. We have seen many instances of the good effects of this measure, and in particular one, where six promising young men and women of one family had fallen victims to phthisis. The seventh was saved by marriage, and successive lyings in; the eighth by repeated blisters. The number we know not; for, after he found the advantages of the remedy, he applied them himself, in every instance, with temporary relief, and ultimately with complete success. Many similar but less striking instances we have witnessed; and in impending phthisis, if steadily followed, this remedy will very frequently succeed.

When phthisis has come on, the case is more hopeless. Yet the disease has, for years, been warded off by the plans just mentioned; and the critical period once passed, the devoted victim has escaped. We have already hinted that among the prophylactics, in the female constitution, the recurrence of the puerperal state is one of the most frequent and effectual. Shall we be forgiven, then, if in such circumstances we recommend matrimony, for it is sometimes not a temporary relief only? When the disease is firmly established, medicine we fear is useless. We have said, that a pulse exceeding, at any period of the day, 90 or 95; with fixed pain in the side; difficulty of lying on one side, often on either; the necessity, for procuring ease, to lie with the head and chest raised; are the circumstances which portend the greatest danger. We did not before mention the expectoration, because its more decisive appearances occur at this period. Patients have usually spit in water, for Sydenham has said, that sputum swims, and pus sinks. This is, however, an equivocal criterion. When treating of INFLAMMATION, q. v., p. 15, we have said that mucus is generally in rounded masses; pus flows more readily: the latter is softer and whiter, with little globules, swimming through it; and, when mixed with a saturated solution of potash, a transparent tenacious jelly is separated, while the same solution produces no such change in mucus. We cannot add to the force or perspicuity of this description, but may only observe, that the white gently flowing pus often excites, in common observers, little alarm, while the green or yellowish mucus is looked on with the strongest apprehensions.

In the cure of phthisis, we are told that we must

obviate the occasional causes of fever; evacuate the purulent matter from the lungs, palliate the most urgent symptoms, and regulate the air, exercise, &c. Other authors, and those of high authority, gravely tell us, that we must evacuate the matter from the abscess, clean and heal it. They teach us also how to affect these important purposes; but unfortunately, though the indications are clear, the effect of the remedies declared to be indisputable, we find them always fail. We must take up the subject more empirically, for dogmatism lends us no assistance.

While the pulse was full and strong, the pain in the side acute, the phlogistic diathesis violent, and the cough harsh and distressing, *bleeding* was naturally suggested. It was employed freely, and with apparent advantage. The symptoms were less violent, and the never failing criterion, the buffy coat, impelled repeatedly the hand of the operator. But while every amendment appeared the pulse sunk, anasarca swellings came on, and the patient died. Such, however, was the prejudice in favour of the remedy, from the symptoms described, that the practitioner never reflected that he was combating an effect only, and that the cause remained undisturbed. Yet bleeding was, for a time, considered as the only remedy, and the more limited evacuations are still employed. At present, by every rational practitioner, it is only used as a palliative for more immediate relief of distressing symptoms, and never carried to such an extent as to weaken the vital powers.

Emetics were generally dreaded in hectics, from apprehension of inducing hæmoptoe, nor, till the publication of Dr. Robinson's work, were practitioners aware that emetics, by their determination to the surface, were among the most successful remedies for bleedings from the lungs, perhaps for many other hæmorrhages. We have not dared to give emetics in hæmoptoe as such, but have never succeeded so well as when we have insidiously excited vomiting. In other respects, emetics are highly useful: they emulge the bronchial glands; they prevent exacerbation of fever; and diffuse a general, genial glow over the surface. They often succeed in moderate doses, so as to excite one discharge only, repeated every other day. We mean not to say that they will cure the complaint, but they relieve the most distressing symptoms, and sometimes keep it from advancing till the critical period of life is over, and nature resumes her succession of offices in a different direction. The choice of emetics we have not found a subject of importance. If the squills would readily excite vomiting, we might prefer them; but they occasion chiefly a long continued and distressing nausea. The metallic emetics employed are the vitriolated zinc and copper, and the tartarized antimony. The two former act quickly, and not with peculiar violence, in moderate doses. We once thought the vitriolated copper peculiarly useful in this complaint, but, from repeated, more attentive observation, we believe the ipecacuanha more manageable and convenient. The antimonials pass into the bowels more rapidly; and in a disease, where the diarrhœa is often a troublesome symptom, this tendency is inconvenient and dangerous. Where no diarrhœa attends, the antimonials are equally useful with ipecacuanha.

Cathartics are seldom necessary, for the internal accumulations are not considerable or dangerous. In the early stages they are sometimes useful to procure that

equable circulation which is so essential to health; and we must recollect the probability of an affection of the liver preceding. We suspect that this is more frequent than practitioners have supposed. In the advanced periods of the disease there is reason to apprehend diarrhoea, and every medicine of a laxative tendency should, of course, be avoided.

Diaphoretics have been forbidden on no very solid foundation. The *sudorifics* are certainly injurious, and even every diaphoretic, which acts in consequence of increased temperature, should be avoided; but we have pointed out medicines of this class, the *diaphnoica*, less liable to suspicion, and some of the milder relaxing diaphoretics may be occasionally admitted. It should be recollected that the copious sweats are the effect of the febrile paroxysms; and that, to obviate these, would be to prevent what is merely their consequence. Keeping up the action of the extreme vessels we found to be the best means of preventing the formation of a paroxysm, and so far only are diaphoretics useful. For this purpose we give emetics in the evening, previous to the access of fever; and mild doses of antimonials, with opium, are found to be equally useful.

Blisters we have already mentioned in the prophylactic course, and must now add, that keeping up a discharge from the thorax, so near as possible to the affected part, is, through the whole of the disease, beneficial. When we could not distinguish any part of the lungs peculiarly injured, we have applied the blister to the sternum. When it is designed to relieve the harshness and violence of the cough, the nape of the neck has appeared the preferable place for its application.

When any common abscess has apparently pointed outwards, a deep caustic is the best remedy; and many practitioners, with good reason, prefer a seton, as it can be more easily continued, and makes a more certain and steady discharge nearer the part affected. Repeated blistering seems, however, in our experience to have had as good an effect as might be expected from any topical discharge of this kind. When, however, the blistered part begins to discharge a white curdled matter, its good effects apparently cease, and another blister in the neighbourhood must be applied.

The *cooling neutrals* through the whole course of the disease are useful, particularly nitre, which may be advantageously taken in any period of the complaint, in milk of almonds, in the quantity of about a scruple or half a drachm to a pint, with which a light opiate may be combined. The citrat of potash and the other neutrals, when there is no reason to apprehend a diarrhoea, may be also given. *Demulcents* are always indicated, and usually employed with great freedom, to relieve the violence of cough. The *spermaceti*, the most common, seems to have little real power, and is of use no longer than while passing over the epiglottis; so that it is best given in form of a linctus. The compound powder of tragacanth is used in a similar way, with as little real advantage. If demulcents to sheath the fauces and lessen the violence of cough are ever useful, no medicine of this kind is more advantageous than gum arabic, held constantly in the mouth; and, during sleep, it may be stuck against the teeth, so as not to endanger suffocation from being inadvertently swallowed.

For the same purpose opiates may be occasionally

given, and the tinctura opii camphorata is the usual medicine employed, without any peculiar advantage. Indeed there is little room for choice in the preparations, except their greater or less degree of solubility. The camphorated and the common tinctures act quickly, but lose their power in three or four hours; so that it is necessary to repeat them, or to employ a less soluble preparation, as the solid opium, combined occasionally with soap, or with the fetid gums; sometimes, to obviate costiveness, with an aloetic pill, or to prevent the suppression of expectoration, with the pillulae æscilla.

Expectorants, through the whole disease, have been freely employed, though seemingly without correct views. In the beginning, when the disease appears to be truly catarrhal, the more stimulating expectorants probably increase inflammation, and prevent the formation of the mild salutary mucus. If we employ the mild demulcent ones, we shall produce, as already hinted, little effect, except sheathing the epiglottis. Physicians, however, early, and in the middle of the last century, employed very stimulating medicines of this kind, the *turpentine*, the *natural* and *artificial balsams*. These if used indiscriminately must be injurious. Yet at the end of the complaint, when expectoration was checked from debility, and a want of irritability of the glands, we have found them useful; and in this state of the disease only. Even the formerly famous *antihæcticum* of *Potterius* we have thought useful in this stage of the complaint. The advantages of the balsams were supposed to consist in their power of cleaning the wound and healing it.

We have suspected that the myrrh owed its credit to a supposed balsamic quality, or to its effects on irritable sores. Whatever be the source of its employment as a remedy, it is certainly in many cases of phthisis an useful one. It seems, as we have said, to be a narcotic bitter, slightly tonic and sedative; and we have suspected it to be injurious in impending hæmoptoe. (See MYRRHA.) Balsams have been recommended in another way, when breathed in the form of vapour. A balsamic ether has been fashionable as a secret medicine, but seems to possess no very superior powers. In an inflammatory state of the bronchial glands warm watery vapour may be useful, and vinegar has been occasionally added, but it seems often to irritate the cough, and the more stimulant vapours are evidently injurious.

When the pneumatic chemistry introduced to our notice many substances in an aerial form, it seemed probable that many advantages might be derived by introducing medicines which would thus penetrate much farther than vesicular vapours of the greatest tenuity, without being changed by the digestive process. These favourable prospects have not been realized. When oxygen was discovered it was soon tried in this complaint, but it was manifestly injurious, increasing the hectic heats, the fulness and hardness of the pulse, sometimes seeming to induce hæmoptoe. Air of a lower quality was then used with some advantage, and the diluted carbonic acid gas was breathed apparently without injury, though not with advantage. We have been since told of the good effects of the hydro-carbonate, of the advantages derived from breathing the breath of cows, and even inhaling the fumes of fresh dung. As these plans are now disused, we may suppose that they

were not permanently useful, though in some of the earliest trials they appeared to be so. The nitrous oxide which so rapidly intoxicates has not been used in its dilute state. The only artificial air given internally in this complaint is the carbonic acid gas, combined with water, sometimes also with an alkali, in imitation of the Seltzer water. All the natural acidulous waters have been also recommended. The chief mineral water employed, though not an acidulous one, is that of Bristol, which is nearly pure, or at least does not possess any ingredient apparently beneficial to the complaint. Perhaps the water alone, perhaps the air and other circumstances not sufficiently attended to, may have relieved. Shall we add, that the fame acquired by it, in some cases chiefly catarrhal, may have led to its more extensive and indiscriminate use?

As the attending fever is a remittent, the bark was apparently indicated; and when its utility in meliorating the sanious discharges of foul ulcers was observed, it was supposed that it might be equally effectual in this disease. We may, however, assert, that in general the bark is injurious. If given in any dose calculated to lessen the fever, it increases the hectic heats, the flushes of the face, the harshness and tightness of the cough, at the same time diminishing the little expectoration that seems often to relieve the more distressing fits of coughing. When, however, the purulent discharge is copious; the patient's strength exhausted; the morning perspirations profuse; the bark is sometimes borne with more ease, and appears occasionally beneficial when it does not increase the discharge from the bowels. Other bitters, as the cascarilla, the angustura bark, the camomile flowers, the quassia, the columbo root, and the uva ursi, are useful nearly in the order stated as tonics, and injurious in the same order as astringents. The first, however, is most frequently inconvenient in this respect. The astringency of the angustura is slight, and, in the others, is not observable. The uva ursi, lately recommended, seems to act exclusively as a bitter, and one of the weakest of the tribe.

Some of the narcotic bitters have been employed and recommended, as the hop, St. Ignatius' bean, the bitter almonds, and the various plants which partake of this virtue. The *LICHEN ISLANDICUS*, q. v. we suspect, if not wholly a nutrient, is of this class. The neglect, however, of these medicines seems to show that they have been disused as inefficacious, or dreaded as deleterious. Other narcotics, as the umbellatæ, of which the cicuta is the principal, and the solanaceæ, particularly the henbane and foxglove, have been employed. The aconite has been also recommended by Dr. Rogers of St. Petersburg. We have never found the cicuta particularly efficacious, in removing the disease, though as an anodyne it is sometimes useful, and seems to act as such, without the inconveniences which often attend opium. The henbane appears equally efficacious, and is said to be also slightly laxative. We have preferred the seeds as more equable in their effects to the extract, and less subject to sophistication. The digitalis, of late highly commended, seems not to have merited all the praises which it has obtained. It often reduces the pulse from one hundred and twenty to sixty, without relieving the principal complaint. In many cases, also, it occasions such a considerable debility that it cannot be long con-

tinued. In every instance, indeed, where the debility induced is not so striking, it probably lessens the vigour of the constitution in a very injurious degree; nor is there, we think, any doubt of its inconveniences far overbalancing its beneficial effects in this disease. Though we do not in every instance deny the latter, they have been greatly exaggerated; nor, on tasking our recollection, can we say that we have ever seen essential service in phthisis derived from the digitalis that might not, in similar circumstances, have been produced from other plans of relief. Opiates we have already mentioned as palliatives; yet it has been supposed that, by their continued use, they might allay irritation, and contribute to the great object, the healing of the ulcer. They have, however, failed in this view, though we cannot refuse their employment to lessen pain, and keep up the calm serenity, the pleasing delirium, in the midst of pain, distress, and a state hopeless of relief. Vide OPIUM.

Metallic salts and oxyds have been employed with different views. The mercurials have been considered as deobstruents, and they have been used to restore the circulation, supposed to be obstructed in the diseased glands. To render the theory more complete, mercury has been triturated (*killed* in the pharmaceutical phrase) with extract of cicuta, to unite two deobstruents of an opposite nature, so that the stimulus of the one may be rendered less injurious by the sedative powers of the other. Experience has, however, confounded this plausible theory, and, together, they have been found useless, perhaps injurious; nor does the *mercurial salivation* recommended by Dr. Rush rest on a more secure foundation. The preparations of iron have been employed as tonics, particularly in the mixture recommended by Mr. Griffiths, with the myrrh and soda. The chemical inaccuracy in that preparation is avoided by previously precipitating the iron from the vitriolated salt, employed by Griffiths, and using it in a smaller dose. The *ferum precipitatum* is now usually combined with the myrrh and natron in the form of pills. In either mode the remedy appears to be useful; but in the more early, inflammatory state of phthisis, we have thought the iron too stimulant, and have therefore usually omitted it. In the latter stages the addition seems advantageous. Of the copper, as an emetic, we have already spoken. It is recommended by Dr. Senter of Philadelphia, by Dr. Simmons, and by John Wesley, probably from an old author. We mention it here to suggest the enquiry, whether it may not be useful as a tonic. The effects of zinc in this view, of BISMUTH, in Dr. Bardsley's reports, from the authors already quoted, vide in verbo, lead us to think the suspicion not wholly visionary.

As a tonic from the mineral kingdom the vitriolic acid has been already alluded to. It is wholly without suspicion respecting any injurious power, and is often useful. It is usually added to the decoction of bark to restrain the perspiration, which often occurs on the solution of the evening paroxysm, about two or three in the morning. The inconveniences arising from the bark have been attributed, with little reason, to the acid; but on the other hand we have not found it, in any form, highly useful. The other acids do not sensibly differ, or experience has not yet discovered any foundation for a preference.

Various circumstances necessary in conducting this very intractable disease yet remain. These are AIR and SITUATION; DIET; CLOTHING and EXERCISE. Of these in their order.

Air and situation are apparently objects of considerable importance in a disease where medicine must confess the inutility of her resources. Change of air is among the remedies constantly recommended; and *to change* is often professedly the only object. From the experiments with oxygen, it will be obvious that the purest air is not the best, and that air of a lower quality is more useful. We have hinted also that the advantages of Bristol have been, probably in part, owing to the low situation of the former lodgings; and that the place has gradually declined in its credit, since the invalids have crept higher up the hill. Whatever becomes of the suspicion, it is evident that the loftiest and most exposed situations are not the most salutary for the hectic patient, and that a dry, gravelly soil, of no great elevation, defended from the east, is preferable. We have not hitherto gone so far to prefer the neighbourhood of marshes; yet the advantages supposed to be derived from breathing the hydrocarbonate, might lead to a suspicion of the utility of such a situation; and it still remains a subject of enquiry, whether hectics have not increased in proportion to the diminution of intermittents. It is common to send phthysical patients to the neighbourhood of the sea, led probably by the decided advantages of a sea voyage. In the spring and early summer, however, the sea is evidently injurious: in the autumn it is often salutary; and in the winter the neighbourhood of the sea affords a milder and more steady temperature than any other situation. In such places frost is seldom continued; fogs are rare; the cold winds uncommon. While, then, in autumn and winter the sea coasts afford such resources, their neighbourhood in the spring and early summer will afford numerous sheltered situations, where the mildness of the shores is combined with the defence of the woods, equally sheltered from the baneful influence of the east, or the piercing colds of the north winds.

A change of climate is often recommended; and our invalids have been sent to Lisbon; to Madeira, to the south of France and to the West Indies. In the three former the climate is by no means so steady as to preclude occasional blasts of piercing coldness; while the habitations, constructed to prevent the access of heat, have often few resources to guard against cold, which the stranger, whose nerves are unbraced by an unaccustomed temperature, feels severely. In general, also, our invalids, endeavour to avoid the winter, when, in reality, they should avoid the spring. If they sail from the south-western shores, they will usually find no inconvenience from cold till near Christmas, and they should remain until the end of May; but they generally migrate in October, and return in February, when they experience the heat of a later summer in lower latitudes, and the cold of a late spring on their return. On the whole, we have scarcely found any advantage gained from excursions abroad; and, when permitted, have always dissuaded the attempt. We have been justified by repeatedly witnessing their ill success. To the West Indies few resort, for they meet there with a worse enemy; and it is not true, as has been asserted, that phthisis is there

unknown. In the article CLIMATE, q. v. we have introduced some remarks which may be applicable in this place.

The *diet* of phthysical patients is an object of no little care, for they require support by the mildest and least stimulating foods. While the Brunonian fed his patients to avoid debility, the other practitioners carried, apparently, their antiphlogistic system too far. It is certainly improper wholly to forbid animal food. Yet its kind, the time of the day on which it should be taken, and the precautions to be enjoined in the conduct, require particular attention. We have noticed these circumstances with a view to the present subject in different articles (see ALIMENT, DIÆTA, LAC). Let us recapitulate shortly what is connected with this subject.

The phthysical patient should rise early, for nothing weakens so much as the perspiration and the drowsy slumbers from six to nine; but as the day would in that case be painfully long, he should be allowed to rest after his mid day meal for an hour or two. He will then rise refreshed on a second morning, not exhausted by perspiration. At rising, or a little before, he may take some thin chocolate, some whey, or asses' milk, and in an hour or two a common breakfast of tea, with ship biscuits, may follow. This will be completed probably by nine, and three or four hours are then at liberty for exercise, for taking medicine, for light employments, or easy conversation. Dinner, for reasons stated (see DIÆTA), should not be delayed long after one, and it should consist of a single dish of light animal food, not prolonged by luxuries, or rendered heavy by the refinements of cookery. The drink may be water, light porter, or cyder with water; and wine will be unnecessary after it, unless custom has transferred this beverage from a luxury to a necessary. Suppers should be slight, and consist of fruit, if the bowels will bear it; light broth, beef tea, sago, tapioca, or arrow root, flavoured by lemon peel or lemon juice rather than wine. The usual refreshment of tea may be supplied by food of the same kind.

The *clothing* should be so regulated as to guard against cold rather than to increase the heat. As hectic patients, from the morning perspiration, are usually sensible to cold, they should be more carefully guarded when they go into the air. It is usual to direct flannel underneath their linen, and in winter it is highly necessary; but in summer excites too great perspiration, and calico should therefore be substituted in its stead. The flannel and the calico should be changed every other day. The feet should be defended with unusual care. It is not uncommon for the coughs of consumptive persons to be highly troublesome on going to bed; and we have sometimes found that the usual opiate given more early, so as to have began its action at bed time, has prevented this distressing attack. Another precaution has lessened the violence of the cough, viz. not taking off the clothes too quickly, for the cough seems often to be excited by the access of the cold air. We have occasionally directed patients to go into bed after laying aside their upper garments only, and to have a proper warmth come on before the others are taken off: a precaution we have observed to be highly useful in guarding against this inconvenience.

EXERCISE. The various exercises, the principles

on which they act, and the grounds of preferring either, we have noticed under the article *ÆORA*. In hectic cases, *riding on horseback, or in a carriage, swinging, and sailing*, are chiefly recommended. *Riding on horseback* is highly commended by Sydenham, and many authors, as a remedy of the greatest utility, and almost a specific in this disease. Unfortunately the complaint has since proved unusually intractable, or the recommendations have been greatly raised above their real value. We do not find, at this time, riding peculiarly advantageous in the true pulmonary phthisis. A carriage is a substitute for the horse, in cases of greater debility; but if the weather is favourable, the open carriage is preferable, as irregular currents of air from the sashes are avoided. *Swinging* requires probably a little more exertion to support the body in a due equilibrium, and it has the advantage of being a more general exercise, of affording a constant succession of free air, with a gentle agitation. It lowers the pulse, and lessens hectic heats, giving often appetite and spirits, with more refreshing sleep. It has not been easy to ascertain the sources of the advantages from *sailing*, but probably they are of a similar kind. A constant exertion is required to preserve the balance; the air is free and open, usually with a current in some direction. There is not the slightest evidence that the fumes of the pitch contribute to the relief. The use of all occasional exercise should be regulated, like diet, by an attention to the usual febrile exacerbations, for those who are benefited often by riding in the forenoon, feel inconvenience from the same exercise in the evening. In general, riding is preferable in cases where the strength is little impaired, and where there is reason to believe the primary disease to be in the liver. If the exercise has an ostensible object it is more useful; and, on this account, a journey by easy stages, or a voyage to meet an old friend, is peculiarly beneficial. The real object to restore health is forgotten, and the spirits kept alive by the artificial one.

In a disease where a cure is impracticable, it is often of service to *relieve pain* and to lessen the more distressing symptoms. The antagonizing evacuations are, we have said, the diarrhœa and the morning sweats. The opiate, which quiets the cough, will sometimes relieve the diarrhœa; but it cannot often be given in a sufficient dose without inducing dyspnœa, by checking expectoration; and, on the contrary, the opiate often increases the perspiration. In the former case, the compound powder of chalk, the logwood, the kino, or the tormentil, will check the diarrhœa; and in the latter the cicuta will frequently quiet the cough, without increasing the sweats. The perspiration itself we have often lessened by exciting a gentle diaphoresis with the relaxing medicines, as opium with antimonials, early in the evening, and sometimes the mineral acids, with a small proportion of the syrupus papaveris albi, will succeed.

Flatulence in the stomach and bowels, by pressing on the diaphragm, sometimes increases dyspnœa; and it is of consequence to distinguish this cause, as it may be so easily relieved. It is known by the ease which the occasional discharge of flatus procures, and is removed most affectually by the asafœtida taken into the stomach, or thrown into the rectum. The asafœtida is the preferable remedy, as it is easily soluble in the form of pills, and may be given in a watery vehicle; it is, at the same time, an expectorant of considerable value, though

seldom used as such. If more warmth be required, the camphorated julep, with a small proportion of ether, of laudanum, or tincture of galbanum, may be joined. A warm plaster to the pit of the stomach will also be often useful.

In the latter stages of the complaint the vessels lose the power of propelling the mucus, and the dyspnœa is highly distressing, particularly in the morning. Though the greater part of the discharge is usually from vomicae, which are not secretory organs, yet the stimulant expectorants seem to relieve, perhaps from associated motions, or from the space obtained by the discharge of the expectoration merely. The squills and the warmer balsams are at this time useful; and indeed the balsam of Peru, which we omitted to mention, is an advantageous medicine at an earlier period as a warm tonic, if given in small doses. An emetic will always relieve, by exciting expectoration; but in the stage of the disease alluded to, it cannot be borne without great inconvenience and some danger. In the morning we have sometimes succeeded in bringing on expectoration by the aqua ammoniæ, in warm tea, which frequently produces a slight nausea, without vomiting.

When phthisis arises from suppressed eruptions, we are advised to give mercurials, with the hydrolapathum, guaiacum, and mezereon; but the plan has, we believe, never succeeded. We shall take this opportunity of observing, that we have never found this mode useful, and have never been able to restore the eruption. In hectic and other fevers, from this cause, the most successful method has been to support the strength by mild, nourishing food, free country air, and such tonics as can be most easily borne. A long time is required for relief; but, in time, it is often obtained.

We have professedly taken up the subject in an empirical view, and given fairly the result of an extensive experience, attained by many a heart ach, at seeing the most amiable part of the creation sinking under a disease, whose daily ravages we must witness without being able to check. We shall add a few words rather in a dogmatical view; and, if we do not succeed in elucidating the complaint, we will not long detain the reader.

We consider it as established that phthisis proceeds from what are styled vomicae alone, for abscesses, even from inflammation will heal, if the suppuration is not communicated to the coats of some indolent vomica. These are apparently conglobate glands, similar to the scrofulous, full of a caseous substance, whose cohesion may be lessened, but which admits of little apparent change. The glandular lymphatic system is peculiar to early youth: as the body expands in manhood, it gradually lessens. When that expansion does not take place, this system disappears more slowly; or perhaps the obstruction of these glands, which hinders their absorption, may be the cause of the evolution being delayed. It is sufficient to mark, in this place, the principle of the connection, which we may find useful in other enquiries.

The obstruction then of these glands continuing beyond their accustomed period, will occasion some contraction in the cavity of the chest, and the delay of the development will still further confine the space in which the lungs are obliged to act: dyspnœa is therefore felt early, and an irritation from these foreign

bodies, as we may now style them, is perceived, as usual, at the extremity of the tube, viz. the epiglottis. In this state the patient often remains for many years, till the expanding frame, or the absorbed glands, leave the lungs at greater liberty. This change, which usually takes place from eighteen to twenty-two, is in these cases often delayed till after thirty, nor is it completely effected till the period of thirty-six. This is the termination of the critical, consumptive period. But we have found that the danger recurs in females at the end of their menstruation; and in men about fifty-two, or fifty four. These cases are, however, rare, and in men peculiarly so. When the discharge ceases in women, the blood is, for some time, determined, irregularly to different organs; so that it is not surprising to find any remaining vomica subject to inflammation. A similar irregularity takes place in the circulation even in males, when the constitution has passed its acmè; but the determination is more commonly to the hæmorrhoidal vessels.

Independent of these general causes of inflammation, the coats of vomica inflame from accidental colds, from irregularities of diet; sometimes we suspect from irritation in consequence of a disease of the liver. In accounting for the phthisis of men just passed the acmè of life we might have referred the cause to the liver, but that we have usually found this secondary hectic in younger persons, and we will never knowingly sacrifice a fact to a system. Irregular determinations, from suppressed eruptions, may have the same effect of exciting inflammations as well as every cause of fever.

These vomica are not in their substance susceptible of inflammation, and on this account we have styled it an inflammation of their coats; for when their contents are discharged, we see scarcely any other difference than a diminished cohesion: the caseous substance assumes a flaky form, and these flakes are *fringed*, we have said, with pus. In the conclusion of the scene, however, the pus is more copious, and the inflammation and suppuration evidently extend to the cellular substance of the lungs themselves. When numerous vomica have suppurated, a whole lobe has been destroyed. The cause, however, which excited the inflammation contributes to support it; and the intractable ulcers which these glands form, in consequence of suppuration, supply a continued irritation to keep up the inflammation around.

When the suppuration of the vomica at the root of the lungs only takes place, the functions of the organ are not greatly injured. The patient can lie on either side, and expand his lungs with freedom, and without pain; but the irritation is, in every case, felt at the extremity of the glottis; and when the functions of the lungs have been apparently free, the organs themselves have been found often flooded with purulent matter at their base.

If the breathing, in decided hectics, is sometimes little affected, so, in other cases, a purely catarrhal inflammation occasionally assumes all the symptoms of a certain decline. This has given a celebrity to Godbold's syrup, Hill's balsam of honey, and the ten thousand quack medicines daily swallowed, whose virtues are seriously attested. It is, we think, certain also, that vomica, in a state of suppuration, have been wholly discharged, and the wound healed by the efforts of na-

ture alone. This event is, however, too rare to account for all that we hear and have seen; so that there is little doubt of the greater number of these successful cases having been merely catarrhal. The resemblance is so great that though we can sometimes discern the difference by that sagacity which experience gives, we know not how to describe it.

One striking feature of the hectic constitution is the great irritability of the arterial system, and this appears to be a leading symptom, for the constitution is marked by peculiar mobility and irritability of the nerves and muscles. We know not how to reconcile this state with what we conceive to be the distinguishing characteristic of the scrofulous habit, a want of irritability in the lymphatic system, admitting of congestion, or still less with a viscid fluid stagnating in the glands. Yet there is some evidence of the scrofulous habit abounding in albumen, since such constitutions contain a very small proportion of azote, the distinguishing characteristic of gluten and fibrin. We know that in these habits the oxygen is a predominating principle, since it is seen in the fair skins and the florid complexions: we know also, that where oxygen is copious, the azote, and, consequently, the ammoniacal salts are less so. Some connection may therefore be traced in this way, but the chemical nature of our fluids has not received its due share of attention; and in this obscurity we cannot decide. We may resume the subject under SCROFULA.

The cure we professedly treated as empirics, not to mix uncertain speculations with the decisions of sounder experience. Yet we think that they illustrate the practice, and it will detain us very little longer to point out the connection. Every mode of cure is directed to the effects only of the principal cause, and with reason, since the vomica itself is not within the extent of the nervous or circulating systems. The great object is to prevent or lessen inflammation in general; to lessen inflammation or accumulations in the lungs; to diminish the irritability of the arterial system; and by medicines which will not stimulate the action of the heart and arteries, or by their astringency impede expectoration, to add to the general strength. Under these heads all the medicines enumerated may be easily arranged; but it may perhaps be useful to repeat them in this form:

I. To prevent or lessen inflammation in general.

- a By abstracting from the mass of blood.
Bleeding.
- b By lessening its impetus.
Refrigerants.
Neutral salts.
Diæta imbecilla.

II. To lessen inflammation or accumulations in the lungs.

- a Topical bleeding by leeches or cupping.
glasses.
- b Blisters, setons, or issues.
- c Emetics.
- d Cathartics.
- e Diapnoics.
- f Expectorants.
Alliaceæ.
Balsamica.

III. To diminish the irritability of the arterial system.

a Narcotics.

Amara frigida.

Cicuta.

Aconitum.

Opium.

Digitalis.

Myrrha.

b Irritants.

Mild climate.

Bristol waters.

Breathing factitious airs.

Hydrocarbonate.

IV. To support the tone of the system.

Amara calida.

Metallic salts or oxyds.

Iron.

Bismuth?

Mercury?

Some hints have been suggested respecting the possibility of dissolving these vomicae, but no probable plan has been brought forward; and as the tumours are out of the circulation, we can scarcely expect that any such can succeed. The theoretical suspicions respecting the predominance of oxygen, and the diminished proportion of azote, are not on a sufficiently certain foundation to warrant us in drawing any consequences from them. They might, however, suggest in early youth the utility of sea water and sea bathing; the advantages of breathing air of a lower temperature. The solvents of calculus are of more probable efficacy; yet experience leads us to doubt whether phthisis is in any case caused by calculi. In the few instances of this kind which we have seen, they were, if not an effect, an accompanying symptom. The hectic was previously established. For the cause of hectic fever see HECTICA. The modern language on this subject we shall consider under the article STAHLIAN SYSTEM, which it nearly resembles, but from which we cannot suspect that it was copied.

PHTHISIS ISCHIA'DICA. See TABES COXARIA.

PHTHISIS PUPILLÆ. See AMAURO'SIS.

PHU. See VALERIANA.

PHYGE'THLON, (from *φυω*, nascor,) is sometimes described as a broad, but not elevated, tumour, resembling a pustule, attended with pain, so violent as sometimes to excite fever, ripening slowly, and but partially converted into pus. Its general seat is in the arm pits, neck, and groins. Celsus observes that this tumour is sometimes called *panus*, and occasionally ranks it among glandular swellings. It is certainly a disease of the

conglobate glands, arising most commonly from poisons conveyed through them. See ERYSIPELAS.

PHYLACTE'RIA, (from *φυλασσω*, to preserve). See AMULETA.

PHY'MA, (from *φωω*, to produce). Preternatural tumours, especially of the surface, arising without any external cause, generated, increased, inflaming and suppurating in a short time. (See Galeni Commentaria in Lib. 6 Epidemicorum.) Paulus (Lib. iii. c. 22.) confines the term to the scrofulous tumours of children, or abscesses from tubercles, &c. It is also a little swelling like a boil, somewhat round and flatter.

PHYMO'SICA ISCHU'RIA. ISCHURIA, from a phymosis, q. v.

PHYSA'LIS ALKEKE'NGI, (from *φυσωω*, to inflate, because its seed is contained in a bladder). See ALKEKENGII.

PHYSCO'NIA, (from *φυσκη*, an inflated bladder,) a hard tumour, occupying a large portion of the abdominal cavity, increasing very gradually, not sonorous, and without fluctuation. Dr. Cullen places this disease among the *intumescentiæ*, defining it a tumour, occupying chiefly a certain part of the abdomen, gradually increasing, neither sonorous nor fluctuating. Its synonyms are hyposarca and hyperserchidios. The species according to Cusson may be distinguished according to the viscera diseased, and are the *physconia hepatica, splenica, renalis, uterina, ovarialis, mesenterica, intestinalis, omentalis, polysplachnalis, visceralis, externa lufialis, externa scirrhouea, externa hydatidosa*, and an excrescence. Some tumours on the skin are also called by the name *physconia*; but in no case is the disease within the reach of art.

PHYSICA, (from *φυσis*, natura). Natural science in general; but now chiefly confined to natural philosophy. It approaches natural history on one side, where it treats of the properties of minerals; and chemistry on the other, where its subject is the more subtle, insensible fluids of galvanism and electricity. See CHEMIA.

PHYSIOGNOMONIA, (from *φυσis*, φυσιος, and *γινωσκω*, to know). It is not our design to trace all the fancies which have disgraced this science, but to speak of it as physiologists, with a view of illustrating some of the phenomena of the human system. It was first noticed in a philosophical view by Aristotle, illustrated by his commentator Baldus; and the observations of the Stagyrice dispersed in different parts of his works were arranged early in the seventeenth century by Fontanus. The doctrine has been supported by our countryman Robert Fludd, and by an author, Dr. Gwither, in our Philosophical Transactions. The subject became very fashionable in the sixteenth and seventeenth centuries; and has within these thirty years been revived by an author of eager zeal and a warm imagination, Lavater, whose eccentricities have rendered it interesting, and whose enthusiasm at one time almost convinced the incredulous.

The first question which will occur is, has this science, which may be styled that of judging from the features of the qualities of the mind, any real foundation except in fancy and enthusiasm? Common observation, the practice of anatomists in their denominations of the muscles, and of painters, have decided in favour of the existence of some foundation. In the great outline it is generally admitted; and when we find that frequent exertion

will add to the bulk of a muscle, rendering it also more mobile or irritable, it is not improbable that an indelible character of countenance may be imprinted. In less stronger points the contemplative countenance is distinguished from the spirited; and no one could see both Newton and Voltaire without at once perceiving the imprint of patient thinking in the one, and the active energy of genius in the other. Complacent attention, a sarcastic sneer, apprehensive distrust, confident resolution, and many other qualities, are visibly depicted, probably by the stronger swell of muscles constantly exercised. It is indeed character which gives the great diversity of countenances, as we have remarked in the article FEBRIS, for a likeness to parents is often observable in the last moments, or even after death, which had been never noticed during life. We have already mentioned this circumstance, and thought the remark new, but have since met with it in Lavater's Fragments; in Bartholine's Anatomical History, Cent iv. Hist. 31. An annotator, whose name has escaped us, we recollect has also remarked, that a returning likeness to parents or ancestors is a fatal symptom. Dr. Smith has observed, that even the peculiar features of negroes are changed when their occupations require study and reflection.

Physiologists have also distinguished peculiar constitutions, which they have styled temperaments, accompanied with appropriate faculties of bodies and minds. These we know appear also in the features; and we connect, from experience, the adust, melancholic temperament with intense thought, deep, abstract speculation, and a mind retentive of impressions; the fair, ruddy, sanguine temperament, with eagerness, volatility, and restlessness. These we know are transferred from parents to their offspring. Various occupations give a distinguishing cast of features, derived from the business in which successive days are employed. Intemperance is distinguished not only by the absence of a prepossessing openness, but that insensibility which in a greater degree characterizes intoxication. Idleness not only destroys expression, but gives a vacuity or confusion. Benevolence, with an expanded eye, contrasted with the contracted squint of suspicion, assumes that appearance which it so frequently employs.

So far will physiology go hand in hand with the physiognomist: yet there is one part of his system which we cannot reduce to these principles, though certainly well founded, we mean the high, arched, and expanded forehead, which generally accompanies genius, observation, and judgment. We can only connect it with one remark, that it distinguishes most strikingly the human form from that of animals which approach it, though with greatly inferior understandings. Shakspeare, when he would describe a transformation by enchantment into something mean and ugly, describes the change as into

———— barnacles and apes,
With foreheads villanous low.

In this we may be thought to approach the fancies of Gall, which we have noticed as the Cynthia of the minute, without engaging in its defence or confutation. By the way we may mention a late contest between Dr. Gall and one of his most eager opponents at Heidelberg, professor Ackerman; a contest of words only. The former, it is said, displayed sagacity and discernment

without depth; a spirit of observation without philosophy; an extensive and accurate memory without a speculative genius. The professor, on the contrary, was precise, energetic, occasionally dogmatical, but strictly logical; though Gall might say

Si quæritis hujus
Fortunam pugnæ, non sum superatus ab illo.

The physiognomist, however, steps beyond his limits when he speaks of distinction from gait, from gesture, &c.; for though guilt will generally be betrayed by suspicion, confidence will often cover the apprehension; and, *mauvaise honte*, will often give the most collected philosopher the appearance of hasty unsteadiness. The physiognomy of an apple, or a glass of wine, is truly ridiculous; we prefer, indeed, but often from the most trivial circumstances.

The great point of distinction, the arched forehead, may occasion some speculations, since the loss of a large part of the cerebral hemispheres is not followed by a diminution of the intellectual functions. Yet we have remarked the large bulk of the brain in the human body, and the necessity of a free communication through, as well as an equable excitement in, every part of it as subservient to intellectual operations; and though a part may have been destroyed, there are few whose intellectual functions are so numerous and varied as to find the deficiency. If the accident occurs only once among ten millions, and the greatest mental exertions are scarcely found in all the individuals of the globe during a whole century, it will be obvious that the loss will not be readily detected in its effects.

The forms of parents descend, we have said, often to the children, and, with their forms, their manners, and very frequently their intellectual distinctions. This similarity, often obvious, when the children have not recollected their parents in consequence of their early death, and which cannot have been the effect of imitation, we have often observed with astonishment; and it seems to show that we are more perfectly material than philosophers have supposed; at least the intellect is modified by the corporeal organs, for the body is the instrument only of the immaterial agent. But these discussions would lead us too far.

One only consideration remains of importance to us as physiologists, viz. whether the resemblance which is often seen between the human face and that of some animals, influences a similarity of disposition. In the opinion of Lavater it does so; but from attentive observation we have not found it to be true. We can only draw this general conclusion, that the farther the form of the head recedes from that perfect commanding look which the Almighty has imprinted on its most perfect creatures, so far are the intellectual faculties inferior.

What may be styled medical physiognomy, or those changes of features indicative of and peculiar to different diseases, is a subject of great importance, and has not been sufficiently noticed. We shall speak of them in general under the head of PROGNOSTICS; but shall find it a difficult task, for want of a technical language sufficiently expressive. How various are the expressions, for instance, of debility only in fever, chlorosis, phthisis, scurvy, syphilis, hysteria, expectation baulked, hope delayed, misery, and despair. Yet they may be distinguished by an experienced eye, at least with no

very great chance of error; but where are the words to describe what a single glance will tell?

See *Physiognomonici Veteres*, 8vo. 1780; Lavater's *Fragments* by Hunter; Lancisi de *Physiognomonia* (in operibus); Baptista Porta de *Humana Physiognomonia*; Helvetii *Microscopium Physiognomoniæ Medicum* Amstelod, 8vo.

PHYSIOLOGIA, (from *φύσις*, nature, and *λόγος*, a discourse). **PHYSIOLOGY**, which, from its derivation, seems to imply a discourse on the objects of nature, has been long confined to disquisitions respecting the cause of the vital, animal, or natural functions of the human body. It treats, therefore, of the internal motions of the animal frame; the offices of the different viscera; the changes in the fluids; as well as the powers by which life is supported. The various senses; the means by which we receive ideas of external objects; the influence of the mind; the changes of our aliment into the animal fluid blood; and the means by which successive generations are raised to fill this sublunary sphere; are equally parts of this subject. We need not enlarge farther in the enumeration, since under the article **FUNCTIONS**, q. v. we have inserted the arrangements of Richerand and Vicq. d'Azyr, illustrating the different parts of physiology.

This branch of medicine was for a long time imperfectly cultivated, and indeed until the circulation of the blood was understood, the various functions of the animal frame must have been obscure. Plastic powers, appetites, or a superintending archæus, solved the various difficulties which arose; and physicians were contented to observe what they were unable to explain. The *anima medica* of Stahl cut the knot; and Hoffman with patient industry made very slow approaches to an explanation of our functions. Lancisi, Baglivi, Hales, and Willis, were more enterprising; and in the latter the curious reader may find many valuable hints, the germs of some modern discoveries. Borelli and Bellini in their own departments added also to our knowledge. In fact, however, physiology did not assume a scientific form till Boerhaave collected the scattered limbs from various authors, particularly the mechanical physicians, and compacted it into a system peculiarly elegant and comprehensive, but unfortunately erroneous, from the little attention he paid to the vital powers. Even in the *Commentaries* of Haller on the *Institutions*, no better reason was given for paleness in consequence of terror, and for blushing, except the contraction of little nerves round the extremities of arteries in one case, and their relaxation in another. In more advanced life Haller distinguished with more accuracy between irritable and inirritable organs.

The *Elementa Physiologiæ* of this eminent author display the most unwearied industry, and contain an immense variety of facts on every branch of the subject. Unfortunately not a ray of genius animates the work; no comprehensive views unite the different observations into a luminous focus; no connecting links show their bearings on each other. They are pearls hung together by the slightest string; and, what is of more consequence, there is seldom any distinction between what is true, doubtful, or evidently erroneous.

Since that period the discovery of the lymphatic system, the experiments of Sir Clifton Wintringham on

the comparative density of the arteries and veins, the pneumatic chemistry, and the analysis of the animal fluids, have greatly contributed to illustrate physiology. In the progress of our knowledge on this subject, Dr. Cullen, by his attention to the functions of the brain and nerves, not only cherished a neglected branch, but combined the whole into a comprehensive system, with a labour and a degree of attention, however, not duly proportioned, for the nervous system was his favourite offspring, which he cherished with peculiar care. Since this era we have received no very extensive views on the subject of our science. Richerand and Girtanner; Ludwig and Spalanzani; Fontana and Campar; Fourcroy and Valli, have cultivated different detached spots, but we yet want a general abstract, comprehensive and connected. The works of Richerand and Dumas are the most complete that we have yet received; and the scattered limbs of the present volumes would afford it, were they brought together; we may perhaps make some efforts to give them an arrangement and a form.

In general, physiology has been closely connected with anatomy, and has always formed a part of the different anatomical courses. It rests indeed on the structure of the parts: and the "First Lines" of Haller are almost wholly descriptive. The slow progress of correct anatomy accounts sufficiently for the imperfect state of physiology; and though many parts of the body are apparently not useful in illustrating any function, yet the connection of the whole is so intimate, that one part only cannot be separated with the slightest prospect of advantage. A solitary branch of the ulnar nerve, coming from the dorsal vetebræ, explains the cause of a separate affection of the ring and little finger, and sometimes leads us to the most effectual mode of relief.

As a basis of physiology, comparative anatomy should also be studied, and we have now excellent assistants in Cuvier and Blumenback. The ancients dissected animals, but they described the organs as belonging to the human body; and comparative anatomy is only useful when the human structure is well understood. It was doubted, for instance, whether the bile was secreted from the liver, or the coats of the gall bladder, till it was found that many animals wanted the vesica; but in no one did this supply the place of a liver: an organ more indispensable to animal life than even the brain.

The dissection of living animals has not so well founded an apology. They teach us how bones grow, and are united when broken; and they show to the eye motions which, without that evidence, we know to exist. We know also that galvanism and electricity excite the action of muscles without mangling living frogs.

The use of microscopes and injections teach us, in some degree, the structure of different organs, but their application is limited. No microscope shows the change which takes place in the simple muscular fibre during its contraction, or the nervous fluid acting in the nerve; no injections teach us why the minute convolutions of vessels in the testes secrete only semen, or arteries, branching at large angles, are necessary for the separation of bile.

All the animal functions consist, it is acknowledged, in motion, and this was the great argument of the mechanical physicians in favour of their own solutions.

They did not, however, reflect that the human machine differed essentially from a passive engine; that violent motions sometimes arose from slight causes; and again, that impediments which ought to have stopped, scarcely lessened and sometimes increased them. They seemed not to be aware that the muscular fibre could be shortened beyond their calculations; and that the motion of fluids in vessels, which continually impelled them, was different from the motion in a canal, which only reacted in proportion to the impulse. These were truths which Haller saw imperfectly when he compiled his physiology; but he neglected them to follow the mechanical explanations which he had collected in the school of Boerhaave. They were truths which Cullen saw, and followed with avidity to their consequences, tracing them also backward, so far as he was able, to their cause.

The order in which physiologists have arranged their observations is different. They sometimes trace the nourishment from its first reception into the stomach to the lymphatics, and into the circulation, introducing the functions of the lymphatic, the arterial, and venous systems. The changes produced in the blood by respiration follow; and an account of the separation of the various fluids either nutritious, digestive, or excrementitious, succeeds. Sensation, motion, with its various modifications in different functions, conclude. Haller has taken a different course. From the fibre the transition to the muscles is easy, and the heart and arterial system, with the circulation, next share his attention. The functions of secretion, of respiration, and speaking follow. The brain, nerves, muscular motion, the external and internal senses, deglutition, digestion, with the various chylopoietic organs, and the successive changes of the aliment into chyle; the urine, semen, the female uterine system, and the fœtus, are described in their order. Life and death close the scene.

This undoubtedly is not a natural order, nor is it the most judicious or convenient. We ought certainly to begin with the *source* of sensation and motion in the brain, following it to the extremities of the nerves as the cause of either. With motion is connected the action of the heart and the arterial system, which should be also followed to the secretory organs, and it will include all the peculiarities of the uterine and genital systems. The supply which keeps up the activity of the nerves and muscles brings us to digestion and all its consequences, particularly the lymphatic system. This again introduces the fœtus, first probably nourished by absorption, to life in its various successive stages, and its ultimate termination in death. See CEREBRUM and CEREBELLUM; SENSATIO; OCULUS; AURIS; TACTUS; NARES; GUSTUS; COR; ARTERIÆ; SECRETIO; JECUR; TESTES; UTERUS; DIGESTIO; LYMPHÆDUCTUS; GENERATIO; FŒTUS; VITA; MORS.

PHYSOCE'LE, (from *φύσα*, *flatus*, and *κῆλη*, a *tumour*). See EMPHYSEMA.

PHYSOME'TRA, (from *φύσα*, *flatus*, and *μήτρα*, the *womb*). A TYMPANY OF THE WOMB; *hysterophyse*; Dr. Cullen places this disease in the order *intumescencie*, defining it a light elastic tumour in the hypogastric region, from figure and situation resembling the uterus. It is formed by air distending the womb, which may be discharged by rendering the os uteri internum pervious.

PHYTOLA'CCA AMERICA'NA, (from *φυλον*, a *plant*, and *λακκα*, because it resembles in colour gum lac). *Solanum magnum Virginianum rubrum*; *solanum racemosum Americanum*: *phytolacca decandria* Lin. Sp. Pl. 631; PORK PHYSIC; PORK WEED; POKE WEED; RED WEED OF VIRGINIA; RED NIGHTSHADE. It is a North American plant, with a strong stem and many branches. The leaves are large, smooth, juicy, oval, and entire, and placed alternately. The root is large and perennial, runs deep into the ground, and divides into many branches.

The leaves are anodyne, and sometimes when young eaten as spinage; and the juice of the root is an active purgative. That of the whole plant is sharp and corrosive: it is not used inwardly; but, inspissated in the sun to the consistence of an ointment, is applied to cancers and to ulcers with callous edges. Its juice when dry is useless. If the roasted roots are beat into a poultice, and applied to ulcers with callosities, it dissolves them. See Medical Museum, vol. i. p. 85.

Solanum Barbadosense, another variety, is distinguished only by its lesser fruit.

PI'A MA'TER. The AFFECTIONATE MOTHER; (from its closely embracing the brain and nerves;) *localis membrana, meninx tenuis*; the membrane which immediately involves the brain, so thin as to be invisible were it without vessels. The brain is divided into lobes, which consist of convolutions, resembling in appearance the intestines. The pia mater covers the whole external surface, and sends processes between these convolutions. The principal vessels that go to the brain are dispersed on the pia mater; so that it connects the lobuli of the brain, and supports the vessels. A third covering, the arachnoides, is placed between the pia and the dura mater, sometimes supposed to be the external lamella of the pia mater; but the distinction is of little importance. See DURA MATER.

PIAN. *Frambæsia Culleni*. See YAWS.

PICA. The PIE, (from the bird, said to be subject to this disease,) *malacia allotriophagia, citia, cissa*, LONGING; is a preternatural appetite in pregnant women, and some sick persons on their recovery. The disorder consists in an appetite for things unusual either to eat or drink. Dr. Cullen places this disease in the order *dysorexiæ*, defining it a desire of eating things not fit for food. In pregnant women it is somewhat relieved by bleeding, and about the fourth month disappears. Chlorotic girls are also subject to this complaint; but whether in pregnant women, persons recovering from an acute fever, or those who labour under obstructions of the natural evacuations, this craving may be safely indulged.

It is in fact a species of cachexia, and the fancies are as numerous as the substances. They are often calcareous; but among the negroes any dirt is devoured, and they are called the dirt eaters. Sometimes the most disgusting substances are coveted; and we have heard a lady relate the artifice by which she procured a loaf to be dropped into a barrel of pitch. In general, however, the sound of brittle substances, as cinders, or pipes, between the teeth, seems to please as much as the taste, and even treading on cinders is apparently grateful. We might easily fill a page with instances and quotations of cases in which this depravity has been observed; but

it is unnecessary to extend the article, except to remark that the supposed final cause, the absorption of acid, is erroneous, since the substances chiefly coveted are not always, or indeed very generally, antacid.

PICE'A, (from *πίσις*, *pitch*). See ABIES.

PICE'LT. See NICOTIA'NA.

PI'CINUM O'LEUM. See BRUTIA.

PICRO'CHOLOS, (from *πίκρος*, *bitter*, and *χολή*, *bile*). A person subject to anger, or abounding with bitter bile.

PI'CTONUM CO'LICA, (from Poitou, where it was endemic). See COLICA.

PIE'DRA DI CO'BRA. See COBRA DE CAPELLO.

PIE'RRÉ NOIRE. See AMPELITIS.

PIGMENTUM. The mucous, coloured substance which gives the splendid hues of the iris, and the darker matter which covers the choroid coat. See OCLUS.

PIG-NUT. See BULBOCASTANUM.

PI'LA HY'STRICIS, (from *pileo*, *to bind together*). See BEZOAR HYSTRICIS.

PI'LA MARI'NA. A species of alcyonium, or a round spherical ball, found on sea coasts, among sea weeds. Lemery describes it to be about the size of a fist, lanuginous, of a dark colour, formed by a collection of hairs, sand, and other impurities of the sea, united by means of a glutinous fluid. It is said to kill worms; and Zwelfer tells us that, when calcined, it is useful in scrofula.

PI'LEUS, (from the same). See CUCUPHA. In anatomy, the coil with which some children are born; and then called *pileo*, *galea*, and *vitta*.

PILMI'CTIO, (from *pilus*, *hair*, and *mingo*, *to discharge urine*). A discharge of fibres, resembling hairs, with the urine.

PILOSE'LLA MA'JOR, (from *pilus*, because its leaves are hairy. See HIERACIUM ALPINUM, and GNA-PHALIUM MONTANUM.

PILO'SUS. See CAPILLARIS.

PILOTHI'SMATA. Applications which take off the hair; DEPILATORIA, q. v.

PI'LULA, (from *pila*, *a ball*), *catapotium*, *gongylion*. PILLS are a form well adapted for medicines which operate in small doses, are offensive to the taste, or so heavy as not easily suspended in, or mixed mechanically with, any fluid. They dissolve with difficulty, and produce very gradual and lasting effects. Gold and silver leaf often hinder the pills from dissolving; therefore should seldom be used.

This is a term also given to several compounds, many of which will be found under some of the principal ingredients, as *pilulæ à gummi*. (See ASAFETIDA.) There is a variety of formulæ of this kind in the Pharmacopœia Chirurgica, composed of very active ingredients, as different preparations of quicksilver, cantharides, cicuta, cuprum vitriolatum, opium, turpentine, and vitriolated zinc, which may be found in that work, under the term *pilulæ*.

PI'LUS, (from *πίλος*, *carded wool*). See CAPILLUS. We resume the subject of hair (see CAPILLUS) to supply some accidental omissions, and to add the late experiments of Vauquelin, which have added somewhat to our knowledge of the subject. We have already mentioned that the hair is hollow, and that it grows from a bulbous root, resembling, in many respects, a vegetable substance. The larger extremity of the oval

root is downwards, and the whole is connected to the skin or to the adipose membrane by small filaments, probably nervous and arterial. The root itself, next the branch, seems to be composed of very fine filaments, and a glutinous substance, probably secreted from its vessels. These filaments unite to form the stem, which is covered by an elongation of the external, somewhat elastic, coat of the bulb. The stem or hair passes usually between the papillæ, and sometimes seems to penetrate a papilla; but when it emerges from the cuticle, the latter appears to closely embrace, and to be continued some way on it; this membrane is gradually lost. When the cuticle is porous, as in the scalp, the hair seems to pass out in a cylindrical form, but where less so, and particularly where the bulb is buried in fat, it passes in a serpentine direction, with great difficulty, as in the axillæ, &c.; and it is then tortuous and angular. It has been supposed that this is partly owing to the warmth, since the same curl is found in the hair of negroes; but the Malay, in an equally hot climate, has straight, cylindrical hair. The hair is nourished by the gluten of the root; and as this is more copious, or more fluid, it is more succulent. When in a smaller quantity, or more dense, the hair is dry, crisp, and soon falls off. When not carried to the extremities, these split and become brittle.

The roots or bulbs of hair are found over the whole body; nor is it easy to say why they continue to vegetate on some particular parts only. They are said to have been found also in abscesses of the abdomen, in the fluid of an ascites, in the veins, on the tongue (Amatus Lusitanus), and in the heart. We can neither confirm nor oppose these assertions; and it is not more difficult to account for such appearances than to explain why hair does not grow on the back, on the shoulders, or the neck. Hair in the ovaria is by no means uncommon, and may be owing to the rudiments or remains of an imperfect conception. It has been supposed that the hair grows after death. To prove a negative is a difficult task; but, were this true, it must have been long since placed beyond dispute. The long hair found in persons, after having been buried many centuries, may have been natural. The observations of most importance on this subject may be found in Heister's Anatomy, and Camerarius' Memorabilia, iv. 47.

The hair evidently partakes of the nature of the simple solid, corresponding with it in firmness or softness. The bulb is nourished by arteries, and supplied with nerves; but there is no reason to suppose the hair itself nervous, and it chiefly grows by gradual additions at its extremity. The circulation through it is probably carried on by capillary attraction, or in the manner in which the sap of vegetables is propelled. By combing we free the fluid from those obstructions which must arise in consequence of its being bent in all directions; and, perhaps, by drawing out the hair, we straiten the canal, and render it more strictly capillary. We promote, also, the circulation through the bulb, and relieve the head from accumulations; for though the vessels of the bulb are small, they are numerous.

Long hair has always been esteemed an ornament, but it has been doubted whether it was not injurious, by the quantity of blood which it exhausted in its nutriment, and the consequent debility which it would produce. When very thick, it is uncomfortable from its

warmth, but we have never known it to be a cause of weakness, except from the perspiration which a large mass of hair must occasion. Cutting off the hair has, within our own knowledge, been often injurious, and attended with every appearance of local plethora. As usual, moderation is the best; and if it hang over the shoulders it is long enough, unless it grows, at the same time, thinner, and in that case it must be cut shorter. As a remedy for the headach, to cut off the hair is as ridiculous as to prevent the access of air, with the design of accelerating evaporation.

Such was our knowledge on this subject when, in the autumn of last year, M. Vauquelin read to the National Institute a memoir on the nature and composition of human hair. Hair was not, he found, soluble in boiling water; but when exposed to a greater temperature in Papin's digester, it was readily dissolved. From a solution of black hair a black matter was deposited, found to be an oil, of the consistence of bitumen, with iron and sulphur. The last ingredient seems to point out the source of the smell of the hair in some constitutions, where, perhaps, it is in excess, or where it may be accidentally combined with an alkali. This idea is confirmed by the analysis of red hair, in which the odour is stronger, for it contains a much larger proportion of oil and sulphur, with less of iron. Alcohol extracts from black hair a whitish oil, and a greyish green oil, which separates as the alcohol evaporates. It is probable, therefore, that the black matter is gummy or albuminous; and the white is said to resemble spermaceti in appearance, though it differs in chemical affinity. Red hair affords a white, and, instead of a greyish green, oil as red as blood.

The other component parts of hair were a mucous substance, iron, oxide of manganese, phosphat and carbonat of lime, flint, and a large proportion of sulphur. White hair contains also phosphat of magnesia, and its oil is nearly colourless. When hair becomes suddenly white, from terror, Vauquelin thinks it may be owing to the sudden extrication of an acid, as the oxymuriatic acid whitens black hair; but it may be, more probably, owing to the sulphur absorbing the oil, as in the operation of whitening woollen cloths. From some experiments made on the matter which occasions the plica polonica, he thinks that disease owing to a superfluous excretion of the fluid which nourishes the hair; but it is sometimes bloody, and, if the hair is cut off, the disease, it has been said, is fatal.

To increase the growth of hair, various preparations have been employed, and each perfumer has his secret, though we know not any are particularly successful. They chiefly consist of warm, stimulating, oily substances, to increase, apparently, the circulation through the bulb, and probably to check the perspiration. A fluid seems to exude through the hair, at its basis, and is probably the black matter which unites with the perspiration, producing the scales that soon form on the scalp, if combing is neglected. Powder is useful in absorbing this matter, and preventing its concretion into flakes; but if this is not used, dark hair soon stains the comb, and proves the existence of its exudation.

Of the boasted DEPILATORIES, q. v. we have mentioned quick lime and orpiment (see RUSMA), which Spon, in his Travels through Italy, mentions as chiefly successful; but various others have been added. Kircher

recommends the blood of a bat (*mundus subterraneus*); Laurentini, the bulb of the hyacinth; Morin, the exudations from a vine; and friction with a pumice stone has been used; but none will succeed, unless the bulb be destroyed, and extirpation is the only remedy. For increasing the hair, we find the aqua stercoris humani recommended by Schroeder; and for blackening it, the stercus hirudinum!

PIME'NTO, (from *pimenta*, Span.). See PIPER JAMAICENSIS.

PIMPERNE'LLA. See ANAGALLIS.

PIMPILIM. See PIPER LONGUM.

PIMPINE'LLA, BIPINELLA, called from the double pennate order of its leaves. BURNET SAXIFRAGE, called *saxifraga*, because it grows out of, and seems to break through, the rocks; *sanguisorba*, *pimpinella minor*, *tragoselinum*, SMALLER BURNET SAXIFRAGE, *pimpinella*, *saxifraga*, &c. Lin. Sp. Pl. 378. A perennial umbelliferous plant, growing in dry pasture grounds. It is sometimes the name for agrimonoides; the *poterium hybridum* Lin. Sp. Pl. 1412.

PIMPINE'LLA A'LBA GERMANO'RUM, *pimpinella saxifraga major*, *gythosphyton*. GREATER WHITE BURNET SAXIFRAGE; *p. saxifraga* Lin. Sp. Pl. 378, β . γ . δ . Some of its leaves are deeply cut; the odd one into three sections; common in Germany, but rarely met with in England. The roots have a hot, pungent, but not durable, taste. When fresh, they affect the eyes like mustard and horse radish. In drying they lose all their volatility; and water partially extracts their virtue, but spirit completely. When distilled with water, they afford a small portion of oil, which is highly acrid. These roots are warm, stimulating, aperient, and diuretic. Bergius considers them also to be diaphoretic and stomachic; and they are often recommended, where pituitous humours are supposed to prevail; as in asthmas, catarrhal coughs, in what has been called *angina serosa*; by Hoffman in chlorosis: it has also been employed by way of gargle, for dissolving viscid mucus, and to stimulate the tongue, when paralytic. Its dose in powder is \mathfrak{z} i. in infusion \mathfrak{z} ij.

The species called *nigra* grows wild in Germany and Switzerland, and yields a bluish oil. Whatever has been said of the value of these, as medicines, by Stahl and others, they are not used in the present practice.

PIMPINE'LLA ANISUM, Lin. Sp. Pl. 379, *anise*, which furnishes the aniseeds of the shops. See ANISUM.

PIMPINE'LLA ITALICA, of some foreign pharmacopœia, is the *sanguisorba officinalis* Lin. Sp. Pl. 169. It is not used in this country. Like the other species of *pimpinella*, it is a stimulant only.

PINASTE'LLUM. See PEUCEDANUM.

PINEA'LIS GLA'NDULA, (from *pinca*, a *pine apple*), to which it hath some resemblance. The PINEAL GLAND. See CEREBRUM.

PINE'US PURGANS. See CATAPUTIA MINOR.

PINGUEDINO'SA MEMBRA'NA, (from *pinguedo*, fat). That portion of the cellular membrane which contains the oily matter or fat. See CELLULOSA MEMBRANA.

PINGUE'DO. See ADEPS.

PINGUE'CULA, (from *pinguis*, fat, because its leaves are oily to the touch). See SANICULA EBOR.

PINHO'NES. See CATAPUTIA MINOR.

PI'NNA, (*πinna*, a wing). The lateral and inferior

parts of the nose are called *finnæ* and *alæ nasi*: the superior broad parts of the ears are also called *pinnae*. See AURICULA.

PINNA' CULUM FO'RNICIS GUTTURA' LIS, (from its resembling in shape *pinna*, a wing). See UVULA.

PINNA' TUS, (from *pinna*, a wing). The epithet of a leaf composed of many smaller leaves growing on the side of the footstalk, like the feathers of a wing.

PI'NON. See BRYTON.

PI'NUS, (from *πίλος*, the pine tree,) *peuce*, *pinus pinea* Lin. Sp. Pl. 1419; differs from the fir tree by its leaves standing in pairs, while those of the fir are solitary. The pine abounds with a resinous juice similar to that of the fir tree. The cones are agreeable to the taste, similar in quality to the sweet almonds; and used chiefly as demulcents. The frankincense, which has been supposed the production of a species of pine, is from a species of juniper, or, more probably, of the *amyrus*. See THUS.

The bark of all the pine trees is astringent, and the tops are antiscorbutic; but their virtues chiefly depend on the turpentine they contain. Raii Historia. See ABIES.

PI'NUS IN'DICA, NU'CLEO PURGA'NTE. See GRANA TIGLIA, under CATAPUTIA MINOR.

PI'PER, (from *πίπτεω*; because it assists digestion,) PEPPER, *arum moschatum*, *piper nigrum* Lin. Sp. Pl. 40, *p. aromaticum* of La Marck, is the small round aromatic seed of a trailing plant, which grows in Sumatra, Java, and Malabar.

When ripe and decorticated it is styled white pepper, supposed formerly to be a different species, and called *leuco piper*. It has been said, however, that there is a variety of the plant which produces the white seeds, which is much superior to the factitious; but we can find no sufficient authority for the fact. The white pepper brought to us is inferior in pungency, as well as in flavour, to the black.

The pepper is externally corrugated by drying in the sun, but the ripest, fullest seeds have the fewest wrinkles, and are the best. Pepper appears to be a more general and permanent stimulus than other spices of equal pungency on the palate; and its stimulus does not reside in the volatile parts or essential oil, but in a resinous substance which does not rise in the heat of boiling water. Pepper infused in water impregnates it very strongly with its flavour, but not with its taste; by a slight boiling more of its pungent matter is extracted, and its flavour dissipated. Distilled with water, a light, mild, limpid oil is obtained, which excites only on the tongue a grateful moderate warmth. Rectified spirit completely extracts the pungent part of the pepper; and when the tincture is evaporated a still more fiery extract is left behind. The quantity of extract is nearly the same from the white pepper, but it is less pungent. Peppers, particularly black, have been used as stimulants and aromatics in vertigo, paralytic and gouty disorders: in large doses it has cured intermittents, though in some instances it has produced fatal consequences from its stimulus. In ulcerated throats, biting constantly pepper corns is an excellent remedy, equal to the capsicum gargle of the West Indies. For its dietetic use see CONDIMENTA.

PI'PER I'NDICUM, *capsicum*, *lada chilli*; *vallia capis*

molago, *solanum urens*, *siliquastrum Plinii*, *piper hispanicum*, *lusitanicum*, *turcicum*, *brasilianum*, *guineense*, *calcuticum*, GUINEA PEPPER, *capsicum annuum* Lin. Sp. Pl. 270, is in long roundish taper pods, divided into two or three cells full of small whitish seeds; a native of the East and West Indies. When this fruit is fresh it hath a penetrating acrid smell: to the taste it is highly pungent and acrid, producing a painful burning in the mouth like that from *arum* root. Rectified spirit dissolves its pungency, and the extract is excessively fiery. This kind of pepper is given in small quantities as a most active stimulus in cold, phlegmatic temperaments, in some paralytic cases, in relaxations and insensibility of the stomach, for promoting the efficacy of aloetic medicines, and the deobstruent gums in uterine disorders. When dry it is without odour or particular flavour, and so readily diffusible that it joins agreeably and conveniently with any sauce. It promotes digestion; but much of its pungency is lost on the palate unless given in pills, and it seems not to be an active stimulus to the arterial system. Bergius has often seen long protracted intermittents cured by the following powder, without any relapse. Six grains of Indian pepper and two scruples of bay berries, in powder, divided into three portions, one of which was given on the approach of the first rigor, another the day following at the same hour, and the last on the third day. (Cullen's Materia Medica). In climates of which *capsicum* is a native, we are told that its use is salutary, that it strengthens the stomach, assists digestion, and corrects the putrescency so common in hot climates: as a stimulant of the most acrid kind it may be found efficacious in some paralytic and gouty cases, or to promote excitement where the functions are languid and torpid. In the cynanche maligna it has been successfully exhibited in a gargle; and in the cachexia Africana, considered as the most frequent and fatal predisposition to disease among negroes, in a dose from six to eight grains it is often useful. (Mackittrick.) A species of this plant called in the West Indies BIRD PEPPER, is the basis of a powder brought from thence under the name of *Cayenne*, or *CAYAN PEPPER*. The four species of this pepper, which grow in Guinea, are the *chilchotes*, *chiltepin*, *tenalchiles*, and *chillpelagua*; that which grows in Peru is called *agy*.

PI'PER JAMAICENSE, *piper caryophyllatum*, *cocculi Indi aromatici*; *piper chiahæ*; *amomum*; *caryophyllus aromaticus Americanus*; *pimenta*; *piper odoratum Jamaicense*; ALLSPICE and JAMAICA PEPPER is the dried unripe aromatic berry of a large tree, growing on the mountains of Jamaica; *myrtus pimenta* Lin. Sp. Pl. 676. It is moderately warm, of an agreeable flavour, somewhat resembling a mixture of cloves, cinnamon, and nutmegs, consequently called *allspice*. On distillation it yields an elegant essential oil, which sinks in water; and is moderately pungent, in smell and flavour approaching to oil of cloves, or rather a mixture of those of cloves and nutmegs. The remaining decoction, inspissated, leaves an unpleasant extract, not pungent, and the berry itself is wholly deprived of its taste as well as flavour. Rectified spirit extracts all its virtue, but yields nothing on distillation. The spirituous extract consequently possesses its whole virtue, viz. a pungent warmth, less fiery than that of the black and white peppers.

A distilled water, from half a pound of this pepper to three gallons of proof spirit, is substituted for the *aqua aromatica*, and the *aqua mirabilis* of former dispensatories. The London College order a water to be made from half a pound of the berries of pimento bruised, put into a sufficient quantity of water to avoid an empyreuma; from which, after maceration for twenty-four hours, one gallon is to be distilled, *aqua pimento*. Ph. Lond. 1788.

The oil of Jamaica pepper is sometimes substituted for the oil of cloves, and is very little inferior to the oil of nutmegs.

PI'PER LO'NGUM, *macropiper*, *acapatli*, *catu-tripali*, *pimphilim*, LONG PEPPER, *piper longum* Lin. Sp. Pl. 41, is brought from the East Indies. The pods are round, about an inch long, containing numerous minute seeds. These are hotter and more pungent than the other peppers; but in pharmaceutic properties the same, though in Dr. Cullen's opinion weaker.

The black pepper is most agreeable to the palate, and chiefly employed as a condiment; the *long* is most used in medicine; the *white* is seldom employed in either. When astringents have failed, a diarrhœa hath been cured by ʒi. of pepper with ʒss. of diacodium, twice a day.

PI'PER LO'NGUM FOLIO'RUM NERVIS, &c. See BETLE.

PI'PER MONA'RDI. See BUYO BUYO.

PI'PER MURA'LE. See SEDUM.

The other species of peppers are of little value in medicine. See Neumann's Chemical Works. Lewis's Materia Medica.

PI'PER CARYOPHYLLA'TUM. See PIPER JAMAICENSE.

PI'PER CAUDA'TUM, and CUTEBA CUBEBS. See NHANDU, and CUBEBA.

PI'PER CHIA'PE. See PIPER JAMAICENSE.

PI'PER TAVASEI. See CASSIA CARYOPHYLLATA.

PIPERI'TIS, (from its biting taste). See LEPIDIUM.

PIRAMIDA'LIA CO'RPORA. The small eminences on the lower part of the MEDULLA OBLONGATA, q. v.

PISCA'TOR RE'GIS, (*pisces*, to fish). See ALCEO.

PISIFO'RME, OS, (from *pisum* and *forma*). See LENTICULARE, and CARPUS.

PISSÆ'UM I'NDICUM. See PETROLEUM BARBADENSE.

PISSASPHA'LTOS, (from *πισσα*, pitch, and *ασφαλτος*, bitumen). See BITUMEN.

PISSASPHA'LTUM. See MUMIA.

PISSELE'UM, (from *πισσα*, pitch, and *ελαιον*, oil). OIL OF PITCH, *bitumen Barbadosense*, is prepared by boiling pitch, over which wool is suspended. When it is soaked with the rising vapour, it is said to be wrung into a vessel, and this is repeated as long as the pitch is boiling. The common method of distilling to obtain essential oil is more probably used. See PIX LIQUIDA.

PISSI'NUM O'LEUM. See BRUTIA.

PISTA'CHIA LENTISCUS. See LENTISCUS.

PISTA'CHIUM, PISTA'CIA, *terebinthus Indica Theophrasti*. The PISTACHIO NUT TREE.

Pistachio nuts are oblong and pointed, about the size and shape of a filbert, including a kernel of a pale greenish colour, covered with a yellow or a red skin. They are brought from the Levant. The kernels are agreeable to the taste, sweetish and unctuous, resembling in their nature almonds. See Raii Historia.

PISTI'LLUM, (from *pinso*, to bruise). A PESTLE. In botany, a PISTIL, or POINTAL, that column or set of columns which occupies the centre of the flower, rising on the top of the embryo, generally surrounded with the chives. They are supposed by Linnæus to be a continuation of the medulla or pith; and differ greatly in their form, for in some flowers they are roundish, in others triangular, oval, or square. The pistillum is the female part of generation, whose office is to receive and convey the pollen to the fruit. It consists of GERMEN, STYLUS, and STIGMA.

PISTOLO'CHIA, (from *πιστος* faithful, and *λαχαια*, parturition; because it was thought to promote delivery). See SERPENTARIA VIRGINIANA.

PI'SUM, (from *πισος*, a garden; because it was a garden vegetable). The PEA. Of these there are various species, but they are not medicinal; they are less nutrient and less flatulent than the bean, and generally more tender; the sweeter and more mucilaginous kinds are the more nutritive. See ALIMENT.

PI'SUM ARBORE'SCENS. See CAJAN.

PITU'ITA, (from *πητυα*, coagulum, from its consistence). PITUITA.

This term strictly means the thin lymph which distils from the nose, and from the Schneiderian membrane in all its extent; but it is most frequently confined to defluations from the nose, and accumulations in the stomach. Pathologists have, however, seized on the term as a convenient appellation for fevers of a particular kind; and much confusion has arisen from the extensive indiscriminate use of the word. We are ashamed to say how much labour has been employed to collect in a comprehensive view what authors have said on the subject; but though we have mispent our own, we shall respect our reader's time.

The original meaning of the word was a defluation from the head, and it was supposed to pass from the brain through the foramina of the cribriform bone into the nose. It is amusing to see the difficulties which the ancient pathologists felt in finding a passage for it; but we are gravely told by some authors that it passes down in the form of vapour; and it is plainly hinted that it is condensed by cold, or rather a cold. In fact, it was synonymous to rheum; but in its condensation by cold, it was gravely asked how the brain escaped being frozen.

The great point in dispute, seems to have been whether the pituita was an excrementitious fluid, and whether generated in the brain, or drawn to it as to an alembic from the stomach or liver. It is useless to follow the disquisition; but we may add, that it was at last determined not to be an excrementitious fluid, not to be generated in, or derived from, the fourth ventricle of the brain, nor from the liver. In fact, it is the mucus of the whole pituitary or Schneiderian membrane; and more generally considered, when exceeding in quantity or morbid in quality, to be a disease of the stomach. Thus, when Horace says, "Nisi cum pituita molesta est," he does not refer to catarrh; though Baxter

gravely tells us that bilious constitutions are subject to catarrhs, but to his habitual weakness of the stomach, for he observes in another place,

——— *Stomacho que tumultum
Lenta feret pituita.*

The humoral pathologists, catching at the language of Galen, supposed that a pituita sometimes abounded in the blood, and was secreted in the stomach, and occasionally the cause of fevers. In the usual progress of epidemics, when the inflammatory form, more common in spring, has yielded, and the bilious constitution of autumn has not come on, the pituitary fevers are said to take place (Grant on Fevers); that is, fevers of no peculiar distinct kind. Not the slightest evidence of a mucous fluid in the blood has, however, been adduced; and still less of its power to produce fevers. We have found mucus or pituita discharged in excess, and with altered qualities, in coryza; in the throat (see ANGINA); in the stomach (see DYSPEPSIA); in the intestines (vide CÆLIACA); in the urinary bladder (CYSTITIS); in the urethra and vagina (GONORRHEA). It remains to enquire how far it is connected with epidemics.

Selle and Pinel (vide NOSOLOGIA) have distinguished pituitous fever, referring it to the gastric remittents; and they have quoted as their authorities Sarcone, Glass, Huxham, and Stoll. These authors, however, describe only the milder typhus, complicated sometimes with aphthæ, sometimes with scarlatina; generally with accumulations in the stomach and intestines; with accumulations, not only of mucus, but of bile and of putrid saburra. Indeed every author who speaks of pituitary fevers considers the stomach and bowels as the chief seat. Baglivi calls them mesenteric, other authors slow, gastric, and mucous fevers; nor is the type, in the opinion of Pinel, more accurately described than in Wagler's work *De Morbo Mucoso*, a putrid fever complicated with dysentery. We shall transcribe the description of this fever from Sarcone, whose account is preferred by Selle.

"Constitution of the air cold; diet bad and unalimentary; manner of living excessively dirty; a scarcity of food; tongue glutinous, as if covered with fat; mouth and fauces sometimes covered with a mucous crust; blood covered with a glutinous coat, consisting of lamellæ containing serum, scarcely inflammable; cruor in a dissolved state; fever slow, with a weak intermitting pulse; urine thin and limpid." To this may be added, that blisters were said to discharge gluten; and, on dissection, the intestines to be covered with a glutinous crust. In the whole of this description we perceive only the milder typhus, which is attended with a white tongue, and when protracted with aphthæ. Blisters, after some continuance, always discharge a white matter; and in proportion as the vessels are less irritable or more weak, this matter appears more early: it is only the gluten of the blood. Pinel, in his description of pituitous fever, from Wagler, mentions as peculiarly characteristic marks, continued nausea, a stomach cough, inducing and increasing pains in the breast; diarrhœa with tenesmus, sharp pains or constriction in the transverse direction of the colon; aphthæ or mucosities on the internal membrane of the

larynx, rendering the respiration painful or stertorous. When the fever was violent, these mucous excretions of the mouth were not obvious; but a thick white mucus, sometimes yellowish, sometimes of a deeper colour, at the back part of the tongue, was accumulated. This fever, he adds, sometimes terminates by an internal ulcer or scirrhus, a mucous congestion in the lungs, or a gangrene of the intestines. We did not remark in the account of Sarcone, because it would be more striking in this place, the appearances on dissection. What he styles mucous exudations in the viscera are evidently the effusions from inflamed vessels, which appear in the lungs, the bowels, &c. after the resolution of inflammation, and which, when the patient survives, form adhesions between contiguous parts. We see in this second description, from the pain, the gangrene, &c. every mark of inflammation having preceded. We may add, therefore, with the author before us, though he meant not to apply the observations to himself, the following truly judicious reflections.

"It is well known that complicated epidemics are constantly described as so many singular novelties; fevers which seem to increase without limits the catalogue of these diseases, and to extend the boundaries of the art of healing. But the spirit of analysis soon shows how much this excessive multiplication may be reduced, when we have seized the character of the principal disease; and has not Wagner himself, when he has described the simplest form of the disease which appeared in the epidemic during the siege of Gottingen, given the history of the mucous malignant fever; the same fever with purple exanthemata, &c.?" We may observe in the same spirit, has Wagler given us any more than a picture of the nervous fever, with aphthæ?

We have, perhaps, enlarged sufficiently on this subject, which is a short specimen only of what we purposed to offer on the varieties of fever; a task which, from its extent, we lately (page 277) declined. The remedies peculiar to the pituitous fever are not different from those of fever in general, though we suspect the symptoms would have been milder, and the disease less fatal, had evacuations from the stomach and bowels been more freely excited. In short, it would have been unnecessary in this work to have enlarged on these supposed varieties, as every direction in the general cure applies strictly to them.

The other directions for the treatment of pituitary congestions chiefly relate to collections of mucus in the stomach. Baldinger recommends tartarized antimony in mild doses; and Stoll (*Ratio Medendi*, i. 228) the sal ammoniac: not very different are the medicines recommended by Martin, burnt sponge; and the lime water of other authors. The warm aromatics and the *Geoffrœa surinamensis* have their advocates; but gentle emetics often repeated, mild laxatives, with the purer biters, and the alkaline salts, afford the best chances of relief.

The remedies for catarrh and for coryza, in all their varieties, may be seen under the distinct heads already mentioned.

PITUITA ALBA. See ANASARCA.

PITUITA'RIA, (from *pituita*). See DIARRHŒA.

PITUITA'RIA GLA'NDULA, the PITUITARY GLAND,

is a small spongy body, lodged in the sella sphenoidalis, between the sphenoidal folds of the dura mater, neither medullary nor glandular; but on the outside partly greyish and partly reddish, and within, white. It is transversely oval, and on the lower part, in some subjects, it is divided by a small notch into two lobes, like a kidney bean. It is covered by the pia mater as by a bag, the opening of which is the extremity of the infundibulum, and it is surrounded by the small circular sinuses which communicate with the sinus cavernosi.

PITUITA'RIA MEMBRA'NA, is the membrane which lines the whole internal nares, the cellular convolutions, the conchæ, the sides of the septum narium, and, by an uninterrupted continuation, the inner surface of the sinus frontales and maxillares, and of the ductus lachrymales, palatini, and sphenoidales; continued down to the pharynx, septum palati, &c. Its name is derived from its office of separating the mucilaginous lymph, called *pituita* by the ancients; and it is of different structures in different parts; sometimes thin, at others thick and spongy. It is thickest on the septum narium, the lower portion of the inner nares, and the conchæ; in the sinuses it is thinner; on the side next the peristomium and perichondrium it is plentifully stored with small glands. See CEREBRUM.

PITUITO'SA, (from *pituita*). See DIARRHŒA.

PITUITO'SUS MO'RBUS. See NERVOSA FEBRIS.

PITYRI'ASIS, (from *πιτυρις*, bran,) *porigo*; a scorbutic disorder of the head, chin, and eye brows. It consists, according to Dr. Willan, of irregular patches of small thin scales, which repeatedly form and separate, but never collect into crusts, and are not attended with inflammation. He distinguishes it from *porrigo*, which is a disease of the scalp, attended with ulceration.

The *pityriasis capitis*, the first species of this author, is called the *dandriff* when it affects young children. It appears at the upper edge of the forehead and temples as a slight whitish scurf, in the form of a horse-shoe. The scales on the other parts of the head are flat, semi-pellucid, and distant, though often contiguous, and even imbricated. When it occurs in elderly persons the exfoliations of the cuticle are larger. The head should be shaved, and the scales removed by soap and water; for if the sordes (see PILUS) collect and unite with them, ulcerations are often the consequence.

The *pityriasis versicolor* of Willan are irregular, brown, or yellow patches on the arms, breasts, abdomen, and clavicles; sometimes branched like a lichen, sometimes in irregular lines like the outline of a map. They consist of small scales, which fall off and are reproduced. The cuticular lines are deeper in the coloured portion of the skin, but the patches themselves have no distinct boundaries. The origin of the colour is below the cuticle; but it is not attended with any complaint except a slight itching on going to bed after exercise, or any stimulating liquor. A slight exanthema, or a lichen pilaris, is sometimes apparently interspersed; but seems to be independent of the principal disease.

The causes have been said to be fruit taken in too

large a quantity, mushrooms, alternations of heat or cold, the friction of flannel, and the heat of a tropical region. It seems to resemble the maculæ hepaticæ of Sennertus, and to differ from the dark spots occasionally on the skins of pregnant women. As these have no scales, it should be also distinguished from those maculæ and ephelides which have a marked border. No internal medicine seems to produce a considerable or a permanent change in these spots.

PITYROI'DES, (from the same). See FURFURES.

PITYU'SA, (from *πιτυς*, because the leaves resemble those of the pine). See TITHYMALUS, ESULA MINOR.

PIX, (from *πισσα*, pitch). PITCH, *burina*, *bunnea*.

PIX BURGUNDICA, BURGUNDY or WHITE PITCH, is the resin of a species of pine with a larger proportion of oil than in the common resin. It is extracted from the *pinus abies* Lin. Sp. Pl. 1421. Burgundy pitch is chiefly imported from Saxony, of a solid consistence, yet somewhat soft, of a reddish brown colour, and not disagreeable in smell. In inveterate coughs, affections of the lungs, and other internal complaints, plasters of this resin, by acting as a topical stimulant, are said to be of considerable service. It is now entirely confined to external use. See ABIES.

PIX LIQUIDA. TAR; *hisselaion*; *alkitram*; *cedrium*; is the produce of all resinous trees; at first procured from cedar, larch, and fir, but now chiefly from pine-trees, particularly the *pinus sylvestris* Lin. Sp. Pl. 1418, and the *p. picea* 1420. (See ABIES.) The wood is inclosed in a large oven, which stands within another, admitting the fire between; from the bottom of the inner oven the tar is carried off by a gutter in proportion as it melts.

Tar differs from turpentine by the disagreeable empyreuma it has received from the fire, and by the acid as well as the gummy matter separated by the heat. It thus becomes soluble in watery fluids, which extract nothing from the purer turpentine.

It affords by distillation the common black pitch, an essential oil, called, from the name of the tree whence the tar is obtained, *oleum pini*, or *tædæ*, and an acid spirit. This oil resembles the oil of turpentine, but is impregnated with the empyreumatic flavour of the tar. A leg of mutton, while roasting, basted with tar instead of butter, and a sharp skewer frequently thrust into its substance, in order to let out the gravy, afforded in the dripping pan a composition said to cure the lepra ichthyosis, by anointing the whole body with it for three or four nights successively, while the same linen was worn. Dr. Cullen mentions it as used in one instance with great success. *Materia Medica*.

Water in which tar has been steeped is an useful remedy in many disorders. It may be drunk either warm or cold. In acute diseases it is taken as freely as the thirst may demand; and in chronical, from a pint to a quart may be taken every day, at three or four times, beginning while the stomach is empty. It is said to be a good deobstruent to warm and stimulate, raising the pulse and increasing perspiration.

Common tar water is made by putting two pounds of Norway tar to a gallon of water, stirring them well together for two or three minutes: after settling two days, the clear liquor must be poured off. Of this a pint or

more may be taken every day. In many instances this preparation, says Dr. Cullen, has appeared to strengthen the tone of the stomach, to excite appetite, promote digestion, and to cure all the symptoms of dyspepsia. At the same time it manifestly promotes the excretions, particularly that of urine; and it may be presumed to have the same effect on others. From all these operations it will be obvious, that, in many disorders of the system, this medicine may be highly useful. *Materia Medica*. See the Bishop of Cloyne's *Treatise on Tar Water*.

Pix nigra, sicca, arida, COMMON BLACK PITCH, DRY OR STONE PITCH; called by Dioscorides *galimphissa*, prepared of pitch, twice boiled.

It is tar dried by heat, or what remains of tar after separating the essential oil, its acid, and aqueous parts. A stimulating plaster, bearing the name *emplastrum picis compositum*, is said to be equally stimulating with the euphorbium plaster, and to possess similar properties. It is made in the following manner:

R. *Picis aridæ* ℥ viij. gum ammoniaci, galbani, āā ℥ iv. liquentur simul; deinde adjiciantur, pulveris radicis pyrethri; seminis sinapios; camphoræ, āā ℥ i. olei terebinthinæ q. s. ad consistentiam emplastri.

Unguentum picis aridæ, made by melting nine parts of pitch and of olive oil, with four of wax, together, is said to be efficacious in ulcers, attended with an extraordinary degree of irritability, distinguishable by their languid, purple, and glassy appearance. In these all terebinthinate ointments are inadmissible.

The *unguentum picis cum sulphure*, made by melting sixteen parts of pitch and one of yellow wax together, adding, while fluid, eight parts of sulphur, is employed in tinea, and esteemed very efficacious; but during its use the head must be frequently shaved, and a green oil-skin cap constantly worn.

PLACE'BO, (from *placeo*, to amuse). A common-place method or medicine, calculated to amuse for a time, rather than for any other purpose.

PLACE'NTA, (from its resemblance to *πλακους*, a cake). In botany it is that part of the pod or husk of a plant to which the seeds are fastened, and by which they are nourished until ripe.

In anatomy it is a thick, soft, vascular mass, thin at the edges, where the membranes go off which cover the fœtus, adhering to the uterus during gestation, called *hepar uterinum*, and, with the membranes and funis umbilicalis, excluded after the fœtus. The whole is called the *after-birth* and the *secundines*. The placenta is sometimes oval, at others, divided into two, adhering apparently to each other by the membranes. The internal surface, where the funis is inserted, is convex; the external concave, and, there, seems composed of lobes, which are most conspicuous when the placenta is hastily separated. When there are two children there are two placentæ; and though they appear as one, they have no communication of vessels. The placenta usually adheres to the fundus, but occasionally to any other part, and is sometimes directly over the os tincæ. It is made up of one vein, and of two arteries, which ramify together, the largest being on the internal surface; and even the apparently parenchymatous substance appears, by injections, to be wholly vascular. The ramifications are very minute, and when separated

by maceration, and injected, they appear to rise from the funis, as branches from a tree. No nerves can be traced into the placenta.

Former physiologists saw nothing in the placenta but a congeries of vessels passing from the mother to the fœtus, and a communication, by continuous vessels, was so natural and obvious, supported also by the hæmorrhages which followed the separation of the cake, that it was apparently unnecessary to look farther. Dr. Hunter, by more attentive examination, found reason to doubt of the existence of continuous vessels. He saw evidently a cellular structure, on the separation of the placenta; and comparative anatomy showed him that cells were more conspicuous in the placenta of ruminant animals. The experiments of Haller on the egg, which proved that a large portion truly belonged to the fœtus, led to an inquiry whether the apparently uniform cake might not be composed of two parts, one belonging to the fœtus, the other to the parent. The result was, that almost the whole of the placenta was truly fœtal, that the maternal portion was inconsiderable, and that the blood of the parent was deposited in cells; from which it was seemingly taken up by absorbing vessels, probably red veins. In this view the apparently mamellated structure of the uterus, at the point of union between it and the placenta, was the whole that belonged to the maternal system, except the decidua. Even the decidua reflexa is supposed to belong to the fœtus; but on this subject physiologists are not perfectly decided.

The circulation thus carried on by absorption, and the deficiency of any nerves passing from the mother to the uterus, led pathologists into some difficulty to explain the effects of fright, apprehension, or fever, on the fœtus; and was still more embarrassing to the physiologist in explaining the source of the *nævi materni*. The present structure is perfectly consistent with the doctrines we have attempted to establish respecting the primordial germ, which admits not of any considerable distention beyond its adult state; and it will be necessary to examine shortly the mode of communication, since a remote connection is at least evident; for the child is certainly influenced by diseases which affect both the circulating and nervous systems of the parent.

There can be little doubt but that the extreme vessels in the maternal part of the placenta possess the peculiar irritability and sympathetic associations which distinguish these extremities of the arterial system on the surface. Their sympathy is also more extensive; and fever or terror, which affects the latter, with spasm or insensibility, will equally disorder the former. The want of a supply is consequently felt, and uneasiness must follow. Violent evacuations will often do little injury; for in that case the supply, though diminished, is not wholly stopped. Though there is, however, no immediate communication between the two systems, by means of nerves, it does not follow that the proximity of the minute nervous fibres, when their nonconducting coats are deposited, may not have some influence. If there is any foundation in the doctrine we have endeavoured to establish on that subject, it is probable that the vibrations of an elastic fluid, on one side, may have some influence on the nerves contiguous to them from

the other. We have indeed contended that divided nerves do not unite, so as again to communicate the nervous influence from the brain, or sensations from their extremities; but this apparently arises from their uniting in the usual way, by accretion and effusion, in short, by an inorganic substance, as is represented in the plates of Fontana. Nor is this nervous influence by approximation wholly without examples, were it proper at this time to engage in the subject.

Some doubts have arisen whether the maternal blood is conveyed, without a change, through the vessels of the placenta; or whether some separation, perhaps some secretion, may not take place. The difficulty has arisen from its being observed that infectious diseases are not communicated to the fœtus, or, at least, not readily and certainly, and from the suspicion that the azotized blood of the mother might, in the earlier periods, be injurious to it. It is now, we believe, admitted that fevers have not their origin in the blood; and it will be obvious that the fœtus can suffer only from the disturbance of the balance of the circulation. Even putrid fevers, in a high degree, have been found not to affect the child in utero; and we know, from the experiments of Parmentier and Deyeux, that in these cases the vital fluid is very little altered; though we should, *à priori*, have suspected that the gelatinous fluids of the fœtus were not very susceptible of putrefactive fermentation. Where poisons are more decidedly present in the blood of the mother, the child is sometimes affected. The small pox has certainly been conveyed to the fœtus, and it has been affected from the time the pustules have begun to dry into scabs, at the period when the maternal blood is most full. The lues, it is said, is not communicated; and it has been supposed, that when the child is affected, the communication of the virus takes place in passing through the vagina. We have given some reasons for supposing this not to be the case (*vide LUES*); and may add, that, were it so, the local disease would probably show itself more frequently in the head than in the genital system, since the head is first, and for a longer continuance, exposed to the contact of the virus. We must, from every view, admit of a communication; but some means are found for lessening the deleterious acrimony of the poison, often of destroying it altogether. It is not impossible that with the blood a milder portion of albuminous matter is secreted; perhaps the fluids of the fœtus may not be susceptible of taint; or the poison be soon carried to the surface: a determination favoured by its being constantly bathed in water.

The nervous communications we must leave among the numerous arcana of physiology, unless the communication by the approximation of the ultimate uncoated fibrils on each side be admitted. We were, at one time, inclined to adopt the existence of a nervous aura communicated to some distance; but found that the different facts would by no means support its existence, and that, in the present case, it would be inapplicable. We soon perceived, also, that the admission of this principle would lead to numerous inconsistencies and improbabilities. The influence of the mother in producing the *nævi*, called from thence *materni*, may be very shortly discussed, by denying it altogether. We have already given our reasons for it.

The placenta is often diseased. It sometimes accretes to the uterus, as observed by Morgagni, Stœller, and Gooch; becoming a firm tendinous mass, or, according to the last author, with beginning ossifications. It is often so closely attached, that no power which we can safely use will separate it; and the whole gradually sloughs away in succeeding menstruations. It sometimes degenerates into cysts, or, probably, hydatids; of both we have instances in Bauer, Haller, Ruysch, and Valisnieri. Of its attachment to the os uteri we have already spoken; and in our plate we have preferred a case of this kind as the general attachment might be better understood from the appearances in this case, than the latter from a representation of the former kind.

The placenta was, in general, removed soon after delivery; but within about thirty years, we believe chiefly from the recommendation of Dr. Hunter, it has become usual to delay the extraction; and it has been delayed for many days. We perceive in the older authors various and opposite opinions on this subject. Some contend that it should be immediately extracted, and that any delay is dangerous or fatal; others, that weeks and months may be suffered to elapse without making any attempt to deliver it. More attentive observation has preserved the medium. The extraction is not hurried; but seldom more than a day or two is suffered to elapse without attempting to bring it away, if nature should not perform the office. When the cord is broken, a little longer delay is occasionally necessary, that a partial separation may take place and give advantage to the operator. The inconveniences of suffering it to remain are a constant drain which debilitates the constitution; a mind unsatisfied and uneasy; often putrid discharges: those of too rapid extraction are, pain; violent floodings; often inflammation; and sometimes, from rashness, inversion of the uterus.

The most ridiculous and absurd medicines are recommended to expel it. Myrrh, the skin of a hare, the dung of different animals, and the testiculi equi, are among these. If myrrh has any effect, as we have suspected, of bringing on hæmorrhage, it may be useful, but should it have such a power there is scarcely time for its action.

In general, therefore, we should wait for some hours after delivery to see if nature will produce the separation, which will be shown by fresh pains recurring, bearing down, and the cord elongating when gently drawn.

It hath long since been observed, that hastening the placenta was one cause of the difficulty in delivering it; and the most eminent practitioners agree that a flooding only can justify its speedy separation. When necessity obliges the accoucheur to introduce a hand into the uterus, the back of it should be toward the uterus, and the palm as close to the placenta as possible, that the womb may not be injured in separating it.

PLACITIS, (from *πλαξ*, a crust). See CADMIA.

PLACTULÆ. See MORPIONES.

PLADAROTIS, (from *πλαδαρος*, flaccid). A fungous tubercle in the inside of the eye lid.

PLAGÆ, (from *πλησσω*, to strike). Solutions of

continuity, as wounds; though stripes, blows, &c. are generally included.

PLA'NCUS, (from $\pi\lambda\alpha\zeta\omega$, to turn aside). See LEIPODES.

PLANIPETALUS, a plant which has plain, flat petals.

PLA'NTA, (from *planus*, flat). THE SOLE OF THE FOOT, also a PLANT OF VEGETABLE, because it originally included only vegetables on the surface of the ground, which are trodden under foot.

We have often remarked the difficulty of discriminating even the largest groups of animated nature, in consequence of the imperceptible shades by which one class of bodies passes into another. Even the animal and vegetable kingdoms can scarcely be distinguished with accuracy from this cause. A plant may, however, be defined a living organized body, without feeling or spontaneous motion; which has the faculty of reproduction; which grows and is nourished by intus-susception, through the medium of other bodies to which it adheres by some of its parts. Plants approach animals by an organized structure; perhaps by a power of preserving a greater temperature than the elements which surround them, by a degree of sensibility and irritability: they approach minerals by not possessing a locomotive power, by having no containing vessels; and, in many cases, by the function of nutrition being in part carried on by apposition.

The anatomy of a plant, if fully detailed, would carry us to disquisitions of a disproportioned extent. It is sufficient to remark that every vegetable is fibrous; and its bulk, like that of animals, formed by an inorganic substance interspersed between the fibres. When these admit of no farther distention the tree dies, and at first on the top, where the impelling force is soonest exhausted. The nourishment is conveyed by vessels which pass through the bark, and from it the woody fibres are deposited. The wood gives firmness and solidity, but the tree will live and put forth shoots though the wood be destroyed, should the bark be uninjured; at least in its whole circumference. It has been disputed whether the vessels of a vegetable are canals conveying a fluid *within them*; or whether the nourishment is conveyed along the fibres. Many authors have pretended to have seen canals in different species of vegetables, and have described them; but future observers have not been equally fortunate, and on the whole it seems clear that the nutritious fluid passes along the fibres, which, by their juxta position, may be supposed to form canals. The most convincing argument in favour of the existence of vessels is, that if the plant is placed in ink, some parts will be coloured and others remain of their natural hue, which at least shows some affinity to different fluids in different parts of the vegetable.

Those who admit of vessels distinguish the *vasa propria externa* disposed in small bundles under the bark, forming a net work with large meshes; the *vasa propria interna*, found particularly in the oak and the pine, appearing to convey a fluid, which, on cutting the *chelidonium majus* transversely, may be seen to pass out; the *vasa propria intima*, found in the inner bark, and sometimes in the wood, which can scarcely be demonstrated, but which Dr. Hill is said to have separated in the *piscidia erythrina*, after a long maceration; and

the *vasa propria*, perhaps the only vessels clearly demonstrated. These are large and numerous, particularly near the surface, convey a viscid coloured fluid, and communicate with the utriculi. They are supposed to receive the sap from the lymphatic vessels, and to prepare the appropriate fluids of the plant.

The lymphatic vessels are numerous, and pass from the roots to every part of the vegetable, conveying the nourishment absorbed from the earth. Those who contend for a circulation of fluids in vegetables, suppose them to arise through these, and descend through the *vasa propria*, between the wood and the bark. Hill has described them as consisting of little cells included in each other, forming a hollow cylinder; but this author's fancy was often too predominant; and these appearances have not been seen by other observers. There are probably also *inhalent* and *exhalent vessels*, which are found in the leaves; a part analogous to the lungs of animals.

The utriculi are described as vessels composed of vesicles slightly contracted at equal distances, but preserving a free communication in the whole length of the canal. They appear, however, to be a mere cellular substance, communicating with the *vasa propria*, the lymphatic vessels, and the medulla.

When the leaf of a plant, as an iris for instance, is broken transversely, and the parts slowly separated, small fibres are drawn out, which appear as if they had formed a vessel by spiral circumvolutions. These have been styled air vessels, or *tracheæ*; but with little reason, for they sometimes appear to contain a coloured fluid. They are found in the minutest parts of the plant, even it is said in the stamina; but later vegetable physiologists suspect that these *tracheæ* are peculiar only to the more adult state. Hedwig and Reichel thought them primordial; other authors have supposed them irritable organs, the source of the motion of the sap; and Desfontaines the rudiments of fibres. Nothing, however, is decided on the subject; but as they are found in the organs most completely developed, we should rather suspect them to be expanded fibres than primordial ones. Were they the latter, as Senebier has justly observed, we might discover them in a state of progress to the fibrous form.

Mirbel, in his late work on the Anatomy of Plants, admits of five species of tubes, which supply the office formerly attributed to the vessels described by authors, viz. *simple* and *porous* tubes which contain the appropriate juices (*succi proprii*); the *tracheæ* and pseudo *tracheæ*, which he considers as tubes without assigning their use; and the small tubes which form the bands and the ligneous strata. Independent of these vessels, Mirbel calls the regular and symmetrical vacancies of a soft texture, formerly by tearing the membranes, *lacunæ*. The tubes and *lacunæ* he supposes to be formed of a membranous substance, which is the primordial basis of vegetables. The former are without pores, which are numerous in the other. These pores are insensible, longitudinal, or glandular, according to the parts or species of plants in which they are found.

The epidermis is composed of longitudinal fibres in the greater number of plants; and in some, as the cherry tree, of transverse ones. The external laminae are sometimes inorganic; the internal frequently consist of distinct strata. The epidermis of the trunk and

branches is regenerated if destroyed; that of the fruits and leaves is never restored. It is evidently composed of a net work, or of numerous reticulated laminæ, resembling spiders' webs; and perforated by the pores of numerous vessels. It enjoys life equally with the plant, and is not wholly a crust formed by the vegetable secretions. The glands of the epidermis of the leaves are called the transparent miliary glands by Guettard; and they are of the colour of the parenchyma, separating in the day oxygen, and in the night carbonic acid gas.

The *parenchyma*, or the cellular texture, is discovered on raising the epidermis, and is a net work formed by fibres or transparent vessels filled with a green fluid, anastomosing at their meeting, and swollen at the intervals between their anastomoses. It is formed by contiguous vesicles, connected horizontally at right angles with the longitudinal fibres. In this part the ultimate elaboration of the fluids takes place, and the different gases are separated. Senebier thinks the colour owing to the remaining carbon, but the green matter is a resinous substance, and consequently does not contain carbon exclusively. The decomposition of the water, the cause of the ultimate change, is owing to the action of the solar light.

The *bark*, or vegetable cutis, has been lately styled cortical strata, formed of a cellular substance, with closer meshes than those of the parenchyma. In the flattened net work we perceive transverse and longitudinal fibres, which communicate with the tubes and cells of the parenchyma. These are the fibres which in flax and hemp are employed to make linen and ropes, ultimately paper, either white or brown.

The *liber* is the inner part of the bark composed of reticulated laminæ with still smaller meshes, adhering so loosely as to be easily separated, and giving the idea of the leaves of a book, from whence its name is taken. The tracheæ are very numerous in this portion of the bark. When there is a solution of continuity in the wood with loss of substance, the liber insinuates itself into the wound, and in a few years fills it with a woody substance. Du Hamel compared it to the periosteum of the bones, led by a false analogy, and erroneous ideas of the nature and formation of a callus.

Between the bark and the wood we find strata of what is styled the *albumnum*, differing from the bark by the white colour and greater density. The vascular and tubular portions are more closely compacted, less numerous, and less sensible than in the bark. Some of the species of *salix*, when macerated, show this part most distinctly. It seems to be the wood in its progress to the ligneous state. This is, however, no part of the bark, but a primordial portion of the vegetable developed to receive the fluid, which is to become wood. It is at first almost wholly albuminous, but from the influence of light becomes resinous; for etiolated plants are never woody. When the bark is removed, the ligneous state is sooner brought on; and it is said to be advantageous to bark the oak one year before it is felled. The albumnum then becomes hard, the wood less perishable and less accessible to the attacks of the teredo navalis.

The *wood*, is the hardest portion, and its laminæ are very compact, containing, instead of fluids, a carbon, as bones contain between their fibres phosphat of lime.

The lymphatic vessels are more numerous than in other parts, and convey the sebum, which, when in excess, is evacuated in drops, styled TEARS. These do not arise from the bark or the albumnum; for to procure it, as in separating sugar from a species of maple, the wood must be penetrated. It is an erroneous idea that the number of ligneous strata show the age of a tree. Those of two successive years are sometimes confounded; and in some years two are deposited, so that the stratum of spring and autumn may be distinguished. Ligneous strata should therefore be banished from the vocabulary of the vegetable system; for in every part of animated nature we find, in the successive growth, only successive developments of primordial parts.

The last portion is the *medulla*, confined to the centre of the dicotyledinous plants, and disseminated through every part of the monocotyledinous ones, according to Desfontaines. It is composed of loose vessels and utriculi, which are spongy and long in drying; resembles the parenchyma, varying like it in density, according to the plant which contains it.

The medullary canal is parallel to the longitudinal fibres, in the middle of which it is placed, and communicates by its cells and vessels with the cellular texture. The fluids of these two parts differ only in colour; those of the latter being green from the access of solar light. Some *medullary productions* pass through the wood, and are gradually lost in the bark, or are spread through every part of the vegetable like the nerves of the spine. The *appendices medullares* differ only in extent, scarcely reaching beyond the innermost fibres of the wood. The medulla is in greatest quantity in young plants, and is then green, but the colour is fainter in proportion as the wood excludes the light. The medullary productions which reach the bark are sometimes green, but the appendices always white. In old trees neither of these are found; and it is said that they then produce fruit without kernels. The ancients uniformly supposed the kernel to be a production of the medulla, and deprived their trees artificially of it to procure fruits without a kernel, which were supposed to be more highly flavoured and succulent (*Geoponica*, lib. xx.); but Du Hamel was unsuccessful in his experiment, though he did not follow with accuracy the ancient process. Perhaps it is impossible to separate every portion of the medulla. The more of this substance they contain, the more easily are they propagated by buds and layers. Linnæus supposed that the medulla had a considerable connection with the sexual parts of plants, and thought that the pistil was derived from it. Hales considered it as the most essential organ to the nutrition of plants; but, as Senebier remarks, the old willows which still flourish without a medulla, refute this opinion. Columb, by boring trees at different depths, found the serum most abundant when the auger reached the medulla, and supposed that through it the juices mounted; and Plenck thought that it was a reservoir of nourishment in dry seasons (*Physiologia and Pathologia Plantarum*); but in such seasons the medulla is as dry as the rest of the plant. It is indeed probable that the medulla contains the nutritious juice of young plants, supplying the milk and the albumen of the cotyledons. At a more advanced period, this appropriate nourishment is unnecessary, and the medulla gradually disappears.

We have mentioned the important distinction of Desfontaines respecting the want of the medulla in the monocotyledinous trees, which, like the palm, are cylindrical from the top to the bottom. He, therefore, divides trees into those which have cylindrical and those which have conical trunks: a division founded in nature, and of the utmost consequence to be kept in view. The more minute distinctions, and the growth of the branches, would lead us too far, so that we shall speak shortly of some other parts of vegetables before we treat of their physiology and pathology.

The *knots* of vegetables are protuberances, formed by buds gradually distending. As this process takes place in the liber, the descending sap is arrested in its course, and forced into the bud. The fibres in this part are less strong, and slightly brittle. The knots are, however, the hardest parts of the wood, from the fibres being compressed by the expanding bud. Successive layers of wood cover them, but they are never effaced.

Articulations are a species of knots proper to herbaceous and woody plants, which usually produce branches. The knots or articulations of reeds, examined in a microscope, present a regularly formed tissue consisting of hexagons, mixed with small round bodies of a finer texture. The knots of a sugar cane form rings about five lines in breadth, whose surface contains five ranges of semitransparent points, arranged in a quincunx. The articulations are richer in juice than the other parts. There is much analogy between branches and knots, respecting their reproduction; for the roots usually proceed from the knots in solaniferous plants, as well as in those multiplied by buds and layers.

Buds and suckers are plants in embryo: they are buttons, with the leaves imperfectly formed, and a year is often required before they can assume the name of a bud: the first appearance of a bud is called an eye; and, previous to this, in its first state of dilatation, it resembles in form a reversed cone. The most favourable moment for the evolution of buds is when the leaves begin to fall, as they then attract the fluids, both from within and without, and begin to enjoy an active life.

Suckers are only buds which grow accidentally in consequence of a wound, which, interrupting the course of the sap, evolves a bud. *Thorns* have been supposed abortive branches, because they occasionally become branches. They seem, however, to be constant in the same species, and to have an active office, that of defence, in the infancy of the vegetable. In those monstrous productions, from excess of nourishment, the thorns certainly sometimes become branches; but they are never fertile. To this we may add, that they are always directed to the earth; or, if apparently horizontal, inclined in a gentle angle to the ground, while the branches rise upwards. Thorns are in the first year covered with a bark, in the second the bark disappears, and after the third they usually die like an inorganic body. They have no power of absorption. If an annular incision is made round the branch below them, and the leaves above are taken off, they die the first year. Comparetti found them to originate from a bulb like the hair, and the bulb of the sting of a nettle was found to contain the acrid fluid which distils from its extremity. Thorny plants are stronger, drier, and more compact than others; and when the thorns are

lost, it seems to arise from greater care and a more succulent food.

The flower is not only the ornament but the most essential part of the plant; for it contains the organs by which the species are continued. The sexual system is now established, and the stamina are allowed to be the organs which distinguish the male, the pistils those of the female, flowers. They are sometimes on distinct plants, more frequently indistinct flowers on the same plant; but most commonly the male and female organs are on the same flower, which is consequently called an hermaphrodite. It has been already shown (see BOTANY) that the arrangement of Linnæus is founded on the sexes of plants, and it will not now be soon disturbed.

The flower in all its splendour is said to be only an expansion of the other parts of the vegetable. The calyx has been derived from the bark, the petals from the liber, the stamina from the wood, and the pistil from the medulla. This, we believe, from the experiments and observations of Grew, Malpighi, and Desfontaines, is now rendered highly probable; and if, as has been conjectured, coloured is only attenuated light, we can attain some knowledge of the source of colour which adorns the parterre. The sight is, however, pleased at the expense of the health; for flowers exhale a deleterious gas, often highly injurious to delicate nervous constitutions. The double flowers are the monsters of the vegetable kingdom; for they are produced by an excess of nourishment, and the additional petals are the stamina which assume that form from excess. Like other monsters they are barren, and produce no fertile seeds.

The stamina are the organs least known: those of the tulip are swollen at the lower part, and hollowed, according to Senebier, in irregular tubes through their whole length. The tops are generally crowned by two ovoid capsules seen in the microscope, which are separated by a membranous septum. Spiral vessels are found in the stamina, particularly in those which are irritable, viz. of the barberry and opuntia; and it has been said that these vessels are the seat of their irritability. Others, without deciding on the cause or the seat, attribute this irritability to the stamina of every plant; and Tessier seems to have proved that in all the cerealia, the stamina at the rising of the sun turn towards the pistils, throwing with some force the pollen from the antheræ.

The opinion of Desfontaines, just mentioned, that the irritability is seated in the spiral vessels, seems to be supported by the experiments of Comparetti on the filament of the urtica and parietaria. Dr. Smith places the seat of the irritability at the base of the filaments, and indeed the joints seem the usual seat of this principle in every vegetable. Other botanists have supposed that the motion is mechanical, depending on the dilatation or contraction of the fluids in the vessels, by different degrees of temperature; but the existence of these vessels has been doubted.

The antheræ, placed at the top of the stamina, contain the true vegetable semen, which seems to preserve its prolific power for a long time, since we know that it may be conveyed by the air, and impregnate the female flowers of dioicous plants at a great distance. The globules, which the microscope discovers, are

apparently not the ultimate form of the pollen; for, when placed in water, they burst, and throw out with considerable force some smaller globules, or a sensible aura. Tessier found the pollen the most animalized of all vegetable substances, next to the gluten of farina: it afforded ammonia in the ultimate analysis, and appeared naturally of a resinous nature.

The number of the *pistils*, the female organs, is the same with that of the seeds, and of the stigmata with that of the cells. On a general view, when the seeds are numerous the pistil appears single; but, on minuter examination, it is composed of as many pieces as there are seeds. Its lower part passes into the ovarium, and its surface is without any epidermis, covered usually with a viscid fluid. It is not yet decided whether the pistil is tubular. Bonnet saw in the orange, lily, and the linden tree apertures at the extremity of the stigma, continued through the pistil to the ovary, large enough to admit the fecundating pollen. It is supposed that in the moment of impregnation these apertures open to convey the pollen, and again close when the orgasm is at an end. Linnæus suspected a similar contrivance, and Spallanzani saw an opening, but could follow it no farther than the middle of the style: in some plants he could not discover the smallest aperture. Hill declared that he saw it through the whole track; but Adanson, who only traced it in some species, supposes that the pollen is conveyed through the tracheæ, when the pistil is not tubular. These, however, have not been proved to be pervious tubes. It is probable, as Linnæus supposes, that the aperture is too small to be discovered; and when we consider the minute division of the pollen, it is scarcely probable that it could be brought within the reach of even the best assisted sight. May not the fecundation of the seeds be affected by a seminal aura, as was formerly supposed to occasion impregnation? The whole analogy of animated nature, and the means of reproduction, oppose this opinion, and we were lately unwilling to admit it where its existence and influence were most probable, viz. in the connection between the mother and foetus.

We have spoken of irritability, and given instances of its existence, though many more striking ones remain to be mentioned; yet no organs in which it is accumulated have been discovered, no source of this principle has been pointed out. The solar light decomposes the water, and its oxygen is exhaled, while the hydrogen remains to form the oils and the green resinous matter of the leaves; nor is it improbable that azote is absorbed from the atmosphere. This process is undoubtedly calculated to assist the circulation of the fluids through the lower parts of the vegetable, but by no means accounts for the motions certainly connected with irritability. An anonymous author has endeavoured to show that in meteorological phenomena the decomposition of water is attended with a separation of the electrical fluid, and in this way accounts for the positive electricity of the atmosphere. (Exeter Essays, 372, &c.) If this be the case, may not the electrical fluid be the source of irritability, and may not the medulla be its great reservoir? The pistil, the most certainly irritable organ, is apparently derived from it; but if this be denied, the use of the tracheæ has not yet been discovered, and the structure of these, calculated greatly to

extend the surface, adapts it for the same purpose. This is, however, conjecture only; nor is the present work a place to render it probable, though various facts occur to us which we think would rescue it from the opprobrium of an hypothesis.

The two great powers which convey the fluids of the vegetable through its vessels, or along its fibres, are the capillary attraction at the roots, and the decomposed water in the leaves, if we are not permitted to add the electricity evolved in the latter process. The sap in the early spring rises in waves, falling during the night, and again rising by day, sometimes like the undulations of the ocean, sinking below its former rise, but still, on the whole, progressive. In the early periods the milky and albuminous fluid of the seeds supplies the young plant, as the maternal fluids in the placenta supply the foetus. While the plumula has yet no power to expand its own leaves, nature has provided the rudiments of this organ in an appropriate form, styled the seed leaves; but its own soon expand, and the plant acquires an independent existence. In the progress of its existence it annually extends in height, and increases in bulk. The wood is deposited from the bark, forming in its intermediate state the alburnum, either from the ascending, or, according to Mr. Knight's very ingenious experiments, in the descending vessels. The former, from the experiments with coloured fluids, seem to surround the medulla; but the minuteness of the vegetable physiology must not detain us.

Thus we find, as in the animal body, the principal parts of the vegetable pre-exist in the germ. Every additional organic part is developed, and inorganic matter only added. We see in the peduncle of the pear the fibres which form the fruit, and can trace them gradually expanding to a determinate bulk; and the flower we can often trace to the bark, the wood, and the medulla. If we compare an animal with a vegetable, we must take one of the lowest rank as an example, for instance the polypus. The last appears to be a congeries of animals, and the vegetable seems also to combine in one body numerous individuals. Each may be propagated by buds; but they differ in one essential respect, that the food is taken into a cavity before it is distributed to the parts around. We know not a single instance to the contrary, unless it occurs, as some authors have suspected, in the lower orders of marine vermes, the asterias, and some others.

Irritability and sensibility, which distinguish animal creation, have been lately attributed to vegetables. We have pointed out a possible source in the electricity separated by the decomposition of water; but its operation or its instruments have not been ascertained. The contraction of the sensitive plant is well known; but in others, particularly the *hedysarum gyrans*, *cactus opuntia*, *cistus helianthemum*, the *amarillis formosissima*, &c. the motions are regular, though not spontaneous, and apparently the result of organization rather than volition. It seems to reside in every part of the vegetable, since, when plunged into cold water, every part seems to contract, and the motions of the *mimosa* are said to be checked by watering it with a solution of opium. The irritability of plants is intermitted during the night, which shows its connection with the light, and almost every vegetable closes its

leaves towards the evening; some in the most striking, remarkable manner. Light, however, is not the only cause; for different flowers open and close at various times, and the convolvulus, for instance, soon after the sun has attained its meridian height. Linnæus, from the opening of plants at different hours, has collected what he fancifully styles *horologium floræ*, a botanical clock, viz. the flowers which show in this way the successive hours of the day. If by *sensibility* we understand the power of feeling, and being affected by external bodies without judging of their effect, plants may probably possess this quality. When a plant bends towards the light, or throws out unusually long roots, to penetrate a barren rock, and reach a more genial soil, we cannot deny it some share of sensibility. The same conclusion must follow when we find plants differently affected by the same nourishment or the same aspects. In this view they often show more sensibility than some of the lower animals, as the polypus, the stella marina, echinus, &c. *Perceptivity* implies some judgment of the effects of sensations, and this quality has been liberally bestowed on plants. Philosophy would appear to put on her most repulsive garb were she to deny what has given interest to an elegant and pleasing poem (Botanic Garden), and some entertaining speculations (Percival's Essays). It is necessary, however, to add, that not the slightest evidence has been adduced of the existence of this quality.

Respiration is a function common to both animals and vegetables, though not carried on with regularity and constancy. Oxygen gas is separated, and carbonic acid air, perhaps azote, absorbed. It has been supposed that azote is also separated in the lungs; but we suspect that it is rather received, since many plants which grow in water alone decidedly show traces of this principle, particularly the tetradynamix. *Circulation*, in the sense of an animal function, is not found in plants. The fluids rise and fall: we have said that no tubular vessels have been discovered, and probably none exist.

Digestion and nutrition in the vegetable kingdom are simple functions. Water is the great source of aliment, indeed, many vegetables are nourished wholly by it; and this fluid, when decomposed, furnishes, as we have seen, the hydrogen to form the oils and resins, as well as the other secreted fluids, while the carbonic acid, perhaps the azote from the air, contribute to the formation of the wood, probably the seeds. Vegetable physiologists have supposed that the fluids either absorbed by the leaves or the roots are carried to the utriculi, and there digested; but not the slightest evidence of this process has been given: at the same time there is apparently an inherent power in the plant, to separate those principles from the air and water which form its appropriate and distinguishing fluids. Pease and cresses will grow in distilled water, exposed to the same air, and yet contain very different principles. This peculiar power has not yet been ascertained, and probably will never be understood.

M. Braconnot has, indeed, very lately examined this subject with more than usual attention; and his labours, which we have just received in the *Annales de Chimie*, vol. lxi. may with advantage detain us for a short time. He examined chemically a rich mould, and found that it contained nothing soluble in water; but that its chief characteristic was a power of retaining moisture. He

found in it the usual substances, which are nearly the component parts of vegetables deprived of the oxygen, and a proportion of hydrogen. M. Braconnot repeated the experiments of Tillet and Van Helmont, and found that plants would germinate in substances which could impart nothing to them, as litharge, flower of mustard, well washed sea sand, and even lead shot, though weakly in the latter, from its not retaining the water; and the products were very nearly the usual ones which are found when they grow in the best mould. Radishes in river sand, well washed, produced rather a larger quantity of ashes than in common earth, with a greater proportion of potash. Where then can plants obtain their carbon? It has been said, from the open air, but they will grow in air deprived of its carbon, and even in an exhausted receiver. We are, however, by no means satisfied with the author's reasons for rejecting Senebier's experiment with lime, since he has only proved that lime is volatile when joined with water or alcohol; and in the experiment it was suspended in the bottle where the vegetable grew. He has, however, sufficiently shown that the quantity of carbon is far greater than the air can impart. This principle must be, therefore, derived from the water, and very probably, as he supposes, by the medium of light. The only principle which can in any respect supply the place of light is hydrogen; and our author suspects some affinity between hydrogen and light. Hydrogen is certainly contained in charcoal, and the diamond, which have been supposed to be carbon in the purest forms.

While we thus speak of the food of plants, we may mention the suspicion that a part of their excrementitious fluids are discharged from the roots. A noxious excretion from the roots is evident, in M. Braconnot's opinion, from the unctuous and dark appearance of the earth round them. In several of the euphorbia and ciceraceous plants it is milky; and in the plants which grow in water the roots are, after some time covered with a glutinous substance. This subject, however, requires farther examination.

The more nutritious food of vegetables is manure. They may be divided, like animal stimuli, into the more steady and permanent, and the more active and diffusible. The former are animal or putrifying vegetable substances, probably in part azotic, but generally containing carbonic acid gas. Quick lime or marl may appear an exception to this idea; but it must be recollected that they are not used alone, and are mixed with other substances before they are applied. The calcination renders them more easily divisible, and the remaining causticity seems of service in dividing the too adhesive clods. The more diffusive stimuli are salts of all kinds, particularly the oxygenated ones, which seem to exhaust the irritability; for they push on vegetation with such rapidity, that the plant soon dies. Light may be equally dangerous in excess, if water is freely supplied. Metals, metallic vapours, and metallic salts, are said to be poisonous to plants; but from some late experiments it seems that at least the latter have been usually injurious from their excess: in smaller proportions they seem to be useful, realizing the canon of Linnæus in the vegetable kingdom also, "*Alimenta a toxicis non natura sed dosis distinguit.*"

Reproduction is the last effort of all organized bodies, and the nearer they approach their end, the more

earnest does nature seem to supply successors. In the vegetable kingdom this is particularly striking; for to make a plant produce flowers and seeds no plan is more effectual than to confine, mangle, or weaken it. Of seeds and the early embryo we have spoken sufficiently; and of buds, shoots, or layers, it is enough to repeat, that a plant is a congeries of organized bodies. Separate one of these from the parent plant, and it is itself an independent active being.

Light, we have seen, is the great stimulus of vegetable motion. It is not, indeed, essential to vegetable life; for Humboldt found plants in the shafts of mines, where no light penetrates. We know, however, that vegetables have a strong affinity to light; and if it is a component part of bodies, which, from late observations, we have reason to think, it is not impossible that they may derive some portion of this principle, in dark situations, from surrounding substances. One singular fact merits notice, that, when deprived of light, well known plants appear in disguise from an altered shape of the leaves. They are more round, as if the points were elongated by the discharge of gas; for at the points it is chiefly emitted. Plants confined in darkness lose their colour, and are blanched, or, as it is called, *etiolated*: they lose also their peculiar taste and their acrimony, as is the case with the endive, the chicoreum, &c. The reason, from what has been said, is obvious.

The gases in large proportions, are destructive to vegetables: with oxygenous, azotic, and carbonic acid gas, a plant dies. With equal parts of carbonic acid gas and atmospheric air it dies also: with $\frac{2}{100}$ of this gas they languish; with eight they thrive vigorously. The most active vegetation goes on when a plant is watered with a solution of carbonic acid gas, in an atmosphere with about $\frac{1}{100}$ of the same. Buds take root most certainly in this way, if the light be excluded, or admitted moderately. It is often sufficient, by excluding the external air, to confine the gas which arises from moistened ground; but it is safer to add a portion through an aperture, which may be again closed.

Various other vapours are injurious to vegetation. We have mentioned quicksilver rising in the toricellian vacuum; but it appears, from some experiments of the Dutch chemists, that it may exhale even under the pressure of the atmosphere. Plants covered with a jar, immersed in water, in which a bottle of mercury was suspended, were covered on the third day with black spots, and on the fifth or sixth were quite black. In the experiments of Senebier the vapour of sulphuric ether prevented germination, without changing the quality of the air. Camphor, oil of turpentine, asafoetida, vinegar, and ammonia, have a similar effect, if inclosed with growing or germinating plants.

Vegetables exposed to impure exhalations of every kind flourish better than in the open air. Even the branches of a tree on the side of a dunghill are greener and more vigorous than on the opposite side, and such plants exhale more copious streams of oxygenous gas. Salts, as we have said, are the most powerful stimuli; but we cannot think the poudrette of the French (pulverized stercus humanum) useful only on account of its salts. The azote seems to claim some share, as well in this manure as in the fumes of the neighbouring dunghill. Odoriferous, and even fetid substances, if

mixed in a considerable proportion with the earth, impart their odour, and sometimes an unpleasant taste.

The effects of the vegetable functions are increased temperature. It is, we believe, generally allowed that the vegetable is warmer than the surrounding air, and resists for a long time the effects of frost, if not succulent, or peculiarly full of fluids. It has been said that this is owing to the high refracting power of the resins, by which they admit of the combination of a greater degree of heat; to the carbon being a bad conductor of heat, which confines it more effectually, as it abounds in the bark; and to the heat of the earth, conveyed to the vegetable by its fluids. Each reason is, however, confuted, by the buds of the tallest trees resisting the effects of cold in winter, when no sap ascends, and no leaves are expanded. If the heat of animals be not a property of life, as there is much reason to suspect, the cause of vegetable heat may be the following. During the summer the combination of light seems, as usual, to separate heat; but as it does not appear at any time in a considerable degree, it probably enters into a new combination with some of the vegetable matter, from which, during the winter, it is slowly evolved. The temperature of vegetables appears to be uniform in the heat of summer and the cold of winter, so that there is, probably, some reservoir for its excess, though, in the present state of our knowledge, it cannot be pointed out.

The great line of distinction between organized and inorganized bodies is, that the latter increase by juxtaposition of particles externally; the former by an intussusception of the nourishment, and its application from within. Organized bodies include animals and vegetables, and it would not be improper to compare the functions of vegetables with those of animals of the lower classes, to show more closely the concurring and discordant appearances, but that it would lead us into too extensive discussions. Some observations have led naturalists to consider different supposed vegetables to be the nidi of animals, and these we must shortly notice.

The tremellæ, which have been usually considered as plants, have neither roots, leaves, nor flowers: they wholly consist of a gelatinous substance, and seem, in reality the nostoch only. The latter, in stony ground, may be seen to assume in part the form of the tremella lichenoides, and in part to retain its own. In fact, the nostoch successively passes into the lichen gelatinosus, crispus, rupestris, and fascicularis, as well as the tremella verucosa; and these again change to other plants, the lichen crispus assuming the form of the lichen granulatus. From these observations, for which we are indebted to Carradori, whose memoir is analyzed in the Annales de Chimie, the tremellæ must probably be banished from the vegetable kingdom. In addition, we may observe that Adanson has seen the threads of the nostoch contract and dilate; Fontana has shown that its filaments, like those of the ergot, were truly animals which die and revive by the action of water only; Corti and Scherer have seen the animals escape from the centre to the borders; and the nostoch, in a chemical analysis, yields ammonia. The last, indeed, is not a decisive argument, for many vegetables afford the same principle; but these have such decided marks of a vegetable nature that no error can arise.

It is with less success that late authors have attempted

to raise the *confervæ* to the rank of animals. It is contended that winged insects are seen to escape from them, and that when these no longer appear the green manding on the water does not increase. This may be true; but the *confervæ* expire oxygen. The nature of mushrooms has also been rendered doubtful, because electricity, which hastens the germination of vegetable seeds, and kills the ova of animals, not only prevents the germination of mushrooms, but even destroys those beginning to expand. Mushrooms, however, from their structure, must belong to the vegetable kingdom.

If we thus partly limit the empire of Flora, the latest microscopical observations have greatly added to it. The spots, the rust, the mould, on various plants are true parasitic, organized vegetables, which have each peculiar distinct forms and appropriate habitations; but these belong to the pathology of the vegetable kingdom, to which we hasten.

The diseases of plants are chiefly external. There is nothing analogous to the nervous diseases of animals, but exhausted irritability from excess of stimuli, or its defect from too great succulence. Wounds are common, and cured like those of animals, by excluding the air. Ulcers, in different parts, and of all the various kinds found in animals, are also common. They chiefly arise from lacerated or neglected wounds. Fractures and clefts are also frequent, and easily understood. Decurtation is the death of the upper branches from debility, either in consequence of a barren soil or a severe winter. As soon as the extent of the tree's power is seen, the branches should be cut off close to the living part, and this should not be too long delayed; for numerous vigorous lateral shoots seem to be thrown out by no more exertion than would push the sap to a very short distance in the dead part. Exostoses sometimes occur in consequence of an excess of nourishment; but often of its deviation from the true direction, induced by some weakness of the bark. On the contrary, the bark is sometimes too firm, and binds the tree so close as to prevent the circulation. This disease is styled *hide bound*, and it is necessary to cut down to the wood, in a longitudinal direction, from the first divarication of the branches to the earth. The bark, on the contrary, sometimes *exfoliates*; and it is necessary not only to guard against the access of air, but of insects.

The diseases of the leaves are numerous, chiefly from parasitic vegetables, or from insects; but the leaves occasionally fall off, from a burning sun following a cold, wet season, and sometimes fade from a sterile soil. In cases of insects, some cause of debility seems to precede. An insect never places its nest on a vigorous leaf, or perhaps the copious exhalations of oxygen may destroy it. The *curl* which happens often to potatoes is not easily understood. It seems to arise from a defect in the seed, and its immediate cause to be an unequal action of the vessels in different parts of the leaf.

The *ergot* demands particular attention, as it is the cause of such dreadful ravages, producing mortification and palsy in whole families, and sometimes districts, when the inhabitants are obliged to feed on ergotized corn. It consists of a total, sometimes only a partial, change in the grain itself, which loses its form, is bent, often appearing at one extremity like a tail. It arises from too great humidity of the soil, which affords an opportunity for some small animals to burrow in the

seed, and to destroy it. Thuillier considers the disease as owing to a mushroom, a species of *clavaria*; but whether it be an animal or a cryptogamous plant, its chemical nature is animal, since it affords ammonia. It has been lately supposed to consist only in an expansion of one extremity of the seed. The cause of *caries* is unknown: the corn is cleaned from it by washing. When the husks are attacked, and the whole ear appear dry and brown, it is called by the French *charbon*. The *rust* is chiefly on the stalks, and, as sir J. Banks has very properly shown, depends on a plant of the mushroom tribe.

Sterility in plants is often occasioned by excess of vigour in the branches and leaves: it is checked by every cause of weakness. In the human race we have equally remarked that the largest families are not those of the healthiest and strongest parents; and that in almost every case of extraordinary fertility, as triplets, the health of the husband was infirm.

Diseases of the whole plant are *chlorosis*, or *etiolation*, when the leaves grow white, and the plant loses its taste and smell; *plethora*, or the excess of vigour, which occasions sterility; *jaundice*, in which the leaves grow yellow, often from too frequent affusions of water during a hot sunshine, from a barren soil, more frequently from insects at the root; *anasarca*, from very wet seasons, when the plants, though green and apparently vigorous, lose their taste, and are either barren or the seeds germinate in the pericardium; the *frost*, from excessive cold, from which, if not long continued and violent, so as to destroy the organization, the plant sometimes recovers, or, if cut off near the root, the latter throws out new shoots. Succulent, plethoric, or anasarcous plants are soonest injured, and most certainly destroyed. If these are expected to bear cold, the water should be gradually withdrawn before the severe season commences. When late shoots come out, which will not apparently bear the cold of the winter, the leaves should be taken off to prevent absorption.

Plants are divided into ANNUALS, BIENNIALS, ALIMENTARY, AQUATIC, CRYPTOGAMIC; ECONOMICAL; ETIOLATED; FAT OR SUCCULENT; CLIMBING; HYBRID; HYGROMETIC; LEGUMINOUS; WOODY; MEDICINAL; ODORIFEROUS; VARIEGATED; PARASITIC; TINCTORIAL; and POISONOUS. We may add a few remarks on each.

Annuals and biennials are sufficiently known: they are opposed to *vivacious* or *perennial* plants, which are those which continue for more than two years. The annuals of our hot-houses are often perennial in their native soils, where the heat is considerable; and, on the contrary, biennials often become perennial, though annuals never become biennial. The marks of this quality, in botanical authors, are derived from a fanciful analogy to the sun and planets. As the course of the sun is completed in one year, its symbol ☉ is applied to annuals. As Mars employs two years in its revolution, its symbol ♂ is the mark of biennials; while that of Jupiter ♃ designates perennial plants.

Alimentary plants, in which we include the *cerealia*, are those employed, in every country, for the food of man. Were we to confine it to those which contain nourishment, to be extracted by art, the catalogue would be immense; for the greatest number of vegetables is supposed to contain a starch. If the *cassada* had not, for instance, for time immemorial, been

extracted, in Africa, from the species of *jatropha*, it might have been accounted a poisonous plant; and those who tried only the leaves of the potatoe would have never thought of eating its root.

Aquatic plants include those of rivers and of the sea. The river plants are only used as manure; those of the sea as manure, and for the production of soda. Some cannot live out of water, as the *nymphæa*, the water lentil, &c.; others delight only in moist places, as the willow, the iris, various reeds, &c. The willow will not live in water. Some French agriculturists have examined with care the different marshy plants, to ascertain those of which cattle are fond. They will not touch the *butomus umbellatus*, the reeds, the *colchicum*, the various species of *carex*, and *sium*: they are not fond of the *eupatorium*; but eat greedily the *spiræa ulmaria*, the *salicaria*, the *arundo vulgaris*, *epilobium*, and *thalicttrum*. It is recommended, therefore, to destroy the former and cultivate the latter. As their seeds are small, they should be mixed with powdered gypsum, to add to their weight, and to distribute them more regularly.

The *cryptogamic* plants are, the ferns, lichens, and mushrooms, which have been sufficiently considered.

The *œconomic* plants contain not only the alimentary, but those employed, in any way, for the service of mankind, except the practice of medicine. The Dictionary of Kerner, published in 1790, in German, contains a description, a history, and figure, of every plant, employed for this purpose. As it is scarcely our object, we shall not, as we intended, make any extracts from this work. The *œconomic* plants are generally called by the French *plantes usuelles*.

Etiolated plants are those whose leaves are whitened and elongated by disease, or excluding the light. This change is designedly produced to lessen the acrimony of some esculent plants, as the endive, celery, &c. The last experiments which we recollect, professedly on the subject, are those of Meese, in the *Journal de Physique*, 1778. It has been asserted, in the same work, that a moist heat, independent of light, will produce the effect; but though, as we have seen, the green colour is often destroyed, the leaves do not become white, except the access of light is prevented.

The *fat* or *juicy* plants are collected by Jussieu in four orders or families, the *portulacææ*, the *ficoids*, the *succulentæ*, and *cactoides*. They are soon distinguished by their thick and fleshy leaves, their moderate height, and their perpetual verdure, often by their spines. They are natives of a hot climate, and carry in their leaves a resource against continued drought. For this reason they are soon destroyed by cold. Each leaf contains a bud, and becomes, when it drops, a perfect plant. If torn off for this purpose, the extremity must be dried before it is planted.

Climbing plants are those which, by means of their bractææ, raise and support themselves against any object: they are opposed to the *volubiles*, or creeping plants, by the latter extending themselves horizontally.

Hybrid plants are produced from the pollen of a different species. They are mules of the vegetable creation, but, unlike mules, produce fertile seeds. In succeeding years, however, the seeds lose their fertility, and the new species is usually lost. See Koelruter in the *Petersburgh Transactions* for 1782 and 1786.

Hygrometric plants are objects of singular curiosity.

The two most curious are the *calendula pluvialis* and the *sonchus sibiricus*. The flower of the *calendula*, in good weather, opens about six in the morning, and closes at four in the afternoon; but if rain is to come on during the day, *unless in storms*, it does not open. When the latter closes during the night, it will be fine weather the following day: if it continues open, rain may be expected. The *carlina vulgaris*, which grows in dry mountainous spots, has similar properties. Its flower, when open, remains dry with the stalk, leaves, and calyx, till the following year; but in moist, cloudy weather the calyx closes, and resumes its horizontal position in a dry season. In a warm chamber the calyx never closes.

Leguminous plants are sufficiently known: the common pea is an example. They are all esculent to some animals; but few are employed in our diet.

Woody plants, as opposed to herbaceous, are those whose stalks have some firmness; while the stalks of the latter never attain the firmness of wood, however soft. They are all perennial, but the converse is not true; for many perennials are not ligneous.

Medicinal plants are those employed in the cure of diseases: but there are none exclusively such; for even the most insipid plant may be useful as a demulcent or a gentle laxative. See *MINERALIA in initio* and *MATERIA MEDICA*.

Odoriferous and *variegated* plants are sufficiently known. In the leaves it is produced by weakening the plant; in the flowers, by a peculiar conduct, which the horticulturist knows, but will seldom explain. The duration is, however, temporary: the beautiful variegations of the tulip, for instance, do not appear in early youth, and in the same ground soon vanish. In the fruit it is more than an accidental variety.

The *parasitic* plants sometimes root on the tree that sustains them, sometimes in the ground, and attach themselves to the tree. The *cuscuta*, the *viscus quercinus*, the *hypocystis*, the greater number of lichens and mosses are of this class.

The *tinctorial* plants are the indigo, the carthamus, the reseda, the isatis, and some others. For the *poisonous* plants, see *VENENUM*.

Since this article was sent to the press, we have received Dr. Smith's elegant and scientific Introduction to Botany, including the Physiology of Vegetables, but too late to enable us to avail ourselves of his remarks.

PLANTA MIRABILIS DISTILLATORIA. See BANDURA.

PLANTA ZEYLANICA. See MENTHA PALUSTRIS.

PLANTA'GO, (from *planta*, from the shape of the leaves). PLANTAIN, *centinervia*, *polyneuron*, is a small perennial plant, common in fields, or by road sides; the leaves lie on the ground, have naked unbranched stalks,

bearing on the top a spike of small, imperfect, four-leaved flowers, followed by little capsules, which, opening horizontally, shed numerous crooked seeds.

PLANTA'GO LATIFO'LIA, *septinervia*, *heptapleuron*, *arnoglossum*. BROAD LEAVED COMMON GREATER PLANTAIN, WAY BREAD, LAMB'S TONGUE, *plantago major* Lin. Sp. Pl. 163, hath oval leaves, seven ribs, prominent on the lower side, running from end to end.

PLANTA'GO MI'NOR, *angustifolia quinquenervia*, *bipinnella*, *pentaneuron*, *pentapleurum*. RIB WORT, the GREATER NARROW LEAVED PLANTAIN. *Plantago lanceolata* Lin. Sp. Pl. 164, β . It hath oblong five ribbed leaves, and short thick spikes.

The leaves of each are ranked among vulneraries, and are mildly astringent; but unnoticed in the present practice. The leaves are applied to fresh wounds and cutaneous sores; and they have been given in consumptions, and profluvia. In spitting of blood the roots have been recommended by Bergius; and from three to six drachms have been given daily in the intermissions of vernal tertians. Two ounces of the expressed juice, or the same quantity of a strong infusion, may be given for a dose. In agues it should be doubled, and taken at the commencement of the fit. C. Aurelianus, according to Pliny, described the virtues of the plantago, in a separate treatise, with all the enthusiasm of a discoverer.

PLANTA'GO CORONOPUS, Lin. Sp. Pl. 166.

PLANTA'GO PSYLLIUM, Lin. Sp. Pl. 167.

PLANTA'RES, (from *planta*, the sole of the foot). See POPLITEUS.

PLANTA'RES VE'NÆ. The tibialis posterior, having descended to the sole of the foot, forms these veins, by dividing into several transverse arches, which communicate with one another and with the saphena, sending ramifications to the toes.

PLANTA'RIS ARTE'RIA EXTE'RNA, one of the divisions of the posterior tibial artery, passes on the concave side of the os calcis, obliquely under the sole of the foot, to the basis of the fifth metatarsal bone, and from thence it runs in a kind of arch toward the great toe, communicating there with the tibialis anterior, which perforates the interosseous muscles. The convex side of this arch supplies both sides of the last three toes, and the outside of the second toe, forming small communicating arches at the end, and sometimes at the middle of each toe, as in the hand. The concave side of the arch furnishes the neighbouring parts.

PLANTA'RIS ARTE'RIA INTE'RNA. A division of the posterior tibial artery, having reached beyond the middle of the sole of the foot, is divided into two, one of which goes to the great toe, communicating with the branch of the tibialis anterior; the other is distributed to the first phalanges of the other toes, communicating with the ramifications from the arch already mentioned.

PLANTA'RIS MU'SCULUS, the muscle whose tendon covers the sole of the foot, is also called *tibialis gracilis*. It rises thin and fleshy from the outer condyle of the os femoris, near its extremity, passes downward between the gastrocnemius and the soleus, is united by a cellular membrane to the tendo Achillis, and inserted into the inside of the posterior part of the os calcis, below the tendo Achillis. Winslow thinks that it is attached to the capsular ligament, and that it serves to keep it from being hurt by the motions of the joint. Dr.

Hunter suspects that it hath some action with which we are not acquainted, seeing it is always distinct; but it is occasionally wanting on both sides.

PLA'NTULA MARILA'NDICA, (a dim. of *planta*). See GENSING.

PLA'NUM, (from *πλανος*, flat). See METATARSUS.

PLA'NUM OS. See ETHMOIDES OS.

PLASTER OF PARIS; gypsum, was employed by Mr. Home in ulcers, to produce an artificial scab, but without success. It is the same as selenite, and occasionally an ingredient in MINERAL WATERS, q. v.

PLA'STICUS, PLASTIC, (from *πλασσω*, to form). An active power in nature, in the opinion of some philosophers endued with a faculty of forming; the refuge of those who wish to exclude the interposition of a Creator.

PLA'TA, (from *πλατυς*, broad). See SCAPULA.

PLA'TANUS, (from its broad leaves). The PLANE TREE. *Platanus orientalis* Lin. Sp. Pl. 1417. The leaves are large and lancinated; the flower amentaceous, formed in a globular figure, containing numerous stamina. The fruit, which is produced at a distance from the flower, is spherical; the seeds numerous, long, and apiculated, intermixed with much down. The leaves are said to cool and repel. See Raii Historia.

PLATES. Since the art of engraving has been more carefully cultivated, or at least that branch of it which represents the objects of nature, the recluse student has had many resources which he could not otherwise obtain. The anatomist can now convey the rare appearances which he has only once seen, the morbid changes, which may not again recur, and give a general, though not always an adequate and satisfactory, representation of the different parts of the human body. The natural historian can convey the discriminating form of the animal which he describes, and the plant recommended either as medicinal or salutary, as subservient to the luxuries or the advantages of mankind; the mineralogist, though with less precision, the shape of the crystal, or the general appearance of the fossil or ore. This happy art is coeval with the invention of printing; for printing was first the impression of letters, conveyed by fixed wooden blocks, on which the characters were engraved; in fact the first printed pages were wooden plates. A specimen of a work of this kind was first published by a physician, Dr. Hartlieb, in small folio, 1448. *Die Kunst Cyromantia-hatt, zu deutsch gemacht*. The earliest medical work, however, which was published from moveable types, is said to have been the *Ruralia Commoda* of Petrus de Crescentia, printed by Schlusser, in 1471: but we observe an edition of Petrus de Apono published at Venice in the same year.

The first plates were apparently botanical, published in the *Ortus Sanitatis*. The editio princeps of this work, without date or place, seems, from evident marks, to have been published at Moguntium by Schoffer of Gernzheim, one of the inventors of the art of printing. The next work of this kind was the *Herbarius*, executed at Padua in 1485, with similar rude representations of plants.

The first representations of animals, not of common ones, but collected and described with scientific accuracy, appeared in a *Dialogus Creaturarum*, by Alexander Anglicus, at Gonda, in 1480; and it was followed in 1482 by Magenberger's "Book of Nature," published at

Ausberg, and by Meydenbach's *Tractatus, de Animalibus, &c.* This last work merits particular notice, as in it was the first representation of the human skeleton.

The first distinct anatomical plates are attributed to Hundt of Magdeburg, whose *Anthropologia* was published in 1501; but the diligence of professor Blumenback has discovered plates of the viscera in the *Fassculus Medicinæ* of Ketham, which appeared at Venice in the preceding year. They were followed, seventeen years afterwards, by the plates of Hack, which, however, were only published at Strasburg in 1519. In this interval, however, Marcus Antonius de la Torre dissected bodies with care, and Leonardo da Vinci drew the forms with red chalk, laying in the bones, nerves, and vessels, with ink. These plates were never published, but are, at present, in the king's library, and Dr. Hunter speaks, with enthusiasm, of their elegance and their accuracy; though in this respect they are by no means uniform. Their era is not known, but Leonardo died about the close of the fifth century. Berengarius, about the middle of the following century, was himself an anatomist and artist; but the triumph of anatomy was the publication of the works of Vesalius, the drawings of which were executed by Titian.

Plates of mineral substances are not common. The first attempts are little more than mathematical diagrams of the general forms, or of the crystallizations; and the first attempt to give a proper display of hard bodies was, we believe, the *Conchology* of George Geve, a painter at Hamburg, in 1755; but this was soon eclipsed by the splendid *Recueil des Coquillages*, published by Regenfus under the patronage of the king of Denmark in 1758. We mention the latter, as besides the shape and relief of the shells, which are admirably delineated, we can almost distinguish their texture and hardness. Many other delineations of fossils may be noticed, but indifferently executed; and the first successful attempt was the delineation of the wood-tin, in M. Klaproth's tract, on the Fossils of Cornwall. In Jacquin's *Collectanea* we find some beautiful and correct representations of fossils; but the chief work was Mr. Rashleigh's specimens of British minerals, selected from his cabinet of Menabilly, published in 1787. They are elegantly and accurately represented; but a Supplement was executed in a very inferior manner. In some late German works we have observed similar attempts, and in the *Annales du Museum National* are some coloured plates of peculiar beauty and accuracy, particularly of the urinary calculi. Mr. Sowerby's delineation of minerals also merits considerable commendation, though by no means so highly finished as the works alluded to.

The originals of the plates in this work, and the reasons for their selection, we shall notice in a separate article at the end. We shall now shortly point out the best plates in the different branches of medicine.

ANATOMY. In osteology we have the plates of Cheselden and Le Sue, which leave us scarcely any thing to wish; and in myology those of Cooper or Bidloc and Albinus. Of the brain, the plates of Vicq. d'Ayzer are without a rival, and of the arteries of the neck, with their relative situation to the muscles, the plates of Haller give ample information. We long wanted an adequate and correct representation of the contents of the thorax and abdomen in their relative situations;

but the defect is supplied by the representations of Sandifort. The uterine system is fully illustrated by Hunter; the lymphatics by Mascagni; the nerves and arteries, in general, by C. Bell; the ligaments by Caldan; the eye by Zinn and Soemering; the ear by Du Verney and Saunders.

The changes produced by diseases are delineated in Dr. Baillie's elegant fasciculi, in the *Thesaurus* of Ruysch; and in the *Pathologia* of Haller, assisted by the numerous periodical works of the present era.

In medical botany we have the magnificent work of Plenck, and one of equal utility, though of less extent, by Dr. Woodville, assisted by various, well executed, plates in the *Linnæan Transactions*, *Annales du Museum National*, and the *Illustrations de La Marck*. The animals which afford medicinal substances are figured in Sonnini's edition of Buffon; the birds in Dr. Latham's *System*, or the *Planches Illuminées* of Buffon; the insects in the works of Olivier or La Treille, and the *Babula Naturæ* of Swammerdam. Of the minerals used in medicine we have no adequate representation.

PLATINA. (See *CHEMIA*.) It is employed in making the nicest chemical vessels, as it is with difficulty oxydated, and scarcely acted on by any menstruum. It is so ductile that it may be drawn to a very fine wire, which powerfully rests the action of heat and cold, either in elongating or contracting. It is with difficulty fused, though when purified its liquefaction is more easy. It is purified by adding to a solution of platina, in nitro-muriatic acid, potash sufficient to produce some precipitation. The remaining precipitation is effected by sulphat of potash, and the precipitate must be washed till the water no longer changes colour by adding prussiat of potash. It is then to be fused with about one and a half of its weight of soda. We have admitted its preparations with some hesitation among the *emetica nauseosa*.

PLATYOPHTHALMON, (from *πλατυς*, and *ὀφθαλμος*, the eye,) an antimonial fucus used to enlarge in appearance the eye.

PLATY'SMA, (from *πλατυς*.) A flat and broad piece of cloth, of plaster, or of metal.

PLATY'SMA MYO'IDES, (from *πλατυς*, and *μυς*, a muscle,) *quadratus genæ; detrahens quadratus; tetragonus; subcutaneus; depressor maxillæ inferioris; cutaneus musculus*, rises from the skin insensibly below the claviculæ, and is inserted into the basis of the lower jaw: it then runs up and joins the *triangularis*, and is inserted into the angle of the mouth and the skin of the cheek. It depresses the lower jaw.

PLE'CTANÆ, (from *πλεκω*, to fold). See *CORNUA UTERI*.

PLE'CTRUM, (from *πληττω*, to strike). See *TEMPORUM OSSA, UVULA, and LINGUA*.

PLETHO'RA, (from *πλεθος* plenitude). A plethora, strictly speaking, is an excess of blood; but we have already noticed the various distinctions of plethora. (See *MORBI FLUIDORUM*.) A sanguine plethora is a predisposing cause of fever, inflammation, apoplexy, or rupture of the blood vessels, if accompanied with inflammatory diathesis; but in a phlegmatic habit it is the cause of debility and languor.

There are few states of the system in which irritability is so considerable and troublesome; and it is of consequence to ascertain the existence of plethora,

since the exhibition of tonics, which are apparently indicated, greatly increases the whole train of symptoms. In such cases, a rupture of a blood vessel, if not in the head or lungs, is the most salutary event. A plethora is, in such cases, ascertained by the habits of life, the age, the sex, and temperament. It occurs chiefly in the luxurious female, whose pampered appetite prepares a superabundance of blood, whose distensible vessels yield with little resistance, and whose secretions, from inactivity, are slow and inconsiderable. The lax habits which, in weak resistance, approach the female, in similar situations equally suffer, and the phlegmatic temperaments are also overwhelmed by a load of fluids. It is the disease chiefly of youth, or from the period of 25 to 40.

The pulse, in such cases, gives but an imperfect idea of the cause. It is often apparently weak; but when pressed with firmness the current of blood is not checked. If, observes Mr. Bromfield, the artery be covered with four fingers, firmly pressed, and then the three upper fingers removed, we shall find the blood rush with some violence against the lowest which remains. In many instances, however, even this criterion fails, and we must judge from the external circumstances above enumerated.

To relieve it, when ascertained, is a task of no less difficulty. Bleeding, sometimes attended with a little temporary relief, is occasionally followed by fainting; and after a little time the former fulness, and the debility, with the irritability, are increased. Evacuations by stool, and a feebler diet, occasion faintness, and exercise is attended with intolerable fatigue. No other plans will, however, succeed, and each must be used in such a gradual, guarded manner, as to prevent uneasiness. At first a meal may be lessened, soon afterwards abridged. A feebler diet, feebler in its alimentary powers, must be slowly substituted; and the exercise, at first, in a carriage may be supplied by the tax cart, and afterwards by the horse, while the walk in a garden may be extended to an adjoining field. After the vessels have been in part emptied in this way, tonics or the cold bath may be safely used. Even when attended with phlogistic diathesis, bleeding must be only employed when apparently indispensable, and the force of the arterial system lessened by cooling purgatives, refrigerants, low diet, and active exercise.

The serous plethora is the disease of the aged, the weak, or the cachectic. It terminates in anasarca, in hydrothorax, or apoplexy. In these cases the serous, excrementitious discharges should be increased, particularly by urine and stools; the expectoration, if not sufficient, kept up; and the strength supported by a nutritious diet and wine.

See Vater *Dissertatio Causæ et Effectus Plethoræ*; Crellius *Sanguinis Jacturam frequentem, Plethoram sustentare*; Ludwig *de Plethoræ differentiis*; Fischer *de Plethora multorum morborum causa*.

PLE'URA, (from *πλευρά*, the side,) *hydropneumonias*. A membrane with which the breast is lined, and which, reflected, covers the lungs and diaphragm, as the peritonæum covers the intestines, the doubling on each side forming the mediastinum, which is close near the sternum, and more distant below. In the duplicature above, the thymus is placed. The use of the pleura is to give the contained viscera a smooth surface, and to

confine an halitus secreted by the extremities of the arteries: the mediastinum keeps the heart more fixed in the centre of the body, and prevents wounds of one side the thorax from affecting the other. The pleura is of a firm texture, with many blood vessels and nerves interspersed; subject to inflammation and abscess. See PLEURITIS and ABSCESSUS.

PLEURITICA. A PAIN IN THE SIDE.

PLEURITIS, (from *πλευρά*.) A PLEURISY OR INFLAMMATION OF THE PLEURA.

Three kinds of pleurisies are described; the true or inflammatory, the false and the spasmodic or flatulent. In Dr. Cullen's system it is a species of pneumonia, and he defines it a pleuritic pneumonia, attended with a hard pulse; a pungent pain, for the most part, of the side, increased particularly in inspiration; a difficulty in lying down on the side affected; a very painful cough, dry in the beginning, afterwards moist, and often bloody. He distinguishes four varieties. 1. *Pleuritides idiopathice simplices*. 2. *Pleuritides complicatæ*. 3. *Pleuritides symptomaticæ*. 4. *Pleuritides falsæ*.

The true pleurisy is an inflammation of the pleura, with pain and fever, in its strictest sense on that side of the membrane which lines the ribs, though frequently communicated to the portion of the membrane contiguous, which covers the lungs.

The pulse is remarkably hard, vibrating, and strong; but the pleurisy is principally known to be present by the pain in the side, with a high fever, a difficulty of breathing, and a short cough. The pain is usually just above the short ribs, increased by inspiration, and less on expiration; the breathing is consequently difficult, and the inspirations are short. The cough is short, suppressed, and in true pleurisy dry; but a mucus is sometimes spit up from the lungs, at first thin, but gradually puriform and bloody. When we have reason to think that the inflammation has extended to the lungs, and the disease has become, in the language of pathologists, the pleuro-peripneumonia.

The existence, indeed, of a pleurisy without some degree of peripneumony has, however, been doubted by Bonetus, and many of the ablest practitioners. The descriptions of almost every author combine apparently the symptoms of each, and it is by no means an easy, perhaps a possible, task to separate them. We shall add, therefore, the distinctions which have, we think, occurred to us at the bed side.

Pleurisy differs from peripneumony by the pulse being stronger and harder, the pain more acute, the inspirations shorter, and more apparently spasmodic. The face is seldom flushed; the head lies low without increasing the dyspnœa; the cough is short and quick, without any expectoration. We think also that pleurisy does not commonly leave the side to affect the biliary system, though we have suspected its translation to the pericardium. Because there is a bastard peripneumony, authors have supposed that there is a bastard pleurisy; but, in their descriptions, we see only the rheumatic affection of the muscles of the thorax.

The distinction between the pleurisy and the inflammation of the mediastinum, or of the diaphragm, is sufficiently easy from the seat of the pain; and, in the latter case, from the painful constriction, around, on breathing. Rheumatism of the muscles undoubtedly assumes at times every genuine mark of pleurisy; but

the distinction is of little importance, as the remedies are the same. Rheumatism, however, often shifts its seat to the joints, and the fever is sometimes diminished by general remedies, without any relief of the topical pain. In almost every instance also, in rheumatism, the part is sore to the touch.

We find some traces in authors of a putrid pleurisy. We cannot indeed deny the existence of such a disease; but from its general nature we think it improbable. Putrid fevers often attack with topical pains; and if these should be in the side, those practitioners who are fond of multiplying diseases may readily suppose that they have discovered a new one. To this error we must probably attribute the observation, that bleeding is sometimes injurious in pleurisy.

Pleurisy terminates, like other inflammations, in effusion, suppuration, and gangrene. The first is the most common; the last is peculiarly rare. Suppuration is most commonly the effect of that inflammation which arises from external violence; and in every instance, if we carefully attend, a fluctuation may be felt between the ribs, and the matter evacuated by a puncture or even a caustic. If the abscess bursts internally, an empyema is the consequence; so that, if symptoms of suppuration come on, the part affected should be examined with care, to solicit by poultices, or by a caustic, the evacuation of the matter through the skin. Suppuration is known to have come on by the cessation of pain, with the usual symptoms of shivering, throbbing, &c.

The causes of pleurisy are those of internal inflammation in general, viz. cold when the body is heated, particularly when partially applied. External blows and injuries undoubtedly bring it on, but a disease from these can scarcely be considered as true pleurisy, except when attended with general fever; and numerous stimulating bodies accidentally swallowed are supposed to bring on inflammation of this membrane. These causes do not, however, vary the regulations necessary for the relief of the disease.

The bad symptoms enumerated by authors are those of debility, with a livid colour in the countenance, breathing shorter though with less pain; in short those which show that a gangrene has taken place. When the pain remits, and shivers come on, we know that a suppuration is advancing; but in this case we can only attend, as we have said, with care, and solicit the pus to the surface. When this is perceived, a blister, an issue, or a caustic, will contribute to assist the external discharge. The mode we have found most effectual is, to cut between the ribs, somewhat below the point, till we form an issue, nearly through the intercostal muscles, large enough to hold a horse bean. This, covered with the blister ointment, excites a discharge in a day or two, and the matter soon passes through the wound, which, after some time, heals readily. If there be no scrofulous taint in the constitution we have never found any difficulty in completing the cure, though the case is sometimes tedious: country air, a milk diet, anodynes, and tonics, greatly contribute to the salutary event.

When we speak of the cure of pleurisy, we must be understood as meaning to treat of the pure disease, unconnected with inflammation of the lungs, an event which indeed seldom occurs; but as it sometimes happens, it is necessary to consider it separately. At the

end we shall state those circumstances of the coincidence of the two diseases which must modify our conduct.

Bleeding, in pleurisy, is so obvious a remedy, that it has been common in every age; and the measure of the evacuation required is such that, when excessive bleeding is recommended, so great as in pleurisy is mentioned as the standard. The disease was apparently more common and more violent in former ages than at present; for even the *Botallistæ*, as they are called, the followers of Botallus, are not reprehended as employing bleeding in too great a degree. The medical world were for more than eight hundred years divided in the dispute, whether the blood should be drawn from the arm of the side affected or the opposite one; and the authority, not of a college but of an emperor (Charles IX.) was called on to decide it. This singular determination, which was to quiet the minds of physicians, was prevented by an unfortunate accident; for the emperor died of a pleurisy, in consequence of being bled on the wrong side, and his successor was too much engaged in his political views to assume the office of a medical dictator. The curiosity of a subject, now almost forgotten, has led us to look into it, and our enquiries have not only been a source of some amusement but of advantage to ourselves. We shall add a short abstract of the whole.

The ancient authors, down to the era of Actuarius, where we limited the term, seem to have employed bleeding as the only remedy, even without adding the assistance of purgatives; and the blood was, in almost every instance, directed to be drawn from the arm of the side affected. The Arabians, on the contrary, seduced apparently by the Galenic doctrines of revulsion, directed the blood to be taken from the opposite side, sometimes from the vena saphæna; and they applied, for similar reasons, the cupping glasses to the legs. Yet when the violence of the disease was quieted, they certainly admitted of bleeding from the side affected. Subsequent to the revival of learning in Europe, the recommendations of practitioners have varied, but, in general, they have followed Hippocrates.

We think we perceive one circumstance which rendered the Arabian practice to be less effectual. They bled frequently, and in small quantities; for it is expressly observed, that much blood must not be taken from the opposite side, lest there should be none left to supply its place, and, of course, no revulsion could follow. The reason for bleeding in the vena saphæna, in cases where suppressed menstruation or hæmorrhoidal discharge was supposed to be the cause, originated in the idea that this evacuation would prevent the morbid matter from rising upwards. Mercurialis and Cæsalpinus have endeavoured to reconcile the opposite opinions of these different sects, but it is unnecessary to enlarge on their reasons, which are futile and unsatisfactory; nor could better arguments be drawn respecting the latter's ignorance of the circulation of the blood than from this part of his works. It may be worth remarking, that, in these authors, *è directo et æt igitur*, mean on the same side.

A circumstance suggested by Vesalius during this controversy merits some notice. In every pleurisy, whether on the right or left side, he contended that blood should be taken from the right basilic vein

Since the arteries on both sides of the ribs, except the third superior, pour their blood into the azygos, and this vein inclines to the right, it is more readily, he thinks, emptied by opening a vein in the right arm; but when the upper ribs are affected, the blood, he observes, should be taken from the left, because these vessels are connected with the left intercostal. It is singular how much this idea caught the fancy of many cotemporary and succeeding physicians, especially when the valves of the intercostal were discovered. Ematus, Salceus, Fallopius, and many others, modified, opposed, or confirmed the opinion of Vesalius, which we now know to have little real foundation.

In the course of this enquiry we have found much reason to conclude that many of the reputed pleurisies were really rheumatic affections, since the pain was felt at the origin and insertion of the muscles of the thorax; an error, however, of little consequence. We have found also several traces of a putrid pleurisy, though not described with sufficient accuracy to enable us to judge whether it was really inflammation of the pleura with a putrid fever, a severe typhus with flying pains, or a putrid peripneumony. Wierus seems to describe the last, since it attended a malignant catarrh; Gesner the second kind, since it was relieved by a gentle diaphoresis. The obscure account of Cardon seems rather to refer to mediastina or carditis. But it is time to return more directly to the subject.

We now know that *bleeding* is chiefly useful by its general depletion, and its diminishing the tone of the arterial system. In violent cases of pleurisy it is therefore useful to take off a large quantity of blood from a large orifice, and, in general, to bleed in a horizontal posture, that fainting may not interrupt the discharge. Less than eighteen or twenty ounces in a robust young man should not be taken at the first operation; and if the pain or the hardness of the pulse be not lessened, nearly as much may be drawn within the next eighteen hours. It frequently happens that it must be again repeated. Incredible are the quantities sometimes taken, with only a slight relief for a very few hours; and these very large evacuations are in strong inflammatory habits essentially necessary. Topical bleedings, with leeches or cupping glasses, are also necessary, if the pulse grows soft without any considerable diminution of the pain; but while the pulse continues hard and strong, the general bleeding must not be remitted.

Blisters are also indispensable remedies; but they should not be employed early, nor until it is found that topical bleeding will be no longer necessary. They may be placed on the part where the leeches have bit with safety; but on the wounds with the scarificator they have been applied more cautiously, lest the absorption of the cantharides should produce inflammation of the bladder. After a short time, however, a little swelling comes on in the lips of the wounds, and then they may be employed with little disadvantage. Such, however, is the violence and the rapidity of the complaint, that there is often little room for hesitation or delay.

Purgatives are spoken of by authors in terms so vague that it is not easy to ascertain their real advantage. We have not seen them produce any striking good effect; and we should suspect that they were not

remedies well adapted to this disease. To avoid irritation from the intestinal canal is always necessary.

Diaphoretics have not been employed, we suspect, with sufficient attention; and, from the analogy of this inflammation to rheumatism, as well as the little danger to be apprehended from checking expectoration, the powder of Dover, with probably camphor and nitre, may be useful.

If the *seneka* root is highly useful in this disease, as has been alleged, the advantages must arise from its united powers of an emetic, a purgative, and a diaphoretic: but emetics alone are not essentially useful; and as the *seneka* has gradually lost its credit, it is probably by no means so highly advantageous as has been supposed.

In this simple view of the cure of pleurisy it is evident that we do not include any degree of inflammation of the lungs themselves, or even of their investing membrane. In peripneumony, though bleeding is useful, and often necessary, we can neither evacuate so largely nor so repeatedly as in pleurisy, for the truly salutary discharge is by expectoration; and if the strength is too far reduced, the sputum is prevented. We may repeat that the fulness and redness of the face often distinguishes peripneumony. If this be observed; if the patient cannot breathe but in nearly an upright posture; if the cough is constant and harsh, with a slight frothy, glairy, or bloody expectoration; we may conclude that the membrane of the lungs, or the substance of the organ itself, is affected; and while we lessen the general inflammation by bleeding, we must cautiously diminish also that of the bronchial glands, and endeavour to bring on a salutary expectoration.

The bastard pleurisy is the disease, we suspect, often confounded with true pleurisy. It consists of a rheumatic inflammation of the intercostal muscles, often of the other muscles of the thorax or abdomen. The disease is distinguished by external soreness, and is relieved by bleeding and blistering. In this complaint the *seneka* is of no service.

See PERIPNEUMONIA; Sydenham's Works; Hoffmann's Med. Rat. Syst.; Fordyce's Elem. part ii.; Cullen's First Lines, vol. i. p. 311; Triller de Pleuritide.

PLEURITIS HEPATICA. A variety of pleurisy, complicated with an inflammation of the liver. See HEPATITIS and PERIPNEUMONIA.

PLEURITIS SPURIA. See RHEUMATISMUS.

PLEURITIS SPLENICA. See SPLENIS INFLAMMATIO.

PLEURODYNE, (from *πλευρα*, and *αδυνη*, pain). Pains in the pleura. See RHEUMATISMUS.

PLEURODYNE FU'GAX. See CRAMPUS.

PLEURODYNE RHEUMATICA. See RHEUMATISMUS.

PLEURO-PNEUMONIA, (from *πλευρον*, and *πνευμονια*, an inflammation of the lungs). A pleurisy combined with peripneumony.

PLEURORTHOPNEA, (from *πλευρον*, *ορθος*, upright, and *πναιω*, to breathe). A pleurisy in which the patient cannot breathe without keeping his neck erect. Blanchard.

PLEUROSTHONOS, (from *πλευρον*, the side, and *τεινω*, to stretch). See TETANUS.

PLE'XUS, (from *plecto*, to weave together,) in anatomy, a net work, or a reticulated complication of vessels or nerves. See GANGLION.

PLE'XUS CARDIA'CUS, or PULMONA'RIS, is formed of the ramifications of both trunks of the eighth pair, and their mutual communications with the filaments of the intercostal or great sympathetic nerve. It is situated above the lungs, on the fore side of the bronchiæ, and distributes nerves to the pericardium, &c. See NERVI.

PLE'XUS CHOROI'DES, *plexus reticularis*, or *retiformis*. When the fornix is cut off, and removed, we see a vascular web, called the *plexus choroides*, with several eminences which it covers. The two first are called *corpora striata*, and the other *thalami nervorum optico-rum*. The first small eminences are united; the anterior are called *nates*, and the posterior *testes*. Le Dran explains the plexus choroides to be a folding of the carotid artery in the brain. See CEREBRUM.

PLE'XUS PAMPIMIFO'RMIS. See SPERMATICA CHORDA.

PLI'CA POLO'NICA, (from *plico*, to knit together). PLAITED HAIR. *Gehena helotis*, *kolto*, *rhophalosis*, the *trichoma* of Cullen, in the class *cachexiæ*, and order *impetiginæ*; a contagious disease, in which the hairs are thicker than usual, and so entangled, that it is impossible to extricate them. This disorder is endemic only in Poland and Lithuania, and consists of several blood vessels apparently running from the head into some of the hairs, which are greatly enlarged, elongated, and closely convoluted.

When the disease impends, porrigo, phthiriasis, profuse discharges of sweat from the head, often hæmicrania, violent pains in the neck, back, shoulders, loins, and the extremities, sometimes even resembling gout, are felt. In some instances, swellings, ulcers, and exostoses, not unlike syphilitic or scrofulous appearances precede; the sight is often dim, and the nails fall off. In other cases, palpitations of the heart, delirium, mania, fevers of different kinds and types, with tingling in the ears, and even deafness, are the precursors of plica. All these symptoms disappear in a single night, and the plica comes on. In females, the predisposition to the disease sometimes appears by a large flow of the menses, and a shooting pain under the sternum. When it does not attack at once, a few locks, on the hinder part of the head, appear matted, and inclining to the thickened state. The hairs on other parts of the body are said also to be occasionally affected.

The disease is attributed to salt or bituminous water; to air confined by forests, and occasionally keen by the blasts from the Carpathian mountains; to dirtiness, or neglect of combing; to viscid or more acrid food. In no other country, however, do similar causes induce the disease. From the history given, it is evidently a critical discharge, which no other can apparently supply; and if checked, the complaint will probably return. It is said, and appearances confirm the probability of the event, that fatal hæmorrhages have been the consequence of cutting off the hair; though other authors contend that this may be done with safety.

The disease is said to be contagious, by wearing the clothes, or using the bed linen of those affected: no stranger suffers from it, unless by the most immediate contact of one labouring under the disease, even though

he has lived long in Poland. The French army, lately in that country, is said to have experienced it; and from them some information may at a future period be drawn, which we shall take an opportunity to avail ourselves of.

The cure consists in discharging the miasma by the safest outlets. As the bulbs of the hair are the organs which nature points out for its evacuation, the discharge from thence should be assisted. Warm fomentations to the head are consequently commended; and the decoctions of lycopodium, in water or beer, are said to be peculiarly efficacious. Erndteli, by a curious error, mistakes the *branca ursina* for the *lycopodium*. The warmer diaphoretics, with camphor, assisted by blisters to the back of the neck, are said to be useful; but active purgatives, emetics, and sudorifics, have been found to exasperate the disease. Though cutting off the hair is injurious, yet the spontaneous separation of the matted locks is attended with no danger. (Sennertus; Acta Naturæ Curiosorum, iii. 102. Acta Vratislaviensia, xiv. 103). Sulphur has also been strongly recommended.

See Erndetelii Warsovia Illustrata, p. 153, &c.; Coxe's Travels; Primitiæ Physio Medicæ ab iis que in Polonia and extra eam Medicinam faciunt collectæ i. 168 and 188; Philosophical Transactions, No. 256, 417, 483; Commercium Norimbergense, 1733. Tabul. iv. Fig. 4; Miscellanea Naturæ Curiosorum, Dec. i. An. 6 and 7, p. 197; Hoffmann. Epist. ad Bontokoe de Plica Polonica Vicat Memoires sur la Plique Polonoise Lausanne, 1775.

PLICA'RIA, (from *plico*, to entangle; because its leaves are entangled together into one mass). See LYCOPODIUM.

PLICA'TIO. A violent shock and bending of a long bone without fracture.

PLI'NTHIUS LA'QUEUS, (from *πληθιος*). See CIRCUS QUADRUPLIX.

PLUMBA'GO, (from *plumbum*, lead). *Plumbago*; *fer carbure* Haüy, iv. 98. BLACK LEAD. It is used for pencils, and not a medicinal substance. See CHEMIA.

Plumbago in the vegetable kingdom, is leadwort, or French dittander, because its leaves are covered with lead coloured spots. *Lepidium dentillaria dictum*; *plumbago Europhæa* Lin. Sp. Pl. 215, is a plant whose root is fibrous, pungent, and perennial; the leaves alternate and entire; the calyx hairy; the flower monopetalous, placed on spikes. It resembles the parietaria, and may be a proper substitute for it.

PLU'MBUM, (from *plumba*, because its colour resembles that of a dove). LEAD. *Saturnus*, *aabam*, *abartamen*, *accib*, *allabor*, *alomba*, *alracas*, *capricornus*, *molybdos*. Greek writers often use the same name for lead and tin; and Latin translators interpret *κασιτερος* by each term.

Lead is of a bluish white colour, but easily loses its lustre, gradually contracting a dark tinge, and at last a whiter hue. When rubbed, it has a peculiar smell, though without taste, and tinges the fingers or paper of a blue colour. Its specific gravity is 11.35, and its hardness $5\frac{1}{2}$; but neither are increased by hammering, like other metals. It is very malleable, though but slightly ductile, and not very tenacious. It melts in a heat of about 590°, and at a higher degree the metal boils and evaporates. Its crystals, when slowly cooled,

seem to be polyhedra, with 32 sides, formed by six quadrangular prisms. Water does not dissolve lead, but facilitates its oxydation by the air, and the oxyd itself is not soluble. It combines with oxygen in different degrees, and the successive oxydations are of a grey, white or yellow, red or brown colour. Lead melted in an open vessel soon affords the grey oxyd, and, if this be scraped off as soon as formed, the whole of the metal may be converted into it; but its true colour is only obtained by a gentle heat, with a slight agitation. If this oxyd is exposed for a long time to a greater heat, it becomes yellow, and is then styled *massicot*. It is singular that the white lead, obtained by corroding plates of lead by the vapour of vinegar, or precipitating nitrat of lead by potash, contains the same proportion of oxygen as the massicot, viz. 0.07. The yellow oxyd, ground to a fine powder, exposed to heat and to *flame*, with constant agitation, is styled *minium*, or *red lead*, and contains 0.09 of oxygen. Nitric acid dissolves 185 parts of this oxyd, leaving 15 of a *deep brown powder*, or, when properly prepared, of a brilliant flea colour, containing 0.21 of oxygen. When heated, it becomes yellow, and vitrifies, emitting oxygen gas; inflames sulphur, when triturated with it, and is reduced by melting on burning coals. All the oxyds of lead vitrify easily, and, *in that state*, combine with all metals except gold, platina, and silver, so that it is employed in separating these from the baser kinds. The separation takes place in a cup, made of the earth of bones, called a *cupell*, through which the vitrified lead sinks, and is recovered again in brilliant reddish scales, called *LITHARGE*, q. v. Lead combines neither with carbon, hydrogen, nor azote; but readily with sulphur and phosphorus, and most of the metals, particularly gold, platina, silver, mercury, copper, and tin. It also admits of an union with oils, see *NUTRITUM* and *EMPLASTRUM*.

The acids unite in general with lead, but the salts have not been carefully examined. They are, in general, insoluble in water, without an excess of acid; but the solutions of those which are soluble are transparent. All have a sweetish and somewhat astringent taste; and the lead is precipitated by sulphurated hydrogen and the hydrosulphuret of potash, in a black, but by the gallic acid in a white, powder. A plate of zinc, in a solution of lead, is covered with the precipitate in its metallic state. All its oxyds do not combine with acids: the white, however, unites with every acid; the brown apparently with the greater number, but its combinations have not been sufficiently considered.

The union of lead with the mineral acids is not easy nor rapid; and the salts are not used in medicine. The phosphat, the fluat, the arseniat, the molybdat, and chromat of lead are equally strangers in the medical world. The carbonat of lead is formed by the union of the carbonic acid with its oxyd; most readily by precipitating the calx from the nitrat of lead, by carbonated alkalis. It occurs, native, in large quantities, and it is the state in which the lead appears, when a white powder is formed in leaden cisterns which contain water, at the surface where it is contiguous to the metal: it contains about 15 of acid and 85 of oxyd, and is wholly insoluble in water.

The acetous acid does not attack lead in close vessels, and only oxydates it when in contact with the acid

and the air; but the oxyd is immediately dissolved as it is formed. This is the sugar of lead, the extract of saturn, and Gowlard's extract, as at present prepared. It is usually in the form of small needlelike crystals, which are four sided prisms, terminated by dihedral summits, sparingly soluble in water, unless with an excess of acid; decomposed by heat, the sulphuric, phosphoric, muriatic, fluoric, oxalic, malic, and tartarous acids, which form a salt nearly insoluble in water. The *malat* of lead is, however, soluble in the acetous, and weak nitric acids. The *lactat* of lead is soluble in water; and the *sebat* soluble in water and the acetous acid. Neumann asserts, that the acetite of lead is susceptible of fermentation, and that in consequence of it a spirit is produced.

The oxyds of lead are employed in coarse earthen ware, as glazing, from their power of sinking into the body of the ware, consequently being less subject to scale. We know of no experiments made on this oxyd. We once kept vinegar on a dish of this kind for twenty-four hours, in summer, without being able to distinguish, by the nicest tests, any saturnine impregnation. Sand is often mixed with the calx of lead, which probably preserves the metal from the action of the acid.

Lead, taken in any quantity internally, is highly deleterious to every animal: externally it is sedative, discutient, perhaps astringent. It destroys irritability, probably sensibility, and is on this account highly useful in external inflammations, in bruises, and those irritable sores which are highly painful and distressing. Internally the preparations of lead lessen the irritability of the arterial system, relieve internal hæmorrhages and spasms. Its effects, however, on the intestinal canal prevent its free and unlimited use; for by destroying irritability it produces what is termed the dry colic, or the colic of Poitou, terminated by nervous spasms, convulsions, and death. From the period when sir George Baker discovered lead in the Devonshire cider every benevolent heart caught the alarm, and so numerous were the ways by which they supposed lead might be taken, that we could scarcely eat or drink from apprehension. It would fill several pages to detail all the terrors of authors; but we shall add a specimen of their observations, with some remarks.

The diseases in the bowels, followed by palsy, which attack smelters, and the various manufacturers in works where preparations of lead are employed, plumbers, painters, and printers, are known to arise from lead; and wines, or cider, when acid and rendered mellow by the saccharine quality of the metal, may undoubtedly be injurious. It is said that the leaden dishes in which apples are pressed in making cider, communicate to the liquor a saturnine impregnation, and the consequence cannot be denied; but it is comparatively rare. If the carbonat of lead was soluble in water, or a weak spirit, we could easily imagine that the oxyd formed in the dish of a pound might be carried into the vessel, and dissolved by the carbonic acid formed during fermentation: it remains, however, to be proved whether supercarbonated lead may not be soluble in cider. Yet this is very improbable, for cider colics are rare even in Devonshire, almost exclusively confined to those who drink the harsh cider made from unripe fruit; and we know that such cider will produce the Devonshire colic

when no lead is employed in the pounds. If a salt of lead is formed in the dishes, it must be a carbonate or a malat of lead. The carbonate is wholly insoluble in water, and the malat insoluble, except in the acetous acid. Such salts, meeting with the acid of a sour apple, may undoubtedly be dissolved in cider; and if such colics arise from lead, they are produced in this way; but the various coincidences which must take place to render the cause efficacious, will show that the effect must be rare, and it is truly so. It is asserted also, by many authors of credit, that saturnine applications to wounds have produced the most violent colics, and we cannot deny it, but must add, that, by some singular fatality, surgeons of the most extensive experience in a large hospital, and no inconsiderable circle of private practice, have never met with a single case of this kind. To the effects of lead on the bowels, these benevolent and timid practitioners have added cardialgia, vomiting, dyspepsia, pains in the limbs, resembling rheumatism, hæmoptysis, terminated by a suppuration of the lungs, a metastasis of morbid matter from the hands to the breasts, in females, palpitation, anxiety, fainting, convulsions, epilepsy, gangrene, atrophy, and death. It is singular that they have not added one effect which we have often seen, viz. bilious accumulations, in consequence of costiveness. In reality, colic pains, with such accumulations, obstinate costiveness and palsy of the hands, the latter preceded often by pains in the arms, and nervous debility, are the only symptoms of this poison.

Undoubtedly the vapours of lead from the smelting houses are injurious, not only to vegetable but animal life, within the reach of its noxious effluvia; but it requires a strong faith to believe that birds of almost every kind have died from drinking water out of a dish glazed with litharge. Dogs may undoubtedly lick up the oxyd of lead from dishes of that metal, where water has long stood, but they will scarcely lick it from clothes; nor will doves suffer from eating particles of lead, chickens from drinking milk from a leaden vessel, or birds from picking seal-wax. In the human body it is equally absurd to speak of the danger of leaden pumps, leaden cisterns, the tinning by which copper vessels are covered, which contains a portion of lead or of pewter. The oxyd produced, if such vessels contain water, we know to be insoluble, and in no instance are they, we believe, employed to hold vinegar, except the tinned copper vessels, which contain lead only in the solder, and so intimately combined with bismuth as not to be affected by the acid. Milk, suffered to become sour in leaden vessels, is, we suspect, a rare occurrence; and butter in such vessels rather grows rancid than acid. Sour milk is the acetous acid, and the solubility of a lactate in water does not apply to it: we have seen, also, that even the acetous acid, when the access of air is prevented, will not dissolve lead.

The distillation of spirits through leaden tubes, and even lining the chamber which receives the oil of vitriol, when sulphur is burnt, or the lead which the ores of the white vitriol may contain, we know, from the more correct chemistry of modern times, can produce no effect on the human body, as lead will not combine with either. The metal itself has been swallowed with impunity, nor can it meet with a menstruum in the stomach, which, without the access of atmospheric air,

can dissolve it. We once heard a medical gentleman assert, that the coagulated fat which swam on the gravy of roasted mutton, on a pewter dish, contained lead, and should be taken off; and Dr. Hardy, from misunderstanding a passage of Pliny, has gravely observed that boiling cabbage in a *tinned* vessel would dissolve the lead in it. Such are the absurdities detailed when all the terrors are alive.

It is undoubtedly necessary to guard against the poison of lead with more anxious care, as its noxious quality is not betrayed by the taste like that of copper; but the properties of its salts, and the relation of the metal to the different acids, which we have anxiously pointed out, will show the folly of supposing that it can be introduced into the system in the greater number of ways described. The mode of discovering it, pointed out by ancient authors, is equally ridiculous, viz. a whiteness and sweetness in the water. The oxyd is indeed insoluble; and if suspended may render water turbid, but its specific gravity will soon precipitate it. Sweetness it cannot impart, unless combined with the acetous acid, which either in wells or in the atmosphere it cannot meet with. The water which arises from the springs in the neighbourhood of Edinburgh, after rains, used to be white and sweetish, without the slightest suspicion of lead. The Bristol waters are soft, approaching to sweetness, without any such impregnation. The best tests of lead are, however, the hepar sulphuris; the hepar antimonii; or the hepar sulphuris arsenicale, dissolved either in water or spirit. They should be used soon after their preparation, or a portion of the sulphur is deposited; and the darker fluids, as wine, should be diluted previous to the experiment. If the liquor to be tried contain chalk, or tartar, the precipitate will afford an uncertain conclusion; and the colouring matter of wines, if such has been used, will often give the appearances supposed to arise from lead only. The *liquor probatorius fortior* of Hahneman is the most certain test, and we shall add the process for preparing it.

Two ounces of acid of tartar are to be dissolved in sixteen ounces of warm water, adding two drachms of calcareous liver of sulphur, very dry, and finely powdered. These must be shaken together in a bottle for ten minutes; and after half an hour the clear fluid decanted into another bottle, which contains about half an ounce of the acid of tartar. The whole must be shaken together, and, after standing one night, decanted into small bottles, to be very carefully stopped.

The means of relieving diseases which arise from the unsuspected introduction of lead properly belongs to the head of poisons; but since they sometimes happen from using it as a remedy, it will probably be more convenient to speak of it in this place.

In what manner the lead is dissolved which is handled only we cannot say. Its absorption is assisted by heat, and it is not injurious unless from constant employment, and then only in particular constitutions. Numerous are the printers, glaziers, and painters, who have never suffered from the saturnine colic, and there are in reality few who ever experience it. The state of the metal, when it colours the hands, is not known. It seems to be an imperfect oxydation, with which we are not acquainted, similar perhaps to that state of mercury when it assumes the appearance of a black powder.

Is it an union of the metal with the electric fluid? The means of preventing it are simple and obvious. When glaziers' lead is flatted in a mill it comes out warm, and this part of his business should be always performed in gloves: indeed these should be constantly worn in every part of his work which will admit of them. The printer cannot employ gloves; but if he feels any inconvenience, it will be a sufficient preservative to wash his hands with soap and water whenever he leaves his work for his meals, and perhaps to smear them slightly with oil when he begins. The painter should have water always at hand, and wash off immediately every atom of paint which accidentally falls on it. Each will find fat meat, particularly fat bacon, in a morning useful; and occasionally, if costive, a dose of castor oil, or two ounces of olive oil, may be taken. By these simple means we have preserved the health of many who have been constantly employed in either business, and experienced repeated attacks of a colic.

When symptoms of a saturnine colic, the first effect of lead, come on, oils, mucilages, diluents, and warm water impregnated with hepatic gas, are recommended; while stools are to be procured by cathartics, particularly castor oil. Without meaning to impeach the propriety of these directions, which are sanctioned by the first names in medicine, we would only contrast the empirical practice of the Devonshire farmer, which we have known to be successful, viz. equal parts of brandy and oil of turpentine. If indeed the irritability of an organ be destroyed, an active stimulus is apparently the best means of restoring it; and if restored, milder purgatives will more certainly succeed. We have never found the oleum ricini sufficiently powerful without the aid of large doses of calomel; though the most active purgatives which have been recommended are the oil, magnesia, the bitter purging salt, and soda phosphorata (see COLICA.) We forgot to mention, when speaking of the colica Pictorum (the colic of the Picts, as Dr. Wallis wisely translated it, who added that the Picts were subject to it,) that the abdomen is usually retracted; and we lately found this symptom an important one, in distinguishing the lead colic of a glazier from a common bilious one, during an highly bilious constitution.

Lead is now almost banished from the practice of medicine as an internal remedy, and the courage of Dr. Reynolds has been spoken of with warm commendation when he ventured to order a single grain of acetated lead. We know, from experience, that it is by no means the hazardous remedy which it is generally supposed; and have given five grains two or three times a day without any disadvantage, interposing only a dose of the oleum ricini every two or three days. It was formerly given in headaches in a much larger dose, and then certainly brought on the dry colic. We strongly suspect, however, that our apprehensions have precluded us from an active remedy, though we would not recommend its use, except under the immediate inspection of an experienced, attentive practitioner.

Lead in its metallic form is rarely used, except sometimes in probes to keep wounds or perforations from closing. The ancients, however, recommended laminae of lead to be applied to the loins in nocturnal pollutions, to discuss scrofulous glands, and scirrhi, threatening

cancer, as well as to give a support to weak joints, and to compress wounded arteries. Malouin (*Chimie Medicinale*, vol. ii.) and Fernellius mention the practice of some quacks who have given small scales of lead to cure leucorrhœa, hæmorrhages, syphilis, and even gout. Van Helmont recommended small bullets in ileus, a practice which Naudeau imitated with success. We shall, as in our former articles on metals, first speak of the more usual preparations, and then shortly notice the forgotten formulæ of ancient pharmacists.

CERUSSA, or WHITE LEAD; *dulcedo saturni, aboit, affidra, arsiora, blanca, effides, pnymmithion, psilothrum*, is, as we have said, the first degree of oxydation, and usually prepared by exposing plates to the fumes of wine or vinegar, assisted by the heat of a dunghill. It is used as a cosmetic, but destroys the colour and the smoothness of the skin, injures the teeth and the constitution. It is adulterated with chalk and lime, so that the flaky masses called *flake lead* should be chosen. The weight will discover the adulteration, or the muriatic acid dissolve what chalk it may contain. If this test be not satisfactory, the lead itself may be reduced by calcining four parts of ceruse with two of fixed alkali and one of charcoal dust, and its proportion will show the purity of the suspected oxyd. This preparation was used in school of the Asclepiadæ at Rhodes, and recommended by Dioscorides, externally to destroy slight excrescences, to heal wounds, ulcers, and excoriations, and to relieve pruritus. It has been also employed in erysipelas, in discharges from behind the ears, and to check the fetid perspiration of the feet; but in each case the most fatal effects are said to have followed.

Pulvis æcerussa compositus, collyrium siccum, pulvis cerussa, is prepared by adding to five ounces of cerussa one ounce and a half of sarcocolla, and half an ounce of tragacanth. (Ph. Lond. 1788.) An improvement of the white troches of Rhazes, and used in inflammations of the eyes.

Vinegar of litharge is made by digesting four ounces of litharge, in a pint of the strongest vinegar, in a sand heat for three days, shaking the mixture occasionally. It is not essentially different from a solution of cerussa acetata, though seldom pure, as the litharge generally contains a portion of copper. When this vinegar of lead is diluted with a large proportion of water, it relieves external inflammations from burns, bruises, &c.; itching and other uneasiness in cancerous ulcers; and, before Goulard recommended it, was used for bathing inflammations of scirrhus tumours to prevent their becoming cancerous.

The acetum lythargyri was also used as a secret remedy to stop bleedings, and cure scirrhus tumours. It is said even to have cured cancers, and to have prevented impending gangrenes.

MINIUM; RED LEAD; *acastum; alumboti*. The state of the lead in this form has been already explained. Its preparation is a distinct business, and its makers melt large quantities of lead at once upon the bottom of a reverberatory furnace built for the purpose, so that the flame acts upon a large surface of the metal, which is continually changed by raking it backward and forward until the fluidity of the lead is destroyed; the calyx is afterwards only occasionally turned. Red lead

is often adulterated with red oker, which is discovered by melting it as directed for discovering adulterations in white lead, omitting the alkali.

Saccharum saturni; cerussa acetata; sal, dulcor, mel et magisterium saturni. Take of ceruse, a pound; distilled vinegar, one gallon and a half; boil the ceruse with the vinegar until the latter is saturated; then filter through paper; and after proper evaporation set it aside to crystallize. (Pharm. Lond. 1788.) Repeat the evaporation and crystallization until no more crystals are formed. The ceruse should be finely powdered before the vinegar is added; and during the boiling it should be frequently stirred with a wooden spatula. The strong acid which remains after distilling vinegar is the most useful. If the heat is considerable, the acid will be dissipated before it combines with the lead. It will be sufficient that the vinegar be hot. When the solution is exhaled for crystallization, a small quantity of rectified spirit of wine may be added.

In all the intentions of the aqua lithargyri acetati, the sugar of lead may be used; and of all the preparations of lead for external use, cerussa acetata is perhaps superior to any, for we are much more certain of the strength of this preparation than of any other. The best mode of applying it is prescribed by Mr. Bell, in his Treatise on Ulcers, edit. 3. p. 43.

Whether this salt be employed in solution, with eight parts of water, as usually directed; or with oil of turpentine, which becomes red, styled by Crollius *bal-samum plumbi*; with olive oil of camomile and water, or other liniments, it is useful in every complaint for which the preparations of lead have been recommended. The various inflammations, even the erysipelatous ones, have been, it is said, relieved by this remedy, externally applied. What comes near to this external application is its use in inflammations of the throat; and in aphthæ, applied by means of a camel hair pencil; warmly recommended by Raulin and others, though not supported by more judicious practitioners. In gonorrhœa and leucorrhœa it is used as an injection when dissolved in water, sometimes with camphor; and after a little time with vitriolated zinc. Girtanner employs it, adding to each ounce of the solution thirty drops of the spiritus nitri dulcis, in which from three to eight grains of opium have been previously combined. In OPTHALMIA, q. v. its use it well known.

In swelled testicles it is a very advantageous application; and in scorbutic ulcers, combined with opium and the white of an egg. It is highly commended in cancers; in foul ulcers; in hæmorrhages; in hysterical attacks, applied on wet rags to the abdomen; in diarrhœas, added to clysters; and in excess of lust, applied to the pubes.

As an internal medicine it has been warmly commended, and as eagerly decried; nor need we stay to enumerate the authorities on either side, since the general opinion has decided on its danger. It has been generally used in hæmorrhages, and all increased evacuations; in hectic; in gonorrhœas: in night sweats; in intermittents; in internal inflammations; in furor uterinus; mania; melancholia; hypochondriasis; headach; dropsies; diseases of the spleen; and more lately in America in chorea hystera; epilepsies, &c. Various have been its combinations for these different complaints,

and various its doses, from a quarter of a grain to half a drachm. To detail them minutely would be useless, since we cannot recommend the imitation.

Extractum saturni, aqua lithargyri acetati, is prepared by gently boiling equal parts of litharge and vinegar for an hour and a quarter. If boiled longer after its separation from the mass, it is styled an *extract*. The London college call it *aqua lithargyri acetati*, and order two pounds four ounces of litharge to be mixed with one gallon of distilled vinegar, boiled to six pints, constantly stirring, then to be set aside; and after the fæces have subsided to be strained. Pharm. Lond. 1788.

Of this a cataplasm is made by adding ʒi. of the water to one pint of rain water, and a sufficient quantity of bread crumbs to form a poultice. It is applied in local inflammation; commended in cancerous and scrofulous cases; for improving the state of unhealthy sores; and in milk tumours of the breast. Of this acetated litharge the *cremor lithargyri acetati* is formed, by adding one drachm of the water of acetated litharge to one ounce of cream; of service in external ophthalmia, applied upon linen rags. It is powerfully sedative, and useful in burns or scalds from the great degree of cold attending its application.

Cerussæ injectio composita. R. Pulv. Ceruss. comp. ʒi. zinci vitriolati gr. vi. aq. rosæ ʒiv. m.; an useful injection in the inflammatory stages of gonorrhœa.

Cerussæ linimentum cum sapone. R. Solutionis saponis ʒij. aquæ lithargyri acetati ʒi. m.; a good application for diseased joints, and for bruises with deep seated inflammation.

Aqua saturni, is called by Goulard the *vegeto mineral water*. He makes it by dropping into a quart of pure water an hundred drops of the extract of saturn, adding four tea spoonfuls of brandy. This is his specific in external inflammations, particularly of the eye, for washing ulcers, cancers, scrofulous tumours, contusions, phlegmons, erysipelas, piles, chilblains, tetters, gangrenes, &c. A solution of the cerussa acetata will probably have the same effect.

Ceratum saponis was introduced into practice by Mr. Pott, and is made by boiling gently together a pound of litharge finely levigated; a gallon of vinegar; and eight ounces of soap, till all the moisture is evaporated. To this must be added a pound of yellow wax, and a pint of olive oil, previously mixed by melting, and the whole must be assiduously stirred from the beginning. It is a convenient and useful dressing for fractures and ulcers; and is nearly the same as Marshall's cerate, though we shall approach nearer to it in another preparation.

From the proofs of the fondness of the ancients for the preparations of lead already given, it will be expected that the ancient formulæ, particularly the external ones, will be numerous. We were indeed surprised at the extent of our list, but shall abridge our account so far as will be consistent with a sufficiently exact and comprehensive view of the subject; and for the sake of perspicuity shall divide those, not already noticed, into oxyds, salts, solutions, plasters, and ointments.

Oxyds. The *magisterium plumbi vel saturni* is the white calyx, precipitated from the saccharum by spirit of wine, more frequently by potash. When vitriolic acid is employed it forms a vitriolated lead; when the

muriatic, a muriated lead, then styled *lac plumbi*. Each is recommended in phthisis, in stomach complaints; even in iliac passion and scirrhus of the liver: but at present both are neglected.

Precipitatum saturni is only the lead precipitated from the extract by dilution. It is used as a cosmetic, particularly in the little eruptions on the eyelids.

Plumbum ustum is prepared by adding a sixth part of sulphur to the lead, and calcining them together. It contains consequently some portion of the vitriolic acid; is of a grey colour, and was used in the age of Dioscorides. The *plumbi cineres* which have often the same appellation, and are used in a saturnine plaster, are prepared by merely roasting lead, without any addition. The *scoriæ argenti* contain chiefly lead, and are used with the same intention as the other calces of this metal.

SALTS. *Extractum saturni* is only the vegeto-mineral water, deprived of all its fluid. The *spiritus saturni*, or as sometimes called, *oleum saturni*, is the vinegar expelled from acetated lead by the strongest force of fire. It first comes over in a thinner, afterwards in an oily, form; at first yellow, and next of a darker colour. It seems to possess only the virtues of a very strong vinegar. It was formerly recommended in lepra, scabies, lues, and melancholia; but has apparently no peculiar virtue. Crolius gave three drops of the oil, mixed with wine, in colic.

Nitrum saturninum is prepared by dissolving three parts of nitre with two of acetated lead, and crystallizing the solution. It seems to be an astringent; is recommended in hæmorrhages, and by Schroeder in asthma. There is apparently little reason to suspect any decomposition, and the salts seem to crystallize together. If a double elective attraction takes place, the result will be nitrat of lead and acetated postash. If the preparation is so highly astringent as its admirers represent, this may be the case.

SOLUTIONS. Acetated lead in a fluid form* occurs under different titles. The *acetum saturni*, in old pharmaceutical authors, has sometimes a small proportion of nitrous acid added; and, combined with a little of the camphorated spirit, has been recommended as a clyster in diarrhœa. The *acetum cerussæ*, and *acetum minii*, sometimes called *tinctura minii*, are similar preparations. The latter is ordered by Salchow in a dose of four drops, four times a day, in a case of gonorrhœa, while the vegeto-mineral water was constantly applied to the testicle, which at the same time was swollen.

The *extractum saturni* of Janin is made by evaporating the acetum lythargyri to the consistence of a paste. Two parts of this extract are then diluted with sixteen parts of warm water, and the whole kept in well stoppered phials. It is supposed to be superior to Goulard's extract in inflammations of the eyes; and when used, four drops of the extract, with three of camphorated spirit of wine, are added to an ounce of water.

Goulard's extract is also an inspissated vinegar of lead, again reduced to a fluid form by the affusion of water. It is only used in this state, except when the author seems to have applied it of a thicker consistence, approaching that of a plaster, to an inflamed tumour of the breast. The extract is employed in all cases where the acetated cerussa has been recommended; and when joined with one third of oil of turpentine, one half of axunge (of a hare), and one forty-eighth of petroleum,

has been applied with success to scrofulous swellings. Added to the extracts of hemlock, henbane, and opium, it is said to have relieved swelled testicles. Bell has recommended it in prolapsus of the iris, as well as in scrofulous, spongy, and torpid ulcers. An anonymous German author speaks of it in terms of commendation, when joined with soap, and applied to cancers; and with aromatics to tumours of the arm. In fomentations, with warm astringent decoctions, it is said to relieve incontinence of urine from a debility of the sphincters, phymosis, paraphymosis, ulcers of the penis, and bubos.

The vegeto-mineral water of Goulard is only the diluted extract, with a double quantity of spirit of wine, that is, double the quantity of the extract. It is recommended in almost every disease already mentioned, and many others, particularly in erysipelas from an external cause; burns of every kind; the bites of insects; gun shot wounds; prolapsus of the rectum; incarcerated hernia; venereal complaints; sinous ulcers; ozæna; fistula lachrymalis; and tumours either glandular or of the joints. Other authors confirm, in part, the various virtues of this fluid; and Salchow adds, that pains in the teeth are relieved by rinsing the mouth with a diluted solution of it, and even gouty pains alleviated. Goulard recommends from twelve to fifteen drops, diluted with a measure of water, in heat of urine, an involuntary discharge of semen, gonorrhœa benigna, and even dysentery.

The *lac virginis* is the same as the *lac plumbi*, formerly mentioned, viz. the acetum plumbi, from which the lead is precipitated by means of alum, or common salt. The *fisoricum Galeni*, whose use is known from its title, is a solution of lead with double its weight of chalcitis, a vitriolated iron, or an oxyd of iron, in vinegar. The *oleum saturni* is made by dissolving the saccharum saturni again in vinegar, crystallizing it, and suffering the crystals to deliquesce in the air. The *tinctura antiphysica* was not long ago in an Edinburgh dispensatory, but deservedly neglected. It is an useful astringent, but owes its virtue to the salt of iron, for the lead is almost completely precipitated.

PLASTERS. These are uncommonly numerous, for preparations of lead have been added to plasters of almost every kind, since the time of Dioscorides. A list of the titles only would be unsatisfactory, and to describe the formulæ would be tedious, for near eighty different plasters have been enumerated. We shall omit them also for another reason. In the form of a plaster the lead is so intimately involved with the wax and oil, that it scarcely exerts its peculiar powers; and by far the greater number owe their utility to the other ingredients.

THE OINTMENTS, including the CERATS, exceed forty, but we shall only enumerate a few of the most important. The *unguentum è cerussa acetata*, the *nutritum*, and the *ceratum saponis*, have been already noticed.

The *unguentum ad ambusta* of Juncken contains cerussa, camphor, powder of olibanum, and oil of roses, with the white of an egg; but that of Jurine is more neat and effectual. A drachm of litharge is dissolved in an ounce of olive oil, to which is added an ounce of wax, and a scruple of opium. In lax, spongy ulcers, the proportion of litharge is increased; and in case of violent pains that of opium is larger. The *unguentum apostolorum* of the Wirtemberg pharmacopœia contains turpentine, with a numerous host of resins and

gum resins of a tendency opposite to that of lead. Bar-bette's *unguentum ad cancrum ulceratum* is rather an astringent preparation than a saturnine. The union of the lapis calaminaris with lead is not uncommon; and the *unguentum à lapide calaminario* of the Swedish, the *desiccativum rubrum* of the new dispensatory, *unguentum de tutia* of Juncken, *unguentum fuscum* of Wurtzius, and *griseum* of Juncken; are of this kind. The *unguentum hæmorrhoidale noricum*, as well as that of *Wedelius*, each contain camphor added to the calces of lead; and in the former is also a proportion of opium. The *unguentum à minio camphoratum* of the Wirtemburgh dispensatory is a similar formula, but containing a larger proportion of lead in different forms; very nearly resembling *Marshall's cerate*. The *unguentum mundificans* of Stahl is made by amalgamating lead with quicksilver in equal parts, to which is added the terra tripolitana, and the unguentum album camphoratum. The *unguentum ad ophthalmiam siccam* of Senertus contains litharge, camphor, and aloes: it is applied on the eyelids, chiefly in ophthalmia tarsi. Numerous are the *unguenta ad scabiem* which contain lead. In that of the Wirtemburgh dispensatory we find also styrax, oil of laurel, and mercurius precipitatus albus; in that of Schroeder, turpentine, common salt, and sulphur; in Juncken's turpentine, styrax, common salt, and juice of lemons.

The *cerats*, as the name implies, are of a greater consistence than the ointments, and for the reasons before assigned probably less useful. The *ceratum à minio*, however, of the Wirtemburgh pharmacopœia, contains camphor; and is said to be highly useful in burns, in inflammations, and in the troublesome suppurations which sometimes arise from blisters. The *ceratum saturninum* of Goulard contains one part of his extract, four parts of yellow wax, and four parts of expressed oil. If a portion of the zincum ustum be added it is said to be more efficacious, and the most fetid ulcers to have been cured by it; taking internally small doses of muriated mercury, or drinking freely of an infusion of malt. Cerated linen spread with a plaster composed of extract of lead, camphor, and wax, are said to be useful in rheumatic and gouty pains; as well as in tumours of the head, from external violence, buboes, and chilblains.

From the very extensive list of saturnine applications employed from the time of Galen to the present moment a fair inference may be drawn, that the external application of lead is not injurious to the constitution in general. Dr. Percival, Stoll, and some others, contend, that it has been occasionally so; and Tode, with a long list of authors on the opposite side, with the consent of the experience of more than 2000 years, declare their innocence. When we add the reflections already suggested, that, even applied to the stomach and bowels, it is less deleterious than has been generally supposed, perhaps imaginary terrors respecting its application will cease.

We may now enlarge a little more fully on its action. All the metals, we have said, are tonics, though we have reluctantly excepted lead. Yet when we consider the various tonics which we employ, we shall find room for suspecting them to contain a narcotic quality. The Portland powder, which was long continued, showed a strong narcotic power; and all bitters, if not occasionally remitted, seem to impair the tone they

were intended to restore. May not then tonics act chiefly by repressing irritability; for though irritability originates in weakness, its continuance leads to its exhaustion? If lead then checks irritability, it may be considered as possessing, in one view, a tonic power; and of course not to differ from the other metals. If then, as we have said, iron is a tonic possessing an inflammatory stimulus, lead, on the other hand, may be such, combining also a power purely sedative. The discussion we must, however, resume, vide TONICA.

Can then its tonic power be obtained without its sedative? or can its sedative effects be procured without endangering the destruction of irritability in the intestinal canal? These are questions which we dare not answer fully, lest we should lead to dangerous, unwarrantable experiments. In the course, however, of this enquiry we have been led, from occasional facts recorded or incidentally mentioned, to think that the combination of mercury, perhaps of iron, may counteract its sedative power; and, from our own experience, we know the interposition of oily medicines will probably preserve the intestinal canal from injury. The stimulus of many spices are confined to the alimentary canal only; and these interposed may perhaps prevent injury from lead. Such reflections may lead to a cautious trial; for a medicine so active, and which, with proper management, might prove so salutary, should not be neglected from imaginary apprehensions, or resigned till it clearly appears that no corrector can be discovered.

See Numann's Chemistry; Cullen's and Lewis's Materia Medica; Goulard's Treatise on the Effects and Various Preparations of Lead; Aitken's Observations on the External Use of Preparations of Lead; Bell on Ulcers, edit. 3. p. 36; London Medical Transactions, vol. i. p. 257.

PLU'MBUM NIGRUM. BLACK LEAD; *fabrilis nigrica; ochra nigra; wadt*. It hath none of the properties of common lead, except that of colouring in drawing lines. It is not now used in medicine, though formerly reckoned drying and repellent. Strictly speaking, in modern mineralogical language, it is phosphorated lead; but PLUMBAGO, q. v. is really meant.

PLU'MBUM CANDIDUM. See STANNUM.

PLU'MBUM CINEREUM. See BISMUTHUM.

PLU'MBUM RUBRUM. See ADROP and PLUMBUM.

PLUMME'RI PILULÆ. PLUMMER'S PILLS. Levigate calomel, and the precipitated sulphur of antimony, of each two drachms, together; add three drachms of the gum, and one drachm of the resin of guaiacum; mix them well, and make them into a mass, with the balsam capivi.

These pills, Dr. Plummer, in the Edinburgh Medical Essays, recommends in spots, pimples, and flushing in the face, virulent gonorrhœa, sciatica, rheumatism, lues venerea, ulcers with pains and swellings in the feet, scrofulous disorders, &c. The combination is undoubtedly an useful one; but too long continued triture renders the calomel less active. The ingredients should be rubbed slightly together; and we have sometimes directed the calomel to be beat in after the mass was made. Indeed their uses are the same as those of the ÆTHIOPICÆ PILULÆ; q. v.

PLU'MULA. A LITTLE FEATHER; (a dim. of *pluma*, a feather). See CORCULUM.

PNE'UMA, (from *πνέω*, to breathe). SPIRIT, AIR,

VAPOUR, or the BREATH. (See ANHELATIO.) It is also the appellation of a water called *scythiscus latex*.

PNEUMATICA. When the existence of an air, peculiarly pure, adapted to preserve life and flame for a much longer period than the atmospheric, was discovered, it was at once supposed that the universal medicine, so long sought, was found; and the sanguine expectations of physicians were still farther raised, when it was shown that it combined with the blood in respiration, giving it a more brilliant hue. Oxygen gas was consequently soon employed in various cases, particularly in hectics; but it was generally injurious, and appeared to increase the florid complexion, and the feverish heats, with all their distressing consequences. In fact it was soon found that this portion of the atmosphere, though necessary to support life, required to be lowered in its powers to prevent its too great stimulus; and we have at last discovered that the azote, the supposed injurious part of our atmosphere, contributes to some important functions, already hinted at, viz. the animalization of the nourishment taken in.

Yet the prospect was too fascinating to be relinquished, and the rapid discovery of various other gases kept expectation alive, and fed with delusive hopes the anxious expectations of the sufferers, and their sympathizing friends. We fear that the injudicious eagerness of some practitioners has contributed to render the disappointment still more painful, and the interested selfishness of others has prevented the discovery of the truth, by withholding the different facts necessary for its development. From the present state of our knowledge, little can be expected in medicine from the employment of factitious airs. We shall, however, shortly notice what experience has fairly shown, and point out those cases where expectations may still be fairly entertained.

The *oxygen gas* is highly stimulant, and, when frequently breathed, increases the irritability of the arterial system, often its tone. In still larger quantities it exhausts irritability, and acts like all stimuli in excess. Yet perhaps it has not been sufficiently tried in combination with air of a lower quality, particularly with carbonic acid gas, or in cases where the irritability of the system is too much diminished, as in chlorosis, scurvy, the cutaneous diseases of old age, in scrofula, &c. In some of these diseases the oxygenated salts appear to be useful medicines; and somewhat may be expected from breathing oxygenous gas, since dry elevated situations are often adapted to such complaints. Oxygen gas should be diluted with perhaps twenty times its quantity of common air, even in cases of diminished irritability, and with twice as much in others.

Carbonic acid gas has not been found efficacious in complaints for which pneumatic medicine has been employed, we mean in phthisis; nor has the air in the neighbourhood of lime kilns appeared particularly salutary, where this gas is copiously mixed with the air of the atmosphere. In other forms it has been found useful. From fermenting poultices it has acted apparently as a powerful antiseptic; thrown on foul ulcers, and occasionally on cancers, it seems to correct the fœtor and amend the appearance of the discharge; and similar effects have followed from washing them with water impregnated with this gas. Internally, in the form of yeast, it is said to correct putrid acrimony in the bowels.

The effects of the super-carbonated mineral waters in strengthening the stomach, and correcting symptoms of dyspepsia, have been frequently noticed.

The *hydrocarbonate* is prepared by decomposing water by means of hot charcoal. Its immediate effects are to produce vertigo, and it should be diluted previous to its exhibition, by about thirty times its quantity of common air. It renders a strong pulse more weak; but if the pulse be previously weak from disease, it will after some time render it slower and firmer, should its effects be salutary. It is said to be useful in hectics; but has not, we suspect, been tried in other complaints. It appears to be in general sedative, and occasionally narcotic; nor are its effects in hectics very different from those of digitalis. We are sorry to be obliged to add that we have never found it peculiarly advantageous.

Hydrogenous gas. The inflammable air of former authors, has had no fair trial as a medicine. Air of a lower temperature, and near marshes, where this peculiar gas appears to reside, is found useful sometimes in hectics, occasionally in asthmas. It has not probably been used in medicine, because it could not be breathed with safety, unless combined with oxygen; and in that state would be subject to explode. We do not recollect this union having been mentioned but by one author, who, speaking of the want of medical enterprise, observed, that if by the electrical spark such explosions were produced within the body, he knew "not what would be the consequence." In this opinion we cordially acquiesce.

Azotic gas. The mephitic air has been considered as so inimical to life, that we believe it has not been tried; but this gas, with a small proportion of oxygen, forms the *nitrous oxide*, which is said to act as a most pleasing stimulant, whose effects arise almost to intoxication without any subsequent languor. This air has not, however, been the subject of any experiments as a medicinal substance, so far as our information extends.

On the whole, perhaps, physicians were too much elated by the first discovery and the prospects it held out, and too soon disappointed by want of success. Much still remains in this department of medicine for a cautious trial. Yet we fear expectation may be again frustrated; for hitherto we have gained little by pneumatic medicine. It may be useful to add that Mr. Watt has contrived convenient portable apparatuses for these purposes, and has added suitable directions for using the different gases. See **AER**.

See Cavallo, on Factitious Air; Dr. Beddoes' Works; and Dr. Thornton's Communications on Pneumatic Medicine, in the Medical and Physical Journal, passim.

PNEUMATOCE'LE, (from *πνευμα*, wind, and *κηλη*, a tumour,) *hernia flatulenta* and *ventosa*; *pneumatosis*. A FLATULENT HERNIA, or WINDY RUPTURE, contains wind only in the herniary sac; but it is very rare. In some putrid fevers, in the small pox, and gangrenes, some parts of the skin frequently crackle like parchment under the finger; and in a very corrupted state of the fluids pneumatocele may be formed. Mr. Bell observes that the term is sometimes confined to a distention of the scrotum by a collection of air. This hath been described by ancient writers as frequent; but all the tumours they describe as containing air were watery or true hernias. That species of hernia to which young children are liable is commonly termed a wind

rupture, as well as the collections of water in the scrotum of new born infants. In wounds of the lungs, air is sometimes extravasated into the surrounding cellular substance, passing into the scrotum, and over the whole body; and in highly putrid diseases air may be separated from the blood, so as to distend the cellular substance of the scrotum, as well as of other parts; but a real pneumatocele has never, probably, existed as a mere local affection of the scrotum. In the case of air diffused into the cellular substance, in consequence of a wound of the lungs, small punctures with the point of a lancet are found to be sufficient for evacuating it. But whenever the disease is induced by such a degree of putrescency as will separate air from the blood, a plentiful use of antiseptics and corroborants is indicated; but the disease will scarcely yield to them.

Mr. Pott positively asserts that there is no tumour of this kind, and in this situation, in a living animal: it is indeed particularly described by many writers, both ancient and modern; but the complaint is either a true intestinal hernia, or a species of hydrocele, frequently a tumour produced by a small quantity of fluid remaining in the lower part of the tunica vaginalis, after its communication above with the cavity of the belly is closed; and a true, but a small, intestinal hernia.

Some late writers mistake the encysted hydrocele of the tunica communis, which connects the spermatic vessels for the wind rupture; though it differs from the wind rupture in its situation: but if the encysted hydrocele of the tunica communis is accompanied with an hydrocele of the tunica vaginalis, or with a true hernia, the case is with difficulty ascertained.

See Bell's System of Surgery, vol. i. p. 496; Parey's Works, vii. 16, 17; Pott's Chirurgical Works, quarto edit.; Cullen's First Lines, vol. iv.; Morgagni de Sedibus, &c. xliii. 35.

PNEUMATO'SIS, (from *πνεύματω*, to inflate,) is considered as a genus of disease including complaints which arise from air in any cavity. It contains the *pneumatoxis spontanea*, which arises without any evident cause, but usually from the separation of air in consequence of putrefaction; the *p. traumatica*, from a wound in the lungs, which suffers the air to escape into every part of the cellular substance; *p. venenata*, from poisons (see **VENENUM**); and *p. hysterica*, when the air is confined in the stomach and intestines. See **EMPHYSEMA**, **PNEUMATOCELE**, and **GASTRODYNIA**.

PNEUMATO'MPHALOS, (from *πνεύμα*, and *ομφαλος*, the navel). See **HERNIA UMBILICALIS**.

PNEUMO'NIA, (from *πνεύμων*, the lungs). An inflammation of the lungs, or its containing membranes. Dr. Cullen places this disease among the *phlegmasiæ*; defining it a febrile affection, attended with pain in some part of the breast, difficulty of breathing, and cough. The species are,

PNEUMO'NIA PERIPNEUMONIA. See **PERIPNEUMONIA**.

PNEUMO'NIA PLEURITIS. See **PLEURITIS**.

PNEUMO'NICA, (from the same). A sense of weight, or a load on the chest.

PODA'GRA, (from *πῦς*, a foot, and *αἴμα*, pain). See **ARTHRITIS**.

PO'DEX, (*à pedendo*, from breaking wind). The **FUNDAMENT**. See **ANUS** and **PRURIGO PODICIS**.

PODOPHY'LLUM PELTA'TUM, (from *πῦς*, a

foot, and *φυλλον*, a leaf, from its shape). See **ANAPODOPHYLLUM**.

PODOTHE'CA, (from *πῶς*, and *τιθημι*, pono). See **CHIROTHECA**.

POEGE'REBA. See **CORTEX POGEREBE**.

PO'HUN WATERS. See **SPAÆ AQUÆ**.

POINCIA'NA, **FLOWER FENCE**, *poinciana bijuga* Lin. Sp. Pl. 544; *frutex flavoninus*; *crista flavonis*; *acacia orbis American*, &c. grows in the east and West Indies: its seed pods, infused with galls, afford the best black ink; but no part of the plant is medicinal. See **Raii Historia**.

POLE'NTA, (from *pollen*, flower). See **ALPHITON**.

PO'LGAHA. See **PALMA COCCIFERA**.

PO'LIUM, (*πολιος*, white, from its white capillaments). *Teucrium* Lin. The two following have been noted in medicine.

PO'LIUM MONTA'NUM LUTE'UM, **SMALL UPRIGHT POLEY MOUNTAIN**; *teucrium polium* Lin. Sp. Pl. 792, α, is a small plant, with square stalks, oblong woolly leaves set in pairs, and labiated flowers.

PO'LIUM CRE'TICUM, *rosmarinum stæchadis facie*; *teucrium frutescens*; *t. creticum* Lin. Sp. Pl. 788; **TREE GERMANDER**; **POLEY OF CANDIA**. The leaves are set on short pedicles, not indented; the flowers stand in loose clusters, each on separate foot stalks.

The leaves and tops of each have a moderately strong aromatic smell, and disagreeable bitter taste. Distilled with water, they yield a small quantity of yellow essential oil; and the extract is very bitter. The leaves and tops are said to be corroborant, aperient, and antispasmodic. See **Lewis's Materia Medica**.

PO'LLEX, **THUMB**; *quod vi polleat*, because in power and strength it is superior to the other fingers. See **DIGITUS**.

PO'LLEX PE'DIS. **THE GREAT TOE**.

POLLINI'CIO. See **CONDIO**.

POLYADE'LPHIA, (from *πολυς*, many, and *αδελφει*, brother). The name of the eighteenth class in the Linnæan system; comprehending those plants which bear hermaphrodite flowers, with three or more sets of united stamens.

POLYA'NDRIA, (from *πολυς*, and *ανηρ*, a husband). The name of the thirteenth class of the Linnæan system, comprehending those plants which bear hermaphrodite flowers, with many stamens, from twenty to a thousand, growing single on the receptacle. The number of the stamens distinguishes this from the first eleven classes; their situation on the receptacle separates it from the twelfth class, *icosandria*; and their simplicity avoids all confusion with the sixteenth and eighteenth classes, *monadelphia* and *polyadelphia*.

POLYCHRE'STUS, (from *πολυς*, much, and *χρηστος*, useful). An epithet of several medicines, assigned to them for their extensive utility.

POLYCHRE'STUM, (from *πολυς*, and *χρηστος*, useful). See **GUAIACUM**.

POLYCHRE'STUM SAL. **SALT OF MANY VIRTUES**. See **NITRUM**.

POLYDI'PSIA, (from *πολυς*, and *διψα*, thirst). See **SITIS**.

POLYGA'LA, (*πολυς*, and *γαλα*, milk, from the quantity of its milky juice), *ambarvalis flos*; *amarella*; *polygala lutea* Lin. Sp. Pl. 990, **COMMON BLUE MILK-WORT**, is a small perennial plant, with the leaves

alternate, uncut, and those on the upper parts of the stalk larger than those on the lower: the flowers are irregular, tubulous, tripetalous, labiated, set in loose spikes on the tops, the cup composed of five leaves, the two larger of which continue after the flower hath fallen, and embrace, like wings, a flat bicellular seed vessel. The stalks of this common sort are procumbent; the lower leaves are roundish, the upper oblong, narrow, or pointed; the flowers are blue, purplish, or red; sometimes white, with a kind of fringed appendix on the lower lip; the roots are slender and hard. It grows wild in dry pastures, and flowers in July. The roots are similar in taste to the seneka, and said to have, in a less degree, the same effect in pleurisy.

POLYGA'LA SE'NEGA, and MARILA'NDICA. See SENEGA.

POLYGA'LA I'NDICA MI'NOR. See COLINIL.

POLYGA'LA VERA, *polygala major massiliotica*; *colutea caule genistæ fungoso*; *polygala vulgaris* Lin. Sp. Pl. 986, α. MILK-VETCH, used in infusion for increasing the milk.

POLYGA'LA AMARA, Lin. Sp. Pl. 987, is a narcotic bitter, and, like many others of this class, has been employed in phthisis pulmonalis, but with the usual success.

POLYGA'MIA, (from *πολυς*, and *γαμος*, *nuptiæ*). The twenty-third class in the Linnæan system, comprehending those plants which bear hermaphrodite flowers, together with male or female flowers, or both. This term, applied to a single flower, regards the intercommunication of its flosculi, as in the first, second, third, and fourth orders of the class *syngenesia*.

POLYGA'MIA FRUSTRA'NEA, (from *frusta*, to no purpose). The third order in the class *syngenesia*, comprehending such of the compound flowers as have perfect florets in the disk, producing seed, but imperfect ones in the ray, which are barren.

POLYGA'MIA SUPER'FLUA. The second order in the class *syngenesia*, in which the florets of the disk are hermaphrodite, and fertile; those of the ray, though female only, fertile.

POLYGONA'TUM, (*πολυς*, and *γων*, a joint; from its numerous knots or joints.) *Sigillum Solomonis*; *convallaria polygonatum*, Lin. Sp. Pl. 451, is a plant with unbranched stalks, oval, narrow leaves, ribbed like those of plantain, generally all on one side; on the other side hang oblong monopetalous white flowers, two or more together, on long pedicles, followed each by a black berry; the root, the part used, is white, thick, fleshy, with several joints, and some flat circular depressions, supposed to resemble the stamp of a seal. It is perennial, grows in woods, and flowers in May. The roots are said to be astringent, incrassant, and corroborant; if bruised and applied as a poultice, it dissipates the black colour from contusions. See Raii Hist.

POLY'GONUM, (from the same). KNOT GRASS; *calligonum*, *centinodia*, *carcinethron*, *corrigiola*; *polygonum aviculare* Lin. Sp. Pl. 519. The root is creeping and fibrous; the stalk and branches full of joints; the stalks recline towards the earth, are smooth, finely channelled, slender, and branched, full of knots or joints, from which grow long, oval, sharp pointed leaves. The root is cooling, astringent, and hath been used against internal hæmorrhages; externally against inflammations. See Raii Historia.

POLY'GONUM BISTORTA. See BISTORTA.

POLY'GONUM PERSICARIA. See PERSICARIA.

POLY'GONUM MINUS. See HERNIARIA.

POLYGY'NIA, (from *πολυς*, many, and *γυνή*, a woman). A class of plants, in whose fructification there are many pistils, the female organs of generation.

POLYMERI'SMA, (from *πολυς*, and *μερος*, a member). Supernumerary limbs or parts.

POLYMO'RPHOS, (from *πολυς*, and *μορφη*, a shape).

MULTIFORM. See SPHENOIDES OS.

POLYNEU'RON, (from *πολυς*, and *νευρον*, a string). See PLANTAGO.

POLYO'STEON, (from *πολυς*, and *οστέον*, a bone). The METATARSUS, which consists of many bones.

POLYPE'TALUS, (from *πολυς*, and *πέταλον*, a flower leaf). MANY LEAVED. See PETALA.

POLYPHA'RMACOS, (*πολυς*, and *φαρμακον*, a medicine; from its various uses). See POLYCHRESTOS.

POLYPHY'LLUS, (from *πολυς*, and *φυλλον*, a leaf). Having many leaves.

POLY'PODES, (from *πολυς*, and *πους*, a foot). See ASELLI.

POLYPO'DIUM, (from the same; on account of its numerous ramifications resembling a polypus. POLYPODY. *Polypodium vulgare* Lin. Sp. Pl. 1544, α, is a fern with long leaves issuing from the root, divided on both sides, down to the rib, into a number of oblong segments, broadest at the base; it hath no stalk or manifest flower; the seeds are a fine dust, lying on the backs of the leaves, in roundish specks, disposed in rows parallel to the rib; the roots are long and slender, of a reddish brown colour on the outside, greenish within, full of small tubercles, supposed to resemble the feet of an insect. It is an evergreen, grows in the clefts of old walls, rocks, and decayed trees. That produced on the oak is usually preferred, though not superior to the other sorts. It yields its virtue both to water and spirit; but the spirituous tincture is the sweetest, though the spirituous extract is only astringent. The leaves have a weak, ungrateful smell, a nauseous sweet taste, a roughness, and a slight acrimony. Its virtues are those of the fern; but it has been lately given in mania, though with little success, and is frequently used in the catarrhs of old people, as, like the fern, it unites a slight astringency with its demulcent qualities. The ancients supposed it to be a purgative, and peculiarly fitted to discharge pituita. They therefore depended on it in cases of melancholia.

POLYPO'DIUM TE'NERUM MI'NUS, *filix querna repens*, *polypodium dryopteris* Lin. Sp. Pl. 1555, OAK FERN; grows in marshy places. If the root is bruised, and applied to the skin, while sweating, it is said to take off the hair.

POLYPO'DIUM FI'LIX FEMI'NEA. See FILIX FEMINEA.

POLYPO'DIUM ANGUSTIFO'LIUM, *lonchitis aspera*, *filix foliis polypodii*; *polypodium lonchitis* Lin. Sp. Pl. 1548. ROUGH SPLEENWORT, grows in rough, uncultivated places. The root is aperient and diuretic.

POLYPO'DIUM FI'LIX MAS. See FILIX MAS.

PO'LYPUS, (from *πολυς*, and *πους*, foot,) *multipes*, MANY FEET. Under this title animals the most dissimilar are arranged; but at present we confine ourselves to the first class of the molluscæ, the coriaceous. (See MOLLUSCA.) Their characters are, a projecting head, a

fleshy body, covered with a coriaceous sac, or case, breathing by branchiæ, sexes separate, generally inhabitants of the sea, but sometimes found in rivers. The name conveys an erroneous idea, for the animal swims, and what have been styled feet are rather tentacula, or arms; and indeed very powerful ones, if, as we are told by Pliny, Ælian, and Aldrovandus, they can draw down and sink the tallest vessels. They are carnivorous, and falsely said to devour, from want of food, their own arms. Polypi are, however, chiefly remarkable as the connecting link between the animal and vegetable kingdoms, since, like plants, they are propagated by cuttings; and, as the cause of the greatest revolutions of the globe, we allude to the formation of new islands and continents, by some species of these minute animals which inhabit and produce corals.

It is not generally known that polypi were luxuries at Greece and Rome, considered also as highly nutritious and aphrodisiac. Machon's Epigram on Philoxenes is quoted by Athenæus. The poet is supposed to be dying of an indigestion, from eating almost a whole polypus, and having bequeathed his poetry, &c. concludes,

*Ut omnia mea abiens hinc auferam
Date mihi quicquid relictum est polypi.*

In the French imitation the fish is the sturgeon, and in the English, the jowl (of salmon). The jest was too good to be lost.

The Romans were particular in fattening it, and nice in their management. It discharged spontaneously sea water, so that no salt must be added; the flavour was contaminated by a knife, so that it must be cut with a reed. Polypi, it is said, are still salted in Dalmatia and Illyria, from whence they are brought to Venice, and the Greek priests dry them for their fast days. The ancients thought them carminative, as well as that they increased the secretion of semen. Ætius recommended them to those who were weak in the palestra. Diphilus and Paulus Ægineta observed, that they were highly nutritious and provocative. Galen gives a similar account. It is said also that the polypus was an ancient hieroglyphic. With its arms closed it represented caution and prudence; when extended, openness and dissipation.

When applied to the human body, the term implies coagulations and concretions of blood. The true polypus is only such a concretion of blood as consists of a whitish, fibrous, and pretty compact substance, formed from the gluten and fibrin, and differs widely from grumous or coagulated blood, which is called the *bastard polypus*. In Dr. Cullen's Nosology it is a synonym of *sarcoma*.

Polypi are seated in the sinuses of the brain, the ventricles of the heart, the jugular veins, the veins of the uterus, and in any large artery or vein, usually formed in the dying moments, though sometimes during life, from a sudden stagnation of the blood, in consequence of terror or surprise. Those which are the subjects of operation are seated in the nose, uterus, and vagina, and are instances of *sarcoma*.

Other causes are said to be large draughts of cold water suddenly drunk after being heated with exercise, a too free use of acids and of spirituous liquors, long continued grief, apoplexy, epilepsy, hysteric fits, or spasmodic asthma.

The signs of a polypus in the heart or larger vessels are, palpitation of the heart, often excited by a slight cause, as commotions of the mind, flatulent aliment, or costiveness; an unequal intermitting pulse, often accompanied with fainting, difficulty of breathing, or a fixed pain about the heart.

The palpitation of the heart, and the anxiety which so often attend, are caused by mental emotions, flatulent diet, costiveness, &c. which, by disturbing the equable circulation of the blood, hurries it towards the heart, and this muscle, from the obstructing body, cannot properly contract. The inequality and intermission of the pulse are owing to the same cause; for when a regularly contracting muscle is impeded in its action, spasmodic exertions are the usual consequence. Polypi happen more frequently in the right auricle and ventricle than in the left, and oftener in the veins than in the arteries; on account of the weaker contractile force and slower circulation. If from any temporary stoppage of the blood a very small part of the gluten concretes, it soon forms a nucleus for additional coagulation.

Polypi, by intercepting the circulation, are often the causes of sudden death; for a more violent and continued intermission is not soon followed by action, even in a healthy organ; but where such morbid obstruction exists, it is not surprising if the heart contracts no more. They also hasten some other diseases to a fatal termination, as peripneumonies, pleurisies, asthmas, catarrhs, consumptions, &c.

As it is impossible to dissolve them, we should be anxious to prevent their increase, and to avoid all violent mental emotions; every cause of increased circulation; to keep the bowels loose, and avoid, by the lightest diet, the stimulus of indigestion.

PO'LYPUS NA'RRIUM, UTERI, &c. *noli me tangere*. The sarcoma, often added, with little accuracy, as a synonym, is generally hard, not hanging by slender roots, but fixed on a large, immoveable basis.

The polypus of the nose is an excrescence whose branches spread among the laminæ of the os ethmoides, and the whole cavity of one or both nostrils. (See BUCCACRATON.) They spread on the laminæ spongiosæ, nearly as the hyatids on the surface of the liver, and proceed from any part of the nostrils, or those sinuses of the cranium lined with the same membrane.

Polypi occur in many organs besides the nose, as in the uterus, the throat, and the rectum. They differ from the former, as they are not merely masses of concremented gluten, but seem to possess independent life, though sometimes supposed to be the enlarged glands of the Schneiderian membrane. This opinion is, however, counteracted by their appearance in other parts, where there are no mucous glands, as in the uterus. No cause can be assigned for the disease. It sometimes appears constitutional, and occasionally hereditary; and is not the consequence of scrofula or lues. The pain is inconsiderable, except when the parts are distended by their increasing size. Hard polypi sometimes suppurate, and form malignant ulcers, which discharge a fetid sanies, but seem not to become truly cancerous. Those tending to such ulcers are usually of a livid hue, and are frequently painful.

Different polypi, and the same at different times,

appear of different sizes and consistencies: their elongation is sometimes very rapid; at others they are stationary for some years. The soft polypi in the nose contract from the constant access of air, but the hard ones are not affected. Each kind is plentifully supplied with blood vessels. The increase may be sometimes prevented by astringent applications, as a solution of alum, or a decoction of oak bark; by alcohol and vinegar. Mercury generally aggravates the complaint, and caustics are of little service, though they sometimes appear to lessen the softer polypi, and destroy small remaining portions.

When a polypus appears soft, and of a pale colour, without pain, it is in the most proper state to extract, and the operation best succeeds, as it has rarely more than one attachment, which is very small. This must be brought away with the polypus, and is easily effected if the forceps can reach or approach near to it. If hard, and apparently scirrhus, it has generally a broad basis, and cannot be extracted. The attachment of the former kind is usually in the anterior parts of the nose; but of the latter in the posterior and higher regions. That kind which is involved with the foramina of the ethmoid bone cannot be extracted. Wherever the polypus appears, it must be extracted anteriorly, for few can bear the introduction of the forceps up behind the uvula.

Mr. Sharp directs the following method of performing the operation: "Introduce a pair of forceps, with a slit at their extremities, for the better hold, an inch and a half up the nostril, to secure the polypus as near the roots as may be; then twist them a little from one side to the other, and continue this action while you pull gradually downwards; if it breaks, repeat the extraction as long as any remains, unless it is attended with a violent hæmorrhage, which is an accident that sometimes happens, and rarely fails, if the polypus is become scirrhus: this hæmorrhage is soon abated by the contraction of the vessels, or the application of lint dipped in some styptic." It may be known that the polypus is removed, 1st, by the sight; 2dly, by the voice; and, 3dly, by the freedom of respiration through the nose. In introducing the forceps, it is difficult to avoid the ossa spongiosa; but for this purpose, the beak of the forceps must be kept as near as possible to the os palati. When the operator draws away the polypus, he may generally bring it away whole, if he draws and moves it very gently. If any part remain, the lunar caustic will destroy it. The ligature, when it can be applied, is often more successful than the forceps.

See Poterius, Rulandus, Wedelius, Celsus, Ægineta, Albucasis, Sennertus, Glendorp, Malpighius, Hoffmann, Levret, Le Dran, Sharp, and Heister. On the use of caustics, Loeffler Beytrage zur Wundarzneykunst, who recommends butter of antimony, and the same work on the extirpation of polypi. For the use of the ligature, Hasselberg Commentatio Chirurgica. See also Bell's Surgery, vol. iv. p. 90; London Medical Transactions, vol. i. p. 407; London Medical Journal, vol. vi. p. 252; Pott's Works, 4to.; White's Surgery, p. 253.

POLYSA'RCIA, (from *πολυς*, and *σαρξ*, *flesh*). *Obesitas; corfulentia; steatitis* Vogel. Dr. Cullen places this disease among the *intumescencia*; and de-

scribes it, a troublesome pinguedinous enlargement of the body.

The cellular membrane of the body is supposed to be distinguished from the adipose by some peculiar structure, which adapts it for retaining the particles of oil secreted from the blood; but no such difference has been demonstrated, unless perhaps in the size of the cells. It appears, however, from the disease before us, that the fact may be collected in every part of the cellular substance, and that the great distinction arises from the greater or less motion to which the parts are subject. Thus the fat, in stall fed oxen, will be accumulated even in the interstices of the muscles in large quantities, while, in the hare, where the loins are considerably exercised, it is rarely found even around the kidneys, or in any other part. Fat is often accumulated in the omentum; but in the fœtus the cells of this membrane contain only a gelatinous fluid, and fat is freely deposited under the skin. The latter certainly depends on the inconsiderable motion of the fœtus; the former is not easily explained. (See *ADIPS*.) The cause which occasions the accumulation of this oily matter has not been ascertained. The disease is, however, often constitutional.

Fat people are in general dull and inactive, subject to pains in the head and difficulty of breathing, apoplexies and palsies; sleep long and heavily, but are proverbially cheerful and good humoured. As it contains an acid, it has been supposed that the disease is owing to an excess of oxygen; but it more commonly occurs in low close situations to those who use little exercise, to butchers, cooks, brewers, and those who drink beer imperfectly fermented.

Its best remedy is exercise, but fat people are usually inactive. If, however, a firm resolution can induce the fat person to abridge his meals and his sleep, and use steady, constant exercise, he may soon lessen his bulk. This, however, should be done with moderation, or he will otherwise injure his constitution. Cyder drinkers are seldom fat, so that he should adopt that beverage.

The fat person should not only abridge the quantity of his food but lower its quality. Dr. Cheyne, by a milk and vegetable diet, reduced his bulk considerably; and a miller is said, in one of the medical collections, to have produced the same effect by similar means. Soap, the acetum scillæ, and common vinegar, have been recommended for the same purpose; but they are seldom effectual till they have destroyed, in a great degree, the digestive powers. Fernelius recommends diuretics; Zacutus Lusitanus, leeches and scarifications; Borellus, chewing tobacco. Other authors recommend coffee, purgatives, and blisters; but the only advantageous plan is that already explained.

See Cælius Aurelianus, Chron. lib. v. c. 11; Cullen's First Lines, vol. i.

POLYTRI'CHUM, (from *πολυς*, and *τριχ*, *hair*). MAIDEN HAIR; so called from its resemblance to hair. See *ADIANTHUM*.

POLYU'RICA, *ISCHURIA*, (from *πολυς*, and *ουρον*, *urine*). See *ISCHURIA*.

PO'MA AURA'NTIA. The ORANGE. See *AURANTIA HISPANICA*.

PO'MA SINE'NSIA. CHINA ORANGE. See *AURANTIA SINENSIA*.

POMA'CEUM, (from *pomum*, an *apple*). **CYDER**, *cidra*, is the juice pressed from apples, and fermented. The more austere cyders are the strongest, and keep longest. Cyder is an useful drink in scorbutic and melancholic habits; nor does it intoxicate so soon as wine, since it contains a large proportion of mucilage. It passes off freely in perspiration, and is often slightly laxative. Moderately used, cyder is more salutary than wine; and whey prepared with it is a much more agreeable drink for patients in fevers than that made with wine.

POMA'MBRA, (from *pomum*, an *apple*, and *ambra*, *amber*). **APPLES OF AMBER** are composed of odoriferous powders, to which oils are added, and these powders are made into balls, with wax, mucilage of gum arabic, &c. E. g. take of mace and cinnamon, of each two drachms; musk, civet, and gum arabic, of each one drachm; gum tragacanth, two drachms. Mix and make into balls. They are used only as perfumes.

POMA'TICÆ. See **COCHLEÆ**.

POMA'TUM, (from *pomum*). It was formerly made with lard, suet, and a species of *apples* called pome-waters; but at present it is only lard beat up into a light curd, with the addition of a little rose water, or essence of lemons.

PO'MPHOLYX, (*πομφολυξ*, from *πομφος*, a *bladder*). A bubble excited in a viscid fluid by air, and from thence the name of a cuticular disease, in the fourth order of Dr. Willan's system, styled the water blebs, resembling the urticaria. The name also of the matter found adhering to the covers of crucibles, in the form of a light downy, whitish powder, which sublimes from the lapis calaminaris in making brass, sometimes called *nihil album*, *white tutty*, or *calamitis*.

PO'MUM, (from *πομα*, *drink*, because a pleasant drink is made of apples). See **MALUM**. An **APPLE**; an appellation of *staphyloma*; and in botany any fleshy vessel containing many seeds: all such plants are termed pomiferous. **ANAPODOPHYLLUM** is called *pomum maiale*, and **MOMORDICA**, *pomum mirabile Hierosolymitanum*. See also **BACCA**.

PO'MUM ADA'MI. A name for the lemon *fructu aurantii*; also for the protuberance in the fore part of the neck formed by the thyroid cartilage. (See **ASPERA ARTERIA**.) This protuberance is thought to receive its name from a whimsical supposition, that part of the forbidden apple, which Adam eat, stuck in the throat.

PO'NDERA, (from *pendo*, to *weigh*). A **WEIGHT**. The varieties of weights and measures have greatly embarrassed the student, and retarded the progress of science; and, while we condemn French innovations, we should be at least certain that no Augæan stable required the active exertions of a reformer. We wanted, however, a *fixed* more than an *accurate* standard; and was the general idea of a given weight the same, what it really was would be of little importance. In our situation, however, we must look both to our predecessors and the present generation, and as we have strenuously urged the perusal of the Greek authors, we must endeavour to explain their language.

The grains among the Greeks was the twentieth part of a scruple, as in our present system, and the drachms and ounces had the same relations as at this

time. The *siliqua*, *κερατιον*, was one half of an *obolus*, and one quarter of a scruple. The *aureus* of the Arabians, and the *denarius* of the Romans, were equal to about a drachm and one seventh, nearly nine grains. Seven denarii, therefore, make an ounce. The *sextula* is equal to four scruples, the *duella* double of the *sextula*, equal to eight, and the *siliculus* equal to two drachms. The *oxybathon* of Galen was equal to an ounce. The *rescuncia* an ounce and a half, or the eighth part of a pound, was equal in weight to the *faba Alexandrina*; the *sextans*, one sixth of a pound to two ounces; the *quadrans* and *triens*, the fourth and third part of a pound respectively. The *semis* is well known to be half; the *septunx* equal to seven ounces; *bes* or *bessis*, bis triens, eight ounces; *dodrans*, *dextans*, and *deunx*, nine, ten, and eleven ounces respectively. The *as*, vel *assis*, is the pound.

The *pound* weight among the ancients had three different values. The *zygostatic*, or *civil weight*, like our *avoirdupois*, was equal to sixteen ounces, called the *μνα*, or *mina medica*; 2. the *Athenian*, *Egyptian*, or *Alexandrian* pound, according to Galen, was equal to a hundred drachms, twelve ounces and a half; 3. the *medical pound*, as at this time, consisted of twelve ounces.

The old French weights and measures differed from ours; but in their eagerness to make science all their own, the philosophers of that nation reformed their old system. It must be admitted that they have laboured their new division with no common care, and have employed the most scientific accuracy in determining the principle on which they rest. This is the quadrant, or quarter of the earth's circumference, or the distance from the equator to the pole, determined by the length of a pendulum vibrating seconds; and their mean measure the **METRE**, the ten millionth part of this quadrant, is estimated at 3 feet 11.3 lines, nearly, 39.37 English inches. The subdivisions and the increments of the metre are in a decimal computation.

Metre	=	39.37	Decametre	=	393.7
Decimetre	=	3.93	Hecatometre	=	3937.0
Centimetre	=	0.39	Chiliometre	=	39370.2
Millimetre	=	0.03	Myriometre	=	393702.2

The toise is equal to 76.734 inches English, and 576 French grains to 472.5 English.

In Long Measure the

	Yards	Feet	Inches
Decametre	=	10	2 9.7
Hecatometre	=	109	1 1
Chyliometre, 4 furlongs	=	213	1 10.2
Myriometre, 6 miles 1 furlong	=	156	0 6

Eight chiliometres are nearly equal to five miles.

Measures of capacity we have already mentioned. We may add, however, that the litre is nearly equal to $2\frac{1}{8}$ wine pints; fourteen decilitres nearly equal to three wine pints; a chilolitre, one tun, 12.75 wine gallons.

The weights are determined by the increments and decrements of the gramme, which we find differently estimated. Its true English value is 15.44 grains English, and the progress is as follows:

Gramme	=	15.44	Decagramme	=	154.44
Decigramme	=	1.54	Hecagramme	=	1544.4
Centigramme	=	0.15	Chiliogramme	=	15444.02
Milligramme	=	0.015	Myriogramme	=	154440.23

A decagramme is 6 pennyweights 10.44 grains, troy; $\frac{2}{3}$ iss. 4.44 grains apothecaries' weight, or 5.65 drachms, avoirdupois.

A hecagramme is 3 ounces $8\frac{1}{2}$ drachms, av.

A chiliogramme 2 pounds 3 ounces 5 drachms, av.

A myriogramme 22 pounds 1.15 ounces, av.

100 myriogrammes 1 tun, minus 33 pounds nearly.

We shall add an easy approximation of the French weights to the English, applicable to medicine, from Swediaur's Pharmacopœia.

Centigramme	=	$\frac{1}{2}$ grain.
Decigramme	=	2 grs.
Gramme	=	20 grs.
$1\frac{1}{2}$ Decagramme	=	$\frac{1}{2}$ ounce.
$\frac{3}{4}$ Decagrammes	=	1 ounce.
Hectogramme	=	3 ounces.
$\frac{4}{5}$ Hectogrammes	=	1 pound, troy.
$\frac{5}{6}$ Hectogrammes	=	1 pound, av.
Killogramme	=	2 pounds, av.
Myriogramme	=	20 pounds, av.

See Journal de Physique, vol. xlviii. p. 460, and vol. xlix. p. 98 and 161.

To return, however, to our own weights, the medical or troy pound is less than the avoirdupois, but the ounce and the drachm are greater. The troy pound contains 5760 grains, the avoirdupois 7000 grains. The troy ounce contains 480 grains, the avoirdupois only $437\frac{1}{2}$ grains. The troy drachm contains 60, the avoirdupois rather more than 27.

The pound and the pint are called *libra* by the Latins; but there is not any known liquor of which a pint in measure answers to a pound in weight. A pint of rectified spirit of wine exceeds a pound weight by half an ounce.

PONS VARO'LII, (from its similarity to *pons*, a bridge,) *Corpus annulare, processus annularis*. Varolius, an Italian anatomist, gave this name to an arch in the cerebellum, which he first discovered. See MEDULLA OBLONGATA.

PO'NTICA VI'NA. ACID, FECULENT, and TARTAROUS WINES.

PO'NTICUM MEL. A poisonous honey.

PO'PLES, (*quod post plicetur*, bent backwards in supplication). The HAM, *ignye, ignys*; the hinder part of the articulation of the knee, or joint of the knee.

POPLITE'A ARTE'RIA, (from *poples*). The arteria cruralis, in passing the ham, is called *poplitea*, and is then covered only by the integuments. It ends by dividing into the tibialis anterior and posterior. Surprising as it may appear, it is a fact, that though the artery in the middle of the thigh may be tied with impunity, and the blood be distributed as usual to the leg and foot, yet the popliteal artery in the ham never can. An aneurism in this artery seldom lasts long enough to cause a caries in the adjacent bones. When it happens, a cure may be effected by taking up the femoral artery. (See ANEURISM.) The artery in this part, when di-

lated, will increase, press on the lymphatics, and induce œdema and mortification of the limb, if the femoral artery is not taken up, or the limb amputated in proper time.

POPLITE'A VE'NA. The crural vein takes this name just above the ham, and at the lower part of the musculus popliteus it divides into the tibialis anterior, tibialis posterior, and peronæa. See CRURALIS VENA.

POPLI'TEUS, (from *poples*). The name of the sciatic nerve when it reaches the ham; it divides into two branches, which spread over the whole leg, called *plantares*.

POPLITE'US MU'SCULUS, (from *poples*, the ham,) *subpopliteus*, from the place of its situation. This muscle rises tendinous from the external condyle of the femur, within the capsular ligament; passes tendinous under the ham inwards; plays upon the head of the tibia, and is inserted into its superior and inner part, serving to turn the toes inwards.

POPULA'GO, (from *populus*, from its leaves resembling those of the poplar). See CALENDULA PALUSTRIS.

POPULA'RIS, (from *populus*, the people). See ENDEMIUS; EPIDEMIUS.

PO'PULUS, (from the multitude of its shoots). The POPLAR, *ægeiros*.

PO'PULUS ALBA, Lin. Sp. Pl. 1463. WHITE POPLAR, *albata*; *farfurus*, grows in moist places; and a decoction of its bark is given to relieve strangury and sciatica.

PO'PULUS NI'GRA, Lin. Sp. Pl. 1464. The BLACK POPLAR, is a tall tree, with dark green, rhomboidal, acuminate leaves, producing imperfect flowers in catkins. The female flowers are followed by membranous pods, containing a number of seeds winged with down. It is indigenous in watery places, and of quick growth. The young buds of the leaves are made into an ointment; and they abound with a yellow unctuous odorous juice, which they readily impart to rectified spirit of wine. The tincture yields a fragrant resin, resembling storax. See Raii Historia.

PO'PULUS TRE'MULA, Lin. Sp. Pl. 1464. The ASP, or ASPIN TREE, grows in woods and marshy places; resembling the *fi. nigra*.

PO'RCUS, (*quasi spurcus, filthy*). HOG; when wild, *aper*; in Greek, *ὄς*, and *χοίρος*; in Latin, *sus* and *scrofa*. Pork is not easy of digestion, and considered by Sanctorius and others to have the strongest tendency to retard perspiration; consequently it has been considered as unwholesome. The Jews, who were generally affected with lepra, were perhaps on this account forbidden to eat it.

As this animal is generally extremely fat, it is considered as highly nutritious to such constitutions as can digest it easily; nor is it, as has been supposed, indigestible when in its younger state. When salted in the form of ham or bacon it is less easily assimilated; but its stimulus renders it in small quantities sometimes acceptable to weak stomachs.

The name *porcus*, and *porcellus*, is given to some fish, particularly the dolphin, because they are said to root up the earth, like swine, with their snouts. *Porcus* also, from the Greek word *χοίρος*, is a name for the *fudendum muliebre*.

PO'RI, (from *πύρον*, to pass through). The pores of

the skin are described by Lewenhoeck as so small, that one grain of sand will cover one hundred and twenty-five thousand: but this was apparently an optical deception; for no future observer has discovered them. The extremities of the exhalents undoubtedly open under the cuticle; but their orifices are not visible.

PORRI'GO, (*à porrigendo*). See **PITYRIASIS** and **FURFURIOSI**.

PO'RRUM, (from *πρῦρον*, to burn, because of its hot taste. **COMMON LEEK**, is similar to garlick, but weaker. It is carminative, and diuretic. The juice of leeks has sometimes succeeded in dropsy, when other medicines have failed.

PO'RRUS. See **SARCOMA**.

PO'RTÆ VENA, vel **PORTARUM VE'NA**, (from *porta*, door, or entrance). The splenic, mesenteric, and mesocolic veins, uniting at the root of the mesentery, form the vena portæ, *janitrix*, or *ramalis vena*. It may be considered as two veins joined at their trunks, one of which is ramified in the liver, the other in the viscera of the belly: the former may be called *hepatica superior*, or *minor*; the latter *ventralis inferior*, or *major*. The trunk of the vena portæ hepatica is called its *sinus*, from which five principal branches are divided and spread through the whole substance of the liver, ending apparently in thick, villous folliculi. In these the bile is secreted, and collected by as many vessels of another kind, whose apertures are called *pori biliarii*, which again unite in one common trunk, *ductus hepaticus*. The vena portæ ventralis is situated under the lower or concave side of the liver, between the middle and right extremity of that sinus; from thence it runs down from right to left under the trunk of the hepatic artery, bending behind the beginning of the duodenum, and under the head of the pancreas; its length exceeds three inches. At the head of the pancreas it divides into the meseraica major and minor, and the splenica. See Winslow's Anatomy.

PORTAI'GUILLE. See **ACUTENACULUM**.

PO'RTIO DU'RA, **MOLLIS**. See **NERVI**, and **NERVUS AUDITORIUS**.

PORTLAND POWDER. A medicine celebrated for the cure of gout, and at one time highly fashionable, from the relief which a duke of Portland was supposed to have derived from it. This powder was composed of equal parts of germander, ground pine, gentian, and centaury, and a drachm of these powders, well mixed, was to be taken in a glass of wine and water, broth, or tea, every morning fasting, and nothing was to be taken for an hour and half afterwards. This course must be continued for three months; three-fourths of a drachm taken for three months longer; then half a drachm for six months. After the first year half a drachm may be taken every other day only for one year longer. It is recommended also in rheumatism, if not habitual. This is an old remedy, traced by Dr. Clephane from Galen down to almost our own times; but he remarks, that the ancients were cautious in employing it, pointing out the danger of its inducing dropsy, pleurisy, and peripneumony, from its constant use, and from its great danger in particular, if the gout has become habitual. Modern

experience has confirmed these cautions, and the medicine is now neglected. See Clephane in the Medical Observations and Inquiries, vol. i. Vide **ARTHRITIS**.

PORTORA'RIVUM, (the door or entrance into the intestines). The **DUODENUM** or the **PYLORUS**.

PORTULA'CA, (from *porto*, to bring, and *lac*, milk, because it is supposed to increase its secretion,) *andrachne*; *allium Gallicum*, *portulaca oleracea* Lin. Sp. Pl. 638. **PURPLE OF GARDEN PURSLANE**, a culinary plant; but the seeds and leaves are supposed to be cooling, antiscorbutic, and moderately astringent.

PORTULACA MARITIMA. See **HALIMUS**.

PO'RUS BILIA'RIVUS, (from *πορος*, a passage.) The beginning bile duct. See **JECUR**, and **PORTÆ VENA**.

PO'RUS O'PTICUS. The point of the retina where the optic nerve enters, which is insensible.

PO'RUS RETICULA'TUS. See **ESCHARA**.

PO'SCA. Vinegar and water mixed.

POSOLOGIA. (See **DOSIS**.) The doses of medicines are chiefly learnt from experience; but some guide is necessary for the young practitioner, and for this reason we shall subjoin a posological table, rather as a general guide than one to be implicitly trusted in every case. The minuter regulations of the dose may be more readily understood from the remarks in the particular article, or under the disease for which it is prescribed. For many reasons, though we shall give the highest and the lowest doses, the latter will be rather beneath than above the standard.

Doses distinguish, we have said, medicines from poisons; and, on the other hand, aliment from remedies. Minute attention is, however, requisite in many cases, since it is not improbable that the specific action of remedies depends on their doses. Our experience with mineral waters shows that some medicines, in a small and minutely divided quantity, are more effectual than in larger doses, and in a more concentrated state. We cannot imitate in any other way the tonic effects of iron, or the laxative powers of neutral salts in proportions so small; and it is highly probable that if we ever find the exhibition of factitious airs highly beneficial, it will be in much smaller quantities than have been hitherto exhibited. Injudicious, particularly young, eager, practitioners having once learnt that a remedy has a peculiar power, think that power will be necessarily augmented with the dose; and if they are capable of distinguishing, a faculty not quite so general as may be reasonably supposed, they soon perceive their error. Camphor, for instance, in a dose of five or six grains is a mild sedative, and often a diaphoretic, in fevers; in a dose of twenty grains it frequently produces nausea, increases the heat, and proves highly injurious. Opium in too large doses prevents instead of promoting sleep, and acts rather as a stimulus on the bowels than a narcotic. The laudanum purgans of an old pharmacopœia owes its laxative virtue rather to the dose than the addition which it receives, calculated chiefly to prevent its being rejected by vomiting. In fact, every medicine beyond its proper dose is usually the source of considerable inconvenience, promoting generally increased or irregular action.

In this estimate of the doses of medicines, we cannot expect to meet the sentiments of every practitioner, nor perhaps always to be minutely and accurately correct. As we have already remarked, this table is intended rather as hints to conduct the practitioner in his own observations than as a guide to be blindly followed; for many are the varieties which will result from age and sex; from temperament and idiosyncrasy. They are, indeed, so numerous that we engaged in the task with hesitation and reluctance; nor are we certain that we may not have done more injury by assisting empiricism than service to the younger practitioner.

In the table of preparations we have followed the London pharmacopœia almost exclusively; not that we confine to it exclusive excellence, for both the Dublin and Edinburgh pharmacopœias merit peculiar attention. We soon found, however, that to include these would not only extend the catalogue beyond its proper limits, but by names similar, yet different, by formulæ vary-

ing often rather in appearance than in their nature, we should require endless explanations to guard against confusion. We gave up the attempt the more readily, as in Dr. Duncan's very valuable dispensatory they may be readily compared. In the tables annexed to that work we find a comparative view of the doses of the more important medicines, according to each dispensatory, with which we shall conclude the present article.

Tables, showing the proportion of antimony, opium, and quicksilver, contained in some compound medicines.

Tartrate of antimony.—Wine of tartrate of antimony contains two grains of tartrate of antimony, or tartar-emetic, in the ounce. Ed.

Opium.—Opiate confection contains one grain of opium in thirty six grains. Lond.

Opiate or thebaic electuary contains in each drachm about a grain and a half of opium. Edin.

Electuary of catechu, or japonic confection, contains

in each ounce about two grains and a half of opium; for one grain of opium is contained in one hundred and ninety-three grains. Ed.

Compound powder of chalk with opium contains one grain of opium in about forty-three grains. Lond.

Compound powder of ipecacuan contains one grain of opium in ten grains. Lond.

Powder of ipecacuan and opium contains six grains of opium in each drachm, or one grain in ten. Ed.

Opiate powder contains one grain of opium in ten. Lond.

Pills of opium contain one grain of opium in five. Lond.

Opiate or thebaic pills contain six grains of opium in each drachm, or five grains contains half a grain of opium. Ed.

Tincture of opium or liquid laudanum is made with two scruples of opium in each ounce of the liquid, or with five grains in each drachm. But a drachm of the tincture appears, by evaporation, to contain about three grains and a half of opium. Ed.

Ammoniated tincture of opium, or paregoric elixir, is made with about eight grains in each ounce of the liquid, or with about one grain in the drachm. Ed.

Tincture of soap and opium, formerly called opiate liniment, anodyne balsam, is made with one scruple of opium in each ounce of the liquid. Ed.

Troches of liquorice with opium contain about one grain of opium in each drachm. Ed.

Quicksilver.—Quicksilver pills contain five grains of quicksilver in each drachm. Each pill contains one grain of quicksilver. Ed.

Quicksilver pills contain four grains of quicksilver in twelve grains. Lond.

Quicksilver ointment contains twelve grains of quicksilver in each drachm; made with double quicksilver, each drachm contains twenty-four grains. Ed.

Stronger quicksilver ointment contains one drachm of quicksilver in two drachms. Lond.

Weaker quicksilver ointment contains one drachm of quicksilver in six drachms.

Quicksilver plaster contains about sixteen grains of quicksilver in each drachm. Ed.

Plaster of litharge with quicksilver contains about one ounce of quicksilver in five ounces. Lond.

Plaster of ammoniac with quicksilver contains about one ounce of quicksilver in five ounces. Lond.

Powder of scammony with calomel contains one grain of calomel in four grains. Lond.

Ointment of nitrated quicksilver contains twelve grains of nitrated quicksilver in one drachm. Lond.

Stronger ointment of nitrat of quicksilver contains in each drachm four grains of quicksilver, and eight of nitrous acid. Ed.

Milder ointment of nitrat of quicksilver contains in each scruple half a grain of quicksilver, and one grain of nitrous acid. Ed.

Ointment of white calx of quicksilver contains in each drachm about four grains and a half of the calx. Lond.

Litharge plaster with quicksilver. Lond. 5

Ammoniac plaster with quicksilver. Lond. 5

One grain of calomel is contained in

Powder of scammony with calomel. Lond. grs. 4

Compound antimonial pills. Dub. - - 2.7

One grain of the grey oxyd of quicksilver is contained in

Ointment of the grey oxyd of quicksilver. Ed. grs. 4

One grain of the red oxyd of quicksilver is contained in

Ointment of red oxyd of quicksilver. Ed. grs. 9

One grain of submuriat of quicksilver and ammonia is contained in

Ointment of white calx of quicksilver. Lond. grs. 13

One grain of nitrat of mercury is contained in

Stronger ointment of nitrat of mercury. Ed. grs. 5

Ointment of nitrated quicksilver. Lond. Dub. 5

Milder ointment of nitrat of quicksilver. Ed. 13

In many instances these proportions are only to be considered as approximations to the truth, as they are calculated from the quantities of the ingredients taken to form the preparation, not from the quantities which exist in it after it is formed. The nitrat of mercury, for example, in the different ointments into which it enters, is estimated as equal to the whole quantity of mercury and nitrous acid employed to form it, although, from the very nature of the preparation, it cannot be so much. In the solutions of opium, the opium is estimated as equal to the whole quantity employed, although not above two-thirds of it be dissolved. Lastly, no allowance is made for the loss by evaporation; and hence, notwithstanding the difference by calculation, the Edinburgh troches of liquorice with opium contain probably as much opium as those of Dublin; for the former, being made with syrup, will lose more in drying than the latter, which are made with the extract of liquorice.

E c

POSSE'TUM. Posset. Milk curdled with wine, treacle, or cider, by foreigners reckoned peculiar to the English. The serum of a posset, called *posset drink* differs from the whey of milk by the addition of the fluid employed to curdle it.

POSTBRACHIA'LE, (from *post*, after, and *brachium*, the arm). See **METACARPUS**.

POSTE'RIOR ANNULARIS; an external interosseous muscle of the hand, which draws the ring finger inwards.

POSTE'RIOR INDICUS; a similar muscle, which extends the fore finger and draws it outward.

POSTE'RIOR MEDII, extends the middle finger and draws it outward.

POSTE'RIOR MU'SCULUS AU'RIS. See **ABDUCTOR AURIS**.

POS'THE, (*quasi*, *πρὸς*, from *πρὸ*, to place before). See **PRÆPUTIUM**.

POSTPOSITIO, (from *post*, and *pono*, to place). When the paroxysm of a fever comes on later than is expected, the paroxysm is said to be postponed; when it begins sooner, to be anticipated.

POTA'SSA. We have, in the articles **ALKALI** and **CHEMIA**, q. v. given every information apparently necessary on this subject; yet, as in some cases the kali is required to be peculiarly pure, we mean chiefly when employed as a re-agent in detecting poisonous impregnations, it may be, perhaps, useful to describe shortly the methods of preparing it without any remaining impurity. Two have been employed; and we shall first mention that of Bouillon la Grange, from the *Annales de Chymie*.

To water, heated nearly to boiling, some highly caustic lime must be added, which will bring on ebullition; and, when slaked, an equal quantity of potash of commerce. The water must be in such a quantity as will bring the whole to a thick liquid. In boxes, whose bottom is covered with well washed river sand, and then with a stratum of finer sand, on a cloth sprinkled with wood ashes, this mixture must be cautiously poured, and covered very gently with water, which, passing through the cloth and sand, is conveyed into vessels by a hole in the bottom of the box. The fluid in the vessels must be guarded from atmospheric air, and water added till its saline taste begins to grow weak. The superfluous fluid must be carried off by a quick ebullition, and any impurity will then separate. To obtain it perfectly pure, it must be evaporated to dryness, and dissolved in alcohol, which takes up the pure potash only, leaving whatever salt contains any carbonic acid.

Lowitz advises the lixivium of potash, freed from the carbonic acid in the usual manner, to be evaporated to a thin pellicle. After cooling, the foreign salt is to be separated, and the evaporation continued in an iron pot, during which the carbonate of potash rises in a pellicle, which must be constantly separated. When no more pellicles are formed, and it ceases to boil, it must be taken from the fire and suffered to cool, continually stirring it till cold. It must then be dissolved in double the quantity of cold water, the solution filtered, and evaporated in a glass retort till it begins to deposit regular crystals. After the formation of a sufficient quantity of these, the brown fluid must be decanted, and the drained crystals redissolved in the same quantity of water. The decanted fluid, become clear by subsiding,

must be again decanted, and crystallized. These operations are repeated till the crystals afford, with the least quantity of water, solutions perfectly limpid.

We know that alkalis are, in general, the product of fire; but in many cases they exist formally in the plant, though often united with an acid in the form of a neutral. Recent discoveries, however, which we shall soon notice (see **SAL** and **SODA**), have lately opened an ample field for speculation. See **CLAVELLATI CERNERES**.

POTENTI'LLA RE'PTANS, (*à potentia*, from its efficacy). See **QUINQUEFOLIUM**.

POTE'RIUM, a cup, (from the shape of its flower). See **PIMPINELLA**.

POTIO, (from *potō*, to drink). A **POTION**: a liquid form of medicine, to be taken at once, a term usually confined to laxatives.

POUPA'RTII LIGAME'NTUM. See **FALLOPII LIGAMENTUM**.

PRÆCIPITA'NTIA, (from *præcipito*, to cast down). Medicines which moderate the motion and heat of the blood, by *precipitating*, as was supposed, its acid.

PRÆCIPITA'TIO. **PRECIPITATION**; the separation of substances dissolved in a fluid, by the addition of a third body, by the abstraction of caloric, or of the quantity of the menstruum. The first is, however, strictly speaking, true chemical precipitation, and it takes place when the added substance combines with the menstruum, rendering it no longer able to hold the first in solution; or where the third body unites with that in solution, forming a substance no longer soluble. The substance separated is called the *precipitate*, if it sink, *cream*, if it swim. Some caution is necessary in these experiments, for in some cases the precipitate is again soluble; but this depends on chemical affinities and the minuter doctrines of chemistry. See **CHEMIA**.

When the matter to be precipitated falls to the bottom of the vessel, the fluid is poured off, or filtered, and what remains behind is to be dried like levigated powders.

PRÆCO'CIA, (from their early ripening). See **ARMENIACA MALA**.

PRÆCO'RDIA, (*præ*, and *cor*, the heart,) a general appellation of the bowels, generally of the contents of the chest. Fernelius, lib. iv. de Febribus, comprehends under this term the region above the stomach, the diaphragm, the liver and biliary ducts, the pancreas, the stomach, particularly its upper orifice. This name has been also given to the metatarsus.

PRÆPARA'NTIA MEDICAME'NTA are medicines supposed to prepare the morbid humours for separation, and their consequent discharge.

PRÆPARA'NTIA VA'SA are the vessels of the spermatic cord, in which it was supposed that the seed was prepared. See **SPERMATICA CHORDA**.

PRÆPARA'TA VE'NA. See **FRONTALIS VENA**.

PRÆPU'TIUM, (from *præputō*, to lope off before). The **PREPUCE** or **FORESKIN**, *epigogion*, *posthe*. When this is wanting the person is called *leipodermos*, when lost, *lipodermos*. See **PENIS**.

PRÆSA'GIA, (from *præ*, before, and *sagio*, to perceive). **PRESAGES**. Fred. Hoffman observes, that three things are requisite to a right presage, viz. 1st, That from due observation we be able to trace and investigate the origin and causes of disorders in order to

oppose them in the beginning by proper remedies, or give salutary directions. 2dly, That we accurately know the various natures of diseases, and their differences in different constitutions, that we may be better able to give medicines which shall remove them. 3d, That we be able to form a right judgment of the operation of medicines, and the event of disorders. See PROGNOSTICA.

PRESENTA'TIO, (from *præsentō*, to offer). In midwifery it is the manner in which a child offers itself in its passage into the world; and the different presentations are denominated according to that part of the child which is perceived at the mouth of the womb, when a woman begins to be in labour.

In preternatural presentations the membranes protrude, for the most part, in a lengthened form; and when the pain declines, no part of the child can be perceived, but the membranes only, as in the beginning of labour; after some time, from the quantity of water, the membranes have a round form; but they have not the usual effect of dilating the os tincæ. If the head presents, it is distinguished by bringing the finger round so as to take in a large portion of it; we then feel an uniform hard substance, and often discover a suture. When a shoulder or a hip presents, they have not that uniform hard feel which is observed when the head offers. If the back presents, the vertebræ are felt; if the belly, the funis umbilicalis discovers it. The breast presenting is known by feeling the ribs; the breech by the private parts, and the discharge of the meconium at each pain; the hand, or foot, by the absence or presence of the heel. See PARTURITIO.

PRA'NDIUM, (from *prandeo*, to dine). *Ariston. DINNER.*

PRA'SIUM A'LBUM, (from *πρᾶσις*, a square border). See MARRUBIUM ALBUM.

PREGNANCY. When, from the previous connection, the fœtus is animated, (see GENERATIO,) it soon escapes into the uterus, if the Fallopian tubes are not obstructed. Its minuteness at that period prevents us from determining with precision the time of its passage; but as it is probably conveyed to the tube at the moment of animation, since an extraordinary action is required to raise the fimbriæ, it probably is not long delayed in its progress. Every part of the uterus is apparently adapted for its attachment, since, wherever the placenta is fixed, we there find its maternal part; the cotyledons of ruminant animals. The early appearances are those only of a slight inflammation, the constant concomitant of increased action, or of evolution, with usually a small proportion of mucus; and, for some time it is only a small body, covered apparently with a light down. See FÆTUS.

The mother for a time feels no alteration, and, indeed, so slight are often the early symptoms, that a woman sometimes does not know that she has conceived till she feels the motion of the child. More frequently, however, symptoms of general irritability and peculiar sensibility come on early. The fancies are singular, the appetite capricious, the features sharp, the complexion pale, but clear; till about six weeks after impregnation, a sickness of the stomach comes on, chiefly in the morning, and most commonly on rising from bed. After the stomach has been freely discharged, some women are frequently easy and cheerful through the

whole day; but many suffer from constant sickness for four months; some during the whole period. We have known women who have never been able to eat or drink without the bason near, in which it was constantly returned, seemingly unaltered in appearance and quantity, and have yet borne healthy children. In most instances, however, the sickness is confined to the first four or five months, though the capricious appetite frequently continues during the whole time.

In the early period, the abdomen is said to be somewhat flatter than usual: it is at least not fuller; but between the fourth and fifth month the uterus rises above the pubes, like a round ball, occasionally on the right or left of the symphysis, and gradually extends, till at the ninth month it reaches the scrobiculus cordis, protruding in its progress the navel.

At a very early period, often within the first two or three weeks, the breasts grow fuller, and pricking pains are felt in them; the areola round the nipple extends, and is brown, often verging to a blackish hue, which continues to enlarge till the moment of delivery. About the fifth or sixth month, sometimes earlier, a little whitish serum can be pressed from them, which at last approaches more nearly the appearance of milk. The catamenia, as is well known, are very commonly suppressed during pregnancy; but in some women they flow with their usual regularity through the whole period of gestation. In delicate females, who use little exercise, it is not uncommon to have one discharge regular in time, but not in quantity or duration, after impregnation; and this slight appearance will recur at irregular intervals during the whole time. If not attended with pain, or flowing copiously, we have never found it dangerous or threatening abortion.

The most unequivocal symptom occurs nearly between the fourth and fifth month, styled the *quickening*, when the motion of the child is first perceived. This sometimes induces a little faintness, which soon passes away; but the commencement is occasionally so slight as to be unobserved. It first resembles a flatulency; and flatus has sometimes deceived even the most experienced matrons; but it soon becomes more distinct, with a somewhat more rapid motion, resembling the fluttering of a bird; and at last it affords so strong a resistance as to raise the clothes, and be obvious to the eye at some distance. The period of quickening is pretty accurately about the twentieth week, and will generally correct any erroneous reckoning from the disappearance of the menses.

These symptoms arise from the peculiar state of the uterus, with which the stomach, the mammæ, and the appetite sympathize. The final cause of the vomiting it is not easy to assign. We have considered it, in another place, as useful to guard against plethora in the earlier months; and it is certain, that the children of those women who have been scarcely free from vomiting, have not been extenuated, or apparently deprived of their proper nourishment.

To determine whether impregnation has taken place requires often very minute attention; and the most experienced practitioners are occasionally deceived. If a young married woman wishes for children, she will catch at every probable appearance, and magnify every accidental symptom. It is necessary to watch the changes already detailed, and to pursue them in their

progress. We have mentioned the principal circumstances in different articles, particularly under ASCITES; and *suspected pregnancy*, in the article MEDICINA FORENSIS. After three or four months the situation may be more clearly ascertained by the touch; and in the sixth or seventh month pretty certainly determined. We shall shortly describe the successive changes in the cervix uteri and os tinæ during pregnancy, to enable the younger practitioner to determine the question by this means; and we shall copy the very comprehensive and judicious description of Dr. Hamilton, in his "Outlines of Midwifery."

"For the first three months the os tinæ feels smooth and even, and its orifice is nearly as small as in the unimpregnated state. When any difference can be perceived, it consists in the increased length of the projecting tubercle of the uterus, and the shortening of the vagina, from the descent of the fundus uteri through the pelvis. This change in the position of the uterus, by which the projecting tubercle appears to be lengthened, and the vagina proportionally shortened, chiefly happens from the third to the fifth month. From this period the cervix begins to stretch, and be distended, first in the upper part; and then the os tinæ begins also to suffer considerable changes in its figure and appearance. The tubercle shortens, and the orifice expands; but during the whole term of gestation the mouth of the uterus is strongly sealed up with a ropy mucus, which lines it and the cervix, and begins to be discharged on the approach of labour. In the last weeks, when the cervix uteri is completely distended, the uterine orifice begins to form an elliptical tube instead of a fissure; and sometimes, especially when the parietes of the abdomen are relaxed by repeated pregnancies, disappears entirely, and is without the reach of the finger in touching. Hence the os uteri is not placed in the direction of the axis of the womb, as has been generally supposed."

To this we can only add, that about the fifth or sixth months, the weight of the uterus is sensible on raising it by pressure on the os tinæ or cervix, and that in the later months the distended cervix is so thin that the head of the child, when it presents, can be often felt through it.

THE DISEASES OF EARLY PREGNANCY are numerous and troublesome, arising chiefly from the excess of irritability just mentioned, and the plethora, which usually occurs in the early months. We must consider them in an inverted order.

Plethora. The diseases arising from plethora are, chiefly, *flushing of the face, fulness, pain of the loins, load in the head, vertigo, and drowsiness.* The women whose stomachs are most irritable suffer less from these complaints; but, when they come on, they require particular attention. It has been usual to direct small bleedings, and such pregnant women bear with ease, and even advantage. Yet the habit is soon established, and they become necessary in future pregnancies, when the plethora is less common. We have endeavoured, therefore, to avoid them, and we think we have succeeded by cool, free air, by gentle laxatives, and a moderately cooling diet; above all, by perfect rest and tranquillity both of mind and body. The swelling and pains of the breasts arise in part from this cause. They should not be confined by ligatures and lacing; nor must it be forgotten, that, in the present apparently free and easy

costume of the ancient Grecians, they suffer as much by pressure from the sides and below as they formerly did by the iron stays. Every thing must now project forward, but it is not on this account a more easy dress when the breasts are swollen.

The greater number of diseases arises, however, from *irritability*; and among these we may reckon the distressing *stomach complaints*. The morning sickness is one of the most painful feelings attendant on this state; and it is one of these which medicine most commonly fails in relieving. A cup of camomile or peppermint tea, taken on first waking, and suffering the patient to lie still for an hour, will sometimes alleviate the distressing sickness; but should it recur during the day, these means will scarcely succeed any farther. Slight emetics will occasionally relieve, but as often fail. Magnesia and columbo root, sometimes with the kali purum, sometimes with the ammonia pura, occasionally with the aromatic tincture, or a slight proportion of the tinctura opii, will be for a time useful; but the sickness will not wholly yield till the uterus begins to rise above the pelvis and freely expand. Dr. Vaughan, in the London Medical Journal, employed nourishing clysters, with anodyne liniments, to the pit of the stomach. We have already observed, that the intention of nature in exciting vomiting seems to be the prevention of plethora, which is often far more dangerous than the increased action of the stomach. If this be true, it will prevent the introduction of nutriment: and the apparent anxiety of nature in every instance to preserve life, particularly in the reproduction of the species, would lead us to be cautious of interfering in an object where her own plans are usually so beneficial. We may alleviate troublesome symptoms, but should not strongly interfere. It is peculiarly rare, we believe it has scarcely ever happened without the suspicion of some fixed organic complaint, that a woman has sunk or miscarried from inanition.

Cardialgia and diarrhæa are troublesome symptoms, but not dangerous. They are generally relieved by magnesia, the compound powder of chalk, with occasionally a few drops of the aqua ammoniæ puræ, sometimes with the tincture of opium. They arise from irregularity in the digestive process, in consequence of the increased irritability of the stomach, and disappear usually about the fourth month. They are increased by acsents rather than by acids, for vinegar can be often taken with less inconvenience than pastry.

Faintings and hysteric affections are the consequences of peculiar irritability of the system. Low spirits are among the early symptoms, and almost every pregnant woman thinks her state a fatal one; but while such is her language, her conduct contradicts it, and indeed, in the intervals of sickness and pain, the spirits of a pregnant woman are often free and cheerful. Despondency is only in her words. The common hysteric remedies, keeping the bowels free, above all a little variety of scene, and the cheerful conversation of a sensible woman, who has already passed the same ordeal repeatedly with success, will lessen every unpleasant symptom of this kind.

THE DISEASES OF ADVANCED PREGNANCY are often more serious. They arise from the pressure or the change of position of the gravid uterus; and though often only inconvenient, are sometimes dangerous.

The diseases which arise from pressure are various,

swellings of the veins of the leg, œdema of the lower extremities, &c. costiveness, piles, and dyspnœa. These are relieved by the common remedies; but while the cause remains cannot be cured. In weak habits the œdema sometimes arises to general dropsy, which continues after parturition.

More serious diseases from the pressure of the uterus are various spasmodic complaints, rising from slight cramps in the legs to violent *epileptic paroxysms*. The immediate causes are irritation from the pressure on the sacro sciatic nerves, communicated to the brain when the convulsions are more general. Sometimes they seem to arise from the motion of the fœtus, and are more common in a first pregnancy than at any future one. The slight spasms are alleviated by opium; but the epileptic fits are highly dangerous, and in a large proportion of cases are fatal. We have already mentioned this disease, vide *CONVULSIONS*; but must now more fully enlarge on it.

Puerperal convulsions are sometimes relieved by copious bleedings; but the event often leads us to regret the loss of that strength which the patient is thus deprived of. They seldom occur with any violence till about the seventh month; but, in general, attack near the full period. It is first necessary to empty the rectum by an active clyster, which will also, in many cases, bring on labour. The next step is to give a large dose of opium, and inject also no inconsiderable one into the rectum. Forty drops of the tincture of opium may be given, and repeated every hour, or oftener if the fits are violent; and at least two drachms should be given in a clyster. If the fits produce any tendency to labour, the relaxation occasioned by the opium will produce some yielding in the os tincæ; and when it is open, though very slightly, labour may be expedited by introducing the finger, and enlarging it, till we can rupture the membranes. In general, during a pain, the convulsions remit, which is a strong argument in favour of expediting the labour. If the os tincæ does not yield, some practitioners have attempted its dilatation by force; a practice by no means to be recommended, though we have not seen it followed, as has been predicted, by inflammation of the uterus. In general it is safer to give large doses of opium till the relaxation which it occasions, joined with the debility naturally produced by the repetition of the paroxysms, brings on labour. We must be cautious, however, not to carry our expectations of labour coming on too far, as the woman may die undelivered, a circumstance peculiarly dreaded by females; and, in emergencies, the forcible dilatation of the os tincæ, however dangerous, is the safer alternative. By this plan more than half of those entrusted to our care have recovered, while the usual calculations of the successful cases offer a considerably less proportion. Before the seventh month, however, we must trust to the opiates and the operations of nature.

Other plans have been recommended. Dr. Denman advises dashing cold water in the face; Dr. Hamilton the digitalis; and other practitioners large doses of camphor given by the mouth and by clysters. The former we have found useless; the digitalis we have not had an opportunity of trying; and we should apprehend that there was not sufficient time for its operation, unless the dose was hurried on with a rapidity

that would be dangerous. The camphor, recommended in the *Memoires de Medicine*, we have tried; but in each case it brought on an alarming stupor, which has prevented us from repeating it, though given in a far less dose than was recommended.

Sometimes the convulsions follow delivery, and generally arise from fright or from terror. This is hardly a part of the present subject, but it is so closely connected that we could not avoid mentioning it, and it will not detain us, since the usual remedies just mentioned will relieve the complaint, if it admit of relief.

In general these convulsions are not so frequently fatal as those which precede labour, though always dangerous.

Ischuria and frequent micturition are complaints which depend partly on pressure, and in part on irritation. Either is an inconvenience which may be alleviated by a slight opiate; but frequent inclination to make water produces considerable irritation, if not gratified; and the pregnant woman should avoid crowded rooms, long journeys, and every situation where this desire cannot be quickly indulged. Should the bladder be greatly distended, the urine will be permanently retained, and the worst consequences follow, particularly the retroversion of the uterus, which, but for this connection, should have been noticed more early.

Retroversion of the uterus usually occurs about the latter end of the third month, when the womb, if prevented by distention of the urinary bladder, or violent fatigue, from rising above the pelvis, falls backward between the vagina and rectum, pulling the os tincæ backward and upward. Obstinate costiveness has been accused of producing this change in the situation of the womb, but will more probably prevent it, for the posterior part of the pelvis must be spacious and empty to admit of the uterus falling backwards. In this case a tumour is felt in the perinæum, bearing down like a child's head, with forcing pains, tenesmus, a retention of the stools and urine. The finger passed into the vagina is soon stopped without reaching the os tincæ; and in the rectum a round hard tumour may be felt. In this situation the uterus enlarges, and increases all the symptoms. The forcing pains are violent; the retention of the urine and fœces obstinate; the load and oppression are communicated to the brain; and coma, or delirium, with fever, come on, often accompanied by convulsions.

The reduction of the tumour affords the only prospect of relief. We must endeavour then, for this purpose, to evacuate the bladder and rectum; but the weight of the uterus draws back the meatus urinarius, and the bulk prevents the passage of clysters or fœces. A finger introduced into the vagina, and another into the rectum, will assist the reduction, while the patient on her hands and knees, bent forward, contributes by her posture to facilitate the return of the uterus. Perhaps if laying on her back, with her nates raised to half a right angle, the reduction might be still more easy. Dr. Cheston, we find, in the second volume of the *Medical Communications*, succeeded in a case of this kind, by puncturing the bladder at the pubes; and a more desperate proposal has been made to puncture the uterus through the rectum to procure abortion. The attempt is, however, truly absurd, for the puncture of the uterus would not restore the situation of the womb;

and if abortion could thus be procured, the fœtus must pass through the wound.

The caprices of pregnant women are numerous and troublesome. They are not wholly fanciful, for the most firm and sensible women, who conceal them, acknowledge the pain and difficulty they feel by the effort. On the contrary, they increase by indulgence, and often become injurious. In speaking of the peculiarities of the Fœtus, q. v., we showed, at some length, that a change in its structure or appearance from any mental affection of the mother was highly improbable; but to deny any reasonable gratification often produces uneasiness and irritation both of mind and body, with loss of sleep, and an increase of the hysteric symptoms. A man will also commiserate the state to which the most lovely and tender part of the creation is thus reduced, and be led by every kindness and attention to alleviate it. Yet the same affection will set limits to indulgence; for the craving truly grows by what it feeds on, and at last may require impossibilities. The refusal will then be doubly distressing. To grant every reasonable request, to soothe, to persuade, and to expostulate, when these requests verge to what is fanciful, what is not easily practicable, or what may become injurious, will gradually place these fancies more under the controul of reason, and the months in which their influence is strongest will gradually pass away. It is singular, however, that the most eccentric caprices of appetite are rarely injurious; and the most unlimited indulgence is often borne not only with impunity but with advantage. Even the heartburn is not increased by large quantities of fruit, if eagerly longed for; and the rest is often calm and refreshing after food apparently the most indigestible. May not then these apparently capricious fancies be often the dictates of nature, the cravings of somewhat salutary to the constitutions by means of which we are ignorant?

PREHE'NSIO, (from *prehendo*, to take by surprise). See CATALEPSIS.

PRE'MNON. See OCLUS.

PREPARATIONS, (from *preparo*), a term applied often to compound medicines, but more commonly, at present, confined to those parts of the human body which are artificially preserved from the usual changes in consequence of putrefaction, or prepared to display their structure.

Preparations are either wet or dry. Dry preparations should be always finished with expedition that the natural colour may be preserved, and great care should be taken that they are not soiled by dust or handling. The fat should be carefully removed; and the preparation may be slightly washed over by some colourless aqua kali puri, and again with water, to dissolve what may remain. If the part is not very thin, this may be repeated; but in general it injures the texture of the preparation, and such subjects should be chosen as have least fat. Objects preserved in this way should be dried in the shade, with a free current of air; but when the danger of putrefaction is considerable, artificial heat, in a degree not to melt the injection which is previously thrown into the vessels. If they are distended with air, small apertures should be made to prevent the rarefied air from bursting them. Dry membranes may be extended by pins on a flat board, with a paper slightly

oiled beneath to prevent their sticking. Hollow substances are best preserved on stands under glass bells. In drying, fly blows and insects may be kept off by washing the preparation with a solution of hydrargyrus muriatus, in alcohol, in the proportion of a drachm to six ounces.

Preparations are sometimes distended, for drying, with wool, cotton, hair, quicksilver, tallow, or plaster of Paris, besides air. The last, however, is preferable, as more uniform; but is apt to escape by minute foramina, which are with difficulty closed. Where the parietes are thick, as dropsical ovaries, uteri, or aneurisms, hair, or wool very slightly oiled, are necessary. Plaster of Paris is chiefly used where the distending substance is suffered to remain, where tortuous canals prevent the use of hair or wool, or where the membrane is so thin as to require an equable distention. Thin injected preparations are also conveniently displayed on plaster. The penis and the internal organs of generation, as well as the lymphatics, are most conveniently filled with quicksilver; the heart with tallow, which may be melted and drained off with a heat less than will melt the injection of the coronaries. The lungs are preserved dry, in small portions, by distending the air vessels with quicksilver; in large portions, by filling them with oil of turpentine. When dry, each fluid may be discharged by an even, longitudinal section.

Dry preparations are varnished to preserve them from mould, to prevent their destruction by insects, and to increase their transparency. The white spirit varnish of the shops is well adapted for large masses; but is too friable when applied on thin membranes. For the latter purpose the oil varnish of the shops is preferable. It is necessary to separate every particle of fat or grease; and in using the spirit varnish to dry the preparation carefully. Externally both are properly laid on with a brush, and repeated coats are applied. In hollow preparations the varnish is poured in and shaken around; in corroded ones poured on them.

Another kind of dry preparation is styled *corroded*, since, after injection, the substance of the containing vessels is destroyed by immersing the whole in a fluid containing three parts of muriatic acid and one of water. From about three to six weeks is necessary for the corrosion. It is then to be placed in a basin; and at first a gentle, afterwards a stronger stream of fresh water is allowed to pass through it. The little adhering pulp in the smaller interstices may be washed away, by directing a current of water through a small syringe to the part. The preparation must then be dried; and should be carefully suspended by a tape, as a cord will probably cut through the wax. If the vessels are not large enough to admit of its being suspended safely, it must be placed on cotton, over which a woollen cloth is spread. It must be supported on a stand, by means of plaster poured into the cavity, in which the trunk rests.

Wet preparations are preserved in spirits; and the peculiar art which raised the credit of Ruysch so high seems to be in part lost. Cotemporary authors speak with rapture of the pellucidity of his fluids, and the brilliancy of his injections. A little boy was so artificially preserved that the Czar Peter, it is said, ran and kissed it. Albinus succeeded well, though less

happily than Ruysch. Yet attentive anatomists have remarked, that the parts preserved in his glasses were peculiarly minute. Various fluids have been tried, but with little success; and we must now explain the methods of the most experienced dissectors.

When a part is to be preserved in spirits, it should be previously macerated in water, continually changing it, to prevent putrefaction, till it passes off pellucid. Every particle of fat and cellular membrane should then be separated, the hollow parts and cavities distended with hair; and the ducts, or more important blood vessels, pointed out by the introduction of bristles, quills, or bougies. If then put into alcohol, it will soon acquire firmness enough to admit of the removal of the stuffing.

Every object does not require spirits of the same strength. Those which are thick and massy require pure alcohol: those which are less so, proof spirit; and the membranous objects, one part of spirit, and two of water. The spirits and water should be previously mixed and filtered. Immersing some preparations in pure colourless oil of turpentine gives them transparency, and shows the internal organization and arrangement of the blood vessels very perfectly; but is adapted only to those which are to be dried. At first the spirits should be frequently changed.

Dr. Monro adds a proportion of vitriolic or nitrous acid to the spirit; and this mixture neither changes the colour nor consistence of the parts, except they contain mucus or serum. The brain of a young child, the crystalline and vitreous humours of the eye, become so firm in this fluid as to admit of handling. The serum and the semen are coagulated in it; and the red injection is rendered more conspicuous. For the more tender albuminous parts, two drachms of spirit of nitre must be added to a pound of spirit of wine. For other parts twenty or thirty drops are sufficient; and this fluid, it is said, comes very near the spirit employed by Ruysch.

To secure preparations and prevent the evaporation of the spirit requires many minute contrivances, scarcely within our scope to develop. The best method is to have the top of the glass accurately ground and polished, on which a piece of plate glass of the same size is to be laid. On the edge of the vessel a drop or two of gum water is placed, and the piece of plate glass laid gently on. The gum water will then, by capillary attraction, run round the rim, closing the little interstices which the polisher may have left. A piece of tin foil should then be moulded over the cover and the edge of the jar, and the whole secured by a wet bladder reaching below the tin foil, covered by a leather closely tied to the neck of the jar, well varnished, especially round the cord. The glass should be thick and free from any irregularities, so as to magnify the preparation without any distortion. With every precaution, however, spirit gradually evaporates. The best way of suspending light bodies is by a floating glass globe; larger ones by a stick fixed across, for a thread continued to the edge of the jar conducts the spirit, and assists evaporation.

PRE'SBYTÆ, (from *πρεσβυς*, old). See AMBLYOPIA, and OCULUS.

PRESERVATI'VA A'QUA, (from *preservo*, to prevent). See ANTIVENEREALIS AQUA.

PRESU'RA, (from *πρεθω*, to inflame). Inflammation of the ends of the fingers from cold; the *phlogosis erythema* of Cullen.

PRIAPÆ'IA. See NICOTIANA MINOR.

PRIAPI'SMUS, (from *Priapus*, the heathen god). A PRIAPISM; an erection of the penis without any lascivious idea or inclination, with violent pain, is a spasmodic contraction of the *erectores penis*, wholly unconnected with the state of fullness of the *vesiculæ seminales*; and the disease of advanced life. Priapismus affords a striking instance of spasm arising from debility. Camphor and opium at night, with bark and warm aromatics in the day time, are the best remedies; but we can in general only palliate: the disease is seldom removed. See IMPOTENTIA.

PRIMÆ VI'Æ. The FIRST PASSAGES; that is, the stomach and duodenum.

PRIMU'LA VE'RIS, (from *primus*). See PARALYSIS.

PRIMU'LA ODORATA. See AURICULA URSI.

PRINCEPS ALEXIPHARMICO'RUM. See ANGELICA.

PRINCI'PIA, (from *princeps*). The PRINCIPLES OF ELEMENTS. In science it is the appellation of rudiments, or of those leading propositions on which the whole depends; thus, to mark the extremes of the scales, we have the *principia philosophiæ*, and *principia medicinæ*.

In analysis, the principles of bodies are those ultimate results beyond which we cannot proceed. According, therefore, to the progress of science, we have rested at different points, returning lately, with Aristotle, to earth, air, fire, and water. Yet air and water are certainly not elements, for water can be decomposed; and when we speak of air, we know it to be a compound, though we are unacquainted with its different bases. In fact, the only elements we can now recognize are earth and fire: yet of the common principle of the different earths we are still ignorant. Principles and elements are, therefore, words which ought to be effaced from chemical nomenclature; or, at least, they ought not to be used but as an expression denoting the last term of our analytical results; and it is always in this sense that the true philosopher uses the word.

PRIOR ANNULARIS INDICIS and MEDII. Interosseous muscles of the hand, moving these respective fingers.

PRIVATI'VI, (from *privo*). PRIVATIONS, OR DEFECT OF POWERS; synonymous with *dysæsthesiæ* and *dysorexiæ* in Cullen's Nosology.

PROBE, (from *probo*, to try). A surgical instrument, employed in examining the condition of a wound; the direction of a sinus; or the state of a bone. It is usually of silver, rounded at one end, and triangularly sharp at the other.

PRO'BOLE, (from *προβαλλω*, to project). See APOPHYSIS.

PRO'BANG. A flexible piece of whalebone, with sponge fixed to the end. See DEGLUTITIO.

PROCA'RDION, (from *προ*, before and *καρδιον*, the stomach). The PIT OF THE STOMACH.

PROCATA'CTICA CAU'SA. The PROCAT-ARCTIC CAUSES, (from *προκαταρχομαι*, to precede). The pre-existent cause. See CAUSA.

PROCE'SSUS. A PROCESS (from *procedo*, to start out). In chemistry, the operation in which a new substance is produced.

In anatomy, it is a protuberance or eminence of a bone. If the process projects in a roundish ball it is called *caput*, and the narrow part *cervix*; when oblong, and unequally rounded, a *condyle*; when rough and unequal, a *tuberosity*. Processes which terminate in a sharp point are denominated *coronoid*; those which form a longitudinal ridge, *spina*, sometimes *crista*; the *labia* are each side of a broad spine; and brims of cavities are named *supercilia*. The use of processes is to assist motion, by allowing a greater surface for the origin, larger attachment, and more advantageous direction of muscles. See *APOPHYSIS*, and *EPIPHYSIS*.

PROCE'SSUS CILIA'RIS. See CILIARE LIGAMENTUM.

PROCE'SSUS MAMILLA'RES. See OLFACTORII NERVI.

PROCE'SSUS VERMIFORMIS. An appendage to the cæcum, resembling a worm, terminating in a point. Its use is unknown. See *APPENDICULA VERMIFORMIS*.

PROCIDE'NTIA, (from *procido*, to fall down). See *PROLAPSUS*.

PROCIDE'NTIA A'NI; *prolapsus*, and *exitus ani*, *exania*; the FALLING DOWN OF THE FUNDAMENT, is a relaxation of the sphincter, admitting the inversion of the internal villous coat of the intestine, with a proportional tumour.

The causes are, weakness, aggravated by costiveness, piles, diarrhoeas, or tenesmus. It is induced also by every cause of violent forcing, as hard labour, or a stone in the bladder; and every cause of paralysis in the levatores and sphincter ani. Hoffman attributes it to a relaxation of the ligaments of the intestines. Infants are the most frequent subjects of this disorder, in consequence of debility.

The tumour, which is of a fleshy colour, sometimes wrinkled, at others smooth and shining, accompanied with an uneasiness, and an ineffectual desire to go to stool, sufficiently distinguishes the complaint, which is sometimes mistaken for the piles. A ligature hath been applied about the prolapsed anus, in order to extirpate the supposed hæmorrhoid.

When costiveness, a stone in the bladder, or labour, occasion this complaint, the cure is sometimes effected: when a diarrhoea follows it is more difficult; if the hæmorrhoids supervene we rarely succeed.

If the disease, as sometimes happens, should proceed from acrid matter, the cause is distinguished by a sharp, pungent pain after every motion, and the relief is effected sometimes by chalk and mucilages; by mucilaginous clysters retained by opium; more frequently by equal parts of wax and soap, with a small proportion of the Theban extract. If the tenesmus is violent, the mucilaginous clysters, with a large proportion of opium, will be necessary, and the latter should be in a solid form. Should it proceed from costiveness, the mildest laxatives, particularly the castor oil, will be most useful. Rhubarb and aloes are highly injurious, and recommended only by indiscriminating empirics.

If the prolapsed intestine be swelled, then cold astringent applications are necessary, and by supporting the tumour with the palm of one hand, the fingers of the other will gradually replace the fallen intestine. We must, however, not violently persevere, but act only

during the relaxation of the spincter. After the reduction the part may be suspended by the T bandage.

When the prolapsed intestine is contracted by the sphincter ani, and cannot readily be returned, Mr. Pott advises bleeding, opium, fomentations, and an anodyne and emollient poultice to the part, to procure the necessary relaxation for the reduction. If extirpation proves necessary, it is best performed by ligature, for the hæmorrhage which would follow excision must be highly dangerous. If the prolapsus is large, a strong needle, double threaded, may be passed through the intestine, tied above on one side, and below on the other. If the prolapsus is small, a double ligature should be passed round its whole diameter; and in both cases be left to drop off. The pain is allayed by poultices, opium, &c. The sphincter afterwards performs its office.

If a gangrene affects the intestinal fold, the discoloured part, slightly scarified, should be repeatedly fomented with warm brandy, applying in the intervals the cataplasma à cumino.

When the prolapsed part cannot be easily retained in grown people, Cheselden recommends taking away a piece of the prolapsed gut lengthways, for, after the cicatrix is formed, it will never descend; a practice which Pott disapproves.

See Gooch's Cases and Remarks; Pott's Works; Turner's, Wiseman's and Heister's Surgery; Bell's Surgery, vol. ii. p. 268; White's Surgery, p. 380.

PROCIDE'NTIA O'CULI. See MALUM.

PROCIDE'NTIA U'TERI, *metroptosis*, *ecytoma*, *hysteroptosis*. Different degrees of this disorder are: 1. *Relaxatio*; A BEARING DOWN OF THE WOMB; when the womb descends down to the middle of the vagina; 2. *Procidencia*, when it descends to the labia; 3. *Prolapsus*, when it falls through the labia pudendi. *INVERSIO*, and *RETROVERSIO*, q. v. are different complaints. See also *PREGNANCY*.

The lesser degrees of this complaint are discovered by the touch, the greater by the eye. If the woman stands upright, a finger introduced into the vagina will discover the disease; and if the os tincæ be felt, the case is distinguished from a descent of the vagina, though the distinction is sometimes difficult. If the disease happens during pregnancy, the weight pressing down renders walking difficult and painful; micturition difficult; costiveness; and a numbness in the legs and thighs.

The pain is usually felt near the insertion of the broad ligaments, though these do not seem to support the womb; and the cause seems rather to be a relaxation of the vagina, which really supports it.

Girls are sometimes the subjects of this disease; but it most frequently happens to women who have experienced repeated hard labours; who have exerted themselves too soon after delivery; and are of a weak relaxed habit.

Leucorrhœa consequently predisposes to this disease, and it often arises from straining, lifting heavy weights, and whatever produces a strong action of the abdominal viscera.

If neglected, the disease becomes painful, obstinate, and inconvenient; sometimes inflammation, ulcers, or a cancer, are said to be the consequences.

It is necessary, therefore, for women to guard, with

great care, against the first feelings of the complaint, and to indulge themselves with rest, as well as to brace the constitution by tonics, cold bathing, and astringent injections. The bowels should be kept free, and every active exertion avoided. If the water be suppressed by the descent of the uterus, the tumour must be replaced, and the patient laid in bed, with her head lower than the trunk; and in making water the tumour may be supported. Should this plan fail, the catheter must be introduced. The prolapsed uterus sometimes ulcerates, from the access, it is said, of the air, or the acrimony of the urine, but in reality from the strangulation of the upper part; and the uterus should be replaced without attending to this circumstance.

In general the cure is only palliative, and consists of replacing the womb, rest, and introducing a pessary into the vagina, to prevent the uterus from falling lower. This sometimes produces a radical cure, and the relaxed parts recover their tone. In lesser degrees of this disorder, the usual confinement in bed during the next lying-in hath effected a cure; and when it occurs in early pregnancy, it disappears when the womb has enlarged so much as to rest on the pubes. A pessary should be introduced as soon as convenient after delivery, and worn for some time after the woman walks abroad. A round pessary is preferable; and it should be so large as to occasion some uneasiness in passing it, since it will otherwise be apt to fall down. See PESSARIUM.

If a lacerated perinæum is the cause, a cushion may be placed with its convex side to the os externum, and secured by the T bandage; and if the prolapsus hath been neglected, and a swelling with inflammation has come on, bleeding, cooling laxatives, fomentations, and poultices, are necessary: if a mortification appear, the bark with astringent ones. A pessary must be applied as soon as the patient can bear it. Whenever a gangrene or a cancer appear, reduction increases the symptoms, or produces, new and fatal ones; but if there are ulcers, the part should be restored with all convenient speed, without waiting for their healing.

When the uterus not only descends, but is turned inside outward, it is styled *inversio uteri*. This only happens immediately after delivery, when the os tincæ is nearly as large as the fundus; and the funis is forcibly pulled to bring away the placenta. Whatever be the cause, the womb must immediately be restored, or the consequence will soon be fatal; for its orifice will contract, and prevent the necessary relief. After emptying the bladder, lay the patient on her back with her hips raised, and with the hand restore the inversion and gently return the uterus, retaining it till a contraction takes place, and afterwards supporting it as in case of prolapsus.

Dr. Leak advises, after the parts are reduced, the frequent use of the following astringent injection. R Aluminis et vitrioli, alb. āā ʒ i. aq. bullient. ꝑ i. solve et cola. At the same time we must endeavour to strengthen the whole system by nourishing diet, chalybeate waters, and the bark. If no internal disease forbid, the cold bath will give great relief.

Should the descent of the tumour prevent the patient from walking, a fine sponge wrung out of alum water may be dried in a compressed state, cut into any convenient form, and introduced as high as possible. It

VOL. II.

will act by its astringency, and by its pressure in a gentle and uniform manner; and during the use of this application the astringent injection may be used twice a day; and the sponge tent should be made gradually smaller as the vagina contracts.

In the Edinburgh Medical Commentaries, vol. ii. p. 43, we are told that a woman of singular fortitude, about fifty years of age, was much afflicted with prolapsus uteri. After trying many remedies in vain, she at length cut into the substance of the uterus with a common kitchen knife. A considerable hæmorrhage ensued; but the uterus gradually contracted, and she had no return of the prolapsus, nor any bad symptom. Having boasted of her success, many women in the neighbourhood afflicted with the same complaint applied for her assistance, and, by a similar operation, were effectually cured.

In the prolapsus vaginæ the same method of cure is still more strongly recommended; and this peculiar case has suggested the idea that scarifications may be sometimes useful.

See Ruysch's Observations, N° 1, 7, 9, 10. and Saviard. London Medical Observations and Inquiries, vol. iii. p. 1. vol. iv. p. 388—400; Medical Museum, vol. i. p. 227—230; Heister's Surgery; Hamilton's Midwifery, edit. 5; Edinburgh Medical Commentaries, vol. ii. p. 43; London Medical Journal, vol. vi. p. 387; White's Surgery, p. 460; Leak's Medical Instructions, edit. 5.

PROCIDENTIA U'VULÆ. See HYPOSTAPHYLE.

PROCIDENTIA VAGINÆ; *colpoptosis*. The degrees of this disease are different; but when the whole vagina or a part appears through the pudendum, it may be called a *prolapsus*; when it descends to the labia a *procidentia*; and when not so far a *relaxatio*. Widemanus relates a case of this kind which had all the appearance of a prolapsus uteri, but not properly distinguished until it was too late to afford any relief; but generally the disease is known by observing the os tincæ, which distinguishes the prolapsed womb from all other cases of descent, and from the *inversio*, which only happens after labour. When the whole vagina is prolapsed it appears like crude bloody flesh; and if it swells violently, attended with inflammation, a sphacelus will soon come on; but if the swelling be slight, without inflammation, the tumour will neither be troublesome nor dangerous. This disorder should be distinguished from a tumour, a fungus, a sarcoma, &c. of the vagina.

The part may be restored with the fingers, and the patient should rest in bed for some days, using an injection of warm vinegar and water; red wine and water; or a solution of cerussa acetata. In most cases the first object seems to be ablution, then reduction, and afterwards corroborants, such as the bark, vitriolic acid, cold bathing, and avoiding all violent exercise. If these fail, the T bandage must be worn.

See Heister's Surgery; Hamilton's Midwifery, edit. 2. p. 247; Edinburgh Medical Commentaries, vol. ii. p. 46.

PROCIDENTIA VE'SICÆ URINARIÆ. The inversion of the uterus never happens without carrying the bladder with it into the perinæum, together forming a tumour. The bladder in this position is no longer exposed to the pressure of the abdominal muscles, and not having force enough in this posture to contract, the

F f

patient is compelled to squeeze the bladder with her hands, or between her thighs. The catheter if introduced must not be thrust inward, but downward, the fundus of the bladder being below the meatus urinarius. See London Medical Observations and Inquiries, vol. iii. p. 1.

PROCO'NDYLUS, (from *πρῶ*, *before*, and *κονδυλος*, *finger*). The first joint of each finger next the metacarpus, ante internodium.

PROCTA'LGIA, PROCTI'TIS, (from *πρωκτος*, *anus*, and *αλγος*, *pain*,) *clunesia, cyssotis*. INFLAMMATION OF THE ANUS. A variety of the phlogosis in Dr. Cullen's system. It is discovered by a hot and acutely painful tumour at the anus, irritated by pressure, obstinate costiveness, and fever. The causes are, riding; violent blows; acrid applications; piles, &c. The disease yields with difficulty, often terminates in abscess, and is sometimes succeeded by fistula. See INFLAMMATIO, ABSCESSUS IN ANO, and FISTULA IN ANO.

PROCTOLEUCORRHŒ'A, (from *πρωκτος*, *anus*, *λευκος*, *white*, and *ρῆω*, *to flow*). A white mucous discharge from the anus.

PROCTORRHŒ'A. A yellowish or sanious discharge from the rectum, accompanied with heat and itching about the anus. Whether, however, the discharge is white, yellow, or streaked with blood, the disease is the same, and consists of increased mucous discharge from the rectum, either from cold or irritation. It scarcely differs, except in its seat, from CÆLIACA, q. v.

PROCU'MBENS, (from *procumbo*, *to lie flat*). Botanically applied to a trailing plant.

PRODU'CTIO, (from *produco*, *to bring forth*). See APOPHYSIS.

PRODRO'MI. See ETESIE.

PRŒ'BIA, PRŒ'BRA. See AMULETA.

PROEGU'MENE, (from *προηγιομαι*, *antecedo*). A PRECEDENT CAUSE; by the Latins called *antecedens*. See CAUSA.

PROFLU'VIA, (from *profluo*, *to run down*). The fifth order of the first class of Dr. Cullen's Nosology. A pyrexia, with increased excretion, not naturally bloody; under which he includes two genera, *catarrhus* and *dysenteria*, as the only instances of febrile profluvia.

PROFLU'VIUM. A FLUX of any kind.

PROFLU'VIUM URI'NÆ. See DIABETES.

PROFU'NDA BRA'CHII VE'NA, vel **PROFU'NDA SUPE'RIOR**, (from its deep situation,) a branch from the basilica, sent off from it below the neck of the os humeri, and near the hollow of the axilla: it runs along the side of the brachial artery, and spreads in the adjacent muscles.

PROFU'NDUS MU'SCULUS MA'NUS. See FLEXOR INTERNODII, TERTII DIGITORUM MANUS.

PROFU'SIO, (from *profundo*, *to pour out*). PASSIVE HÆMORRHAGE. A genus in the class *locales*, and order *apoceneses* of Cullen, who defines it a flux of blood, and distinguishes it from active hæmorrhages, as not febrile, but occurring from wounds, leeches, &c.

PROGERMINUS ABSCE'SSUS. An abscess arising from a viscid and almost corrupted phlegm.

PROGLO'SSIS, (from *πρῶ*, *before*, and *γλωσσα*, *the tongue*). See LINGUA.

PROGNOSIS, (from *πρῶ*, *before*, and *γινωσκω*, *to know*), the foretelling of what may happen to the patient,

either with respect to a future, or the progress or termination of a present, disease.

The prognostic of an impending disease may be drawn from the appearances, the mode of living, the changes in habits or situations, and the critical periods of life. If a person, from a healthy state, becomes sallow, weak, with loss of appetite and spirits, or with disturbed sleep, we may easily suppose that some disease threatens. If these appearances come on slowly, with a slight yellowness of countenance, obstructions in the primæ viæ or the liver have probably taken place; if more rapidly, with slight shiverings occasionally, a fever impends. A regular evening exacerbation, with cough, portends a hectic; a more violent shiver, with considerable heat, a continued fever, a deep redness in the face, with inflammation in the eyes, plainly point out accumulations in the head, and chiefly venous ones; but these often arise from diseases impeding a free circulation through the lungs, so that the state of these organs must be considered in forming the prognosis. They often exist together, and aggravate each other. Violent fixed pains in the head, recurring at irregular intervals, and usually excited by every cause of increased circulation, generally show that some fixed obstruction prevents the free course of the blood through the organ; and this is followed by convulsions, sometimes insanity, and frequently a sudden termination of life. A fulness in the stomach and abdomen are certain signs of accumulation, and it depends on the comparison of the other symptoms, whether it be water, infarcted viscera, accumulated contents, or merely flatus, and the prognostic must be regulated by comparing the symptoms of each disease. If a slight pain in the back be increased by stooping, and moving forward either leg, an affection of the psoas muscle may be apprehended; and if the pain is in the hip bone, shooting out at the knee, with a dragging of the leg on that side, some injury has taken place in the hip joint.

The *mode of life* will often lead us to form some prognostic of an impending disorder. Late hours cannot be borne with impunity, except by a very few, and their principal effect is to induce obstructions in the chylopoietic or other abdominal viscera. If connected with drinking spirituous liquors, the effect is usually felt in the liver. The sedentary student has reason to apprehend biliary accumulations, with costiveness, and a train of hypochondriac symptoms; but activity, however great, if sleep be allowed, leads to no complaint. Nature will not be deprived of her rights with impunity; nor can any one detract from his hours of sleep, in any considerable degree, without detracting, at least in a certain proportion, from the period of this life. Excess in eating or in drinking will equally lead us to foretel diseases of the stomach, often of the head, connected with the stomach; but retributive justice is frequently seen to punish the former error with the greatest severity, in the feelings of the patient, by loss of appetite. Almost every situation is apparently consistent with health, if free air be admitted; but its deficiency leads to a variety of diseases from debility, which may be easily foreseen, and can only be avoided by a change. Such creatures of habit, however, are mankind, that this chief assistant to health, free open air, can be dispensed with, often with impunity. The diseases of artificers are scarcely parts of the present subject; nor indeed have we found an appropriate portion of our work for their consideration.

The different parts of the enquiry are, however, scattered in various articles, under the appropriate complaints.

Changes of habits and situations are frequently the source of different diseases, which we can often prognosticate, and sometimes guard against. Abstemiousness, suddenly adopted after free living, and the contrary, are sources of disease, the former chiefly of complaints arising from insufficient stimulus, the latter from too great excitement. A sedentary, after an active life, is often attended with languor, low spirits, and visceral accumulations; the contrary, at first with languor and fatigue, soon followed by increased tone and vigour. The pure air of mountainous regions is a too active stimulus to lungs accustomed to the exhalations of marshes; and, on the contrary, a low situation, after a more elevated one is often followed by intermittents, cachexy, and dropsy.

The *critical periods* of life merit attention also in our prognostics of various diseases. We have thought that PITHUISIS, q. v. was connected with a slower evolution of the body in its progressive stages; and we know that if scrofulous affections do not yield in the first, or, at most, in the second septenary, there is little prospect of a cure. The same may be said of epileptic paroxysms, and of chorea, though to the latter there are many exceptions. The critical period of the female life is that of the cessation rather than appearance of the catamenia, for unless hectic symptoms come on, the discharge, though at the distance of many years, becomes regular. The period of cessation, if not preceded by free, often copious, discharges of the menses, prognosticates a less healthy old age. If lancinating pains in the bottom of the abdomen attend; if the countenance is dark, and the discharge blackish; a local disease in the uterus may be suspected. The German authors are equally gloomy prophets respecting the appearance of the hæmorrhoidal flux in men, but in this country there is little room for such apprehensions.

Such is the outline of what might form a useful work on the prognostics of impending diseases, of which we have had hitherto no example. We must next consider the *prognostics of death or health from the symptoms of diseases which are present*. This part of our work also, in a general and scientific view, has scarcely been attempted.

Prognostics in diseases are usually drawn from the vital, animal, or natural actions. The vital actions which give the best information, are the states of the circulation and the respiration. The first is chiefly known by the pulse, and on this subject we must, in part, anticipate what we shall soon explain. A pulse which strikes the finger with firmness, and is with difficulty compressed, shows a strong action of the artery, and a general firmness of the whole system, in which we should suspect little danger, except from excess of excitement. Yet its counterfeit, a throbbing pulse, which strikes the finger with apparent but not real firmness, will sometimes mislead. The latter has not the same firm continued resistance; it strikes sharply, but not strongly, and the relaxation is as rapid as the impulse is transitory. When there is internal irritation the throbbing pulse will continue often to the last, showing, in every succeeding moment, its peculiar character more strongly; but in the commencement of fevers it often so

nearly resembles the strong pulse as to deceive. A small pulse may be mistaken for a weak one, unless by a practitioner of experience; but the lightness of its strokes depends on the small size, sometimes the depth of the artery. In general, the strong, slow pulse is favourable, except in affections of the head, or occasionally after narcotic poisons. In these cases it is often extremely slow, and shows that the irritability of the heart is diminished.

A large and small pulse refer rather to the contents than the strength of the artery. The former, connected with fulness, shows also a weaker tone of the solids; the small pulse can scarcely be distinguished from a weak one: neither are favourable. Each shows want of energy; nor is this increased by a combination with plethora. What is styled a hard pulse combines fulness with considerable strength. The artery strikes the finger as a large firm cord, and this occurs only in the most violent inflammations, where evacuations can be borne with great ease.

A quick and slow pulse are referrible to their numbers in a given time; but in some cases, as mentioned above, the stroke is rapid, and the intervals long, which is called a *pulsus celer*; when the stroke is long and the intervals short, it may be called, by way of distinction, a retarded pulse. Each are marks of a weakened circulation, particularly the former, which shows the contraction to be in part spasmodic.

The number of the pulse is not perhaps of so much consequence as the young physician imagines, who keeps his stop watch with anxiety in his hand; for it not only varies in different constitutions, but is excited to an inconceivable rapidity in hysteric patients, by the slightest circumstances, without portending danger. In general, the physician should feel the pulse on his departure, as well as in coming. A natural pulse is from about 60 to 80, more strictly from 65 to 75. If a pulse is at 55 or 50, there is reason to apprehend some compression on the brain. If, in the early stages of fever, it rises to 120 in a female not peculiarly irritable, it portends considerable danger, either from debility or irritation. If, at any stage, it exceeds 120, or considerably exceeds it, except for a very short time, we have the greatest foundation for apprehension. A very quick pulse in complaints where the circulation is not usually much affected, is a symptom highly dangerous. In fevers, the pulse, if above 96, generally exceeds 100, and there is seldom any medium between 108 and 120.

The only other distinction, relating to the prognosis, is the regular and intermitting pulse. The last is a dangerous symptom, unless it be habitual: a circumstance not uncommon. In such constitutions, the usual intermission, on the access of fever, often disappears, and the first symptom of amendment is the return of the intermission, which, at the end of a long fever, may appear alarming, if not connected with other favourable symptoms.

The state of the circulation is also known by the appearance of the complexion. A sallowness and a want of transparency shows that the blood is not carried to the extreme vessels; and even when the cheeks are flushed, if the skin round the lips and nose is of an opaque, sallow whiteness, the conclusion will be the same, and the strength of the constitution is considerably impaired. The appearance of the eyes is equally indicatory of strength and weakness, as already explained

see OCLUS), and the character of the features is preserved in proportion to the remaining strength (see FEBRIS and PHYSIOGNOMIA). Each appearance depends on the state of the circulation.

Respiration is a vital action connected with the state of circulation, and of the greatest importance as a prognostic. We mean not to allude to the state of this function in disorders of the chest, where it is necessarily disturbed, but to speak of it as a symptom in more general diseases. A free unincumbered respiration is usually a favourable sign; but from the due performance of this function there are many deviations. In point of strength it differs in increased and diminished motion, styled strong and weak. The first is occasionally full and deep, the latter slight and insufficient. If the accessory organs are called into action, it is styled short and suffocating. In point of celerity it is quick or slow; of regularity, synchronous or intermittent; of sound, stertorous, stridulous, or rattling.

Respiration *slow, full, and deep*, shows the strength and all the vital organs to be unimpaired, and in every situation is highly favourable. The *weak, slight, and insufficient* respiration is, in general, a mark of weakness; the *suffocating*, of obstruction; the *quick*, of considerable irritation, exciting rapid expiration. The *stertorous* shows insensibility, from compression on the brain; the *stridulous*, inflammation of the trachea; the *rattling*, accumulations of phlegm often unconquerable; and the *intermittent* attends the last efforts of expiring life. In health, about three or three and a half pulsations of an artery take place in the interval of each inspiration; but this, like the number of the pulse, is subject to many variations.

The animal actions from which we may draw prognostics are, the senses, muscular action, and sleep. When the internal and external senses are uninjured in acute diseases, the prognostic is favourable; for in chronic complaints, unless in the last moments, they are seldom affected. Violent delirium is a symptom of active inflammation in the brain, and is dangerous only so far as it shows a violently acute disorder. The wandering delirium in fevers of a low kind is also a symptom of no great danger, unless it comes on early, and in a degree disproportioned to the state of fever. In other complaints it will excite serious apprehensions, and shows that the inequality of excitement depends on debility. If it persist after the cessation of the fever, unless evidently in consequence of debility, there is reason to suspect an organic injury in the brain, and more so if violent delirium has occurred in the early part of the complaint. The injury is generally an abscess, whose most common seat is the basis of the brain. Sometimes, however, a general fulness of the vessels only can be discovered. Delirium, arising from want of sleep, is said not to be dangerous; but the want of sleep itself is generally owing to a languid inflammation of the brain. General restlessness is a symptom of the same kind, from the same source.

Of the external senses, and their organs, the eye affords the most particular symptoms by which the event may be foretold. We have already spoke of its dimness, glare, and glassiness, when explaining the structure of the organ. Besides these, a fixed look, without an object, is a symptom highly dangerous. The sensation of black spots, which induces the patient to pick the

clothes, as if he could remove them, is attributed to a partial insensibility in different portions of the retina. In fact, however, it rather depends on the immobility of the eye. We have remarked that, from the spot where the optic nerve enters, no sensation is conveyed; but, from the rapid motions of the eye, this is not perceived in health, and is only obvious when the eye is fixed. It is certainly, however, a highly dangerous symptom, though by no means a desperate one, as it has been represented. A dimness of sight, particularly in fevers, is highly dangerous; and double vision shows an irregular, perhaps a spasmodic action of the muscles, which is truly alarming. It is in general an early symptom of hydrocephalus. Each is sometimes temporary, and ushers in the attack of hysteric or epileptic paroxysms. When the eye lids fall, and can scarcely be elevated by the exertion of the will, it shows considerable weakness, and when the patient sleeps without closing them, great insensibility. The latter symptom is, however, often owing to an irregular contraction of the muscles of the eyes; for in such cases the pupil is drawn up under the lid. The symptom is not, however, on this account less alarming. The clear natural appearance of the eye is a favourable symptom; but too great brilliancy, or too quick motions of this organ, show approaching delirium. A severe fixed look is a similar symptom. The appearance of the eye lids sometimes points out a weak state of the system, particularly when there is a blackness in the lower lid towards the inner canthus.

A noise in the ears in fevers is said to be a sign of approaching delirium, though frequently a symptom of weakness only, and often occurs from this cause in weak and old people. If this noise occurs in the beginning of fevers, it is said to foretel a violent and a tedious disease. Hearing peculiarly acute is often a precursor of delirium, and, without fever, is the effect of strong excitement in the brain. The author of this article, when he has sat at his literary labours for some hours undisturbed, has distinguished words at a distance where others could scarcely hear a sound, and has found his pulse often below 60, sometimes even at 50. Dimness of hearing, in cases where the head is not peculiarly affected, is dangerous; in fevers it is said to be a favourable symptom. It certainly is not unfavourable.

The distinction of *taste* in fevers is generally lost, though it is a favourable symptom, if it is in some degree retained. A nauseous taste in the mouth is generally a symptom of putrid matter in the stomach, very often of bile, and the latter is generally more conspicuous by a slimy, putrid taste far back in the throat.

A lassitude, a disinclination to *motion*, and a weakness when compelled to exertion, show, we have said, impending disease; and when in a peculiarly considerable degree on the attack of fevers, it is a symptom of a highly asthenic complaint. It arises from the want of sensorial energy, and is sometimes in so great a degree as to produce a *fainting*, which is always a very dangerous occurrence. If attended with a considerable wandering, the danger is greater.

It is a favourable sign if in the beginning of a fever the patient can sit erect with his head elevated. In the progress the head requires support; the erect posture is painful, and must be changed for a recumbent one; turning in bed next becomes difficult; lying on the sides requires some effort; so that he is after some time

confined to his back, and at last he cannot support his situation in bed, but gradually sinks down. The more early the appearance of these progressive symptoms, the greater is the danger; and if the last occur so early in a fever as the eighth day, the case will be almost desperate. If the patient can support himself in bed, and occasionally turn on his side, about the twelfth day, circumstances are favourable. In chronic complaints the debility is considerable, and observes, in some measure, a similar progress, though not equally regular; but in these the patient sinks not from debility only, but from organic disease. In many diseases the patient can move and assist himself to the last moment. Spasms and convulsions, as marks of debility, are highly dangerous; but they seldom occur in fevers, without some suspicion of irritation combined. In infants, whose habits are more mobile, they are not equally dangerous, though generally alarming.

Sleep, if calm and refreshing, is always a favourable symptom; but if interrupted, broken by terror, excited by dreadful images in dreams; if, instead of tranquil rest, the patient starts, catches, talks in a hurried manner, though not conscious of terror, it is unfavourable. The nature of the dreams furnishes also a prognostic. To fall from heights, to be immersed in a gulf, or in the sea, are images of more dire portent than others apparently not less terrible. On the other hand, dreams, though frequent, if not terrible, are not unfavourable. As a religious mania is more dangerous and obstinate than any other kind, so these dreams, where the imagination is haunted by the fears of an offended God, and eternal punishment, are those of the most dangerous kind, because the reason, when awake, is less able to combat with the unreal image. *Deep sleep* is itself a disease, and shows considerable oppression on the brain: yet, at the period of a crisis, if attended with a soft pulse, moderately slow, and a soft, moist skin, it is salutary. After a crisis the deepest long continued sleep is not dangerous, if not attended with stertor, or with a pulse preternaturally slow.

The *natural actions* which furnish prognostics are digestion and its consequences, and the various excretions. In fever the *appetite* is at once destroyed; nor is it a favourable sign, in an acute disease, that it should remain or return too soon. In fact, the appetite does not always keep pace with the digestive powers, and the stomach craves, or is allured, while the digestion is still imperfect. In general, appetite, in acute diseases, should be distrusted, and gratified sparingly. In chronic ones it is sometimes unimpaired and ravenous, and may be indulged with little danger, but seldom with advantage. While it continues, the friends are gratified, and expectation is alive, but an attention to the effects will destroy the delusion. If it does not add to the load, and to the disease, it does not strengthen. In obstructions of the mesentery, sometimes of the liver, it continues unimpaired, and its gratification is attended with no injury. In hectic, where it sometimes continues, food of every kind is followed by oppression and sleepiness. In the former case it is only not injurious.

Thirst is one of those indications which we can apparently gratify with the least injury. As a prognostic it shows dryness of the mouth, acrimony in the stomach, perhaps in the whole system, and is generally the con-

sequence of excessive effusion from the exhalent arteries into the cavities, or cellular substance. In each case it is an unpleasant symptom; because its gratification will not always relieve the cause; for watery fluids alone are immediately thrown off by the excretories; and when, from increased exhalation, the fluids swallowed add often imperfectly to the secretion, and sometimes more certainly to the exhalation. It seems only useful when acrid saburrae exist in the stomach. We know not that it is, in other instances, highly injurious; though certainly not beneficial. *Deglutition*, unless in organic diseases of the oesophagus, is easy or difficult, in proportion as the appetite is good or bad. In hysterical cases it is also opposed often by wind, and in hiccup by the convulsion: in each case, however, the circumstances will correct the prognostic.

The appearance of the tongue is closely connected with the sense of thirst, and is of considerable importance as a prognostic. Many persons, however, have a tongue constantly white; but, in general, whiteness of its surface is a sign of fever. If white and dry, it shows the fever to be more considerable; but each appearance begins at the root, proceeds gradually forward in a triangular form, the apex of which is at the tip. This triangle gradually extends till it reaches the sides, and it recedes in the same progression. In the progress of a fever it becomes in the same order brown, a darker brown, and even black; and these colours are usually seen when the tongue is dry and hard. While the edges continue clean, and of their natural speckled appearance, there is little danger; and indeed fevers have terminated favourably, though the tongue has been, for many days, dark, dry, and even black. In one or two epidemics we have found the tongue swell and become black, without being dry, though the fever has terminated favourably. The tongue sometimes, in the course of a fever, becomes suddenly clean, and of a shining red. This, in general, shows that the fever will be of some continuance. No separation of the fur is, however, salutary, that does not leave the tongue of its natural hue, and the papillae distinct. We have thought that when the tongue has assumed this shining red colour, it has portended aphthous eruptions in the throat, for these sometimes follow, and their appearance is known by small mucous spots on the shining surface. These, however, are not dangerous, except in fevers highly putrid. The tongue sometimes cleans slowly in elderly and debilitated constitutions; and, independent of fever, in such habits the tongue is often black at the back part. Neither is a white tongue always a sign of fevers; since, in the greater number of people, anxiety of mind, and even a restless night, will produce this change.

A sense of heat in the upper orifice of the stomach shows either acrimony chiefly acid, sometimes oily; occasionally an extraordinary sensibility of the cardia. In each case we can draw neither a favourable nor an unfavourable prognostic; for it is a symptom chiefly of indigestion. A heavy load in the stomach is an unfavourable symptom, unless it arise from indigestible food, since it shows either an accumulation of viscid mucus, or a want of energy in the organ. When the irritability of the stomach is exhausted by excessive stimuli, the effect is a heavy load.

Vomiting is the connecting symptom between affec-

tions of the digestive organs, and those of the secretory ones. When violent and incessant, without previous accumulations of bile, it is an unfavourable symptom, as it generally arises from irritation on the brain. Even when from bile it is distressing, for the act of vomiting emulges the biliary duct, and the inverted motion of the duodenum carries the bilious fluid back into the stomach, thus furnishing new fuel for the flame. In general, therefore, it should be steadily checked, after the contents of the stomach have been evacuated. In exhausted constitutions, either in consequence of age or free living, particularly from excess of spirituous liquors, a black flaky matter is discharged sometimes from the stomach; a symptom of the most dangerous kind, which may be palliated, but the patient seldom wholly recovers.

A frequent *diarrhæa*, independent of mucous inflammation, is dangerous, as it shows considerable debility, and a difficulty of retaining the food so long as is necessary for its assimilation. If the discharge be chylous, it is more unfavourable, as the digestive process is evidently imperfect. If mucous, with straining and tenesmus, the danger is not so great, as it then generally arises from irregular action of the lower part of the intestine; if fetid and sanious, there will be great reason to apprehend a malignant ulcer; if with lancinating pains, a cancer. Too little action of the bowels is highly inconvenient, particularly in pregnant women, but seldom, in other circumstances, dangerous, except from organic obstruction, or palsy of the moving fibres. The former is rare, and the latter not common except in old persons and in exhausted constitutions.

The other excretions, which have attracted attention as prognostics, are, the *perspiration*, the *sputum*, and the *urine*. The former was considered as the truly salutary discharge, but the want of those distinctions which we endeavoured to establish in the article *DIAPHORETICA*, q. v. seems to have occasioned the greatest inconveniences. Sweat was excited, while the diaphoe was only salutary. It is now generally acknowledged, that the salutary perspiration is not attended with heat, is not clammy to the touch, is generally diffused, without any load, uneasiness, or anxiety. The sweat of an opposite kind does not relieve, but debilitate. Cold, clammy sweats arise from a total relaxation of the exhalents, and are, in general, the preludes of death. In some constitutions, perspiration is almost wholly absent; and this is one of the idiosyncracies often within the limits of health. In fevers, however, which attack constitutions of a different kind, a dry, harsh skin is an unfavourable symptom.

The *sputum* is chiefly examined as a prognostic in hectic and peripneumony. In each we have already noticed it; but we may now add, that all *mucous discharges* which are salutary consist of a bland, apparently equable, fluid, capable of being extended in strings, and containing, when examined in a microscope, minute globules.

The prognostics from the *urine* have filled volumes, which modern practitioners have ungraciously neglected, indeed, we suspect, with good reason. Yet a work of this kind must contain not only what is useful, but often what may appear ridiculous, if it has formed a part of the science; for it is our duty to delineate what it has been, and what it is.

The urine claimed the particular attention of practitioners, because they considered it as denoting the degree of concoction, and they often neglected, in their anxiety to mark this change, the varieties which arise from sex, temperament, and the time of discharging it. A very simple precaution was omitted. The morning urine was selected; but, if none had been discharged in the night, not only that which was *secreted* during the remission, but that also separated during the exacerbation, was mixed. If, in the progress of a fever, the urine be carefully examined, with these precautions, it will be at once seen how little dependence can be placed on the usual observations. As in the intermittent pulse, there is also an anomaly in the urine of some constitutions. The urine of many persons in health deposits little or no sediment; but in fevers the sediment appears copious, and often red. The returning health, in these cases, is marked by urine remarkably clear.

Urine must be examined only after it has been made for some time, and it should be poured into glasses while yet warm. A portion of the urine, made every time, should be reserved, and the time it is discharged, as well as the quantity, should be noted. The glasses should be kept in air moderately cold. With such precautions, some useful lessons may, perhaps, be drawn from its appearance.

The quantity of urine varies in different persons, and, in the same, at different periods. From this no conclusion can be drawn; and the greatest apparent deficiency, unless other cachectic symptoms, and a tendency to accumulation appear in the different cavities, is not dangerous. In general, where it is remarkably deficient, it is at other times equally redundant; and this chiefly occurs in hysterical constitutions. The excess is also at no time dangerous, unless the quality of the urine is changed, since it only depends on irregular action of the renal vessels. The natural urine is of a yellowish colour. When of a deep dark red, its quantity is small, and either fever, or dropsical effusions, are the cause. To this, however, there are exceptions. When the urine is in small quantity its colour is necessarily high; and at the conclusion of a gouty paroxysm, as well as of a paroxysm of an intermittent, it throws down a brick coloured sediment, styled *lateritious*. When highly red, without depositing any sediment, in the language of the Galenists, it shows the greatest crudity and great difficulty of concoction; in other words, a violent and probably a long fever. When floculi, instead of a light cloud, are seen in it, or an oily pellicle appears on the surface, we have thought it showed a weakness of the habit, and have been accustomed to expect little energy in the constitution to shake off the complaint. We know not, however, that observation will fully support this opinion. The progress of the cloud in the urine, in cases of fever, is regular. It is at first suspended at the top, gradually falls, though for a day or two often stationary near the middle of the glass, and at last reaches the bottom. It falls to the bottom often some days before it is accompanied by any sediment; but when a white or reddish sediment also falls down, the crisis is nearly complete. We sometimes find, in the middle of a fever, a sudden fall of a reddish sediment, which is transitory; for the urine again becomes clear, so that the prognosis from the urine must be corrected by appearance of amendment in other respects, and by the critical day of

the fever. The urine is sometimes turbid, if not at the moment of discharging it, very soon afterwards; and this, according to the authors of prognostics, is said to show an insidious disease. If, at an early period of the fever, ("in the days of crudity,") and no deposition takes place, it seems to portend a violent degree of fever and great debility.

Frothy urine, or which long retains the air bubbles, is said to show a tedious disease, or a slow consuming fever. In fact, it is owing to a separation of gluten or albuminous matter, and often occurs after severe fevers. It is sometimes found, as well as a pellicle on the surface, in scorbutic cases, and is occasionally iridescent. In bilious fevers, and in jaundice, the urine is sometimes yellow, occasionally black or green. The yellow urine is not, in general, an object of apprehension; but, when green or black, it is supposed to show a highly putrid state. Green urine, however, is generally bilious, with an excess of the urea, and its colour may be restored by adding an alkali. The black is more dangerous, but, unless highly fetid, we have often seen it without its being followed by a fatal event. Fetid urine in violent fevers is undoubtedly dangerous; but, in other circumstances, it often occurs without danger.

In chronic diseases, red urine, depositing a copious, red, scaly, or branny sediment, is a mark of considerable debility. It occurs in dropsy, in scurvy, and phthisis; and the most unfavourable prognostic must be drawn from its appearance. A mucous and viscid sediment is usually alarming from the apprehensions which it excites of abscess in the bladder. Mucus is, however, light and equable, wholly free from fætor; and arises, as we have seen in many instances, from an inflammation of the mucous membrane; see CATARRHUS VESICÆ. It arises also from any irritation of the neck of the bladder; sometimes from irritation from the rectum or prostate; and it is a frequent symptom of gravel and calculus.

The nature of the *alvine discharge* is of considerable importance. In acute diseases the discharge is often estimated by the number of motions rather than their appearance; and we have been told that there has been a free discharge from the bowels when the stools have not had the slightest feculence. The physician should therefore always examine them with attention. Liquid, frothy, watery motions, with little colour or smell, show, in general, a tedious fever; for in every fever there seems to be an obstinate retention of the fæces, and motions of this kind show that the spasm is peculiarly violent. When the stools, in the beginning, are highly fetid and bilious, it has been accounted a dangerous symptom; but if the discharge be free and copious, they are rather favourable. Calomel will, through the whole course of a fever, often bring off such motions, either by its superior power on the biliary secretion, or from some change which its irritation occasions: we have sometimes suspected the latter cause, and at least have not found it an essentially necessary cathartic to produce the salutary evacuations. Small black, pitch-like motions are always dangerous, and show equal weakness in the alimentary canal and the biliary system. On the contrary, the appearance of scybala, brought off with little straining or colic, is favourable. Fetid motions, in fevers, are common; and,

unless combined with other unfavourable symptoms, by no means dangerous.

In hectics, highly liquid and offensive motions are peculiarly dangerous, as they show a metastasis of purulent matter; nor can they be checked without danger. In jaundice, a change in the usual whiteness of the stools is a favourable symptom; but when they have continued of a dark colour, with little change, from the beginning of the complaint, which sometimes unaccountably happens, we are deprived of this source of our prognostic. In other chronic diseases we find little certain foundation of prognosis from their appearance.

See the *Prænotiones* of Hippocrates (including the prognostics and *proretica*), with the Commentaries of Heurnius, Mercurialis, Montani, Trincavellius, Duretus, Cardanus, Brendel, and a Fonseca; Galen de *Præcognitione et Præsagium*, vol. v.; Rhazes de *Prognosticis*; Gaubii *Pathologia*; Vater de *Præsagiis Vitæ et Morbis*; Prosper Alpinus de *Præsagienda Vita et Morte*; Vogel *Prænotionum Pensum*; Juncker *Monita circa Prognosis* et de *Cauta Prognosi*; Ludwig *Institutiones Medicæ*; Welther in Eyerel's Collection; Baglivi *Opuscula*; Horstius de *Signis Prognosticis*. Dr. Moffat has translated the *Prognostics* of Hippocrates into English.

PRO'HIBENS, (from *prohibeo*, to forbid). See ANTEDEIXIS.

PROJE'CTIO, (from *projicio*, to cast forth). PROJECTION, in chemistry, is the casting any substance to be calcined into a crucible, by a spoonful or a small quantity at a time; sometimes an addition of a small quantity of a substance to a greater quantity of a metal, in order to meliorate the latter. See Wilson's Chemistry.

PROJECTU'RA, (from the same). See APOPHYSIS.

PROLA'BIUM, (*pro*, before, *labium*, the lip; *περοχίλα*, from the corresponding Greek words). The RED PART OF THE LIPS. Under the epidermis in this part, called *epithelium*, is a collection of fine, long, villous papillæ, closely connected together, covered not only by the epidermis, but by that pellicle which covers the glandular membrane of the cavity of the mouth: this villous substance is of exquisite sensibility.

PROLA'PSUS, (from *prolabor*, to slip down). *Procidencia*, *delapsio*, *exania*, *proptoma*, PROPTOSIS, q. v. A disease in the class *locales* and order *ectopiæ* of Cullen. A prolapsus is the displacing of a soft part, so that it is generally obvious to the sight; or a tumour arising from such displacements, as in the bearing down of the rectum, or an intestinal hernia. See PROCIDENTIA.

PRONA'TIO, (from *pronus*, upside down). PRONATION. When spoken of the hand it is when the thumb is turned towards the body, and the palm of the hand is downwards.

PRONA'TOR RA'DII QUADRATUS, *transversus*; a muscle which rises tendinous from the inner part of the ulna, and is inserted into the inner part of the radius. One end of it is fixed to the lower part of the ulna, and the other to the concave side of the lower extremity of the radius, to which it passes in a transverse direction.

PRONA'TOR TE'RES, or RADII TE'RES, *obliquus*, rises from the internal inferior part of the os humeri, and tendinous from the coronoid process of the ulna. The

median nerve passes between these two portions. It is inserted into a line at the anterior convex edge of the radius about the middle of the bone.

PROPHY'LACE, PROPHYLA'XIS, (from *πρῶ*, before, and *φυλάσσω*, to preserve,) *diaphylacticos, diastostica*, the method of preserving health, and averting diseases. See **HYGIEINE** and **CONTAGIO**.

PRO'POLIS, (from *πρῶ*, before, and *πολις*, the family,) *ceranthemus*. **BEE GLUE, or BEE BREAD**, is a wax like kind of glue, found in the entrance of bee hives, formerly used as an emollient, but in the present practice neglected.

PROPRIETA'TIS ELI'XIR, *elixir aloes*, and *tinctura aloes, composita*. See **ALOE**.

PROPRIETA'TIS ELI'XIR VITRIO'LICUM. See **ALOE**.

PROPTO'MA, (from *προπίπτω*, to fall out). A less degree of **PROLAPSUS**, q. v. generally applied to laxations of the upper lip, *mammæ*, or *scrotum*.

PROPTO'SIS, (from the same,) synonymous with *procidencia*. When the eye is so enlarged as to project beyond the eye lids, it sometimes bursts; and the disease is called *oculus elephantinus, bovinus*, and *bulbus*.

In the Medical Communications, vol. i. p. 409, &c. are the following remarks on the mode of cure of hydrophthalmia, or proptosis:

The cure of the disease by seton is to be adopted only where the vision is entirely lost, as the intent of the operation is merely to remedy the inconveniences occasioned by the increased bulk of the eye. These inconveniences are, frequent pain, inflammation of the diseased eye, head ach, restlessness, difficulty of closing the eye lids, a constant effusion of tears down the cheek, and a great deformity from the bulk of the tumour. The other eye is often liable to inflammation, and the patient commonly incapable of reading, &c.

In the following operation, the surgeon and his patient should be seated in the same manner as for extracting the cataract. The seton needle being armed with six threads of white sewing silk, is to be passed from the external angle, about a quarter of an inch from the edge of the cornea, through the posterior chamber of the eye, and brought out at the same distance from the inner edge of the cornea. The pain arising from using the speculum oculi in this operation seems to overbalance the advantage gained by its fixing the eye. The threads, when fastened, must not be drawn tight, lest they should cut through the cornea before the cure is completed.

The external applications should be of the sedative kind, as the saturnine water of Goulard, applied warm. A degree of inflammation and fever come on soon after the operation, but readily give way to a cooling regimen, bleeding, and gentle laxatives. A swelling of the eye lids, and a thickening of the coats of the eye, also follow the operation; but these commonly begin to subside about the eighth or ninth day, when some of the threads may be taken out; and the swelling gradually sinking within the orbit, the patient finds a comfortable alleviation of the most painful symptoms.

For a month after the operation some of the threads may be kept in, which, after the first inflammation is removed, do not occasion much irritation. See *London Medical Journal*, vol. i. p. 346.

PRO'RA, (from *πρῶρα*, the prow of a vessel). See **OCCIPUT**.

PRO'RÆ SUTU'RA. See **LAMBDOIDES**.

PROSARTHRO'SIS, (from *πρῶς*, to, and *ἄρθρον*, to articulate). See **ARTICULATIO**.

PROSTA'TA, (from *προσταμαι*, to be adjacent to; because it stands near the bladder). The **PROSTATE GLAND**; *corpus glandulosum, adenoides*. The prostate is situated at the neck of the bladder, shaped like a heart, and about the size of a walnut; the basis lying towards the bladder, on the rectum, and the apex towards the urethra: the lower surface is the largest, and the upper ones are both flat. The membranous part of the urethra runs through it, and apparently divides it into two lobes, from whence it has sometimes a plural termination. The vasa deferentia pass also through its substance. It is a spongy body, and in each lobe there are several folliculi, which open into the urethra at its commencement. That part of the urethra between the apex of the gland and its bulb passes through a ligament at the back part of the symphysis pubis. This ligament is, of course, between the apex of the prostate and the bulb of the urethra, and this portion has been styled the *neck of the urethra*, while the part between the body of the bladder and the prostate is distinguished as the *neck of the bladder*. When the prostate gland is inflamed from a suppressed gonorrhœa, every means should be used to restore the discharge; for if this inflammation terminates in suppuration, whether the abscess break into the urethra, bladder, intestine rectum, or perinæum, it will always be attended with disagreeable consequences. The symptoms of an inflammation or swelling of this gland are known from the pain and difficulty of making water; and if we should be doubtful whence they proceed, the finger in the rectum will clearly teach us. If a suppuration has already taken place, mercury internally and externally will be necessary, with occasional laxatives. Blisters must be repeatedly applied to the perinæum, and hemlock given in large doses. If a total suppression of urine is feared from the bulk, suppuration will prevent worse mischiefs. A scirrhus, however, in this part is often untractable, though, with Girtanner, we employ the burnt sponge and hemlock, or, with Hunter, keep up a constant discharge by a blister. Michaelis in Richter's *Bibliotheca Chirurgica*, vi. b. 157, 185.

PROTORRU'TOS, (from *πρῶτος*, *primus*, and *ῥίω*, *fluo*). See **CAPNELÆUM**.

PROTUBERA'NTIA, (from *protubero*, to bud forth). See **APOPHYSIS**.

PRU'NA, (from *πρῦνον*, the sloe bush, plum tree). A name for *carbunculus à perurendo*, from its burning pain. Prunes are distinguished by epithets joined with it, viz.

PRU'NA DOMESTICA, *Gallica parva sativa*. **COMMON or FRENCH PRUNES**, the **LITTLE, BLACK, DAMASK PLUM**; *prunus domestica* Lin. Sp. Pl. 680.

This species is without spines, and covered with a smooth bark, of a dark brown colour: a native of Britain: it flowers in April and May.

Our garden plums, when ripe, and taken moderately, are pleasant, but unwholesome and indigestible: unripe, they produce colic, diarrhœa, or cholera. They are cooling and laxative, particularly the French prunes

imported from Marseilles; though, by drying, their laxative power is diminished. In costive habits they are given boiled with senna, or other purgatives, and are ingredients in the electarium à sennâ.

PRU'NA BRIGNOLENSIA, *prunello*, or BRIGNOLE PLUM; *pruna domestica*, var. α , from Brignole in Provence. It is of a reddish yellow colour, and of a very grateful, sweet, subacid taste.

PRU'NA DAMASCE'NA, the DAMASK PRUNE, DAMSONS; *damascena pruna nostrata*, *pruna domestica*, var. β . This species is generally supplied by the common prune, which it resembles in its general qualities. The prunelloes quench thirst more effectually than the others; and the French plums are most laxative.

PRUNE'LLA, (from *pruna*, a burn; because it heals burns). See BRUNELLA and BUGULA.

PRUNE'LLA. See PRUNA BRIGNOLENSIA.

PRU'NUS BRASILIENSIS. See ACAJA.

PRU'NUS PRUNI'FERA. See NUX VIRGINIANA.

PRU'NUS SPINO'SA, SYLVE'STRIS, *spinosa domestica agriococcimela*. The BLACK THORN, or SLOE BUSH, *prunus spinosa* Lin. Sp. Pl. 681, is a prickly bush, very common in hedges, producing an austere fruit, smaller than an ordinary cherry, and too harsh to be eaten before the frosts have softened them. The juice expressed before they are ripe, or affected by the frost, inspissated by a gentle heat, is called *acacia Germanica*, and generally sold for the *acacia Egyptiaca*. It differs, however, in being harder, heavier, darker coloured, of a sharper taste, and giving out its astringency to alcohol, while the Egyptian acacia is scarcely at all soluble in spirit. This fruit is an agreeable and useful astringent.

A conserve is made of the sloes by steeping them in hot water, taking care that they do not burst: and when they are soft enough to pulp, they are pressed through a hair sieve, and to one part of the pulp three parts of lump sugar must be added. (Pharm. Lond. 1788.) Sloes have been recommended in diarrhœas, hæmorrhages, in tumefactions of the tonsils and uvulæ, as gargles. Dr. Cullen considers the sloe as the most powerful of the fructus acerbi, and has often found it an agreeable and useful astringent. The conserve possesses these properties. The flowers with their calyces are moderately purgative, and, for this purpose, an ounce infused in a sufficient quantity of water, or rather whey, was found to be an useful and pleasant laxative. The powdered bark, in doses of a drachm, is said to cure agues. The dry tender leaves are considered as a good substitute for tea. See ACACIA GERMANICA.

PRU'NUS LAUROCE'RASUS. See LAUROCERASUS.

PRURI'GO, PRURI'TUS, (from *prurio*, to itch). A VIOLENT ITCHING. This is established by Dr. Willan as a genus of disease wholly independent of those contagious pustules styled the itch, and it is one of the most distressing complaints with which mankind is afflicted.

Dr. Willan makes the prurigo the third genus of his first order of cutaneous eruptions; an itching of the skin, accompanied with an eruption of papulæ, the colour of which scarcely exceeds that of the adjoining cuticle. This he denominates prurigo, and as it is not characterized during its first stages by an eruption of pustules, it is classed among the papulous diseases of the skin. He divides it into three species; *prurigo mitis*, *formicans*, and *senilis*, adding the local affections of the same

nature. The first species, *p. mitis*, is known by soft and smooth elevations of the cuticle, somewhat larger than the papulæ of the lichen, retaining the usual colour of the skin, seldom appearing red, or much inflamed, except from violent friction. They are attended with an almost incessant itching, particularly on undressing, and for some hours after going to bed. When by rubbing or scratching, the tops of the papulæ are removed, a clear fluid oozes from them, and gradually concretes into thin dark coloured scabs. The itching does not, however, abate; and, from the constant unavoidable friction, inflamed pustules resembling PHLYZACIA, q. v. are sometimes produced. These, when they appear early in the complaint, must be considered as incidental, not as proper to the complaint. This disease originates without any previous indisposition, generally in the spring, or the beginning of summer; affecting chiefly young persons, producing irritation, and preventing the freedom of perspiration. The eruption extends to the arms, breast, back, and thighs; and is troublesome rather than dangerous.

Itching, however, when in a greater degree, and in some other parts, is a disease highly distressing. It is scarcely, or only for a short time, removed by scratching; and at last this remedy fails, in consequence of the wounds which the nails inflict. It has been supposed that pain and itching are incompatible sensations, but those who suffer severely from the third species express their complaints so warmly, that perhaps the opinion holds only when the prurigo is in a less degree. Itching is sometimes connected with acrimony discharged by the exhalant arteries, but more certainly with diminished perspiration, though in general both causes are united; for acrimony freely discharged, or obstructed perspiration, independent of acrimony, seldom produces the complaint. The various causes assigned seem to support this idea. Valisnieri attributes it to gout; Riedlin to repelled evacuations; other authors to scurvy, to ulcers improperly healed, and to worms. We commonly attribute the itching of the nose of children to the irritation of the latter. In the first species, the acrimony is apparently inconsiderable, and is easily eliminated by the free use of soap and water; but when more pungent, it not only by its action on the nerves of the cutis excites the sensation of itching, but raises, with the distended exhalant artery, the minuter nerve which accompanies it in the minute papulæ, which distinguishes the complaint. These, when wounded, exhale a fluid, which adds to the distress by extending its source.

PRURI'GO FORMI'CANS, (from *formica*, an ant,) so called from the sensation on the skin resembling the creeping of an ant. In this disease the papulæ are sometimes larger, sometimes more obscure, than in the *prurigo mitis*; but always attended with a continual and almost intolerable itching. They are diffused over the whole body, except the face, feet, and palms of the hands; and appear in greatest number about the neck, loins, and thighs; parts subjected to tight ligatures. Besides the sensation of small insects creeping on the skin, it sometimes resembles the stinging of ants, sometimes of hot needles piercing in different places. When warm, these sensations are more violent; and when any part of the skin is strongly rubbed, it becomes red, and large tubercles or wheals are produced, which subside when the irritation ceases. If the cuticle is

abraded by scratching, the surface of the body is spotted with small thin scabs; and this is frequently the only obvious appearance, for the papulæ are often indistinct from their minuteness. Where they are of a large size, headach, sickness, and pain of the stomach, precede their eruption, returning if the eruption is suddenly repelled. Though not obviously connected with a pain of the stomach, the prurigo formicans is generally attended with a cachectic state; and elderly persons of a sallow complexion, who labour under obstructions in the viscera, are most liable to it: the same conclusion may be drawn from its causes, which are grief, watching, fatigue, and poor diet. This disease usually affects adults, commencing at all seasons of the year indifferently; and its duration is from four months to two or three years, with short intermissions: want of cleanliness, certain modes of diet, living much upon fish, and other animal food in the summer season; drinking freely of wine, and other spirits, powerfully aggravate the complaint. In general those affected with it have a harsh dry skin; and as from the predisposing causes the acrimony may be more considerable, so from this state of the surface its discharge will be more difficult. The prurigo formicans has been supposed contagious; but there are some reasons which seem to prove the contrary. It is in general a disease of the habit, and is not communicated to those whose connection is most intimate, nor does it ever terminate in a contagious pustular disease. Various remedies for this complaint have been tried without success. It is necessary to restore by appropriate medicines the general health; and, after this, the natron preparatum of the London Dispensatory, sometimes alone, sometimes combined with sulphur, joined with the infusion of sassafras, or the tops of juniper, freely drunk; or the aqua kali, with the addition of a small portion of tinctura opii, have gradually alleviated the disagreeable symptoms, and conquered the complaint in a month or six weeks. With respect to external applications, it is necessary to keep the skin free from sordes, by frequent washing with warm water; but, should this fail, the medicated baths are recommended, particularly those prepared with alkalinized sulphur; sea bathing has been successful in some cases. On the head of diet it is only necessary to observe, that in general it is requisite to live upon light, soft, and easily digestible food; to avoid all heating and stimulating substances, particularly white wines and spirituous liquors. Whey, milk and water, asses' milk, and goats' milk, constitute a part of the proper regimen.

All the variety of remedies usually prescribed, viz. mercury and antimony, whether separate or combined; oleum vitrioli, purgatives, neutral salts, and sulphur, have failed. Externally, mercurial and sulphureous ointments, decoction of white hellebore, lime water, solutions of white vitriol, and corrosive sublimate, have been equally ineffectual.

PRURIGO SENILIS is, as the name imports, an affection of old age. In this species the patients are tormented with a violent and universal itching; the papulæ are for the most part large, though not inflamed; and sometimes the whole surface has a shining appearance, is irregular, or granulated, without an eruption of distinct papulæ. Scurf, or scales, succeed, which prove an additional cause of irritation from their

repeated separation and renewal; and when, by scratching, the cuticle is abraded, a mingled sensation of itching and smarting rises at times beyond all human sufferance. This disease does not differ greatly in its symptoms and external appearance from the foregoing species, but has still been thought to merit a distinct consideration from its peculiar inveteracy. From the dry condensed state of the skin and cuticle, with the additional acrimony of the fluids, which takes place in old age, this species of prurigo is perhaps aggravated, and becomes more permanent. The melancholic and mixed temperaments are most subject to this complaint, and it appears to be connected with a languid state of the circulation, and weak digestion. If the disease should be in a high degree, during life there is little comfort to be expected. A warm bath is the only application which allays the itching and irritation, though in general its effects are temporary. Greater advantage is experienced from baths of warm sea water, or of the sulphureous waters of Harrowgate; the latter of which should be administered internally at the same time; and, indeed, these waters appear to be the best remedy for the complaint with which we are at present acquainted. Cold brandy, used as a wash, is sometimes successful. On the skin and linen of a patient labouring under this disease, Dr. Willan observed a number of small insects of the genus *pulex*; and remarks, that neither the patient's wife nor any of the family were similarly affected, nor could any of the insects be found upon them. Indeed, the influence of insects in every case of prurigo is not improbable. In this case a strong solution of the hydrargyrus muriatus was the most efficacious remedy, though it was not a radical cure, for the complaint returned within three weeks; but by the same application the patient was enabled to live comfortably. Decoctions of tobacco and of the coccus Indicus were also useful. The disposition of the skin in the prurigo senilis is favourable to the production of pediculi humani, body lice; which are bred abundantly among the inhabitants of jails, sordid dwellings, workhouses, &c. &c. and are the offspring of filthiness; but, notwithstanding the most strict attention to regimen and cleanliness in this disease, they arise and multiply so rapidly that, from their perpetual irritation, the patient endures extreme distress; but these pediculi are only found on the skin, or on the linen, not under the cuticle, as some authors have represented.

PRURIGO PODICIS is occasioned by ascarides, hæmorrhoidal tumours, and other obvious causes, and cured by the removal of the complaints from whence it originates; but in persons engaged in sedentary occupations, it probably arises, independent of the foregoing causes, from a morbid state of secretion in these parts, founded perhaps on a decay of strength. At times, it appears to be a salutary deposition of matter, which, in a different direction, might have produced a more fatal disease. Women, who are sometimes affected with this complaint, in autumn or winter, about the cessation of the catamenia, have frequently also an itching eruption of papulæ on the neck, breasts, and back; a swelling and inflammation of one or both ears; and a discharge of matter from behind them, as well as from the meatus auditorius. Vinegar is more advantageous than any other lotion for allaying the itching; but the relief is not permanent. The unguentum hydrargyri

nitratī is the next in advantage; but warm or cold water, lime water, or saturnine applications, have little effect. Plummer's pill has been found beneficial; and in weak relaxed habits Peruvian bark and chalybeates expedite the cure. When a symptom of lues, an ichorous discharge, and an excoriation of contiguous surfaces, is the consequence of its neglect. The parts affected are covered with a sebaceous matter, but the ulcerations are superficial. A mercurial course requires the addition in this case of saturnine washes and ointments. A light cooling diet should be adhered to; great moderation in the use of wine, and a total abstinence from spirituous liquors. According to Dr. Lettsom in the Medical Memoirs of the London Society, vol. iii. it may be considered as frequently preventive of other diseases; as various long indispositions; a disorder of the chest, attended with a weak and intermitting pulse; vertigo, attended with strong symptoms of an approaching apoplexy; were relieved by its appearance: at the same time it may be observed, that the repulsion of the acting cause, in some cases, may be succeeded by fatal consequences; as was the case of a patient, much relieved from great debility, occasioned by frequent fits of the gout, from the appearance of prurigo podicis, who, in order to lessen the troublesome itching, applied a strong saturnine solution for a few days, and suddenly expired in his chair.

PRURI'GO PRÆPUTII is owing to an altered state of the secretion on the glans penis and inner surface of the prepuce. Keeping the parts clean by the use of warm water, or soap and water, will alleviate the complaint; and should the secreted fluid be too copious, the excess may be restrained by lotions made with the aqua lythargyri, or by applying the unguentum cerussæ acetatæ.

PRURI'GO URETHRÆ occurs in females of all ages, without any appearance of organic affection. It probably arises from a morbid state of the neck of the bladder; particularly in instances attended with pain and difficulty in making water. The use of bougies in these cases has proved successful; a remedy recommended by the late Dr. Hunter. In men it is sometimes produced by small broken hairs fixed in the entrance of the urethra, which occasion an itching, or slight stinging, particularly in walking. The removal of the hairs effects the cure.

PRURI'GO PUBIS is extremely troublesome, as papulæ, which arise on the pubes, become painfully sore if their tops are removed by scratching. These papulæ are occasioned by neglect of cleanliness, but more commonly by a species of pediculus, named MORPIO, q. v. A strong mercurial ointment, sometimes with the unguentum cerussæ acetatæ, is the best remedy.

See Willan on Cutaneous Diseases, part i.; Hafnereffer Nosodochium; Mercurialis and Lorry de Morbis Cutaneis, Valisneri Opera; Riedlin, Lin. Med. 1700.

PRURI'GO PUDENDI. See PUDENDUM MULIEBRE.

PRU'SSIAS. PRUSSIAT. Salts formed by the union of the Prussic acid, or the colouring matter of Prussian blue, with different bases. They are not used in medicine.

PRU'SSIC ACID. (See CHEMIA.) It may probably become an object of importance in the hydrology of our

fluids, as it has been occasionally discovered in them, and is found in the bitter almond, laurel leaves, and the narcotic bitters of this tribe.

PSALLOIDES. The inner surface of the fornix, which appears as if stringed like a dulcimer, from ψαλλος, a stringed instrument, and εἶδος, likeness. See CEREBRUM.

PSALTERIUM, (Latin, a harp,) lyra, the medullary substance that unites the posterior crura of the fornix of the brain, resembling in its striæ the strings of a harp.

PSELLISMUS, and PSELLO'TIS, (from ψιλλίζω, to stammer). STAMMERING, or a faulty articulation. Dr. Cullen places this local disease in the order *dyscinesia*, defining it a defect in pronouncing words. The species are, 1. *Psellismus hæsitans; battarismus; ischnophonia*, when there is difficulty to pronounce the first syllable or word. 2. *P. ringens; blæsitæ; traulotis; and rottacismus*, when there is a fault in pronouncing the letter R, which is always aspirated, and as if doubled. 3. *P. lallans; lambdacismus*; when the letter L is sounded improperly, or in the place of the letter R. 4. *P. emolliens; traulotes*; when the harsh letters are expressed too soft, as the letter S is too frequently sounded. 5. *P. balbutiens; aranula*; when from a large tongue the labial letters are too much heard, and are often sounded instead of others. 6. *P. acheilos; mogilalia*; when the labial letters are difficultly if at all sounded. 7. *P. lagesotomatus; cocatismus*; when, from a division in the palate, the guttural letters are not well pronounced. Neither complaint is ever the object of medical practice; pronouncing carefully, under the direction of a nice ear, is the only means of relief.

PSEU'DES, FALSE OR BASTARD. Hence is derived the word *pseudo*, with which many names begin.

PSEU'DO A'CORUS. See IRIS PALUSTRIS.

PSEU'DO A'STHMA. An asthma excited by an abscess, or a vomica in the lungs.

PSEU'DO BLE'PSIS, *phantasma, suffusio*. FALSE SIGHT; or seeing in imagination what does not exist, or existing things differently from the perceptions of others. Dr. Cullen places this disease in the order *dysæsthesia*, distinguishing two species. 1. *Pseudo blepsia imaginaria*. For a variety of this, see MARMARYGÆ. 2. *Pseudo blepsia mutans*; as when an existing object appears changed. See DIPLOPIA.

PSEU'DO BU'NIAS. See BARBAREA.

PSEU'DO BU'NIUM. See BUNIAS.

PSEU'DO CA'SSIA. See FOLIUM.

PSEU'DO CHI'NA. See CHINA OCCIDENTALIS, and SUPPOSITA.

PSEU'DO CORA'LLIUM. See CORALLIUM NIGRUM.

PSEU'DO CO'STUS. See PASTINACA OLUSATRA.

PSEU'DO DICTA'MNOS. BASTARD DITTANY, *gnaphalium, veterum marrubium pseudo dictamnus* Lin. Sp. Pl. 817, is a plant which resembles the horehound in its virtues, but is not used at present.

PSEU'DO HELLE'BORUS. See CALENDULA PALUSTRIS.

PSEU'DO I'RIS. See IRIS PALUSTRIS.

PSEU'DO LI'ENES. Some glands which Ruysch observed near the spleen.

PSEU'DO LO'TUS. See GUAJACANA.

PSEU'DO MELA'NTHIUM. See NIGELLASTRUM.

PSEU'DO MO'LA. See MOLA.

PSEU'DO NARCI'SSUS ANGLICUS. See NARCISSUS LUTEUS SYLVESTRIS.

PSEU'DO NA'RDUS. See LAVENDULA LATA and ANGUSTIFOLIA.

PSEU'DO PLA'TANUS. See ACER.

PSEU'DO SA'NTALUM. See BRASILIUM LIGNUM.

PSEU'DO SEL'NUM. See CAUCALIS.

PSEU'DO SE'NNA. See COLUTEA.

PSEU'DO SYCOMO'RUS. See AZEDARACH.

PSI'DA, or PSI'DIUM. See GUAIAYA.

PSILOTHRA, (from *ψιλω*, to denude). See DEPILATORIUM.

PSILOTHRUM, (from the same; because it was used in depilatories). See BRYONIA ALBA.

PSIMMY'THION, (from *ψια*, to smooth; because it was used in cosmetics). See PLUMBUM.

PSO'Æ, (from *ψοαι*, the loins,) *alopeces; nephrometræ; neurometeres*. The names of two pair of muscles in the loins.

PSO'AS; *lumbalis, lumbaris internus, psoas magnus*; a thick strong muscle placed obliquely on the sides of the vertebræ, running under Poupart's ligament to each thigh. It rises fleshy from the sides of the last vertebræ dorsi, and those of the upper vertebræ lumborum, and, from the upper surfaces of their transverse processes; and is joined under Poupart's ligament by the iliacus internus, which lies upon the concave part of the ilium, and takes its origin from the anterior edge of the bone. It runs down before the psoas, and makes one mass with it: together they run over the head of the bone, and pass upwards to be inserted, tendinous, into the little trochanter, and fleshy into the bone a little below that process. Between this tendon and the ischium is a large bursa mucosa; and at its origin it is slightly connected with the diaphragm and quadratus lumborum.

Its office is to bend the femur, by bringing it forwards, partly to rotate it, and to turn the toes out. The kidneys often press upon this muscle, and over it runs a nerve. Those, therefore, who have stones in the kidneys often feel a numbness in the thigh of that side.

PSO'AS, seu LUMBO'RUM, ABSCE'SSUS. Psoadic, or LUMBAR ABSCESS, has been considered as a species of ARTHROPOUSIS, q. v. and we have admitted it inadvertently among the synonyms. The seat, the nature of the complaint, and the remedies are, however, very different. It consists in an inflammation of the muscle itself, and consequent suppuration. Mr. Pott hastily transferred it to the lymphatic glands; because he found the vertebræ in the neighbourhood usually carious; and Mr. Justamond thinks the disease wholly owing to caries of the vertebræ.

Mr. Abernethy supposes that the cellular substance interposed between the peritonæum and the loins is the common seat of these abscesses, since this substance is in greater quantity at the sides, where it connects that membrane to the psoas and quadratus lumborum muscles, than in the middle, where it forms an attachment to the spine. Where this substance is most abundant, the abscesses are most frequently formed; and for this reason we find them usually limited to either side of the vertebræ, and seldom extending across them. If

matter was formed in the middle, opposite to the bodies of the vertebræ, its gravity and the want of resistance would, however, determine the descent to either side. As the peritonæum would readily yield to the protrusion of the matter collected behind it, from the separation of the cellular substance connecting it to the vertebræ, it is improbable that a caries of the bones should be the consequence of an ordinary lumbar abscess. Dr. Hunter observes, that matter is sometimes lodged in this part at the crisis of a fever, and he hath seen instances of matter proceeding from the liver into this situation, after making its way through the peritonæum. As the muscle with the cellular substance and integuments forms a thick mass, the matter seldom points outwardly on the back, but running down between the fibres, makes its way into the groin, thigh, ham, the inner condyle of the os femoris, &c. When on the right side, it may penetrate the colon which lies upon it, and thereby occasion a large discharge of matter by a stool, and possibly a fistulous sore. Of this possible event we have not seen or been able to discover a single instance in any author.

The disease invades insidiously; the pains are situated in the back, rather lower than the region of the kidneys, and usually so slight as to be mistaken for a rheumatic affection or a slight strain. It consequently proceeds with little check; for were it more early distinguished, the abscess might be often prevented by bleeding, purging, and the medicines proper for inflammations, aided by the necessary local applications. After the abscess is formed, the pain often increases, and the matter may be discharged into the cavity of the abdomen, where it would be soon fatal. It more usually, however, follows the course of the psoas muscle, and points externally a little lower than the inguinal glands, or it may pass down the thigh, dissecting the muscles, and forming sinuous abscesses. Sometimes, though rarely, the matter passes through the muscles of the back, and is discharged in the loins, or it may fall into the cavity of the back part of the pelvis. This abscess is, therefore, highly dangerous; since in the most fortunate circumstances it is so long in pointing out at the back, that the patient sinks under the early hectic, or from the subsequent discharge, and in the event of the other terminations the lengthened sinuses can scarcely ever be brought to heal. Usually, the first symptom that the patient feels in cases of the psoas abscess is not where the disease originates, but a pain in the lower part of the thigh of the side affected; he stands on his toes, and does not complain of the part for some time: but by attending to the circumstances from the beginning, and laying the person affected on his back, lifting up his thigh, then, between inspiration and expiration, carefully examining the part, a tumour may be often felt near or in the region where the disease originates. The leg of the affected side seems to be shorter than the other, but it is not so. In other cases the disease proceeds rapidly, sometimes very slowly; and at length appears in the groin, on the affected side; the muscles of the thigh become exceedingly emaciated, and the whole body wastes. When it proceeds thus far, the patient rarely, if ever, recovers; the symptomatic fever that generally attends closes the scene. In some cases the patient feels in an early period a slight pain in the back, so inconsiderable that he scarcely notices it; and when questioned

at a later period of the disease, often does not recollect it. If at this time he is desired to bend his body, and to raise either leg, turning out at the same time the toe, he feels a sharp pain in the middle of the back; and these symptoms occur previous to the formation of matter, ascertained by the symptoms just described. At this time there is no fever, nor any circumstance to discriminate the case: for a pain in the back, on stooping, is common; and perhaps the pain felt on turning out the toe is the only diagnostic.

This disease is often confounded with the abscess of the hip joint, yet they are very distinct and different in their origin, seat, and progress. The psoas abscess originates sometimes, perhaps, in the lymphatic glands near the receptaculum chyli, and the vertebræ in the neighbourhood are occasionally diseased and carious; in other instances in or about the loins, if not higher in the abdomen; but, in general, it seems to be a true inflammation of the psoas muscle, and the affection of the glands, as well as the caries, to be the consequences. We know that the matter may be long retained without any ill consequences, if the air is excluded, and this is the foundation of Mr. Abernethy's method of cure. The symptoms mentioned above continue for some time; but at length the disease appears externally; the limbs and the whole body waste. The hip joint abscess originates in the hip joint; when it attends, the leg of the affected side is shorter than the other; the pain begins in the part where the disease originates, and about the great trochanter. The most frequent situation of the psoas abscess is before or by the sides of the psoas muscles, from whence the fluid collected sometimes extends itself laterally, making its way between the three strata of abdominal muscles, and presents itself beneath Poupart's ligament, elevating the fascia of the thigh. If the patient be laid on his back, the tumour of a psoas abscess may be pressed into the cavity of the belly; but in an external one no alteration takes place, and if there be two lumbar abscesses, the compression of one will fill the other. A stone in the kidneys hath been taken for this disease; but in the former the pain is very acute, the stomach often affected with vomiting, and stony concretions, occasionally blood with the urine, have sometimes passed. See *ABSCCESSUS ISCHIATICUS*.

If an absorption take place before the abscess hath burst externally, the patient often dies; and if a fetid ichor is discharged, or the bones are affected, little or no hope remains. A symptomatic fever generally closes the scene; but in general the fever does not come on while the matter is confined, nor to any great degree for forty-eight hours after it is discharged: a circumstance probably owing to the admission of the air.

This disease, whilst in its inflammatory state, is generally neglected or mistaken, otherwise it might be easily cured, perhaps by bleeding. We recollect an anonymous communication, in which it was said that very copious and repeated bleedings were a certain cure, and farther information was promised, though never received. It was probably, therefore, one successful instance, exaggerated in the eagerness of youth, and of early confidence. It is not difficult to see why the early practice has been so unsuccessful. The inflammation is of that torpid kind which arises sometimes in the liver, sometimes from the brain in *CONCUSSION*, q. v. It proceeds without any alarming symptom, or exciting

any increased activity of the circulation, till it has already attained that degree which disposes to suppuration, often till suppuration has come on. From hence it has been styled strumous, lymphatic, caries of the bones, &c. while it is merely languid inflammation of a muscle constantly in action, constantly irritated. Dr. Fordyce observes, that this disorder should be treated in the same manner as inflammation of the liver, except for the situation, both in the state of inflammation and suppuration; but we know of no peculiar treatment of hepatitis, except blisters, purgatives, and calomel; neither of which succeed in the present disease. We have tried every variety of plan in vain. We have bled copiously; we have emptied the bowels freely; determined copiously to the surface by the sudorific powder of Dover, without being able to prevent the consequent suppuration. We have been told of the success of others; but when we have been able to ascertain the facts, we have found them common rheumatisms, or abscesses not deeply seated. We have seen persons recover; but there was reason to attribute it rather to the efforts of nature than the utility of medicine: and in general, keeping up the patient's strength sufficiently to enable him to undergo the discharge, by a nourishing diet and clear air, the bark, the dilute acid of vitriol, is the most promising plan; to which we would add absolute rest, and the occasional use of laxatives. Other practitioners, particularly Mr. Bell, advises evacuation as soon as the matter is formed, lest the bones should be injured. Dangerous as this complaint always is, and fatal as it is generally supposed, Mr. Abernethy has supplied some cases where success has attended his endeavours. He observes, that whilst the condensed cellular substance, which forms the cyst of an abscess, remains entire, it continues free from inflammation, and the contained pus is not altered; but whenever the abscess is opened, either by ulceration or the hand of the surgeon, a sudden and generally considerable inflammation extends itself over the whole cyst, followed by a copious discharge of pus, frequently fetid. If, however, he adds, when we evacuate fluids from cavities, we immediately close the aperture, we prevent the inflammation which would otherwise ensue. If, also, the matter of an abscess is discharged, its cavity becomes much diminished by the contraction of the cyst: a contraction greater in a chronic lumbar abscess than in those of a more inflammatory nature. These considerations led him to evacuate the fluids in part, and immediately close the aperture, repeating, after some time, the operation. The practice founded on these principles seems to have answered the intention, and it is pursued on the following plan. The pus is discharged by introducing a lancet through the integuments, then passing it obliquely, for a small distance, between the skin and the fascia, and by depressing the point of the lancet there puncturing the cyst. The matter should be drawn off in an uninterrupted current, if possible, and the abscess completely evacuated. The aperture should then be immediately and exactly closed, by dressing the orifice with lint, and bringing the edges into close contact with sticking plaster. In aid of this plan, Mr. Abernethy gives vomits of vitriolated zinc and copper, passes gentle electrical shocks through the abscess, and keeps up the action of the external vessels by rubbing the surface with a solution of tartarized antimony. The second discharge of the pus has generally

been postponed for a fortnight; but if the cavity soon fills again, and the newly healed punctures are irritated by the pressure of the contained fluid, there is an absolute necessity for evacuating the contents of the abscess at an earlier period. In this second operation, he is less anxious about the obliquity of this aperture, as coagula are found in the matter, which it is necessary to discharge; and he generally delays it till the tumour is so large that on opening it there is no danger of injuring the vessels below. He sometimes thought an injection of opium useful. In this mode the matter is to be evacuated from time to time, until the abscess becomes so superficial as to be treated in the method common on such occasions.

Elements of the Practice of Physic, part ii. by G. Fordyce; Cheston's Pathological Inquiries; Abernethy on Lumbar Abscess; De Haen Ratio Medendi, pars iv.; Penciz Acta et Observationes Medicinales; Medical Observations and Inquiries, v. 193.

PSOAS PA'RVUS. A little psoas is found on the anterior part of the great, where it exists. It arises fleshy from the upper vertebrae of the loins laterally; is inserted, by a long, flat, thin tendon, into that part of the os pubis where it joins the ilium. From this tendon many fibres are sent off to form a thin fascia, which covers part of the psoas magnus, and iliacus internus, gradually losing itself on the fore part of the thigh. Its use is to assist the recti abdominis in drawing the os pubis upwards, as in raising ourselves from a decumbent posture.

PSO'PHOS, ($\psi\phi\phi\varsigma$, *crepitus*). Crackling or rattling of the bones.

PSORA, ($\psi\omega\pi\alpha$, Greek primitive). In Dr. Cullen's system this disease is strangely referred to the order *dyalyses*, and we need not, after this, be told that "in the arrangement of local diseases he has been somewhat careless." The itch is now known to be a local complaint, and to be cured only by local remedies. We find, however, in many authors of credit, striking accounts of the danger of repelling it, which induce us to think that the nature of the eruption has been mistaken; or it may have continued so long that the derivation to the skin has become habitual. The disease first appears in little white vesicles, which itch violently, particularly when the heat of the bed determines more powerfully to the surface. By scratching, these vesicles inflame, and assume a peculiar redness, which distinguishes the complaint. Such, however, is the variety of papulous eruptions, that it is often mistaken, and we know no language sufficiently precise to point out the real complaint. The experienced eye will alone decide, and the most experienced practitioners have, at times, been mistaken.

The disease usually first appears about the wrists, and between the fingers; then on the arms, legs, and thighs, particularly under the knee, but never in the face or head. It is sometimes attended with a scurfy, scaly eruption, and is then called the *dry itch*. A kind of itch, called *deftigo*, is said to roughen the skin; but this is a different disease. We need not add, that the itch is contagious; but it is, by no means, highly so; and merely touching the hands, or even handling any thing after an infected person, will not convey it. A very moderate share of attention will prevent it spreading through a family, otherwise cleanly and delicate.

After the psora is imperfectly cured, an eruption sometimes comes out, in little white pustules, not larger than the size of the head of a large pin, filled with a white puriform serum. This may be called the *secondary itch*. It does not itch violently, and is not contagious.

The itch has been said to be chronic; critical; returning on the climacterics; endemic; epidemical; returning monthly, particularly during the increase of the moon: but these are apparently fancies or errors. The German authors adduce numerous instances of the fatal, or at least injurious, consequences of its suppression; and among our own countrymen, Dr. Bissett and sir William Fordyce have related some instances of the same kind. Hundertmark advises a recent infection to restore it, when suppressed; and we have been informed that, in some private receptacles of lunatics, it has been designedly conveyed to increase the circulation in the extreme vessels.

The causes of psora, adduced by authors, are numerous and ridiculous; among the rest are the fancies of the mother and matrimony. When an acarus was found in the pustules, it was generally believed to be the cause of the complaint; but even at first this source was violently combated: and we apprehend that some microscopical authors of credit have lately sought for the insect, without success. It is, however, highly probable that this is the cause; though, if it be so, we cannot easily account for the spasms, convulsions, &c. said to arise from its suppression, nor for the change of its appearance, when imperfectly cured. The question is of little importance, since its remedies are so well known.

The cure by sulphur is certain; but this is often inconvenient, and it is necessary to find less obnoxious remedies. The root of the white hellebore is often highly useful, and a solution of muriated mercury will frequently cure it. The tar ointment, with kali, or alum, and a small proportion of sulphur, is said to be quickly effectual; and this is nearly the application employed by those who profess to cure it in a few hours and really succeed. We have seen an inveterate itch cured, within twenty-four hours, by similar means, for the professed time of six or eight hours, is to be understood as the period of the application only.

A very effectual ointment is that recommended by sir John Pringle, consisting of four parts of axunge, two of flowers of sulphur, and one of the root of white hellebore, or of sal ammoniac. A very elegant and effectual wash is the following. A drachm of muriated quicksilver dissolved in half a pint of water, adding two drachms of crude sal ammoniac and half an ounce of nitre. An ounce of the powder of white hellebore may also be boiled in a pint and a half of water; and to a pint of the strained liquor two ounces of spirit of wine, and two drachms of alum, may be added. The same medicines are sometimes formed into an ointment, and each is effectual. The solution of muriated quicksilver cannot be discovered by the most intimate acquaintance, and scarcely in any instance fails. The hands are washed with it night and morning, and a little applied with a clean sponge, by degrees, to the other pustules. It is safer to use it gradually, and precipitation is unnecessary, as, after a day or two, there is little danger of infection.

About the year 1762, Buchner published his dissertation, at Halle, on the internal use of oil of vitriol in

some species of itch; and Dr. Gahn, in the Edinburgh Commentaries, about ten years afterwards, introduced this remedy to the English practitioners. Stoll, in his Lectures, and Smith in the first volume of the Medical Communications, also spoke of its efficacy; but the origin of the practice is in Salas, in his Anatomie Vitrioli, who used vitriolated salts joined with the ointment of tobacco. Dr. Percival ingeniously conjectured that it became sulphur in the blood; but sulphur internally is of little use, and though Faber recommends the spirit of vitriol externally, it has been seldom employed.

The other remedies which have been employed are numerous. A decoction of arsenic with sulphur is recommended in the Memoires de Chirurgie; hemlock (Storck, Quarin, and Locker); bitter almonds (Zacutus Lusitanus); alum, kali, sea water (Russell); antimony (Brisbane); cold and warm bathing; the ashes of the soles of old shoes (Bartholine); ants (Kircher); diuretics (Link, in the Edinburgh Commentaries); tobacco; opium (Rulandus); plumbago joined with oil, and used externally (Memoires de Médecine); a bath of a decoction of oak leaves; human and cow's excrement variously prepared; with many others, doubling at least the number of those mentioned. In turning over some old authors with this view, we were greatly struck with the numerous and high commendation of Jasser's ointment, and at last discovered its nature. It consists of white vitriol, bay berries, and oil. We may add, that Vogel, in a dissertation published at Gottingen, has suggested some doubts of the safety of sulphureous applications, but with little reason.

The dry itch is not affected by external medicines, and is only relieved by mercurials, with the Lisbon diet drink, &c. It is, in fact, a species of PSORIASIS, q. v. The secondary itch, which we have not found described in any author is cured by internal medicines of a similar kind. It is by no means an obstinate complaint.

After this full account of the opinions and practice of authors, ancient as well as modern, any particular references are unnecessary. Indeed, had we found any full account of the disease, and its remedies, this article would not have been so extensive.

PSORIA'SIS. This term has been limited to the species which affects the scrotum, rendering it unusually hard; but Dr. Willan has extended its use, and under his auspices we shall now describe it.

The disease which Dr. Willan has established under this denomination is confounded by ancient authors, under the title of psora; but it consists in scales, and is neither a papulous nor a pustular eruption, so that it is, with strict propriety, separated. The term occurs in the ancient Greek authors, and is confined to scales in different parts, either at the corners of the eyes, or in the scrotum; and a similar change was supposed to take place in the bladder, when the urine deposited a branny sediment. It is defined by Willan, a rough and scaly state of the cuticle, sometimes continuous, sometimes in separate patches of different sizes; but of an irregular figure, generally accompanied with fissures of the skin. We have considered it as a variety of lepra; for as it recurs at different periods, and is attended with some general complaints, it may form a link between lepra and pellagra. It is more strictly the dry itch, which, in compliance with authors, we have mentioned under the last article. The varieties described by Dr. Willan

are the *psoriasis guttata, diffusa, gyrata, palmaria, labialis, infantilis, and inveterata*.

PSORIA'SIS GUTTATA consists of small, distinct, irregular patches of laminated scales, in a form sometimes angular, at others in serpentine processes, distinguished from lepra by the form; for in the latter the patches are usually circular, or approaching to a circle. The scale is thin, easily detached, leaving a red, shining surface on the skin. They appear on almost every part of the body; but in the face are seldom covered with scales. In children it is preceded frequently by a slight general disorder, and then spreads over the body in two or three days. In adults it commences in the extremities, and proceeds gradually to the other parts, chiefly in the spring, succeeding violent pains in the head, stomach, and limbs. The patches disappear often in summer, leaving the skin of a dark red, sometimes of a livid, colour. A similar eruption attends lues; but these patches are more nearly circular, and their colour darker. They are scarcely elevated above the skin till the scales appear, and the circumference is often higher than the centre. The syphilitic eruption appears chiefly on the forehead and breast; on the inside of the fore arm and thighs. It is singular that the scales often disappear, while the principal disease remains; but after using mercury they soon drop off. In the negro the eruption is whitish; and the skin below, when the scales drop off, is unusually black, slowly recovering its natural hue.

Psoriasis diffusa spreads into large, irregular, reddish, rough, chappy patches, with scales interspersed. It usually commences with numerous minute asperities of the cuticle, scarcely visible, though easily distinguished by the touch. On these small distinct scales are formed, adhering by a dark central point, while the edges appear white and detached. After a few weeks the intervening cuticle becomes rough and chappy, raised and wrinkled, the lines of the skin sinking in deep furrows. Sometimes a large portion of the skin assumes the appearance described, without any papulæ preceding; and at other times the patches are at first separate, not unlike those of the former species. The lichen simplex, after frequent returns, often assumes the appearance of this disease.

The cheeks, the chin, upper eye lids, and the corners of the eyes, the temples, the external ear, the neck and fleshy parts of the lower extremities, and the fore arm, are chiefly subject to this eruption. The fingers are nearly surrounded by loose scales; the nails crack and exfoliate superficially. In general, it affects the different parts successively, sometimes returning to its first situation. This disease is attended with a burning heat, and a troublesome itching, especially at night, and has little disposition to form crusts like lepra. The chaps on the skin are sore; and when the scales are removed, the parts below are red, smooth, shining, and elevated. The deep furrows of the cuticle are also covered with a slight scalliness. When the surface is excoriated, it discharges a thin lymph, mixed with some drops of blood, and concretes into a thin dry scab, succeeded by a white scalliness, spreading in different directions. When, from a well directed plan of cure, the scabs are removed, the cuticle is at first thin and shrivelled, but soon recovers its former texture.

The *P. DIFFUSA* is often preceded by want of appetite, head ach, pain, and sickness of the stomach, cramp,

coldness of the extremities, with universal languor and debility. These symptoms gradually disappear; but they precede every return of the complaint. Its continuance is usually from one to four months, sometimes longer; but in such cases there is an exacerbation about the usual periods of its return. When it disappears in the summer, the returns differ greatly in their degree and violence. Sometimes it is a single patch only.

The *baker's itch* is of this kind, extending on the back of the hand from the knuckles to the wrist. The fissures of the skin are most numerous near the joints: they are often highly inflamed, and painful, but no discharge proceeds from them. The back of the hand is swollen; and, when the disease has advanced, is reddish and glossy. The furrows of the cuticle are filled with slight scales. This variety usually disappears about Midsummer, and returns in the cold weather, or about the beginning of the year: nor is it constant; for, after having once appeared, it is often absent for three or four years; and when the business is discontinued, it does not soon disappear. The occupation is, therefore, only an exciting cause; and it depends on the hygro-metrical affinity of flour, which absorbs moisture rapidly. The *grocer's itch* is of a different kind, and strictly a pustular disease.

The *washerwoman's itch* arises probably from the soap dissolving the oily matter, which softens the skin. It generally appears on the hands and arms; rarely, except from predisposition, on the face and neck. It forms scales, separating in large circular flakes, sometimes quadrangular. Syphilitic psoriasis seldom assumes this form, except from the coalescence of the patches of the former species.

PSORIA'SIS GYRATA appears in stripes approaching a spiral form, sometimes resembling earth worms; the deepened furrows of the cuticle giving the annulated appearance. Slight scales are separated from the surface, but no incrustations are formed. These serpentine patches are often singularly uniform on each side; and a smaller degree of the complaint, affecting young women and children, is often confounded with that form of herpes styled the ring worm.

This eruption has also its exacerbations or returns, and approaches the *p. diffusa* by irregular patches on the face and extremities, while the rings occupy the trunk. It continues frequently for months before it desquamates, and is usually preceded by headach, pains in the limbs, debility, and emaciation. Lues sometimes assumes this form; and when the scales separate, the skin below is of the dark colour usual in syphilitic eruptions; sometimes the rings suppurate, leaving a centre of sound skin.

PSORIA'SIS PALMARIA begins by a scaly patch, and at last occupies the whole palm, extending in a slighter degree to the inside of the fingers and the wrist. The surface is rough, the colour brown or black, and the cuticular furrows deep, divided at the bottom longitudinally, so as to bleed on extending the fingers. A sensation of heat and stiffness attends this disease, and it is usually most distressing in winter and spring. Sometimes it disappears, or occasionally remits only in summer. It is the disease of shoemakers, braziers, tinmen, and silversmiths, usually attributed by the last to the vitriolated salts or mineral acids, and by shoemakers to

the wax. It sometimes comes on after delivery, occasionally alternates with paroxysms of gout, and chiefly affects debilitated constitutions. It sometimes attacks the soles of the feet and the prepuce, occasioning phimosis, sometimes requiring circumcision. It is also a symptom of lues; but the venereal patches are distinct, white, and elevated, nearly of the consistence of a soft corn. The fissures usually discharge an offensive fluid; but when this disease affects the soles no discharge takes place. The fingers and toes are never affected in the syphilitic form of the *p. palmaria*.

PSORIA'SIS LABIALIS. This form of psoriasis affects the prolabium; the scales are large, and their edges loose, while the centre is fixed. The new cuticle formed under the scales soon becomes dry and shrivelled, cracks and exfoliates, giving way to another layer of the same kind. It is of consequence to distinguish this variety from the chaps produced by frost; and it may be known by its occurring at different seasons, though often aggravated by frost. The under lip is most frequently affected; and those who have full lips are chiefly subject to the complaint.

PSORIA'SIS SCROTALIS resembles the other varieties, and differs only in its seat.

PSORIA'SIS INFANTILIS affects children from the age of two months to two years. The general appearances are those of the *p. diffusa*; but it is sometimes succeeded by inflamed pustules, which suppurate, and often accompanied by scabs in the internal nostrils, which occasion snuffling. When the eye lids are affected, the eye brows and eye lashes fall off. The scaly patches are interspersed with smooth, shining elevations of the cuticle, a little flattened at the top, having a roundish base: they are sometimes reddish; but often retain their usual colour. When the eruption appears on the nates, it occasionally suppurates, and resembles a venereal tubercle. In general this variety resembles the scaly patches which occur as a secondary symptom of syphilis, and is only distinguished by the concurrence of other symptoms of the latter disorder, assisted by the circumstances which afford suspicion.

PSORIA'SIS INVETERATA. The same disease in a more violent degree, often covers the whole body, except a part of the face sometimes the palms of the hands and soles of the feet. The skin is so stiff as to impede motion; and the scales are constantly separating, so as to occasion a most troublesome itching. The nails of the fingers and toes become convex, fall off, and are succeeded by others of the same form. The joints of the thumb and fingers are sometimes enlarged, and contracted or bent back. Painful excoriations are produced by the ligatures of the clothing, or the attrition of contiguous surfaces. Sometimes the excoriations are extensive, a thin lymph is for a time discharged, and the cuticle which succeeds is dry and horny, separating from time to time in large pieces. It sometimes attacks young persons, but it is then less violent. The *p. diffusa* and prurigo senilis sometimes degenerate into this complaint.

The psoriasis is often hereditary, but never infectious. It most commonly attacks those who are neither of a sanguine nor a melancholic temperament, but who show marks of each: the weak and irritable are most liable to it, and women rather than men. It is always apparently connected with some disorder in the

constitution, often with gout and rheumatism. When not thrown out, as in cases where it is hereditary, we have found the persons die young of anomalous diseases, styled hectic, though often a very different complaint; and Dr. Falconer has found convulsions, constant vomiting, with loss of strength wholly irrecoverable, from the repulsion of the eruptions.

The causes assigned have been errors of diet, particularly eating dried and salted meats, crustaceous fish, pork; or, on the other hand, acids, wines, and fruits, and the unseasonable use of the cold bath. The only distinct cause, however, that can be assigned is cold, applied either externally or internally, while the body is heated. In general, it affects those who are subject to frequent alternations of heat and cold; but this cause is probably only an exciting one. The seminum of the disease is apparently in the constitution.

Dr. Willis recommended bleeding, cathartics, and alteratives, as acidulous chalybeate waters, &c.; the expressed juices of several plants; whey, either alone or impregnated with the juices of succory, fumitory, and sharp pointed dock; decoction of the woods; preparations of iron, and mercury.

Dr. Willan observes, that he has never seen a case in which bleeding or purging could be properly applied; and we own that these remedies are so distant, in our opinion, from the nature of the disease, that we have never thought of using them, even when psoriasis affected the eyes. The numerous antiscorbutics are too "weak ministers" to be relied on.

Guaiacum wood, willow, sarsa, elm bark, sassafras, juniper tops, burdock, mezereon, and the dock roots in decoction, are useful auxiliaries; and the dock, with the sarsa and mezereon, when long continued, has often greatly relieved the complaint. It is seldom radically cured. When the disease is strikingly connected with debility, the chalybeate waters are often useful in restoring tone; but the chief benefit is derived from the sulphureous springs. Every sulphureous water seems to have been useful, in proportion to the strength of the impregnation. Mercurials, in Dr. Willan's hands, have not succeeded. We think that, with the mezereon and dock root, we have been more fortunate. We mean not to say that the patient has been secure from a relapse; for that perhaps would not be a fortunate termination; but the return has been protracted, and the disease in its recurrence rendered milder.

The three first species, after an emetic and a purgative of calomel, are relieved, according to Dr. Willan, by the fixed alkali, assisted by a light moderate diet, frequently washing with tepid water, abstinence from fruits, acids, as well as fermented liquors. If more violent, the free use of antimonials, the warm bath, with repeated friction, and the sulphureous mineral waters, are necessary. "The decoctions of elm bark, sarsaparilla, dulcamara, &c. have also their share of utility." When mezereon has been successful, it is said to soften the whole patch, or to heal it from the circumference towards the centre. When removed by other means, the salutary change chiefly occurs in the centre.

The *psoriasis inveterata* sometimes affects the shin bone, producing an ulcer not deep, but with an uneven basis, and a red, thin, smooth edge, liable to bleed from slight impressions. This ulcer itches violently, and discharges a glairy fluid, heals slowly, or soon breaks

out again. It is often healed by applying ointment composed of an ounce of calaminaris cerate, with a scruple of the unguentum hydrargyri nitrati. Should the skin afterwards remain dry and brittle, the leg should be held over the steam of warm water, and oiled silk be worn round the leg. The latter directions are highly proper also in the *ps. palmaria*.

The mildest, softest applications are only useful in the *ps. labialis*. In the *ps. scrotalis*, besides frequent bathing and a constant attention to cleanliness, attrition should be prevented by an ointment composed of three parts of unguentum ceræ, and one of the unguentum hydrargyri nitrati.

The *ps. infantilis* is relieved by antimonials and warm bathing. When considerable excoriations take place, they should be defended by the common sedative applications.

We have thus followed Dr. Willan, with only occasionally interposing some slight remarks. We shall add, however, shortly, the result of our experience. In general, we have found mercurials in small doses, long continued, highly serviceable in this disease; and the best form has been Van Swieten's solution of muriated mercury. In slighter cases, the pills of Plummer, especially if made, as formerly suggested, by adding the calomel after the rest of the mass was formed, have completed at least a temporary cure. This has been greatly assisted by decoctions of guaiacum with mezereon; of sarsa with mezereon, or of the water dock alone; of either a pint should be drunk daily, and every other morning a dose of the magnesia vitriolata, or any other neutral, be interposed. The diet is to be almost exclusively confined to milk and vegetables. In some instances the muriated lime has been successful; and the oxygenated salts, when the disease attacks elderly persons, are often useful. We have not found the mineral acids peculiarly efficacious, though the nitric has appeared sometimes salutary.

Relapses have been prevented by the same diet, interposing the salt, or salt water, every other day, with the utmost attention to bathing, and frequently washing the parts formerly affected with warm water. We mean not to represent the use of the mercurials with the decoctions just mentioned as infallible, for they often fail; but we think this plan has been more useful than any other which has been suggested.

PSORICA, (from $\psi\omega\alpha$, the itch). Medicines for the itch.

PSOROPHTHA'LMIA, (from $\psi\omega\alpha$, and $\sigma\phi\theta\alpha\lambda\mu\iota\alpha$, an inflammation of the eye). An itch or scurf of the eye lids, particularly in their edges, which renders them sore, and sometimes scabby. It is often a symptom of scrofula, and is at times joined with an herpetic eruption; whence the distinction of the two species *ps. crustosa* and *herpetica*. See TRACHOMA and OPHTHALMIA TARSII.

PSUCHAGO'GICA, (from $\psi\upsilon\chi\eta$, mind, and $\alpha\gamma\omega$, to move). Medicines which recal life in an apoplexy or syncope.

PSUCHROLU'SIA, (from $\psi\upsilon\chi\pi\sigma$, frigidus and, $\lambda\alpha\upsilon$, lavo). BATHING IN COLD WATER.

PSYCHO'TRIA EME'TICA, vel HERBA'CEA. See IPECACUANHA.

PSYDRA'CIA, ($\psi\upsilon\delta\rho\alpha\kappa\iota\varsigma$, pustula). Small tubercles on the head which resemble pustules, and corrode

the skin. Trallian describes them as small watery pustules, which, when seated on the head, are called *psydracium*. Dr. Willan assigns this name to minute pustules, irregularly circumscribed, producing but a slight elevation of the cuticle, and terminating in a laminated scab. Many of these usually appear together, and become confluent. When mature, they sometimes contain pus; but, in general, in the earlier stages, after breaking, they discharge a thin watery fluid.

PSY'LLIUM, (from ψύλλος, a flea; supposed to destroy fleas). **FLEA WORT**, *fulicaris herba crystallina*; *cynomoia*, *plantago psyllium* Lin. Sp. Pl. 167. It grows wild in the warmer parts of Europe, and is raised in our gardens. The seeds which have formerly been brought from the south of France are small, smooth, slippery, of a shining brown colour, of an oblong flattish figure, supposed to resemble a flea, whence the name of the plant, and perhaps its supposed virtues.

A drachm of the seeds renders a pint of water moderately mucilaginous and gently laxative: they have been used as demulcents. See Raii Historia; Lewis's Materia Medica.

PTA'RMICA, (from πταίω, to sneeze, because it provokes sneezing,) *pseudo pyrethrum*, *dracunculus fratensis draco sylvestris*, *sternutatoria*, **SNEEZE WORT**, **BASTARD PELLITORY**, *achillea ptarmica* of Lin. Sp. Pl. 1266, is a plant with long, narrow, serrated leaves, and radiated discous flowers, set in umbels on the tops of the branches. It is perennial, grows in moist shady grounds, and flowers in June, &c. throughout the summer. The roots have the hot pungent taste of pyrethrum, with which they agree in their pharmaceutic and medical properties. See Lewis's Materia Medica.

PTE'RI'S, (from its resemblance to πτερον, a wing). See **FILIX**.

PTE'RNA, (πτερυγα, the bone of the heel). See **OS CALCANEUM**.

PTEROCA'RPUS. *Santolinus*. See **SANTALUM RUBRUM**.

PTERY'GION, **PTERY'GIUM**, (from πτερυξ, a wing). A FILM ON THE EYE, called a WEB. (See **ALBUGO**, **UNGUIS**, and **OPHTHALMIA**, p. 309.) There are four varieties of this disease, viz. the *f. ungula*, thin, transparent, and cineritious, apparently growing from the semilunar membrane; *f. crassum*; *f. annus*, thick, and of a red colour, stretching over the cornea; *f. malignum*, dark and painful, supposed to be cancerous; *f. pingue*, a soft, fatty substance, without pain, near the external angle of the eye. Extirpation is the most certain means of relieving those species which are troublesome; but Richter recommends bringing on a discharge by means of nitrated mercury. (*Observationes Chirurgicæ*, fas. iii. No. 1.) See Richter *Commentar. Nov. Gottingen*, vol. viii. In Celsus, lib. vi. cap. 19, it means a disorder of the nails, resembling a caruncle, accompanied with great pain. To these a mixture of alum and honey, in equal parts, is applied.

PTERYGO'DES, (from the same). An appellation of those whose chests are narrow and flat, so that their scapulæ are prominent, like wings. Hippocrates.

PTERYGOIDE'US EXTE'RNUS, vel **MI'NOR**, (from the same,) *alare externum*, because they rise from the wing like processes of the os sphenoides, first described by Fallopius. They rise also from the neighbouring parts of the os sphenoides, and are inserted

into the neck of the condyle of the lower jaw, and into the cartilage of the condyle, which is hollowed, to move upon the tuberosity of the os temporis. The part not concealed by the pterygoideus internus is covered by a membranous expansion, originating from the inner edge of the glenoid cavity of the lower jaw, immediately before the styloid process of the temporal bone.

PTERYGOIDE'US INTE'RNUS, vel **MA'JOR**, rises from the cavity between the lamella of the processus pterygoideus, and is inserted into the inside of the angle of the lower jaw. It lies on the inside of the lower jaw, almost as the masseter does on the outside, being of the same figure, but smaller and narrower. When these muscles act together, they move the lower jaw horizontally forwards; when singly, forward, and to the opposite side.

PTERYGOIDE'US PROCESSUS, (from πτερυξ, a wing, and εἶδος, form,) *aliformis*. See **SPHENOIDES OS**.

PTERYGO-PALATI'NUS. See **SPHENO-PTERYGOPALATINUS**.

PTE'RYGO-PHARYNGÆ'I, (from πτερυξ, and φαρυγξ,) the name of the *cephalo-pharyngæus*. In the edge of the internal alæ of the apophyses pterygoideæ these muscles rise, then run backward, and are inserted into the linea alba of the pharynx. See **PHARYNX**.

PTE'RYGO-STAPHYLI'NUS SUPE'RIOR, (from πτερυξ, and σταφυλή). The external portions of the sphenosalphingostaphylini.

PTE'RYGO-STAPHYLI'NI INFE'RIORES. These muscles are very small, and inserted at one extremity into the uncus pterygoideus, and by the other into the septum, near the uvula.

PTILO'SIS, (from πτελος, bald). A person who hath lost his eye lashes. A baldness of the eye lashes, from a callous thickening of the edges of the eye lids, so that it is a complication of a madarosis and lippitudo.

PTI'SANA, (from πτεσσα, to decorticate, or bruise). *Ptisan*, barley deprived of its hulls by pounding, which was formerly effected, after macerating it in water, by drying. It was ground into meal, made into balls, by first boiling and then drying it to a due consistence.

Ptisan was also made of other kinds of grain; and the name of the grain was added, *cafe hoc ptisinarium oryzae*. Hor.

These balls, or ptisans, were boiled in from ten to fifteen times their quantity of water, until the meal swelled: then they added a little vinegar, sometimes oil or animal fat, and aniseeds, occasionally salt. The ptisan thus boiled and strained is called the cream of ptisan. When not strained, it is called entire ptisan; when diluted, gruel, or juice of ptisan. Hippocrates styles it *adipson*, because it cures thirst.

PTO'SES. Tumours caused by protrusion; *phalangosis trichia*.

PTO'SIS, (from πτεω, to fall,) is a descent of the upper eye lid, from a palsy of the muscles which elevate it, or inflammatory or erysipelatous tumours which depress it. It is the *blepharoptosis genuina* of Sauvages: in the London Medical Journal, iv. 340, a case is described, where a complaint of this sort returned at irregular intervals. Smoking tobacco always induced it, and putting on a pair of spectacles not only carried it off, but prevented its return. After cleaning the primæ viæ, asafoetida and valerian were given, and a blister applied

to the forehead, near his eye brows. This treatment completely succeeded. In another case the disease was occasioned by an injury done to the levator palpebræ superioris, so that the patient was unable to raise that portion of the eye lid. The disease was cured by dividing the lacerated fibres with a knife. In a third instance the complaint was purely spasmodic. The patient was a young woman twenty years of age, who was subject to occasional spasms, not only of her eye lids, but of the other muscles of her face. In this case the affection yielded to musk and small doses of emetic tartar. We have twice seen it, without being able to attribute it to any particular cause, and it yielded to the common stimuli, applied externally.

PRO'SIS IRIDIS. A protrusion of the iris through a wound of the cornea, sometimes, in weak states, independent of a wound, of which we once saw an instance. It appears in the form of a blackish tubercle, and the laminae of the cornea rise around it in an external bur. When long continued, it is attached to the edges, and becomes callous.

PTYALIS'MUS, (from πτυαλιζω, *to spit*). A frequent and copious discharge of saliva, generally arising from mercury. (See SALIVATIO.) Dr. Cullen defines it a flux of saliva, adding, that, if ever idiopathic, it is from relaxation. When originating from mercury, it is continued from relaxation, and may then be considered as a separate disease. It is very obstinate, and yields only to time, and to tonics used internally, or astringent gargles. Sometimes blisters behind the ears seem to be useful. A singular case of a troublesome ptyalism being cured by chewing dry bread, and swallowing it, is related in the London Medical Transactions, vol. ii. p. 34. Nineteen symptomatic species are enumerated.

PU'BA. See CASSADA.

PUBERTAS, (from *pubes*). The period of puberty is that in which the genital organs of each sex begin to evolve, and assume that organized structure which fits them for their respective functions. It is a period of great delicacy, and sometimes danger, though boys suffer much less than females. As in all other considerable changes, before the balance of the circulation is fairly established, there is considerable irritability, and all nervous diseases are increased: some, particularly chorea, often at this time appear. The period commences in boys at about thirteen, and in girls at eleven; but is scarcely completed in two years. Instances of peculiar precocity in this respect appear in the collections of wonders; and the accounts of Boset, in the Journal des Savans, and of Geoffroy in the forty-third volume of the Philosophical Transactions, are scarcely more credible.

PU'BES, (from βυζων, *the groin*). The private parts, covered in the adult with hair. The down also upon plants.

PU'BIS INTERRO'SSEUM LIGAME'NTUM is a strong triangular ligament, fixed by two of its edges in the inferior branches of these bones, so far as their symphysis; the third and lowest edge is loose: this whole membrane, the middle of which is perforated, is stretched very tight between the two bones, and under their cartilaginous arch, to which it adheres very closely.

PU'BIS O'SSA, the **SHANK BONES** (*ephebæon; epischion; pecten; pubes, episcion*), are situated in the middle,

anterior, and internal part of the os innominatum. On their superior part is a ridge, which runs on a continued line with another of the os ilium, distinguishing the cavity of the belly from that of the pelvis. Between the pubes and ischium is the foramen magnum ovale, in the recent subject filled up with a ligament. The symphysis of the os pubis is composed of two cartilages and one ligament; the two cartilages cover the surface of each bone, and the ligament is interposed. Hunter in the London Medical Observations and Inquiries, vol. ii. p. 333.

As a substitute for the Cæsarean operation, the section of the symphysis of the pubis has been recommended by the French accoucheurs, the advantages and inconveniences of which we have shortly noticed. We must add, however, their method of performing the operation, for those who differ in opinion from us may choose to imitate it. The instrument used on this occasion is a common dissecting knife, with a convex edge, a little blunt in the point, lest it should injure the bladder, and thin, that it may have a finer edge. The woman is placed on her back, at a height convenient to the accoucheur; the thighs somewhat opened, and the mons veneris shaved. A catheter is then introduced into the bladder. The inferior part of the integuments are drawn down, and the incision begun about two or three lines above the pubes. The first incision must not be carried farther than the middle of the symphysis. From this first incision little hæmorrhage will follow, and the cartilage will be fully exposed. By cutting in the middle of the symphysis, the suspensory ligament of the bladder will be partly divided, and in procuring the necessary separation it will be lacerated, which may occasion an incontinence of urine. There are cases in which this complaint can be attributed to no other cause than the laceration or relaxation of the ligament of that viscus, so that we must avoid cutting in the middle of the cartilage. If the division is made on either side, part of the suspensory ligament of the bladder will be preserved; and if the bone on that side be touched, a more speedy reunion will be effected; and the left pubes appearing after the section to recede more than the right, there will be a greater opening on that side. The neck of the bladder also, and the fundus uteri being rather more inclined to the right, lead us to choose the left side. Directing, therefore, the catheter to the right, the operator must cautiously divide the symphysis on the left side, when it is said the pubes recede, in a greater degree, as the thighs are more expanded. If the separation is very sudden and considerable, the interior ligaments will be distended too suddenly; it is, therefore, advisable to keep the thighs moderately open during the operation; and afterwards to widen them gradually, until the necessary separation is obtained.

After the operation, it is recommended to turn the child, and deliver it immediately, as every other method would increase irritation and inflammation. The integuments, which were greatly distended during pregnancy, now will subside, so as to cover the symphysis. A bladder must be fitted to the end of the catheter, in order that the patient may not stir when she wants to discharge her urine, and in case the bladder hath been injured, that the wounded part may heal without any additional irritation.

For the wound, nothing more is necessary than dry lint moistened with brandy, and discutient embrocations upon the posterior articulations of the pelvis. A bandage must be applied, to keep the parts in contact, to which there must be two tapes fastened, to be conveyed between the legs, and tied before. The mother should suckle the child for eight or ten days, and laxatives with tonics may then be directed according to circumstances, with a constant attention to keep the parts at rest.

The idea of this operation was suggested by an observation, most probably unfounded, that the bones of the pelvis are connected by a substance which, during the latter period of pregnancy, swells and softens, and that if cut through, the two fore parts of the pubes recede from each other to the distance of from two inches to two inches and a half, diverging proportionally forwards.

When the diameter of the brim of the pelvis, from the sacrum to the pubes, measures from two inches and a half to three inches and a quarter, this operation is recommended.

In a case recorded by Dr. Leake the space gained in the dead subject was considerable; but on more careful and exact inquiries neither the space gained nor the facility of the operation were found to counterbalance the inconveniences: the former was inconsiderable, and the operation is no longer attempted.

See Practical Observations on the Childbed Fever, by Dr. Leake, edit. 5. page 238—255. Comparatio inter Sectionem Cæsaream et Dissectionem Cartilaginis et Ligamentorum Pubis in Partu, &c. Auctore C. C. Siebold, M. D. London Medical Journal, vol. iv. p. 141. Bell's Surgery, vol. vi. p. 143. Walter De Dissectione Synchronoseos Ossium Pubis in Partu difficili.

PUBESCENTIA, (from *pubesco*, to bud forth). In botany, the arms of plants, by which they are defended from outward injuries.

PUDE'NDA, (from *pudor*, modesty,) the GENITALS; *aoidea*; *patrimonium*; *naturalia*. See GENERATIO.

PUDE'NDI ABSCE'SSUS. See ALÆ.

PUDE'NDI ARTE'RIA. See PUDICA ARTERIA.

PUDENDA'GRA, (from *pudendum*, and *αγρα*, *captura*), *cedma*. In this disorder there is a discharge of a purulent ichorous matter from the vagina, supposed to produce inflammatory symptoms in the penis, after cohabitation; the infection, however, is soon removed by bleeding, and some cooling laxatives. It is an affection of the vagina alone, in the beginning; the other parts afterwards suffer. The predisposing cause is a too rigid chastity, and the more immediate cause an indulgence of the venereal appetite, at times when the uterus is disordered. An excessive flux of the menses, and the fluor albus, aggravate the pudendagra, which is not properly confirmed until the uterine nerves, having entirely lost their sensibility, are no longer capable of distributing the menstrual flux. Excessive venery hastens the insensibility of the uterine nerves.

Such are the accounts of authors, who seem to have had no distinct ideas, and were consequently unable to communicate any. A disease of this kind we have never seen; and can distinguish, in these confused descriptions, only a leucorrhœa with a more acrid discharge in the intervals of too copious or too often repeated menstruation.

On dissecting those who have died whilst labouring under the pudendagra, it hath been observed that the parts leading to the uterus were particularly relaxed, and that the uterus itself was enlarged by scirrhus and other tumours.

PUDENDO'RUM CA'RIES. See CHANCRE.

PUDE'NDUM MULIE'BRE, *hortus*; *porcus*; *boubalios*; *byssus*; *caverna*; *amphicaustis gynæcomystax*. See GENERATIO.

The pudendum muliebre is subject to a complaint somewhat analogous to the prurigo scroti, bearing a similar name. (See PRURIGO.) It is situated in the labia pudendi, and entrance of the vagina; and often attended with the appearance of tension and fulness in those parts, and sometimes with inflamed itching, papulæ on the labia and mons veneris. From the strong and perpetual itching inconceivable distress arises; and venereal sensations take place, from the constant direction of the mind to the parts affected. Deep ulcerations seldom occur, but aphthæ on the labia and nymphæ are not uncommon. Women, after the fourth month of pregnancy, often suffer greatly by this disease; sometimes succeeded by extensive ulcerations, which have destroyed the nymphæ, and produced a fatal hectic; but this occurs very rarely. In general the complaint has some intervals or remissions; the aphthæ usually disappear soon after delivery at the full time, or a miscarriage. Saturnine lotions, saline solutions, lime water, vinegar, and oily emulsions, with fixed alkalis, a decoction of lintseed, with poppy heads, or tinctura opii, afford temporary relief; but half a scruple of corrosive sublimate, dissolved in half a pint of lime water, forms the most certain remedy, when applied daily; postponing its use if there are painful fissures of the skin, till they are relieved. See Willan on Cutaneous Diseases.

PUDE'NDUM VIRI'LE; *genitura*. See GENERATIO.

PU'DICA, vel PUDE'NDA ARTE'RIA, comes out between the pyriform muscle and the spine of the ischium; runs downwards between the two ligaments, the one of which comes from the tuberosity of the ischium to the sacrum, and the other from the spine of the ischium to the sacrum, on the inside of the tuberosity. In its progress it gives ramifications to the anus, the external hæmorrhoidal, and then goes to the crura penis.

PU'DICÆ EXTE'RNÆ ARTE'RIÆ. See CRURALES ARTERIÆ.

PU'DICÆ EXTE'RNÆ VENÆ. As the crural vein passes from under the ligamentum Fallopii, it sends out branches to the inguinal glands, the musculus pectineus, and the parts of generation; these are called *pudicæ externæ*, and they communicate with the *pudicæ internæ*.

PU'DICÆ INTE'RNÆ VENÆ. The veins that convey the blood from the parts of generation; branches from the venæ hypogastricæ.

PUERI'TIA, (from *puer*, a child). See ÆTAS.

PUERPERIUM, (from *puer*, a child, and *pario*, to bring forth). DELIVERY. Much care is usually necessary in these circumstances; for lying in women are liable to many disorders. Immediately after delivery, every thing wet should be removed, and dry warm linen in readiness for her use; supplying fresh

when necessary. It is generally necessary to keep the breasts warm, by means of flannel cloths, until the milk flows freely. The room should be supplied with free though not cold air; and during the first three or four days the diet should be thin, but not stimulating. The common allowance is caudle, oatmeal boiled in water until it is of the consistence of a thin jelly, and then rendered agreeable to the palate by the addition of a little sugar, sometimes ale; more generally wine is added, but if the stomach is subject to acidity, a little brandy is preferable. Rest must by every means be promoted; and, if required, opiates may be given for this purpose. Costiveness should be guarded against, though a diarrhoea at this time is not favourable. The child should be applied to the breast in about ten or twelve hours after its birth, if the mother intends to suckle it; for the sooner the secretion of milk can be promoted, the less danger will there be of a milk fever, or an abscess. See PARTURITIO, and the following article.

PUERPERA' LIS FE' BRIS, (from *puerpera*, a lying-in woman). The PUERPERAL OR CHILDBED FEVER. See PERITONITIS.

This peculiar fever has only been discriminated with accuracy within the last thirty years, and even at present is often confounded with various other complaints incident to the puerperal state. In order to distinguish it and to elucidate its pathology, we must enlarge a little on the changes which take place on delivery, and their consequences. This perhaps might have been comprised in the preceding article; but in this place we thought it might be more striking, as its consequences would be more immediately obvious.

In the last months of pregnancy the arterial system of the hypogastric region is contracted by the pressure of the uterus, while the return of blood by the veins is equally retarded. When the pressure is taken off, the flow of blood is, of course, increased, and it is freely poured out by the uterine arteries. Within the compass of a few hours, from twelve to thirty-six, or at most forty-eight, this discharge lessens; but it is compensated by an increased flow to the mammae, thus relieving the plethoric state of the hypogastric region which might otherwise ensue. We thus find two altered determinations, the first sudden and rapid, the other more slow; and we know that every change in the balance of the circulation is attended with a peculiar state of irritability. This state is a constant and striking attendant of childbed; and from it many of the symptoms arise, particularly that susceptibility of nervous impressions which is often so injurious. Independent of these, what are termed the after pains, the discharge of clots from a spasmodic contraction of the uterus is sometimes attended with rigor; but the first effect of the change of determination is often more decidedly febrile, and is termed the *weed*. After about thirty-six hours, often sooner, the next change of determination, that to the mammae, is also ushered in by shivering, accompanied by heat. These different feverish attacks have misled practitioners, and the true puerperal fever has been confounded with them, supposed to be the same, or a continuance of these accessions. It is now necessary to distinguish it.

The rigor of the true puerperal fever comes on more than forty-eight hours after delivery; in medical language, on the third day. If, however, the woman is delivered about four in the afternoon, the attack on six of

the third day is scarcely more than fifty hours, while, if the child was born at two in the morning, the interval is sixteen hours more. The third evening is, however, strictly critical, and whatever rigors occur at any other period are seldom dangerous. The rigor is also severe, attended with peculiar debility, and the hot fit with headach of no common kind, viz. a tension, as if a cord was forcibly bound round the forehead: at the same time there is a considerable tension, very generally great soreness of the abdomen. We can assert, with the fullest confidence that these symptoms are pathognomonic of the true puerperal fever. They may occur in different degrees, but they are always present. To these we may add, a sinking of the features, and a peculiarly vacant stare of the eyes: a symptom perhaps not equally constant, but rarely absent. The fever remits very strikingly in the morning, and returns at night: these remissions are discernible for the three or four first days.

The lochia are gradually suppressed, and the milk by degrees also disappears. The head is each succeeding day more affected, and delirium comes on early. There is little sleep; the pulse is rapid and weak, with thirst, load at the precordia, dry parched tongue, constant sighing, despair in the countenance, and often an inflammation in the eyes. The tongue is of a glossy red, and very dry; the skin also is hot and dry; cough, with pain of the breast and side often intervene, and the scene closes with a low muttering delirium, sometimes with convulsions; often the placid complacency which attends putrefaction.

The disease is at all times dangerous, and fatal perhaps in the greater proportion. If the lochia return; if the milk can be preserved; if the expression of the countenance is not greatly altered; if the head remains clear; and a gentle diaphoresis comes on, the patient generally escapes. The circumstances attending the delivery afford no favourable prospect. It comes after the happiest and easiest labour; and we have seen it after such a profluvium, as from its violence has endangered life, while in cases of the most difficult and painful, where the placenta has been long retained, and the lochia in small quantity, it has not appeared. This fever is also often epidemic; and its progress is so decidedly that of typhus with local inflammation, that we have not a doubt of considering it as a typhoid peritonitis: for this membrane has been generally found inflamed or suppurated, often covered with an albuminous effusion, which have induced the French physicians to style it *un depot lacteux*.

If it is, however, unconnected with the lochia, it is equally so with the milk: for if it be a milky deposition, its degree should be in proportion to the suppression of the milk, and to the period of this suppression; but neither is the case. The fever sometimes comes on with violence, while the milk is only diminished; and the secretion generally continues, except in the most dangerous cases, till the eighth, often till the tenth day, though diminishing gradually in quantity. The deposition also is not milky, but albuminous. Others, who attribute the fever to inflammation of the uterus, have not found on dissection this viscus essentially injured. It has shown no marks of inflammation or mortification; nor is there a more striking contradiction to this operation than the case just hinted at, that fever of this kind has come on after profuse floodings. The peritoneum, sometimes the omentum, is confessedly

inflamed, and often mortified. In explaining, therefore, the circumstances of this disease, these are the only changes that we can admit.

The fever, we have seen, is so strongly marked, that it cannot be explained on the idea of its being an accidental or a sporadic one. The *annus infestus* of Bartholine marks its epidemic tendency; and our own experience has proved that the larger proportion of cases has occurred at particular seasons. The fever then is an epidemic typhus, appearing only in this peculiar form, from the circumstances of the puerperal state.

If then we consider the situation, the peculiarly irritable state, of a puerperal woman, and compare it with what we have remarked respecting the altered balance of the circulation, as the essence of fever, we shall not be surprised at the affection of the brain; but this affection, though sometimes violent, for the delirium *ferox* is not uncommon, more often consists in unequal excitement, from a diminution of the active powers of the circulation, while every mark of accumulation remains. The consequence is, the languid inflammation, described as the consequence of concussion. The active energy of the circulation is more conspicuous in the hypogastric region. In the remarks on INFLAMMATION, q. v. p. 13, we endeavoured to show that a weakness in the affected vessels, joined with an increased *vis a tergo*, was the evident efficient cause; and that all the varieties of inflammation depended on the proportionate degrees of debility, and the impelling power. In the present disease, the vessels of the hypogastric region pressed on by the uterus, during gestation, and their active power thus confined, are necessarily debilitated; and when fever comes on, increasing the action of the larger arteries, inflammation must be the consequence. This disease cannot take place in the uterus itself, for there the vessels are not compressed, and they are completely emptied by the lochial discharge. In the neighbouring organs, however, the circumstances are different, and there inflammation comes on. If then the causes of typhus exist, and any accidental circumstances call them into action, the symptoms of puerperal fever will be the consequence; nor can we wonder at the fatality of the disease, when we reflect on the increased irritability of that state, the local debility of the vessels, and the general weakness from the discharges.

The period of the fever is uncertain. It sometimes extends to the twenty-first day; but where the delirium is violent, its termination is often more rapid. In general, when the lochial discharge has been considerable, we have thought that the disease has been more dangerous and more quickly fatal.

The treatment of puerperal fever in the hands of different practitioners has greatly differed; but, unfortunately, each has been equally unsuccessful; and, on the whole, we are almost tempted to think, that to guard against the most troublesome and dangerous symptoms will be the most salutary practice.

Bleeding, the first idea that occurred to the ancient physicians, was freely employed. It is not easy to reconcile this remedy to the nature of the disease, yet we have little doubt but that it was successful, and we can only explain it on those principles which have already assisted the explanation of the good effects of this remedy in plague and putrid fever. If practised early and copiously, it enables nature to resist the load, and restore

more effectually the balance of the circulation. Constitutions may, perhaps, at this time differ, or we may act less decisively: bleeding, however, does not at present succeed, nor can we advise this remedy. The puerperal state attracts general attention, and a failure in its attendant complaints, especially if the remedy is violent, or unusual, may be highly injurious to the practitioner. At all events, we think bleeding should be avoided, except in the young and plethoric; where the delirium is violent, and the determination to the head excessive.

Emetics are remedies of less doubtful powers, and so efficacious, that some years since, they were considered in France as specifics in this disease. We have little hesitation in saying from our own experience that they greatly mitigate the fever, nor, if given at the moment of the attack, should we disbelieve M. Doucet's assertion of their wholly checking it. If the emetic is given previous to the next evening exacerbation, the good effect is more doubtful, and previous to the third it is almost useless. From what we have said of the effects of this remedy, and the nature of the complaint, there must be little doubt of the source of its advantages.

Cathartics are remedies whose real value is scarcely ascertained. In general, they are commended; and authors have expressly remarked, that a purging is salutary. We shall not be accused of prejudice against their use; but beyond those gentle ones which keep the bowels soluble we have not found them advantageous. On the contrary, violent purging seems to have lessened the strength, without diminishing fever. It must be remembered also, that, in more active peritonitis, stools did not seem to be useful.

Gentle *diaphoretics* appear to be salutary; but on the one hand to force sweats by excessive heat, or to elicit diaphoresis by relaxing antimonials, seems equally injurious. The saline neutrals, camphor in moderate doses, with opium, if easily borne, are the most effectual remedies of this class.

Blisters are highly recommended, and certainly at times useful in diminishing the pain and tension of the abdomen. Applied also to the neck they relieve often the tension of the forehead, and bring on sleep; but their effects are seldom considerable or permanent.

As we have spoken slightly of the most active medicines, it may be expected that we are about to recommend a new and more effectual plan. In fact, however, we engaged in the practice of medicine at the time of the numerous publications on this subject, with all their various plans before us, and expected to subdue the fever with little difficulty. We found ourselves, however, disappointed; and that the younger practitioners may not experience similar disappointment, we shall state shortly the result of our experience.

The fever attacks, we have said, on the third evening, that is, the next evening but one after delivery. Attention ought, therefore, to be alive at that time, and every rigor at this critical season should be immediately met with an active emetic. Except miliary fever, attended with particular anxiety, sighing, &c. a disease now almost unknown, no fever occurs at this period, and miliary eruptions are not peculiar to it. Were they so it would be no contraindication of the emetic. After the emetic, light saline medicines, with an opiate, and on the following day, a laxative, will be necessary. The succeeding evening must be carefully watched, and on

the return of rigor, the emetic with the opiate again exhibited. What can be gained by medicine is by this time attained. The laxatives must be given to prevent irritation from the bowels, blisters applied to the abdomen to lessen inflammation, and to the neck to procure sleep. We gain nothing in the result but the diminution of symptoms; for the disease will run its course. Yet, though we cannot stop the disease, we may regulate its progress; and it is necessary to add some rules for this purpose. The degree of discharge from the bowels is regulated by the strength, the appearance of the stools, and the ease with which they are borne. If black and offensive, they should be numerous, while these appearances continue, and if not followed by faintness, we may be less anxious respecting their number. Should the pulse at the same time become slower and softer we may persevere. Such, however, is seldom the case. The stools are dark, but they appear to debilitate; the pulse often becomes more contracted, the affection of the head, the wandering delirium, increased. These circumstances have often held our hands, even while the stools have been dark.

The blisters require little regulation, and the diaphoresis, if kept up by mild, warm liquids, by camphor, and moderate doses of opium only, will proceed in a salutary degree.

Tonics, particularly bark and the acid of vitriol, have been given early, and in large quantities, but, in our hands, with little advantage. Others seem to have been more successful, and we would with pleasure join in their commendation, did experience warrant us.

In fact, then, as already hinted after the emetics, we have been able to do little by medicine, except, as in other fevers, to conduct the disease more easily and safely to its termination; and, indeed, the advantages derived from medicine in this respect seem less striking in the present complaint than in the greater number of fevers. In this respect it resembles the pure nervous fever, with which it is very nearly allied in all its symptoms and its progress. The most perfect tranquillity, free cool air, the most soothing manners, the most gentle medicines, have appeared most effectual. A diet mild, diluting, and gently diaphoretic, evacuations the least irritating, medicines the most soothing, have appeared the most useful; and camphor with opium, occasionally with the anodyne liquor of Hoffman, the most salutary. Wine is seldom required, except in the last stages of debility. Let us most earnestly deprecate any violent interference; for even the most promising plans, if attended with irritation, have been injurious.

PUGI'LLUS, (from *pugnus*, the fist). A PUGIL, or PINCH; *dragmis*, the eighth part of a handful, or as much as can be taken up by the thumb and two fingers.

PULE'GIUM VULGA'RE, *pulegium regale*, and *latifolium*; *glechon*; PUDDING GRASS, COMMON PENNYROYAL, *mentha pulegium* Lin. Sp. Pl. 807, hath oval obtuse leaves, and trailing stalks, which strike root at the joints. It grows wild on moist commons, and flowers in June.

All the mints, particularly pennyroyals, are warm and pungent; but the latter are more acrid, less agreeable both in smell and taste, less proper than mint in nausea, but more efficacious as warm carminatives in hysteric cases. This species is the strongest, though the least ungrateful, and has been considered useful in the chin-cough, as an antispasmodic and emmenagogue, but in each respect its powers are inconsiderable. Cullen's Materia Medica. Haller, however, who was not a practical physician, recommends an infusion of the herb, with steel, in white wine, for promoting uterine evacuation, and speaks of it as infallible.

The active principle of the pennyroyals is their essential oil, which is more valuable than that of mint. It comes over at the beginning of the distillation with water, and rises in a great proportion with spirit of wine: it tastes and smells strongly of the plant; and may be given from grt. i. to v.

The London college directs a simple water and a spirit to be distilled from pennyroyal, from a pound of which they make a gallon of each, besides the essential oil, which they ordered to be procured by distillation. An infusion of it is equal, however, if not superior; and the whole virtue of the herb may be extracted, either by water or by spirit. See Lewis's Materia Medica.

PULICA'RIA, (from *pulex*, a flea). See CONYZA MINOR, &c.

PULICA'RIS HE'RBA. See PSYLLIUM.

PULICA'RIS MORBUS. See PETECHIA.

PULMONA'RIA, (from *pulmo*, the lungs; from its utility in affections of the lungs). *Musculus pulmonarius*; *hieracium Alpinum*; *lichen pulmonarius* Lin. Sp. Pl. 1612.

PULMONA'RIA MACULO'SA; *pulmonaria symphytum maculosum*; SAGE OF JERUSALEM; JERUSALEM COWSLIP; SPOTTED LUNGWORT; *pulmonaria officinalis* Lin. Sp. Pl. 194, is a hairy scabrous plant, with leaves of a dark brownish green colour on the upper side, and spotted for the most part with white. Underneath it is of a pale green; and the lower leaves are oval, set on broad pedicles, those on the stalks narrower, long pointed, set alternately without pedicles; the flowers monopetalous, of a purple or blue colour, and sometimes white, followed each by four seeds inclosed in the cup. It is perennial, grows wild in many parts of Europe, and flowers in April or May; resembling in virtue the *adiantum nigrum*.

PULMONA'RIS ARTE'RIA. See PULMONES.

PULMONA'RI   VE'N  . See PULMONES.

PULMO'NES, (Plin. πνευμον, Attice, πλευμον). The LUNGS are two spongy bodies, reddish in children, greyish in adults, and bluish in the aged, divided into two principal lobes, hyperchoryphoses, and inclosed in two

distinct bags, formed of the pleura, so that the right and left lobes have not the least communication. The pleura covers the lungs by passing over and round them, as the peritoneum covers the intestines; and the same membrane is reflected, covering the ribs internally. An inner lamella of the pleura passes into their substance; a circumstance discovered in infants. On the right side, the lobe is divided into three lesser ones, a superior, an anterior, and an inferior; the latter lying upon the diaphragm. On the left side are two lobes, only divided by a fissure. The space between the lungs is filled up by the heart below; by the thymus and trachea above; behind by the œsophagus and spine. Their shape corresponds to that of the thorax.

The whole mass of the lungs is composed of air and blood vessels, lymphatics, nerves, and cellular membranes.

The air vessels are very small branches continued from the windpipe, with which, in a sound state, they have a free communication, and at every inspiration are filled with air. See BRONCHIA.

In the minute ramifications the cartilages of the trachea disappear; but the mucous membrane is continued. When in this minute subdivision the tubes have attained their smallest size, each is widened at its extremity into a follicle, which are usually collected in bundles, styled *lobuli*. The cells of each lobule communicate freely; but the different lobules seem to have little communication. The lobules are divided by cellular substance, so that in the lungs there are two distinct sets of cells, which are affected in different diseases. In the catarrhus suffocativus, for instance, the follicles are filled; in the hydrothorax, the surrounding cells of the cellular membrane. The cells on the surface appear to be circular; but internally, perhaps, also, externally, when confined by the thorax, they are angular.

The blood vessels are the pulmonary, and the bronchial arteries and veins. The pulmonary artery rises from the right ventricle, runs upwards to the left of the aorta, dividing on the curvature into two branches, which lie before that of the trachea; the right branch is longer than the left, for the same reason as the trachea is so. When passing into the lungs, it divides into two or three branches; after it has divided into very small branches, they do not anastomose, like the small branches of the aorta, but they join again, and form veins, which uniting, go to the left auricle of the heart, commonly in four or five trunks. The lungs are tied down to the vertebræ by a broad ligamentous band, continued from the division of the arteries into the diaphragm. The large vessels run in the large interstices, and in the small parts the branches still run on in the interstices of smaller lobuli, and are connected by a cellular membrane, as in the other part of the body: at last the arterial ramifications terminate in a fine net work, upon the cells, called *rete Malpighi*, where it is supposed that the blood undergoes some alteration, as there it is nearly contiguous to the air, a very thin membrane being only interposed. From this net work the veins begin, and carry the blood back. In the minute subdivisions the pulmonary artery and vein are corrugated during expiration, and elongated on inspiration, so that the circulation is only free during the latter; and the blood is then exposed most carefully to

the air. The pulmonary artery receives and returns the whole mass of blood which circulates through the lungs before it passes to the rest of the body, probably that the injurious parts of this fluid should be carried off by respiration. The bronchial arteries are destined to the nourishment of the lungs; and the lymphatic vessels are distributed on their surface to convey the lymph back to the mass of blood. The nerves are very small, chiefly from the eighth pair. The cellular membrane fills up the intermediate spaces between the vessels. See BRONCHIALES ARTERIÆ. For the use of the lungs, see RESPIRATIO.

The substance of the lungs is more vascular than any other part, and a greater quantity of blood passes through them in a given time. The aspera arteria, minutely ramifying through every part of the substance, terminating in air vesicles, is peculiar to them, and by respiration they are kept in a perpetual motion. When the lungs are diseased, their motion is not only increased by the respiration being quickened, but they often suffer violent concussions by means of coughing; but, notwithstanding these concussions, wounds in the lungs often heal readily, and inflammations, except when vomicae are present, seem scarcely more obstinate than in any other part.

Numerous are the instances in which the lungs have been wounded by a small sword, and even by balls, from which the patients have happily recovered. Bierling mentions one, in which one hundred and twenty ounces of blood were lost; and a German author describes a case, in which a ball, passing through each lobe, did not prove fatal. In one instance the right lobe was wholly exposed, and in several a part of the lung was cut off. Abscesses also in the lungs, when not from vomicae, heal easily; though calculi, which are confined to the bronchial glands, are usually forerunners of hectic.

The adhesion of the lungs to the pleura, which we have mentioned as a common effect of peripneumony, or pleurisy, often occurs without producing any difficulty of breathing. Rivinus, Haller, and De Haen, have recorded numerous instances of the little injury which has resulted from the concretion; and one lung has been almost completely destroyed, without any considerable inconvenience. Gangrene of the lungs we have mentioned among the consequences of peripneumony, and we perceive it recorded by Malpighi among the consequences of a putrid epidemic which occurred at Pisa in 1648. A dissolution of the lungs is mentioned by Fontanus; and a considerable change in their texture, in the *Memoires de Médecine*, from Haller. In the same collection we find a remarkable case of their being found in a dry state.

A spasmodic stricture in the lungs has been mentioned as a cause of asthma; but we do not find in any part of their structure those contractile fibres which may become the subject of such disease. It has been referred to the cellular texture, which has been supposed irritable; but which we have rather been inclined to consider as an inorganic substance. It is probable, however, that the extreme ramifications of the lungs may be muscular, since gases, vapours, the powder of different substances dispersed in the air, will, in many instances, suddenly bring on spasm; and if we do not

allow them muscularity, we must admit of their being very acutely sensible, and to sympathize with the diaphragm and intercostal muscles. The smallness of the nerves sent to the lungs is the principal argument against either supposition.

De la Mettries' account of a rheumatic affection of the lungs cured by a gangrene of the foot coming on, is a singular and not very credible history. Rheumatism of this part is almost exclusively confined to the muscles of the thorax.

Foreign bodies, inhaled with the atmospheric air, have been found in them, sometimes more solid substances, passing accidentally into the trachea. The great causes of mischief in these organs are, however, the vomicae, chiefly found at the root of the lungs, which we have sufficiently noticed under the article PHTHISIS, q. v.

PULMONIA, (from *pulmo*, the lungs). See PERIPNEUMONIA.

PULPA, (*qua pulte mistura vesebatur*). PULP; the soft part of the fruit which surrounds the seeds or kernel. It is separated by pressing through a sieve, after suffering the juices to separate spontaneously; or extracting them either by the addition of boiling water, or by boiling them in water. They are evaporated, when too fluid, in a salt water bath.

PULPEZIA. See APOPLEXIA.

PULSATILLA *Nigricans* Storck, Ph. Edinb. *Anemone pratensis* Lin. Sp. Pl. 760: it resembles the pulsatilla vulgaris, or pasque flower; but is less, and of a darker hue: it is a native of the south of Germany, and the neighbouring countries. All the anemones have a considerable degree of acrimony, but this seems to possess the largest share. The whole plant, when chewed, impresses the tongue with a sharp, burning, durable taste; but the root is mildest. Water carries over its virtues in distillation: and the remaining extract is also considerably active. From numerous trials, Storck celebrates the efficacy of this plant in various chronic diseases of the eye; in venereal nodes and nocturnal pains; in foul ulcers with caries; in serpigo; and suppressed menses. He relates instances of its curing blindness of many years continuance, by dissipating and dissolving films and obscurities of the cornea. In these cases, its good effects were first indicated by considerable pain excited in the eye. The sensible operation of the medicine was nausea and vomiting, particularly when the distilled water was used; an increased flow of urine, and sometimes colic with looseness. Many German physicians have tried the effect of this remedy in diseases of the eyes with success; but Schmucker, Bergius, and Richter, found it inefficacious in these complaints, though the doses were increased beyond what Storck himself directed.

As this plant is acrid, Dr. Cullen thinks it may be active; and from the singular matter resembling camphor, which its distilled water contains, that it may have peculiar powers and virtues. The too eager commendations of Storck have excited suspicion: but Dr. Cullen recommends the trial of it in amaurosis; as the disease may depend upon different causes, some of which may yield to remedies, though others do not. Cullen's *Materia Medica*.

The dose of the distilled water to adults is about half an ounce twice or three times a day; of the extract,

reduced to powder, with the addition of sugar, five or six grains. The Edinburgh college had adopted the distilled water of pulsatilla, but has now changed it for the extract. See Lewis's *Materia Medica*, edit. 3.

PULSATIO, (from *pulso*, to beat). This can scarcely be called a disease; but it is often a symptom, and frequently a source of alarm. Any person, if thin, will often, on lying on his back, perceive a pulsation somewhat below the pit of the stomach, and, if low spirited or hysteric, will be alarmed by this unexpected sensation. It is, however, owing to the falling back of the intestines, which brings the pulsation of the aorta under the fingers. This is the case in ninety-nine of one hundred cases, and is particularly noticed in the second volume of Haller's *Bibliotheca Practica* from Columbus. We must not conceal, however, that Bonetus has recorded it as occurring from a compression of the aorta, below, and Severinus and Bonetus from an aneurism of the cœliaca. Weisborn has described a case in which it occurred from the aorta being pressed from its place. A similar cause must have occasioned the sensation of pulsation on the right side. A pulsation of the veins is recorded by Homberg in the *History of the Academy of Sciences*, 1764, apparently from increased action of the arterial system.

PULSUS, (from *pulso*, to beat; also *phlebopælie*). The PULSE is well known to consist in the reciprocal contraction and dilatation of the heart and arteries, by the former of which the blood is propelled through every part of the body.

It may be easily supposed that the pulse could not be understood, or employed as a source of prognostic, while the circulation was unknown. Hippocrates therefore slightly mentions it; and Herophilus is said to have been the first who considered the pulse with some accuracy. In the time of Celsus the pulse was frequently consulted, though he calls it *res fallacissima*. Galen, however, wrote most voluminously and laboriously upon this subject; an epitome of which may be seen in Prosper Alpinus de *Præsagienda Vita et Morte*. Boerhaave, in his *Institutes*, collects all that the ancients knew concerning the pulse in a short compass, which is well explained by his commentator, Haller. Long experience, however, has rather confirmed than contradicted the opinion of Celsus, for notwithstanding the multiplicity of pulses, which have been enumerated, they often mislead, unless the practitioner is accustomed to their examination.

In feeling the pulse no little attention is required. They should be examined at coming into the room and on leaving it. The presence of the physician sometimes quickens it; and the recollection of the complaints, or the talking only, will have the same effect. The artery should be first felt gently, and if any doubt arises whether the pulse is weak, it should be compressed strongly by three fingers, and the two uppermost slowly raised. If the pulse is strong, and seemingly weak only from oppression, the blood, rapidly returning, will strike fully the finger below. If really weak, it gradually recovers its former force. It is necessary in estimating the strength or weakness of the pulse to consider the state of obesity in the patient, and the size of the artery. A fat person has naturally a weak pulse; but it beats also to a disadvantage beneath a layer of fat. This circumstance should be attended to in our estimate. The size of the

artery we can often estimate, for we can feel, in thin persons, two-thirds of its circumference, and errors can scarcely arise from this source.

The great object of enquiry respecting the pulse is, their frequency or slowness. In this respect, sexes, temperaments, idiosyncracies, and ages, differ. The pulse in women is quicker than in men; in the sanguine than in the melancholic temperament; in youth than in age. If the pulse in men varies from sixty to eighty, in women its range is usually from seventy-five to eighty-five. In a sanguine temperament a natural pulse is often eighty; and in a melancholic one frequently under sixty. Idiosyncracies can be reduced to no standard; but we suspect that the supposed varieties, if not referrible to age or temperament, often arise from disease. Dr. Heberden, who examined the pulse with accuracy in this respect, observes that the pulse of a healthy infant, on the day of its birth, while asleep, is from one hundred and thirty to one hundred and forty. The mean rate, during the first month, is one hundred and twenty; and it is rarely under one hundred and eight. During the first year, its range is from one hundred and eight to one hundred and twenty; during the second from ninety to one hundred; the third from ninety to one hundred and eight. It varies little till the seventh year, when it is about seventy-five; and in the following year scarcely exceeds seventy. These numbers are subject to great variety. The pulse are quickened at different times of the day (see *DIÆTA*); after a full meal; after exercise or any agitation. They are also quicker when standing than sitting, and in the latter posture than when lying down.

The pulse may be counted with some degree of accuracy till it reaches one hundred and forty strokes in a minute, perhaps, by strict attention, to one hundred and seventy. Beyond, all is rude conjecture, and the number is of little importance; for even in a child one hundred and forty strokes in a minute indicate extreme danger. We can admit that De Haen (*Ratio Medendi*, xii. 83.) could observe one hundred and sixty strokes in that small period; but scarcely allow that Wendt (*De Pulsus Mutatione insigni Erlang*, 1778) could have distinguished two hundred and forty-three.

A constant pulse of ninety in a minute, rising occasionally to one hundred and eight, shows a considerable irritation in the system, and is not without danger. We once saw, however, in a fever, a pulse constantly exceeding one hundred and forty; and three months after recovery it seldom sunk below one hundred and twenty; though after about two years it resumed the usual standard. In general, however, to exceed one hundred and twenty is a symptom highly dangerous, whatever may be the other appearances.

Pathologists have occasionally described a more frequent contraction in a particular artery; but except in the irregular oscillations, as they are styled, of the capillaries, this scarcely in any instance takes place. Gaubius asks, "An topica (pulsus frequentia,) datur in singulari systematis arteriosi parte?" Answering, "Dabitur si vera febris particularis."

A pulse from rest, and avoiding all stimuli, may be unusually slow, and, as we have said, (see *PROGNOSTICA*), even down to fifty in a minute. In diseases, however, this degree is highly dangerous; and should stupor also attend, it shows a degree of compression on

the brain which will probably soon end fatally. Within a few hours, we observed it, after an apoplectic stroke, under forty. Hyoscyamus and digitalis often render the pulse remarkably slow by lessening irritability. Causes of debility only increase its quickness, for the heart contracts from the increased irritability before it is full; and the ventricle, in consequence of weakness, is seldom wholly emptied. In Sarccone's account of the epidemics of Naples, the slowness of the pulse arose from insensibility. Cheyne remarks, in his *English Malady*, that colonel Townshend had attained so great power over his pulse as to stop it almost entirely; and we remember hearing a celebrated professor in a neighbouring university declare, in his youth, that he had a similar power in a less degree. He described the means by which he effected it, to be recalling some melancholy images, and yielding to gloomy reflections. His recovery, as may be expected, was attended with excessive anxiety. The pulse wholly stopping is not always a fatal symptom, though if it continues any time it is desperate. In a case recorded in the Breslaw collection, it failed eight days before death; and in one in the *Commercium Norimbergense*, five. Morgagni has recorded a similar occurrence from a dropsy of the pericardium. On the contrary, the pulse sometimes remains firm and good even a few hours before death, particularly when life is extinguished by causes which have no effect on the circulation. Even in a case of suffocation, from a suddenly supervening stricture in the upper part of the trachea, the pulse was not affected five minutes before death.

When the number of strokes continues the same, the pulse may be strong and hard, or quick (*celer*), and apparently weak. A strong, firm, pulse is consistent with high health; for the heart contracts only when full, and then acts with vigour. But the strongest pulse has some degree of softness if healthy. If it strikes the finger like a tense cord, it shows a tendency to disease, distinguished by the appellation of *diathesis phlogistica*, consisting in morbidly increased tone of the arterial system. If, with this hardness, it is increased in frequency, inflammatory fever is present.

It has been doubted whether the *pulsus celer* can be distinguished from the *pulsus frequens*. By the former term, which, for distinction, we shall style the *smart* pulse, is meant, that in which the systole is completed in a less time than the diastole. The rival professors at Halle, Stahl and Hoffman, differed in this point; but there is little doubt that such a distinction exists. It is not, however, obvious, but in a pulse of moderate quickness, and we should greatly doubt if it could be ascertained, when the number was above ninety; for that would require a distinction of the differences in the division of $\frac{1}{180}$ th part of a minute. Yet this we think, a delicate finger can ascertain. The cause of this more rapid contraction is the presence of a stimulus; but if it occurs chiefly in putrid fevers, in mortification, in hectics, and in all cases where a stimulus is combined with debility, as Haller contends, it will imply a spasmodic contraction of the artery, when the ventricle is not yet full. We think that our own observation confirms this idea. The *pulsus rarus* can undoubtedly be distinguished from the *pulsus tardus*. The latter we have already mentioned. The *thin* pulse is when the artery does not strike the finger as if it was full, when

the dilatation is slow and apparently incomplete. In this case the artery seems to hang on the finger; for as it is filled in slow succession the stroke is longer continued. This kind of pulse often attends asthmatic cases, and an enlargement of some portion of the heart, or the larger vessels.

The *intermitting pulse* is usually referred, though with little reason, to this head. It certainly is a symptom of considerable debility, and diminished irritability; for the heart, when less irritable, is excited only from over distention: and when at the same time weak, cannot, by one effort, remove the load of blood. It occurs too in the most dangerous pulmonic cases, when there are organic affections; and, according to Solano, presages a diarrhoea. This alarming view of the subject requires, however, some alleviation. An intermitting pulse is with many persons natural, and seldom absent, but when irritation takes place in the system, particularly febrile irritation. In many instances it is owing to fulness of the stomach and bowels, and often arises from agitation of mind. In fact, it is frequently only the irregular action of mobile habits; and in the greater number of cases, where no serious indisposition at the same time occurs, of little importance.

The *rebounding pulse* is nearly of a similar nature. This very certainly arises from obstruction. Lancisi observed it as a symptom of aneurism of the aorta, and we have more than once seen it in hydrothorax, and ossifications of the valves of the heart. It consists in two, sometimes three, rapid pulsations, with a long interval. The Latin name *dicrotus*, implies only two rebounds, so that we have preserved the English term; but some later authors have distinguished the three rebounds by the term *coturnizans pulsus*.

We remember a singular effect of the digitalis on this kind of pulse. After it had been for some time continued, the second and third rebound grew weaker, and in the course of a single night disappeared, reducing the number of pulsations from one hundred and fifty to fifty in a minute, without the smallest change in any function, or in the nature or violence of the disease. Solano considers the *pulsus dicrotus* as a presage of impending hæmorrhage from the nose: and a story is recorded of Galen, on observing it, calling for a basin, which was scarcely brought before the blood gushed out with violence. If, however, he had no other marks, he might call for the basin ten thousand times before his prognostic would be again fulfilled.

The *inciduus pulse* is when a stronger stroke succeeds a weak one, and a third, still stronger, the second, as in a swelling sea the waves are successively more violent. A pulse of this kind has never occurred to us; but Solano considers it, if soft, as presaging a sweat; if hard, a jaundice.

Bordeu has been more minute in his distinctions, though he has added little but words to the observations of former pathologists. He distinguishes pulses into critical, and not critical. The former as soft, *dilated*, and free; the latter harsh, small, and contracted. These are subdivided from the nature of the disease and other circumstances. If the disease is in the upper part of the body, and the critical evacuation is to be expected from above, the *pulsus dicrotus* occurs, which he styles *pulsus superior*. If the complaint is in the breast, and the discharge is expected from that part, the pulse will

be soft, flowing, and equable: if in the throat, somewhat harder and quicker, approaching the "cephalic pulse," which is still more hard, quick, and strong; truly a rebounding pulse. The *pulsus inferior* has unequal intervals, and is not seldom an intermittent one, joined with subsultus. It will portend vomiting, if at the same time hard and unequal; evacuations from the intestines, if more unequal, almost intermitting, and mixed with subsultus. A pulse presaging hæmorrhoids is rebounding, hard, frequent, and less unequal. The whole, however, is a superstructure raised on the foundation of Solano; but it is certainly, in a great degree, imaginary, and we find, from De Haen's Epistle to Haller, that Bordeu himself trusted little to it. The doctrine is at least inapplicable to the artificial cure of fevers by emetics and cathartics. It may be asked if this is an improvement? We can reply most certainly; for, instead of a treatise on fevers being, as was said of Hippocrates' epidemics, "a meditation on death," febrile complaints are seldom dangerous. A critical jaundice is a certain proof that the proper alvine discharges had been neglected.

Some other minute peculiarities of little importance have been noticed respecting the pulse; but we have sufficiently enlarged on that subject, farther perhaps than its application to more rational practice will warrant.

See Galeni Tractatus varii de Pulsu in Operum, vol. iv.; Massaria de Urinis et Pulsibus; Bellini de Urinis et Pulsibus; Solani Lapis Lydius Apollinis, folio, abridged and republished in 12mo. in 1737, and again at Vienna in 1753; De Haen Ratio Medendi, Pars ix. and xii.; Nihel on the Pulse; Hoffman Dissertatio de Pulsuum Natura et Praxi; Stahl de Differentia Pulsus Celeris et Frequentis; Floyer's Pulse Watch; Boerhaavii Institutiones cum Commentario Halleri.

PU'LVINAR, (from *fulvis*, dust, or chaff, with which they are filled). See EPITHEMA.

PULVINA'RIA. CUSHIONS, or PILLOWS, made with chaff, mixed with medical ingredients coarsely powdered. Those made with hops are said to be efficacious in producing rest; an apparently idle fancy, rendered famous from the rank of the patient on whom it was tried.

PU'LVIS, (from *pello*, to drive about, because it is easily agitated). A POWDER is composed only of such materials as may be reduced to this form, and kept in it without any loss of virtue, or which, from their levity, will not increase the bulk, or by their taste render the medicine nauseous. Bitters, fetids, acrid medicines, alkaline salts, and gums, are generally improper for keeping in this form. The dose of powders should not exceed ℥ ij; and if light, ℥ ss.

Compound powders were formerly called species.

PU'LVIS ALOE'TICUS. See HIERA PICRA.

PU'LVIS ANTILY'SSUS. See LICHEN CINEREUS.

PU'LVIS ANTIMONIALIS. See ANTIMONIUM.

PU'LVIS JACOBI. The POWDER OF DR. JAMES. An antimonial preparation, of which we found various prototypes in our enumeration of the older antimonials (see ANTIMONIUM). It was originally prepared by himself, but has since descended to the rank of a quack medicine; though, from the ingenuity of Dr. Pearson, we now approach very near it in the London Pharmacopœia.

It is supposed that, in the first preparations, calomel was added, and it has been said that Dr. James did not trust to it for the cure of fevers, but used it only as an evacuant previous to the use of the bark; and that he did not originally design to keep it a secret. It has, however, been anxiously employed since his time, and at one period the quantity exported was immense. This may probably continue.

The specification is worded with all the ambiguity of an ancient oracle, nor can it be prepared by the process described. Its succedaneum also, from many circumstances, is uncertain in its result. Dr. Pearson discovered that this celebrated powder consisted of the earth of bones, and the antimonial calx, forming a double compound, in the proportion of fifty-seven parts of the calx to forty-three parts of the earthy salt. It was doubtful, however, whether the ingredients of the earth of bones were not united with the antimony in an intimate chemical union, forming a triple compound. A little calx of iron appeared to be an accidental impregnation. The chemical state of the calx is, however, peculiar. About three-fourths may be dissolved in muriatic acid, and will afford the powder of algaroth. The remainder is insoluble in this acid, and is seemingly vitrified. If the bone ashes (phosphorated lime) are calcined in the above proportions, with the calx of antimony, and then exposed to a white heat, the result very nearly resembles James' powder. The uncertainty of the medicine apparently depends on the last part of the process. With the utmost care we have not been able to prepare it twice exactly alike.

In a medical view, James' powder is less active than its imitation. It affects the bowels and stomach very slightly, and passes off more readily by perspiration. In general, however, the difference is so inconsiderable, that we need scarcely regret the want of the real receipt of the inventor. We have thought that by uniting two grains of the pulvis opiatum with three of the antimonial powder, we imitated very nearly the effects of Dr. James' preparation. The opiate, however, certainly forms no part of the medicine sold. See Dr. Pearson in the Philosophical Transactions.

PU'LVIS FEBRI'FUGUS CRÆ'NIL. See ANTIMONII REGULUS MEDICINALIS.

PU'LVIS AD GUTTE'TAM. See GUTTETA.

PU'LVIS EPILE'PTICUS. See GUTTETA.

PU'LVIS REFRI'GERANS FALCK. See DYSURIA.

PU'MEX, (from *spuma*, froth; supposed to be the froth of some liquefied mineral,) *lapis bibulus*, *lapis scyrus*, PUMICE STONE, is found in volcanos, and hath been used as a dentifrice; but if frequently employed destroys the enamel. It is light and brittle, of a white or greyish colour, and generally contains mica. It is a volcanic product.

PU'NCTA LACHRYMA'LIA, (from *punctum*, a point,) are two small holes on the upper and lower eye lids, opposite each other, on their inner edge, near the internal angles, contiguous to a small eminence. They convey the tears into the lachrymal sac, and from thence into the nose.

PUNCTI'CU'LA. PUNCTICULA'RI'IS, vel PU'NCTULA, (dim of *punctum*, a point). See PETECHIE.

PU'NCTUM AU'REUM, PUNCTU'RA AU'REA. When a hernia of the intestines is reduced, an incision was made through the skin and membrana adiposa,

quite down to the upper part of the spermatic vessels; then a golden wire was fixed and twisted, so as to prevent the descent of any thing down the tunica vaginalis. Modern practice rejects this method.

PU'NCTUM SALIENS; the first rudiments of the heart in the formation of the fœtus. The point where a throbbing motion is first observed. See FÆTUS.

PUNCTU'RA. A SMALL WOUND. Synonymous with vulnus.

PU'NICA. See GRANATA MALA.

PU'NICA GRANA'TUM, &c. See BALAUSTINUM.

PUORRHŒ'A, (from *πυον*, pus, and *ῥεω*, to flow). A purulent discharge from the belly.

PUOTU'RIA, (from *πυον*, pus, and *ουρα*, mingo). A purulent discharge from the bladder. See URINA.

PUPILLA O'CULI. The PUPIL OF THE EYE, (*à pupa, quod intuentibus similitudo pupæ redditur*). The aperture of the iris, for the passage of the light to the retina: as the iris expands or contracts the pupil is larger or less. See OCULUS.

The pupil is sometimes closed, occasionally by the iris receding from the cornea, and has been opened by an operation, described by Pellier in his *Recueil de Memoires*. It is occasionally torn in the operation for the cataract, and sometimes displaced; but in either case without injury to the sight. Chandler remarks that its mobility is not always in proportion to the sensibility of the cornea. See Janin *Memoires*; Richter's *Essays*; Weissenborn de *Papilla nimis coarctata vel clausa*.

PUPILLA'RIS MEMBRA'NA, (from *pupilla*). *Vellum pupillæ*. In the fœtus of five, six, and seven months, a fine vascular membrane, with large arteries, passes across the part where the pupil is afterwards seen. See OCULUS.

PURGAMENTUM STELLA'RUM, (from *purgo*, to cleanse). See CÆLIFOLIUM.

PURGA'NTIA, (from the same). *Cathartica, cathartica, catoretica, catoterica, dejectoria, alviduca*. See CATHARTICA.

PURPURA A'LBA, and RU'BRA. See MILIARIS FEBRIS.

PURPURA A'LBA. A species of eruption to which plethoric men of a phlegmatic temperament are inclined.

PURPURA SCORBU'TICA; the *herpes* of Vogel; the *purpura* of Hoffman; the *serpigo* of other writers. Hoffman considers it as wholly scorbutic; but it is distinguished by the eruption of exanthemata of a very peculiar kind, sometimes accompanied with an acute and even a malignant fever; on other occasions without fever continuing for a greater length of time, and scarcely disturbing the functions. The small papillæ which appear on the surface are sometimes of a red, sometimes of a white, colour: in the former case, there are vesicles containing a fluid; but the latter consists of small knots, fixed deep in the skin, about the size and figure of millet seed, rough to the touch, and filled with a thick purulent matter. When the eruption first appears, it is attended with corrugation, roughness, and dryness of the skin; and none of the exanthemata so suddenly disappear and recur. This return of the eruption, as well as its first appearance, is in general attended with a sense of heat, of itching, or pricking in the part; and the pustules are chiefly observable on the neck, breast, back, and arms.

Patients, disposed to this disease, are advised to use

for their common drink either mineral water, or pure water with a mixture of wine, and to avoid malt liquors, as well as whatever produces costiveness. Exercise, change of air, tranquillity of mind, and amusement, are of great service in preventing it. High seasoned animal food, close rooms, and excessive heat, are said to be injurious; milk and whey serviceable. Cooling medicines, gentle diaphoretics, with moderate discharges from the bowels, are only necessary.

From respect to the authority of Hoffman, we have preserved, with some corrections and curtailments, the article of the former edition. Yet we cannot help remarking that the whole description is apparently confused and inaccurate, mixing two diseases of very different kinds. The former is a species of millaria, the latter a pustular complaint of a very different nature. See Hoffman's Works.

PU'RPURA URTICA'TA. See URTICARIA.

PURPURA'TE, (from *πυρρὺς*, purple, from the colour of the eruptions, vulgarly called the *purples*). See PETECHIÆ.

PURULENTIA, (from *pus*, *furis*). See SUPPURATIO.

PUS, (*πύον*, from *πύω*, putresco). PURULENT MATTER; that which appears on the surface of healing wounds, or on opening well digested abscesses. It is unctuous, yellowish, nearly of the consistence of fresh cream, without any particular smell, and of a mild taste, resembling that of chyle.

We shortly considered this subject under the article ABSCESSUS, q. v. chiefly to point out rather than discuss the different opinions, as it was peculiarly connected with suppuration. The nature of pus, however, is still involved in considerable obscurity, and we can only offer some approaches to a knowledge of it.

As in abscesses there is always a loss of substance, it was a natural conclusion that at least the cellular substance, perhaps the muscular fibres, were dissolved in purulent matter, and the surgeon removed it from wounds with anxious care. Granulations of new flesh, however, appeared under it; and if in the first period it was a solvent, in the second it contributed to reproduction. Riedlin supposed it to be pituita, that fancied humour which obeyed every hypothesis; but Pringle and Gaber led the way to inquiry, though they did not succeed, by supposing it to be serum inspissated by heat, and changed by fermentation, probably a beginning putrefaction. Dr. Hendy, in an inaugural dissertation, opposed this opinion. He found that pus was less liable to putrefaction than serum; that serum and lymph confined in wounds, producing good pus, did not assist or hinder its formation, but themselves became putrid; and if red blood were added, the putrefaction was more rapid and considerable. Previous to this period, De Haen had contended that pus was derived from the blood (*Ratio Medendi*, pars ii.); afterwards that it might be separated without either pain or fever (pars ix.); and at a subsequent period that an ulcer was not necessary for its production. We have seen the appearances which De Haen describes, but they are certainly equivocal. If by ulcer is meant a loss of substance, no ulcer existed, but the investing membrane was destroyed, and the surface was covered with an albuminous matter. In this state the question remained for some years; for though in this period there were numerous

publications on the subject, but little was added to the evidence.

Mr. Home, in his Dissertation on the Properties of Pus, observes, on the authority of Mr. J. Hunter, that the characteristic of pus is the appearance of globules swimming in it, but that these are not coeval with its first formation. It then resembles, in consistence, a jelly, but the globules are formed, while the gelatinous fluid lies on the surface of the sore, in a period of fifteen or twenty minutes. It differs from the blood in the nature and colour of the globules, for the purulent ones are not soluble in water; and the fluid in which they swim is coagulable by a solution of sal ammoniac, which does not coagulate serum. Mr. Hunter, in his peculiar unscientific language, informs us that the vessels assume the nature of a gland, as if they had an active power, and as if it had been demonstrated that a gland had a peculiar organization. The objection to this doctrine consists chiefly in this, that pus is formed where no glandular structure apparently exists: but we know not in what such a structure consists; and, as a change in the state of the vessels can wholly alter the nature of a secreted fluid, it is impossible to say that it may not equally produce one. In this case, suppose, for the sake of hypothesis, it be admitted that the fluid effused is gluten, it meets in the cellular membrane with an oily matter, from which its nature may be altered, or suppose that from a hydrocarbonate, which it finds there, oil is formed, the chemical affinities of the fluid will then be changed. These we mean no other than suppositions, merely to suggest enquiry. Yet we own that they are not the hasty effusions of the moment, but have some collateral support.

Mr. Home concluded from his experiments that pus contains substances similar to those of the blood; that it is in a recent state free from any tendency to putrefaction; that it is friendly and bland to the parts which produce it, though it may irritate neighbouring ones. Its appearances also vary according to those of the constitution, and are affected by irregularities, anxiety of mind, &c. It is readily absorbed; and, in Mr. Home's opinion, without injury to the constitution. The parts which afford it become extremely vascular, and it is formed sooner in proportion as the part approaches nearer a glandular structure: thus in the internal surfaces it is often formed in five hours; in the skin, which is very vascular, in twenty; and in common muscles in forty-eight hours. It is composed, as already remarked, of globules swimming in a fluid, and is thinner when first poured out than after stagnation. In almost every respect we thus find pus resembling secreted fluids; and we certainly find secretion take place where there are no follicles, or any appearances of a complicated structure.

That pus existed independent of inflammation, and was a secreted rather than a fermented fluid, was for a considerable time a favourite opinion on the continent, though we are unable to say whether it occurred previous to Mr. Hunter's offering this explanation, since it was promulgated in his lectures, at a period not specified. The same opinion, however, was entertained by Plenciz, by Murray, Schroeder, and others, as well as by De Haen, formerly quoted; nor does any doubt remain, we believe, of the truth of this doctrine. Mr. Home is correct also in his idea, that though bland to

the part which produces it, pus is an irritating fluid to other parts, agreeing in this, as in almost every other circumstance, with the different secreted fluids. When reabsorbed we have said that it produces hectic, though Mr. Home thinks it may be so without injury to the constitution. Our reasons have been already assigned. Pus, when absorbed in a considerable quantity, is discharged often by other secretory organs, acting in this respect like any other foreign matter in the system; nor does there appear any difference, except that it seems more suddenly absorbed, and often more rapidly determined to some particular gland than any other substance. The discharge from the skin is not indeed an immediate effect; but that it is owing to the purulent matter is highly probable, since, when the perspiration is checked, a diarrhoea comes on. The metastasis to the kidneys, and on some occasions to the abdomen, is often rapid.

The use of the purulent matter is obvious in open wounds, since it affords a bland, protecting fluid for the tender granulations. Its distinguishing appearances show a healthy state of the system in general, and of the vessels of the part; for, if these are diseased, the fluid is thin and acrid, by no means calculated to protect the young flesh. Mr. Hunter involved himself in difficulties in his enquiries into the final cause of this secretion, by supposing the fluid which produces pus existed previously in the constitution. Like all other secreted fluids it exists materially, but not formally: like the rest it is the blood altered by its passage through vessels of a particular structure or organization, and formed only in the emergencies which require it. Pus seems sometimes to act as an assimilating fluid. We draw a seton through a part, or apply a blister or an issue near it, when we wish to bring an indurated tumour to suppuration. Either the inflammation of the skin excites increased action in the tumour, or the pus, produced, assimilates the other fluids. Suppuration generally, in consequence, takes place, at first from the parietes of the containing sac, afterwards from the tumour.

When a purulent discharge takes place naturally, or artificially, it is often the inflammation rather than the purulent evacuation which is of service. In a critical abscess there is no reason to think that the morbid matter is there collected and confined, for in general the fever remits previous to its formation, but the balance of the circulation is not regularly restored. The fluids thrown with impetuosity on one part in consequence of the previous weakness of the vessels are impacted, and the organization of the part is destroyed. The adjacent vessels inflame and separate purulent matter, by which the substance of the abscess, now become a matter foreign to the constitution, is separated. See INFLAMMATIO.

We purposely refer to this article to mark its inconsistency with the present. The opinion there given was adopted early in our lives, but more careful reflection and more extensive examination have induced us to change it. We have no objection at any time to offer more matured sentiments, and feel a gratification in reflecting that we daily grow wiser.

The distinction between mucus and pus is difficult, but experience will often detect a difference, to which words are inapplicable. We have already noticed the more striking characteristics of each (see PHTHISIS);

but shall now add the common methods of distinguishing them.

Mucus detained in the lungs often resembles pus; but if pus be slightly agitated with water it is easily diffused, and after standing a few hours falls to the bottom of the vessel. But previous to its subsidence, if a fixed alkali be added, it is precipitated in a gelatinous mass (Grasmayer). Mucus is with difficulty diffused in water, requiring strong agitation, and then forms a permanent ropy fluid. The quantity of pus mixed with mucus may thus be often ascertained.

Another experiment is more conclusive. The expectorated matter must for this purpose be dissolved in vitriolic acid, or in caustic alkaline lixivium; and then to both solutions pure water added. If there be a fair precipitation in each, some pus is certainly present; if in neither, the matter is entirely mucus. Should it not dissolve in the alkaline lixivium, there is also reason to believe it to be pus.

See Morgagni de Sedibus, &c. ep. xxii. § 28, &c.; Home on the Properties of Pus; Salmuth de Diagnosi Puris; Plenciz Acta et Observationes Medicæ; Murray's Opuscula, vol. i.; Quesnay Traité de la Suppuration; Medical Commentaries, Edinburgh, vol. vii. p. 193; Bell on Ulcers, ed. 3d. p. 55—7.

PU'STULA, (a dim. of *pus*). A PUSTULE, or LITTLE PIMPLE; *ecthyma*; *eczema*; *eczema*. Pustules appear often in the spring, and are of various kinds; sometimes resembling those marks of irritation produced by the application of a nettle, or the obstruction of sweat, called by the Greeks *exanthema*; at other times of different sizes and colours. Dr. Willan defines a pustule to be an elevation of the cuticle, sometimes globate, sometimes conoidal in its form, containing pus, or a lymph which is in general discoloured. Pustules are various in their size, but the diameter of the largest seldom exceeds two lines. He enumerates four different kinds of pustules, distinguished by medical authors under specific appellations, viz. PHLYZACIUM, a small pustule containing pus, raised on a hard circular inflamed base, of a vivid red colour, succeeded by a thick, hard, dark coloured scab. PSYDRACIUM; a minute pustule irregularly circumscribed, slightly elevated, terminating in a laminated scab. See also ACHOR and PHLYCTIS.

PU'STULA O'RIS, (from *putreo*, to be corrupted). See APHTHÆ.

PUTAMEN. The bark or paring of any vegetable. In medicine the green rind of the walnut is only used, and it has been highly celebrated as an antivenereal. It is mentioned as an antivenereal remedy, in the form of a decoction, by Borelli and Ramazzini. Mr. Pearson, though he admits its utility in the pains and indurations which remain after the disease, thinks it has no salutary effect in the lues itself.

PUTICARAGA. An Indian plant, whose seeds are bitter, probably tonic. Jones in the Asiatic Researches, ii. 351.

PUTRE'DO, vel PUTREF'ACTIO, (from *putris*, putrid). PUTREFACTION.

Putrefaction has been considered as a species of fermentation, and with reason, if fermentation be defined the spontaneous decomposition of bodies, with the assistance of heat and moisture. In the vinous and acetous fermentations (*vide in verbo*) we have seen the decomposition of vegetable bodies gradually taking place; the

aerial products again united in new combinations; and the fluids gradually attenuated, till the ultimate resolution by putrefaction reduces the whole to its last elements. Solid bodies undergo similar changes, till all organization is destroyed, till the earth falls down in its native form, the water combines with the air, and the gaseous products mix with the atmosphere. The phenomena, however, of this important change differ in vegetable and in animal substances; again in the dead and living animal matter. We must examine them in each state.

When vegetable substances have undergone the former processes of fermentation, which often pass so rapidly as to be little noticed, the last important dissolution comes on. A degree of heat is, however, necessary, though no considerable one; but it seldom proceeds with any rapidity under 46° of Fahrenheit, nor at a temperature so high as to hasten evaporation. Open air assists the process, but is not essential to it. Without some degree of moisture, however, putrefaction never goes on. It is probable that in this gradual decomposition the hydrogen is separated early; for this gas is a more powerful solvent of different substances than any other. The peculiar aroma of the vegetable is apparently combined with this air, and gives the appropriate fetor, which distinguishes the putrefaction of each. It is sometimes combined with sulphur, as in cabbage; sometimes apparently with phosphorus, as in the alliacæ; sometimes with ammonia, as in the cruciform plants, and those parts of vegetables which, in approaching animal substances, contain gluten, as the husks of the cerealia, &c.

When animal matter putrefies, its colour becomes paler, and its consistence lessens; a watery matter exudes, which becomes reddish or green. All traces of organization begin to disappear: the smell is disagreeable approaching that of ammonia; and the bulk diminishes. If the substance be confined in a close vessel, the process at this period slackens; the smell is purely ammoniacal, and all the chemical marks of alkalinity attend. If the communication of the air be admitted, the alkaline effluvium yields to an intensely putrid one, which is in part corrected and confined by ammonia. It is this peculiar smell which is so deleterious and so dangerous to animal life. After this smell has in part disappeared, the process proceeds with more rapidity. The substance swells with bubbles of air, and again subsides; the appearance of fibres is almost lost in an offensive, uniform mass, of a soft brown or greenish colour, of little consistence, of a faint nauseous smell, and of a poisonous nature. The smell then gradually disappears, the substance becomes more solid, the colour deeper, and at last it resembles a brown, nearly friable, earth.

During this process heat is usually extricated, and various gases are emitted, chiefly hydrogen, holding in solution sulphur, carbone, or phosphorus; ammonia; water, carbonic, and occasionally, for a short period, nitric acid and azotic gas. The residuum is an earth mixed with carbone, oil, and a small portion of ammonia.

The human body, when buried, undergoes a peculiar change. As the gaseous matters are prevented from escaping, by a new play of affinities a singular compound is formed, a kind of ammoniacal soap, with an excess

of frothy matter, containing also some phosphat of lime. The oily matter, separated by a diluted acid, and dried, resembled spermaceti; and a manufacture of this kind was established near Bristol, at first with some success; but it was almost impossible to deprive it of an unpleasant smell; and the attempt has, we believe, been for some time discontinued. A stream of water passing through the animal matter seems almost essential to the success of this singular change.

These chemical facts have been applied somewhat rashly to the human body, and a putrid dissolution of the fluids and solids has been too generally spoken of as no uncommon occurrence. In the human body the concurring causes of putrefaction, heat, and moisture, are constantly present; yet the system is preserved, and by its own powers. What these powers are, or by what means their effects are produced, we know not. The putrefaction of animal food is quickly corrected in the stomach; and that we may not attribute too much to the fancied powers of the gastric fluid, the same effect is produced by placing a bit of putrid flesh in the cavity of an ulcer. The prevention of putrefaction has been attributed to the discharge of excrementitious fluids, and the constant accession of fresh nourishment. The extent, however, of these effects is inconsiderable, and will not explain the facts just mentioned. It is not more singular that the stomach should correct putrefaction, than that it should have no power of digesting what has life. Each must be left among the arcana of physiology: arcana that we can never explain till we know what life is.

The effect of putrid matter in the stomach is nausea, with considerable debility, sometimes faintness and convulsions. If not evacuated, and if the stomach is unable to correct it, death must ensue. In general, however, the fatal event is avoided by its exciting vomiting, but its poisonous effect is too rapid to enable us to explain it from an assimilatory process. Breathing putrid air produces nearly similar symptoms, so that it must act as a sedative power on the nervous systems. From Dr. Evans' inaugural dissertation, published at Edinburgh in the year 1790, we find that putrid matter injected into the veins is almost immediately fatal. The human system, by habit, will, however, constantly breathe air infected to a certain degree with putrid miasmata, without injury. The constitution either resists their power, or gradually throws them off. If, however, any sudden cause of debility concur, they immediately show their peculiar virulence; and so rapidly, that we must attribute the previous immunity to the former cause. In general, also, as the effect of putrid matter communicated to the system is debility, so putrefaction only takes place in the human body from a diminution of the activity of the living principle. In the worst cases of putrid fever the blood we have found scarcely altered; for what change actually takes place is diminished by the discharge from the excrementitious excretories. The stools, the urine, the breath, and the perspiration, are offensive, while the albuminous part of the blood is only slightly attenuated. One apparent symptom of putrefaction in the blood is certainly owing to debility, viz. petechiæ. These arise from the laxity of the exhalents; and the blood, when out of the vessels, is subject to the usual changes of dead matter, while the power of the living principle is so greatly diminished.

When the powers of life are nearly destroyed, putrefaction soon takes place, and we then perceive the additional heat which attends this process. De Haen found the heat in a man, dying in a high degree of a putrid fever, two or three degrees above the usual standard; and a greater degree of heat in the hands of persons in a similar state has been the subject of observation and astonishment. It may add to the force of the former arguments to remark, that all causes of death which act immediately on the principle of life, as appears by their destroying irritability, are followed by an almost immediate putrefaction. The chief of these are lighting and narcotic poisons.

The means, then, of obviating putrefaction in the living body is to support the energy and activity of the living principle. In fact, we have no other resource; for, while the circulating fluids are little changed, we cannot expect great effect from mechanical action of astringents, except we admit the reasoning we shall soon adduce. The nature, the kinds, and the comparative power of these it is, however, necessary to consider.

Putrefaction is prevented by cold, and by a high degree of heat in circumstances which favour evaporation. Meat is preserved in ice, and by smoking, though in the latter process the pyroligneous acid may have some effect. Heat, however, alone, while it dries, checks putrefaction. All astringents are supposed to be also antiseptics; for an obvious reason, that they contract the fibres, and separate any watery fluid that they may contain in their interstices. One other suggestion may come in aid. The tannin and the gallic acid have been lately found to be nearly connected in their nature, and in different proportions these are found in all astringents. Their action is on the albumen or gelatin, which they precipitate; and it will not escape probably the recollection of an attentive reader, that the only change which Parmentier and Deyeux could discover in the blood of persons in putrid fevers, was in this portion. May not then astringents precipitate this morbid ingredient, and may not the same change gradually taking place in every part of the body, which contains even lymph, correct the tendency to putrefaction in the whole system? It may be said, that after having combated the humoral pathology, we are reverting to it. We might plead guilty, and declare that we will not obstinately shut our eyes to any fact, however it may militate against our principles. In cases of dissolved fluids from putrefaction, however, we find often decided advantages from the purest astringents, if given in large doses, and steadily continued, particularly the oak bark; and it would be highly improper to reject a medicine essentially of service because its effects cannot be readily explained.

The action of other antiseptics is not always clearly perceived; but a slight attention will support the reasoning just mentioned. Salt of amber, alum, myrrh, and asafœtida, are by far more powerful antiseptics out of the body than many astringents, but have little effect on putrid diseases. The bark, which is a powerful tonic, is not an active antiseptic in a phial; and chalk, which seems to accelerate putrefaction, is by no means injurious in putrid fevers.

If sea salt be taken as a standard, all the other neutrals seemed, from the experiments of sir John Pringle,

to exceed it in power. Nitre and kali were four times more powerful, and they appear to act by abstracting water, since their constant effect is to harden the meat. Alum, for a similar reason, appeared thirty times more powerful. Catechu, as may be understood from its astringency, was nearly equal; but we cannot easily explain the foundation of the power of asafœtida, myrrh, aloes, and, above all, fixed air, camphor, and charcoal, which are said to exceed sea salt three hundred times. The circumstances of the experiments have not been clearly detailed. These substances as remedies are chiefly applicable to topical putrefaction or local gangrene.

We shall not detail these experiments more minutely, nor endeavour to reconcile many contradictions in different authors, since we find scarcely any facts applicable to medicine; and shall, therefore, point out the sources of more extensive information in the different writers. See *PUTRIDA FEBRIS* and *SCORBUTUS*.

See sir John Pringle's *Diseases of the Army*, appendix; Macbride's *Essays*; *Essais pour servir à l'Histoire de Putrefaction*; *Dissertationes sur les Antiseptiques qui ont concourues*, &c. Dijon; Percival's *Essays*; Belengieri *Considerazioni intorno alle Maladie Putride*; Cartheuser de *Remediis Antiseptis*; Cullen's *Materia Medica*; Gaberi *Experimenta de Putrefactione in Melanges de Philosophie*, &c.

PU'TRIDA FE'BRIS, (from *putris*). Putrid fever, *febris continua putrida*, the plague, spotted or petechial fevers, pestilential, malignant, camp, jail fever, &c. See Cullen's *Nosologia*; genus *typhus*.

A putrid fever has been the subject of alarm in every country, and at every period. It has on this account claimed the peculiar attention of physicians; but we can scarcely recognize it as a distinct variety, since the putrefaction is a symptom only. There is a striking distinction, as we have seen in the exacerbating and more continued fevers; yet each may become highly putrid. Medicine has recorded no more fatally putrid diseases than the malignant remittents; and if these do not show so great a deprivation of the fluids as the fever we are now to describe, it depends only on the predisposition of the patients; for this is the fever of jails and hospitals.

In reality, the putrid fever is the typhus gravior of nosologists, distinguished by a comparative mildness of the early inflammatory symptoms, and increased debility in the progress, particularly in the latter stages. This debility, joined with the predisposition of the usual victims, occasion the high degree of putrefactive symptoms, which give it a character and a name. From the preceding article it will appear that the latter can have no other source. See *NERVOSA FEBRIS*.

Putrid fevers attack with more violence than the nervous; the cold is greater, the heat sharper and more permanent. The rigors, at first, are sudden, transient, and remitting; the pulse is more tense and hard, though generally quick and small, sometimes slow and regular, then fluttering and unequal. During the first twenty-four hours the alternate heat and cold are usually considerable; the fever increases every evening, and in the second week the patient becomes delirious. About the end of this period the delirium changes to a stupor; and about this time he is sometimes relieved. If a crisis does not, however, take place about the fourteenth day, or if some remarkable amendment is not observable about that time, the putrid symptoms

increase both in their number and degree, and the patient sinks under them. In the beginning the headach and vomiting are violent; there is often a pain in the temples, over the eyes, and in the bottom of the orbit: the eyes are full and heavy, yellowish, a little inflamed; the countenance bloated; the temporal arteries throb, though the pulse at the wrist be small. Tinnitus aurium; great dejection of spirits; faintness; difficult respiration, mixed with sighing: breath hot and offensive; pains in the loins and limbs; an universal weariness; a load at the stomach, attended with pain and heat; a nausea, and often a discharge of blackish or bilious matter, add to the distress. In the beginning the tongue is white, then grows drier and darker, sometimes livid, black, or of a dark pomegranate colour. In the increase of the fever the thirst is greatest, and every liquor is mawkish and bitterish to the taste; but often the sense of thirst is inconsiderable during the whole of the disease. The lips and teeth are furred with a black tenacious sordes; in the beginning the urine is pale and vapid, high coloured in the advance, and at last very brown or blackish, with an offensive smell; the stools blackish and very offensive, often passing off insensibly. After profuse evacuations by stool, the belly sometimes swells, and is tense; livid spots appear on the skin; hæmorrhages, and cold clammy sweats sometimes, though not usually, with convulsions usher in death. This happens at different periods, from the fifth to the eighteenth day.

In this fever the degrees of debility, oppression, and nausea, are more considerable than in any other; the prostration of strength, sudden and violent, has for its associates extreme despondency, or insensibility, and want of apprehension to an uncommon degree. The loss of appetite, or loathing of food, sickness, languor, with a dull pain of the head, are in the beginning always more severe than the inflammatory, though seldom so violent as in the nervous, fever. The smallness of the pulse; the dejection of the spirits; the early insensibility; the high coloured urine and thirst; the broken texture of the blood; the purple spots, and the putrid state of the excrements, distinguish it from the milder typhus, and from inflammatory fever. Its formation is distinguished by coldness and shivering, accompanied with nausea, vomiting, confusion of the head, an extreme and sudden prostration of strength.

The prognostics are generally very uncertain. A red rash, and an inflamed scab below the nose, or about the lips, are usually favourable. Deafness at the decline is said to be a promising symptom; but it is often the effect of insensibility, which is always unfavourable. A change of voice, a wild stare, difficulty of swallowing, inability to put out the tongue, a constant inclination to uncover the breast, urine that deposits a dark or blackish sediment, insensibility to thirst, inflamed fauces, a diarrhœa with a swelled belly, bloody saliva, purple or livid spots on the skin, black aphthæ, laborious respiration, ichorous and fetid stools, cold sweats, or convulsions, are highly dangerous; and if many of these concur, little expectation of recovery can be entertained.

This fever chiefly attacks those who live in confined air, whose spirits are depressed by affliction, whose vital energy has been weakened by previous diseases or excesses. The weather most calculated to predispose the constitution to it, is a hot summer after a mild winter,

fogs and rain without wind, and with a considerable temperature. A poor diet, diseased corn, and stagnant water, equally depress the living principle, rendering every cause of fever more peculiarly debilitating, and the disease itself, of course, putrid. In jails and hospitals, the confined effluvia from the human body readily become an exciting cause: in other situations, cold with damp, indigestion, the repulsion of evacuations, terror, apprehension, grief, or any cause of debility, will excite putrid fever.

The cure of putrid fever will appear from this and the preceding article to depend on every means of supporting the vital energy; but our attempts for this purpose must be conducted with some care, not only to prevent the matter already depraved and putrid from being confined, but to avoid danger from those local accumulations, which appear to constitute the essence of fever.

Bleeding is, in every view, inadmissible; but yet it has been employed, and we have repeatedly stated the foundation on which it may be useful; though in every asthenic fever we cannot advise the imitation of this rash practice.

The early appearance of nausea will appear to indicate *emetics*, and they should certainly be used, though with some degree of caution, so as not to exhaust too violently the strength. We have often remarked, that nausea is an effect of weakness, and where the vis vitæ is so certainly depressed, we should, at least, keep in our view that it may arise solely from such depression. The ipecacuanha only should be used; for we do not always know how far the operation of antimonials may extend, and it should be followed by a warm cordial draught.

For all the reasons formerly assigned (see FEBRIS and CATHARTICA), *laxatives* are useful; but the acid ones, as tamarinds, prunes, and cream of tartar, are preferable. If a quicker action is necessary, the senna or jalap should be joined. Rhubarb, as a bitter and a tonic, has been sometimes employed; but the former kind has appeared to us preferable; though in the later stages, when the debility is considerable, we must trust only to clysters. Very few hours, however, should be lost in these preparatory steps; for the disease often hastens on with rapidity, and the worst symptoms sometimes occur so early as the fifth day.

Tonics, *cordials*, and *antiseptics*, must be very soon employed. The great dependence of practitioners is on the bark, and it must be given in considerable doses. This medicine will, even in these cases, sometimes produce a considerable stricture on the skin, and increase the uneasiness. This may be sometimes removed by the addition of camphor, which will also contribute to the benefits derived from the bark; but when this is insufficient, the aqua ammoniæ acetatæ may succeed. Should the bark be still borne with difficulty, we are constrained to add an antimonial: the safest is the powder of James; yet this can be seldom trusted, without a drop or two of the tincture of opium. The dose of bark should not be inconsiderable. If we begin with half a drachm of the powder or extract, in a suitable draught of the decoction and tincture, every six hours, and find it agree with the patient, it may be soon increased to two scruples every four hours, and even farther if necessary. We have no other vegetable tonic of equal

efficacy in this variety of fever, and it forms an exception to the general rules laid down under the article. The oak bark may sometimes supply its place, but the dose must be much larger; and its astringency checks all discharges from the exhalents of the bowels, so as to bring on obstinate costiveness. Of the arnica we have no experience. The German physicians speak highly of its effects in putrid fever; but, from its sensible properties, and its botanical analogy, it seems to be only a narcotic bitter, with some acrid stimulating principle. (See ARNICA and BOTANY, nat. order *discoideæ*.) The other tonics most useful are the mineral acids. Of these the vitriolic is much employed, though by some authors the muriatic is chiefly recommended. They do not, at least in this disease, apparently differ: each is a valuable addition to the bark. Zinc and phosphorats have been employed apparently with the same views, but with little success.

Of every other medicine cordials only would supersede the bark; and with these putrid fever is sometimes successfully conducted, when the bark disagrees, or is rejected. The chief is *wine*, which it is necessary often to give in large quantities. We must recollect, however, that wine is an indirect stimulus, followed by a narcotic effect; so that when we begin, we must continue its use until nature can exert herself. In this case, and in all instances of putrefaction, whether general or local, our remedies are intended to supply the powers of nature. When these are roused, our exertions may be safely remitted; and we find that this effect is produced in general fever, when the pulse becomes fuller and softer, the eye more quick, the skin more clear, and the tongue more clean and moist; in partial gangrenes by a beginning separation of the mortified part. When wine disagrees with the stomach, good London porter is an excellent succedaneum, especially to those accustomed to it; and brandy may, though with less decided success, supply the place of either: to these aromatics will prove useful assistants. We say assistants; for alone they are unequal to the removal of the complaint. By the proper combination of such auxiliaries we have certainly succeeded in combating putrid fever, when the bark was inadmissible. In the latter case it has been sometimes given in clysters, we suspect with little real advantage.

There are numerous useful medicines which may be classed indifferently under the head of STIMULANTS, or WARM DIAPHORETICS. They act probably in both ways, though chiefly as diaphoretics. We mean the *contrayerva*, the *serpentaria*, and the *camphor*. The two former were commonly employed by the Boerhaavians, and, indeed, often *misapplied* to the common bilious epidemics. In putrid fevers they are, however, sometimes useful, though less so than the cordials just noticed. The camphor is a remedy highly useful in this fever. It calms the low delirium, produces a genial glow on the surface, and seems to act as a steady permanent cordial. We have no reason to attribute any of these changes to an antiseptic power. *Opium* has often similar effects, though by no means so advantageous in putrid as in other fevers.

Of BLISTERS authors have spoken differently, according to the opinion formed of their effects. Their stimulus was supposed useful by some who dreaded

the consequences of their evacuation; and the latter was thought the chief source of their utility by those who expected little from their stimulus. We have found them, on the whole, useful; have obtained little advantage from their stimulus; and had no reason to dread the debility arising from their evacuation. Having first given the result of experience when the theory had not occurred, we will add the explanation.

The usual accumulations in the head of fevers, if we except the nervous fever, the typhus mitior, seems to be accompanied with some action of the vessels, producing a degree at least of inflammation. In this variety, the vessels, in consequence of debility, yield without reaction; and the symptoms are those of fulness only, which blisters will remove; but their effects will not be so striking as when they counteract also increased activity. It has been the custom to apply numerous blisters, not only to different parts of the head, but to the arms and legs, apparently with a view of stimulating. When the patient has been capable of feeling the pain, these have been highly troublesome, and apparently exhausted the little irritability which remained. It is a practice to be wholly discouraged, as it is never useful, and often detrimental. Cataplasms to the feet, to render the circulation more equable, if not to rouse the patient, is a more probable remedy. Yet, we think, we never saw them advantageous.

Through the whole course of the disease, the bowels, either by the acid laxatives, by fruits, or by clysters, should be kept soluble, without such a discharge as to weaken. Two or three stools daily may be safely borne, though if so great an evacuation should appear to debilitate, even this number must be curtailed. It may be owing to this plan that we have never found the fixed air, in the form of *yeast*, necessary. Yet the experience of others speaks highly in its favour; and it is a remedy so easily procured, and at the same time so innocent, that to neglect it in emergencies is unpardonable. It has been used under our eyes; but apparently to us without benefit or injury. If the petechiæ suddenly disappear, a blister should be applied to the head, and large doses of camphor, with the warmest cordials, be given; but the patient can seldom be preserved. If vomiting continue, after the first exhibition of an emetic, the columbo root, with a slight opiate, will often relieve it. Too great evacuation by stool is best prevented by rice gruel, with cinnamon, and by clysters containing about sixty to eighty drops of tinctura opii.

From this view of the treatment of putrid fever, which contains the observations of the first practitioners, it will be seen how little dependence is placed on the most powerful antiseptics, and how much on cordials and general tonics. Asafoetida, for instance, is equally powerful as an antiseptic with camphor; but is never substituted for it. In this enumeration of the remedies, we have neither mentioned volatile alkali as a diaphoretic, nor the powder of chalk as a restringent; for both are septics. Yet we can truly add, that we have used each in the worst putrid fevers with advantage, for the purposes mentioned. Putrid fevers are, however, now so uncommon, that in this article we have been obliged to recur to cases of a very distant era. We can perhaps truly say, that we have not seen more than two accidental instances of putrid fever in thrice as many years at least; while, within a year, at a more distant

period, we have visited thirty. However it may be accounted for, such is the fact.

The general management of putrid fevers is not peculiar. The room should be large and airy, the liquors cold; the diet acid and acescent, consisting chiefly of the vegetable acids. Acid vapours, or even heated vinegar, in private practice, are of little use, if free ventilation be admitted. The stools, &c. should be immediately removed, the linen frequently changed, the communication with the external air kept up in different degrees day and night. The nurses should be frequently changed; and when relieved they should carefully wash themselves, and very often change their linen. With these precautions there is little danger of infection.

See Stoll, Aphorismi de Febribus et Ratio Medendi, part i. ii. and vii.; Hoffman Historia Febris Malignæ Petechizantis Halæ Grasantis, Supplem. ii. 2; Stahl de Malignitatis precipue Febrilis indole; Saalman Descriptio Februm Malignarum in genere; Bianchini Lettere Medico-pratiche; Sarcone Istoria ragionata di Maladi a Napoli; Huxham, Grant, and Pringle on Putrid Fevers; Fordyce's Elements, part ii.; an Inquiry into the Causes, &c. of Putrid Fevers, by W. Fordyce, M.D.; Sydenham's Works, p. 201.

PYCNO'TICA, (from πυκνω, to condense). See INCRASSANTIA.

PY'GÆ, (πυγή, the buttocks). See CLUNES.

PYLO'RIC ARTERIA, (see PYLORUS,) is a branch of the hepatic artery, which runs and is ramified on the pylorus, from thence to the cardia, anastomosing with the arteria gastrica dextra, and terminating on the pylorus by an anastomosis with the coronary artery of the stomach.

PYLO'RIC VE'NA is a branch from the vena portæ ventralis, sometimes a branch only of the gastrica dextra. It passes over the pylorus to the short arch of the stomach, where it anastomoses, with its coronary vein.

PYLO'RUS, (from πυλῆ, a door, and αἰεω, to guard,) the right orifice of the stomach; janitor; portorium, ostiarius. It is a circular aperture, surrounded by a broad, thin, circular border, which consists of a duplication of the two internal coats of the stomach, with distinct fleshy fibres in the doubling of the nervous coat. The inner edge of this ring is plaited and turned obliquely towards the stomach, and it certainly acts as a sphincter.

This part is subject to many diseases. In the Medical Observations and Inquiries is a case where it was contracted by an union with the liver; and Haller has observed it filled with abscesses. Contractions in this organ have arisen from substances swallowed, as a piece of money (Kerkringii Spicilegium); by cartilages (Bonetus); by callosities (Richter); by scirrhusities (Andry Histoire de la Société Royale de Médecine, and Cortier apud Haller Bibliotheca Medica); by steatoma and strumous glands (Brunner). It is diseased also by wounds, by cancers, and by palsy. Each disease is unfortunately beyond the reach of medical aid.

PYO'SIS, (from πυω, to suppurate). See HYPO-PYON.

PYRACA'NTHA, (from πυρ, fire, and ακανθα, a thorn; as its pyramidal leaves were supposed to re-

semble the flame of a candle). See LYCIUM BUXI FO-LIIS.

PYRAMIDA'LES MU'SCULI. The PYRAMIDAL MUSCLES OF THE BELLY present themselves next to the ascending and descending oblique muscles, and were first discovered by Fallopius. They are situated before the extremities of the recti, arising from the fore part of the os pubis, close to the symphysis. They grow smaller as they proceed, end in a point like pyramids, and are lost in the linea alba, or the recti. Fallopius called them succenturiati, auxiliary muscles, from a supposition that they are only supplemental to the recti in their action, as the order of the fibres in both agree; and the latter are absent when the recti are continued fleshy to the juncture of the ossa pubis.

PYRAMIDA'LIA CO'RPORA. (See MEDULLA OBLONGATA.) The SPERMATIC CHORD, is also called *corpus pyramidale*.

PYRAMIDA'LIS NA'SI MUSCULUS, is also called *triangularis* and *anterior*. One extremity is inserted in the synarthrosis of the os frontis, and ossa nasi; from whence it runs down the side of the nose, and is again inserted into its cartilage.

PY'RAMIS, (so called from its shape). See CONUS FUSORIUS.

PYRETHRUM, (from πυρ, fire; because of the fiery heat of the root). *Buphthalmum Creticum, bellis montana putescens acris; salivaris herba; PELLITORY* of SPAIN; *anthemis pyrethrum* Lin. Sp. Pl. 1262, is a trailing perennial plant, with finely divided leaves, and naked thick stalks, bearing each a large flower, with a yellow disk, surrounded with white petals on the upper side, and of a fine purple underneath. The root sinks deep in the ground like a carrot, is of a brownish colour on the outside, and white within. It is a native of the warmer climates, and is brought to us from Italy, but bears the cold of the northern regions, flowering from January to May. The roots which grow in England are larger than those from abroad.

The root is hot and pungent to the taste, but has little or no smell. Its pungency, which resides in its resin, is scarcely extracted by water, but completely by spirit. In distillation neither water nor spirit carries over any portion of it. The watery extract is most copious, the spirituous most active. It is chiefly used as a masticatory in tooth aches and rheumatic affections of the face, to produce salivary discharge; and it has also been recommended as a stimulant in lethargic complaints, and paralysis of the tongue. Internally it is given in palsy, in amœnorrhœa and cachectic cases, where the circulation is languid, in the same manner as arum root, in a dose of from five to ten grains. Dr. Lewis recommends a decoction of these roots with the tinct. aloes in clysters for the saturnine colic. As a stimulant gargle it is considered useful. R. Pyrethri contusi ʒss. aquæ distillatæ ꝑi. coq. ad dimidium, colaturæ adjiciantur aquæ ammoniæ ʒij. m. It is not certain that the pellitory of the moderns is the same with that of the ancients. See Neumann's Chemical Works; Lewis's Materia Medica.

PYRE'XIÆ; πυρετικος, (from πυρετος, febris, and that from πυρ, fire). FEBRILE DISEASES; the first class in Dr. Cullen's Nosology. See FEBRIS.

PYRIFO'RMIS MU'SCULUS, (from pyrus, a pear, K k 2

and *forma, shape*.) *iliacus externus*, rises from the lower part of the os sacrum, where it is joined to the os ilium, passes through the sciatic notch, and is inserted into the inside of the root of the trochanter major, serving as a rotator, an extensor, or abductor, according to the direction of the thigh. See QUADRAGEMINI.

PYRITES, (from πυρ, *fire*.) *marcasita, fer sulphure* of Haüy, iv. 65, is yellow, resembling bronze, crystallizing in regular octoedra, of a specific gravity from 4.1 to 4.7. It strikes fire with flint; and is for this reason sometimes styled fire stone. It contains sulphur; and when exposed to the air the sulphur attracts oxygen, producing sulphuric acid. Pyrites are never used in medicine.

PYRIUS PULVIS, (from πυρ, *fire*). **GUNPOWDER**.

PYRMONTANA AQUA. **PYRMONT WATER**, one of the principal chalybeates, is found in the county of Pyrmont, in the circle of Westphalia, in Germany. The spring is situated in one end of the village, and the water, as it rises up from the springs, seems to boil in its basin, and sparkles in a glass like the brightest champagne. It seems to yield different quantities of solid matter, at different times. Dr. Rutty mentions that the residuum which he obtained was of a pale brown colour, with a nauseous bitter taste, not deliquescent; of which about one third was vitriolated magnesia, mixed with a little of sea salt, the remainder consisting of selenite, calcareous earth, and ochre. Bergman found the Swedish kanne, containing 42,351 grains of this water, to be impregnated with ninety cubic inches of aerial acid, which is in the proportion of 130½ cubic inches from the English gallon of 61,440 grains: and the solid contents from his analysis were, from the English gallon of aerated iron, 4½ grains; of aerated lime, 29½; of vitriolated lime selenite, 55½; of aerated magnesia, 65½; of vitriolated magnesia, 36½; of common salt, 10½. Dr. Higgins obtained from a Winchester gallon of Pyrmont water, of selenite, two pennyweights 13.2 grains; carbonated lime, one pennyweight 22 grains; carbonated magnesia, 15.6 grains; vitriolated magnesia, 15.6 grains; oxide of iron, 2.6 grains; vitriolated magnesia, one pennyweight 6.7 grains; sea salt, 10.1 grains; with 192 measures of acidulous gas. At Pyrmont, the quantity of two, three, or more English pints of this water are sometimes drunk in a morning, and it chiefly operates by urine. Its laxative effect is often assisted by the addition of vitriolated magnesia. It is chiefly used in debility of the stomach, and in biliary complaints. See *AQUE MINERALES*.

PYROLA ROTUNDIFOLIA, (from *pyrus*, because its leaves resemble those of a pear tree). See **PARNASSIA**.

PYRO-LIGNEOUS ACID, (from πυρ, *fire*, and *lignum, wood*.) an acid obtained by distillation from beech, birch, or box wood, of a brown colour, and a somewhat acid, burnt smell. Fifty-five ounces of very dry beech chips yielded seventeen ounces of rectified acid, of an amber colour, not empyreumatic, somewhat heavier than distilled water. It has all the qualities of an acid, and supports the action of heat when joined to an alkaline base; but by a strong heat alone it is burnt like all other vegetable acids. It has a greater affinity to lime and barytes than to pure alkalis; but in other respects

follows in the order of its affinities the acetous acid, from which it only differs by holding in a strong union a small portion of empyreumatic oil.

PYRO-LIGNIS, (from πυρ, *fire*, and *lignum, wood*). **PYROLIGNITES**. Salts formed by the union of the pyrolignic acid with different bases.

PYRO-MUCOUS ACID is obtained from sugar, gum, and mucilages, by distillation, in which process carbonic acid and hydrogen gas are first copiously evolved, and a spongy coal remains. When rectified it has only a slight yellow tinge, and it cannot be concentrated by heat, as it is equally volatile with water; but by freezing it is rendered stronger, and has a pungent taste. When burnt in close vessels it leaves a coal like that of sugar; and is apparently a mixture of acetic and oxalic acids.

PYRO-MUCIS, (from πυρ, and *mucus*). **PYROMUCITES**. Salts formed by the union of the pyro-mucic acid, and different bases.

PYRO-TARTAROUS ACID. The acid produced by distilled tartar in the naked fire. It differs little from tartar except in an acrimony derived from its oil.

PYRO-TARTRIS, (from πυρ and *tartarum*). **PYROTARTRITES**. Salts formed by a combination of the pyrotartarous acid and different bases.

PYRO-PUS, (from πυρ, *fire*, and ωψ, *aspect*). See **PHOSPHORUS**.

PYRO-SIS, (from πυρω, *to burn*). The **WATER BRASH**, in Scotland; **BLACK WATER**, in England; *pyrosis suecica* of Sauvages; *cardialgia sputatoria* of Linnæus; Dr. Cullen places it among the spasms, defining it a burning pain of the epigastrium, with a quantity of water, usually insipid, sometimes acid, discharged by the mouth. He considers the pyrosis as an idiopathic disease; and observes that it is frequent among people in lower life, occurring also, though more rarely, in people of superior rank. It appears more frequently in persons under middle age, but seldom before that of puberty. When it has once taken place, relapses are common, though but seldom in persons considerably advanced in life. It affects both sexes, but more frequently the female, when unmarried, or when pregnant, sometimes those only who are in that condition. The fits of this disease usually come on in the morning and forenoon, particularly when the stomach is empty. The first symptom is a pain at the scrobiculus cordis, with a sense of constriction, and as if the stomach was drawn towards the back: it is increased by raising the body into an erect posture, and is often very severe. After continuing for some time, it brings on an eructation of a thin watery fluid in considerable quantity; sometimes acid, but more frequently insipid. The eructation is frequently repeated without relieving the pain which preceded it, though at length it terminates the fit. No exciting cause can be discovered; but it more frequently attacks those who live on milk and farinacea. Cold applied to the lower extremities, and often every considerable emotion of mind will appear to bring them on. The disease, according to Dr. Cullen, seems to begin by a spasm of the muscular fibres of the stomach, communicated to the blood vessels and exhalents, so as to increase the impetus of the fluids in the vessels, while a constriction takes place on their extremities. The increased impetus pours out a

larger quantity of fluid than usual, while the constriction upon their extremities allows only the pure watery parts to pass, analogous in every respect, he thinks, to what happens in the diabetes hystericus. Opium relieves the paroxysm. The vitriolic ether, volatile alkali, &c. are sometimes of service; and Linnæus speaks of the nux vomica as useful. These, however, relieve only for a time, and to prevent the returns of this disorder is not easy. The metallic tonics have not been sufficiently tried; and the zinc, perhaps the bismuth, may be salutary. See Cullen's First Lines, vol. iv.

It is also the name of a disease in the ear, which affects the patient as if a burning coal was applied.

PY'RUS, (because its fruit is shaped like the flame of a candle). The PEAR TREE, *apios*. The tree and fruit are sufficiently known: from pears the liquor

called *herry* is obtained by expression; a light pleasant drink, though without a sufficient strength to agree with weak stomachs. Like champagne, it abounds in an aerial fluid, probably carbonic acid gas.

PY'RUS CYDO'NIA. See CYDONIA.

PY'RUS MA'LUS. See MALUS SYLVESTRIS.

PY'THON. See OB.

PYU'LCON, (from *πυν*, *pus*, and *ἔλκω*, *to draw*). An instrument to draw the matter from the cavity of the breast or any sinuous ulcer.

PYU'RIA, ARTHRI'TICA, MUCO'SA, vel VIS'CIDA, (from *πυν*, *pus*, and *ουρον*, *urine*). See DYSTURIA.

PYXIS, a box; sometimes the name of the acetabulum of the hip bone, from its resemblance to a box.

QUACKS, and QUACK MEDICINES. The appellation of QUACK arose from *quacksalber*, the German appellation of quicksilver; since on the first appearance of lues the irregular practitioners only employed this reputedly dangerous medicine. At present it is confined to those who sell a pretended nostrum, the preparation of which is kept secret; but may be applied to every practitioner who, by pompous pretences, mean insinuations, and indirect promises, endeavours to obtain that confidence which neither success nor experience have entitled him to.

The human mind is captivated by confident promises, especially if, like the oracles of old, they are couched in ambiguous language, and if they are directed to those points which are most interesting, and which chiefly influence the imagination. We have often observed that the idea of a latent lues is with difficulty eradicated; and that no failure is so sensibly felt as that connected with the function by which the species is reproduced. For these reasons, remedies are held up with the most indecorous ostentation as infallible in such cases; and the mind is allured by promises that the medicine is equally safe and secret. We know a single individual who, on the latter pretence, for years expended from 70*l.* to 100*l.* annually, in trash like the solar tincture, and the balm of Gilead; and the author of this article was asked if he had not a high opinion of Dr. Freeman, by a patient who professed himself almost ruined in the pursuit of quacks, and had determined to leave them.

There are undoubtedly various remedies sold by plausible, captivating titles, which are truly insignificant; others of some service; others highly useful. Had the remedies of quacks been always despised, we should have wanted the compound powder of ipecacuanha; the sudorific powder of Ward; some of the aloetic tinctures and pills; the powder of Dr. James; the paste of Ward, &c. The nature of these remedies is now known; but there are others which are valuable, whose nature we know, though the particular preparation we are unacquainted with.

We had intended to have noticed the quack remedies at some length, and could have pointed out the principles of many with some certainty; but we found that

Q U A

we "walked on burning coals ill concealed by delusive ashes." We shall, therefore, add only a few remarks on the different classes just distinguished.

Of the trifling, insignificant remedies, those recommended for coughs and consumptions are the most inert. The balsam of liquorice, of lungwort, and honey, are little more than opiates in disguise; for it is well known that the valuable parts of each medicine consist in mucilage, which is incapable of concentration. Godbold's balsam is of a similar kind. We have, however, reason to believe that it was first prepared from the various, supposed expectorants of an old herbal, since Godbold (the elder,) though an ignorant, seemed an honest man; and he professed that he had given us the receipt. This idea is since supported in a late periodical publication, the "*Medical Observer*." At present, however, it is certainly only vinegar and honey, with a proportion of laudanum, and some aromatic, varied apparently at different times. The solar tincture, the balm of Gilead, and the whole tribe of pretended restoratives are at best trifling, unless, as is suspected, the balm contains a stimulus, which gives temporary activity at the expense of the little remaining strength. Many of these cordials owe their reputation to the spirit; and we knew a lady who thought she could not live without them, till her brother filled an empty bottle with brandy only, which she continued taking without discovering the difference till he explained it, and convinced her of her folly. Our own country, however, does not exclusively furnish dupes. The continent, particularly Germany, swarms with them; and one of the latest as well as the grossest impositions of this kind was Dr. Lendhart's liquor for accelerating delivery, which was found to be a solution of Glauber's and Epsom salts, disguised by an innocent colouring. But though in itself an imposition, it were to be wished that every quack remedy were ultimately so useful; for by inspiring confidence it reconciles the patient to delay, when nature frequently succeeds in the attempt. Numerous are the valuable remedies introduced, in this secret way, first in Germany; among the rest is the zinc, styled the *luna fixata Ludemanni*, first detected by Gaubius.

There are certainly many medicines of some utility under this disgraceful form; and if those who object to the charges of an apothecary will be contented in this way to pay them ten times told, the revenue will gain, and no one be materially injured. There can be little

doubt of Dr. James' analeptic pills being accurately prepared at a moderate expense, and Anderson's pills may undoubtedly be sold at an inferior price of equal goodness. The antimonial in the pills of Dr. James probably suggested to Mr. Barclay, as it did many years since to ourselves and many others, the union of emetic tartar with the resinous purgatives. It undoubtedly quickens and facilitates their action; and Barclay's pills are a warm, useful laxative, particularly convenient for those to whom aloes may be injurious. It is not to our purpose to add, that every apothecary's apprentice could have composed an equally useful medicine, and one less inconvenient from its bulk, or that from any apothecary it could have been purchased at a much cheaper rate. *Si populus, &c.* It reminds us, however, of an application made by a druggist to an apothecary to furnish a composition of this kind, which he engaged to vend in considerable quantities, by the simple expedient of affording a larger allowance to the retail trader than he received by any rival medicine.

Whitehead's essence of mustard is a similar medicine, and an elegant form of turpentine, with camphor, perhaps opium, which was well known, and used long before Mr. Whitehead's existence. The various remedies for the whooping cough, when internal, are either opiates or the white vitriol; when external, the polish embrocation of oil of amber, ammonia, &c. The soda water is well known; and the sodaic powder, which is, however, a solution of soda, with a rapid *extrication* rather than the *union* of fixed air, we have already mentioned. If added to the water, and the whole immediately confined with wire in a strong jug, soda water may undoubtedly be prepared from it; but an effervescing saline draught is, in its proposed form, an equally efficacious and a more elegant remedy.

There are other preparations which contain active medicines, which should not be entrusted to common hands. Of these the secret remedies for the venereal disease, which stare every one in the face, at the appropriate corners, where the disease is most felt, are particularly obvious. All these preparations undoubtedly contain mercury in its most active forms, and the authors defy detection by the smallness of the dose, the deep colour, and the viscosity of the fluid which contains it. Modern chemistry has, however, many resources, which cannot fail to discover the deception. Gowland's lotion is equally a mercurial, and highly pernicious. Numerous are the lives which have been sacrificed to it within our own observation; and those who have escaped, have passed their remaining days in torture or distress. Spilsbury's drops, a solution of muriated mercury, are less injurious, because the dose is small and they do not repel; but indiscriminately used have been highly injurious.

The composition of Ching's lozenges is well known, and they contain calomel; in the brown kind united to resin of jalap. They are undoubtedly active medicines, and often on that account injurious when indiscriminately employed; nor is it certain in these preparations that the calomel is always properly prepared. The opium in Godfrey's cordial and Dalby's carminative is also frequently dangerous, by indiscriminate use, and many children's lives have been sacrificed to the impatience of nurses, though in proper hands each is a pleasing and

useful anodyne. The concentrated essence of ginger, in the same manner employed in the relief of colic, has more than once induced inflammation of the bowels under our own eye.

We have thus selected some of the most common medicines as instances of the different forms which empiricism assumes, viz. merely picking the pocket, without any advantage; demanding an extravagant price for common medicines, and holding up confident promises by medicines of real activity, which, by undistinguishing ignorance, become really injurious. The legislature demands the receipt of the remedy before it grants the patent; but this is eluded by general directions, by multiplying useless steps in the process, as in Whitehead's specification, often concealing some leading observation essential to its success; nor is any security given that the medicine shall be always prepared according to this process. Every patent requires, we apprehend, that the *principle* should be new; and if it be not, an action cannot lie for its infringement. If this be true, we would engage to show the principle of every patent medicine in works long since published, and very often the process described much more accurately than in the specification.

The confident promises are supported by numerous attestations. How these are procured is well known; and common names, in remote parts of the metropolis, or in distant provincial villages, are secure from detection. The answer of one man, who had given a countenance, perhaps an attestation, to every quack who visited the town in which he lived, will perhaps explain the mystery. "I thought it an honest way of gaining half-a-crown; for I did no one any injury."

The conduct of those in superior ranks of life, who sanction by their names the circulation of the most injurious medicines, demands some severer strictures. "What," it will be alleged, "should hinder me from publicly saying that I was relieved from a given disorder by such a medicine?" The very circumstance that, as you know not the disease, you cannot ascertain the reality of the cure; nor can you say it was owing to the medicine. A physician who has spent his life in study and observation finds himself often baffled in these conclusions; and yet they are rashly drawn by persons wholly unacquainted with the subject, whose minds have received little cultivation, or who have directed their attention to very different sciences. Credulity and confidence are the constant companions of ignorance; and the wisest man must be ignorant of professional subjects if that profession has claimed no share of his attention.

QUADRAGE/SIMUS DIES. The fortieth day was, in the opinion of the ancients, the last to which acute distempers could extend. Dr. James observes, that he hath seen an acute disease which continued sixty days; but the logical, rather than the medical, accuracy of the observation might be questioned, if the subject merited a moment's consideration.

QUA'DRANGULA'RIS, (from *quadrus*, four square, and *angulus*, an angle). A leaf of a plant that has four prominent angles in its edge.

QUA'DRANS. See **CYATHUS**.

QUADRA'TI MU'SCULI. See **OCCIPITALIS MUSCULUS**. **DEPRESSORES LABII INFERIORIS.**

QUADRATUM, (from *quadra*, a square). See CUBOIDES.

QUADRA'TUS BU'CCAS DE'TRAHENS. See ADDUCTOR AURIS.

QUADRA'TUS FE'MORIS. This muscle is flat, thin, and fleshy, by no means square, it rises tendinous and fleshy from the lower edge of the tuberosity of the ischium, and is inserted into the line between the trochanter major and minor, serving to bring the thigh outwards.

QUADRA'TUS GE'NE. See PLATYSMA MYOIDES.

QUADRA'TUS LA'BII INFE'RIORIS. See DEPRESSOR LABII INFERIORIS.

QUADRA'TUS LUMBO'RUM, *quadrigeminus*, and *lumbaris externus*. This muscle rises from the posterior part of the spine of the ilium, whence it goes to the transverse processes of the four upper lumbar vertebræ, and partly from these transverse processes to the last rib, and by a small tendon passing under the diaphragm into the side of the last vertebra of the back. This muscle, therefore, lies between the contents of the belly and the erectors of the back, serving to pull the body to one side, by bringing the last rib down. See ABSCESSUS LUMBORUM.

QUADRIFO'LIIUM, (from *quatuor*, four, and *folium*, a leaf). A grass with four leaves on each stalk. See TRIFOLIUM.

QUADRI'GA, (from *quatuor*, and *juga*, yokes). *Cataphracta*. A bandage for the sternum and ribs, called from its resemblance to the trappings of a four horse car. It is twenty-four feet long, three or four fingers broad, with two heads, to bind upon the thorax and sternum when the ribs are fractured. The middle is placed on one side of the body; the two heads are carried so as to intersect on the opposite shoulder; they are brought back to where they begin, and then pass circularly round the body.

QUADRIGE'MINI, (from *quatuor*, and *geminus*, double). A name for the following muscles taken together, viz. *pyriformis*, *gemini*, and *quadratus femoris*.

QUADRIGE'MINUS. See QUADRATUS LUMBORUM.

QUADRIJU'GUS, (from *quatuor*, and *jugum*, a yoke). A leaf composed of four pair of folicles.

QUADRILO'BUS. A leaf consisting of four lobes.

QUADRILOCULA'RIS. A berry with four cells.

QUANTICAMO'TLI. See CASSADA.

QUA'QUARA. See CHINA ORIENTALIS.

QUARANTINE. (French.) QUARANTINE, or QUARANTAIN. The term is derived from the space of forty days, being the time which a ship suspected of infection is restrained from any intercourse or commerce, lest that infection should be communicated to the inhabitants of the country. We have already made some observations on this subject (vide PESTIS), to which quarantine is chiefly applicable. Infection, however, is not so much dreaded; and, as we have remarked on the subject of the yellow fever, the apprehensions need not in many cases be considerable, unless the constitutions of the inhabitants could be imported with the disease. See Howard on Lazarettos.

QUARTA'NA FE'BRIS, vel QUARTA'NA LEGI'TIMA. An AGUE, or QUARTAN INTERMITTENT FEVER, which Dr. Cullen defines similar paroxysms

within the space of twenty-four hours nearly; the accessions coming on in the afternoon. (See INTERMITTENS, vol. ii. p. 38.) It receives different names from its symptoms, viz. *quartana comatosa*, *siphylitica*, &c. (See Cullen's Nosology.) A quartan is usually both more violent and obstinate than a tertian, and is called spurious when the fit begins at any other time of the day than about four or five o'clock in the evening.

The quartan is distinguished by the steadiness of its attack, about four or five in the afternoon, seldom anticipating or retarding, and by the shortness of its paroxysm. It is seldom attended by much agitation; but the coldness continues often for more than two hours. Vomiting and diarrhœa are less frequent than in tertians. The heat is less violent; but the sweating is inconsiderable. The intermission is never perfectly complete, and is sometimes very imperfect, much fever continuing in the intervals. It has then the name of *quartana continua*.

The quartan was supposed to be the opprobrium medicinæ; and to cure a quartan was supposed to be the acme of the art, and the highest power of any febrifuge. We have said, that in thirty-five years practice we have seen but one quartan, brought from Coxheath camp. This had resisted every remedy; but was at last cured by arsenic; perhaps by a change of air.

QUARTA'NA SPURIA. SPURIOUS QUARTAN, hath no certain period for its returns, which generally occur in the forenoon: the heat also is greater, and affects the patient more than the cold fit does.

QUARTA'RIVS, (from *quartus*, fourth). A measure which contains about four ounces, or one quarter of a pint.

QUARTA'TIO, QUARTU'RA. QUARTATION is an operation in chemistry, by which the quantity of one thing is made equal to the fourth part of the quantity of another. Thus, when gold, alloyed with silver, is to be separated, we are obliged to facilitate the action of the aqua fortis by reducing the quantity of the former of these metals to one fourth part of the whole mass, which is done by sufficiently increasing the quantity of the silver, if it be necessary. Some extend this name to the operation of parting. See DEPART.

QUA'SSI LIGNUM, vel QUA'SSIA AMA'RA. QUASSI WOOD, or BITTER QUASSIA, called from a negro who lived at Surinam, and used it medicinally, with success, in intermittent, malignant, and putrid fevers; *quassia amara* Lin. Sp. Pl. 553. The wood hath no smell, and is a very pure bitter, without any astringency. An infusion in boiling water is the best preparation. A drachm may be infused in a pint of boiling water, and an ounce may be given for one dose; but the proportion of the wood is sometimes greater, without adding to the virtues of the medicine. The watery extract is given in a dose of from ten to twenty grains.

It scarcely differs from a pure bitter; but was given with serpentaria, in the intermission of malignant tertians, when the bark could not be borne. Any other bitter would have had a similar effect; nor has the quassia superior powers to the gentian or the camomile flowers, except in the optics of weak minds or quacks. We observe among the quack medicines the *anima quassia*. It is the *soul* of the author, as of the licentiate in the Introduction to Gil Blas. Cullen's Materia Medica.

QUA'SSIA, *simarúba*. See SIMARUBA.

QUATE'RNUS, (from *quater*, *four times*). When the leaves of plants stand four on each side.

QUA'TRIO, (from its four sides). See ASTRAGALUS.

QUE'RCERA. See EPIALA.

QUE'RCULA, (a dim. of *quercus*), *calamandrina*. See CHAMÆDRYS.

QUE'RCUS. The OAK TREE, *quercus robur* Lin. Sp. Pl. 1414. The COMMON ENGLISH OAK TREE. The bark is a strong astringent, moderately bitter, without any particular smell; striking with iron an inky blackness. It hath been used with success in intermittent fevers, for restraining hæmorrhages, alvine fluxes, and other immoderate evacuations; in gleet, gangrenous wounds, and ulcers. (See PUTREDO.) It yields its virtues both to water and rectified spirit, and is used as an astringent, in decoction, in slight tumefactions of the mucous membrane of the fauces, a prolapsus uvulæ from a slight cold, and a cynanche tonsillaris; as a fomentation, or lotion, in *procidentia ani et uteri*. Alum often renders it more efficacious. Half a drachm of the powder given every two or three hours during the intermission of a fever, joined with camomile flowers, is said to have prevented the returns of paroxysms of intermittents. The same virtues are said to belong to the scaly cup, which embraces the bottom of the acorns, called *glandes*, and *balani*. Cullen's *Materia Medica*.

The bark is often used in the following form as an astringent lotion. R *quercus contusi* $\frac{3}{4}$ li. *aquæ distillatæ* $\frac{1}{2}$ ij. *coquantur ad* $\frac{1}{2}$ i. See GALLÆ.

QUE'RCUS COCCI'FERA. See CHERMES.

QUERCUS MARI'NA. See KALI.

QUE'RQUERA, (from *querquero*, *to quake*). See PHRICODES.

QUIETA'LES, (from *quies*, *rest*). Diseases in which the voluntary, the involuntary motions, and the senses, are diminished; a class in the nosology of Linæus.

QUI'NA QUI'NA. See CORT. PERUV.

QUI'NCUNX. See CYATHUS.

QUINQUE-COCCUS. Having five berries.

QUINQUEFO'LIIUM, (from *quinque*, and *folium*), *pentaphyllum*. COMMON CINQUEFOIL, FIVE FINGERS, or FIVE LEAVED GRASS, *potentilla reptans* Lin. Sp. Pl. 714, is a trailing plant, with serrated leaves, set five together, on long pedicles; perennial, growing wild on clay grounds, and flowering in June. The roots are astringent; yielding their virtue to water and spirit. The leaves resemble in their nature the roots. See Raii *Historia*.

It was employed by Hippocrates in the cure of intermittents, and according to Ray still used by the peasantry with this intention. The external or cortical part of the root, containing chiefly the medicinal quality, is employed internally in diarrhoeas and other fluxes, and externally in gargles and astringent lotions. As the cinquefoil is inferior in efficacy to many other plants of

the same class, it is now rarely used, though it may be found no bad substitute for several of the other astringents. Dose in substance, one drachm.

QUINQUE-JU'GUS, (from *quinque*, *five*, and *jugum*, *a yoke*). A leaf composed of five pair of lesser leaves.

QUINQUE-LO'BUS. Composed of five lobes.

QUINQUE-PARTI'TUS. A leaf consisting of five divisions down to the base.

QUINQUI'NA, (corrupted from *cinchona*). See CORT. PERUVIANUS.

QUINQUE-NE'RVIA, (*quinque*, *five*, and *rupa*, *strings*). See PLANTAGO MINOR.

QUIN'TA ESSE'NTIA. The peculiar, most concentrated essence of a plant prepared by agitating with any essential oil twelve times its quantity of pure alcohol till the oil disappears. If these are distilled in a close vessel, with a fire of 90°, the alcohol will rise with only the purer part of the oil. If the thinner part is several times carefully separated, by repeated gentle cohobation, the alcohol will be impregnated with a still purer oil, or, in other words, the oil will gradually disappear.

What are styled quintessences are sometimes made by dissolving an aromatic oil in alcohol, adding ten times its weight of sugar, finely powdered, and placing the mixture in a proper vessel to exhale the spirit. The sugar will remain dry, but with the virtues of the oil in it. A scruple in a glass of wine is a good cordial, but both are now disused.

QUINTA'NA, (from *quintus*, *the fifth*). An AGUE, the paroxysms of which return every fifth day, while the second, third, and fourth, are free from fever. This, as well as the *sextana*, *septana*, *octana*, *nonana*, *decimana*, &c. are generally denominated *erratica*; for the periods are never regular, and they require no peculiar treatment. For the varieties, see Sauvages' *Nosologia Methodica*.

QUISQUI'LIIUM. See CHERMES.

QUOTIDIA'NA FE'BRIS, *amphemerina*, *amphemerinos*; *methemerinos*. A QUOTIDIAN INTERMITTENT intermits, but returns every day, generally early in the morning: when the fit approaches at any other time, it is called spurious or anomalous. Dr. Cullen defines it an intermittent fever, in which similar paroxysms occur in the space of twenty-four hours; the paroxysms attacking in the morning. When its attack is general, returning at the same hour in the morning, it is called simple or true quotidian; when partial, it receives the name of the part affected, as *quotidiana cephalalgica*, *ischiadica*, &c. &c. The hysteric, catarrhal, and strangurious quotidians which have evening paroxysms, appear to be only symptomatic. See INTERMITTENS FEBRIS. When the intermissions are not distinct, it is called a remittent, sometimes a *continued quotidian*.

QUOTIDIA'NA SOPORO'SA, vel TERTIANA CAROTICA. A tertian fever attended with comatous affections.

R.

R A C

R. The abbreviation of *RECIPE*, the inelegant commencement of a prescription, concluded often more barbarously. The imperative mood, though it was conspicuous in every line of the former edition of this Dictionary, is always inelegant; and the verb *recipere* has scarcely in any instance a meaning analogous to the English word, "take," which should be confined to the pages of Hannah Glass. How much more elegant would be a commencement of this kind: *Habeat haustus solvatur, misceatur, &c.* previous to the enumeration of the ingredients, and *haustus hujusmodi sumatur*, instead of *misce fiat haustus*? The pages of Celsus contain no such word. We cannot, however, expect a reform in this respect, while prescriptions are written by those to whom the grammatical construction of their own language is often a science yet untaught.

RABDOIDES, (from *ῥαβδος*, *virga*, and *ειδος*, *similis*). See *SAGITALLIS SATURA*.

RA'BIES CAN'NA, (from *rabio*, *to be mad*). See *HYDROPHOBIA*.

RACE'MUS, (a dim. of *ramus*, *a branch*). A BUNCH OF GRAPES, OF IVY BERRIES, OR OTHER fruit which grows in clusters; sometimes a stalk divided into several branches, sustaining each a flower or fruit, set thick together.

RACHIA'LGIA, (from *ῥαχίς*, *spina dors*, and *αλγῆ*, *dolor*). Pains of the bowels, supposed to arise from the nerves of the spinal marrow. See *COLICA*.

RACHIA'LGIA PI'CTONUM; **META'LLICA**; **AB ADIAPNEU'STIA**; **TRAUMA'TICA**. See *COLICA*.

RACHI'TÆ, or **RACHIÆ'I**, (from *ῥαχίς*, *the spine*). The muscles belong to the back.

RACHI'TIS, (from *ῥαχίς*, because it was supposed to be a disease of the spinal marrow). The *RICKETS*, *cyrtonosus*; the *ENGLISH DISEASE*, because it first appeared in England about the middle of the seventeenth century, and from thence is said to have spread over Europe. Dr. Glisson thinks that it was first observed in the west of England, between the years 1600 and 1620; but from many passages of Latin authors ridiculing deformity; from Thersites, the supposed Æsop of Greece; the Vari, Volgi, &c. of the Romans, deformities almost exclusively derived from this disease, we may reasonably suppose it a very ancient one, especially as it certainly does not arise from any specific infection.

R A C

Van Sweiten and Trinka contend for its novelty, Zeviani for its antiquity.

Usually the first appearance of this kind is in the eighth or ninth month of the child's age. The several parts of the body by degrees become disproportioned, the skin grows lax, the belly flaccid, the muscles are extenuated, particularly those of the neck; the joints of the hands, arms, knees, and feet, are enlarged, so that there seem to be excrescences on the bones of the wrists and ankles; the bones and the spine, too weak to support the body, are at length incurvated; the child walks with more difficulty, until this exercise becomes too troublesome to be continued; the carotids and jugulars swell, but the other blood vessels disappear; the head grows large; the sutures are more visible; the fontanelle is often membranous; the neck too weak to support the head steadily. The countenance is, however, lively, and the child is more sensible than usual at the same age; the breast is strait, and compressed on its sides; the sternum rises up in a point, and the extremities of the ribs are enlarged and crooked; the hypochondria swell; fever, with symptoms of consumption, comes on, and the patient sinks from debility. In children predisposed to rickets the teeth come forward slowly, and soon decay. The appetite, however, seldom fails; but digestion is seldom perfect.

The rickets chiefly prove fatal from the attending hectic, consumptive symptoms, or asthma. If the disorder continues after the fifth year of the child's age, the body usually continues weakly and deformed for the whole life. When from a damp air or a bad diet, if succeeded by the small pox, the itch, or other cutaneous eruptions, and not accompanied with considerable incurvation of the bones, or inability to motion, the cure is not very difficult. The bones of the legs, though very crooked, will become nearly, often perfectly, straight during the growth of the child, if it becomes strong and healthy.

It is a species of cachexy, thus defined by Dr. Cullen. The head large, and much swelled anteriorly; the knees swelled; the ribs depressed; the abdomen tumid, and the other parts of the body emaciated. He distinguishes two varieties, the simple and the complicated rachitis. On dissection the muscles are found pale and flaccid, the livers indurated, the mesenteric glands enlarged and hardened, the bones spongy. Its usual period of attack is from six months to two years. Stoll

in his Lectures, and Thomas in the *Journal de Médecine*, mention its attacking adults. The top of the spinal marrow is said to have been uncommonly hard and obstructed; water is sometimes found between the dura and pia mater; and the brain is enlarged.

The remote causes are those of debility only. A cold moist atmosphere disposes to the disease, and it is, therefore, more frequent in marshy countries, as in Holland, at Halle, in Saxony, and in the marshy districts of this kingdom.

The exciting causes are want of exercise, and unalimentary food, particularly those substances which abound with water, which are not susceptible of change by the process of digestion, and consequently are not animalized. This defect of animalization, as hinted in the article *MORBI SOLIDI SIMPLICIS*, q. v.; seems the chief cause of rickets. The digestive powers and the general strength are impaired before the disease comes on; the belly swells, from flatulence and a retention of the more solid matter, in consequence of an obstruction in the lymphatic glands. We have observed, in the article just referred to, that animal gelatine differs from vegetable jelly chiefly from the addition of nitrogen; and this addition renders it less soluble in water. The bones of young infants are gelatinous; and in this jelly the osseous matter, we have said (see *BONES*), crystallizes. If this jelly, then, is not animalized, at least in some degree, it is dissolved in the water of the blood, and washed away. This view of the disease connects very strikingly the early symptoms and the cure.

A deficiency of bony matter in the system has been supposed, by some late French pathologists, to be the cause of rickets; but if the observations just adduced have any weight, the disease should rather be attributed to a want of the proper matrix in which the bony matter is deposited. We now know, from the later experiments with madder, that the serum rather than the bony matter is the medium of its deposition and removal; nor is it improbable that the watery state of the lymph is the real cause of the softness of the bones in this instance. By these means also we remove the objection, started by a late author, that the mollification of bones has been found connected with gout, where the phosphat of lime is apparently in excess; an objection, however, of little importance, and perhaps easily replied to on other foundations.

The ratio symptomatum is perfectly obvious. The ribs fall down from want of resistance; the child straddles in his walk, from the bulk of the belly, and from debility, and the legs are consequently bent. The upper part of the bones, where the cancelli are most numerous, yield most easily to the pressure, and consequently are enlarged in their diameter. The head swells in consequence of the diminished resistance of the bones to the distending arteries; the sutures and the fontanelle consequently separate.

We know not whether the freer circulation through the brain may render the intellectual powers more clear and brilliant. It is, however, highly improbable, when we compare the state of the cranium in different diseases with the changes in the intellectual functions; and we would rather refer the increased acuteness to the less active life, to more frequent opportunities for observation and reflection; which we find in many diseases, where the young patient is confined to his chair.

As the digestive powers are apparently injured, it is the first object to clear them from mucus, and every impurity which would impede digestion or absorption. The directions, therefore, in every practical author, are to begin with emetics, followed by gentle, steady laxatives. The rhubarb, as a bitter, has been selected, sometimes calomel. Tonics are then employed; and steel, either in filings, combined with ammonia, or in tincture, has been preferred, and sometimes used with rhubarb. Copper, as a tonic, is recommended by Buckner and Dupau. Peruvian bark is spoken of in general terms, as if not tried, or used with little decisive effects. Our own experience in this disease is inconsiderable; but we should certainly prefer tonics, which had no admixture of astringency, and even the pure bitters to the bark.

Fourcroy recommended breathing oxygen gas; but it was probably not successful, for it has not been imitated. Madder has been frequently given in this disease, though we are unable to ascertain the principle of the practice, except the vague idea of its having the strongest affinity to the bony matter, which we now know to be fallacious. Joined with fixed alkali, according to the plan of Abilgaard, in the Copenhagen Medical Transactions, it may be apparently of service from its accompanying medicine. The cicuta is warmly recommended by Storck; but his cases and reasoning are more astonishing than convincing.

Saponaceous medicines are mentioned as deobstruents; and in the fourth volume of the *Edinburgh Medical Commentaries* we find a striking instance of the good effect of the fixed alkali joined with bark. We can easily perceive the source of the relief derived from the former medicines; for the alkali would probably contribute to dissolve the lymphatic tumours, or might possibly supply azote to the blood. The empirical practice in the western islands strongly confirms the theory of the disease which we have suggested; for they rub the arms and wrists, and successively the whole body, with the oil of the skate. It is evident that this furnishes a supply of animal matter to the blood, for it excites fever; and when this effect is no longer produced, the surface to be rubbed is increased, and at last the shirt is wholly impregnated with it. *Edinburgh Medical Commentaries*, vi. 165.

Dry frictions and the warmest stimulating liniments are also recommended, and sea bathing is often very salutary, though if the child be very weak, the tepid sea bath, at about 82°, should be premised.

The diet should be generous and nutritious, chiefly animal, though in a fluid form; and the stomach may be stimulated by a slight addition of spice. The air should be dry and moderately cold, and the child kept much abroad, occasionally allowed to walk, but seldom for a long time together, so as to fatigue. The swing will afford proper exercise, and occasionally he may be carried on a horse.

Wine is seldom highly useful; nor do we find that the mineral acids are spoken of with warm commendations, though a promising remedy. If alkalis, however, are eminently successful, no great advantages can probably be derived from their opposite. The French physicians, in pursuance of their theory, have given phosphat of lime, but without any decided benefit.

See Boerhaave's Aphorisms; Buchner de Rachitide;

Sydenham's Works; Glisson de Rachitide; F. Hoffmanni Opera, tom. iii. p. 487, &c.; Medical Museum, vol. i. p. 66. 71.; Edinburgh Medical Commentaries, vol. ii. and iv.; Cullen's First Lines, vol. iv.; Zaviani della cura de' Bambini, attachati della Rachitide; Mémoires de la Société de Médecine.

RACHO'SIS, (from *ραχωσ*, *lacro*). Excoriation of the relaxed scrotum.

RACK. A Tartarian liquor, highly intoxicating, prepared from mare's milk.

RADIÆ'US, (from *radius*). See **FLEXOR CARPI RADIALIS**.

RADIÆ'US EXTER'NUS. See **EXTENSOR CARPI RADIALIS**, **LONGIOR** and **BREVIOR**.

RADIA'LIS, (from the same). The nerve so called. See **CERVICALES**.

RADIA'LIS, vel **RADIÆ' A ARTE'RIA**, is a branch of the humeral artery, running down the side of the radius, covered by the supinator longus. At the wrist it divides into two; one, passing over the palm of the hand, is lost in the fleshy part of the thumb; the other, in its progress between the metacarpal bone of the fore finger and the first bone of the thumb, plunges into the palm, and forms an arch. In its course it sends off branches, which run on both sides of the hand, communicate with the cubical branches, and are lost among the metacarpal bones.

RADIA'LIS MU'SCULUS. See **FLEXOR CARPI RADIALIS**.

RADIA'LIS EXTE'RNA VE'NA. When the cephalica hath reached the bend of the arm, it divides into two principal branches, one of which, spreading over the fore arm, has this appellation.

RADIA'LIS INTE'RNA VE'NA, a long branch from the mediana cephalica.

RADICA'TUS, (from *radix*, a root). Leaves from which roots shoot out. This is the case with the succulent plants, the ficoides, stapeliæ, and aloes.

RADICULA, (a dim. of *radix*, a root,) strictly speaking, the small fibres of the principal root; in a medicinal view, equally active in most instances with the body of the root. See **RAPHANUS HORTENSIS**.

RA'DIUS, one of the bones of the fore arm, denominated from its resemblance to the spoke of a wheel; *cercis*; *focile*. Its upper extremity is formed into a small circular head, hollowed for an articulation, by arthrodia, with the tubercle of the os humeri at the side of the trochlea; and the half of the round circumference of the head, next to the ulna, is smooth, to be received into the semilunated cavity of that bone. The part below the head, rendered smaller by the action of the supinator radii brevis, is called its *cervix*; at the external root of which a tuberos process rises for the insertion of the biceps flexor cubiti. From this a spine runs downwards and inwards, for the insertion of different muscles.

Internally, it has a sharp spine, to which the interosseous ligament is fixed; but this is wanting at the upper end, where the supinator radii brevis, and flexor digitorum profundus, are connected. Both ends of the bones of the fore arm are first cartilages, and then epiphyses at the earlier periods. The lower extremity of the radius is much larger than the superior, flattened before, and grooved backwards by the tendons of the muscles. The extremity of the radius is hollowed for

the reception of the bones of the wrist. The reason why the fibres of the interosseous ligament run obliquely upwards from the ulna to the radius is, that, as the latter is very slightly articulated to the os humeri, the force of it would in a fall be communicated to its upper extremity, and easily dislocate it, if this ligament was not to take off the force of the shock. The fibula is also so called.

RA'DIX, (from *ῥαδιξ*, a lower branch). A root, that part of a plant by which it receives nourishment. Some roots are fleshy, others fibrous, others woody. Linnæus divides them into fibrous, bulbous, and tuberous, which are again subdivided, chiefly in the following manner:

RA'DIX ASPHODE'LI, composed of several oblong fleshy knobs, as the king's spear, and the day lily.

RA'DIX BULBO'SA, composed of several coats, involving, or of several scales lying over, one another. The first of these is called tunicated, as the onion; the last, squamous, as the lily.

RA'DIX CARNO'SA. **FLESHY** or **ESCULENT** ROOT, as the carrot.

RA'DIX FISTULA'RI. **TAP** ROOT, or that part which runs perpendicularly deep into the ground. In taking up trees, it should be neither cut nor broken; and in planting them, a hole should be made proper for its reception.

RA'DIX FIBRO'SA, consists only of small fibres, like hairs, as those of grass and corn.

RA'DIX GRANULO'SA, consists of many small fleshy knobs, which resemble grains of corn, as the white saxifrage.

RA'DIX GRUMO'SA, usually a pendulous root, consists of many oblong fleshy knobs, joined to one centre at the top, as that of the ranunculus.

RA'DIX PALMA'TA, a tuberous root divided apparently into several fingers, so as to resemble a hand, as the handed orchis.

RA'DIX TESTICULA'TA, a double tuberous root, consisting of two knobs, resembling the testicles, as in the orchis. Roots are sometimes styled *comosæ*, which send out fibres from the top, at a knot between the trunk and thicker part of the root; *fusiformes*, when they gradually lessen to a point; *entire*, as in liquorish, and *parted*, as in St. John's wort. Perennial roots are styled *radices fruticosæ*.

RA'DIX TUBERO'SA, consists of an uniform fleshy substance, and is generally roundish, as that of the potatoe.

RA'DIX BRASILIENSIS. See **IPECACUANHA**.

RA'DIX DULCIS. See **GLYCYRRHIZA**.

RA'DIX I'NDICA LOPEZIANA. *Radix serpentum ophi-orrisa mungos* Lin. Sp. Pl. Pharmacopœiæ Edinburgensis; Gaubii Adversar. cap. vi. The root of an unknown tree, growing at Goa, or Malacca, and brought to Batavia. The pieces are sometimes of two inches diameter. The woody part is whitish and very light, softer, more spongy, and whiter next the bark, including a denser, somewhat reddish, medullary part. The bark is rough, wrinkled, brown, soft, woolly, pretty thick, covered with a thin paler cuticle, without any remarkable smell or taste, or any appearance of resinous matter. When boiled in water it has no smell, and the strained liquor, of a yellow hue, is almost insipid, impressing the tongue with a very light bitterishness,

without viscosity. The tincture is brown and equally insipid. The extract obtained by evaporating the decoction is equally void of sensible activity. After drawing off the spirit from the tincture a balsamic matter remains, which bubbles and flames in the fire, with a bitterish taste, like that of opium.

This root is regarded in the East Indies as a medicine of extraordinary efficacy in diarrhœas. Gaubius found it effectual in abating colliquative diarrhœas, particularly those attending the last stage of consumptions. It seems to be a narcotic bitter not unlike the simaruba, but in Gaubius' opinion more efficacious. The powder is given in doses from fifteen to thirty grains, repeated three or four times a day. A tincture made with common spirit is said to be equally effectual with the root; and its dose was a tea spoonful three times a day: a dose somewhat disproportioned to that of the root and to its sensible qualities. Lewis's *Materia Medica*, edit. 3.

RA'DIX RHO'DIA. See RHEDIA.

RA'DIX RU'BRA. See RUBIA.

RAI'JIS DE MOSAMBIQUE. See COLUMBO.

RAMA'LIS VE'NA, (from its minute branches). See PORTA VENÆ.

RA'MENTA. SHREDS OF FILINGS.

RA'MEX, (*ramus*, a branch, from its protruding forward like a bud). See HERNIA.

RA'MEX VARICO'SUS. See CIRSOCELE.

RA'MUS, (*quòd radice manet*). A BRANCH, the subdivision of a stem of a tree.

RA'MUS INFE'RIOR. See MAXILLARIS INFERIOR NERVUS.

RA'MUS SUPE'RIOR. See FRONTALIS NERVUS.

RA'NA, (Hebrew, *ranah*, to croak). The FROG, or PUDDOCK. The spawn of frogs was formerly used as a refrigerant, but now wholly neglected. See RANULA.

RA'NA ESCULEN'TA. The hind legs of the frogs are only eaten. They resemble delicate veal, and are much less luscious than the tortoise.

RA'NA RUBE'TA. See BUFO.

RA'NGIFER, (from *ramus*, a branch, and *fero*, to bear, named from its branching horns). See CERVUS RANGIFER.

RANI'NÆ ARTE'RIÆ and VE'NÆ. (*Quia nigrae sunt instar ranularum*). See SUBLINGUALIS.

RA'NULA, (a dim. of *rana*, a frog). *Batrachos*, *hypoglossus*, *rana*. An indolent tumour under the tongue, named from its situation in the venæ raninæ, or perhaps from its altering the voice of the patient. This tumour is formed in the salivary glands, and is seated on either side of the frænum: it is often of a scrofulous kind, defined by Vogel a folliculous tumour, containing a thick or tofaceous matter; but the nature of the matter varies, and it is sometimes like the white of an egg, at others more solid, and even sandy, purulent, or differing from each. It has been styled a hydatid, and is said by Siebold to be an expansion of Wharton's duct. When it grows suddenly, both the speech and swallowing are impeded with much pain; but it generally increases gradually, and its effects are not violent. Instances, it is said, have occurred of these tumours degenerating into cancers; but this is highly improbable, for they are with great difficulty dispersed or brought to suppuration, and generally require the knife for their removal. The actual cautery has sometimes been

employed, and the oil of hypericum recommended. If a tumour of this kind is seated where the salival ducts enter into the mouth, incisions must never be attempted, because of the danger of wounding these ducts, and we must wait till nature discharges the contents. If seated on either side, great care is required, lest the nerves or the blood vessels should be injured; but if we hold up the tongue, and make an incision transversely into the tumour, the matter will be safely discharged. The wound must be dressed with honey of roses acidulated with spirit of vitriol, that the cyst may also be destroyed, to prevent a return of the disease. Mr. Justamond relieved a patient who would not submit to an operation, by rubbing it daily with a strong solution of alum.

See Heister's Surgery; Bell's Surgery, vol. iv. p. 325; White's Surgery, p. 275.

RANUNCULOIDES PRATE'NSIS, (*ranunculus*, and *ειδος*, likeness). See CALENDULA PRATENSIS.

RANU'NCULUS, (because found in marshy places where frogs abound). CROW FOOT, is a plant with perennial, pentapetalous, rosaceous flowers, set in five leaved cups, and followed each by a round cluster of naked seeds. A name also for the *myosuros*.

RANU'NCULUS BULBO'SUS, Lin. Sp. Pl. 778, *tuberosus major*, ROUND ROOTED OR BULBOUS CROW FOOT, hath a round tuberous root, the size of an olive; the leaves are divided commonly into three segments, and further subdivided; the stalks are erect, the flowers of a bright glossy yellow, their cups turned downwards; common in pasture grounds, and flowers in May. This is one of the caustic species.

RANU'NCULUS LONGIFO'LIIUS PALU'STRIS MINOR; *ranunculus flammula* Lin. Sp. Pl. 772. *citrinula*, SPEAR WORT, OR SMALLER WATER CROW FOOT, with fibrous roots, long narrow leaves, acuminate at both ends, leaning on procumbent stalks; growing in watery places or moist meadows, and flowering in June. The roots and leaves have no smell, but an acrid fiery taste. Internally they appear to be deleterious, even when boiled in water so long as to discover no pungency to the palate. The effluvia of the less acrid species, or varieties cultivated in gardens, when freely inspired, have occasioned headaches, anxiety, vomitings, and spasms. The leaves and roots applied externally blister the part, and destroy it. For this purpose they are used in Mrs. Plunket's remedy for cancers. Indeed all the species are highly acrid, exciting itching, inflammation, blisters, and ulceration on the tongue or on the surface. In the stomach they have all the effects of an acrid poison. The most virulent species are the *r. bulbosus*, *sceleratus*, *acris arvensis*, *thora*, and *illyricus*; but the acrimony resides, sometimes in the roots, occasionally in the stalks, leaves, or flowers. The acrimony of the *ranunculus alpestris*, according to Haller, is most considerable; but no medicine will counteract the virulence of this tribe. The wild plants are more acrid than the cultivated ones; their pungency is diminished by drying, and destroyed by long keeping. See Raii *Historia*; Lewis's *Materia Medica*; Kraft *Experimenta de nonnullorum Ranunculorum Venenata Qualitate*, Vien. 1766; Mayr de *Venenata Ranunculorum indole eorumque usu*, Viennæ, 1783.

RANU'NCULUS VI'RIDIS. The name of a species of frog: the term *ranunculus* is also given to several other of the vegetable class, viz.

RANU'NCULUS FICA'RIA and VE'RNUS. See CHELEDONIU' MINUS.

RANU'NCULUS NEMERO'SUS. See MOSCHATEL LINA.

RANU'NCULUS PHRAGMI'TIS. See ANEMONOIDES.

RANU'NCULUS TRIDENTA'TUS VE'RNUS. See HEPATICA NOBILIS.

RAPA, (from the Arabic term *raphagh*, to germinate). The TURNIP, or ROUND ROOTED TURNIP, *raphum*, a plant with jagged leaves, yellow flowers, with small round, smooth, reddish or blackish seeds, in long pods. The garden turnip is supposed to be a variety produced by culture from the smaller sort, which grows wild in sandy grounds in some parts of England. It is biennial.

Turnips are to many an agreeable food; but watery and flatulent; in weak stomachs inconvenient. They are said to be detergent, laxative and diuretic; are mild rather than sweet, but contain no sugar, and very little amylaceous matter. The yellow turnip has a sweeter and more mucilaginous taste, and is therefore apparently the most nutritious. (Cullen's *Materia Medica*.) The liquor pressed from them, after boiling, and sometimes from the raw root, is taken medicinally in coughs and disorders of the breast; and applied to the mouth in aphthæ, the seeds are styled *alexipharmic*, *diaphoretic*, and *diuretic*; they have no smell, but to the taste are mildly acrid. The female turnip is of a less rounded shape, and preferred. See Raii *Historia*; Lewis's *Materia Medica*. See RAPISTRUM.

RAPHA'NIA, (a disease supposed to arise from eating the BASTARD RADISH. *Raphanus raphanistrum* Lin.). *Convulsio soloniensis*; *eclampsia typhodes*; *necrosis ustilaginea*; *kriebel, krankheit*; is defined "a spastic contraction of the limbs or joints, attended with convulsions and excruciating periodical pain."

Rothman observes that it had been frequently epidemic in Sweden, though considered as a new disease, and he has traced it in the works of different authors from the year 1596 to 1727, so that it has been common in other parts of Europe. He adds, that this dreadful distemper sometimes continued for three or four weeks, and that it terminated fatally from a diarrhœa or convulsions. The poorer people were the chief subjects of this complaint, and were usually attacked in autumn, soon after eating bread made of new corn. The lolium temulentum, and the disease of corn styled ergot, by which the end of the seed is elongated like a horn, have been accused, as well as the charlock (*raphistrum*), of producing the disease; but it most probably proceeds from the ergot.

Valerian, castor, camphor, and other similar antispasmodics, were given with little advantage. Camphor has been sometimes combined with vinegar, and the animal oil of Dippell, with scarifications, blisters, and emetics, have been repeatedly employed with no decided success. See Pulteney's *View of the Writings of Linnæus*; *Memoires de la Société Royale de Médecine*, at Paris, Année 1776, 1786; Rothman's *Dissertatio de Raphania*; *Amœnitates Academicæ*, vol. v.; Rosenstein de *Morbo Convulsivo Spasmodico*; Tissot *Epistolæ Medico-practicæ*; Marcard von Einerder *Kriebelkrankheit*.

RAPHANI'STRUM, (from *raphanus*, in consequence of its likeness to the *raphanus minor*). It

agrees with this plant also in its medical virtues; and is sometimes the appellation of *miagram*.

RA'PHANUS, (*ῥαπα το ραδιος πανερθαι*, from its rapid germination). The RADISH.

RA'PHANUS AQUA'TICUS. See SISYMBRIUM AQUATICUM.

RA'PHANUS HORTEN'SIS, *radicula*, *raifort*; *raphanus sativus* Lin. Sp. Pl. 935; COMMON GARDEN RADISH. The root is attenuating, occasionally carminative; and all the parts of the plant are antiscorbutic. The roots are more acrid after drying than when fresh, but this acrimony is soon dissipated by boiling. It is commonly eaten raw with its cortical part, in which its acrimony consists; and this rather serves as a condiment to its acescent substance, and which therefore seldom proves flatulent. It is, however, in weak stomachs indigestible.

RA'PHANUS RUSTICA'NUS, MARI'NUS, and SYLVE'STRIS. HORSE RADISH, *cochlearia armoracia* Lin. Sp. Pl. 904. The leaves are large, long, and indented about the edges. It is found wild about the sides of ditches and rivulets, but for medicinal and culinary purposes cultivated in gardens; perennial, flowering in June. It rarely perfects its seeds, but is propagated by transverse cuttings of the roots.

The smell and taste of the roots are quick and penetrating; but they contain also a sweet juice, which sometimes exudes in little drops upon the surface. Its pungent matter is very volatile, dissipated in drying, and carried off in distillation, both by water and spirit. As the pungency exhales, the sweet matter, though partly dissipated, becomes more sensible. It impregnates both water and spirit by infusion or distillation very richly with its acrimony, and in distillation with water yields a small quantity of essential oil, exceedingly penetrating and pungent. This root differs from mustard seed in the volatility of its pungent matter, and its solubility in spirit. It is properly employed as a condiment with animal food, as it stimulates the stomach and promotes digestion. Externally applied, it is an useful rubefacient in palsy and rheumatism. Its infusion often cures hoarseness, when it depends on the interrupted secretion of mucus; and it readily proves emetic, when taken in infusion, or assists the action of other emetics. Infused in wine, it stimulates the whole nervous system, and is useful in palsy; but employed in large quantity it is often injurious by the excess of heat which it excites, though on this account useful in chronic rheumatism. Cut down into very small pieces, without bruising, and swallowed without chewing, according to Bergius, it has been extremely useful in arthritic cases, perhaps of the rheumatic kind. Its pungency passes to the kidneys, and often proves a powerful diuretic; and by promoting urine and perspiration, it has long been known as a powerful antiscorbutic. Held in the mouth it proves a certain and good sialagogue. The syrup of horse radish is made by infusing one drachm of the root in four ounces of water, and forming that into a syrup, in a moderate heat, with sugar. An infusion of it with bruised mustard seed, either in wine or boiling water, acts as a stimulant and diuretic, and is often prescribed with success in dropsical and paralytic complaints. An infusion of this root in milk is also one of the safest and best cosmetics.

If the root be kept in a cool place, and buried in dry

sand its virtues are long retained. Dr. Alston thinks that it may be dried and powdered without losing any considerable portion of its virtue.

The London college directs the following compound spirit, *spiritus raphani compositus*, to be kept.

Horse radish root fresh, the exterior rind of Seville orange dried, of each two pounds; fresh garden scurvy grass, four pounds; bruised nutmegs, an ounce; are added to proof spirit of wine, two gallons, with water, a sufficient quantity to avoid an empyreuma: distil two gallons. *Pharmacopœia Londinensis*, 1788. See Neumann's Chemistry; Lewis's and Cullen's Materia Medica.

RA'PHANUS SYLVE'STRIS. See LEPIDIUM.

RAPHE, (from *ραφή*, a suture). The longitudinal eminence which divides the scrotum, passing through the perinæum to the anus.

RAPHE CEREBRI. The longitudinal eminence which divides the corpus callosum.

RAPHONTICOIDES LU'TEA. See BEHEN ALBUM.

RAPI'STRUM, (from the resemblance of its leaves to those of the turnip). *Rapha lamifera*, *miagra*, *sinapi arvense fræcox semine nigro*, CHARLOCK, CHADLOCK, KEDLOCK, or WILD MUSTARD; a plant said to be antiscorbutic, but never employed in practice.

RAPOCAULIS, (from *rapha*, and *caulis*, the cabbage). See BRASSICA CONGYLODES.

RAPU'NCULUS, RAPUNTIIUM, (from *rapha*). Plants which much resemble the campanula in external appearance. See CERVICARIA.

RASH. A familiar name for any papular eruption.

RASPATORIUM, (from *rado*, to scrape). A SURGEON'S RASP.

RAUCE'DO, RAU'CITAS, (from *raucus*, hoarse). A HOARSENESS, a diminution of the voice, sometimes attended with a preternatural asperity or roughness of the parts affected, the aspera arteria, and particularly the larynx. It is generally a symptom of catarrh, but sometimes a species of PARAPHONIA, q. v.

It is chiefly occasioned by an inflammation, sometimes a want of tone in the nerves of the part; for whether the whole larynx acts as a wind, or its ligaments bring it nearer to a stringed instrument, a due activity of the nerves is necessary. In the first case it is a symptom of cold, or it may arise from swallowing acrid powders. When it occurs also from measles, small pox or repelled eruptions, it is probably owing to the same cause.

It is, however, often a symptom of hysteria, and then is probably owing to an altered state of the recurrent nerve; for the voice involuntarily changes from an acute to a grave tone, goes off, and returns suddenly. Sometimes hoarseness comes on from swallowing deleterious substances, as in the instance recorded by Plater, where a beetle swallowed produced it; sometimes it is said to be a symptom of pregnancy.

Its most common causes are, however, fixed organic diseases of the trachea and neighbouring parts, often from syphilis. An ossification of the thyroid and cricoid cartilages; a thickening of the first ring of the trachea (Fantonus); an erosion of the epiglottis (Haller); an ulcerated larynx (Wathen's Memoirs of the Medical Society, London, vol. i.); and an erosion of the uvula (Lentilius), are all said to have produced the

disease. Substances fixed in the œsophagus are said, in the Memoirs of the Academy of Surgery, to have had the same effect.

Various are the remedies prescribed for the complaint, not always with a rational view of its cause. If Plenck found the arnica, the bark, and the aqua vulneraria useful, it must have been in a case of debility. The erysimum and horse radix often given in the form of a syrup, must have succeeded on the same principle. Breathing watery vapours, bleeding, whey, cold water, and demulcents could only be of service in the inflammatory disease; the seton of Hildanus, when it arose from a topical complaint; and mercury when it was a symptom of the venereal disease.

RAU'CITAS. See BRANCHUS and RAUCEDO.

REA'LGAR, *arlada*, *auripigmentum rubrum*, *arsenicum rubrum factitium*, and *abessi*. A composition of sulphur, orpiment, and unquenched lime; of a red colour, always glossy, but not always transparent. See ARSENICUM ALBUM.

RE'BIS, *abessi*, *azoth*. The alvine sordes, in old authors; or the hair of choleric or plethoric men. Amongst alchemists it means the seed from whence gold is generated; and it has obtained the barbarous name *rebis*, because its first two ingredients, by long coction, become one in species and number. For a similar reason the *mercurius duplicatus philosophicus*, consisting of sulphur and mercury, is called *rebis*.

RECEPTA'CULUM CHY'LI, vel PECQUETI, (from *recipio*, to receive,) *diversorium*, *sacculus chyliferus*, the RECEPTACLE OF THE CHYLE, first demonstrated by Pecquet at Paris, 1651, 1652, though Eustachius and Asellius were in some degree acquainted with it. It lies on the right side of the aorta, at the union of the last vertebra of the back with the first of the loins, and is in reality the union only of the different lymphatics somewhat enlarged; but by no means a sac in the human body, as it is sometimes described. The upper portion lies between the aorta and the vena azygos, and forms a particular canal which runs up through the thorax, called the DUCTUS THORACICUS, q. v. See MONRO'S Osteology.

RECEPTA'CULUM. A RECEPTACLE, by Ray called *sedes*; by Boerhaave, *placento*; and by Vaillant, *thalamus*, is the basis upon which the other six parts of fructification are fixed.—1. *Receptaculum commune*, connecting many flosculi. 2. *R. floris*, a basis to which are fixed the parts of the flower exclusive of the germen. 3. *R. fructificationis*, common to the flower and fruit. 4. *R. fructus*, a basis for the fruit only. 5. *R. proprium*, belonging to the fructification only. 6. *R. seminum*, the basis on which the seeds are fixed within the pericarpium.

RE'CIPE. TAKE. It is usually placed at the beginning of prescriptions, and is generally wrote thus, R. or R. or with the character for tin, \mathcal{R} . As this is the astronomical character for Jupiter, it has been ridiculously supposed an invocation for success. See R.

RECLINA'TIO, (from *reclino*). An inactive state of the muscles; in botany a leaf which bends down, and whose top is lower than its base.

RECTIFICA'TIO, (from *rectifico*, to make clear). See DEPURATIO.

RE'CTOR SPI'RITUS. See SPIRITUS.

RE'CTUM INTESTI'NUM, (from *rectus* straight,)

apenthysmenos, longanon, archos, cyssaros. This last of the large intestines is every where covered by longitudinal muscular fibres, and hath strong circular ones for expelling the fæces. It is not furnished with bands like the colon, nor covered with the peritonæum, as the other intestines. At the lower extremity of the rectum are cryptæ, supposed to be the seat of worms, and vascular ridges between the cryptæ, the seat of hæmorrhoids, apparently raised by the fat between the membranous and muscular coats, interspersed with little glandular follicles, which separate mucus. The folds near the extremity are longitudinal, forming little lacunæ of a semicircular form, turned upward towards the intestine. This gut is a continuation of the last convolution of the colon, which, having passed below the lowest vertebra of the loins to the inside of the os sacrum, is bent backward in the concave side, to which it is connected; and having reached the os coccygis it runs in the same direction, bending a little forward, terminating beyond its extremity. The arteries are from the hæmorrhoidalis interna, the last branch of the mesenterica inferior, which communicate with the hypogastrica, and particularly with the hæmorrhoidalis externa. The veins are branches from the mesaraica minor, or hæmorrhoidalis interna, which communicate with the hypogastrica. The nerves are from the plexus mesentericus inferior and the plexus hypogastricus.

Sometimes hard, scirrhus lumps, without pain, are seated near the anus, which are thrust out at every effort to void the fæces, and are then slightly painful; but at no other time, unless handled. If they have a small basis, Mr. Pott advises their speedy removal; for otherwise they certainly prove fatal. The early symptoms do not elucidate their nature: the first sensation is that of wanting to void a large stool, but without effect. This unavailing inclination frequently returns, and on trying a clyster, the pipe is obstructed by a hard substance. The nature of the case is often discovered; but we can in general only palliate. A tumour perhaps of this kind was apparently dissolved by the external application of the beladonna. Medical Commentaries, i. 464.

Another disease of this gut is a general relaxed state of its whole substance. When extruded through the anus, it is bound by the sphincter muscle, and resembles a fungus with a narrow basis; a true fungus is, however, uniform, and the finger may pass round it; it is soft to the touch, yet from irritation may be as painful as a cancerous one. It is, therefore, proper to distinguish them with accuracy, as the first may be cured, but the latter cannot. The cancerous fungus within the rectum is seldom uniform, but generally unequal, spreading from a large basis, and discharging an offensive ichor or gleet.

Another disease of the rectum is a scirrhus contraction. It occurs usually about an inch or two above the anus, and the first symptoms are obstinate costiveness, alternated by a watery diarrhœa, of a short continuance. The fæces are usually retained. Hemlock, and all the variety of medicines, have been tried with little success. The cure is palliative only. The existence of the disease can often be ascertained with accuracy, as it is within the reach of the finger.

The anus is sometimes contracted by hæmorrhoids,

sometimes by venereal tubercles; and in the Memoirs of the Academy of Surgery, vol. i. and iii. there are instances of an abscess formed in this part, in consequence of swallowing some foreign bodies, or of substances forced into the gut. In the Medical Commentaries of Edinburgh, a case occurs of a calculus formed in it. Palsy and gangrene, sometimes cancers, of this part are said to have followed the abuse of drastics; and ulcers of the rectum are endemic in the Brazils. They are always with difficulty cured, though Dr. Rowley boasts of his success with antimonials and salts. See FISTULA.

Siebold Dissertatio de Morbis Intestini Recti; Wrisberg de Preternaturali, Intestini Recti cum Vesica Coalitu; Rowley's Seventy-four Cases; Memoirs of the Medical Society, London, vol. ii. art. 2 and 25; Edinburgh Commentaries, ii. 373.

RE'CTUS. STRAIT. The name of several muscles, denominated from the rectilinear direction of their fibres.

RE'CTUS ABDO'MINIS. The recti muscles of the belly arise from the os pubis, are inserted into the sternum, and are expanded upon the cartilages of the fifth, sixth, seventh, and sometimes of the eighth ribs, having expanded into a thin aponeurosis, which passes under the pectoral muscle, and is said sometimes to extend far up the sternum. In their course they are divided into four or five portions, by tendinous intersections, most apparent on the anterior surface. They lie on the fore part of the belly, immediately under the integuments; and the vessels which pass underneath the upper parts are the mammary artery descending, and its vein ascending; those of the lower part are the epigastric artery ascending, and its vein descending. In this muscle certain white lines and impressions are perceptible, called by Vesalius *perigraphæ*. Its use is to compress the abdomen, and to assist in raising the body.

RE'CTUS ANTE'RIOR. See RECTUS CRURIS.

RE'CTUS A'NTICUS BRE'VIS. See RECTUS INTERNUS MINOR.

RE'CTUS A'NTICUS LO'NGUS. See RECTUS INTERNUS MAJOR.

RE'CTUS ATTO'LLENS. See GENIO HYOIDÆUS.

RE'CTUS CRU'RIS; *rectus femoris, rectus anterior*, or *gracilis anterior*, rises by a strong tendon from the anterior and superior process of the ileum, and from the cartilaginous tip of the acetabulum, and is inserted into the upper part of the patella.

RE'CTUS DE'PRIMENS, et INFE'RIOR O'CULI. See DEPRESSOR OCULI.

RE'CTUS EXTE'RNUS O'CULI. See ABDUCTOR OCULI.

RE'CTUS INTE'RNUS; *gracilis internus*, rises close to the edge of the os pubis, where it joins to the ischium, and runs to the internal condyle. It serves to bend the thigh forward.

RE'CTUS INTE'RNUS MA'JOR; *rectus anticus longus, flexor capitis*, lies before the rectus internus minor; rises commonly by as many tendons from the transverse processes of the fifth, fourth, third, and second cervical vertebrae, and is inserted into the anterior part of the cuneiform process of the os occipitis, bending the neck forward.

RE'CTUS INTE'RNUS MI'NOR, A'NNUENS: *rectus*

interus minor of Cowper; *rectus anticus brevis* of Winslow; is also named *renuens*. It rises from the root of the transverse process of the atlas, and is inserted into the cuneiform process of the os occipitis, just behind the groove where the lateral sinus forms the beginning of the internal jugular. This muscle gives the head a lateral motion upon the atlas.

RE'CTUS INTE'RNUS O'CULI, rises from the bottom of the socket near the hole by which the optic nerve enters the orbit, passes on the side of the globe next the nose, and is inserted into the sclerotica. It draws the eye towards the nose. See ABDUCTOR OCULI.

RE'CTUS LATERA'LIS, rises from the transverse process of the atlas, and is inserted into the os occipitis and os temporis, near the mastoid process. It bends the head to one side.

RE'CTUS MA'JOR; *rectus capitis posticus major*, rises from the upper part of the spinal process of the dentata; runs upwards and outwards, and is inserted by a flat tendon, near where the os occipitis is joined to the os temporis, serving to bring the head backwards. It is in part a rotator of the head, and, though styled *rectus*, is in reality an oblique muscle.

RE'CTUS MI'NOR; *rectus capitis posticus minor*, rises from the knob which answers to the spinal process of the atlas, and passes thence to the head. It can only move the head upon the atlas.

RE'CTUS SUPE'RIOR O'CULI. See ELEVATOR OCULI.

RECU'RRENS, (from *recurro*, to return). The RECURRENT NERVE. See PAR VAGUM, and NERVUS.

REDDLE. An argillaceous ocre, formerly used as a tonic, and externally as an astringent.

RE'DUC, vel RE'DUX, (from *reduco*, to bring back). A FLUX, or a POWDER by which oxyds are reduced to a metallic form. Fluxes are generally either of the vitreous or the saline kind: by the former are meant all those that are, or readily assume a glassy form in the fire; the chief of which are the glass of lead, or of antimony, and borax: by the latter those composed of salts. There are fluxes of a yet cheaper kind; such as dried wine lees, dried cow dung, dried horse dung, dried river mud, fuller's earth, iron filings, &c.; and a variety of compound fluxes, some of which are chiefly adapted for particular ores: indeed almost every operator has his favourites. For the common black flux, see CALCINATIO.

REFECTI'VA, (from *reficio*). See CARDIACA.

REFRIGERANTIA, (from *refrigero*, to cool). A class of medicines of peculiar utility in all cases of increased tone or action of the sanguiferous system. As increased action of the vessels produces increased heat, so, on the other hand, different causes of the latter influence the former. If it were necessary to make any distinction in a class of medicines so simple, we should say, that they are adapted either for a sudden or a permanent effect. Of the former kind, cold is the principal remedy; of the latter, a diet of weak alimentary powers, or, more strictly, every means of lessening the proportion of the gluten in the circulating mass.

Cold is administered in the form of cold air, cold water, or the different fluids which attract caloric. The more temporary effect of cold produces, we have seen, reaction, so that the continuance of its application is

necessary. The neutral and earthy salts are, in different degrees, refrigerant; and nitre is perhaps the most powerful, or a combination of nitre with crude sal ammoniac. The acid fruits and the native acids appear to be refrigerant from the same principle, though they have some influence, when long continued, as weak aliments.

Sedatives, however, repress inordinate circulation by an action apparently chemical, and hold a middle rank between cold and the diminution of the denser parts of the blood. Emetics in nauseating doses are of this kind; probably the acid products of fermentation; more certainly the preparations of lead. Avoiding all stimuli must be also a comparative cause of diminished action.

The great source, however, of the change intended by this class of medicines is the diminution of the denser parts of the blood. Thus all evacuations of blood are permanently refrigerant; for though watery fluids are quickly supplied to fill the vessels, the gluten and red globules are of slower production. Low diet is a remedy of the same kind; and when we consider the effects of vinegar in reducing the bulk, we are tempted to believe that it may have some effect on the digestive process, and added to its sedative quality, obvious in the mouth and on the lips, may also lessen the proportion of gluten in the blood.

The great utility of refrigerants is chiefly seen in all inflammatory affections, and in all the pyrexia of Dr. Cullen, which depend on increased action, particularly hæmorrhages and inflammations. In these cases the diminution of the symptoms only affix the limits; but in the continued action of refrigerants of every kind we have reason to dread the most permanent chronic debility. The greatest caution is consequently necessary, in their employment.

REFRIGERA'TIO. See HORROR.

REFRIGERATO'RIMUM, (from *refrigero*). A REFRIGERATORY; the vessel filled with water, through which the worm passes in distillations, to condense the vapours as they pass through it.

RE'GIA A'QUA. See NITRUM.

RE'GIMEN, (from *rego*, to govern). The REGIMEN, or the regulation of the diet with a view to preserve or to restore health. See DIÆTA; (Stahl de Regimine). In chemistry it is the regulation of fires.

REGIONA'LIS MO'RBUS, (from *regio*, a country). See ENDEMIUS.

REGI'STERES, (from *rego*). REGISTERS, or OPENINGS, in different parts of furnaces, to be shut occasionally. By their means the fire may be regulated, for the heat is increased or diminished in proportion to the access of air. These holes should be from two to four inches wide, if the internal diameter of the furnace does not exceed a foot.

RE'GULIS BARBADE'NSIS, vel JAMAICE'NSIS. See PALMA NOBILIS.

RE'GULUS. A metal in its metallic form; from *rex*, because the alchemists expected to find gold in the metal.

RELAXA'TIO, (from *relaxo*,) *chylasis*. See PRO-CIDENTIA UTERI, and ATONIA.

REME'DIUM, (from *re*, and *medeor*, to heal,) a REMEDY; *boethema*; a medicine by which any illness is cured. See MATERIA MEDICA.

M m

REMITTE'NTES, (from *remitto*, to abate). REMITTING DISEASES are fevers in which the paroxysm abates without wholly receding.

As we have spoken so fully of intermittents, diseases of a similar nature with remittents, we have less temptation to enlarge on the present subject. Some considerations were, however, referred to this article. We have seen that the true regular intermittent has but one paroxysm in twenty-four hours. When a remittent first assumes the form of an intermittent fever, the remission is regularly more distinct; the sweat comes on, and the urine drops a more copious sediment. This remission becomes, by degrees, more perfect, and after the sweat there is some interval of apyrexia. The disease then soon becomes an intermittent. When the contrary change takes place, the paroxysm is prolonged, and its crisis is less complete. It is seldom prolonged to the period of the next attack; but the fever remains in a less degree, and its violence is gradually increased in each interval till the remissions are indistinct.

In general, every fever begins with exacerbations and remissions, but the exacerbations of the true remittent are, on the alternate days of the continued fever, every evening, and more slightly every day about eleven or twelve. Every fever approaches, however, the tertian type. Remittents generally show it very strikingly, and the most continued fevers have, as already observed, their more remarkable changes on alternate days, down to the fourteenth; the period, independent of accidental circumstances, of every continued fever. With respect to remittents, however, this is perceived most strikingly, for twenty tertian remitting epidemics are described for one quartan or quotidian remittent. In examining the symptoms of different epidemics, the succession of the paroxysms may appear to oppose this opinion, and quotidian remittents to be more common than we have represented. On a closer examination, however, these apparent amphimerinæ are in reality double tertians. Stahl has pointed out numerous instances of this kind in his dissertation *De Tertiana, Febris genium universum manifestante*. It is a principle which should be always kept in view, in every consideration relating to the progress of fever.

We found it difficult to explain why, after a complete solution of the paroxysm of an intermittent, the same series should recur. With respect to remittents there is little difficulty, for almost every epidemic of this kind is attended with asthenic symptoms, or rather with the most extreme debility. At the conclusion of the paroxysm, the sensorial energy is not restored: the fomes remains, till the returning evening exacerbation, or, more often, the returning tertian tendency renews the train of symptoms. These considerations render it highly probable that the true reason of the renewal of intermitting paroxysms is the imperfect restoration of the sensorial energy by the former fit; a cause already suggested, and which the remaining languor in the intervals strongly supports. This reasoning acquires more force when we find that all the febres comitatæ of Torti are remittents, and that the accompanying symptoms are chiefly those of debility. As we may suppose the nosology of Dr. Cullen to be generally known, it is sufficient to refer to his enumerations of the tertianæ

comitatæ of Torti, page 53, vol. ii. 1780. To this we may add the various accounts of the yellow fever of the West Indies and America; the epidemics observed by Sarcone at Naples; and the different publications respecting camp fevers, and those occurring in long voyages, especially in transports conveying large bodies of troops.

It is easy to say with our predecessors in this work, that we must "empty the bowels and throw in the bark." It is the language of inexperience and ignorance; but we need not enlarge on the more difficult parts of the treatment, as we have already noticed them in our account of the yellow fever.

The asthenic remittents of warm climates are the diseases in which cold applications are found chiefly useful; and the account which sir John Chardin gives of the treatment of the fever which he experienced at Gombroon is a good example of the practice. It consisted in cold drinks and cold applications. Cold affusions are too violent repellents of the blood from the surface; and sponging the body with cold water and vinegar is all that can be allowed in this line. The bark may assist recovery, but there is seldom any proper period for its use during the fever.

RE'MORA ARA'TRI, (from *remoror*). See ANONIS.

REN, (a kidney,) *nephros*. See RENES.

RENA'LES ARTE'RIÆ, (from *renes*, the kidneys,) *emulgentes arteriæ*, are generally two in number, and go out on each side from the lower descending aorta, immediately under the mesenterica superior. The right is situated more backward, and is longer than the left, because the vena cava lies on the right side between the aorta and the kidney. They run commonly without division, almost horizontally to the kidneys, into the depressions of which they enter by several branches which form arches in the inner substance of the viscera. From these arches many small branches go out toward the circumference, or surface of the kidneys. Sometimes two arteries go into one kidney. Generally the right renal artery passes behind the vena cava, and the renal vein in the other side; and the left artery first behind, and then before the vein. Sometimes they send branches to the glandulæ renales, membrana adiposa of the kidneys, and even to the diaphragm.

RENA'LES VENÆ, *emulgentes venæ*, spring from the inferior cava, when it arrives at the kidneys, into which these branches are sent. They are the largest veins connected with the vena cava, between the liver and the bifurcation. The right emulgent is the shortest, the left the longest; for it crosses the trunk of the aorta. Usually the left emulgent vein receives the left spermatic vein.

RENE'LIUS. See RHENCOS.

RE'NES, (*απο τῷ ᾠνι*, from the flow of urine). The KIDNEYS are two oblong flattened bodies, extending from the eleventh and twelfth ribs to the fourth lumbar vertebra. The right kidney lies under the great lobe of the liver, and is lower than the left, which is situated under the spleen. They resemble in shape a large bean, of which the concave side is towards the vertebræ. Their length is double their breadth, and the latter double their thickness. The upper extremity is broader and more incurvated than the lower, and the depression

in the concave side is oblong, surrounded by small tubercles. The kidneys themselves are covered chiefly with a cellular substance; for the peritonæum is extended only over the upper and fore side, so that, when the kidney adheres to the muscles, matter and even stones may be discharged through an abscess, without danger from access of air to the cavity of the abdomen. The aorta descendens, and the vena cava inferior, lie between the kidneys, pretty close to the bodies of the vertebræ. (See *RENALES ARTERIÆ* and *VENÆ*.) Each artery is surrounded by a nervous net work, from which the nerves enter with the arteries. The kidneys are covered on one side by the peritonæum, and the whole substance is invested by a capsule, composed of two laminae, connected together by cellular substance. The external lamina is thin and smooth, rendering the kidney uniform, and passing by numerous elongations into its substance. In children, the convex part is divided into little lobules; a form sometimes continued in adults. The substance of the kidney is divided into the external or cortical, and the internal, tubular, or mammillary portion, the latter of which is made up of a number of pyramidal bodies, about twelve in each kidney, whose points are received into the pelvis, so that the cortical part not only lies round the outer surface of the kidney, but its processes pass into the interstices. The cortical part is wholly vascular, but in minute injections, certain appendages, called *CORPORA LOBOSA*, are observable. These are natural cells, where the small arteries seem to be expanded. Ruysch thinks them only convoluted arteries. In the veins no cryptæ are seen, so that they are not extravasations; they are also uniform, and confined to the cortical part.

The ramifications of the blood vessels are peculiar; for in their ultimate branches they resemble stars, and in this form are lost on the proper membrane of the kidneys. The medullary, the striated, and the mammillary portions, are apparently continuations of the same substance, differing only in the proportion of red vessels. Every anatomist has refined in his observations on the structure of the kidneys; but these refinements are sometimes doubtful, and scarcely in any instance applicable to physiology. Each mammilla lies in a kind of membranous calyx, or infundibulum, which opens into a common membranous cavity, called the pelvis. After the infundibula have contracted into a conical form round the apices of the mammillæ, each forms a small short tube, which, uniting at different distances along the bottom of the sinus of the kidney, constitute three large tubes, passing from the sinus obliquely downwards, and uniting into one trunk called the *ureter*. This excretory duct runs down obliquely on each side, with a small degree of inflection, to the lateral parts of the inner side of the os sacrum, and passing between the rectum and bladder, terminates in the latter at its inferior part, near the vesiculæ seminales. The ureters perforate each coat distinctly in a slanting manner; so that their oblique insertion answers the purpose of a valve, when the bladder is distended. The internal ligamentary membrane of each ureter does not end with its passage into the bladder, but is continued toward the prostate gland, where it seems to be inserted; keeping the lower part of the bladder from too great distention, and the ureters fixed. The artery is in the upper part of the sinus of the kidney, and partly before the vein; the

vein is about the middle, and between the artery and the ureter, which is in the lower part, a little behind the vein, and partly surrounded by a branch of the artery. Nephrotomy therefore appears impossible; and the operation, however represented, is only opening an abscess in the loin, when, from inflammation, a concretion between the kidney and peritonæum has taken place. See *NEPHROTOMIA*.

One kidney is occasionally absent (Stoll *Ratio Mendendi*, ii. 386), sometimes of a monstrous size, from calculus or from purulent matter: it has been found to weigh thirty-five pounds. (*Histoire de l'Academie des Sciences*, an. 1732, and Haller de *Renibus Monstrosis*.) When one has decayed, the other has been enlarged. (Morgagni de *Sedibus*, &c. ep. xl. 14.) The most frequent changes are, however, a depraved substance and a diminished bulk. It has been found by Warton (*Adenographia*, p. 96.) so small as not to weigh more than a drachm; to be gangrenous; eroded; full of hydatids, or tubercles; and ossified. (Fearon in the *Medical Communications*, i. 27.) The principal complaint is, however, ulceration, of which we have numerous instances in the works of physicians of every age from the time of Hippocrates. (See *NEPHRITIS*.) Worms have been sometimes found in the kidneys; but rarely in the human kidney, except when ulcerated or consumed. Wounds in the kidneys are sometimes healed (Haller *Pathologia Obs.* 69.); but frequently fatal. Haller, in the *Gottingen Commentaries*, describes a case in which it was displaced, and also degenerated; and, in his *Opuscula Minora*, iii. 40, is an instance of the two kidneys coalescing. See also *CALCULUS*.

RE'NES SUCCENTURIA'TI, (from *succenturio*, to *supply or fill up*). These supplementary kidneys are sometimes peculiarly large, sometimes wanting, and occasionally double, without any peculiar affection of the function, and their use is little known. See *CAPSULÆ ATRABILIARIÆ*.

RENI'SUS, (from *renitor*, to *resist*). *RESISTENCE*, properly belongs to hardness, which resists impressions, or to perfect elasticity, if such existed. The *renitentes corporis dispositiones* are those powers of the body which resist the effects of morbid miasma, or contagion. Galen, and Vander Linden.

RENOVA'TIO, (from *renovo*, to *renew*). *RENOVATION*, or the restoration of a mineral body from an imperfect to a perfect state.

RENU'ENS MU'SCULUS, (*renuo*, because it throws back the head). See *RECTUS INTERNUS MINOR*.

RENUNCIA'TIO, (from *renuncio*, to *declare openly*, *elogium*, an opinion or judgment given by a physician or surgeon to a magistrate or judge with respect to the mortality of a wound; of poison being taken, &c. See Ambrosius Paræus, *Tractatus annexus Chirurgiæ de Renunciationibus*).

REPELLE'NTIA, (from *repello*, to *drive back*). *REPELLENT MEDICINES*; those which prevent such an afflux of a fluid to any part as would excite tumour or inflammation. These are chiefly astringents and stimulants. See *DISCUTIENTIA* and *INFLAMMATIO*.

RE'PENS, (from *repto*, to *creep*). The epithet of a plant which creeps on the ground.

REPRODUCTIO, (from *reproduco*, to *reproduce*, or *renew*). *Regeneratio*, *resurrectio*. This function has

been considered as more extensive and important in its operation than sound observation will support. In the lower orders of animals, composed like vegetables of a congeries of buds, each part can become a living animal, and this power is greater in proportion to the simplicity of the structure; but we have remarked, that fibrous, primordial parts are not reproduced in their original organized forms. We greatly doubt of the reproduction of the glans penis, recorded in the Medical Essays of Edinburgh, for this reason, that even the sensation is said not to have been injured; and totally disbelieve the Ephemerides Naturæ Curiosorum, where veins and the tongue are said to have been regenerated. If either could happen, it would not occur in solitary instances. See REUNIO.

Ambrose Parey Opera Chirurgica, lib. xxii.; Domier de Viribus Naturæ in Reparandis Partibus, &c.; Goldhagen de Reproductione Partium.

REPU'LSIO, (from *repello*, to drive back). REPULSION, an action of bodies opposed to attraction: a principle of the most extensive application in chemistry, indeed equally with attraction. It is supposed to depend on a polarity in the particles of bodies, analogous, if not similar, to that observed in magnetism. This is, however, explaining ignotum per ignotius; for we know little of the causes of magnetic phenomena. Repulsion, however, we know to be connected in general with caloric; but as antagonizing attraction it apparently acts independent of caloric. The French philosophers often confound it with resistance and elasticity.

RES NATURA'LES. According to Boerhaave these are life, the cause of life, and its effects, which remain in some degree, whatever may be the disease. See CIRCUMSTANTIA.

RE'SEDA, (from *resedo*, to atfese; from its allaying inflammation). See BARRAREA.

RESINÆ, (from *resin*, because it flows from vegetable substances). Resins are the productions of the vegetable kingdom, and sometimes exude spontaneously from trees, and at others are separated by chemical art. Except when they spontaneously exude, they are usually mixed with extractive matter and with gum. From the first they may be separated by sulphuric ether, and from the latter by alcohol. Yet in each case the resin is seldom wholly pure.

Resins are usually in some degree transparent, and their taste is sometimes pungent, though this vegetable substance is more frequently tasteless. Its colour is yellow or brown; its specific gravity about 1.10, and it is an electric. It is insoluble in water, soluble in alcohol, ether, and volatile oils; easily melts; burns with a white flame, much smoke, and a strong smell. When distilled it yields a large proportion of volatile oil, with a very inconsiderable one of acid: the latter is sometimes absent. When its solutions in alcohol, ether, or oils, are evaporated, the resin remains unchanged, with a smooth shining surface, styled a varnish. It is scarcely acted on by alkalis or acids, and, distilled in close vessels, furnishes some acid, and a large proportion of empyreumatic oil.

From these facts it might be supposed that resin is another form of oil; and, in fact, if volatile oils are exposed to oxygen, they become resins, forming in their change a little water, so that they probably lose a portion of hydrogen. If we wish to discover whether any

vegetable substance contains resin, we should pour on it sulphuric ether, and expose it to the light; when the resin, if any exist, will become of a brown colour. Resin has, therefore, apparently the same analogy to volatile which wax has to fixed oils.

Resins appear to be of almost infinite variety, and, indeed, every difference in the taste and flavour of the essential oils influences the sensible qualities of the resins derived from them. The principal resins are, *Chio turpentine*, from the *pistacea terebinthus* Lin.; the *Venice turpentine*, commonly employed in medicine; the *Strasburg turpentine*, from the common fir; *pitch*, from the *pinus picea*; *elemi*, from the *amyris elemifera*; *mastic*, from the *pistachia lentiscus*; *guaiacum*, from the *guaiacum officinale*; *ladanum*, from the *cistus ladaniferus*; *dragon's blood*, from the *dracena draco*; *balsam of Mecca*, from the *amyris opobalsamum*; *balsam of copaiba*, from the *copaifera officinalis*. Benzoin, the balsams of Peru and Tolu, and the storax, contain resin joined with the benzoic acid. See BALSAMUM.

All vegetable extractive matters, by an union with oxygen, seem to be in part changed to resin; so that the London college has properly directed decoctions of bark to be boiled only for a short time in close vessels. There are a variety of gum resins used in medicine, of which the principal are the fetid gums, aloes and opium.

The acrid resins exhibited by themselves often adhere to the coats of the intestines, irritating and inflaming them. These inconveniences are remedied by alkaline salts, by soap, and in a great degree by sugar, if previously triturated with the resin. Essential oils are said to correct resins; but the oil soon separates in the stomach, and the resin is equally active with the added stimulus of the oil.

The action of these medicines is extended beyond the primæ viæ, as is evident from the children being purged by the milk of those nurses who take them. See Neumann's Chemical Works; Aikin's Dictionary of Chemistry.

RE'SINA A'NIME. See ANIME.

RE'SINA FLA'VA remains after the distillation of oil of turpentine, and is the common resin of the shops, chiefly employed in external applications. It forms part of the composition of several plasters, and gives a name to one ointment, *unguentum resinæ flavæ*. (See BASILICON.) Lewis says, in taste it is considerably bitter, and sometimes given as a corroborant and diuretic, in preference to the turpentine, as containing less of its stimulating qualities. On trial we could not find any remarkable medicinal virtue in it, even in large doses. *Materia Medica*. See ABIES.

RE'SINA LUTEA AUSTRALASIE. The yellow resin of New Holland, is produced from a low herbaceous plant, which bears its fructification at the end of a long hollow reed. The resin seems to exude from different parts of the plant; but is found in the earth after the tears have separated, and may be obtained in large quantities. Its most powerful menstrua are alcohol and ether; but it is wholly soluble in the water of pure kali. It seems to be slightly tonic and antispasmodic, to which pectoral qualities have been liberally added; but does not promise to be an important addition to the materia medica.

RE'SINA RU'BRA AUSTRALASIE. The red resin of

New Holland, is a production of the *eucalyptus resinifera* of Willdenow, ii. 977, and Linnæan Transactions, iii. 84. It resembles in every respect the gum kino; nor is it in a medical view superior.

RE'SINA TO'STA, FRICTA, NIGRA. See COLOPHONIA.

RE'SINÆ FLAVÆ UNGUENTUM. See BASILICON FLAVUM.

RESPIRATIO, (from *respiro*, to take breath).

BREATHING, *anafncusis*, the action of taking in and discharging the air from the lungs, including, therefore, inspiration and expiration.

This function is of the most extensive importance, since there are few animated beings to whose circulating fluids the occasional access of air is not essentially necessary, either in its gaseous state, or as combined with water. In general the weight of the air is alone sufficient for its impulse, and it is necessary only to make some vacuum to admit either air or water. In the amphibia, and in fish, the aperture of the mouth, and the action of the jaws propels the fluid, either air or water, into the lungs or over the gills, that the blood may partake its salutary influence. In insects we find no apparatus to assist its action, though some such apparently exists, since the spiracula lead to canals which pass through the whole body, anastomosing freely with each other. The numerous spiracles seem to show, independent of these anastomoses, some separate influence, since by varnishing them in succession, so as to prevent the access of the air, the parts become successively paralytic; but the animal does not die till the upper apertures are closed.

In the human body air is received into the lungs in consequence of a vacuum formed by the elevation of the ribs. With their action the diaphragm seems to correspond; and from a convex form towards the cavity of the thorax, it becomes nearly straight. It has been represented as becoming concave; but this is wholly inconsistent with the phenomena of muscular action. When the action of the intercostals is remitted, the chest falls in consequence of the elasticity of its ligaments, and relaxation is a constant alternating state with contraction in every muscle, unless when diseased. This statement is now generally acknowledged to be correct; nor need we enlarge on the very different opinions which have been offered on the subject, or attempt to elucidate the difficulties, which, on other views, have been felt. The only remaining difference of opinion relates to the respective share of the diaphragm and intercostals in this function. The latter are said by some late authors to fix the ribs only, and that the enlargement of the chest is chiefly effected by the contraction of the diaphragm. Each, however, produces some effect, though the chief agent is undoubtedly the diaphragm. In women the intercostals seem to have a greater share in enlarging the thorax than in men, from the greater arches of the ribs, and the final cause is to assist respiration, when the motion of the diaphragm is impeded by the enlarged uterus. We have said, that all the ribs are raised, and this is perhaps strictly true, though Sabatier contends that the lower ribs descend. (*Memoires de l'Academie Royale, année 1778.*) Other physiologists have, however, drawn different conclusions, both from the structure of the parts, and from observation. It has been contended also, that as the external and internal intercostals cross each other obliquely, their action must be different, and

even opposite; but this has been fully contradicted by an experiment of Haller. In this experiment, it was also found, that in inspiration the ribs did not approach, but rather receded, and the space was, in part, gained by their protruding the sternum.

If, as we find in pregnant women, near the time of delivery, the intercostals carry on the function of respiration almost exclusively, so at other times it is chiefly, if not wholly, effected by the diaphragm. The union of the ribs with the sternum has been ankylosed sometimes with little injury to respiration, though more often with dyspnœa. When, from various causes, respiration is difficult, or, in other words, when water, inflammation, or other causes prevent the access of the air, or the elevation of the ribs, different neighbouring muscles are brought to the assistance of the usual agents, particularly those of the thorax in inspiration, and those of the abdomen in expiration. To give a more fixed point to the former, the elevator scapulæ are exerted, and the shoulders are raised.

In the whole of this function, the lungs are passive. Contiguous to the pleura, or at least separated only by an halitus, they are in contact with that part of the membrane which lines the ribs, both in inspiration and expiration, following in each the motions of the chest. The apparent object in this function is to expose every particle of blood, in succession to the air. The circulation seems to stagnate through serpentine vessels during expiration, and to flow freely when these are distended by the distention of the lungs. This, though apparently obvious, has been denied, chiefly on the principle, that the regular return of blood irritates the heart to regular contraction. Yet, when the lobules are distended, the canals of the vessels are necessarily straiter, and when respiration is more frequent, the pulse is quickened. Whatever be the state of this function, there is always sufficient blood carried back, to stimulate the heart to regular action. The blood vessels, we have seen, dispersed freely on the cellules into which the extremities of the bronchiæ terminate, and the containing coats are there so thin, that the wax of the injection exudes. Whether air can pass or repass has been the subject of some controversy; and however discordant the calculation respecting the extent of surface to which the blood is exposed, physiologists have generally agreed that it exceeds considerably the whole surface of the body.

The capacity of the thorax, the quantity of air taken in at each inspiration, and that remaining after complete expiration, has been differently estimated. Dr. Goodwyn, Mr. Coleman, Dr. Menzies, Mr. Kite, and Mr. Davy, by different experiments, have endeavoured to determine these questions; but the results have greatly differed. The subject does not appear to us one of considerable importance, so that, without any extensive disquisition, we shall adopt the conclusions of Dr. Bostock, in his late Essay on Respiration. He thinks, that about forty cubic inches of air are taken in, at each inspiration; that the lungs, in their natural condition, contain about 280 cubic inches; and that about 109 cubic inches are left after an ordinary expiration. Were we inclined to be critically minute, we think we could show that each number is somewhat too high; though, on the whole, these conclusions are supported by the

best physiologists. According to this calculation, however, about one seventh of the contents of the lungs are discharged by an ordinary, and somewhat more than half by a violent, expiration. A bulk of air nearly equal to three times the contents of the lungs will be thus discharged in a minute, and about 4114 times their bulk in twenty-four hours.

The uses of respiration were for a long time unknown; and imaginary effects were imputed to this function, particularly a more intimate mixture of the blood, by its fancied rapidity through the lungs. The whole mass of blood was supposed to pass through the lungs in the same time that it did through the rest of the body, and, of course, it was thought that its course must be more rapid, though it would be apparently obvious, that if the circuit was shorter, the celerity need not be so great. There is, however, no evidence, except the most uncertain calculation, that the whole mass does pass through the lungs in a corresponding period with its circulation through the whole system: nearly the same quantity is returned in the same time; but if we can measure, or at least approximate, the capacity of the vessels of the lungs, we are unacquainted with the extent of the vessels of the general, or as it may be styled, the aortic system. The nerves, in their passage through the diaphragm and the liver, from the compression of this muscle, were supposed to be affected; and the alternate contraction and relaxation of the diaphragm, as well as of the heart, were attributed to it. The nerves in general, however, pass through the more tendinous portion; and, as the diaphragm in its contraction is only less concave, the pressure on the liver cannot be considerable. The concurring actions of the stomach and abdominal muscles are the only powers which seem to emulge the biliary ducts. The influence of respiration on the course of the chyle in the thoracic duct is wholly imaginary; for pressure would only be useful if there were valves in it; but there are none; and, in experiments on living animals, the chyle is seen to move in the duct, though respiration be impeded or prevented.

The necessity of a supply of fresh air in respiration must have been known from the earliest periods; but the source of this necessity was little understood, till Boyle found the respired air loaded with aqueous vapour, and diminished in bulk. Mayow, whose fair fame has lately been rescued from oblivion, showed that some principle, which he called a volatile ethereal spirit, was imbibed from the air, and Dr. Black found that air respired contained carbonic acid gas. In this view of the subject, the unfitness of the air for the continuance of life was attributed to its diminished elasticity; for it was only suspected that carbonic acid gas was not fit for the continuance of this function. At last, after a period of more than twenty years, the constitution of the atmosphere was taught by Scheele and Lavoisier. They found that the apparently homogeneous atmosphere was composed of two gases of different properties, the oxygenous and the azotic, in the proportions, if bulk be considered, of 22 to 78, if the weight, of 26 to 74. This proportion of a fluid unfit for respiration, in air essentially necessary to life, was at first astonishing, till it was found that oxygen, like ardent spirit, was poisonous, by its destroying, from excessive stimulus, the excitability, and that, like it, to be innocuous, it must be lowered. Late experiments,

however, seem to show that the azote is not wholly useless. In explaining the process of animalization, we found the necessity of some principle, which could reduce the newly absorbed nutriment to an animal nature, and this appears to be azote. Yet the idea is encumbered with difficulties. Azote is an excrementitious fluid; and the changes produced in the blood, from its circulation through the lungs, are apparently those from oxygen only. It is not, however, a very absurd idea that a principle, at first necessary, may in the end be injurious from excess. In fact, Mr. Davy, in some very accurate experiments, found a remarkable deficiency of azote, amounting in twenty-four hours to about four ounces and a half.

The changes, produced in the atmospheric air, from respiration, are found chiefly to affect its oxygenous portion: this is diminished; and water, in the state of vapour, with carbonic acid gas, are substituted. It is not certain whether the latter gas is separated, or that its basis, carbone, with the oxygenous gas inspired, are its ingredients. The latter is more probable; and, though air contains a small portion of this gas (about 0.01) naturally, its proportion in expired air is very considerable. The oxygenous portion is undoubtedly that part most essential to life in general; and, from the highest order of animals to the lowest, the great difference seems to be, that in the latter the oxygen is more slowly and more completely separated. A man dies while the air still retains a comparatively large proportion of oxygen; snails separate the whole completely (Vauquelin *Annales de Chymie* xii. 278; Spallanzani on Respiration). In general, the greater the heat, the larger proportion of oxygen is necessary: birds, in general, die when two thirds of this principle are exhausted. In the human body the greater the rapidity of the circulation, whether from increased temperature, muscular action or fever, the larger proportion of oxygen is required. From a hundred parts of oxygenous gas, were lost in respiration, during an hour and quarter, when the animal breathed with great difficulty, three and a half cubic inches; and of the remainder sixteen and a half were absorbed by potash. In another experiment, the proportions lost and absorbed were somewhat greater; and it seems probable that the purer the air, the greater is the proportion of carbonic acid gas, as if at least a portion of the oxygen was converted into it. The quantity of oxygen, consumed by a man in twenty-four hours, is nearly 46.000 cubic inches, or about two pounds eight ounces troy; and the quantity of carbonic gas formed probably exceeds three pounds troy. The diminution of the bulk of air by one respiration is about $\frac{1}{18}$ of the whole. Mr. Abernethy supposed, that in common respirations the bulk of air was actually increased. It must undoubtedly be expanded by the heat of the body, a circumstance perhaps not sufficiently taken into the calculation; but he supposed also, that the carbonic acid gas was a superadded portion by exhalation from the vesicles of the lungs, while the diminution, apparent when an animal was long confined in air, arose, in his opinion, from its absorption. The quantity of moisture which is discharged has been differently estimated. It appears to have varied from 11180.57 to 13704 grains in twenty-four hours: the average is 12442; but perhaps the quantity of watery fluid, discharged at different times, varies. It is supposed, by Lavoisier, that this water is formed by the union of the oxygen with hydrogen.

Other physiologists have attributed it to a common exhalation; but, when the quantity of oxygenous gas which disappears is accurately examined, it will be found greater than can be accounted for, if we even admit portions to be employed in forming the water and the carbonic acid gas. It is highly probable, therefore, that it is in part absorbed. It is not, however, equally probable, that the water arises from the union of the oxygen with hydrogen. In general, the union of these gases is effected with some difficulty, and we suspect that, in every instance, the co-operation of the electric fluid is requisite. This fluid is generally found free, in the atmosphere, and may become an intermede in the present process. In the change also from a vegetable to an animal nature, hydrogen is generally lost; so that, though some of the water in expired air arises from exhalation and evaporation, some perhaps may be formed.

The changes produced on the blood by respiration are now more clearly understood than in the time of Boerhaave and Haller. Blood which has passed through the lungs is of a brighter colour than the venal blood, and has a greater capacity of heat. The colour we now know to be owing to the influence of the oxygenous gas, and the darker colour of venal blood to carbone. Blood, stagnating without the access of air, becomes of the nature and colour of venal blood: it assumes the same appearances, when exposed to any of the unrespirable gases.

When we considered (see DIGESTION) the different nature of the alimentary substances taken in, which are generally in part vegetable, we found an accumulating portion of carbone, and sometimes of hydrogen, while in the animal fluid these in part disappeared, and the predominating principle was azote. We can detect the source of the carbone in the blood, in conformity to this idea, from the thoracic duct, and we perceive that the newly formed aliment is anxiously conveyed, immediately on its reaching the blood vessels, to the lungs. The oxygenous gas is there united with it, and carbonic acid gas immediately formed, which is carried off by the air. At the same time probably a portion of hydrogen becomes water, while the azote taken in more completely animalizes this new fluid, and adapts it for furnishing the different secreted fluids. In the course, however, of the circulation, the oxygen more completely unites with the remaining carbone, so as to form an oxide, which thus assumes a dark colour, and requires a new supply of oxygenous gas, to change it to carbonic acid air, and fit it for its discharge.

The change thus induced by the circulation is chiefly chemical, since it may be imitated out of the body, and the successive variations, from the florid colour to the darker hue, and the contrary, may be effected by confinement from air, and again restoring the blood to the access of oxygen. The oxygen, in this instance, will have its effect through a small bladder, or indeed any vessel of the body, if the cellular substance be removed. The effect, therefore, will be more certain and speedy through the thin vessels of the lungs, whose diameters admit but a small proportion of the blood. It acts also through the serum, and, as Mr. Davy supposes, by its previous solution in this fluid. The reason of the more striking change to the florid hue we do not, however, understand, as we are so little acquainted with the na-

ture of the red globules. Their colour is found from some late experiments to be owing to phosphorated iron, with perhaps some uncombined oxide of the same metal. That the oxygen and hydrogen may form this acid, which immediately unites with the uncombined oxide, is not an improbable, though an unsupported suggestion; but we are apparently on the eve of obtaining more satisfactory information. The azote absorbed in this function contributes to form the gluten of the blood, which probably differs, in this respect only, from albumen; and, in an increased proportion, the fibrin. Whether this last principle can supply any waste or destruction of the truly fibrous parts of the body is doubtful. We have never been able to detect any such supply, nor has, in any instance, a truly organic portion of the body been reproduced, within our observation or recollection. Where organs are reproduced, it is not probably in a single animal, but in a congeries of animals propagated, analogously to vegetables, from buds.

One effect of respiration has been already considered, viz. the heat of animals. (See CALIDUM INNATUM.) We again introduce the subject to remark, that were this the effect of the chemical changes which take place in the lungs, this part of the body should be warmer than any other, which is by no means true. It is probable, therefore, that if wholly owing to a chemical change, it is produced by the gradual incorporation of the oxygen with the carbone, during the circulation, an opinion first suggested many years since by Dr. Duncan. The increase of heat which actually takes place in the lungs, from the play of affinities, is apparently compensated by the cold produced by the evaporation of the moisture.

With respect to other gases, the hydrocarbonate is the only one decidedly injurious from powers certainly sedative; for nitrous, vitriolic acid, and alkaline airs, are only these substances in a gaseous form. The carbonic acid air cannot be breathed for any considerable time, even when diluted, without pain; and hydrogen and azote appear to be only injurious inasmuch as they exclude oxygenous gas. Carbonic acid air, unmixed, produces an immediate spasm on the lungs, and cannot be taken into them. The last experiments of Lavoisier (*Memoires de l'Academie des Sciences*, 1789,) we perceive, afford great room for doubt whether the last is capable of any great advantage or injury, unless from constant use.

Annales de Chymie, vols. iv. v. vii. ix. xii. xxi. xxiv. xxix. xxxiv. xxxvi. xliii.; *Journal de Physique*, vols. xxv. xxviii. xliii. xlv. xlvii. lii.; *Memoires de l'Academie des Sciences*, pour 1739, 1724, 1729, 1777, 1778, 1780, 1789, 1790; *Memoires de la Societe Royale de Médecine*, année 1782-3; *Philosophical Transactions*, 1776, 1779, 1797; *Hales' Statical Essays*; *Richerand's Physiology*; *Blumenbach's Institutiones Physiologiæ*; *Fourcroy Médecine Eclairée par les Sciences*; *Davy's Researches*; *De la Rive de Calore Animali*; *Goodwin on the Connection of Life with Respiration*; *Kite's and Abernethy's Essays*; *Menzies and Coleman on Respiration*; *Lavoisier's Elements*; *Higgin's Minutes*; *Thompson's Chemistry*; *Bostock on Respiration*; *Spallanzani on Respiration*.

RE'STA BO'VIS, (because it hinders the plough).
REST HARROW. See ANONIS.

RESTAURA'NTIA, (from *restoro*, to revive). RESTORATIVES, *analeptica*, *resumptiva*. Medicines suited to restore lost strength; but chiefly confined to those medicines which repair the waste of fluids, and in that sense nearly synonymous with the *nutrientia* and *stimulantia*. See CARDIACA.

RESUPINA'TUS, (from *resupino*, to turn upwards). A leaf of a plant turned the lower side uppermost.

RESUSCITATIO, (from *resuscito*, to revive,) the art of reviving persons apparently dead. Apparent death, as remarked in the article MEDICINA FORENSIS, arises from narcotic poisons, either fluid from intoxication, or deleterious gases introduced into the lungs; excessive evacuations, extreme cold, sudden terror, hanging, or drowning. A stroke of lightning has been added to the causes; but the apparent death from this cause is real: the victim rarely recovers. The signs of death we have also enumerated in the same article; but having remarked their equivocal nature, we need scarcely add, that unless the cause has long continued, or the symptoms are peculiarly decisive in their degree, they should not deter us from continuing our attempts.

The principal cause of death in these instances is the destruction of the irritability of the muscular fibres, or a diminution of the fulness of the vessels to such a degree that they are no longer able to support the due tension of the brain. Hanging or drowning as connected with topical injury, we shall reserve for a separate consideration under the appropriate articles SUSPENSIO and SUBMERSIO.

The apparent death from loss of tension in the brain occurs where the evacuations, chiefly the sanguineous ones, have been excessive, or where it has followed sudden terror, which seems to paralyze the heart, or at least greatly to diminish its force. In the first case, if the sanguineous discharges continue, we must not too eagerly attempt resuscitation, as death will probably ensue from the return of the hæmorrhage. It requires the most careful attention, and the exhibition of such restoratives as will preserve life, but will not powerfully excite the action of the heart and arteries: such cases are not usually fatal, and we recollect no instance where increased discharges of any other kind produce apparent death, which requires the exertion of the medical powers of resuscitation.

Sudden terror partakes of each cause; for though it immediately destroys the irritability of the heart, yet it is fatal by depriving the brain of the tension which it derives from the fulness of the vessels. Its remedies will, therefore, be considered under the next head.

To restore the irritability of the sanguineous and nervous system, plans apparently the most improbable and absurd have been employed, sometimes with success. Bleeding is one of these, and when the immediate cause of the loss of irritability is a congestion in any system of vessels, or when a debilitating cause, from relaxation, occasions an accumulation of fluids, this evacuation is often useful. Thus it is equally beneficial in those cases of apparent death which follow a suddenly altered determination of the blood, or which proceed from deleterious gases of a sedative nature. Taking off from the load will often occasion an immediate contraction, as we know from the observation of Mr. Coleman, so often repeated; and when a chain of actions is once begun, it is usually followed by those

before associated with it. The blood in this case should be taken from a large orifice, that the necessary discharge may be made in the smallest space of time, and produce the desired alteration with as little debility as possible. For this reason topical bleedings, though directed to the affected part, are less beneficial, since the discharge is slow.

Emetics have been directed from an indiscriminating empiricism, rather than sound argument or judicious induction. Yet so general has been the practice, that it would be rash to deny their utility in some cases. The first action of emetics inducing nausea is undoubtedly sedative; and during the whole of this introductory process, emetics are debilitating powers. We know not that on this account these remedies should be rejected, since relaxation, in many instances, is the *novi motus initium*. Yet reasoning of this kind is too fallacious to support their use. The action of vomiting, on the other hand, we have found useful, even, we suspect, in cases where there is a considerable congestion of blood in the head. If then we can produce this action, without any, or with a very slight preceding nausea, we may perhaps assist recovery without adding to the debility. This effect may be produced by the vitriolated zinc, assisted by mustard whey, or camomile tea, with the aqua ammoniæ; or, if we still want a more active power, by a few grains of vitriolated mercury. It is obvious, however, that this remedy is confined to that period of recovery, or that degree of asphyxia, where the patient has retained, or possesses the power of swallowing.

Cathartics are also confined to the period when the powers of life have been partly roused, or are not wholly lost; and they should be of the most active kinds; but in the form of clysters they are among the earliest and most useful aids. In a moment of emergency three or four ounces of common salt may be dissolved in a pint and half of water; three or four ounces of soap, or a large table spoonful of the soft black soap, in the same quantity. If more time be allowed, three drachms of the pulp of colocynth may be boiled in a pint and half of water to a pint, and a bunch of groundsel, a weed found in every garden, will add to its activity. Tobacco clysters are subject to the same objections as emetics, and indeed are chiefly used for the relaxation they produce. Those who adopt the idea of relaxation contributing to a new chain of associated motions may employ them; but, though the theory might be rendered plausible, experience will contradict it, and tobacco clysters, with nauseating emetics, should be banished from the resuscitating powers.

Of the *diaphoretics* warmth and friction are only admissible, and these, with a few exceptions, are to be very early employed, and steadily continued. Clysters contribute to resuscitation by their warmth; and warm air blown into the lungs is highly useful. Expanding the chest we found the chief agent in the function of RESPIRATION, q. v. and in every case of apparent death there is usually an accumulation of mucus in the lungs, which the warm air will contribute to dissolve. Air of a higher quality, if at hand, will be more useful. Carbonic acid gas, and, as we shall find, water in persons drowned, produce a constriction on the glottis, which may not be removed; and indeed the difficulty of inflating the lungs, except by the most experienced operator, is considerable. Bronchotomy has been there-

fore advised; and this operation may be easily performed by a small, flat trochar, which may be introduced safely through the rings of the trachea, after cutting the skin, to lessen the resistance, which would otherwise require so great a force as might carry it beyond the posterior part of the tube.

General stimulants of the most active diffusible kind are immediately necessary, and the good effects of friction are greatly increased by every rubefacient, as common salt, flour of mustard, aqua ammoniæ, tinctura cantharidum, diluted vitriolic acid, &c. When the patient can swallow, wine or spirits, as nearest at hand, and most congenial to the feelings of the attendants, are generally employed, and they will not be improper: the volatile alkali is, however, always more useful, since these, though diffusible, are indirect stimulants. If given, they should be followed by warm fluids, impregnated with some of the common aromatic herbs, and particularly by nourishing broths, warmed by condiments, as the cayen or common pepper. Among the stimulants electricity and galvanism have been usually reckoned; but as higher degrees of each destroy by exhausting irritability, even the lowest are suspicious; nor can either be safely admitted in the form of shocks. Drawing sparks by an electrical machine will undoubtedly stimulate with less danger; but in this view it is by no means a powerful agent, and we have not yet learned to manage galvanism in the same way.

We have hinted at exceptions to the general directions respecting warmth, and we alluded to the cases of apparent death from intoxication, deleterious gases, and perhaps sudden terror. In these *cold water*, dashed against the face and breast, is often quickly efficacious. The seamen immerse their comrades in the sea; and the poor victims of the carbonic acid gas, in the Grotto del Cani, are recovered by throwing them into a neighbouring lake.

RE'TE, (from the Hebrew term *reshta*). A congeries of vessels, or any contexture of fibres resembling a net.

RE'TE MALPI'GHI. See PULMONES.

RE'TE MIRA'BILE, *dictyoides*, a congeries of blood vessels in the brain.

RE'TE MUCO'SUM. *Corpus mucosum* and *reticulare*. The true skin on its whole surface is covered with two lamellæ; the inner, styled *rete mucosum*, the exterior, the cuticle. The former is the principal seat of colour in man; in Europeans transparent, in mulattoes brown, and in negroes black. One of its uses is, to keep the papillæ moist, which would otherwise be unfit for sensation; and its colour apparently depends on the blood, which is darker in the African than in the European: the bile and semen of the Africans are said to be darker than of the Europeans. Wherever the cuticle thickens, the rete mucosum becomes thicker in proportion; and in the fœtus of nine months the rete mucosum is yellower than the cuticle. In Africans it is more easily separated from the cuticle than in Europeans.

RETE'NTA, (from *retineo*, to keep back). See EX-GRETA.

RETICULA'RIS MEMBRA'NA, (from RETICULUM, q. v.). See CELLULOSA MEMBRANA.

RETI'CULUM, (a dim. of *rete*, a net). The second stomach of a ruminating animal. (See ABOMASUM.) It sometimes means the *omentum*.

VOL. II.

RETIFO'RMIS, *amphiblestroides*, an epithet applicable to any net like appearance, used to express the coat of the eye, encircling, according to Galen, the vitreous humour; in modern language, the *choroides* which forms the plexus choroides, or retiformis. See CHOROIDES, and PLEXUS CHOROIDES.

RE'TINA, *amphiblestroides*, the expansion of the optic nerve on the inner surface of the eye. Though it is supposed to be a production of the medullary substance of the optic nerve spread like a membrane, and from its resemblance to a net, called *retina*, its medullary substance cannot be clearly traced as continued on to form it. There is, however, little doubt of its being an expansion of the nerve, and the seat of vision. (See OCULUS.) Haller records a case in which it was changed to a solid substance.

RETRA'HENS AURI'CULUM, (from *retraho*, to draw back). See ABDUCTOR AURIS.

RETROVE'RSIO U'TERI, (from *retroverto*, to turn backward). See PROCIDENTIA UTERI. In this disorder the womb falls backward, between the rectum and vesica, with its fundus on the intestinum rectum, raising the os tincæ to the upper part, and drawing the meatus urinarius from its natural position. It sometimes happens that the fundus is thrown over the os pubis, and the meatus drawn backward; but this cannot be a *retroverted* uterus, and indeed seldom occurs but in women who have borne many children. The retroverted uterus often happens in the early stages of pregnancy, seldom later than the fourth month, occasioning first a difficulty, then by degrees a suppression of urine, soon after of the intestinal discharge. The urine is in this case to be drawn off by means of the catheter, and a stimulating clyster injected. The woman is then placed on her knees and elbows, with her head downwards, and by introducing one hand up the vagina, we endeavour to draw it forwards, assisted by two fingers in the anus. After repeated trials in different positions, we often succeed, and we must then be cautious to keep the woman in the most perfect state of rest till the uterus rises above the pubes. See London Medical Observations and Inquiries, vol. iv. p. 388, &c. Hunter's Tables; Denman on the Retroversion of the Uterus; White's Surgery, p. 163.

REUNIO, (from *reuniri*, to unite again). The union of parts separated by wounds or accidents. This is a very important function of the human system, and most happy provision of nature to prevent the consequences of injuries. When any part is wounded, an inflammation of the extreme vessels apparently takes place, and an effusion, as in common inflammations of membranous parts, follows. This effusion consists of the gluten, perhaps the fibrin, of the blood; and when the solution of continuity is in the bone, the divided arteries retain their function of separating the calcareous phosphat. The watery parts, in which the gluten and the fibrin were dissolved, are absorbed, and the solid substance constantly assumes a looser texture; in fact, becomes a cellular membrane, more or less dense in proportion to the quantity of fibrin; in other words, to the strength of the constitution. Sometimes arteries seem to shoot into the inorganic mass of a firmer texture, which seems to defend the divided extremities, and suggested to Mr. Hunter his opinion of the vitality of the blood; but this extension of the arterial system is limited,

N n

and not in a greater degree than can be accounted for by the convolutions of the extreme vessels. In reality, with the utmost attention we have been able to exert, we have never seen in the human system the reproduction of an organized part; nor in the cellular substance any thing but inorganic matter. See REPRODUCTIO.

RE'XIS ANE'BION. See ANCHUSA.

RHA VE'RUM ANTIQUO'RUM, (*Ρα, from the river Rha, the Volga, upon whose banks it grew*). See RHAPONTICUM.

RHABA'RBARUM, RHUBARB; *rheum*; *lappathum Orientale*; et *Chinense*. The latter Greeks are said to have called it *barbaricum*, because it was brought from a country lying on the Sinus Barbaricus.

It is the *rheum palmatum* Lin. Sp. Pl. 531, a plant resembling the docks. The seeds of different species were at various times brought to us, particularly those of the *rheum compactum et undulatum*; but the seeds of the true kind, the *rheum palmatum*, we owe to the care of Dr. Mounsey; though different naturalists contend that rhubarb is sometimes procured from the other species just mentioned. The leaves are palmated, acuminate, and slightly hairy. The root, the only part in use, is brought from China, and from Siberia, by way of Russia. The latter is generally brought to us from the Levant, and has consequently obtained the name of Turkey Rhubarb. It is of a finer grain than the Chinese, is perforated in the middle, and less active as a purgative, though supposed to be a more powerful astringent. The English rhubarb is a still more active laxative; but inferior in every other respect. The root is always raised too soon, for it should not be less than twelve years old. All the foreign rhubarb is, however, brought from nearly the same place, a chain of high mountains near Sini in China, extending from the thirty-fifth to the fortieth degree of north latitude: the difference owing, it is said, only to the care in selecting and drying the roots. The Turkey rhubarb is in flatish round pieces, perforated in the middle, the Chinese (East Indian) in cylindrical ones.

The rhubarb which is in smell aromatic, in taste subacid and bitterish, of a lively colour when cut; firm, and solid, but not hard; easily powdered; when powdered of a bright yellow; and, when chewed, imparting to the saliva the same colour, without a mucilaginous taste in the mouth, is always preferable.

Rhubarb yields its purgative quality most freely to water; after digesting with water it becomes inactive; but after repeated digestions with alcohol, it retains a portion of its purgative virtue. The powder is most active, given in a dose from ℥ i. to ℥ i. An infusion in

water follows; but the spirituous tincture, though less purgative, retains more of the aroma and of the astringency of the root. The watery infusion, reduced to an extract, is less powerful; but the spirituous extract is nearly of the strength of the powder.

The tincture of rhubarb of the London college is directed to be prepared in the following manner: Take of rhubarb sliced, two ounces; smaller cardamom seeds, husked and bruised, half an ounce; saffron, two drachms; proof spirit of wine, two pints: digest for eight days, and strain.

The compound tincture of rhubarb is prepared by digesting two ounces of sliced rhubarb; ginger powdered, and saffron, of each two drachms; liquorice root bruised, half an ounce, in twelve ounces, by measure, of proof spirit for fourteen days, adding a pint of distilled water.

Wine of rhubarb.—Take of rhubarb sliced, two ounces and a half; smaller cardamom seeds, bruised and husked, half an ounce; saffron, two drachms; Spanish white wine, two pints; proof spirit of wine, eight ounces by measure: digest for ten days, and strain. Pharm. Lond. 1788.

These are intended for stomachics and tonics, as well as for purgatives. Spirituous liquors chiefly extract that part of the rhubarb in which the two first qualities reside. When given with the first intention, a spoonful or two is a dose; but when used as purgatives, from two to three ounces must be given.

The Edinburgh college directs an infusion in water, in the proportion of an ounce to a pint, adding to each pint an ounce of the spirituous cinnamon water.

Toasting rhubarb, supposed to add to its astringency, only diminishes its purgative power, so that a larger dose may be taken.

Rhubarb is a mild cathartic and astringent, strengthening the intestines, and leaving the belly costive. It is consequently preferred in diarrhoeas and dysenteries; but in the latter is often inconvenient from its astringent property. It is by no means peculiarly advantageous as a purgative, though for ages highly valued, since it acts with considerable irritation and much pain. It is chiefly useful in weak stomachs as a laxative, uniting an astringent power; and often as a cholagogue, since it seems to irritate in a peculiar manner the orifice of the biliary ducts.

It is often advantageously joined with neutral salts, and these appear to form an useful laxative in fevers, as the salts seem to act more quickly, and to assist the solution of the rhubarb. Soap, in obstructions of the bile, is not only a convenient addition, but the medicine appears to act with more success. In the diseases of children, it is apparently useful by dislodging the viscid mucus, and discharging the bile; and in this effect it is assisted by magnesia. Alkalis, absorbent earths, and neutral salts, change its yellow colour to a red, and seem to produce some chemical change in its nature; for with these additions it is more quick in its operation, and apparently more mild. Chemistry has not, however, taught in what this change consists; for rhubarb has ceased to be the fashionable medicine it once was. The extractive matter is the chief repository of its virtues; but the aroma apparently consists in the resin; and when rhubarb has lost the aroma, its purgative powers are greatly diminished. As the extractive matter is soluble both in water and alcohol, it probably

contains a portion of resin, which is dissolved in the aqueous fluid by the intermede of the gum. The vinous tincture, which we have described, is apparently its best preparation. Neumann obtained from 480 grains 180 of alcoholic, and afterwards 170 of watery extract. By inverting the process, the former amounted only to five grains, and the latter to 350. Rhubarb also contains some tannin, and about one sixth of oxalate of lime.

It has lately been applied to ulcers with some success, though the particular species of ulcers to which it was best adapted, or the principle on which it is supposed to act, have not been explained. It is sprinkled over the wound lightly, once, sometimes twice, a day; but in cases of great irritability, one part of powdered opium is added to eight of rhubarb. The compound powder of rhubarb, formed of equal parts of rhubarb and ipecacuanha, has been employed for the removal of warts.

See Lewis and Cullen's *Materia Medica*; Neumann's *Chemistry*.

RHABA'RBARUM A'LBUM. See MECHOACHANA ALBA.

RHABA'RBARUM DIOSCO'RIDIS. See RHAPONTICUM.

RHABA'RBARUM MONACHO'RUM. See LAPATHUM HOR-TENSE.

RHABA'RBARUM SIBERICUM, *rheum undulatum* Lin. Sp. Pl. 531. See RHABARBARUM.

RHABDO'IDES, (from *ῥαβδος*, a straight twig, and *ειδος*, form). See SAGITTALIS SUTURA.

RHACHIS. See SPINA.

RHACHISA'GRA, from *ῥαχίς*, and *αἶμα*, pain). See ARTHRITIS.

RHACHIÆ'T, or RHACHITÆ, (from *ῥαχίς*). The muscles belonging to the spine of the back.

RHACO'SIS, (from *ῥακος*, a rag,) *detritio*. A ragged excoriation of the relaxed scrotum.

RHA'GADES, (from *ῥηγνυμι*, to break off). CHAPS, CLEFTS, or FISSURES in the SKIN; are usually caused by a want of moisture, either from a defect of perspiration, or from an unusual dryness of the air. They are seated about the anus and various parts of the pudendum muliebre, the corners of the mouth, nostrils, eye lids, nipples, &c. From these chaps issues a thin, sharp ichor, sometimes venereal, or the production of other acrimony; at times they are very painful. If newly contracted, they are easily removed; but if their lips are deep, callous, and inflamed, the difficulty is considerable. Emollient and sedative applications are the most useful; but the hard, callous lips must be scarified. See a Treatise on the Venereal Disease, by N. D. Falk, M. D. edit. 2. 1774.

Different from the rhagades, in appearance, are the chaps in the palms of the hands and soles of the feet; proceeding often from syphilitic virus, but more frequently either from too great dryness, or some occupations which destroy the organization of the cuticle and cutis, as dyeing, brass work, soldering, &c.

RHA'MNUS, (from *ῥαίω*, to destroy, because of its thorns). *Spina cervina, solutiva, purgatrix, infectoria, cervi*; *hippophæes*. BUCKTHORN and PURGING THORN, *rhamnus catharticus* Lin. Sp. Pl. 279, is a prickly bush, or a low tree, common in hedges, having pointed leaves; producing small green flowers in June, and in the beginning of October black berries, which contain a dark green juice, with four seeds in each.

It is usual to find these berries mixed, with the berries of the black elder, and of the dog berry tree; but the juice of the buckthorn berries is green; and the buckthorn berry hath four seeds. These berries have a faint unpleasant smell, a bitterish, acrid, nauseous taste; operate briskly by stool, and have frequently been employed as hydragogues. They occasion dryness in the mouth and throat, with thirst, and pain in the bowels, unless warm liquor is frequently drank during the operation. Twenty of the fresh berries; forty or sixty in decoction; a drachm or a drachm and a half of the dried berries: an ounce of the expressed juice, or half an ounce of the rob, or extract, are the usual doses: but the juice made into a syrup is generally preferred by physicians, though it is rarely prescribed alone. If the berries are not pressed, the juice is more pleasant, and also more active as a purgative. The inner bark of the tree is said to be a strong purgative, and to occasion vomiting.

The London College order the syrup of buckthorn to be made in the following manner: take of the juice of the berries of buckthorn, ripe, and fresh gathered, one gallon; ginger bruised, one ounce; pimento in powder, one ounce and a half; sugar, seven pounds. Strain the juice after it has stood some days to subside; and in a pint of it macerate the ginger and pimento for four hours, and strain. Boil the remaining juice to three pints; add that part in which the ginger and pimento has been macerated, and make the whole with sugar into syrup. (Pharm. Lond. 1788.) From one to two ounces are given for a dose, but it is rarely used, on account of its nauseous taste, and sometimes its violent operation. When the berries, however, are not pressed, its taste is pleasing. See Cullen's and Lewis's *Materia Medica*; Neumann's *Chemistry*.

A name also for the *paliurus, hippophæes, alnus, nigra*, and *frangula*.

RHA'MNUS ZI'ZIPHUS. See JUJUBA.

RHAPO'NTICUM, (the Rha of PONTUS). RHAPONTIC, *rheum*; *rheum ponticum*; *rha verum antiquorum, rheum Dioscoridis; rhapsonticum Alpini; rhabarbarum Dioscoridis*; ENGLISH RHUBARB; *rheum raponticum* Lin. Sp. Pl. 531. Leaves smooth and roundish, pedicels somewhat channelled: grows wild on the mountains of Thrace, whence Alpinus brought it into Europe about the year 1610; and it bears the hardest winters in our climate. The roots are often mixed with those of the true rhubarb, but are detected by their mucilaginous taste when chewed, and not tingeing the saliva of the bright yellow of the true rhubarb. The rhapsontic when cut through appears regularly marbled in a radiated manner; is dusky on its surface, and of a loose spongy texture; more astringent than the *rheum palmatum*, and less purgative; requiring for the latter purpose two or three drachms. See Raii *Historia*; Tournefort's *Materia Medica*.

RHAPO'NTICUM VULGA'RE, *rhapsonticum folio heleni incano, centaureum majus, centaureum magnum*. GREAT CENTAURY, COMMON RHAPONTIC; *centaurea rhapsontica* Lin. Sp. Pl. 1294, is a large plant with leaves composed of oblong serrated segments set in pairs on a middle rib, edged in the intermediate spaces with a serrated margin; the stalk dividēs towards the upper part into several branches, which bear on their tops, round, soft, scaly heads, from which arise bluish flosculi, followed

by down, inclosing the seeds. It is perennial, a native of the southern parts of Europe, and raised in our gardens. The root is of a dark black colour on the outside, internally reddish, yielding, when fresh, a juice of a deep red; with a slight, not disagreeable, smell, and in taste viscid, with sweetness, roughness, and some degree of acrimony. It is considered as an aperient and corroborant, and supposed to be particularly useful in diarrhœas; but very much inferior to the true rhapontic. See Raii Historia; Tournefort's *Materia Medica*.

RHATANIA, a native of South America, not yet introduced into any botanical system. This root is about the size of a crow quill, and the cortical part is very thick, the ligneous very fibrous. When recent it is succulent, and full of extractive matter, which, when pressed out and evaporated, furnishes what has been styled the *American extract of bark*, and an astringent, coloured, ingredient for the red wines of Portugal. The extract mixes readily with water; and the powder resembles that of the pale bark. It precipitates a greater proportion of tannin than the Peruvian bark, is more pleasing, it is said, to the taste, and sits easier in the stomach. Half a drachm of the extract makes a turbid solution in eight ounces of water, said to equal in virtue the same quantity of a strong decoction of the Peruvian bark.

RHE'NCHOS, (from *ῥῆγχα*, to snore). *Rhochmos*; *ronchus*; *stertor*, SNORING; a sound supposed to be made betwixt the palate and nostrils by persons asleep. Independent of sleep, this noisy respiration is a symptom of apoplexy, in which the mucus from the fauces is forced through the nostrils. Slevoght attributes it in some instances to the premature healing of the parotid ulcers of children. See Halleri *Dissertationes*, ii. 43.; and Alberti de *Rhoncho Dormientium*.

Cerchon or *cerchnos* is that rattling noise made in respiration, from the larynx, or the aspera arteria, when the air passes through an accumulated fluid, in cases of asthma, or the last struggles of exhausted nature.

RHE'ON, and **RHE'UM**. See **RHAPONTICUM RHABBARUM**.

RHENOPHO'NIA, (from *ῥηνόφωνια*, vox peregrina). See **PARAPHONIA**.

RHEU'MA, (from *ῥεω*, to flow). A defluxion of fluids, in the language of former pathologists, on any part. More properly an increased, and often an inflammatory action of the vessels of any organ, generally confined to inflammatory action of the mucous glands, attended with increased discharge and an altered state of their excreted fluids.

RHEU'MA, CATARRHA'LE, and **EPIDE'MICUM**. See **CATARRHUS** and **INFLUENZA**.

RHEUMA'TICA, (from *ῥευμα*). The **RHEUMATIC FEVER**.

RHEUMATI'SMUS, (from *ῥευμα*). The **RHEUMATISM**, a painful disease, affecting the muscles in different parts of the body; sometimes it is supposed the viscera also. It is with or without a fever; called the *acute*, or *chronic rheumatism*. Dr. Cullen places it among the *phlegmasiæ*, defining it a disease arising from an external, and for the most part from a perceptible cause, attended with fever, pain about the joints, fol-

lowing the course of the muscles, affecting the knees and larger joints, rather than those of the hands and feet, increased by external heat. The acute rheumatism is called *myositis*, when the pain is seated chiefly in the muscles; *lumbago*, *lordosis*, *nephralgia rheumatica*, and *tabes dorsalis*, when in the loins; *ischias*, when in the muscles of the hips; *pleurodine rheumatica*, and *pleuritis spuria*, when in the muscles of the thorax.

The chronic rheumatism is considered by Dr. Cullen as generally the mode in which the acute rheumatism terminates, and he styles it *arthrodinia*, defining it, after the rheumatism, some violent exertion, or subluxation, pains of the joints or muscles, much increased, particularly on motion, more or less erratic, and alleviated by the heat of the bed, or other external heat. The joints are weak, rigid, very readily or spontaneously growing cold, not attended by any febrile affection, and for the most part without any swelling.

Each variety may be either acute or chronic; yet the latter, though often a sequela of the acute, is in many instances truly a distinct disease; and, as already observed, nearly allied to palsy. In the progress from one to the other state, as in ophthalmia, there are many shades of difference, so that we can scarcely say where the one begins or the other ends. Yet when each is fully established, there can be no doubt of ranking them as distinct species. By assuming articular pain as a genus, independent of fever, we have been able to connect these diseases, without losing sight of the operations of nature, or the rules of classification.

Persons of any age may be afflicted with the acute rheumatism; but it is usually the disease of the young, the strong, and active: while the chronic rheumatism occasionally affects those more advanced in life, and in these it is often peculiarly distressing and obstinate.

The acute or inflammatory rheumatism is attended with fever, pains in the limbs, generally felt in the joints, preventing their motion, and often accompanied with heat, redness, and swelling of the part. When the redness is fixed, and a swelling comes on, the fever and pain abate, though they sometimes continue many days, generally, though not universally, increasing in the evening.

In many instances the fever first appears, and is highly inflammatory, assuming only its peculiar local appearance after some days. The pain is often felt in the muscles, but it shoots out with the greatest violence in the joints; and as it is there felt most severely, the attention of the patient is chiefly directed to them. In many instances it is apparently as much a disease of the joints as the gout itself.

After some days, the pain commonly quits one part and attacks another; but the knees, hips, loins, nape of the neck, shoulders, shoulder blades, arms, and elbows, are its usual seats; sometimes the feet, ankles, and wrists, are similarly affected, but seldom the fingers or toes. The tenderness of the parts diseased is extreme. The violence of the acute rheumatism sometimes continues about fourteen days, but generally longer, and unexpectedly recurs, when it has appeared to vanish. A weakness and swelling will often remain for a long time.

Rheumatism is generally attended with copious

sweats; but these contribute to support the opinion we endeavoured to establish in the articles DIAPHORETICA and FEBRIS, q. v. that warm fluid sweats, while the skin underneath feels tense and harsh, are not salutary. They certainly are not so in the disease before us, and until the sweat is less clammy, attended with less heat, and a free soft pulse, no relief follows. The urine often deposits a sediment of a dark red colour through the whole course of the disease; but this seems to arise in part from its paucity, since the discharge is compensated by the sweating, and in part from the febrile spasm not being communicated to the renal vessels. Yet we recollect one instance, if we mistake not, in Leigh's History of Lancashire, where it is said that the urine did not contain its usual saline contents. Sometimes a red sediment is supposed to be critical; but in such cases there is reason to apprehend a mixture of gout. The blood is always sily even in constitutions otherwise debilitated; and in the most asthenic states of chronic rheumatism. Miliary eruptions are said to be critical; but it is observed by Dr. Rutherford, that no sweating proceeds from the pained parts, except when the disease yields; and when the perspirable matter has been retained, it often flows with such rapidity as to be stopped under the skin, and to produce papular eruptions. This seems to be the cause of miliaria, when it appears critical.

The distinction of rheumatism is often peculiarly difficult. With gout it is sometimes mixed; but more often the mixture of the two diseases is supposed to exist by those to whom accurate discrimination is an inconvenient task. We have already noticed the distinguishing symptoms under ARTHRITIS, q. v.; and we would only correct the diagnosis in one respect, viz. the remitting form of the disease. Each remits; the gout, however, irregularly; the rheumatism follows the common febrile periods of remission and exacerbation.

We have observed, that rheumatic pains in the chest resemble peripneumony, or pleurisy, and in the abdomen, enteritis. In each case the soreness to the touch, the pain felt at the origin or insertion of the muscles, while the more appropriate symptoms of the real inflammation of the part are absent, will sufficiently distinguish the nature of the disease. The lumbago sometimes resembles nephritis, or a stone in the kidneys or ureters; but may be easily distinguished. A stone in the kidneys is attended with some irregularities in the secretion of urine, generally with sickness in the stomach; in the ureters, by sickness, a pain shooting down the thigh, with a numbness of the thigh, or a retraction of either testicle. In each case also there is no difficulty of bending the body, which is a constant symptom of lumbago. The sciatica cannot be easily confounded with any disease.

The seat of rheumatism has varied according to the fancy of every author; for reason and observation have seldom lent their aid. Dr. Motherby is decidedly of opinion that its seat is the cellular substance, and its cause acrimony, without inquiring whether the cellular substance is sensible, or what is the source of the acrimony when the disease arises from cold. Dr. Smyth, in the Medical Communications, fixes it in the muscular fibre; but of the nature of the fibre, independent of its vessels and nerves, we know nothing. Some au-

thors suppose it seated in the ligaments, others in the cartilages; but in general it is supposed to arise from acrimony, either from the air, from dysentery, from pituita, suppressed gout, repelled eruptions, from lues, or scurvy. These opinions have been apparently suggested from rheumatism succeeding such diseases in particular cases; but neither system will bear the test of examination as a general cause.

Rheumatism is undoubtedly an inflammatory disease, and its seminum at least is inflammatory diathesis, which consists, as we have said, in increased tone of the arterial system. This is proved by the usual victims of the disease, who are the robust and strong; by the symptoms, those of inflammatory fever; and by the remedies, such as oppose inflammatory diathesis. Even in the weak and emaciated the pulse is harsh, the blood coriaceous, and bleeding often indispensable. It is an inflammatory affection also of the muscles; for motion is painful, the muscles are sore to the touch, and we may assume as a position, at present granted, that muscular organs are only affected. Though the muscles are the seat of the disease, the pain, we have said, is chiefly felt in the joints; and this Dr. Cullen explains by the general principle, that when membranes are affected, the pain is chiefly perceived at their extremities, as the irritation of a vomica in the lungs is felt at the epiglottis, and of a stone in the bladder at the extremity of the urethra. This explanation, however, we are unwilling to admit, as the present disease seems to have no analogy with membranous inflammation. In general, the more closely compacted organs, though insensible in a sound state, are more acutely painful when diseased; and whatever becomes of the question respecting the continuation of the muscular fibres in the tendons, yet both receive arteries from the same trunk, and both must suffer when these arteries are diseased; the tendons, in consequence of their structure, most severely; and thus the pain is chiefly felt about the joint, where the arteries with greater difficulty admit of distention.

It is not easy to say in what consists the difference between rheumatic and membranous inflammation; in other words, between inflammation of the arteries themselves and the membranes on which they are dispersed. That there is a difference is evident; for rheumatism seldom terminates in effusion, scarcely ever in suppuration. The joints indeed sometimes continue puffed, and the limb itself occasionally swollen. We recollect, too, that Morgagni records a case in which rheumatism terminated in suppuration (Ep. lvii. art. 20), and a similar one occurs in the second decad of the Medical Commentaries (iv. 198). We may reply, however, by the old logical axiom, *exceptio probat regulam*; so few are the cases of suppuration, that this is not the natural termination. It is not improbable that, while topical debility occasions the obstruction in the common inflammation, too great action may be its cause in rheumatism; so that while the former is relieved only by effusion, the latter is carried off by the powers of the vessels themselves. This idea is in some degree supported, when we reflect that rheumatism, of all the internal inflammations, is best relieved by stimulants after the phlogistic diathesis has been removed by bleeding.

Rheumatism, therefore, appears in every view of the

subject to consist in inflammatory action of the arterial system, and probably inflammation of the coats of the arteries themselves. This idea will meet every circumstance of its appearance, and connect the various remedies of the most experienced practical physicians. We certainly see rheumatism distinctly only in the voluntary muscles; but if these opinions have any weight, there is no reason why the internal organs should not suffer in the same way. Authors have spoke of rheumatism having affected the heart, the diaphragm, the liver, the intestines (Eyerel), and other organs, when transferred from the limbs. In cases of metastasis only the nature of the inflammation can be exactly perceived; for if these parts are originally attacked, the symptoms will not differ from common inflammation.

The remote causes are cold applied when the body is heated, or indeed any cause of the true inflammatory fever may be occasionally attended with rheumatism. It has been sometimes described as epidemic, and it may appear so in weather unusually cold and uncertain; but we suspect that these epidemic rheumatisms are truly synochi, which are often at first attended with irregular wandering pains in the limbs. The remark of Plencis is of more importance, that rheumatisms are influenced by the nature of the reigning epidemic. *Acta et Observata Medica*, 94.

Rheumatism is seldom fatal; but it is often a disease of peculiar obstinacy, and, in a more or less acute form, sometimes continues for many months. In these cases the phlogistic diathesis of the vessels continues, while the strength in general decays, and prevents the most salutary discharge by bleeding. The pain continues with a violence somewhat remitted, but with severe occasional exacerbations; the limb wastes; the strength, and the colour of the countenance, decline; the face sinks, and the patient often continues in this exhausted state for many months, sometimes for years. But to the disease in this chronic form we shall return, and now only add, that rheumatic patients are subject to relapses; and, as in other inflammations, the vessels, by repeated increased action, become more irritable, and more subject to spasmodic contraction.

The experience of many ages has established the utility of BLEEDING in acute rheumatism; and blood must be drawn from a large orifice, in a considerable quantity, frequently repeated. The severity of this evacuation, described under the article PLEURITIS, q. v. is not too great for the present complaint, if the patient be robust and strong. The usual guide is a more soft and slow pulse, a diminished heat, and a moist skin. We are always cautioned, however, that if we carry this evacuation too far, we may lessen the strength, and induce the disease in its more chronic form. There is probably a foundation for this caution, since, if we diminish the vis vitæ so far as to prevent the evacuation, next in point of advantage, that by the skin, we have no means of taking off the phlogistic diathesis but a repetition of the bleeding, which the strength will not bear. In general, then, when the hardness of the pulse remits, the bleedings should be stopped, and we must apply to other means of perfecting the cure.

Topical bleedings would appear highly advantageous; but we gain little from them while there is any remaining fever. The disease continues, and the affection of the limb is only a symptom; for by bleeding topi-

cally in an early stage of rheumatism we often occasion a metastasis to some other part. Another reason which seems to render topical bleeding less advantageous is, that the pain is often felt in the joint when the disease is in the whole muscle, for the reasons already assigned, so that the remedy is only in appearance topical.

Though *cathartics* generally diminish phlogistic diathesis considerably, yet they do not greatly relieve rheumatic pains; and the reason will be obvious, if our idea be correct, that rheumatism is an inflammation of the arterial system. Purging is also highly inconvenient, from the trouble and pain of moving the body; yet, on the whole, we have thought that interposing occasionally active laxatives, which contain a considerable proportion of calomel, have been useful in shortening the disease, though they have not greatly mitigated the pain. The neutral salts have been sometimes preferred; but they have not appeared to us so effectual.

The chief remedy are the *diaphoretics*, and the advantages of this evacuation must be obvious on the principles laid down. When the heat and fever are considerable, the more cooling kinds, as nitre, saline draughts, with camphor, are preferable. But the crude sal ammoniac, with the acetated ammonia, may be soon employed, and with each class the antimonials may be advantageously combined. The chief remedy we owe, however, to the sagacity or the lucky combination of Dr. Dover, his sudorific sweating powder, viz. the pulvis ipecacuanhæ compositus of the last London Pharmacopœia. The principle of this combination we have already explained (see DIAPHORETICA); and scarcely inferior to this is the sweating powder of Ward, which contains the white hellebore instead of the ipecacuanha. We have sometimes thought it superior. These remedies relax the skin so completely that we can often venture to add some stimulant, as the acetated ammonia; sometimes, as recommended by Dr. Hamilton and Dr. Riedly, calomel; and, in general, infusions of our own aromatic vegetables. It is particularly remarked by Dr. Cullen, though unaccountably overlooked by some late practitioners of eminence, that the sweating, when once begun, should not be intermitted, and when it has relieved, should be suffered very gradually to decline. The warm bath is an inconvenient remedy, as it requires painful muscular exertion: it would be otherwise more frequently used in this complaint, as with moderate heat it is well adapted to its relief. The vapour bath, from its superior temperature, is better adapted to the chronic form.

The other diaphoretics of a gentler power, which require a longer continuance, are chiefly adapted to the disease, when its acute form is in some degree conquered. Of this kind are the mezereon, the seneka, the bardana, and guaiacum. In the period of the disease just mentioned each is sometimes useful, and in general some ammoniacal salt, or the ammonia itself, may be combined with the decoctions of either. The volatile tincture of guaiacum, if employed too early, has been sometimes injurious.

Narcotics have been often used to relieve pain; but opium alone, unless directed to the skin, by relaxing sudorifics, seems injurious. This circumstance has been the chief support of the opinion, that opium stimulates; but in this disease a very essential discharge is the perspiration, and if this be not produced

every medicine appears injurious. Other narcotics which have been employed we may mention in this place, though they have chiefly been employed in chronic rheumatism, viz. the rhododendron, which seems to combine a sudorific power; hyoscyamus, dulcamara, hemlock, and aconite. Each seems occasionally to lessen pain and procure sleep.

We have not considered *mercurials* under the head of diaphoretics; because it would appear as if we wished to bend every thing to a system. We, therefore, have preferred selecting the facts. The practice of Dr. Hamilton, who found calomel with opium useful, (Edinburgh Medical Commentaries,) we have already mentioned; and by different authors, who are, however, chiefly army physicians, the sublimate mercurial friction, and calomel, have been recommended. We suspect, however, that these medicines have been chiefly useful when the inflammatory stage has, at least in part, disappeared. We have remarked, that we thought the purgatives which contained calomel were more effectual than others; but dare not say that any part of the relief was owing to the mercurial.

The remissions, and in some cases the intermissions, of this disease, have suggested the use of the *bark*; and this medicine has been highly commended. It has not been our fortune to have seen it beneficial; but we cannot deny our confidence to the assertions of practitioners of the highest respectability. The utility of *arnica*, recommended in the first volume of the Berlin Transactions, may rest on a similar principle.

Of the *external remedies*, we have already mentioned topical bleedings, and the next in point of utility are *blisters*. These are of little service while the general inflammatory state continues; and we have found, that to render them useful in acute rheumatism, bleeding, in a quantity proportioned to the strength, should be premised. We had adopted the practice of bleeding previous to the fresh application of each blister, for the blisters must be frequently repeated, long before we entertained the ideas now suggested respecting the nature of the disease. All external applications, if employed too early, remove the pain from the part then affected, but drive it to another limb.

The tartar emetic ointment is by some practitioners employed as an external stimulus, since it is supposed to produce a more permanent effect. This may undoubtedly be the case; but the little foul ulcers which it produces soon impede its use, and other stimulants cannot afterwards be employed. Baldinger has recommended ginger, over which alcohol has been burnt, and others the spirit of turpentine, joined with ammonia. The actual cautery has been applied, and the burning with moxa is no uncommon remedy in the east. Blisters, however, and topical bleeding, are almost the only external remedies employed in the acute stage.

RHEUMATISMUS CHRONICUS, arthrodynia. The gradual change from the acute to the chronic state of this disease admits not of any accurate limits, except, perhaps, the state of fever. Yet in rheumatisms strictly chronic there are evening exacerbations, which seem to destroy this distinction. In general, however, the fever is slight and almost imperceptible; the limb cold, almost immovable, dry, or covered only with a cold clammy sweat; the pain acute, especially on

changes of weather, or when heat is withdrawn; and the whole system highly debilitated. This form of the disease often continues for a long time, with little variation; nor does it sometimes terminate, except with life. The lumbago and the sciatica are frequently of this kind, and the knee is very often the part affected.

There can be little doubt of the state of the parts in this form of the disease. It is evident that the circulation is carried on imperfectly, from a debilitated state of the vessels, which occasions the frequent recurrence of spasm, especially when external heat, or internal stimuli, do not contribute to assist their action. As this atony affects the arteries exclusively, it must evidently arise from the previous inflammation; but if this inflammation was not of a peculiar kind, we should find a similar consequence after other phlegmasiæ. It is highly probable, therefore, that the disease is in the coats of the arteries themselves.

Conformably to this idea practitioners have found every internal and external stimulus of the highest service. Cantharides, the mineral acids, camphor, ammonia, the essential oils, particularly those of turpentine, cajeput and amber, flour of mustard, and the juice of horseradish, have been used singly, or combined in various forms, often with opium. Electricity and galvanism have had their advocates, though they have of late been seldom employed. In a more solid form the cummin seeds, the mustard, and ammonia, have been made into a cataplasm, with black soap, or into a plaster with euphorbium. All these are useful stimulants, and often successful.

Warm bathing, and warm pumping, are, however, remedies of greater utility; and the waters of Bath, combining probably a stimulant power, are often peculiarly useful. The application of sea salt or brine is often serviceable, and the tepid baths of our sea coasts have in many instances cured, when employed from about 86° to 92°. When the system is not greatly debilitated, even sea bathing is used with success; but the reaction in the part affected must be generally assisted by friction, and the most stimulating liniments. Issues and setons near the part have been proposed, but have seldom been found useful, as they are chiefly adapted to inflammation deeply seated.

The internal medicines are the more active stimulants, and those tonics which determine to the surface. The internal stimulants which have been most successful are the arum, the seneka, the mezereon, the guaiacum, and the turpentine. The arum, in the form of a conserve, with an equal part of sugar, is often highly useful. The seneka and mezereon are exhibited in decoction, often with mercurials. The guaiacum in this form is inert, and the gum is employed with more success. The greater number of medicines has yielded, however, to Dr. Dawson's remedy, the ammoniated tincture of guaiacum, given in a dose of two or three drachms, sometimes extending to half an ounce: it is much more effectual when combined with opium, or a small portion of Dover's powder. We have tried various combinations of ammonia, gum guaiacum, and opium, in a solid form, but by no means with equal success.

A very general and active stimulus is the ethereal oil of turpentine; and, according to the method recommended by Cheyne, if incorporated by melting in a

gentle heat, with an equal part of honey, a much larger dose can be taken without offending the stomach. It is in every case of chronic rheumatism a valuable medicine.

Another stimulus of considerable utility is the oleum jecoris asselli, the oil of the liver of the cod fish, recommended by Dr. Percival. It is in reality the *train oil* of the shops, and we have found it to relieve when other medicines have failed. It must be long continued, and fortunately the taste soon becomes familiar. From the sensible effects of the liver of the skate (see RACHITIS), we should expect some benefit from it in chronic rheumatism.

The tonics which determine to the surface are the metallic, of which the principal is mercury; a medicine more successful when combined with antimony. Calomel every night, in the dose of a grain, was, if we recollect rightly, recommended by Dr. Fothergill. Other authors have employed the muriated mercury; but the Plummer's pill, in its original form, assisted by the decoction of mezereon, sometimes by the more complicated formula, the Lisbon diet drink, we have found more successful.

What share in the success the sarsaparilla may have is uncertain. One violent case of chronic rheumatism is said to have been cured by the sarsa in substance, taken in the quantity of a scruple two or three times a day. The relief, however, was found at the end of a summer, after two winters of peculiar mildness; a change of climate is a well known remedy for this disease. The seasons in this case meliorated our northern region.

The only other metal which has been employed is arsenic. From the few trials made by Dr. Bardsley it seemed to be highly useful. We have not been equally successful; but, in the infancy of its use, it is probable that the cases to which it is adapted, have not been sufficiently distinguished.

See Cullen's First Lines; Smith in the Medical Communications, vol. ii.; Essay on the Nature and Cause of Rheumatism, 8vo. London, 1776; Heister de Rheumatismo; Lancisi de Nativis et Adventitiis Cœli Romani Qualitatibus, ad Calcem; Fordyce's Fragments; Demiani Adversaria; Ploucquet de Myositide et Neuritide; Sydenhami Opera, pp. 344 and 732, &c.; Saalman Descriptio Rheumatismi Acuti; Theden N. Bemerkungen, vol. i. p. 130; Stoll Ratio Medendi, p. 3 and 5; Bardsley's Reports.

RHICNO'SIS, (from *ῥιχνος*, *rugged*). LEANNESS and WRINKLES.

RHI'GOS, (from *ῥίγω*, *to shake with cold*). RIGOR; the slight convulsive tremors, most commonly following the cold fit of fevers. Dr. Cullen considers them as the first marks of reaction; but they appeared to us (see FEBRIS) rather as the effects of debility. They are not confined to fever; but sometimes arise from any disgusting object, and in some persons from the introduction of the catheter into the urethra. Bellini seems to confine it to diseases of the head, and Bonetus thinks it peculiar to inflammations of the uterus, pleura, or liver. In general, when heat does not follow, it seems a fatal symptom, and in the worst fevers the cold is often fatal without producing rigor. See Boneti Sepulchretum, lib. i. sect. 14. obs. 16. Hippocrates *περί νευρων*; Ga-

lenus de Tremore, &c.; Opera tom. iii.; Baglivi Praxis Medica, i. 9.

Rigor sometimes signifies an inflexible hardness and tension of the muscles; but the more proper appellation is *rigiditas*. See HORROR.

RHO'CAS. See EPIPHORA.

RHO'CHMOS. See RHENCHOS.

RHODI'NA RADIX, and RHO'DIUM LIGNUM, (from *ῥόδον*, *a rose*). See ASPALATHUS.

RHODODE'NDRON, vel RHODODA'PHNE, (from *ῥόδον*, *a rose*, and *δένδρον*, *a tree*; or *δαφνη*, *the laurel*), for its flowers resemble the rose, and its leaves the bay. See NERION.

RHODODENDRON CHRYSANTHEMUM. YELLOW FLOWERED RHODODENDRON, DWARF ROSE BAY, *rhododendron chrysanthum* Willdenow, vol. ii. p. 605, has been recommended in chronic rheumatisms, painful affections of the joints and bones, particularly venereal pains: it is now very generally employed in various parts of Europe, though seldom in Britain. The plant is a native of Siberia, growing in mountainous situations, and flowering in June and July. Dr. Koelpin, of Alten-stetin, used an infusion of it in water, kept twenty-four hours in nearly a boiling heat, in the proportion of two drachms of the leaves and tops of the plants to ten ounces of water. It was sometimes made of double this strength, and the dose was two ounces, to be repeated after a few hours, and continued as required. Dr. Home found it an astringent, and powerfully sedative; he directs it in infusion, from half a drachm to three drachms for a dose. When taken internally it produces, according to Koelpin, a feverish heat, intoxication, sometimes a stupor, with a singular pricking sensation in the limbs, or other parts of the body: the intoxication leaves neither headach nor nausea. During the heat, the patient complains of intense thirst; and drinking cold water is followed by a violent but salutary vomiting, especially in complaints of the bowels; and a copious sweat on the parts affected with rheumatism or gout. In some instances the pains grow worse at first; but this increase of disease is soon followed by a remarkable relief: the pulse is rendered weaker and slower, and in venereal rheumatism its effects are very considerable. The infusion at first often produces heat and constriction in the fauces; a proof of some little acrimony: but this effect speedily disappears. In robust habits it operates quickly, and with a degree of violence; in the infirm and feeble, more slowly, so that the dose should not be hastily increased. It sometimes proves fatal, and Morgagni has recorded the appearances on dissection of a woman who was killed by it, Ep. lix. § 12 and 14, though probably this plant was the *nerium oleander* Lin. Sp. Pl. 305, sometimes called *rhododendron*. Another species of this genus, the *r. ferrugineum* Lin. Sp. Pl. 562, has similar powers.

RHOMBOIDES MU'SCULUS, (from *ῥομβος*, *a square figure*, and *ἰδως*, *form*), rises from the ligamentum colli, the spinal processes of the third, fourth, fifth, sixth, and seventh cervical vertebræ; and the first, second, third, and fourth dorsal. It is also attached below to some of the ribs, runs beneath the latissimus dorsi, and is inserted into the whole length of the basis of the scapula to bring it upwards and backwards. The rhomboides is sometimes divided into the major

and minor: the minor is then above, and the major below.

RHOPA'LOSIS, (from ῥοπαλον, a club, probably from the increased size of each hair). See **PLICA POLONICA**.

RHUS, (from ῥεω, to flow, because it checks fluxes,) *byrsodepsicon*, *rhys coriaria* Lin. Sp. Pl. 379, COMMON SUMACH, is a shrub, with oval, pointed, serrated leaves, and clusters of yellowish or greenish flowers, each of which is followed by a small, red, flattish berry, including a roundish reddish brown seed. It is a native of the south of Europe, and cultivated in our gardens. The berries have an acid, austere taste, are cooling and restringent. The leaves and young twigs are powerfully astringent; but it is chiefly used by dyers and tanners, though recommended by foreign authors in hæmorrhages and mucous discharges. The *r. typhinum* is similar in its virtues. See Tournefort's *Materia Medica*; Neumann's *Chemical Works*.

RHUS SYLVESTRE. See **MYRTUS BRABANTICA**.

RHUS VERNIX, Lin. Sp. Pl. 380, is the poison wood tree, whose juices are so acrid as to blister the hands of those who gather them. Internally, in infusion or extract they seem less deleterious; as Fresnoi, a French physician, took twelve of the petioles (for the leaves are pinnated) in infusion, which greatly increased the urine and perspiration. He was from thence led to use this infusion in herpes and palsy, which, in his opinion, were cured by it. The leaves are in their greatest vigour in June, and thirty-two pounds of water, distilled from four pounds of the leaves, yielded a fluid somewhat odorous and highly pungent. Each pound of the leaves yields about half an ounce of extract, highly successful in our author's hands in the cure of pertussis. Half a grain dissolved in syrup was a sufficient dose.

RHY'AS or **RHŒ'AS**, (from ῥεω, to flow). The existence of this disease has been doubted; but Galen describes it as an affection of the eye, diametrically opposite to *encanthis*, consisting of a too great diminution of the lachrymal caruncle. Riverius allows the cause of it to be a consuming, exsiccating, or corrosive matter, succeeding or accompanying a fistula lachrymalis. Eyes thus affected are denominated by Ætius, ῥυαδης, *vel ῥυαδης οφθαλμος*, *Fæsius*.

RHYSSE'META, (from ῥυσσω, to wrinkle). A WRINKLED FACE.

RI'BES NI'GRUM, Lin. Sp. Pl. 291. BLACK CURRANTS seem to possess a slightly sedative power, and are used in sore throats. They are said also to be diuretic. The leaves of all the currants are narcotic, resembling peach leaves.

RI'BES RU'BRUM, (from raib, Arab, or rivah, Hebrew,) *grossularia non spinosa*, *ribes rubrum* Lin. Sp. Pl. 290. RED CURRANT. Currants in general have a cool, acidulous, sweet taste, agreeable both to the palate and the stomach; resembling the other subacid fruits in their medicinal qualities. They may be used with considerable advantage to allay thirst in febrile complaints; lessen the increased secretion of bile; to correct a putrid, or scorbutic state of fluids. Hoffman and Boerhaave had great confidence in the efficacy of these fruits in obstinate visceral obstructions. The white currant tree is merely a variety of the red; the fruit therefore possesses similar properties.

RI'CÆ, ῥίκος. A veil which covered the heads of

the Roman women during the time of sacrifice; hence *rica*, the kerchief. The great kerchief, called by the French *le grand couvre chef*, is used after trepanning. It is made of a square cloth, and, when dexterously applied, confines strictly the dressings. By observation and experience only can a dexterity in the application be obtained. *Couvre chef en triangle*, is a square cloth, folded in the form of a triangle: the middle of the longest side is applied to the forehead, the two ends tied behind the head, and the angle, which falls behind the head, secured to the confined ends of this kerchief. Its use, in general, is to fix the dressings on the face and head.

RICI'NI O'LEUM, (from *ricinus*, the spurge seed). See **CATAPUTIA**.

RICI'NUS, (quasi ῥις κυνος, a dog's nose, because they stick to dog's noses). The TICK or TYKE, a reptile which infests dogs. The name also of the spurge laurel, whose seeds resemble the tick.

RICI'NUS AMERICA'NUS MA'JOR. See **CATAPUTIA MINOR**.

RICI'NUS MI'NOR. See **CASSADA**.

RICINOI'DES, (from *ricinus*, and εἶδος, likeness). *Cataputia minor*. See **HELIOTROPIMUM TRICOCCUM**.

RI'GOR. See **RHIGOS**.

RIG'OR NERVO'SUS. See **TETANUS**.

RI'MA. A CHINK, applied in anatomy to any longitudinal aperture.

RIM'ULA. A diminutive of *rima*.

RINÆ'US, (from ῥις, the nose). See **NASALIS**.

RING-WORM. A species of herpes, or rather of lepra, in which the eruptions are annular.

RI'SAGON. See **CASSUMUNAR**.

RIST. See **CIST**.

RISUS, (à ridendo). LAUGHTER scarcely requires a definition. It is occasioned by short, imperfect, convulsive expirations after a full inspiration, with a contraction of the glottis, which produces a sound in men resembling those of o and a, and in women i and e. The lesser degree, a smile, which the verb chiefly imports, is unconnected with respiration, and consists only in the contraction of the buccinator and zygomatic muscles, while the cheeks are slightly raised, and the eyes in some measure closed. The former is the expression of boisterous mirth, in minds untutored and unregulated; the latter of complacency and pleasure.

It is singular that laughter generally proceeds from a mental cause, in most instances without any corporeal influence, and sometimes from an irritation of the nerves, wholly independent of mirth. Of the former kind is the loud laugh in hysteria; and the convulsive laugh in hysteric paroxysms, sometimes induced by the most distressing events: of the second, tickling is the cause, which in excess has been used as a kind of torture to induce confession. The causes of laughter are obscure. Pleasure produces cheerfulness and complacency; unexpected happiness more frequently draws tears; and the loud repeated laugh of the bacchanal, or of the spectator of the comic humour of Munden, if analyzed, will be found to arise from a source very different from pleasure. One cause of laughter is a combination of incongruous images. Chrysippus is said to have died from laughing at the idea of an ass being invited to a banquet. A similar fate, according to Valerius Maximus, attended Philemon; and we are told of a pope who died in the same way, from seeing the

tiara placed on the head of a monkey. A question which has perplexed both moralists and metaphysicians is the cause of that laughter which ensues from seeing another person fall. It is often irresistible though considerable injury be apprehended. The maxim of Rochefoucault has been quoted on this occasion, that there is something in the misfortunes of our best friends which does not displease us; but we would, for the honour of humanity, rather refer it to a sudden agitation. We know a gentleman who, on such an accident to himself, and he has often fallen from his horse, is seized with violent laughter; and Binninger has remarked, that a fall on the sinciput is generally attended by this convulsive expiration. The conclusion, therefore, must be, that it is a tremulous action of the diaphragm, not necessarily connected with mirth, but rather with surprise. The well regulated mind, accustomed, *nil admirari*, is, therefore, seldom betrayed into it; and immoderate, frequent laughing is usually the effect of mental imbecility. Such was the decision of lord Chesterfield; and whatever ridicule may be thrown on his system of education, it must be admitted that no one was more intimately acquainted with all the intricacies of the human mind.

Laughter is peculiar to the human race. It has been observed in a child just born (*Ephemerides Naturæ Curiosorum*), and Schelhamner remarks of one of the wild boys found in woods, that he could laugh, but not speak. We have observed dogs and monkeys grin, when pleased, apparently from imitation. The more immediate causes of laughter, or rather the connection between it and surprise, or the titillation of distant nerves, is wholly inexplicable.

Laughter is said to be useful from the effect of the succussions in expediting the passage of the blood through the system of the vena portarum. Laughters are proverbially fat, and generally long lived; but weak minds are commonly exempt from care. The injuries from sudden and immoderate laughter are numerous. The circulation through the lungs is impeded, and the blood accumulated in the head: the records of medicine are filled with narratives of ruptured vessels in the head and lungs from laughing, with some more consolatory instances of a fortunate rupture of an abscess. Castellus mentions a case where a thorn was thrown up from the throat in consequence of immoderate laughter; and Erasmus was saved from death by a fit of laughter, which burst an abscess.

The *risus sardonicus* is rather a smile, or, more properly, a grin, than real laughter. Even Hippocrates quotes, as an old observation, that it arises from a wound in the diaphragm, which modern authors have confirmed from their own experience. (Joubert du Ris apud Halleri Bibliothecam, ii. 135.) Franck records it as a symptom in a bilious peripneumony, connected with rheumatism. The name was derived from the herb *sardoa*, to which it was attributed. We cannot now exactly ascertain what this plant is; but it had the leaves of parsley, and was sweet, two circumstances which meet in the *œnanthe crocata*, a powerful narcotic. It is the sardonic grin, which Van Helmont tells us is so unfavourable a symptom in wounds of the nerves.

The *risus sardonicus* has also been owing to swallowing the root of the *ranunculus palustris* (*Ephemerides Naturæ Curiosorum*, Dec. iii. an. 2, obs. 87); and in

the same collection of a former year, we find an instance where it was induced by terror, and was a fatal symptom in a puerperal case. Saffron has been accused as a cause by Sennertus, apparently with little reason.

See Lyserus de Risu; Alberti de Risus Commodo et Incommodo; Platner de Risu a Splene; Halleri Physiologia; Plinii Historia, lib. xi. 629; Schelhamner de Affectibus Animi.

RIVINIA'NÆ GLA'NDULÆ. See SUBLINGUALES GLANDULÆ.

ROASTING. A culinary and chemical process. In the latter, metals are exposed to an open fire, to dissipate their inflammable or volatile parts. In the former the meat is rendered more moist, perhaps more soluble; but, as we have observed, the empyreuma communicated to the fat and skin renders roasted meat often inconvenient in weak stomachs.

ROB, (from the Arabic *rob*, dense,) *robub*; a galenical form, in which fruits and leaves are preserved by sugar and evaporation, often by the latter alone. Acids, however, suffer some decomposition, and are not afterwards equally miscible with water, or equally salutary in scurvy. See EXTRACTIO and SAPA.

ROBORA'NTIA, (from *roboro*, to strengthen.) See CORROBORANTIA, TONICA, and ASTRINGENTIA.

ROCELLA; *lichen rocella* Lin. Sp. Pl. 1622; a blue dye, but, like other lichens, used in hectics. From its allaying coughs, and particularly hysteric coughs, it seems to possess some narcotic power.

RODA'TIO, (from *rodo*.) See TARSUS.

RO'NCHUS. See RENCHOS.

RORE'LLA, RO'RIDA, and RO'SA SOLIS. See ROS SOLIS.

RORISMARI'NUM SYLVE'STRE. See LEDUM PALUSTRE.

RORISMARI'NUS. See ROSMARINUS.

ROS CALABRI'NUS. See MANNA.

RO'SA, (from *ῥοσος*, or *ῥόδος*, the rose.) White roses are the weakest; so that when the damask, the *rosa pallida*, or *centifolia* Lin. can be procured in sufficient quantities, they only are used. Their odour is imparted to water and to spirit, but chiefly to the latter; and they lose little by drying, or keeping, if well managed. On distilling large quantities, a small portion of a fragrant butyraceous oil, of a yellowish colour, is obtained, which concretes in a slight degree of cold: both the water and the oil are chiefly used as perfumes.

The red rose, *rosa centifolia* Lin. Sp. Pl. 704, has but little of the fine flavour of the pale sort: to the taste the leaves are bitterish and somewhat astringent. The astringency is the greatest before the flower opens, and this quality is improved by hasty drying in a gentle heat; but by slow drying both the colour and astringency are impaired. Water they tinge with a deep red colour, and spirit with a pale one. The extract from a watery infusion is austere, bitter, and subsaline; that from spirit in a greater degree. The fixed matter of the petals is slightly laxative, and the syrup is sometimes given for this purpose to children. Former dispensatories had a *syrupus rosarum solutivus*. (See Lewis's *Materia Medica*.) The London College have directed several preparations.

Aqua rosa.—Take of the fresh petals of damask roses, the white heels being cut off, six pounds; water sufficient to prevent an empyreuma: draw off one gallon.

Conserva rosæ rubræ.—Red roses are to be gathered before the petals are unfolded, the heels cut off, and the leaves treated in the same manner as the worm wood. (See *ABSINTHII MARITIMI CONSERVA*.) The virtue of the roses is supposed to be found in this composition, and probably their best effect will be produced, when given in substance, and in considerable quantity. In phthisis and hæmoptoe they have been employed, sometimes with success, especially when joined with a diet of milk and farinacea, and gentle exercise in open air. At most, two parts of sugar to one of roses would be sufficient, and afford a better medicine than the larger proportion.

A cataplasm is made of the conserve, and employed in the latter stages of ophthalmia; one drachm of alum finely powdered is mixed with two ounces of conserve.

Mel rosæ.—Take the petals of the red rose not yet unfolded, the heels being taken off, first dried, four ounces; boiling distilled water, three pints; clarified honey, five pounds; macerate the petals in the water for six hours; afterwards with the strained liquor mix the honey, and boil the mixture to the consistence of a syrup.

Syrupus rosæ.—Take of the petals of the damask rose dried, seven ounces; purified sugar, six pounds; distilled boiling water, four pints; macerate the petals in the water for twelve hours, and strain: evaporate the strained liquor to two pints and a half, and add the sugar to form the syrup. For infants, the dose, as an aperient, is from half an ounce to an ounce; though its purgative effect is very inconsiderable.

Infusum rosæ.—Take the petals of the red rose in bud, the heels taken off, half an ounce; diluted vitriolic acid, three drachms by weight; boiling distilled water, two pints and a half; purified sugar, one ounce and a half. Pour the water first on the petals in a glass vessel, then add the acid, and macerate them for half an hour; strain the liquor cold, and add the sugar. *Pharmacopœia Londinensis 1788.*

This is an elegant preparation, but its virtue consists more in the vitriolic acid than the roses. See Cullen's *Materia Medica*.

The attar, or essential oil of roses, so highly esteemed as a perfume, is prepared in India. Forty pounds of roses, with their calyces, are put into a still with sixty pounds of water. After the ingredients have been well mixed, a gentle fire is lighted, and when fumes begin to arise, the cap and pipe are properly luted on. When the impregnated water begins to come over, the fire is lessened by degrees, and the distillation continued four or five hours, till 30lb. of fluid is come over. This water is to be poured again upon 40lb. of roses, and fifteen or twenty pounds more are to be drawn off. It is then to be poured into pans of earthen ware, or tinned metal, and exposed to the fresh air for the night. In the morning the attar will be found congealed, and floating upon the surface of the water. Its smell exactly resembles that of roses. It is only slightly pungent; but has been recommended as a cordial and analeptic.

The roses of India do not appear richer in oil than those of Europe. From two to three drachms of oil are procured from one hundred weight; while Tachenius procured half an ounce of oil from that quantity, Ham-

berger one ounce, and Hoffman two. It is adulterated sometimes with the oil of sandal wood; but this oil does not congeal in common cold, and its peculiar smell predominates, sometimes with that of a sweet grass. The latter imparts a green colour, and the oil does not easily congeal in a moderate temperature. The colour, however, is no criterion of its genuineness, since the real attar differs greatly in this respect. Colonel Polier in the *Asiatic Researches*, vol. i.

RO'SA CANI'NA et SYLVE'STRIS. See CYNOSBATUS.

ROSA'CEA, (from *rosa*, a rose). ROSEA. See GUTTA ROSACEA.

ROSA'TUM. See DROSATUM.

RO'SÆ ODO'RÆ LI'GNUM. See ASPALATHUS.

ROSEOLA, of Willan. See GUTTA ROSEA.

ROSMARI'NUS, RORISMARI'NUS, (*folia albescentia quasi rore, ut in maritimis, inspersa*.) *libanetis coronaria*; *dendrolibanus*; COMMON ROSEMARY; *rosmarinus officinalis* Lin. Sp. Pl. 33; is a large shrubby plant, with long, narrow, stiff leaves, set in pairs, of a dark green colour, above, and hoary beneath, with flowers of a pale bluish colour. It is a native of the southern parts of Europe, where it grows wild in dry gravelly ground; common in our gardens, where it smells stronger in proportion as the soil is dry and gravelly.

Rosemary hath a warm, pungent, aromatic, bitter taste, and a fragrant smell, approaching to that of lavender, joined with a camphorated odour: the leaves and tender tops are the strongest, and next to these the cup and the flowers. The flowers are the weakest, but most pleasant; and whatever virtue has been attributed to them resides in the cup. This plant is said to stimulate and strengthen the nervous system, and is recommended for nervous headaches, deafness, vertigo, palsy, hysteria, and dyspepsia, yet its active power scarcely extends beyond the stomach, which it gently stimulates; though recommended by Bergius as an emmenagogue, and chiefly useful in chlorosis. For distillation the calyces and leaves are preferable, partially dried.

The leaves and tops yield their fragrance, in a great degree, to rectified spirit, leaving in the extract the greatest share of both their flavour and pungency, with some portion of the aroma.

The active matter of the calyces and flowers is more volatile than that of the leaves, the greatest part of it rising with spirit.

Spiritus rorismarini, or Hungary water.—Take of the fresh tops of rosemary, one pound and a half: proof spirit of wine, one gallon. Distil in a water bath, five pints. (Pharm. Lond. 1788.) This with the essential oil are the only preparations now kept; but the rosemary is an ingredient in compound spirit of lavender, and some other preparations. A conserve formed of its flowers is now expunged both from the London and Edinburgh Pharmacopœias.

To make the Hungary water in perfection, the spirit must be very pure, the leaves at their full growth, gathered without bruising. If the flowers are suspended in the retort, and a gentle heat applied just sufficient to raise the spirit, the vapour lightly percolating through them will, it is said, add to the fragrance.

Aqueous liquors extract some portion of the virtues

of rosemary by infusion, which pass over in distillation. With the water a considerable quantity of light, thin, green, or yellowish essential oil rises.

See Tournefort's, Lewis's, and Cullen's *Materia Medica*; and Neumann's *Chemistry*.

ROSMARINUM STOECHADIS FA'CIE. See POLIUM CRETICUM.

ROS SOLIS, *rosa solis, rorella, sponsa solis, rorida*; RED ROT; SUN DEW; *drosera rotundifolia* Lin. Sp. Pl. 402; is a small low plant, with a little fibrous root, from which spring small, round, hollowish leaves, on foot stalks of about an inch long, covered with short red hairs, which make the whole leaf appear red. It grows in boggy ground, and flowers in June and July. It is injurious to cattle if eaten, and very caustic; but has been commended as a cordial. See Raii *Historia*.

ROSSALIA. See SCARLATINA.

ROSTELLUM, (a dim. of *rostrum*.) A little beak. See CORCULUM.

ROSTRUM, (from *rodo*, because birds tear their food with it.) A BEAK.

ROSTRUM LEPORINUM. The piece of flesh which hangs betwixt the division of the hare lip, resembling a beak. See LABIA LEPORINA.

ROTA'TOR MI'NOR, MA'JOR, and NA'TIS, (from *roto*, to turn.) See FEMORIS OS.

ROTTEN STONE. A partly decomposed granite from which the felt spar has been separated; resembling the petuntze of the Chinese, and used in making porcelain.

ROTULA, (a dim. of *rota*.) The PATELLA, q. v. In pharmacy a round lozenge.

ROTUNDA LIGAMENTA, (from *rota*, a wheel.) THE ROUND LIGAMENTS OF THE WOMB are two vascular ropes, composed of arteries and veins, lymphatics and nerves, arising from the fundus uteri, running under the duplicature of the broad ligaments to the rings of the abdominal muscles, and, passing under Poupart's ligament, are lost on the groin. They run in a contorted form, and are capable of being elongated. The nerves of these ligaments compressed in time of labour, between the uterus and abdominal muscles, may cause the pain felt in the inside of the thighs at that time.

ROTUNDUS MUSCULUS. See TERES MAJOR.

ROUCOU. See ACHIOTL, and ORLEANA.

ROUTROU'S SOLVENT. See ANTIMONY, vol. i. p. 136.

RUBE'DO, (from *ruber*, red). An uniform redness of the skin, seldom rising into pustules, or even papulæ. See GUTTA ROSACEA.

RUBEFACIENTIA, (from *rubrum facere*, to redden,) are usually simple stimulants, and such as do not raise vesications. They resemble in their effect blisters, but their power is inferior and more transitory.

RUBE'OLA, (from the same.) See MORBILLI, and RUBIA CYNANCHICA.

RUBE'OLA MONTANA OD'ORA. See ASPERULA.

RUBE'RCUM MA'CULIS, (from the same.) See GUTTA ROSACEA.

RUBE'TA, (from its living among brambles.) See BUFO.

RUBIA, (from its red roots.) *Rubia tinctorum* Lin. Sp. Pl. 158 β ; *erythrodanum*; *rubia major*; DYER'S

MADDER, is a rough procumbent plant, with square jointed stalks, and five or six oblong pointed leaves, set in the form of a star at every joint; from the top arise greenish yellow flowers, followed by two black berries. The root is long, slender, juicy, red, both externally and internally, with a whitish woody pith in the middle. The plant is perennial, and cultivated in different parts of Europe for the use of dyers.

The roots are bitterish, somewhat austere, with very little smell, imparting to water a dark, to rectified spirit and distilled oils a bright, red colour, preserving in each the taste unchanged. Taken internally it renders the urine red and milky; and tinges the bones of animals fed with it, from its affinity, as already shown, to the serum, rather than the calcareous phosphat: the flesh and cartilages continue unaltered. From its supposed effect of tinging the earthy salt of which the bones consist, it was considered as a powerful aperient, and from its effects on the urine a diuretic. But it is neither; for it only tinges the serum. Its power as an emmenagogue is equally equivocal.

When first recommended, distrusting the author's accuracy, we gave it at the same time in a case of mænorrhagia and amænorrhœa. The former complaint disappeared, the latter continued without any change. In fact, we believe it wholly useless. It has been given in dropsy, in jaundice, and in ecchymosis from bruises, in the dose of a scruple, or from this to half a drachm.

It is also a name for the rubeola, a species of crosswort, and of horse tail.

RUBIA SYLVATICA LÆVIS; *gallium mollugo* Lin. Sp. Pl. 155; MOUNTAIN BASTARD, or WILD MADDER. Its virtues are at least equal to the *rubia tinctorum*.

RUBIA CYNANCHICA; *rubeola cynanchica* *Lugdunensis*; *asperula*; *saxifraga*; *asperula cynanchica* Lin. Sp. Pl. 151; SQUINANCY WORT, hath a black, thick, woody root, which runs deep into the earth, with many capillary fibrils divided into a multitude of heads, and shoots up in many smooth, slender, ungulose stalks. At every joint are four short and broad leaves: the flowers are on the top of the stalks and branches, forming umbels of a red colour, in smell resembling the jasmine; and each flower is followed by two rough seeds, which when dry are of a yellow colour. It is found on chalky grounds, and said to be of use in quinsies; but at present neglected or forgotten.

RUBINUS VERUS, (from *ruber*.) See CARBUNCULUS.

RUBRICA FABRI'LIS, (from the same.) See OCHRA.

RUBUS, (from its red fruit.) See DUMUS.

RUBUS ALPINUS and PALUSTRIS HUMILIS. See CHAMÆMORUS.

RUBUS IDÆUS, Lin. Sp. Pl. 706; *batinon*, *moron*; RASPBERRY, is a native of Britain, usually growing about woods and hedges, and in moist situations, producing its flowers in May and June. The raspberry is commonly cultivated in our gardens, and we find three varieties, the red, white, and smooth. The fruit is sweet tasted, accompanied with a peculiarly grateful flavour; and like other fruits it allays heat, quenches thirst, and promotes urine. A syrup is made of the juice in the common way.

RU'BUS VULGA'RIS; COMMON BRAMBLE; BLACK OR DEW BERRY BUSH; *rubus fruticosus* Lin. Sp. Pl. 707; *batos*; *chamabatos*; grows wild in hedges and in woods. The berries have a faint taste, with a moderately agreeable flavour, and the leaves are slightly astringent. The flowers appear in July, and the fruit is ripe in August and September; but neither the bush nor its productions are employed in medicine.

RUCTA'TIO, RU'CTUS, (from *ructo*, to belch). A discharge of wind from the stomach; a symptom of dyspepsia.

It is usually attributed to flatulent food, and is often owing to a defective digestion; for we have remarked that the flatus, separated in the early stage of the digestive process, is again combined with the food, in the second period. We consequently find that whatever disturbs this function produces flatulence, and consequently eructation. This variety of the disease is best remedied by moderately warm stimulants, and rest after eating. If the cause be more violent, or the food of that kind which quickly hastens to putrefaction, the eructations show the peculiar nature of the contents of the stomach by acidity, or what are styled *nidorous eructations*, in taste resembling a rotten egg. The former are removed by absorbents joined with aromatics, and the latter most effectually by vegetable acids.

Eructation does not, however, always arise from the contents of the stomach. It is sometimes a convulsive action, and the wind discharged is only the effect of the relaxation of the previous contraction. It is thus a common symptom in hysteria, of a stomach weakened by over distention, drinking spirits, &c. The disease is sometimes alarmingly violent, and we are told has, in one or two instances, induced appearances of hectic. (Commercium Norimbergense, 1743.) It is singular to observe eructations attributed to the imagination; but we find this cause assigned, not only in a dissertation by Alberti, but in a tract of Muller de Morbo Motuum Habituali ex Imaginatione.

The cure of this nervous eructation is generally attempted by tonics: but more immediate relief is often necessary; and opiates, with the fetid gums, are, for this purpose, chiefly useful. The opium should not, however, be given in such a dose as to produce costiveness; or rather this state should be counteracted by eccoprotics, frequently interposed. The best tonic is the bark, to which the valerian is with advantage added; iron, and sometimes zinc, are used; and, from some late observations of Dr. Bardsley, there is reason to suspect that the oxide of bismuth may be beneficial. The oil of amber is recommended by Zacutus Lusitanus, and we find the mineral acids have been occasionally employed.

Borborygmi are produced by nearly the same causes, and may be relieved by the same remedies.

RU'FI PI'LULÆ; *pilulæ ex aloë cum myrrha*. Two parts of aloes are combined in this composition with one of myrrh, one of saffron, and a sufficient quantity of syrup. See ALOË.

RUM. A spirit distilled from the sugar cane. It is oily, and has been supposed more useful on this account in catarrhs and coughs. The difference, however, between this and other spirits is inconsiderable. When new it is injurious, and has been said to produce the Poitou colic.

RU'MEX ACETO'SUS, PRATE'NSIS, SCUTA'TUS et HELVETICUS, *Linnaei*, (from *ramach*, a spear). See ACETOSA.

RU'MEX AQUA'TICUS, and HYDROLA'PATHUM. See LAPATHUM AQUATICUM.

RU'MEX ACU'TUS. See LAPATHUM ACUTUM.

RUMINATIO. This is a part of the process of digestion peculiar to some animals, chiefly belonging to the pecora of Linnæus, of which the cow is an example. The herbage received into its first stomach is there macerated, and, by an inverted motion of the œsophagus, is again brought into the mouth, to be more completely masticated. This operation is commonly called *chewing the cud*. Its object is apparently to combine the vegetable aliment more completely with the saliva. Rumination would be scarcely a part of our subject, if it did not occasionally occur in the human system, and an instance of it is recorded by Dr. Cullen. Meyer in 1792, Ackford in 1783, in dissertations published at Erlang and Halle respectively, have mentioned instances of it, and we find numerous descriptions of a similar operation in different foreign authors.

We have seen some approaches to it; but the rumination has then not been regular and constant. It has seemed owing to eructation, and the food has come into the mouth with the flatus. The remedies for RUCTUS, q. v. seem to be chiefly indicated, and will probably be successful.

Schurig Chylogogia; Slare Philosophical Transactions, No. 193; Morgagni de Sedibus, xxix. 4.; Boneti Sepulchretum, Lib. iii. § v. 9, 10.

RUNCINA'TUS, (from *runcina*, a saw). SERRATED; leaves of plants with indented edges.

RUPICA'PRA, (from *rupes*, a rock, and *capra*, a goat). See CAPRA ALPINA.

RUPELLE'NSIS SAL, (from *Rupellum*, Rochelle, where it was first made,) *sel de seignette*, *natron tartarigatum*, and ROCHELLE SALT, is a soluble tartar, made by combining twenty ounces of natron, by weight, with two pounds of crystals of tartar, in boiling distilled water, ten pints. The natron should be melted by heat, that it may shoot more easily into crystals. Half an ounce or six drachms of this salt is a gentle cooling purge; but it should be mixed with a large proportion of water.

RUPTU'RA, (from *rumpe*, to break). A RUPTURE; the English term for HERNIA, q. v.; from the idea that the peritonæum was ruptured when the intestine protruded through the ring of the muscles. The word rupture is most properly applied to a cartilage, a ligament, or a tendon, when divided by violence.

RU'SCUS, (from the carnation colour of its berries,) *bruscus*, *oxymyrrhine*, *myrtacantha*, *myacantha*, *scofia regia*, WILD MYRTLE, KNEE HOLLY, BUTCHER'S BROOM; *ruscus aculeatus* Lin. Sp. Pl. 1474, is a low woody plant, with oblong, stiff, prickly leaves, joined immediately to the stalks: from the middle ribs of the leaves, on the upper side, issue small yellowish flowers, succeeded by red berries. The root is thick, knotty, furnished with long fibres matted together, of a pale brownish colour on the outside, and white within. It grows wild in woods and heaths, is perennial and evergreen; flowers in May, and its berries ripen in August. The root tastes sweet, and is slightly bitter; is aperient and diuretic, yielding its virtues to water and spirit; and on inspissating the tincture they remain in the extract.

The young shoots are eaten instead of asparagus. See Miller's Botany.

RU'SCUS HIPPOGLO'SSUS, or LATIFOLIUS. See LAURUS ALEXANDRINA.

RUSH NUT. The root of the *cyperus esculentus* Lin. Sp. Pl. 67, which is mucilaginous and oily, resembling chestnuts.

RUSMA, (*nouret* of the Arabians,) a depilatory generally used in the Turkish bagnios, supposed to be so precious as to be equal in value to its weight of gold. We learn, however, from Sonnini, that it is a very common preparation, consisting only of seven parts of lime, with three of orpiment. It must be laid on in a warm bagnio moistened with water, and the effect is almost immediate; but the hair grows again, and the operation must be repeated. Sonnini Voyage dans la Haute et Basse Egypte, vol. i. p. 303; Belon Observat. lib. cap. 33.

RU'TA, (from *ῥῦν*, to preserve, because it preserves health). RUE. *Armala, besasa, peganon, ruta graveolens* Lin. Sp. Pl. 548, LARGE WILD RUE, is a small shrubby plant, with thick bluish green leaves, divided into numerous roundish segments. On the tops of the branches rise yellowish flowers, followed each by a capsule, divided into four partitions, full of small, blackish, rough seeds. It is cultivated in gardens, flowers in June, and is an evergreen.

Rue hath a strong unpleasant smell, a penetrating, pungent, bitter taste; if much handled, apt to inflame the skin, a property lessened by cultivation. It is commended as a powerful stimulant, aperient, antiseptic, and antispasmodic, useful in crudities, indigestion, in uterine obstructions, hysteric diseases, and to guard against infection. It is, however, only a warm antispasmodic, of no considerable powers. Externally, in a fomentation, it is thought to be discutient and antiseptic.

Its virtues are extracted by water and spirit of wine, but most perfectly by the latter. On inspissating the spirituous tincture, very little of its flavour rises with the menstruum, nearly all the active parts of the rue

remaining in the extract, which is warmly and durably pungent, and in smell it is rather less unpleasant than the herb. This is the best preparation of rue: water, in distillation carries over a part of its aroma. The principal virtues reside in the essential oil, which is not very volatile.

Distilled with water, a yellowish or brownish essential oil is obtained; and the remaining liquor may be inspissated into a warm, pungent, bitterish extract, inferior, however, to the spirituous.

Rue leaves, distilled for their essential oil, should be fresh, and gathered when the flowers are ready to fall off: the seeds with their capsules should be added, and macerated previous to distillation.

Rue is directed in form of an extract, is a principal ingredient in the pulvis cum myrrhâ compositus, and often given in the form of tea. To it was attributed, by Hippocrates, the power of resisting the action of contagion, and other kinds of poisons; and in this view it is highly extolled by Boerhaave. For making the extract, see CHAMOMÆMELI EXTRACTUM.

See Tournefort's, Lewis's, and Cullen's Materia Medica; Neumann's Chemistry.

RU'TA CAPRA'RIA. See GALEGA.

RU'TA BA'GA A coarse esculent beet, highly commended as the "*root of scarcity*;" but now deservedly neglected.

RU'TA MURARIA, *asplenium ruta muraria* Lin. Sp. Pl. 1541, WHITE MAIDEN HAIR, is slightly astringent, and has been used in hectic, though at present neglected.

RU'TA SYLVE'STRIS. See HARMEL.

RUTADOSIS. A sinking of the cornea from a wound, old age, or death.

RUYSCHIANA TU'NICA, (from *Ruysch*, the discoverer). See CHOROIDES.

RY'SAGON. See CASSUMUNIAR.

RY'THMUS, (from *ῥυθμός*, measure,) a term used by musicians with respect to time in music; but, since the era of Herophilus, employed to express the time, motion, or modulation of the pulse. See ARYTHMUS.

S.

S A C

SABADI'LLA. See CEVADILLA.

SABI'NA, *savina*, *brathu*, COMMON OR BARREN SAVINE, *juniperus sabina* Lin. Sp. Pl. 1472, is an evergreen shrub, with short, narrow, prickly leaves. When old it bears blackish berries, like those of the juniper. It is a native of the southern parts of Europe, and is raised in our gardens. The leaves and tops have a strong disagreeable smell; a hot, bitter, and acrid taste; yielding a large proportion of their active matter to watery liquors, and the whole to rectified spirit. Distilled with water they afford much essential oil, which smells strongly, and tastes moderately of the savin: its dose is from two to four drops.

The decoction yields an extract which retains much of the pungency, warmth, and bitterness of the plant. On inspissating the spirituous tincture, the extract is a yellow, unctuous, or oily, bitterish, and pungent, mixed with a black, resinous, tenacious, subastringent, and less acrid substance.

Savin is styled a stimulant and aperient, useful in uterine obstructions, proceeding from a want of irritability in the vessels, heating and stimulating the whole system, and promoting the fluid secretions. It seems to be an efficacious emmenagogue, chiefly suited to relaxed and weak habits, but improper in plethoric ones. Of the powder the dose is from \mathfrak{z} i. to \mathfrak{z} i. twice a day; of the extract (see CHAMOMÆMELI EXTRACTUM) from ten to thirty grains.

Pulvis sabinæ compositus is composed of equal parts of sabine and ærugo, and employed as an escharotic for warts and excrescences, upon which it is to be sprinkled every day. The powdered savine alone, if fresh, is sufficiently active, when the epidermis is removed. The oil impregnates the urine with its smell, and contains the whole of its virtues. See Lewis's *Materia Medica*; and for the *tinctura sabinæ composita*, ELIXIR MYRRHÆ COMPOSITUM, under MYRRHA.

SA'CCHARUM, (from *sachar*, Arab). SUGAR, *μῆλις*, *καλῆμινον*, *Αἰς*, *Ἰνδικός*, *sackohar*, *sakchari*, *salcharion*, *sphodian*, *cantion*; and when unrefined, *cas-*

S A C

sonada. It is procured from the *saccharum officinarum* Lin. Sp. Pl. 79, COMMON SUGAR CANE.

Sugar seems to have been exclusively the production of India in the old, and of South America and the American islands in the new, world. It was apparently brought from India to Arabia, and from the Arabians we seem to have received the first description of the cane and its contents. If any part of the world besides those mentioned, can claim the sugar cane, it is the Canary islands. Sugar seems to have been first refined by the Venetians about the end of the eleventh century, but the process only practised in England about the middle of the sixteenth. The form in which sugar was previously imported from the east seems to have been that of sugar candy. Actuarius, the last of the ancients, apparently first used sugar instead of honey in medicinal prescriptions.

The expressed juice of the sugar cane is clarified with the addition of lime water, and when boiled down to a thick consistence is removed from the fire, when the saccharine part concretes into a granular mass, the *saccharum rubrum*, leaving an unctuous liquor, called *molazzo*, or molasses; from its consistence commonly *treacle*. This red sugar is clarified in conical moulds, by spreading on the upper broad surface some moist clay, whose watery part, gently percolating through the mass, carries with it a large portion of the treacle; and this is further refined by dissolving it in water, and mixing it with the whites of eggs, or bullock's blood, which, coagulating, carry down the remaining impurities. It is then covered with clay again in the mould, and becomes the *saccharum album*, Ph. Edinb. This process again repeated produces the *saccharum purissimum*, Ph. Lond. Brown sugar boiled to a proper consistence is placed in a hot room, to shoot into crystals upon sticks placed for the purpose, and it is then called *saccharum candidum*; and *candum*; *canthum*; *saccharum cantion*; *sugar candy*; or clarified, and the thinner parts evaporated, so that it forms a brittle substance, which, when made into small rolls, is called *barley sugar*. The term sugar candy is only with propriety applied to the crystallized white sugar, unless, with Salmasius, we derive the term from *καυτιον*, angular, or, with other authors, from *khand*, or *kend*, an eastern appellation of sugar; the latter is most probable.

Sugar, when pure and crystallized, is perfectly trans-

parent; when in a more confused granular form, opaque, with little shining crystals, soluble in water, and with the assistance of heat in alcohol. It melts into a yellow, tenacious liquid, and burns with a strong flame, exhaling an acid vapour. It is almost exclusively a vegetable production; and even the milk may be traced to a vegetable principle, except in animals wholly carnivorous. It is contained in almost every part of different vegetables, the flower, the leaves, the trunk, the root, and the fruit; but in each is confined to the period of maturity, and contaminated with mucilage and other vegetable principles. In the seeds of the cerealia it is formed by the addition of oxygen and of hydrogen from the decomposition of water.

Sugar is an oxide composed of carbon, hydrogen, and oxygen, of which 0.64 are oxygen, 0.28 hydrogen, and 0.08 only carbon. With an excess of oxygen it forms oxalic, or oxalic with malic acid, and with considerably less carbon, and a larger proportion of oxygen, it becomes the sugar of milk. When distilled without addition, it affords a pungent acid liquor of a yellow colour, called the pyromucous acid, which is also furnished by mucilage. Hydrocarbonate gas, mixed with carbonic acid, come over at the same time, and the residuum is a charcoal of peculiar purity. No other substance is contained in this hydrocarbonate oxide, so that it is peculiarly pure.

Mucilages are, we have seen, nearly allied to sugar, and we have pointed out one connecting substance whose farther analysis would greatly elucidate the chemical nature both of sugar and mucilage, viz. MANNA, q. v. Mucilages contain the same principles as sugar, with lime and azot. Sugar, in part deoxygenated, resembled mucilage in its chemical properties; but gum could not by any process of oxygenation become saccharine. In fact, it required that its azote should be separated. Gum, treated with nitric acid, produces the malic and deposits the mucous acid. The former, by the farther addition of nitric acid, becomes the oxalic.

Vegetable farina may become sugar, by the addition of oxygen and water, the last of which is apparently decomposed. Sugar deoxygenated is no longer susceptible of the vinous fermentation, as it is well known to be before, and neither vegetable nor animal mucilages, alone, afford either vinous or acid fluids. The combination of the principles which form sugar sometimes take place a little unexpectedly, as in diabetic urine, and the acetite of lead. The latter, Neumann tells us, may become the subject of a vinous fermentation, and the former affords a true sugar. These subjects require a farther examination. Sugar has been procured also from the birch, the skirrett, the white beet, and the sugar maple; but these processes scarcely belong to our subject, which is sugar in the abstract, from whatever source it may be procured, and its effects on the human body.

To treat of the advantages and disadvantages of sugar is a difficult task, since with one class of authors it is the most salutary food and the best of medicines; with others, little less than a poison. Sugar, unless it produces heart-burn, is probably harmless; no does it injure the teeth, or contribute to the production of worms. It is highly nutritious; since in the crop season the most sickly negro and the leanest pig become fat and healthy. Yet somewhat in these effects must be attributed to the mu-

cilage with which the sugar is mixed in the cane, and something to the fresh vegetable substance in which a powerful antiscorbutic property resides, though we cannot detect its source or its nature. If sugar, too, contributes to evacuate worms, as Dr. Moseley contends, it must be in part attributed to its laxative power, and in part to its salutary, nutritious tendency; for he describes the amendment in the general health, while he speaks of the discharge of worms. It has been supposed to attenuate the juices, by contributing as an intermede to their more intimate mixture, and consequently to resolve obstructions. On this principle it is said to cure hectic, and to relieve infarctions in the viscera: but this power is wholly chimerical; for we have no proof that it enters the blood in its saccharine state, or that, from its chemical properties, it is capable of assisting the mixture of the oily and watery portions of our fluids. Dr. Stark's experiments seem to show that it really possesses an attenuating power; but his saccharine diet was the last of his wanton experiments, and we cannot depend on the general effects of any medicine from what may have been the result in an exhausted constitution. Others have contended that it thickens the fluids, and occasions infarctions; but this effect is equally visionary, and derived only from its nutritious qualities. Sugar is undoubtedly a demulcent as well as a nutrient; but we have no evidence of any farther advantages: it produces often flatulence and acidity in the primæ viæ; but we know of no other inconvenience. Impure sugar is slightly laxative. Externally to wounds sugar is slightly stimulant and escharotic: burnt sugar, from the evolution of the pyromucous acid, more active in each respect.

In experiments out of the body sugar is a very powerful and useful antiseptic; but it shows no effect of this kind when internally taken. In pharmacy it is used to preserve vegetable substances; but for this purpose its proportion must be considerable, and the whole inspissated, or it will accelerate the changes it was intended to prevent. It is generally used also to render medicines more palatable, without consulting the taste or often the circumstances of the disease. We have seen antacid lozenges produce more acid from their sugar than their proportion of an absorbent earth could destroy.

Sugar, when depurated, boiled in rose water, and cast into troches, is called *Christi manus*; when pearls are added, *manus Christi perlata*.

By the assistance of heat, sugar dissolves in rectified spirit; but the greatest part separates when cold, concreting into a crystalline form. On this foundation saccharine concretions are obtained from saturated spirituous tinctures of several of our own plants, the saccharine part separating when the tincture is cooled, while the resinous and other matter separated from the plant remains in the solution.

See Moseley on Sugar, second edition; Neumann's Chemistry; Lewis's and Cullen's Materia Medica; Slare on Sugar; Cruickshank's Experiments in Rollo on Diabetes.

SA'CCHARUM CANADE'NSE, and ACERINUM. See ACER.

SA'CCHARUM ALU'MINIS. See ALUMEN.

SA'CCHARUM LACTIS: the SUGAR OF MILK has been long known and highly esteemed; probably,

however, beyond its real value; but its real nature is not yet generally known. Kempfer has informed us that it was prepared by the Bramins; though Fabricius Bartoldi first mentioned it in his *Encyclopædia*, published at Bologna in 1619, under the title of manna, or nitre of milk. It was long highly esteemed in the forms prepared in Switzerland, viz. of tablets and crystals. The tablets were only inspissated whey, prepared from rennet. These tablets are dissolved in water, depurated by the white of an egg, and set to crystallize. The first crystals are beautifully white; but those which follow require another depuration and evaporation. They are not sensibly acid, rendering oils miscible with water, and preventing the separation of cream from milk. Sheep's milk, though seemingly the sweetest, afforded the least proportion, and asses' milk the largest; goats', cows', human, and mares' milk followed that of sheep's in the same order; goats' milk producing the least, and mares' the greatest quantity next to asses' milk.

The crystals of the sugar of milk are rhomboidal; their taste is sweetish, or rather mawkish, and they are soluble in four parts of boiling water, and about twelve of cold. It seems to contain the radical of the saccharine acid, without any separate acid or alkali, with what is styled a saponaceous substance, but is, however, mucilage. In reality this boasted remedy, which has been used in hectic, &c. is little more than a mucilaginous substance, with an excess of the radical of saccharine acid. It was supposed to be the subject of, or at least to assist, the vinous fermentation; but this suspicion Fourcroy has shown to be unfounded.

SACCHARUM SATURNI. See PLUMBUM.

SA'CCHO-LACTIC ACID differs, as will be obvious from the former article, from the *mucous*. It is prepared by treating the sugar of milk repeatedly with nitric acid, during which the saccho-lactic separates in a white powder, and from the remaining sugar some crystals of oxalic acid are formed. This white powder is sparingly soluble in hot water; but it reddens the blue vegetable juices, effervesces with chalk, expelling the carbonic acid, and forms neutrals, styled *saccholats*, which have not been examined. It is probably a mucilage, with a little saccharine or oxalic acid slightly adhering, or what is more probable, an oxalic acid disguised by the union of animal matter. See Scheele's *Essays*; Hemstadt in *Crell's Chemical Journal*.

SA'CCHO-LAS, (from *saccharum*, sugar, and *lac*, milk). SACCHOLATS. Salts formed by the union of saccholactic acid, with different bases.

SA'CCULI ADIPO'SI, (dim. of *saccus*, a bag, and *adeps*, fat). See CELLULOSA MEMBRANA.

SA'CCULI MU'CO'SI. See BURSAE MUCOSÆ.

SA'CCULUS and SA'CCHUS. See EPITHEMA.

SA'CCULUS CHYLIFERUS. See RECEPTACULUM CHYLI.

SA'CCULUS CO'RDIS. See PERICARDIUM.

SA'CCULUS LACRYMALIS. The LACRYMAL SAC is an oblong membranous bag, situated behind the caruncle at the inner canthus of the eye, by which the tears are conveyed from the surface of the eye to the nostril on each side. It receives the tears at the lachrymal points, from whence it conveys them to the os turbinatum inferius, where it opens into the nostril. The body of the bag is in the grooves of the os unguis, and os max-

VOL. II.

illare, which form the passage. See PUNCTA LACRYMALIA.

SA'CCUS, (from the Hebrew term *sak*, because it is only open at one end). The *intestinum cæcum*, *anus* *diacheomenus*.

SA'CER MU'SCULUS, (from *sagur*, Heb. *secret*), *transverso-spinalis lumborum* of Winslow, is composed of several oblique, converging, or transverso-spinal muscles, and lies between the spinal and oblique apophyses of the loins, reaching to the os sacrum. The lowest is fixed to the upper lateral parts of the os sacrum, and to the posterior superior spine of the os ilium; the rest are fixed to the three lowest transverse apophyses, and to the four lowest oblique apophyses of the loins and their lateral tuberosities; from thence they run up to all the spinal apophyses of the *vertebræ*.

SACERDOTIS VIRILE. See ARUM.

SACK. A wine much drank by our ancestors, and celebrated in the pages of Shakspeare. It seems to have been a stronger Rhenish, which is at first sharp and unpleasant. We suspect it to be of this kind, because it was sometimes adulterated with lime. "There's lime in this sack," says sir John Falstaff. Sugar was occasionally added: but this does not furnish an argument on either side; for our ancestors were always fond of sweet liquors. Howell calls it a dry Spanish wine, *vin sec*; others derive it from the *borachios*, in which it was probably brought from the mountains; but these were never called *sacks*. Sack is called by Venner, "a penetrative wine, a quality retarded by sugar;" and we should suspect, that by penetrative he means pungent.

SA'CKCHAR, SA'CKHARI. See SACCHARUM.

SA'CRA ARTERIA, (from *sacer*), goes out from the back part of the aorta, at the bifurcation, on each side respectively. Sometimes there are three or four, and sometimes but one. They occasionally rise a little higher from the *lumbares*, or from the *iliacæ*; and are ramified on the os sacrum and the neighbouring parts of the *peritonæum*, *rectum*, and *fat*, penetrating into the substance of the bone.

SA'CRA HERBA. See VERBENA.

SA'CRA TI'NCTURA, NOW ALOES VINUM. ALOETIC WINE, is made by digesting eight ounces of *socotorine aloes*, and two ounces of *canella*, in seven pints of Spanish white wine, to which a quart of proof spirit has been added. It will be of use to prevent the aloes, when moistened, from running into concretions, to mix the aloes and *canella*, separately powdered, with pure well washed white sand. (Ph. Lond. 1788.) This is esteemed a warm purgative, in doses from six to sixteen drachms. Three or four drachms, with a drachm of spirit of lavender, repeatedly taken about noon, or at bed time, have been thought useful in cases of indigestion and headaches: large doses of the wine or the tincture of aloes have been directed to produce the bleeding piles where they have been suddenly suppressed, and their return supposed to be necessary.

SA'CRA VA'SA. The arteries and veins which belong to the os sacrum and the adjacent parts.

SA'CRA VE'NA sometimes proceeds from the bifurcation of the *vena cava*, at others from the origin of the left *iliaca*, and accompanies the artery of the same name.

SA'CRI ACU'MEN O'SSIS. See ACUMEN.

P p

SA'CRO LUMBA'RIS, vel **LUMBA'LIS**. This muscle is a part of the *longissimus dorsi* at its origin; but soon divides, and is inserted by digitations into the angle of every rib. The uppermost tendon is inserted into the transverse process of the last cervical vertebra.

SA'CRO LUMBA'RIS ACCESSO'RIVS; *accessorius sacro lumbalis*; *cervicalis descendens*, *cervicalis dorsi*, is a continuation of the *cervicalis dorsi*, lies on the outside of the complexus, and coming down from the transverse processes of the lower *vertebræ colli*, is continued down under the *sacro lumbaris* to the ribs, which it depresses, as well as the *sacro lumbaris*.

SA'CRO NE'RVI. Five or six branches of nerves from the spine pass through the *os sacrum*, and from thence obtain their name. The three first join the fourth and fifth lumbar nerves to form the sciatic nerve. The third sacral nerve gives some branches to the pelvis.

SA'CRO COCCYGE'US. See **COCCYGE'US POSTERIOR**.

SA'CRUM OS, (from its magnitude and importance, since it is the support of the spine,) *os basilare*, *albagiazi*. This bone is of a somewhat triangular shape, broad above, narrow below, convex behind, for the more advantageous attachment of the muscles, and concave before, to enlarge the cavity of the pelvis. In the fœtal state it consists of five distinct bones, which in adults are united, though the marks of the former separation continue. On the outside there is a ridge, which is called the spine; and the bodies of the *vertebræ* are united to the processes by strong bony bridges, which support the weight of the whole spine. Oblique processes are only found in the upper bone of the sacrum, and these are connected by strong ligaments to the processes of the last lumbar vertebra. Where the oblique processes in the bones below should be, we find only tuberosities. The transverse processes are united, and the three first form two irregular cavities, of which that behind is divided by a transverse ridge. The *transverse processes* of the last two bones are short, and from these to the ilium the *sacro sciatic ligaments* pass. The *spinal processes* of the three uppermost bones are nearly erect, short, and sharp: the lower ones are opened behind, and the fourth is more blunt or bifurcated, without the two legs forming a spine. Sometimes they do not form a canal by their union, but a fossa by their approach. The canal contains the lower part of the spinal marrow, which gradually grows smaller, terminating, as we have seen, in filaments styled *cauda equina*, and the cavity is proportionally diminished. On the fore part there are four pair of holes for the transmission of the nerves. The holes on the back part are covered by membranes, which admit of the passage of small nerves, but the largest nerves pass anteriorly. The size of the holes, as of the canal, lessens as they descend. This bone is connected with the *ossa innominata* by *symphysis*, and forms the posterior part of the pelvis; its substance is spongy. Below, the *os sacrum* is connected with the *os coccygis*.

SA'FFRAN DE TE'RRRA, (from the Arabic term *xafar*, yellow). See **CURCUMA**.

SAGAPE'NUM, *serapinum*, is the gummy resinous juice of an oriental or rather an African plant, supposed to be a species of *FERULA*, q. v. It is brought from Alexandria, either in distinct tears, or in large masses; externally it is yellow, internally paler, and clear like horn; but sometimes of a greenish hue, soft, and stick-

ing to the fingers when handled. Pieces of bdellium, sometimes sold for it, may be distinguished by their weaker smell: that of *sagapenum* is alliaceous, and resembles a mixture of *asafetida* and *galbanum*. The taste is moderately hot and pungent. This gummy resin is superior to the *opoponax*, *galbanum*, and *ammoniacum*, approaching nearest to the *asafetida*. It is generally used as an expectorant, deobstruent, and antispasmodic, often in the same cases as the *ammoniacum*, or *asafetida*. Boiling water dissolves about three fourths of it; rectified spirit about one half. From 480 grains, 306 of spirituous and 108 of watery extract were obtained; by an inverse operation, 170 of watery and 241 of spirituous extract. Water brings over with it in distillation much of the flavour of the *sagapenum*, and a small portion of essential oil, but the distilled spirit is not wholly destitute of flavour. It is an ingredient in the *pilulæ gummi*, now *pilulæ galbani compositæ*. See Lewis, Tournefort's and Cullen's *Materia Medica*; Neumann's Chemistry.

SAGIT'TA, an arrow. **ARROW HEAD**, from its leaves resembling the head of an arrow. *Sagittaria sagittifolia* Lin. Sp. Pl. 1410, β. At first the leaves of this plant resemble those of plantain, but afterwards the bearded head of an arrow; the fruit consists of a collection of seeds like the strawberry. It is said to possess similar virtues with the plantain, but is rarely used. Its roots are esculent.

SAGITTA'LIS SUTU'RA, (from its resemblance to an arrow,) *virgata*, *obelæa*, *rhabdoides*, the **SAGITTAL** or **STRAIT SUTURE OF THE HEAD**, which runs from the *os frontis* to the *os occipitis*, between the parietal bones.

SAGITTA'RIA ALEXIPHA'RMICA, (from its use in counteracting the poison conveyed by darts,) *aguti-guepo-obi Brasiliensis*, *Malacca radix*, *canna Indica*, *thalia geniculata* Lin. Sp. Pl. 3, **ARROW ROOT**, **DART WORT**. It is found in the West Indian islands, is two or three inches long, as thick as a man's thumb, jointed and white. See Raii *Historia*.

SAGITTA'TUM, the leaf of a plant shaped like an arrow.

SAGOU. (See **PALMA JAPONICA**.) It is procured from the *cycas circinalis* Lin. Sp. Pl. 1658, which grows in Amboyna, Sumatra, and the Molucca islands, in marshy grounds; and there are two or three species, or at least varieties, of it not accurately described. Its trunk rises to ten or twelve feet in height, and the medullary substance is interposed between the fibres. It bears fruit only when arrived at its full growth, or rather when it is near the decline; and as the fruit is nourished at the expense of the medullary farina, the natives endeavour to retard the period of fructification. When the medulla has attained its perfection, the leaves are covered with a white powder, which seems to be a transudation of this substance. Sometimes the trunk is perforated, a part taken out, and rubbed in the hands, to ascertain the state of the farina.

When the period of the collection of this *fæcula* is arrived, the tree is cut down, divided transversely into billets, which are split in three or four pieces. The medulla, then cleared from its involucre, is bruised, agitated in water till it is entirely suspended, and then strained. What remains on the filter is given to the hogs, or thrown into the garden; what has passed through it is separated by rest, and after some time the

fluid is poured off. If the more solid parts which do not pass through the filter are thrown into the garden, mushrooms of an exquisite flavour are soon produced, and larvæ of weevils, which are not less esteemed as food, soon swarm on the residuum.

The fæcula which thus subsides is cut into little cakes, and dried in the shade. This is the true sago of which biscuits are made; but as it is not susceptible of fermentation, it will not produce bread. Soups are thickened with it, and it is an ingredient in sauces of every kind in India, and the adjacent islands.

Sago, kept dry, may be preserved for an indefinite period; but to bear the vicissitudes in climate in a long voyage it must be roasted in a furnace, and the surface slightly browned. In this last form it is generally brought to Europe.

With us it is usually eaten in a simple state, boiled with water or milk, sometimes seasoned with spices, sometimes warmed with wine. It is a light and nourishing food, adapted to the extreme of either period of life, to hectic patients, as well as those recovering from long fevers, or diseases where the digestive faculties are much weakened. Its chief recommendation arises from its not fermenting, and consequently from its being neither flatulent nor acescent.

Potatoes, it is said, will afford a similar fæcula, and the caryota, with many other palms, contain apparently a medulla of the same kind.

SAL, (from *αλς*, salt). SALT. Difficulties on every side have met those chemists who have with the greatest care attempted to define salts, and the reason will be obvious from what we have often had occasion to observe, that nature has no limits: those which we perceive are the result of our imperfect knowledge, and when the lacunæ are filled by progressively extending science, our definitions are useless. The saline taste is a simple idea, of which common salt is a familiar example; and if we were to define it, we should say that it is a pungent taste, without heat, or biting acrimony. The best authors who have defined salts from their properties consider them as remarkable for their sapidity, soluble, incombustible, and capable of crystallization. Yet many neutrals have no taste, and some metallic oxyds a sensible one. Vitriolated barytes crystallizes, but is scarcely soluble in water; and many bodies certainly not saline are incombustible, as the various earths of the micaceous genus. In short, objections rise on every side, nor will chemical analysis assist us. If azot is a principle of some salts, oxygen is of others; if some are apparently simple, others are compounded; if some are fixed, others are volatile. The difficulty, in fact, arises from a name having been assigned when science was in its infancy, and having been obstinately retained when it was found neither scientific nor accurate. We shall, therefore, not consider them in the abstract, but divide them according to the following scheme:

I. Simple salts.

α Alkaline.

Potash, natron, ammonia.

β Earthy.

Barytes, lime, alumine, magnesia.

γ Acid.

Mineral; vitriolic, nitrous, and muriatic.

Vegetable; tartar, the acid of sugar, of wood sorrel, of fruits, &c.

Metallic; arsenic, columbium, &c.

Animal; phosphoric, uric, bombic, formic, lactic.

Aerial; carbonic acid gas.

δ Neutral.

Alkaline, with the different acids.

Earthy, with the same.

ε Triple or quadruple compounds.

It is needless to pursue this subject, which is merely chemical; for the salts used in medicine occur under their proper heads, and we shall add only tables of the synonyms of the different salts, and of their respective solubility.

TABULA OF SYNONYMORUM.

Emetique Gallorum.
Tartar emetic.

We had ultimately reserved for this article the result of the experiments on the composition of the muriatic acid and soda, suggested by MM. Pacchioni, Peele, and Guyton. It is with feelings of mortification and disappointment we must add, that the experiments of the galvanic society at Paris, and the very minute delicate examinations of Mr. Davy in the Philosophical Transactions of the present year (1807), have nearly set the question at rest, and shown that the acid and the alkali apparently produced were separated either from the apparatus, or the fingers of the operator. Mr. Davy's researches have, however, pointed out a very refined mode of analysis by means of the galvanic fluid, which promises the most important results.

Very few hours had elapsed, after writing the last sentence; when the discovery of Mr. Davy, thus predicted, was announced. By the galvanic fluid he discovered both potash and soda to be metallic bodies, attracting oxygen so powerfully as to decompose water, and they thus appear in the form of oxyds. No fluid, except naphtha, will retain them in their metallic state. They are chiefly remarkable, as metallic oxyds, for their inconsiderable specific gravity; but we shall, however, add in this place the abstract of Mr. Davy's experiments from a respectable journal, and follow it with

a table of the solubility of different salts from Dr. Duncan's excellent Pharmacopœia.

Mr. Davy, in the last Bakerian lecture, suggested the probability that other bodies, not then enumerated, might be decomposed, or exhibited in more simple forms, by electricity, particularly that excited by the galvanic apparatus. Since that time, by means of several very powerful galvanic troughs, consisting of 100 pairs of plates six inches square, and 150 pairs four inches square, he has succeeded in decomposing potash and soda. This was effected by placing the alkali moistened on a plate of platina, and exposing it to the galvanic circle; when oxygen was disengaged, and the primitive base of the alkali left on the plate, in form and appearance much resembling small globules of mercury, and of an highly inflammable nature. These globules are lighter than any fluid, as they swim in distilled naphtha. The base of potash is of a specific gravity as six, that of water being ten. At the freezing point these globules are hard and brittle, and when broken and examined with a microscope they present a number of facettes with the appearance of crystallization; at 40° of Fahrenheit they are soft, and can scarcely be distinguished from globules of quicksilver: at 60° they are fluid, and at 100° volatile. When exposed to the atmosphere they rapidly imbibe oxygen, and reassume their alkaline character. In distilled naphtha they may be kept four or five days; but if exposed either to the atmosphere or to oxygen gas, they almost instantly become incrustated with a coat of regenerated alkali: this incrustation can be removed, and the reduced globule will remain in naphtha, or separated from all contact with oxygen, as before: the naphtha forms a thin film round the globule, and excludes the contact of oxygen.

One part of the base of alkali and two of mercury, estimated by bulk, (or about 1 part of the base to 48 of mercury by weight,) formed an amalgam, which when applied in the circle of a galvanic battery (which, produced an intense heat), to iron, silver, gold, or platina, immediately dissolved these, and converted them into oxyds, in which process alkali was regenerated. Glass, as well as all metallic bodies, was also dissolved by the application of this substance; the base of alkali seizing the oxygen of manganese, and of minium, potash was regenerated. One of these globules placed on a piece of ice dissolved it, and burnt with a bright flame, giving out an intense heat. Potash was found in the product of the dissolved ice. Nearly the same effects followed when a globule was thrown into water; in both cases a great quantity of hydrogen gas was rapidly liberated.

The specific gravity of the base of soda is as seven, that of water being ten; it is fixed in a temperature of 150°, and fluid 180°.

The specific gravity of the amalgam was found by means of a mixture of oil of sassafras with distilled naphtha, in which a globule remained either buoyant at top or quiescent at bottom, in a fluid weighing as nine, water being ten.

Mr. Davy tried its effects on the phosphats, phosphurets, and the greater part of the salts of the first and second degree of oxydizement, all which it decomposed, seizing their oxygen, and reassuming its alkaline qualities.

From the medium of a number of analytical, and of nine synthetical experiments, it appeared that 100 parts of potash contain 15 oxygen, and 85 of inflammable

base; and that the same quantity of soda contains 20 oxygen and 80 base.

Mr. Davy tried a great number of complex experiments on volatile alkali, in which he was assisted by Messrs. Pepys and Allen; by these he ascertained, that oxygen is also an essential ingredient in ammonia, 100 parts of it containing 21 of oxygen: but this result depended too much on eudiometrical calculation to be received as an established fact.

The earths of barytes and strontites were likewise examined, as being most analogous to the alkali's, and both yielded considerable quantities of oxygen. Mr. Davy related also some miscellaneous experiments on the muriatic and fluoric acids, which completely refutes the strange opinion held by some, that they did not contain oxygen, as these experiments proved in the most satisfactory manner that oxygen is one of their constituent principles.

TABLE of the SOLUBILITY of Saline and other Substances, in 100 parts of Water, at the temperature of 60° and 212°.

<i>Acids.</i>						60°	212°

Gelatin,	-	-	-	-	soluble.	more so.
Urea very soluble.	-	-	-	-		
Cinchonin.	-	-	-	-		

Salts not soluble in 100 times their weight of water.

Sulphates of baryta, strontia, and lime, and sub-sulphate of mercury.

Phosphates of baryta, strontia, lime, magnesia, and mercury.

Fluate of lime.

Carbonates of baryta, strontia, and lime.

Muriates of lead, and silver, and sub-muriate of mercury, (calomel).

Sub-acetate of copper.

SOLUBILITY of Saline and other Substances in 100 parts of Alcohol, at the temperature of 176°.

All the acids, except the sulphuric, nitric, and oxy-muriatic, which decompose it, and the phosphoric and metallic acids.

Potass, soda, and ammonia, very soluble.	
Red sulphate of iron.	
Muriate of iron,	100
lime,	100
Nitrate of ammonia,	89.2
Muriate of mercury,	88.3
Camphor,	75.
Nitrate of silver,	41.7
Refined sugar,	24.6
Muriate of ammonia,	7.1
Arseniate of potass,	3.75
Nitrate of potass,	2.9
Arseniate of soda,	1.7
Muriate of soda, (Mr. Chenevix).	Alkaline soaps. Magnesian do. Extractive. Tannin.
Volatile oils. Adipocere. Resins. Urea. Cinchonin.	

Substances insoluble in Alcohol.

Earths.

Phosphoric and metallic acids.

Almost all the sulphates and carbonates.

The nitrates of lead and mercury.

The muriates of lead, silver, and soda.

The sub-borate of soda.

The tartrate of soda and potass, and the super-tartrate of potass.

Fixed oils, wax, and starch.

Gum, caoutchouc, suber, lignin, gelatin, albumen, and fibrin.

SAL is also a term affixed to several saline substances, which, for the sake of the references to the present work, we shall add. *Sal vol. salis ammoniaci; sal e. cervi.* See ALKALI VOLATILE. *Sal absinthii; tartari; soda,* see ALCALI. *Ammoniacum,* see VOLATILE. *Alkalinus salis marini,* see ANATRON: *cyreniacus,* see AMMONIACUS SAL: *fossilis, rupeus,* see GEMMA SAL: *ca-tharticus Glauberi; Dauphiny; mirabilis; admirabilis;* see GLAUBERI SAL: *Sennerti,* see DIURETICUS SAL: *fusionis; fixionis;* see ALEMBROTH: *gemmæ; communis; marinus,* see MARINUM SAL: *alkali fixum,* see CLAVELLATI CINERES: *petræ; prunellæ; polychrestum* see NITRUM, &c.*

SALACITAS, (perhaps from *Salacia*, the goddess of the sea, *Venus*). *Hysteroecnesmus, nymphomania, hystero-romania, pruritus uteri, furor, lagnia, satyriasis.* We have introduced this article with some hesitation, as we have constantly avoided every method of furnishing any incentive to the prurient imagination, and have been at last determined, by reflecting that, as it often arises from obscure and unsuspected causes, we may relieve what is frequently a troublesome disease, and rescue from suspicion a moral character in a case where the complaint is wholly corporeal.

It is a disease often of early youth, and not unfrequently of advanced age. An unsuspected source of the complaint is often irritation from diseases of neighbouring organs. Thus it sometimes arises from diseased ovaries, from calculus in the bladder or kidneys, from leucorrhœa, from inflammation of the womb, from acrid purgatives, from the irritation of cantharides on the neck of the bladder, from flatulence, and is hence probably the disease of melancholic temperaments, from whipping, from the diuretic effect of acidulous waters, from a disproportioned clitoris, and from worms, particularly ascarides. A general acrimony is accused by Schurig; but we find more decisive proofs of its effect in hydrophobia and lepra; in the effects of aromatics; and, if the facts are well

founded, in the use of satyrium. General fulness, plethora, and continence, are obvious causes, and require no remark; but the use of tea, connected with plethora, is accused, probably with little reason. Riding on horseback is equivocal in its effects, and we find it sometimes enumerated among the causes, and sometimes among the remedies. It is certainly not a remedy.

When the disease proceeds from any of the causes enumerated, the cure must depend on their removal. When it originates from increased excitement of the vessels of the respective organs, the remedies which we shall enumerate will often relieve; and these will mitigate the complaint, though it arises from other, more distant, irritations.

Cold is the principal remedy, and even cold water has been injected into the vagina by Nicolai. Nitre, as a means of abstracting heat, and diminishing the action of the vessels, is highly useful; but large doses of camphor, as we have often mentioned, are still more effectual. Hahn directs this medicine in combination with vinegar. A similar remedy is the acetated lead, recommended in the *Ephemerides Naturæ Curiosorum*, Annus ii. 121.

Every means of diminishing the quantity of fluids is useful. Venesection yields, however, a temporary and precarious relief. Saline purgatives are more effectual, and a cooling diet of acid fruits and vegetables is more permanently beneficial. The portulaca has been particularly recommended, though without any sufficient foundation.

Narcotics have not been fairly tried. Opium has seemed useful; but the cicuta, digitalis, and aconite will be apparently more so. Amusing the mind, and avoiding every lascivious idea, will be highly necessary; for Ovid's Cure of Love is peculiarly applicable to this disease. *Res age tutus eris.* We find instances where ulcers or the small pox have relieved; but the idea has not been pursued so as to recommend a drain by means of a seton or issue.

See Moschion de Morbis Mulierum; Ambrose Parey, xxiii. 64; Mercurialis de Morbis Mulierum; Schurig Gynæcologia.

SALAMA'NDRA, (because it is not destroyed by fire, a property reported of the salamander). See **AMIANTHUS**.

SA'LEP, vel **SA'LEB**. See **ORCHIS**.

SALICO'RNIA, (so called from its salt taste and horn like shape, from *sal* and *cornu*). Jointed **GLASS WORT**. Its leaves are gathered and pickled instead of samphire. See **KALI**.

SALI'TRON. See **ANATRON**.

SALIUN'CA. See **NARDUS CELTICUS**.

SALI'VA, (from a salt taste,) is that fluid by which the mouth and tongue are continually moistened in their natural state, and is supplied by glands, from thence called salivary. This fluid is thin and pellucid, not concreting by heat, almost without taste and smell. By chewing, it is expressed from the ducts, and is intimately mixed with our food, the digestion of which it greatly promotes. In hungry persons it is more acrid, and copiously discharged; and in those who have fasted long it is highly so, so that the fasting spittle has been styled resolvent: about twelve ounces have been discharged in a day. The saliva contains chiefly water, with mucus, sea salt, and probably some animal matter. It is coagulated by alcohol, inspissated by a small proportion, and dissolved by a larger one of mineral acids. The sea salt is not obvious to the taste, from our constant experience of it, but the muriatic acid is in part also combined with ammonia, since lime and caustic alkali separate ammonia from it. The animal matter appears from the tartar on the teeth, and it sometimes is found in the form of a calculus in the salivary ducts. Its specific gravity is greater than water. Saliva probably hastens fermentation, since it is apparently the ferment to the bowls of Kava in the South Sea islands. Pringle found it an antiseptic; though it easily becomes putrid in warm air, out of the body, a quality counteracted probably by the action of the stomach. (See **DIGESTION**.) When wanting, the functions of the stomach are greatly disturbed.

The saliva is variously diseased. When we spoke of the sweet taste in the mouth, analogous to the sweetness of diabetic urine, we considered the observation as new; but we have since met with it in Schurig's *Sialogia*, in Riedlin, and the Copenhagen Transactions. The saliva is occasionally yellow, particularly in jaundice, and sometimes it has been said to be blue. From too active salivation Nuck informs us that it is sometimes bloody.

It is well known that the infection of a rabid animal is conveyed by the saliva, and more than one instance has occurred of its producing nervous affections when conveyed during a violent fit of rage. (Hoffman de *Saliva ejusque Morbis*.) We find also that the bites of epileptic persons have been attended with disagreeable consequences. It is sometimes deficient in quantity from inflammation and obstruction of the salivary duct, occasionally from calculous concretions. Worms, it is said, also have been found in it. Diseases have been occasionally conveyed to children by the disgusting custom of tasting the pap, or, in part, masticating the food: each should be severely reprobated.

A too copious evacuation of it produces thirst, loss of appetite, bad digestion, and an atrophy.

VOL. II.

See Haller's Physiology, in the article of Mastication; Boerhaave's Institutes; Fordyce's Elements, part i. p. 23.

SALI'VA'LES GLA'NDULÆ, (from *saliva*), the **SALIVARY GLANDS**, are commonly reckoned three pair, viz. the parotid, the maxillary, and the sublingual; but Dr. Hunter would refer the last to another class.

Various subordinate glandular bodies, distributed round the fauces and throat, seem also to furnish saliva, though probably their chief use is to supply a mucus, to defend the tender skin of the mouth. The parotids, the largest of these glands, are irregular and oblong bodies; but these we have already described. (See **PAROTIS**.) The maxillary have also been already noticed. (See **MAXILLARES GLANDULÆ**.)

The sublingual glands are smaller, oblong, and flattened, situated under the anterior portion of the tongue, on the lateral portions of the mylo-hyoidei. The extremities are backward and forward; the edges obliquely inward and outward. They are covered by the external membrane of the tongue; their ducts are small and short, opening near the gums in distinct orifices. The musculi genio glossi separate the two sublingual glands and the two maxillary ducts. The arteries are derived from the lingual, and the nerves from the fifth pair, which supply the tongue.

To these may be added the **MOLARES GLANDULÆ**, q. v.; the buccales and labiales, which are rather mucous follicles than glands. We may just add, that the situation of the salivary ducts is not always constant, and that the calculous concretions are often found in them. They are subject also to tumours from other causes, particularly inflammation. (Murray de *Tumouribus Salivalibus*.)

When obstructions have taken place in the duct, suppuration is often the consequence, and the saliva flowing through the wound causes a fistulous ulcer. (Memoires de l'Academie de Chirurgie, iii. and v.) It is cured sometimes by compression, occasionally by the actual cautery (Saviard); by the gluten of parchment burnt with opium (Riedlin); sometimes by caustics (Gill in the Medical Commentaries, and Louis in the Memoires de Chirurgie, v. 10. iii. 18); chiefly the lapis infernalis. Tessart employed a seton with success.

SALI'VA' LIS DU'CTUS STENO'NIS. The **UPPER SALIVAL DUCT**, is the duct which carries the saliva from the parotid gland into the mouth. See **BUCCINATOR MUSCULUS**.

SALI'VA'NTIA, (from *saliva*). Medicines which excite a salivation.

SALI'VA'RIS HE'RBA, (from its exciting a discharge of saliva). See **PYRETHRUM**.

SALI'VA'TIO, (from *saliva*). A **SALIVATION** is an extraordinary discharge of spitting, chiefly excited by the use of mercury; a practice seldom employed in any considerable extent. As it may be, however, requisite to excite a gentle spitting, we shall offer a few remarks on the most convenient method of producing and conducting the evacuation, after we have spoken of the increased discharge of saliva from different causes.

A salivation, or *ptyalism*, is sometimes a symptom of disease, more often excited for the purpose of curing. As a symptom it is frequently salutary, though at times, as in paralytic patients, the effects of debility only. We know, for instance, that in the natural

Q q

small pox the discharges of saliva, about the acmé of the disease, is a favourable symptom; in fevers it has been sometimes found critical, and the fluid of dropsies has been occasionally discharged in this way. Yet we perceive from some references to authors whom we have not been able to procure, that it has been fatal, perhaps from its excess, or from the great debility previously induced. Salivation is said to be sometimes periodical, sometimes epidemic.

Its causes are numerous. Suppressed evacuations are very frequent ones, and suppressed fluor albus, ischuria (Daniel in the Medical Communications, vol. i.), suppressed lochia, and perspiration of the hands, have been found to produce it. The state of the stomach is a frequent cause, and it is a common attendant on dyspepsia; generally preceding vomiting. From this effect the squills and antimonials have been probably considered as causes. Acrid substances masticated are common causes, and the irritation of tobacco smoke is well known. It is only necessary to add, that the continued use of smoking produces a debility of the salivary glands, and often renders the salivation permanent. From debility, also, it is a common symptom in scurvy, often in jaundice. Neighbouring irritation sometimes excite the action of these vessels. We have seen it, we think, owing to scrofulous tumours; and Dr. Power mentions its arising from wool kept too long in the ear.

We know no internal medicine which acts with certainty on the salivary glands, except mercury; for, though we have mentioned the nitric acid, it was introduced with doubt and hesitation. See MATERIA MEDICA.

The cure of salivation will, in general, depend on its causes. Of mercurial salivation we shall afterwards speak at some length; but this discharge from other causes is chiefly relieved by tonics, with astringent gargles. The latter should, however, be employed with caution, for many inconveniences are recorded to have arisen from hastily suppressing the discharge. (Sylvester's Medical Observations and Inquiries, iii. 241.) Yet these relate rather to what we may style the more acute salivation from mercury: the more chronic kind, from debility, is not so easily suppressed. It often continues for the whole life, without any change, notwithstanding the most active astringents are employed. The chief vicarious evacuation is that by urine.

Mercurial salivation is chiefly used in LUES, q. v. but sometimes for other complaints, particularly obstructions of the liver, and lepra. In the two latter it is seldom carried far; and in the first the discharge is now comparatively slight. It is of little importance by what preparation it is excited, if of sufficient activity to increase the salivary secretion without injuring the stomach or irritating the bowels. Each practitioner has his favourite form, and each may be indulged. In general, mercurial ointment rubbed in externally is the safest; and calomel or mercury, divided by mucilaginous or fatty fluids, are the most general internal preparations; perhaps inferior to none. The practice of rubbing the calomel into the gums and fauces originated with Mr. Clare, not "Mr. Cline," to whom, by a typographical error, it was attributed in the article "LUES." He applies it also under the prepuce and within the labia, by which he thinks the cure is expedited.

Mr. Cruikshank, in an Appendix to Mr. Clare's publication, observes, that there is no doubt of the absorption of a fine powder taking place on the inside of the mouth, of the præputium, of the labia, &c; for the particles of the blood, seen in the simple microscope, are at least ten times larger than those of the levigated calomel, yet the absorbents are often turgid with red blood. The particles of quicksilver, in the best prepared mercurial ointment, appear in the same microscope as distinct from each other as the red globules of the blood; yet they are very readily taken up by the absorbents of the skin. Mr. Hunter hath frequently directed calomel to be rubbed on the skin with the volatile liniment, and it has been followed by the effects of the unguentum hydrargyri. The inside of the cheek is a better absorbing surface than perhaps any other accessible to friction in the body; and probably calomel becomes milder in its operation this way, as the divided quicksilver becomes milder when absorbed by the skin. It is also a less tedious, less laborious process than that of rubbing the unguentum hydrargyri. These are undoubtedly advantages; yet they may be considered as affording a favourable view of the comparative merits of the two preparations. The friction is by no means so easy as is represented; and we have heard that it has been followed by troublesome sores in the mouth. But by whatever preparation salivation is excited, the medicine should be slowly accumulated, unless when employed in the urgent cases of hydrocephalus, hydrophobia, croop, &c. When used in lues, a warm bath may be used two or three times before the unguentum hydrargyri; and the patient, during its use, should be kept in a warm room, wear a flannel shirt, having previously lived on a low diet for a few days. Except in strong constitutions, from a pint to a quart is a sufficient discharge of the saliva in twenty-four hours. The patient's strength should be supported with a light, nourishing, and mucilaginous diet; and, if faint, a little wine whey, or mulled wine, may be allowed.

The quantity of mercury necessary to excite salivation differs greatly in different circumstances and constitutions. In debilitated, scorbutic, and perhaps scrofulous habits, we have found three grains of calomel given in the dose, or one grain on three succeeding nights induce the discharge. It has been brought on by sprinkling precipitate on a wound (Hildanus); by a mercurial injection in a fistula; by a mercurial girdle; and the mercurial ointment employed to kill lice. In these cases, the idiosyncrasy of the patient seems to influence the effect; and, therefore, this should be, if possible, ascertained before mercury is exhibited in any considerable quantity. The inflammation which this medicine induces is rather erysipelatous than phlegmonic, and it sometimes attacks the inside of the cheeks, producing small, irritable, creeping ulcers, with a very slight or no affection of the gums. The latter are, however, most commonly inflamed.

It is usual at present to produce this discharge in a very moderate degree; but some action on the gums is necessary, to show that the medicine has been introduced into the system. This is particularly the case in lues and chronic inflammations of the liver. In other complaints it is less essential if the symptoms disappear. The effectual relief of these is the only certain criterion by which we are taught to leave off the medicine, and it will be prudent to continue it for some time

after these have disappeared. On omitting the mercury the salivation gradually subsides.

The discharge of saliva is, however, sometimes too violent, or it continues long after the symptoms have disappeared, from the increased irritability induced by excess of excitement. This increased discharge is obviated by purgative medicines, by opium, and by sulphur. If any mercury remains in the system, these will sometimes relieve; but if so long a period has elapsed that we may suppose the whole discharged, the cure must rest on the general indication of increased irritability from debility. The medicines just mentioned are not all of equal efficacy. Mr. Hunter thinks purgatives useless; and we certainly have not found them highly beneficial, though sometimes they lessen the discharge. Opium we have thought highly useful, particularly in the form of Dover's powder. Sulphur is known to lessen the activity of mercury out of the body; and as it enters the circulation with little change, it may have the same effect in the circulating system. But this, like other finely spun theories, deceives us in practice. Sulphur is by no means highly useful in these circumstances. Diuretics, which seem to excite what appears to be a vicarious discharge, have not been tried, or, if employed, not effectual. We believe every practitioner, by the means mentioned, has been able to mitigate salivation; but by no remedies, in every instance, to conquer it wholly.

See Hunter, Swediaur, Bell, and Howard on the Venereal Disease; Stahl de Salivatione Mercuriali et Alberti de Hydrargyrosi.

SA'LIX, (from the Hebrew term *sala*). *Itea*, the common white or the Dutch willow tree; *salix fragilis* Lin. Sp. Pl. 1443, is distinguished by its oblong, pointed serrated leaves, hoary on both sides, though most so on the lower, and in the branches being tough. See Raii Hist. Plant. Philos. Trans. 1763.

The bark of the branches of this tree is considerably bitter and astringent; and has been recommended not only in intermittents, but in all those cases which require tonics and astringents. Dr. Cullen thinks it a promising substitute for the bark; and we have found it equally useful in dyspepsia, profluvia, and every case of chronic weakness. His experiments were made with the bark of the *salix pentandria*, which, in Bergius' hands, failed to relieve intermittent fevers.

SALLADS, (*à sale*). The term is derived from the salt, an ingredient which enters in the smallest proportion. This species of vegetable nutriment consists of vegetables, undressed, either etiolated ones, thus deprived of their acrimony, as endives and celery, or of the tetradynamia, whose seed leaves are only employed, or the others in their earliest periods. We eat in their natural state chiefly the lettuce, the lamb's lettuce, and the water cresses. With all we usually mix vinegar, and oil united with the vinegar by means of the yolk of an egg. The reason for employing oil we have not heard; but have suspected it to have arisen from the apprehension of the accidental mixture of poisonous plants, and the egg is added to combine it with the vinegar. In general, sallads are wholesome, but not admissible in cold, flatulent stomachs; though, in these, the water cresses seldom produce any inconvenience.

SALPI'NGO-PHARYNGÆ'US, (from *σαλπιγξ*, a trumpet, and *φαρυγξ*, the pharynx,) rises near the Eu-

stachian tube, and is inserted into the pharynx. Valsalva and Douglas think it one of the origins of the muscle of the pharynx. See PHARYNX.

SALPI'NGO-STAPHYLINUS, (from *σαλπιγξ*, and *σταφυλή*, the uvula,) arises fleshy from the bony part of the tube of the ear, and is inserted into the basis of the uvula with that on the other side. They draw the uvula upward and backward.

SALPI'NGO-STAPHYLINUS INTERNUS. See PETRO SALPINGO-STAPHYLINI.

SALSAPARILLA. See SARSAPARILLA.

SALSO'LA. See KALI.

SALUTA'RIS DI'GITUS. See DIGITUS.

SALVATE'LLA VE'NA, (from *salus*, health, from the supposed salutary effects of opening this vein in melancholy,) *splenitis*, runs on the back of the hand, from the little finger and that next to it. It has been said to proceed from betwixt the thumb and the fore finger, and to run up to the ulna.

SA'LVIA, *salvus*, (from its salutary effects, which were formerly supposed to be so considerable as to justify the axiom, "*Cur moriatur homo cui salvia crescit in horto*"). *SAGE*, *elelisphacos*, is a low shrubby plant, with square stalks, obtuse, wrinkled, dry leaves, and large bluish flowers, fixed on loose spikes on the tops of the branches. It is a native of the southern parts of Europe, but bears the cold of our climate, and flowers in May and June. Its seeds are called *ebel*.

SA'LVIA BO'SCI. WILD OR WOOD SAGE, from *boscus*, a wood, where it grows.

SA'LVIA ÆTHI'OPIS. See ÆTHIOPIS.

SA'LVIA HO'RMINUM. See HORMINUM.

SA'LVIA MA'JOR. GREATER OR COMMON GARDEN SAGE, *salvia officinalis* Lin. Sp. Pl. 34. The leaves are nearly oval, but pointed; of a green, red, or variegated colour; but all are found on the same plant. The leaves are moderately aromatic, and used in debilities and relaxations both of the nervous and muscular system, as a stimulant, carminative, and tonic. Their smell is strong, but not disagreeable; their taste warm, bitterish, and subastringent; with a solution of vitriolated iron they strike an inky blackness. This species is more agreeable, but not so strong as the lesser sage; the flowers of both are weaker, but more agreeable than their leaves. The best preparations are the watery infusion, and a tincture or extract made with rectified spirit of wine, which contain the whole virtue of the plant. The watery infusion, acidulated with the juice of lemon or of orange, is an agreeable common drink in fevers. From 3 ss. to 3 i. of a conserve made with sage leaves is said to cure weak stomachs, if repeated twice a day. (See SALVIA MINOR.) By distillation with water a small quantity of essential oil is obtained, which possesses only the aromatic part of the herb. See Tournefort and Lewis's *Materia Medica*.

SA'LVIA MI'NOR, *salvia virtutis*. LESSER SAGE, *salvia minor aurita*, and *non aurita*, of Caspar Bauhine; *s. officinalis*, β. Linnæi. Its leaves are narrower than those of the greater sage, whitish, and never red; they are stronger, but less agreeable; though in other respects the same.

Sage has been much employed as a sudorific, for preventing the recurrence of intermittent paroxysms, for restraining colliquative sweats, infused in spirits, or wine (Van Swieten), and the milk of nurses who had

weaned their child: it is also supposed to resist putrefaction. Cullen's *Materia Medica*. See *SALVIA MAJOR*.

SALVIA SYLVESTRIS, *scorodonia*, *scordotis chamaedrys fruticosa*, GERMANDER SAGE, WOOD SAGE. *Teucrium scorodonia* Lin. Sp. Pl. 789, grows in woods and hedges. In smell, taste, and medical virtues, it resembles the scordium rather than the sage; but is less disagreeable than the former, though more so than the latter.

Among the reputed species of sage is the phlomis, or yellow sage, *phlomis fruticosa*, β. Lin. Sp. Pl. 818, which is astringent and vulnerary.

SAMBU'CUS, (from the Hebrew *sabuca*, a musical instrument made of this tree,) *acte*, *infelix lignum*, COMMON ELDER. *Sambucus nigra* Lin. Sp. Pl. 385. COMMON BLACK BERRIED ELDER, is a tree or shrub whose branches are full of fungi, covered with an ash coloured, under which lies a thinner green, bark, and below a white one. It flowers in May, and ripens its berries in September.

The young leaves, when budding, are said to be cathartic; but the parts employed medicinally are the inner bark, flowers, and berries. The first has little smell or taste: on first chewing it impresses a degree of sweetishness, followed by a very slight though durable acrimony, in which its powers seem to reside, and which it imparts both to watery and spirituous menstria. Sydenham directs three handfuls of the inner bark to be boiled in a quart of milk and water to a pint, half of which is to be drank every night and morning, and repeated for several days: it operates upward and downward; and upon the evacuations its utility depends. Boerhaave gave its expressed juice from 3 i. to half an ounce for a similar purpose. In smaller doses it is said to be an aperient and deobstruent in various chronic disorders. These effects are sometimes confined to the ebullus, or dwarf elder; but both have been used without any remarkable advantage. An infusion of the fresh flowers is gently laxative, and of the dried ones diaphoretic, and consequently useful in eruptive disorders. Externally they are employed in fomentations, &c. The London college orders the following *unguentum sambuci*. R. *Florum sambuci* p. ℥ iv. *sevi ovilli* p. ℥ iii. *olei olivæ* m. ℥ i. decoque flores in sevo et oleo donec friabiles sint, deinde exprime et cola. The juice of the berries, when inspissated to a rob, is styled a dissolvent and aperient: it is gently laxative, promotes urine or perspiration, and is recommended in dyspepsia, and debility of the urinary passages, in doses of from one to two or three drachms. See Lewis's *Materia Medica*; *Anatomia Sambuci* per M. Blockwitz; Sydenham's Works.

SAMBU'CUS E'BULUS; *HERBACEA*; and *HUMILIS*. See *EBULUS*.

SAMBU'CUS SANAMUNDA. See *EMPETRUM THYMALI FOLIIS*.

SAMIEL. A poisonous wind in the desert of Arabia, which kills without any apparent change on the body, except a total privation of irritability, and sometimes a distention of the blood vessels, and extravasation of their contents. It comes from the north west quarter, announced by a haze in that direction; but the rest of the atmosphere is clear. The Samiel seems to be a blast of hydrogenous gas, the source of which we shall afterwards explain. See *SIMOON*.

SAMP. A preparation of Indian corn, in which the hard coat is first separated by maceration in an alkaline ley, and the grain is next softened by long continued simmering, in a temperature below the boiling point. It is then said to be a palatable food, with some common condiments, and to supply very effectually the place of bread. It is chiefly used by the Aborigines of America, in the back settlements, both north and south.

SAMPHIRE. The *crythmum maritimum* Lin. Sp. Pl. 354, *feniculum maritimum* of Caspar Bauhine, is slightly aromatic, with a taste not unpleasant. It is sometimes used as a pot herb, but is more commonly pickled, and taken as a condiment.

SA'MPSUCHUM, (from *ψαω*, to preserve, and *ψυχη*, the mind; on account of its cordial qualities). See *ORIGANUM*.

SA'MPSUCHUS. See *MARUM* and *MAJORANA MAJ. FOL.*

SA'NCTÆ HELE'NÆ RA'DIX. *Cyperus Americanus*, *cyperus longus* Lin. Sp. Pl. 67, is a long knotted root, black without, and white within: in taste it resembles the galangal root, and is brought from St. Helena, in the province of Florida, where it is used in pains of the stomach, and in nephritic complaints.

SA'NCTUM SEMEN. See *SANTONICUM*.

SANDARA'CHA. *SANDARACH*, (from the Arabic *saghad*, *narak*), a gummy resin, of a yellowish white colour, in small lumps, dry, brittle, of a pleasant smell, of a resinous and gently acrid taste; it is brought from Africa, and is the production of the *juniperus cedrus* Lin. Sp. Pl. 1471. See *JUNIPERUS*, and *ARSENICUM*, of which it is also an appellation.

SA'NDIVER. See *AXUNGIA VITRI*.

SANGUIFICATIO, (*sanguinem facere*). The animal process by which our fluids are converted into blood. We have seen that blood consists of a watery fluid, styled serum, gluten, fibrin, and the red portion, which in the microscope appear to be globular. The serum contains an ammoniacal salt, by which it seems to dissolve a portion of the gluten. The difference between this fluid and the nutriment taken in, then, apparently consists in the formation of gluten, of the salt, the fibrin, and the red globules. The nature of ammonia we well know; and as its component parts are found in the system, it is not necessary to inquire anxiously into its source. The gluten, we have seen, differs probably from albumen in its proportion of azot, and the fibrin is a more animalized gluten. The source of the azot we have also attempted to investigate. (See *NUTRITIO* and *RESPIRATIO*.) Of the red globules we know little, and their source has not yet been explained. Mr. Hewson supposed them to be manufactured in the spleen, and certainly the red globules are peculiarly copious in this viscus; but admitting all the facts, we advance but little in our knowledge of the process of their manufacture.

The formation of the red globules is connected with the strength and vigour of the constitution; for in the cachectic state they are few, and their colour unusually pale. They are sometimes dissolved in the serum, and escape by every excretory. In other cases the whole of the circulating mass seems to be remarkably diminished; and Lieutaud and others have left us accounts of dissections, in which the circulating system

was found nearly exhausted of its usual contents. Unfortunately we have not been acquainted with the previous symptoms, an omission too common in the collections of that author.

SANGUIFLU'XUS, (from *sanguis*, blood, and *fluo*, to flow). See **HÆMORRHAGIA**.

SANGUINALIS and **SANGUINARIA**, (a sanguine compescendo). *Polygonum aviculare* Lin. Sp. Pl. 519. See **POLYGONUM**.

SA'NGUINIS INO'PIA. A tabes from loss of blood. An instance of the atrophica inanitorum of Cullen.

SA'NGUIS, (απο του σαιιν γυια; because it preserves the body,) *dehene*; *hæma*; BLOOD, the fluid which is contained in the arteries and veins. See **BLOOD**.

SA'NGUIS DRACO'NIS; *cinnabaris Græcorum*, *dracanthema*, *asagen*, DRAGON'S BLOOD, is a resin of a red colour, obtained from the *calamus rotang* Lin. Sp. Pl. 463; *dracena draco* Willdenow, ii. 155, and *pterocarpus draco* Willdenow, iii. 904. The dragon's blood covers the fruit of each tree: one sort is in oval drops, wrapped up in flag leaves; another in large masses, often impure, but sometimes little inferior to the former. Its colour is of a deep red, and when powdered, crimson. It readily melts and flames, almost totally dissolving by the help of heat in rectified spirit of wine, to which it imparts a dead red colour; soluble also in expressed oils; but yielding little or nothing to water. Dragon's blood has no remarkable smell or taste, though when dissolved it seems slightly acrid. The Dutch often adulterate it with mixtures of gum arabic, Brazil wood, alum, &c. which dissolve in water, crackling without burning in the fire. It is recommended as a gentle incassant, desiccative, and restringent, but owes its credit to its union with other astringents in the pulvis stypticus. It is totally inert, and now disused. Lewis's *Materia Medica*. See **GUMMI RUBRUM ASTRINGENS GAMBIESE**.

SA'NGUIS DRACO'NIS HE'RBA. See **LAPATHUM RUBRUM**.

SA'NGUIS HERCULIS. See **CROCUS**.

SANGUI-SO'RBA, (from *sanguis*, and *sorbeo*; because it stops hæmorrhages). See **PIMPINELLA**.

SANGUI SU'GA, (from *sanguis*, and *sugo*, to suck). See **HIRUDO**.

SANI'CU'LA. **SANICLE**, (from *sanando*, healing,) *cucullata*, *dodecatheon*; *symphytum petraeum*.

SANI'CU'LA ALPI'NA LUTE'A. See **AURICULA URSI**.

SANI'CU'LA MAS, *diaphensia*, *cortusa*, *sanicle*, **SELF-HEAL**, *sanicula Europæa* Lin. Sp. Pl. 339, is an umbelliferous plant, with shining, dark green, roundish, serrated leaves: the seeds are rough, and stick to the clothes. The plant is perennial and evergreen, grows wild in woods, on hilly grounds, and flowers in May. It is mildly astringent, is slightly rough, and bitter to the taste, with an acrimony which chiefly affects the throat. Both the watery and spirituous extracts retain its virtues.

SANI'CU'LA EBORACE'NSIS, *pinguicula*, *sanicula montana* flore calcarum donata *viola palustris*, **BUTTERWORT**, **YORKSHIRE SANICLE**, *pinguicula vulgaris* Lin. Sp. Pl. 25, is a small plant, with a few glossy unctuous leaves which lie on the ground; perennial, grows in elevated marshy grounds, and flowers in spring.

Its unctuous glutinous juice is used as a liniment for chaps, and as a pomatum for the hair: it is said also to be purgative, but none of the species are used in general practice.

SANI'CU'LA FEMINA. See **IMPERATORIA NIGRA**.

SANIDO'DES, **SANIO'DES**, (*savidos*, the genitive case of *savis*, a flat table). **FLAT CHESTED**.

SA'NIES, (*quad ex sanguine corrupto nascitur*). See **ICHOR**.

SANKI'RA. See **CHINA ORIENTALIS**.

SA'NTALUM, (from the Arabic, *Zandal*). **SAUNDERS**.

SA'NTALUM ALBUM, **WHITE SAUNDERS**, is similar to the yellow, but so weak that it is now neglected. The *santalum citrinum*, *santalum album* Lin., is the medullary part of the same tree, of which the *santalum album* is the *alburnum*, or outward sappy part. See **ALBURNUM**.

SA'NTALUM CITRI'NUM, **VEL PALLIDUM**, **YELLOW SAUNDERS**, *santalum album* Lin. Sp. Pl. 497, is a pale yellowish or brownish coloured wood, with a close even grain, an agreeable smell, and a bitterish aromatic taste, accompanied with a slight pungency. Distilled with water, it affords an oil which thickens into the consistence of a balsam, and smells like ambergris, leaving the remaining decoction bitterish. Rectified spirit extracts more than water; and an extract from this tincture is six times stronger than the wood itself. Hoffman says its virtues are similar to those of ambergris; but he has apparently been too extravagant in his praises.

SA'NTALUM RU'BRUM. **RED SAUNDERS**, *pterocarpus santalinus*, Willdenow iii. 906, is of a dull red colour, with little or no smell, or taste; chiefly used as a colouring drug, tinging water with a yellowish hue, and rectified spirit with a deep red; but not dissolving in expressed oil. It is said to be an astringent, probably from its being the product of a species of the genus which affords the *Sanguis Draconis*, q. v. See Lewis's *Materia Medica*.

SA'NTALUS ADULTERI'NUS. See **BRASILIIUM LIGNUM**.

SANTE'RNA, *senin-nitra* Chald. See **BORAX**.

SANTOLI'NA, (because it smells like saunders). See **SANTONICUM**.

SANTOLI'NA, **CHAMÆCYPARI'SSUS**. See **ABROTANUM**.

SANTO'NICUM, (from *Santonica*, its native place,) *sanctum cinæ et zedoariæ*, *semen contra vermes*, *lumbricorum semen*, *sementina*, *santolina*, **WORM SEED**, from the *artemisia santonica* Lin. Sp. Pl. 1183, is a small, light, oval seed, of a yellowish green colour, with a cast of brown; easily friable; brought from the Levant, usually mixed with bits of sticks and leaves. These seeds yield their virtue to water and to spirit; but the spirituous infusion is the most agreeable. In evaporating the watery infusion, only a simple bitter remains. They are seldom genuine, but mixed with the seeds of southernwood; and when good are full, of a greenish colour, strong smell, a bitter and aromatic or rather a subacid taste. They are esteemed to be stomachic, emmenagogue, and anthelmintic; but are chiefly used to destroy and expel worms, from which their appellation is derived. For adults, the dose is from one to two drachms of the powder, twice a day.

As a bitter, the watery extract is esteemed the best preparation; but as an anthelmintic, the spirituous extract is preferable. For children, a syrup is made of the infusion, and administered in this form. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

SA'PA, (from its pleasant taste,) *apochilisma, succago, robub, rob*, and *Oenus Siræos*; the juice of any vegetable boiled up with sugar to the consistence of honey. See *EXTRACTIO*.

SAPHÆ'NA VE'NA MA'JOR, (from *σαφης, visibilis*). About an inch below the passage of the cruralis from out of the abdomen, it sends off a large branch, called *saphena*, in its whole course to the foot only covered with the integument. It follows the direction of the sartorius muscle, until it arrives at the inner condyle of the thigh bone; then runs on the inside of the tibia, sending off branches as it passes along; and at the lower part of the tibia a branch which runs over the joint of the tarsus to the outer ankle. The extremity of the saphena passes on the fore side of the inner ankle, and runs betwixt the first two metatarsal bones, towards the great toe. See *CRURALIS VENA*.

SAPHÆ'NA MI'NOR VE'NA, is a branch from the saphena major, which separates from it soon after passing from the inguen; and runs down below the ham, communicating with the saphena major. Another branch, which proceeds from the cruralis a little above the ham, and runs to the outer ankle, is called *saphena externa*.

SA'PHERA. See *COBALTUM*.

SAPIE'NTIÆ DENTES, (because they do not appear till the age of wisdom,) *cranterres, genuini dentes*; the last of the molares, which sometimes do not appear till the twenty-sixth year; in a few instances not at all. See *DENS*.

SAPIE'NTIÆ OLEUM. See *LATER*.

SA'PO, (from the Hebrew *sapon*.) SOAP, *asabon*, is a composition of oils and fats, with alkaline salts, incorporated into a milky semi-transparent liquid.

From the principles of this combination the union of every oil with alkaline salts is styled a soap, and the term has been extended to the combination of resins, not only with oil, but with salts of every kind. In the Boerhaavian school saponaceous fluids have been discovered in a variety of plants, and these have been styled resolvers, detergents, and deobstruents. In fact, Boerhaave, overlooking the strictness of chemical combination, has transferred the term to milky fluids, to combinations of oil with water by means of mucilage; while modern chemists have, by a similar laxity of language, styled the extractive matter saponaceous. We shall adopt the term in all its chemical strictness, and consider soap as the union of oil with salts, whether alkaline or acid. We thus exclude spermaceti, milk, chyle, the blood, and even bile.

Soap, in its strictest sense, is a white, solid, insipid substance, soluble in water, precipitated by acids, and by neutrals, whether saline, earthy, or metallic; and from this definition the acid soaps are only excluded, which perhaps scarcely merit the appellation. The purest and most perfect soap is made from olive oil and soda; but there are numerous shades of the less perfect material. Potash we know to have a strong affinity to water, and the soap formed by its means is less solid

and granular, until the water is carried off by common salt, and in some manufactories by alum. The alkali in each case must be pure, in the language of the old school, caustic. Various oily substances have been employed, as olive oil, animal fats, rancid butter, rape, poppy, and cole seed; beech mast, hemp, and lintseed; horse and whale oil. The seven last oily matters seldom afford soap of a firm consistence. In general equal parts of the alkali and oil are necessary; but in the large way about eighty parts of the salt are sufficient for one hundred of oil. The addition of common salt has been said to harden the soap by abstracting the water; but it has less affinity to water than the alkali has, though probably greater than the united alkali and oil. The idea of Pelletier is, however, more probable, that a double decomposition takes place, and that the soda of the common salt displaces the potash, while the muriat of potash escapes in the ley. At all events, supposing the common salt to remain, its proportion is not more than two elevenths of the whole, in the best conducted manufactories. The remaining ley is carbonated, and on that account probably effete and useless; though Pelletier endeavours to prove, that some carbonic acid is necessary to the production of soap. In this he seems to have refined too far: the truth lies nearer the surface.

The other chemical qualities of soap are its absorbing a large quantity of water, and swelling when wetted. Its solution is of a yellowish grey colour, forming frothy iridescent bubbles. It is more soluble in hot than in cold water, and in dry places remains for years unaltered. In moist situations the alkali separates, and, if soda has been employed, effloresces on the surface. When distilled, the oil first rises in tolerable purity; but at the end is fetid. Soap is less perfectly soluble in alcohol. When an acid, which first separates the oil from alkaline soaps, is added in excess, an acid soap is formed; but the latter union is so slight as to be destroyed by a boiling heat. When a solution is curdled by earths, particularly by lime, barytic, or strontian water, the oil unites with the respective earth. The precipitate formed by lime, or rather the union between the lime and oil, for the earth seems to have a stronger affinity for oil than the alkali, is decomposed only by a carbonated alkali, in consequence of the powerful attraction of the lime for the carbonic acid, which weakens its affinity for the oil. A carbonated ammonia has the same effect, and produces an *ammoniacal soap*, which is more pungent than common soap, and more soluble in alcohol than in water. This soap is made also by adding muriated ammonia to common soap; but in every mode of compounding it the union of the salt and oil is weak, and the soap never hardens. M. Berthollet, in the *Memoirs of the Royal Academy* for 1780, has examined the properties of the different compounds, formed by precipitating the oil in soap by earths or metals. They are of various colours, more or less cohesive, and generally soft, except when acetite of lead is employed; and we know from the former observations (see *EMPLASTRA*) that oxyds of lead have a powerful attraction for oil. The result of the experiment with this metallic salt is, of course, the diachylon. Some of the oleo-metallic compounds are dissolved by alcohol without heat: others require its assistance. Expressed oils do not dissolve the oleo-calcareous

or aluminous compounds. We must not pursue a subject wholly chemical; but may express a wish that the medical effects of the oleo-metallic compounds might be cautiously tried.

In a *medicinal view*, though we detract from the warm commendations of the Boerhaavians, we shall find soap highly useful. As a compound it appears to be a demulcent and a laxative. Dr. Cullen attributed the latter quality to the common salt which it contains; but this is in a very inconsiderable portion, as we have already remarked, and it is highly probable that it escapes with the water; for a very small proportion of salt will prevent soap from dissolving. In the barilla soaps also no muriated soda is employed. The laxative power of soap most probably arises from the union of its ingredients, since it is efficacious in clysters, where there is little probability of its being decomposed, and no time for the decomposition to take place. As a demulcent it is employed in catarrhs and peripneumonies, in diseases from acrid poisons, as well as in diarrhoeas and dysenteries. We have already remarked that we can scarcely suppose it to reach the bronchial glands without decomposition; yet that observation supplies some evidence of its demulcent powers even in the secretions of the bronchiæ, though similar effects may arise from the oil. When acrid poisons have been swallowed, soap is highly useful, to sheath the very sensible coat of the stomach, and often by its alkali either to decompose or neutralize the deleterious substance. (See *VENENUM*.) In old diarrhoeas, where the vilous coat of the intestines is preternaturally sensible, in consequence of being deprived of its mucus, the laxative power of the soap must be corrected, either by opium, by uniting it with wax, or by both: in dysenteries it has also been a custom to combine it with opium or astringents. Soap is supposed to have an anthelmintic power from the oil which it contains, as every oily matter is supposed to destroy worms, by closing their spiracula. This power is, however, equivocal; and if it has any effect of this kind it is on ascarides, when injected in the form of a clyster.

According to Bergius, and some very respectable followers of Boerhaave, soap is an aperient, a solvent, and a detergent, useful in obstructions of every kind, particularly in those of the chylopoietic viscera. In different parts of this work we have found it difficult to affix any precise ideas to these words, except that obstructions are relieved by gentle laxatives. Soap is one of these; but there is no reason to think it more useful than small doses of rhubarb, of neutral salts, or the saline mineral waters.

While speaking of it as a compound, we have been unavoidably led to notice the effects of its oleaginous ingredient. It is, therefore, only necessary now to observe, that its alkali is often highly useful as a dissolvent of calculi in the bladder; and the quantity introduced into the system, defended by the oil, is more considerable than can be taken in any other form. When the pure alkali is given in veal broth, a similar compound is formed, though not strictly saponaceous. It has been supposed that the alkali is equally effectual in dissolving biliary calculi; but experience has not confirmed the eager expectations of those who anxiously sought in this remedy a very general solvent. Among other fancies of this kind it has been given in cases where an imaginary pituita prevailed in the blood, to

children where the croop was supposed to be hereditary, and where mucous discharges were frequent. The most rational of these views seems to have been to dissolve the heavy viscid mucus of the stomach, which is sometimes highly troublesome, resisting every attempt to remove it, except by vomiting. In this case also, for it is a fancy we have indulged, it has appeared useless.

Soap is used as an intermede for mixing different oily fluids; but is in this respect inferior to the pure alkali, or even mucilage. It is, however, a convenient substance for forming pills; and as it promotes the solubility of wax, is an essential ingredient in the exhibition of the latter. In employing it, however, for pills, its levity must be attended to, or they will be otherwise too large; but, in general, soap will combine with an equal quantity of any resinous powder, as rhubarb, or jalap; and will advantageously unite with an equal quantity of wax.

Acid soaps are unknown in medicine. Sulphuric acid, in nearly an equal proportion, added to oil, by slow degrees, resembles in appearance tar; but, when well washed, it is like brown wax, specifically heavier than water, solid, and brittle, soluble in alcohol, uniting with water, and forming a whitish fluid (*Journal de Physique*, xvi. 411). A pure alkali, magnesia, chalk, oxide of lead, filings of iron, and zinc, as well as many saline, earthy, and metallic neutrals, form a coagulum, which resembles in appearance and properties wax. Nitrous vapour and oxymuriatic acid produce a similar change. Oxymuriat of potash, with a little oil, forms a soap, which explodes by a slight stroke.

Ammoniacal soaps we have already mentioned. These are employed medicinally as external stimulants. The volatile liniment, as it was formerly styled, is an instance of this combination.

Essential oil soaps have been styled *Starkey's*, from their first inventor, or rather from the person who first introduced them. Starkey's process consisted merely in mixing dry carbonate of potash with oil of turpentine, by agitation every day for six months. Baume has refined the process, and directed the oil to be rubbed in the proportion of thrice its weight with the potash. When mixed to the consistence of a soft extract, it is suffered to deliquesce, at rest, in damp air. The alkali united with water falls to the bottom, the uncombined oil rises to the top, and the soap occupies the middle of the cucurbit. It is separated by filtering. It has been employed in medicine; but apparently merits little attention. The saponaceous liniments chiefly consist of essential oils combined with soap. The eau de luce is of this kind.

Black soaps are generally soft, composed of an impure alkali and train or whale oil. They are useful in forming stimulant cataplasms, with more active rubefacients, and sometimes peculiarly active in clysters, though in this form they produce often sickness and general disorders of the system.

SA'PO A'LBUS; *sapo Hispanicus*, HARD, or SPANISH SOAP, is made in Spain, with olive oil and the Spanish barilla, by a process similar to that directed for the soap of almonds.

SAPONA'RIA, (from *sapo, soap*). *Struthium, lanaria, lychnis sylvestris, ibixuma*, BRUISE WORT, SOAP WORT, *saponaria officinalis*, Lin. Sp. Pl. 584, is a smooth herb, with leaves resembling the plantain, and

clusters of red, purple, and whitish flowers: the root is long, slender, spreading to a great distance, of a brownish colour on the outside, and white within, with a yellowish fibre in the middle. It grows in moist grounds, and flowers in July.

The plant is called *saponaria*, because its juice, like soap, cleans clothes. The roots and leaves are glutinous and sweet to the taste, but in the roots there is also a slight pungency, and in the leaves a bitterishness. The soapy matter dissolves either in water or in spirit of wine. The Germans prefer the root to the sarsaparilla. Andry gave its inspissated juice with success in gonorrhœa, in the dose of half an ounce daily; and in general the cure was effected in about a fortnight, without the assistance of any other remedy. Segy orders from two to four pints of the decoction to be daily taken in lues; and, in bad cases, the patient takes at the same time the plant in powder, or in the form of an extract. This is said to be advantageous in venereal, scrofulous, and impetiginous affections; in visceral obstructions and jaundice. This plant is also applied externally to venereal ulcers, either in fomentation, or in a dry form, by sprinkling it in powder over the sores. Two ounces of the root yielded eleven drachms of watery extract; but this quantity seems to be variable. It is sweetish, followed by some pungency. The spirituous extract is less in quantity, but more pungent. Decoctions, the extract, and even the leaves, resemble in appearance and quality solutions of soap: they have even been used for the same purposes. See Lewis's *Materia Medica*; Neumann's *Chemical Works*.

SAPONARIÆ NUCULÆ, *baccæ Bermudenses*, vel *Bermudæ*. SOAP OR BERMUDAS BERRIES; a spherical fruit about the size of a cherry, from the *sapindus saponaria* Lin. Sp. Pl. 526. The cortical part is yellow, glossy, and so transparent as to show the spheres which rattle within, and includes a white kernel. It is the produce of a small tree in Jamaica, and other parts of the West Indies: the kernel, when steeped in water, raises a froth like soap suds.

These berries are supposed to be powerful in removing obstructions in the liver and spleen; in relieving cachexy, dyspepsia, and chlorosis. The best preparations are, a tincture made with white wine, or spirit, and the extract from the spirituous tincture. See Lewis's *Materia Medica*; Medical Museum, vol. iii. p. 538.

SAPONIS CERATUM. See PLUMBUM.

SAPOTA. The fruit of the *achras sapota* Lin. Sp. Pl. 470, which is highly luscious, resembling marmalade. It is a native of South America; and its seeds have been used as demulcents.

SAPPAN LI'GNUM. See CAMPECHENSE LIGNUM.

SAPPHIRI'NA A'QUA, (from its colour). See CUPRI AMMONIATI AQUA.

SA'PROS, (from *σπρω*, to putrefy). See MORTIFICATION.

SA'RA. See ESSERA.

SARA'SSAS. See CORALDODENDRON.

SARCOCE'LE, (from *σαρξ*, flesh, and *κλῆ*, a tumour,) is a firm enlargement of the testicle, differing in the resistance it affords to the finger, and sometimes degenerating into a scirrhus hardness. The sarcocele, or hernia carnosæ, according to Mr. Pott, in a general sense, means any induration or diseased flesh, though

in this case confined to the testicle; adding that the sarcocele, distinguished by the ancient writers into the sarcocele, the hydro-sarcocele, the scirrhus, the cancer, the caro adnata ad testem, and the caro adnata ad vasa, are really little more than descriptions of different states and circumstances of the same disease. The caro adnata ad testem is a scirrhus beginning in the epididymis; the caro adnata ad vasa a scirrhus of the epididymis somewhat increased, apparently springing from the spermatic vessels. In the hydro-sarcocele the testicle is enlarged and hardened; or rather it is both scirrhus and dropsical. (See Pott's Works, 4to.) The sarcocele is indisputably a disease of the body of the testicle, from which it resembles a hard fleshy substance, instead of its natural soft vascular texture. Its more favourable appearances often continue without change for many years, while in others the disease quickly passes through its different stages. Sometimes the first appearance is a mere simple enlargement and induration of the body of the testicle, without pain or inequality of surface, producing no uneasiness nor inconvenience, except what is occasioned by its weight. In a few instances it remains in this state for a considerable time, without visible alteration; but in others, soon after its appearance in this mild manner, it suddenly becomes unequal and knotty, is attended with very acute pains, darting up to the loins and back; but the integuments continue entire. In short, such is the variety of the appearances of this disease, that description can hardly afford an adequate idea of it. Sometimes the disorder seems to be merely local, at others there is a pallid or leaden countenance, indigestion, nausea, colic pains, sudden diarrhœa, &c. sufficiently indicating a vitiated habit and diseased viscera. Its progress also from the testis upward is very uncertain; the disease affecting the spermatic process, in some subjects, for a long time; while, in others, it injures the testicle very soon, and almost as soon seizes the spermatic cord. The testicle sometimes enlarges to an enormous size, and this is not an uncommon disease among negroes. In the *Philosophical Transactions* for 1783 it is said to have extended to the weight of fifty pounds. The sarcocele has been said to affect the right rather than the left side, and small bones are sometimes said to be found in the tumour.

Amongst the mistaken causes of a scirrhus testicle, Mr. Pott reckons the *hernia humoralis*; not that a sarcocele never follows a hernia humoralis, but that it does not necessarily produce it. Mr. Bell observes that a hardened state of the testis and epididymis, produced originally by a venereal taint, in some instances degenerates into the worst species of sarcocele. In general, however, the hernia humoralis is one of the diseases which should be distinguished from the sarcocele. A quantity of water is sometimes collected in the vaginal coat of a scirrhus testis, and it has been erroneously supposed that this water renders the testis scirrhus. This, however, is not the case.

The only remedy from which any advantage can be expected is the removal of the diseased parts by extirpation. But before the operation is attempted, the cause of the sarcocele and the state of the spermatic cord from the ring to the testicle are objects of necessary consideration. When it proceeds from a blow on the part, the operation will be more successful than when caused by cancer or struma; when either of these last is the cause, they will generally be found to exist also

on other parts; therefore, though the diseased testicle be removed, the cause will remain, and again appear in other organs. In strumous habits the glands of the mesentery, the lymphatics, &c. are generally obstructed; therefore, external applications are useless, and proper internal medicines must be employed: in children this disorder seldom occurs without an enlarged belly, which, before any further attempts are made, must be lessened.

Of the internal medicines, mercury, hemlock, and sulphur, have been principally recommended. The balsam of sulphur was the favourite remedy of Rulandus; but to neither does the disease usually yield. The external application of mercury is more successful, and the mercurial friction has occasionally removed it. Cavillini apparently succeeded with the cold stillicidium, alternated with a cataplasm of bean flour, and Schultetus with a plaster of gum ammoniac. The actual cautery, and the subsequent discharge from the separation of the eschar, is sometimes recommended; but, in general, extirpation is the only successful method.

It is usually remarked that if the spermatic cord is soft, and of its natural size, castration may be safely performed; but if much enlarged, that the operation is not advisable. This is not strictly true; for the spermatic cord may be enlarged by varices, or by effusion, neither of which contra-indicate the operation; but when the feel is irregular and knotted, when lancinating pains shoot upward or downward, and the unequal hardness is too high to admit the ligature above it, the operation will be useless or dangerous.

The use of the knife is sometimes deferred till darting pains come on in the loins or testicles. This may not be wholly improper; but when these appear, the operation should be no longer delayed; for a local scirrhus will soon affect the constitution, and indeed when the countenance becomes of a leaden colour, the evening exacerbation strongly marked, with morning perspirations, it is often too late to attempt it. Yet it is a last resource, and, even in these circumstances, will sometimes succeed.

After a venereal gonorrhœa, improperly treated, Dr. Swediaur observes, that one or both testicles sometimes grow hard. In a few instances the disorder is accompanied with a sensation of a painful pressure; but is frequently without any pain. He adds, that, in these cases, mercury given internally, or rubbed externally into the perinæum and scrotum, twice a day, with the constant application of a warm poultice made of the root of the *atrofia mandagora*, &c. are often useful. Cicuta, applied internally and externally, may perhaps be tried, with prospect of advantage; and an emetic has been sometimes found effectual. The decoction of the mezereum, internally, with a poultice of it externally, has lately been recommended; but these swellings usually remain unaffected, except the discharge from the urethra is restored, which has sometimes been effected by a recent infection, or, according to Swediaur, by a gonorrhœal inoculation. When a hardness of the testicles does not yield to the means commonly employed, such as moderate evacuations of blood, when these are indicated, a soft easy diet, a lax belly, the use of a suspensory bandage, and especially when mercury, which, on the chance of the disorder being venereal, is very commonly tried, are all used without any effect; we

VOL. II.

may, according to Bell, suspect that the disease is of a malignant nature: when more inveterate symptoms come on, and the disorder, from the state of an indolent hard tumour, becomes painful, castration must be attempted. See Sharp's Operations; Pott's Chirurgical Works; Bell's Surgery, vol. i. p. 498; London Medical Journal, vol. v. p. 32; Edinburgh Medical Commentaries, vol. ix. p. 336; White's Surgery, p. 335; Heister de Hernia Carnosa; Warner's Account of the Testicles; Morgagni de Sedibus, &c. xliii. 38, &c.; Pohl de Herniis et Sarcocoele.

SARCOCO'LLA, (*σαρξ*, *flesh*, and *κόλληω*, *to glue together*, from its supposed power of conglutinating wounds,) is a gummy resinous juice, from the *penæa mucronata* or *sarcocolla* Lin. Sp. Pl. 162, brought from Persia and Arabia, in small spongy grains of a whitish yellow, sometimes of a deep red colour, about the size of a pea: the whitest and most bitter are preferred. Its bitterish subacid taste is followed by a slight sweetness; it softens in the mouth; bubbles and catches flame from a candle; dissolves freely in water, and in a large proportion in spirit of wine; but its medical qualities are inconsiderable. See Lewis's Materia Medica; Neumann's Chemistry.

SARCO-CIRSOCE'LE. A combination of sarcoma with CIRSOCELE, q. v.

SARCO-EPIPOCE'LE, (from *σαρξ*, *flesh*, *ἐπιπλοον*, *omentum*, and *κῆλη*, *tumour*). A compound rupture, consisting of a descent of the epiploon during the existence of a sarcocele. Sometimes a rupture of the indurated epiploon, either umbilical or scrotal.

SARCO-HYDROCE'LE. A combination of sarcoma with HYDROCELE, q. v.

SARCOLO'GIA, (from *σαρξ*, *flesh*, and *λογος*, *a discourse*). SARCOLOGY, including myology, splanchnology, angiology, neurology, and descriptions of the integuments.

SARCO'MA, (from *σαρξ*, *flesh*), a fleshy tumour on any part of the body; *horrus*; *sarcophya*; *nævus*). This adventitious soft substance is not contained in a cyst, and does not yield to the impression of a finger, nor is it moveable. Dr. Cullen styles it soft extuberation not painful. It sometimes arises from the sockets of the teeth, but most frequently from the labia pudendi, or the more internal parts. Extirpation is the only remedy; and if the basis be narrow, a ligature may be used; but if broad, the knife will be necessary. See Turner's Surgery, vol. i. p. 201. The name also for *folysus narium*.

SARCO'MPHALON, (from *σαρξ*, and *ομφαλος*, *the navel*). A fleshy excrescence at the navel.

SARCO'PHAGUM, (from *σαρξ*, and *φαγω*, *to eat*). See ASSIUS LAPIS.

SARCOPHY'IA, (from *σαρξ*, and *φύω*, *to grow*). See SARCOMA.

SARCO'TICA. SARCOtics, (from *σαρκοῦ*, *to heal*.) Medicines which generate flesh in wounds.

SARDIA'SIS, **SARDO'NICUS RI'SUS**, (from *σαρδάνη*, an herb supposed to cause a convulsive laughter,) *spasmus cynicus*, *gelasmus*, defined by Vogel an involuntary laughter, in which the mind is not elated with joy, but affected with pain, and often with anger. The sardonias is said to be a species of ranunculus. Ætius Tetrab. iv. serm. i. cap. 66. See RISUS.

SARPE'DO. See LICHEN.

R r

SA'RSA, and SARSAPARI'LLA, (from *zarza*, *bramble*, and *parilla*, a little vine, Spanish,) *carivillandi*, *iva pecanga*, *macapatti*, *smilax aspera Peruviana*, is brought from South America; the slenderer pale sort comes from New Spain, the dark and thick from Honduras, the darkest and thickest from Quito. That most esteemed is the *smilax aspera Peruviana*, C. B. *smilax sarsaparilla* Lin. Sp. Pl. 1459. VIRGINIAN IVY LEAVED ROUGH BIND WEED, light, white within, but not easily powdered. The root consists of a number of strings, as thick as a goose quill, flexible, free from knots, and composed of fibres which run their whole length. On their outside is a thin, brown, or yellowish ash coloured skin; within, a thicker, white, friable substance, and in the middle a woody pith.

The roots have a mucilaginous bitterish taste, and no smell. Neumann obtained from 960 grains, 360 of watery and ten of spirituous extract; inversely 240 and 220. In 1563, the Spaniards brought them into Europe, as a specific in the lues venerea; and indeed a decoction is still esteemed an excellent auxiliary to mercury. When children are affected with lues from their parents, or nurses, the powder of this root has been added to their food. It promotes perspiration, is said to attenuate viscid humours, to relieve venereal headaches and nocturnal pains; particularly when the bones are carious, or in other respects disordered from the venereal disease. Ulcers, nodes, and other symptoms of the lues, which have resisted the effects of repeated salivations, are said to yield to its use, and the health after the use of mercury to be more speedily restored. Whether given in decoction or powder, it should be continued in large doses, and for a considerable time.

The best preparation is the following decoction: R. Rad. sarsaparillæ incisæ $\frac{3}{4}$ vi. aq. distillatæ ℞. viij. In a heat of about 195 degrees, let it be macerated for two hours; afterwards take out the sarsaparilla and bruise it; then let it be returned into the liquor, and again macerate it for two hours more. Boil the liquor till it is reduced to four pints, pour off the fluid, press the sarsaparilla, and strain the whole. This will be more palatable if a little liquorice root be added at the end of the boiling.

The London college order a compound decoction of this root. R. Radicis sarsaparillæ incisæ et contusæ p. $\frac{3}{4}$ vi. corticis radicis sassafræ ligni guaiaci rasi, glycyrrhizæ contusæ singulorum p. $\frac{3}{4}$ i. corticis radicis mezerei $\frac{3}{4}$ iij. aquæ distillatæ ℞. x. These must be macerated in a gentle heat for six hours, then reduced by boiling to five pints, adding the mezereum during the latter part of the process, and the decoction strained. These decoctions are given in venereal, scrofulous, and hepatic affections. The dose of the first is half a pint, four times in twenty-four hours; the second half the quantity in the same space of time. The long stringy part only is useful.

The sarsaparilla forms a principal ingredient in the Lisbon diet drink, supposed to be thus made: R. Sarsaparillæ concisæ, radicis Chinæ sing. $\frac{3}{4}$ i. nucum juglandis cortice siccaturum, No. xx. antimon. crud. $\frac{3}{4}$ ij. lapidis pumicis pulverizati $\frac{3}{4}$ i. aquæ distillatæ ℞. x. The powdered antimony and pumice stone are to be tied loosely up in separate rags, and boiled along with the other ingredients, and this boiling continued till the

liquor is reduced to five pints. This appears to be an inferior medicine to the former; for the addition of the antimony and pumice stone can add nothing to the efficacy of the other ingredients. Notwithstanding the virtues above enumerated, and the commendations of many authors, Dr. Cullen never found it an effectual medicine in the lues venerea, nor any other disease, in whatever shape it has been tried.

Since that period, Mr. Pearson has given us a very instructive account of the real virtues of these subsidiary medicines in the cure of lues. He found, as we have ourselves observed, that it neither would cure lues, nor render a less dose of mercury necessary. Yet he thinks that, for a time, it would suspend the action of the virus, and remove the remaining complaints, after the principal disease was subdued, which arose either from its effects, or those of the medicine. Of its "suspending" power we have not found sufficient evidence; but its removing the remaining symptoms is indisputable. See Cullen's Materia Medica, and Pearson on the Effects of some Medicines in the Cure of the Lues Venerea. See LUES.

See Lewis's Materia Medica; Neumann's Chemistry; London Medical Observations and Inquiries, vol. i. p. 149, &c.

SARSAPARI'LLA. See ARALIA.

SARSAPARI'LLA GERMANORUM. *Carex arenaria* Lin. Sp. Pl. 1311, is often used in chronic rheumatisms instead of the sarsa. Some other species of *Carex*, as the *C. distans* and *hirta* 1387, 1389, are also employed.

SARTORIUS, (from *sartor*, a *taylor*,) *fascialis*. It is called *sartorius*, or the TAYLOR'S MUSCLE, because taylor's cross their legs by its action. It arises tendinous from the anterior superior spinous process of the os ilium, runs inwards contiguous to the blood vessels, and is inserted by a thin tendon into the inner part of the tibia. It partly rotates the thigh.

SA'SSAFRAS, (*quasi saxifraga*, because the decoction was supposed capable of breaking a calculus,) *anhuiba*, is the root of the *laurus sassafras* Lin. Sp. Pl. 530, light, and covered with a rough and fungous bark, externally of an ash colour, and internally of the colour of rusty iron; brought from Virginia and other parts of America. The wood, which is called *feniculi vel feniculatum lignum*, hath a fragrant smell, a sweetish, subastringent, aromatic taste: the bark is more fragrant than the internal woody part, and the small twigs than the larger pieces. Spirit of wine dissolves the whole of its active power, and water a large portion. Distilled with water it affords an essential oil, limpid at first, but afterwards yellow, or of a reddish brown: the remaining decoction affords a bitterish subastringent extract; but an extract made from a spirituous tincture possesses all the virtues of the root. It is considered as serviceable in cuticular eruptions; and is an ingredient in the compound decoction of sarsaparilla: its essential oil is given in doses of from two drops to ten.

Sassafras is used chiefly in decoction as a mild diaphoretic and corroborant in cutaneous, scorbutic, catarrhal, and cachectic disorders. Like the sarsa, it is supposed to assist the action of mercury in lues; but its real virtues do not rest on a better foundation. It is indeed inferior to the sarsa in rheumatic and syphilitic cases. (See Tournefort and Lewis's Materia Medica; Neumann's Chemistry.) Dr. Cullen has found copious

draughts of the watery infusion effectual in promoting sweat, without being able to determine the appropriate advantages of this evacuation.

SATELLITE VEINS, are those which accompany the brachial artery to the bend of the elbow.

SATUREIA SATIVA, (from *satyri*, because when eaten it is supposed to create lascivious desires,) *cunila sativa*, *thymus*, *thymbra*, SUMMER'S SAVORY; *satureia hortensis* Lin. Sp. Pl. 795, is a low shrubby plant, somewhat hairy, with small, oblong, narrow leaves, set in pairs. Its flowers are in clusters in the bosom of the leaves, and of a purplish colour. It grows wild in the south of Europe, and is sown annually in our gardens. The leaves are warm, aromatic, and smell like a milder thyme. Rectified spirit takes up all their virtue; water the smell only. By distillation with water a small quantity of essential oil is obtained. It is supposed to be heating, somewhat diuretic and emmenagogue; but its chief use is for culinary purposes.

SATUREIA MONTANA, Lin. Sp. Pl. 794; similar in its virtues to the former. WINTER SAVORY. See *Raii Historia*.

SATURNI EXTRACTIONUM. See **PLUMBUM**.

SATURNI AQUA. See **PLUMBUM**.

SATURNI NUM UNGUENTUM. See **NUTRIMENTUM UNGUENTUM**.

SATURNUS, (from the heathen god). LEAD. See **PLUMBUM**.

SATYRIASIS, (from *σατυρος*, a lascivious animal,) *brachuna*, *satyrisimus*, *arascon*, and *arsatum*, *priapismus*, *salacitas*. A violent desire of venery, in such a degree as to destroy the reason. Dr. Cullen places it in the order *dysorexia*, defining it an unconquerable desire of venery in males. The species are:

1. *Satyriasis juvenilis*, when the functions are otherwise but little disturbed. 2. *Satyriasis furens*, when, with the excess of venereal appetite, the body is diseased with fever, &c. The pulse is quick, the breathing short, the patient is sleepless, thirsty, and loathes his food; the urine is evacuated with difficulty, and a fever soon comes on. See **SALACITAS**, and **FUROR UTERINUS**, a similar disease in females; *Cælius Aurelianus*, lib. iii. c. 18. de *Acutis*.

SATYRICA. See **ENTACTICA MEDICAMENTA**.

SATYRION. A name for several species of **ORCHIS**, q. v.

SATYRISMUS. See **SATYRIASIS**.

SAUR KRAUT. See **BRASSICA**.

SAURURUS, (from *σαυρα*, the lizard, and *ουρα*, a tail). A plant called the lizard's tail, resembling in virtue the arum.

SAVINA. See **SABINA**.

SAXIFRAGA, (from *saxum*, a stone, and *frango*, to break, medicines which dissolve or break the stone in the bladder). See **PARONYCHIA**, **FILIPENDULA**, **MEUM LATIFOLIUM**, **PIMPINELLA**, **EUBIA SYNANCHICA**.

SAXIFRAGA ALBA; *sanicula sedum*; WHITE SAXIFRAGE; *saxifraga granulata* Lin. Sp. Pl. 576, is a plant with kidney shaped, yellowish green leaves, round, purplish, branched stalks, on the tops of which are short loose spikes of white flowers. The root is composed of small fibres, intermixed with little tubercles. It is perennial, grows wild in sandy pastures, and flowers in May. The tubercles of the roots have a

sweetish, slightly acrid taste, and are supposed to be aperient and diuretic; but these qualities, adopted from the *signaturists*, are derived from the resemblance of the tuberculated roots to calculi. See *Lewis's Materia Medica*.

SAXIFRAGA ANGLICA. ENGLISH OF MEADOW SAXIFRAGE; *saniculum erraticum*; *angelica*; *hippomarathrum*; *puccedanum silaus* Lin. Sp. Pl. 354, is an umbelliferous plant with winged leaves, flowers of a yellowish white colour; the root is long, and about as thick as a finger, brown or blackish on the outside, and white within. It is common in meadows and pasture grounds, and flowers in June. The root, leaf, and seeds are said to be diuretic, aperient, and carminative, and in each respect preferable to those of the white saxifrage. See *Lewis's Materia Medica*.

SAXIFRAGA MONTANA MINOR. See **BUNIUM**.

SAXUM CALCARIUM. See **CALX**.

SCABIES, (from *scaber*, rough). A SCAB: a hard substance covering superficial ulcerations, and formed by a concretion of the fluid discharged from them. A name also for a disorder of the bladder mentioned by *Ætius*. If, after a painful discharge of the urine, branny scales appear in it, with many slender filaments, which subside, the ancients call it a *scabies*, considering it as an indication of a corrosion of its mucous and villous coats. To relieve the disease *Ætius* recommends a vegetable diet, milk, broth, &c. In *Linnaeus's Nosology*, it is an order in the class of *vitia*, and signifies cutaneous diseases; see **PRURITUS**, and **PSORA**: and it is the name also of a plant, see **LICHEN**.

SCABIOSA, (from *scaber*, rough, from its rough hairy surface). COMMON FIELD SCABIOUS; *scabiosa arvensis* Lin. Sp. Pl. 143, is a rough hairy plant; growing wild in pasture grounds, of a nauseous bitter taste; and flowers in June. It is styled *aperient*, *sudorific*, and *expectorant*; used externally for the itch, from whence its name is derived.

SCABIOSA INDICA ARBOREA. See **CATTU SCHIRAGAAM**.

SCABRIDÆ, (from the same). An order of plants whose bark is rough.

SCABRITIES, (from the same). The rough surface of the barks of some trees.

SCADIDACALLI. See **EUPHORBIVM**.

SCALLA SACRA, from *σκαλις*, a ladder). See **CLIMAX**.

SCALENUS MUSCULUS, (*σκαληνος*, a figure with three unequal sides,) *triangularis*, takes its origin from the transverse processes of the vertebræ colli, grows larger as it descends, and is then collected into two masses; the anterior inserted into the inner edge of the first rib, on each side of which the subclavian vein and artery, with the bronchial nerve, pass out; and the posterior attached to the posterior part of the first rib, partly running to the second: its office is to raise those two ribs, and to move the vertebræ colli to one side, or when acting together to bend it forward. More minute anatomists, as *Douglass* and *Albinus*, divide it into many additional portions; but this minuteness is useless. A middle one may be distinguished, inserted tendinous into the outer and upper part of the first rib, from its root to about an inch from the cartilage.

SCALPELLUM. A SCALPEL. The common dissecting knife.

SCA'LPO. To SCALP; to lay the skull bare. The operation is performed by making an incision through the integuments and pericranium equally and at once, with the edge rather than the point of the knife, especially if a fracture is suspected. After making the incision, the pericranium must be raised a little from the bone with the edge of the knife, to clear the bone, and the scalprum employed.

In pursuing a fissure, a rectilinear incision is preferable; but in most other cases an oval one. Arnaud and Gooch have made a crucial incision upon the temporal muscle with good success, the muscle still continuing its action. See Gooch's Treatise of Wounds, p. 253.

SCALPRUM, (from *scalpro*, to rasp, or raise). A DENTICULAR, RASPATORY, or RUGINE, any kind of iron instrument with which a rotten bone is rasped or scraped. Sometimes scalprum means a little chisel for amputating the fingers.

SCAMMO'NIA MONSPE'LICA. See PERIPLOCA.

SCAMMO'NIUM, (a corruption of the Arabic terms *chamozah*, or *mammuzah*). SCAMMONY, MAHMOODY, *convolvulus scammonia* Lin. Sp. Pl. 218, SYRIAN BIND WEED, or SCAMMONY. The root is very long, and about three or four inches thick, the tops of which, while in the ground, are cut in June, and from this incision a milky liquor exudes, which is received in shells, &c. and when hardened by evaporation forms the scammony.

This gum resin is brought to us in light spongy masses, glossy, of different shades, from a grey or yellow white almost to a black, appearing when broken bright and shining; and easily crumbling between the fingers. If touched with a wetted finger it becomes milky; if broken, and put into water, it dissolves into a milky liquor of a greenish hue. An inferior sort is brought from Smyrna, more pungent than that from Aleppo, and mixed with much extraneous matter. Though different parcels of scammony vary so much in their colour, when powdered they are all of a brownish white. That which easily crumbles between the fingers, is pellucid, grows instantly white on being wetted, and leaves but little fæces when dissolved, is the purest and best. It is often adulterated with wheat flour, sand, or ashes, which are discovered by dissolving the scammony in water, when the impurities sink to the bottom.

The Greek and Arabian physicians employed it internally as a purgative, and externally for tumours, scabies, tinea, fixed pains, &c. Since the time of Boerhaave it has been considered a safe though stimulating cathartic, and frequently given uncombined without producing tormina, or an excessive discharge. It is, however, a very brisk purge, and usually given in cold phlegmatic constitutions.

Inflammatory disorders are sometimes increased, and very irritable habits occasionally injured by it. It needs no corrector, though for this purpose it has been exposed to the fumes of burning sulphur; but we thus only lessen its activity. When scammony has undergone this operation, it is called *diagrydium*. The resin and gum are nearly in equal parts, so that it dissolves equally in water and in spirit.

See Lewis's Materia Medica; Neumann's Chemistry; London Medical Observations and Inquiries, vol. i. p. 13, &c.

Electuarium scammonii, formerly *electarium caryocostinum*, is made by adding to an ounce and half of scammony in powder, cloves and ginger, of each six drachms; essential oil of carraway, half a drachm by weight, with a sufficient quantity of syrup of roses. Mix the species, powdered together, with the syrup, then add the scammony, and afterwards the oil. Dose ʒ i. to ʒ i.

Pulvis scammonii compositus, cerberus, triceps, cornachini pulvis.—Take of scammony, hard extract of jalap, each two ounces; ginger, half an ounce; powder them separately, and mix them. Dose gr. x.—ʒ i.

Pulvis scammonii cum aloe, consists of six drachms of scammony; hard extract of jalap, socotorine aloes, of each an ounce and a half; ginger half an ounce. They are powdered separately and mixed. Dose gr. x.—ʒ i.

Pulvis scammonii cum calomelane, contains two parts of scammony to one of calomel, and as much fine sugar. The dose is from ten grains to a scruple. Pharmacop. Lond. 1788.

Scammony is also an ingredient in *pulvis è sennâ compositus*; *extractum colocynthidis compositum*; and in the *pilula ex colocynthide cum aloe* of the Edinburgh Pharmacopœia.

SCAMMO'NIUM ORIENTA'LE. See GAMBOGIA.

SCAMMNUM HIPPOCRATIS. See BATHRON.

SCA'NDIX, (from *shandak*, to sharpen). *Acus Pastoris*, *Scandix*, *Pecten Veneris* Lin. Sp. Pl. 368, SHEPHERD'S NEEDLE, or VENUS' COMB, grows in the fields in Europe, is oleraceous, and aromatic. It is said to be antiphlogistic, diuretic, lactiferous, and it is given in dropsies and vertigo.

SCA'NDIX CEREOFOLIUM, Lin. Sp. Pl. 368. See CHÆREFOLIUM.

SCA'NDIX ODORA'TA. See MYRRHA, and MYRRHIS.

SCA'PHA, a SKIFF, (from *σκαπτο*, to dig, formerly made of an excavated tree,) is the name for one of the cavities of the ear (see AURICULA); and for a species of bandage. See DELIGATIO.

SCAPHO'IDES, Os, (from *σκαφη*, and *ειδες*, forma,) os naviculare and naviforme, or cymbæ and cymbiforme, the first bone of the first row in the wrist, articulated to the thumb. In infants it is wholly cartilaginous; also the third bone of the tarsus. See CARPUS.

SCA'PULA, (from the Hebrew term *schipha*). The SHOULDER BLADE; *epinotium*; *homoplata*; *omoplata*; is a triangular bone, situated on the outside of the ribs, fixed to the upper posterior and lateral part of the thorax, extending from the second to the seventh rib: its sides are unequal; the posterior side or basis is the longest, the inferior costa is shorter, and the superior costa is the shortest. The body of this bone is concave towards the ribs, and convex behind, where it is called *dorsum*. Three processes proceed from the scapula, the CORACOIDES, q. v.; the spina scapulæ, or intra-scapulum, which rises from the posterior convex surface, and divides it unequally: it is small at the base, and becomes higher and broader as it advances. The extremities of it are broad and flat, and hang over the cavity of the os humeri. To this part of the spine, called *acromion* or *ephomis*, the clavicle is articulated. The third process is produced from the neck of the bone; and is hollowed on its anterior part by a glenoid cavity, which is an oval, whose greatest diameter is from below upwards. The cavity in the extremity of the

neck of the scapula, in which the head of the humerus is placed, is called *omocotyle*.

The superior costa is perforated near the base of the coracoid process by a semicircular indentation, closed by a ligament, through which vessels and nerves pass. There are other indentations between the coracoid process and the head of the bone, as well as between its neck and the acromion. The scapula is thin at its middle part, in consequence of the action of the muscles. Its use is to give a fixed point to the muscles of the superior extremity, and by its motion to admit of a change of direction in the socket of the humerus. It defends also the ribs behind. The base, the acromion, the coracoid process, and head of the scapula, are cartilaginous at birth, and the three former are joined as epiphyses. The head, with the glenoid cavity, is gradually produced by a continuation of the ossification of the body.

SCAPULARIA, (from *scapula*). The SCAPULARY. See DELIGATIO.

SCAPULARIÆ ARTERIÆ. The SCAPULARY ARTERIES. The external scapular artery, *muscularis arteria*, passes through the notch in the superior costa of the scapula, to the *musculus supra spinatus et infra spinatus*, *teres major et minor*, and to the articulation of the scapula with the humerus.

The internal scapular artery rises from the axillary, near the axilla, and runs backward to be distributed to the *subscapularis*, giving branches to the *serratus major*, the axillary glands, the *teres major*, &c.

The superior scapular artery is a branch from the subclavian, running downwards to the inside of the clavicle, and following the tract of that bone from whence it goes to the adjacent muscles.

SCAPUS, (from *καπεω*, to lean upon). See CAUDEX.

SCARABÆOLUS HÆMISPHERICUS COCHINELIFER. See COCCINILLA.

SCARABÆUS, (from *καρ*, *κατος*, dung, its supposed origin). BEETLE. See CICINDELA.

SCARIFICATIO, (from *scarifico*, to scarify). SCARIFICATION; *afoschasis*, *afoschasmus*, *encharaxis*. The word generally signifies those incisions that are made with the instrument called *scarificator*, and which is used in the operation called *cupping*. See CUCURBITULA, and ANASARCA.

SCARIO'LA. See ENDIVIA.

SCARLATINA, vel SCARLATINA FEBRIS. The SCARLET FEVER, called from the colour of the patient's skin; *rosselia*. Dr. Cullen places this disease among the *exanthemata*, defining it a contagious inflammatory fever, in which, on the fourth day of the disease, the face becomes a little swelled, with a florid redness all over the skin, with broad spots, running at last one into another; after the expiration of three days forming furfuraceous scales, and falling off: to which often an *anasarca* succeeds. He distinguishes two species.

1. SCARLATINA SIMPLEX, when not accompanied with a sore throat.

2. SCARLATINA CYNANCHICA, when attended with ulcerated fauces.

Sydenham observes that children are its most frequent subjects; and when epidemical, it is usually so at the close of the summer. It begins with a chilliness and shivering, the whole skin is covered with red spots,

which are more numerous, larger, and redder, but not so uniform as those of the measles; a dejection of spirits, prostration of strength, and often a stiffness of the neck, followed by a burning dry heat, and at night frequently delirium, particularly about the end of the third day, and not attended with watery eyes or other symptoms of coryza. A sore throat sometimes comes on early, but chiefly obtrudes itself on our notice about the end of the second or beginning of the third day. It is sometimes wholly absent, but in every case a redness of the fauces is conspicuous, apparently a continuation of the affection of the skin.

It is not agreed whether the angina is a constantly accompanying symptom of this disease. From the general florid appearance of the fauces, we think that it is so; yet, as authors seem to discriminate a variety, which they style *anginosa*, we shall reserve our observations on this subject for the following article. A pungent pain is commonly felt all over the body, and the stiffness of the muscles of deglutition overpowers the uneasiness from thirst. The redness soon extends from the face to the neck, and thence over the whole body: in many instances it is a general suffusion, without any discriminated maculæ, and scarcely in any case is there an elevation of the cuticle. When the eyes become peculiarly red, delirium impends; but delirium during the nocturnal exacerbation is not uncommon through the whole course of the disease.

After about six or seven days, the scarlet colour is succeeded by a browner hue, and the change occurs first in the face, afterwards on the breast and extremities; but the fever and delirium seem to abate with the intensity of the colour in the face. We have known the scarlet continue brilliant on the extremities during the whole of the convalescence. The strength and appetite return slowly. During the whole course, and even during the delirium, the pulse is often quick and low, seldom strong or full.

All the appearances of this disease are fallacious. The most violent delirium does not always portend danger, and the recession of the scarlet effusion, apparently the most regular, is followed in many instances by tumefied glands, a slow fever, prostration of strength, and *anasarca*. The skin usually separates in branny scales, and these are apparently reproduced when they have once fallen off. In cold weather, and in northern climates, the effusion will sometimes become pustular, though in few places, and in slight pimples.

Much difficulty has been apparently felt in discriminating this disease, but the experienced eye requires little assistance. Petechiæ are distinct spots of a dark red, not a florid scarlet effusion, and the catarrhal symptoms universally distinguish measles. Erysipelas swells considerably: scarlatina slightly, if at all; and the fever of the former, particularly the nocturnal exacerbation, is much less considerable. Erysipelas is also a disease of the adult, scarcely ever attended with any affection of the fauces: scarlatina of a younger period, with, in every instance, a scarlet hue on the throat. A slight erysipelas, styled the *gutta rosea*, sometimes nearly resembles the present complaint, but it is so inconsiderable as to require little attention, and if scarlatina is equally slight, distinction is unnecessary. The period of the fever at which the suffusion comes on furnishes a general discriminating mark.

Every symptom of the disease points out a specific virus as its cause. The scarlatina is evidently infectious, generally epidemic, and usually affects persons once only in their lives. It is almost peculiar to children, for it seldom attacks adults, and those only most exposed to infection; and in them also it is peculiarly mild. After the most apparently severe attacks, we have seldom seen an adult in danger, and this we think chiefly arises from the worst effects of the disease falling on the lymphatic system. If a specific infection be admitted, the fever and all its consequences are not uncommon. The affection of the lymphatic system is obvious in the neck; and, when the swellings are not conspicuous in that part, they seem from the effects to be in the mesenteric glands. The anasarca swellings are chiefly from debility, for the urine is found to contain an unusual portion of albumen. The fever is evidently of the typhus kind, though attended with considerable heat, in consequence of the affection of the surface; and the delirium seems, as in erysipelas, to arise from a general determination towards the common carotid, and not from any metastasis, for it accompanies the most florid hue of the surface.

The variety of plants and medicines recommended by different authors would alone show that the disease is intractable, and its treatment not well understood. All the appearances, we have said, are fallacious; and the best concerted, apparently the most successful, measures are frequently followed by an unexpected reverse. The disease undoubtedly varies with the climate, the season, and the constitution of the patient; but it is probably never inflammatory to any considerable extent, and never requires *bleeding*. Even leeches in the most violent delirium are rather injurious than useful: yet bleeding is at times recommended, and we fear too often practised.

From a general view of the disease, we can seize one discriminating feature, viz. a violent determination to the skin, with excessive heat, accompanied also with a determination to the head. Conformably to the general plan, therefore, in febrile cutaneous diseases, our great object should be to moderate that determination, while we support the general strength and lessen the impetus of the blood within the cranium. *Emetics* are particularly necessary, and in general highly useful. *Cathartics* are, we think, equally so, though rejected by some authors as increasing debility, or from a fanciful apprehension of diffusing the poison usually confined to the throat through the whole intestinal canal. Since the publication of our first part, we have, under the guidance of Dr. Hamilton, employed laxatives in scarlatina more freely, and have, we think, succeeded better than before. At least we are certain that the objections just mentioned have not the smallest foundation. We have usually employed the cooling ones, as salts with senna, and have found that procuring three or four motions daily has mitigated the fever, and conducted it more safely to its termination. Glandular tumours have also been more rare.

Blisters appear to be indicated from their effects of deriving the fluids from the head; but they have not been highly useful in scarlatina, since the affection of the head depends on general rather than local excitement. We have sometimes thought that they produced, or assisted the formation of, glandular tumours.

The low state of patients labouring under scarlatina has led to the use of cordials and sudorifics; we need not say with manifest injury. The heat must be repelled rather than encouraged; and though nitre and other cooling medicines have seldom been given, cold applications, as we shall find, have been beneficial. A late author has spoken warmly in praise of ammonia, but he used it late in the epidemic, when its violence was abated, and late in the disease, when the strength began to fail. We have not imitated the practice, but have found little to recommend it in the reports of those who have adopted the plan.

The bark would appear peculiarly useful in this complaint, from the asthenic state, and the tendency to putrefaction; but it is not only useless, for it increases both fever and delirium, checks the perspiration, and impedes sleep. Opiates are scarcely more useful, though combined with camphor they sometimes calm the restless irritability. *Camphor*, with the antimonial powders, is almost the only diaphoretic, if it deserve that name, which is admissible, for even the relaxing effects of the Dover's powder have not been eminently beneficial.

The exhibition of *diuretics* rests on a very uncertain foundation. We know not to what indication their use was owing, except that the urine is an evacuation, vicarious to that of the skin, or that they might have counteracted the tendency to anasarca in a subsequent stage. Dr. Withering, if we mistake not, recommended the alkaline salts with this view, but he has had few imitators, probably from the want of success.

In this very uncertain state, Dr. Currie, by a happy boldness, has pointed out a new path, viz. by cold affusions. It is not enough to sponge the body once or again, but the cold water must be dashed against the patient repeatedly till the heat is subdued, and the process must be repeated as fast as it returns. The heat is to be conquered by cold, and the cold be freely, boldly, and steadily applied. The success which has evidently attended this plan leaves little doubt of its efficacy, yet we fairly own that we cannot commend it from our own experience. We have already, however, laid down the data on which the operation of the remedy may be explained, and we shall add the summary.

In all cutaneous diseases the morbid matter is hurried, we have observed, with peculiar rapidity to the skin, and the eruption depends on its being stopped under the cuticle. We know, from the facts stated in the article DIAPHORETICA, q. v., that the readiest way for the discharge is to lessen this impetus; and from the modern practice in small pox, that the eruption may be in a great degree, if not wholly, prevented by cold. In this disease cold water is peculiarly applicable: the heat is considerable, the determination to the head violent, the debility alarming. It is not, therefore, surprising that cold affusions should have been so successful. Why, therefore, it will be added, have you not practised them? We will frankly say, because we shall compact in this way the principal points of the practice.

On the attack of all fevers an emetic is usually premised, so that it is commonly exhibited before the nature of the complaint is known. The emetic is followed by a laxative, and before its operation is fully completed the nature of the disease usually becomes evident. In this case, then, the regular exhibition of laxatives, with the camphor and antimonial powder, in

some cases with the addition of a slight dose of opium, will succeed. The heat and the delirium will sometimes return for two or three nights, but the steady repetition of the laxatives prevents their increasing to a dangerous degree. At the same time, cool drinks, spacious apartments, and free cool air, are peculiarly necessary. The retrocession of the eruption from cold, or the danger resulting from such retrocession, Dr. Currie has taught us to consider as imaginary inconveniences.

We know no disorder which represses so powerfully the constitutional energy. For months, no exertion is often made to restore health. The complexion continues pale, the strength inconsiderable, with anasarca, and often glandular swellings. It has been said that these consequences are avoided when the disease is extinguished by cold: we know that they are greatly mitigated when laxatives have been freely used. In general, however, this state of debility is not dangerous. It yields to tonics, to country air, to a generous diet, and, above all, to time. Glandular swellings require no peculiar treatment. Of the sore throat we shall speak in the following article. We shall add our predecessors' remarks, as a specimen of the practical directions of the former edition.

It seldom requires much assistance from art, except there is an approach to that putrid state to which it inclines in the advanced degrees. Bleeding is rarely required. The patient may be kept in his room, but not much in bed; his drink may be acidulated with the vitriolic acid, or with Clutton's febrifuge spirit; and if a stool is required, rhubarb will be the most convenient: when the skin peels off, a more active purge may be given.
